Therefore, in our case, the more efficient variants among these two, is the first one.

4. Some Conclusions Regarding the Implications of Time on the Economic Efficiency of the Capital Investments

The several aspects presented above refer at the fact that the economic efficiency of a capital investment, as an extremely complex economic category, cannot leave aside the influence of time.

Therefore, beside the investment efforts and effects that are taken into consideration when evaluating the economic efficiency of a capital investment, time should also be taken into account.

Without considering the influence of time, the results of the calculated indicators are irrelevant.

More than that, it is not excluded the possibility, as seen above, that, from the static point of view, a variant is better for a certain indicator and calculating the same indicator in dynamic (updated) form, another variant is preferred.

As shown above, in such a situation, it is a priority to use dynamic calculations when making an investment decision.

At the same time, another fact is important, respectively the comparisons to be made between the static and dynamic levels of one and the same indicator.

If we refer, for example, at the recovery period of a capital investment, in static and dynamic forms, as the results presented in the above table show, the main categories of comparison that can be made for the two investment variants are the following:

- 1) on horizontal, between the static levels of the indicators, a certain variant is better;
- 2) on horizontal, depending on the dynamic (updated) levels of the same indicators, the same variant is better, as in the first case; in this situation, the dynamic (updated) results would have priority in making the decision;
- 3) on vertical, within each variant, between the dynamic and static levels of the same indicator;

The differences between the two reminded levels do not represent anything else than the influence of time.

For example, the above example, which presents the difference between 12.1 years and 5 years at the first variant, represents the influence of time. In other words, at first sight, it seems that the respective investment will be recovered in 5 years, but, in reality, the recovery takes place in 12.1 years, taking into account the influence of time.

Obviously that the influence of time on the economic efficiency of a capital investment does not refer only at the few aspects

presented above; the reminded influence is much vaster and manifests on other multiple plans which should also be known by any investor for making a correct investment decision.

Abstract

This paper focuses on the correlation between education and sustainable development unveiling the human dimension of development process. In authors' opinion, success in revising unsustainable trends will, to a large extent, depend on the flexibility in understanding the type of education needed for sustainable *human* development.

For the national level of analysis, it has been used neo-institutional mental models to interpret the environment in which education takes form. Knowledge acquisition is underlain by perceptions derived from the process of collective learning across generations, and is a cumulative process subject to social and cultural filtration. As learning incentives are also influenced by culture, there is nothing to guarantee that the amount of experience gathered by society can adjust the incentives so as to support the solution identification for sustainable development. The inertia of path dependence phenomenon much impedes the progress towards the implementation of the sustainable development goals.

From a European perspective, education for sustainable development is a lifelong process and goes beyond formal education. By promoting essential social and civic values such as equality, tolerance, respect and active citizenship, education makes a significant contribution to strengthening

social cohesion and thus mutually human cooperative actions.

For the global perspective on the issue some incremental mentality and paradigmatic shifts toward global intelligence are needed. That is developing ability to understand, respond to, and work for what is in the best interest of and will *benefit all human beings and all other life on our planet*. The global intelligence presupposes a holistic mode of thinking, a transdisciplinary one, and also new kinds of knowledge emerged from intercultural cooperation. This is indeed a drastic change in the rhetoric of sustainable development, one that will bring viable alternatives for the unilateral economic logic.

Keywords: education, sustainable development, national, regional, and global perspectives

JEL Classification: B52, B59, O15, Q01.

1. Introduction

Education has the potential to induce behavioural changes to achieve/reinforce sustainable development. It should contribute to all three axes of sustainable development, namely:

- The Social perspective – education strengthen social cohesion by investment in human capital;
- The Economic perspective – education contribute to building a knowledge society

based on sustainable economic growth; and,

- The Ecological perspective – education are crucial for changes in citizens' behaviour on issues such as: consumption, transport, use of sustainable energies, etc.

Nevertheless for all the three axes the economic logic is prevalent. In the light of this paper success in revising unsustainable trends will, to a large extent, depend on the human accent and the flexibility in understanding the type of education needed for sustainable *human* development.

2. Education - a national strategic factor for sustainable development

Political discourses, curricula and plans related to Romania's sustainable development are generously filled with sentences capitalizing on education. At first glance, one may argue that the Romanian society acknowledges that education is a strategic factor in the national development, given its vital contribution to the multi-faceted and anticipative shaping of the human capital. Yet, this is all, of course, wishful thinking.

The educational policies aiming at including minority group into the educational system are closely intertwined with the efforts made on the line of sustainable development. They should become the vector of the educational reform. Development should start from long forgotten areas by this phenomenon; extending and improving the educational network, increasing teaching career opportunities, improving school transportation in rural, poverty-stricken areas are formal measures, yet meant to rekindle long forgotten feelings: respect for school and learning. To this end, the passage from economic to human sustainability becomes shorter and obstacle-free, as high-quality education is likely to develop responsible attitudes toward community and environment.

For a deeper understanding of the matter, one should pay specific attention to the distinctiveness of the types of learning: formal, non-formal and informal education.

- Formal education: learning that occurs within an organized and structured context (i.e. formal education institutions such as schools, colleges, vocational training institutes and universities), and follows a particular structured design. It typically leads to a formal recognition (diploma, certificate). In those cases, the issue of sustainable development tend to be inserted in the curriculum of the institution;

- Non-formal education: learning which is embedded in planned activities that are not explicitly designated as formal learning, but which contain an important learning element, such as vocational skills acquired on the workplace;

- Informal education: learning resulting from daily life activities related to work, leisure, free-time, etc. This type of learning is sometimes referred as experiential learning.

Early education is one area to cover especially for the case of Romania. "The seven year education at home" is the period to delineate the process of individual becoming, the period in which parents teach their children to tell apart the good from the evil. This parental responsibility is both natural yet difficult in a society whose social values are continually perverted and social hierarchies undermined. People with doubtful behaviour reach the top of the ladder. Unfortunately, in the Romanian society, the setting of example has undesirable results. The achievements and the efforts of the authentic elite are too often discarded. Consequently, consistent efforts to self improvement do not attract large numbers of supporters. We are still charmed by the myth of the "overnight success". Everything is analyzed from a money-oriented perspective and in a short time span.

Such considerations urge us to recommend in-depth educational reforms, aiming at restructuring learning incentives and informal educational institutions. We strongly consider that formal education should be built on the solid foundation of informal education. In real life, however, reforms aim to restructure the higher levels of education to perfection as they consider that the foundation will inevitably be laid

anyway. It goes without saying that a technical solution to this edifice is difficult to find.

Generally, educational reforms target formal education only, and overlook the inertia induced by informal/non-formal education. The reforming ability to learn new things is determined by informal education, those time-moulded values which describe social tolerance against the progress of knowledge. The adepts of neo-institutionalism consider that acquiring theoretical knowledge (a vital element meant to boost economic performance on long term) is influenced by financial rewards and positive social attitudes to science.

The overall social approach to the benefits of expanding knowledge (in various stages of historical development) is the major source of long term change. Likewise, educational improvements are dependent on the features of social institutions and the institutions are variables strictly influenced by the level of education. Therefore, fostering the progress in the theory of social change involves, doing away with the hypothesis of rationality (as in traditional economic principles) and constructively explore the nature of the learning process.

The accumulation of knowledge requires the development of a structure meant to interpret various signals received by senses from the environment. The provisional architecture of such a structure is genetic and it gradually undergoes the process of metamorphosis, as a result of personal experiences. Such a structure is made up of categories and taxonomies gradually developing, which reflect the way in which individuals organize their own perceptions, record and classify their memorized experiences. Using such taxonomies, individuals construct mental models meant to interpret reality. Both the categories and the mental models develop throughout time, either emphasizing or altering previous positions. On the other hand, beliefs are transformed into social and economic structures by institutions (which can be seen both as formal and informal behavioural constraints). The following

quotation is illustrative for the stage of our research:

“There is a close relation between mental models and institutions. Mental models are internal representations created by individual cognitive systems in order to interpret the environment. Institutions are external mechanisms created by individuals to structure and order the environment.” (translation mine, North, 1993, p.12-13)

Consequently, knowledge develops and determines our perception of the environment and in their turn, such perceptions inscribe the need to improve our knowledge. The learning process depends on the way in which values filter experience-derived information and on the various experiences lived by individuals and societies throughout time.

Under such circumstances, it is essential to understand the “path dependence” phenomenon; once a national economy is on the upward / downward trend or stagnates, it is very difficult to reverse such trends on the long term. Knowledge acquisition is underlain by perceptions derived from the process of collective learning across generations. The act of learning is a cumulative process subject to social and cultural filtration. As learning incentives are also influenced by culture, there is nothing to guarantee that the amount of experience gathered by society can adjust the rewards / incentives so as to support the solution identification process.

When the social and economic development is on a set path, the network of externalities, the learning process within organizations and the subjective interpretation of the problems encountered by society will strengthen the path. It is difficult to reverse a downward trend mainly because of political institutions and the values taken on by social actors. History has given evidence that it is not enough for statesmen to be aware of economic problems and to come up with “reasonable” solutions. The mere transfer of formal political and economic regulations from a successful market economy to underdeveloped economies does not automatically ensure high economic performance, as economic results

are also influenced by informal /and gradually changing rules and by the enforcement of formal regulation.

The act of renewing social institutions takes time and asks for extensive reforms. Still remains the dilemma: Has indeed the formal education the potential to bring about welfare? If yes, for sure it implies a gradual and time consuming process.

As it was shown above the economic theory has developed mental models to understand the mechanism of producing welfare. This is a legitimate field of knowledge to the extent in which it serves for improving the quality of life for all human beings.

3. Issues of the European discourse on education and sustainable development

The European discourse on the relation between education and sustainable development has a pragmatic and programmatic character. In turn, the Education for Sustainable Development Strategy stated by the UN Economic Commission for Europe in 2005, recognizes that:

“Education for Sustainable Development is a lifelong process from early childhood to higher and adult education and goes beyond formal education. As values, lifestyles and attitudes are established from an early age, the role of education is of particular importance for children. Since learning takes place as we take on different roles in our lives, Education for Sustainable Development has to be considered as a "life-wide" process. It should permeate learning programmes at all levels, including vocational education, training for educators, and continuing education for professionals and decision makers.”

Education has intrinsic value and is a key field to enable individuals realising their full potential and achieve personal fulfilment in all aspects of their lives. It plays a crucial role in their intellectual, moral, social, creative and physical development and, by promoting essential social and civic values such as equality, tolerance, respect and active citizenship; it

makes a significant contribution to strengthening social cohesion.

Whilst acknowledging the wide range of roles which education fulfil, an important part of education's role in fostering social cohesion lies in its ability to equip people with the knowledge, skills, competences and attitudes needed to enter and remain in the labour market. Integration into the world of work gives individuals an opportunity to have a full stake in society, thus contributing to their social inclusion, active citizenship and personal fulfilment.

In terms of enhancing employability, the capacity of Europe's education and training systems to ensure a supply of highly qualified people mastering the requirements of today's working world and contributing to innovation both as employees and entrepreneurs will be decisive, if Europe is to maintain and improve its competitive position in the global economy.

4. Changing the rhetoric for a global perspective

So far the economic logic was preponderant. At national and regional levels the education is important for its promises for future economic growth and development. Even the neo-institutional theories depart from the human intrinsic cognitive systems and follow all the way to the same end point: economic performance.

This is not the only way, but it is one of the most sophisticated economic demonstrations for the role played by education in the contemporary world.

Yet there is a growing awareness that we all are lost if continue to follow the economic way. Some global approaches to world education change the direction toward a *global intelligence*. That is: “the ability to understand, respond to, and work toward what is in the best interest of and will benefit all human beings and all other life on our planet. This kind of responsive understanding and action can only emerge from continuing intercultural research, dialogue, negotiation, and

mutual cooperation; in other words, it is interactive, and no single national or supranational instance or authority can predetermine its outcome. Thus, global intelligence, or intercultural responsive understanding and action, is what contemporary nonlinear science calls an emergent phenomenon, involving lifelong learning processes". (Spariosu, 2005, p.3)

How can global intelligence be acquired?

It involves remapping traditional knowledge, accumulated and transmitted by various educational disciplines, and finally dropping out the disciplinary mentality. The global intelligence presupposes a holistic mode of thinking, a transdisciplinary or integrative one, and also new kinds of knowledge from an intercultural perspective.

Yet, a global mode of thinking will emerge from "local" knowledge with its own historicity. Knowledge is always bound to a specific time and place, to a specific culture or system of values and beliefs or, indeed, to a specific lifestyle. A global approach attempts to identify the cultural specificities of knowledge, explore commonalities and differences among them, and negotiate, if need be, among such specificities. It also presupposes that, in the process of exploration of cultural commonalities and differences in the way in which we acquire and utilize knowledge, new kinds of cross-cultural knowledge emerge through intercultural research, dialogue, and cooperation, and new kinds of integrative cognitive and learning processes become possible. (Spariosu, 2005, p.8)

Then there is a need for designing educational models to foster the kind of local-global learning environments and intercultural, intellectual climate that are needed for sustainable human development in the next few decades.

The current educational system privileges imitation students, not creative, critical, and analytic professionals with a broad and disciplinary free understanding of society at large. The core challenge for educational institutions is to turn away from

conventional lecturing to learning situations based on the search for solutions to real-life, open-ended problems. (Denzin et al., 2003, p.134)

Innovative education practices for sustainable human development covering all three types of education (formal, informal, and non-formal) must be encouraged. These practices will be configured to provide a good spread of activities focussing on all three pillars of sustainable development: environmental, economic and social. Their innovative character should come from mission and objectives assumed, the delivery method of educational services and the institutional frameworks.

There is a large scope for systematic and transnational educational reform to change the current situation of powerful constellation of forces through cooperative and innovative practices.

5. Conclusions

Paradoxically, the ongoing economic determinism of development process can be counterproductive. All the demonstrations of the economic development theories formalized or not, are very interesting intellectual exercises that unfortunately bring just little long termed benefices for human beings. Even more these benefices are not shared equally and equitable to all the people of the world. It is high time for return to natural and simple things. People always had the inclinations to struggle for survive or to cooperate for surviving. The economic institution – market is probably the most populated field of battle throughout history. *Are we prepared to imagine a world in which competition is totally replaced by cooperation?* And yet we wonder the project of global economy undertake only the disappearance of many types of frontiers? In market terms this means that finally we'll have a larger battle field.

This is the call for mentality and paradigmatic shifts. It should be abandoned the mentality of confrontation and look for other ways of organizing human relations,

as well as our cognitive and learning processes. The shift will take place gradually, much impeded by the tendency of path dependence. This shift enhances a learning process that changes the national cultural filter and prepares the emergence of a global culture. Once such conditions installed, it will enable proliferate of global intelligence. From the paradigmatic perspective, in our opinion the neo-institutional approaches still find a place in this landscape of scientific inquire based on mutually, intercultural cooperation. A new set of economic, social and politic institutions should be crafted to guide all of our future interactions on this planet. This new rules of game borne from cooperative actions, but not confrontational selection process will naturally lead ourselves to the achievement of the final goal – that of the sustainability of human development.

„Not everything can be numbered and not everything of what can be numbered matters”

Albert Einstein

Abstract

The main idea on which is based this paper is the one that education and health or what the economists distantly called „human capital” and had a major role in any theoretical and empirical model of the economic growth and development. Of course, no economy can have success only with a workforce that is educated, there are other factors that must be taken into consideration. It is certain that in a capitalist context the educated workforce can give a major impulse to the economy, when other factors are not present.

The present article goes on the line of the economic growth following to delimit the interdependent factors that cause and support the growth of the GDP (gross domestic product) per inhabitant in a durable way, with predilection the role of education, of the human capital.

Key words: economic growth, human capital, education

JEL Classification: I21, O15, O40

1. Introduction

We are interested in the human capital because we hope to explain and, eventually, to contribute to carrying out the economic growth, which is traditionally measured by the increase of goods and services of a country (what economists call gross domestic product or GDP).

In many respects, the traditional indicators make an excellent job. The GDP (gross domestic product), for example, express the size of an economy, being an indicator, with many valences. It is used in a wide palette of

areas and, in general, the periodical update makes possible the comparison of the economy performances at an international level. This is also a main indicator that offers a wide image of the state of an economy. In fact, the GDP is so useful that it effectively became the gold standard of the economic progress: the governments show off with this one when it is growing, and search for justifications when the GDP is not growing or it stagnates.

The GDP has a lot to say about the economic activity, but when we analyze if this activity is good or bad for the society, the GDP expresses nothing. It was established a pretty strange thing: car accidents contribute to the GDP because the cost of the medical treatment for the victims in the crashed car and the purchase of a new car supports the increase of the GDP. From the point of view of the GDP, car accidents are good, while from the point of view of the society, they are bad.

In many respects, the fact that the economic growth is reflected by the increase of the GDP, it is a mixture of good and bad. In general, this process is of positive nature, in the meaning that, the economic growth offers the societies, resources for fighting against poverty, it assures resources for education and at the same time it contributes to the health services improvement, and also to the options

expansion that the governments and the societies have at their disposal.

For the natural persons, this can mean, also, the incomes increase, that allows them to invest in their own welfare, health and happiness. On the consequence path, the presence of the winners could be accompanied by that of the losers: individuals and communities that, because of the lack of resources for competing in the economic development, they found themselves trapped in this cycle of poverty.

Figure 1. Economic power (GDP/capita)
Mld USD, 2007

Source: OECD Factbook 2009

<http://www.oecdpublising.org/mobile/factbook/en/020101-sizegdp.html>

No aspect of the economic activity complexity is expressed in the GDP, and if we are to be realistic, the GDP is only one of a series of indicators that the economists use; others, such as the Gini coefficient, offer a series of answers to problems, such as the incomes inequality. That is why, this is one of the reasons for which there is a growth of the interest in the use of the alternative indicators that might offer a wider perspective of understanding of the societies health, and also their capacity to continue the growth.

At the present moment, the importance of the economic growth is obvious; at the base, the economic growth is essential not because the people are greedy or excessively materialist, but because they want to improve their lives. It is a normal desire, and only with the help of a high economic result it is possible for most of the people to have a better and more satisfying life. Of course, the economic growth is not the only purpose in life, the economists being the first to draw the attention

on the fact that there are always advantages and disadvantages: more work means less time for fun or family; a higher economic result is often accompanied by unwanted side effects, such as pollution.

Still, more rich nations are, more resources they will have to diminish the side effects of the economic growth, and also the different diseases that shorten lives or make them less satisfactory.

In order to understand why economies grow, we will have to ask ourselves why the economic activity takes place. In the heart of the classical school it is remarked the general consensus on the fact that there are four things-“the four factors of production”- that we need for progress. The first one is, of course, the land; without land, there will be no longer possible the growth of plants or there will no longer be the necessary base for building factories or farms; the second one is the workforce or the working class; they are followed by the capital and at the end, the enterpriser / entrepreneur or what the economist John Maynard Keynes called „*animal spirits*” (in other words the initiative that transforms a piece of land in a factory).

The premise from which we start in the analysis of the *human capital, as a factor of influence in the economic growth* is the one that economies are complex systems, that can not be reduced only to a few central factors and that can not be changed only applying one or more of the policies recommended by some many years by different institutions or economists.

The economic mechanism has a few interconnected elements that work together, and it can vary from one country to another and according to time; the context, history, culture, they all matter; there is not a single detailed plan for being applied to each country. The fact that different countries reached rapid growth rates, using sort of different institutional structures, represents a proof in this sense.

In a certain meaning, the understanding of the economic growth process is similar to preparing a cake: you just have to find the recipe. The recipes for preparing a cake include a few basic ingredients (sugar, flour, yeast, etc), work (being measured in hours and minutes) and some equipment (a mixer and an

oven). In the case of the economies there are as many recipes as products and services, but they all need, in essence, the same three elements: raw material, work and mechanisms (also called physical capital)[1].

Baumol and Litan in the paper “ *The good capitalism, the bad capitalism and the economy of development and prosperity* ” highlight, again, that there is also a fourth ingredient, and that is the technological evolution; they suggest that just as the mixers and ovens are more efficient in our days and they work better than in the past, the technological progress in the whole economies led to the appearance of some new products and services that are preferable to the market ones and also more efficient methods to generate and deliver the new or the already existing products. Also, they talk about two categories of recipes for the economic growth, meaning: “the growth by raw force” (meaning the accumulation of more entry factors, and we refer here to more work and more capital) and “intelligent growth” (meaning technological progress).

But let us go back to the second category of production factors that was mentioned before; meaning the workforce. With a few exceptions, the classic economists assimilated the employees/ workers of a raw force that sets in motion the production having as main role the physical work and them less highlighted the inherited or acquired abilities and intellectual knowledge.

An exception from this way of looking at things is represented by Adam Smith’s papers; he is the one that, since the XVIIIth century felt that the economic activity was nourished not by the raw force of the individuals but by the “*useful abilities and knowledge of the inhabitants or of the society members*” [2]. An individual must pay a price for gaining the: “useful” abilities and knowledge, says Smith, but once obtained, they represent a fix and completed capital, if we can say so, in his person.

Smith’s ideas, by the simplicity of the message, they obtained grandeur and permanence so that the father of the political economy influences even nowadays the economic life, offering a series of answers that lasted over centuries only through his competence and synthesis spirit.

Anyway, his belief in the fact that the “useful” abilities and knowledge of the human being seen as a machine, having associated costs and the capacity to produce in exchange incomes, are a form of capital and make Smith a founder of the human capital theory.

The economists that followed him neglected the study of this particular type of capital, considering that what must contribute decisively to the growth of the production of goods and services are the plants, lands, buildings, etc and their proper investments.

Initially, it was omitted from the analysis the impact of the different level of education or the quality of the workforce on the economic growth. The periodical ulterior preoccupations related to the formal education, studying at the place where people work, health, fertility, the migration of the workforce represented the signals of the appearance of a new thinking current that was turned towards explaining the impact of some material factors, more difficult to identify and quantify, on the dynamic of the world economies.

The economic science needed almost two centuries for coming back to the Smithian remark according to which the *investments in the individuals’ knowledge and abilities produce profit and participate directly to the enriching of a nation*; the explanation is given by the quantitativist tint, that characterized the neoclassic analysis. These changes produced gradually and up to the beginning of the 60’s there were controversial opinions regarding the influence factors, especially in which concerns the importance of the human factor (the individual’s abilities, knowledge and skills- or in other words, the human capital) on the economic growth.

2. Education – engine of the growth or the opposite?

The human capital seen as a quality of the workforce is just a factor that determines the economic growth. Nations can have, at a large scale, similar levels of education, but, at the same time, they can manifest wide variations in their growing rhythm. There are too many examples of educated countries in which the economic performance was deplorable; the former Soviet Union and the countries of the Eastern block, including Romania, they were

proud of the excellent primary and secondary educational results, for a large part of the population, but after the fall of the communism the world realized that these economies were in a much more precarious condition than some western people believed.

William Easterly, in his study on the economic growth, indicates another anomaly; he observed that as the poor countries substantially increased their investments in education in the period 1960-2000, the growth rate of these countries dropped constantly [3]; it is possible that the education improved in many of these countries, but the corruption and the military violence or other factors can counteract any impact of education in promoting the economic growth.

In consequence, we do not support the idea that education is irrelevant for the economic growth or for improving the functioning of the national societies (whether these are governed in a democratic way or not); education contributed to the economic growth from the last decades, but it only proves that it *represents a necessary condition, but not sufficient of the economic progress*. Other factors that compose this puzzle of the economic growth are those *demographic (especially the report of young people and old people in a population), technologies, innovation, free international trade, the quality of institutions and of the economic policies*.

A vast literature was written on the theme of the human capital from the desire to offer consistent and well-grounded answers to a crucial question: The education brings economic growth or the growth determines individuals to consume more education?

The OCDE experts, through the study entitled „Education at a Glance 2005” declared that “in practice the causality relation operates in both directions” [4]. In this sense, North and Thomas sustain that “*the enumerated factors (innovation, scale economies, capital accumulation, etc) are not causes of the growth; they are the growth*” [5].

The human capital plays and important role in the economic growth, its importance being observed since the XIXth century, when the mass education increased; and as the majority of the relations, it is not a simple connection.

No matter how meticulous, subtle and useful would be, the estimations of the

economic growth sources say nothing about the last causes of the economic growth. They do not present the motivations that led to the appearance of economies or investments or why the innovations or the capital accumulation were bigger in a society or in a period or another. They do not follow the growth sources until their origin: “they take it on the line of the river waters up to the brooks and lakes from which they come, but they do not explain the rain” [6].

In essence, education creates a workforce that is capable to obtain more complex and better paid jobs, but, at the same time, the existence of such jobs makes useful for the students to attend classes, eventually all the unpaid classes when they were in school, they will be transformed in a job that will compensate the time allocated to education and not the pecuniary earnings.

In the same way, the countries with high levels of education tend to become richer; so there are more resources destined to education. This fact can be mistaken with the eternal dilemma “the hen and the egg”; but it is not like that; the historical evolution of some countries like Germany or the USA, indicates how the appearance of the mass education at the end of the XIX-th century preceded an economic growth at a large scale.

Another example, among others, are the Asian tigers- Singapore and South Korea- that had a relatively high level of literacy before beginning the spectacular growth in the 1980s and the beginning of the 1990s.

Lee (2001) and Lall (2001) presented the way in which it evolved the resources assignment on different educational levels in Eastern Asia when, in the initial development phase, this region gave priority to elementary education in the years 1970, reaching a rate of almost 100%, the secondary and tertiary levels of education becoming a propriety after 1980. The economies from the South-eastern Asia made a lot of efforts for increasing the quality of their universities the main initiatives form the natural sciences areas from Singapore and Korea underlining the fact that this thing already takes place.

What must be remarked, is the fact that, *for the economic growth, more important than the quantity of resources meant for education is the way in which they are allocated between*

the primary, secondary and tertiary cycle; this fact is also explained by Judson in his paper „*Economic growth and investment in education: how allocation matters*”.

Admitting the idea that, in the appropriate institutional conditions, education represents an important factor for the economic development, there still remains the question if economies obtain a superior profit. Despite a population of almost 1 billion people, India still suffers from a lack of well qualified graduates, according to the statements given by managers from the information technology.

Self and Grabowski in the study entitled „Does education at All Levels Cause growth” India, a case Study [7] reach the conclusion that, in the case of India, the elementary education presents the biggest influence, even if the algorithm of India is of concentration of the investments among the elite.

Practically, the model chosen by India is nowadays responsible for its success in the businesses associated to the information technology, but this sector represents only 2% from the results and the workforce of the country (even if certain estimations indicate the fact that this one would rise up to 7% in 2008) [8].

In a wider meaning, the population of India reached much lower levels of education than China, Korea and Taiwan, only 61% of the Indian adults can read, while in the countries of South Eastern Asia, the number is above 90% according to the studies made by UNESCO. Hundreds of millions of Indians have an insufficient education, while in countries from South Eastern Asia the accent was put on the general elementary education when they found themselves in similar phases of economic progress. This strategy made that much bigger segment of the workforce to be gifted with specific skills for working in factories of intensive production that became, a few decades later, not only the most advanced technologies, but also they represented true sources of innovation.

As a consequence, which are the consequences for the developing countries where the rate of illiteracy is pretty high and the educational opportunities are not exactly universal? More exactly, these countries should try to imitate the universal model applied in South Eastern Asia or the elitist one,

like in India? In many developing countries there are elites that send their children to study abroad, just like happened in the rigid system of castes from India, while the educational system was regularized. In the case of India, the university departments were established with the help of educated young people abroad, who at maturity, they came back in the country. Other countries probably, do not have a sufficient big population for following this strategy based on merit, not even the advantage of India of having a big number of English speakers that can be easily assimilated in the global commercial system. There are arguments that make us support the general accepted opinion concerning the encouragement of the developing countries for making the basic, universal education accessible, rather after the model of South Eastern Asia and East Europe than adopting the elitist model of India. It is not an easy measure to take, especially in the poorest countries of the world, where the falling ill rate is very high, precarious health and poor nourishment. There are more than 100 million children that have the age for the elementary school that are not registered at any educational institution, of which 70% in South Eastern Asia and in Sub-Saharan Africa, according to UNESCO [9].

In the year 2000, the inhabitants of the Sub-Saharan region from Africa had, on average, 3.5 years of education, in comparison with 9.8 in the developed countries[10]. From those 155 developing countries, only almost half of them have sufficient elementary schools for all the children that have the necessary age[11].

And even more existing schools do not have the necessary facilities; for example, more than 90% of the pupils from the VI-th grade from Tanzania go to schools that do not have books, and 2/3 of the schools from Ciad do not have toilettes[12]. Another reason, for which the children from the developing countries do not receive the necessary education, is that of the fees costs and the distance they have pass until school, a fact underlined by Gene Sperling, the manager of the Centre for Universal Education of the Foreign Relations Council. “The decision to send the children to school, considers Sperling, that it is often taken by the parents who live in extreme poverty conditions and for whom the cost of education exceeds its

benefits” [13]. Obviously, these represent problems that are difficult to eradicate. In an obvious way, the *strategy oriented towards the general education seems more advantageous than the focalized approach of India*. An elitist educational strategy would lead, inevitably, to even greater income disparities that can worsen the social discontents, a problem that certain countries can not solve.

Besides the option for general education or for a superior one, another dispute is given by its applicative or theoretical character. In the paper „*Skill Specific rather than General Education: A reason for US-Europe Growth Differences?*” Krueger and Kumar analyze the problem of general or vocational education. The two analysts create a model that incorporates the decisions of the companies and of the individuals to adopt a certain type of education and they analyze the effect of education on the economic growth. Practically, the model proves that the growth rate is bigger in the economies where there are allocated more resources to the general education; so the general education, even if it is more expensive, it primes in which concerns the economic growth, to the detriment of the vocational one. The study reveals the fact that only the workers with general education can operate with new and risky technologies and, while the workers with vocational training are efficient in using the old and stable ones [14].

There still remains the question if the concentrated financing leads to bigger profits in which concerns the national income. Edificatory are the educational policies from Europe and the USA, Krueger and Kumar studying the impact of these educational policies. The causes for initiating this study were, among others, the deepening of the evolution differences between Europe and the USA, the intensification of the technological differences between the USA and Europe and the social attention given by the USA to the general education (74,5%) and by Europe to the vocational one (30%), the registration rates in the vocational education at a secondary level being much higher in Europe [15]. It was observed, from the point of view of the GDP and from the work productivity in the manufacturing sector, a weak economic growth in Europe in the years 1980 in comparison with the USA; on the consequence

path, we can say that the economies that concentrate themselves on the vocational education remain far behind those who choose the path of the general education.

3. Instead of conclusions

There are two main ways to which countries can appeal in order to educate the citizens, either “horizontal” or “vertical”.

The “horizontal” approach has as purpose to assure almost the same basic education – in an ideal way, the high school equivalent- to the whole population of the country. The public or private funds can support universities, but that is not what must be stressed, at least not in the beginning. The countries that followed this model opened the university education to the best students, financing their studies abroad (usually in the USA, but also in Australia, Canada and Europe).

The “vertical” approach come in opposition with the “horizontal” one because it is centered on the education of the most talented individuals on a local plan, in local academic institutions, giving less importance to the general education especially by limiting the number of the years of basic education for the less skilled individuals. This thing is carried out through an appropriate financing, the departments being developed whether at home, or through studies abroad for the teaching staff.

The optimal solution for the less developed countries, at least initially, is the one of sending a number of teachers with good potential over the boarders to training probations, of course with tempting financial rewards in order to assure their return, and who, on their turn, must train other teachers.

Practice shows countries that used both strategies for creating the human capital. The Asian and East-European countries prefer the “horizontal” educational approach, apparently successful, while India offers the best example of “vertical” or “elitist” educational approach. The pupils of the elementary schools and high schools from the East-European and Asian countries obtain, regularly, very good results to the international and mathematics exams and the percentage of illiteracy is among the lowest, in comparison with India, where this percentage is pretty high.

Still, even if it took it a few decades, India managed to create some of the world's most famous engineering universities. The access is strictly made on merit and the students' annual exams who want to be admitted in these superior institutions represent major events in their lives and not only, even for their schools, neighborhoods and cities in which they live.

We can say that India assumed the risk of letting some of the highest qualified students to immigrate to the USA, hoping that a part of them will come back and start a business in their home country. Even if a few decades passed until the results to show up, now they are visible; many of those who came back contributed to the development of the Indian economy [16].

China has an intermediary position regarding education, a country that educates in an extraordinary way the most talented students, especially in the technical disciplines, in elementary schools and high schools, investing enormously in the university education, even if the graduates do not seem to be as good as those from the Indian institutions.

The "vertical" (elitist) approach and also the "horizontal" (universal) one succeeded in stimulating the general economic growth, but with very different results, according to the offered educational opportunities. What was noticed was that when the educational resources are focused only on one direction and the earnings will be unevenly distributed. This explains the discrepancy between the relatively equal income from the economies of South-Eastern Asia, on one side, in comparison with the much bigger contrast from India and China on the other side.

With all these, it is not sure yet if the universal or elitist approach leads to a much pronounced economic growth. These happen because, as the economies become richer, they can afford to apply both strategies simultaneously and it can be difficult or even impossible to determine exactly which approach contributed more to the development.

For example, the main economic and social problem that India and China face, is the need to expand the economic growth on those significant parts of population, that benefited

from the rapid growth of the living standard, enjoyed the dynamic and educate people.

Both countries met social disorders and that is why, even in China the present conflicts are due to the more and more need of political freedom. The situation is not easy, not even for the rich countries that must fulfill their duties to the universal basic education, but also those regarding the quality of the superior education institutions. The USA for example, seemed to succeed in both ways, but, despite the high percentage of high school enrollments, there are still problems related to graduating from high school and obtaining the necessary abilities for an appropriate career in the case of the pupils who come from families with a low income.

Another position is occupied by the countries from the Western Europe and Japan that have prestigious educational programs for the elementary and secondary schools that got on the international top, but did not have the same success with the universities. Israel has performances in both- at the elementary and secondary level, and also in world wide universities – but a part of this success is due to the large number (reported to population) of overqualified immigrants from the former Soviet Union in the 90's [17].

Teleworking Survey

Chiru Claudiu

Greco Iulia

Spiru Haret University

claudiu_chiru@yahoo.com

elianro@yahoo.com

Abstract

This paper examines teleworking, a modern concept, more and more present in the work relationships in our society. We will review some introductory elements, the evolution, the current status of teleworking in Europe and US and the development of teleworking in Romania.

Key words: teleworking, cost, benefit, telecenter, productivity.

JEL Classification: Q33;

1. Introduction

Teleworking can be defined as the use of Information Technology and Telecommunications to work at home and in the mean time to keep contact with work colleagues, customers or the central offices of the employers' companies. Teleworking offers large benefits to communities, employees or employers. For communities, teleworking may determine the decrease of the unemployment rate and offers a chance for the persons with disabilities that can not travel to work or to the retired persons or to those who work in remote areas. Teleworking also reduces traffic congestion. For companies, teleworking offers a large pool of workforce selection, reduces costs, raises productivity. For individuals teleworking drastically reduces time spent with commuting, reduces fuel consumption, introduces a flexible way of work.

There are different forms of teleworking by considering where the teleworking is taking place, by looking at the amount spent in teleworking, by considering the individual or collective forms of teleworking, by considering the economic

sector where the teleworker should work.

Teleworking is suitable for data analysis activities, book reviews, elaborate reports, intensive telephone speaking activities, conference organizing, computer based activities such as data input, text processing, programming. There are still work positions that are not suitable for teleworking. These positions require the physical presence on the job at all times, extensive face to face meetings with supervisors, other employees, customers or the public, access to materials with high security requirements or that can not be moved from the office.

2. Teleworking evolution

It seems that 1972 year marks the beginning of teleworking when Jack Nilles also known as "The Father of Telecommuting" conducted an extensive research in this area at the University of Southern California.

In 1973 Jack Nilles made the first teleworking demonstration. The project involved 30 employees from a private company and was supported by the National Science Foundation. Jack Nilles became one of the most famous experts in teleworking programs implementation, wrote books and articles on this subject. In 1979 Frank Schiff, Vice President and Chief Economist of the Committee of the Economic Development introduced the term "flexiplace" and published one of the most important telework articles in Washington Post ("Working at Home Can Save Gasoline").

In 1980 one of the first telecenter was established in Marne-la-Valle, France. The second was established in Nykvarn, Sweden and the third in Benglen Switzerland. A variety of private and public

companies began implementing pilot teleworking programs. Federal Agencies like NASA, IRS, Army, Air Force, etc. implemented small teleworking projects and performed studies on telework.

In 1982 Gill Gordon organized the first Conference on Telecommuting in US. In 1985 California State launched the first large scale telecommuting center. In 1992 The European Community Telework Forum organized the first conference on telecommuting in Europe with Jack Nilles as a keynote speaker in Den Helder the Netherlands. California Department of Transport (CALTRANS) and US Federal Highway Administration funded the Neighbourhood Telecenters Project which established 15 telecenters across California.

In 1993 The Office of Personnel Management approved the use of telework by the federal agencies. The US Department of Transportation published the first report on the implications of telework in transport activity.

In 1995 AT & T proposed an education program called "Telecommute America".

In 1996 International Telework Association and Council announced that more than 11 million people telecommute compared to 8 million in 1995.

In 2000 President Clinton issued an executive memorandum instructing all agencies to identify work positions that may be used in teleworking.

Teleworking had an accelerated development in the recent years being stimulated by the information technology development. The teleworker has real time access to high quality video and a high transfer rate. It is now possible to organize video conferences, virtual offices or to transfer gigabytes in several minutes.

3. Teleworking in European Union

As a result of the negotiations at European level, on 16 July 2002 social partners BusinessEurope, the European Association of Craft, Small and Medium-sized Enterprises (UEAPME), the European Centre of Enterprises with Public Participation and of Enterprises of General Economic Interest (CEEP) and the

European Trade Union Confederation (ETUC) signed a document called the European Framework Agreement on Telework. This framework regulates employment and working conditions, health and safety, training and the collective rights of teleworkers. The signatories agreed not to implement this document through an European directive but by implementing specific measures in each EU state member.

In June 2006 the social partners published a report about European Framework Agreement on Telework implementation and in 2008 European Union Commission published its own report on the implementation of this agreement.

According to statistics given by the EWCS report in the analyzed 27 UE member states (table 1), Czech Republic has the highest percentage of teleworkers 15.2% and Bulgaria has the lowest percentage 1.6%.

There is a big difference between percentage of people involved in telework at least a quarter of the time or more and the percentage of people involved almost all of the time. This confirms that telework is used often as a part time job and not as a full time one.

Looking at the figures describing the percentage of teleworkers we can observe that there are several groups: one group of western countries with a high percentage of teleworkers (Belgium, Denmark, The Netherlands), a group where teleworking is significant (Czech Republic, Poland, Latvia, Estonia, Finland), a group with a low rate of teleworkers (some East European and South Europe countries – Bulgaria, Romania, Italy, Portugal) and a group with percentage close to the average (UK, Slovakia, Greece).

Figure 1 [1] reflects the development of teleworking in the 2000-2005 period. The percentage of teleworkers has been constantly increasing and in some countries (Czech Republic for example) it has increased five times. Some western countries like Belgium and Denmark experienced in 2005 a double percentage of teleworkers compared to 2000.

Luxembourg and Bulgaria are the countries where the percentage of teleworkers has decreased.

Table 1. Incidence of telework in the EU27 and Norway, 2005 (%)

	% involved in telework at least 'a quarter of the time' or more	% involved in telework 'almost all of the time'
Czech Republic (CZ)	15.2	9.0
Denmark (DK)	14.4	2.6
Belgium (BE)	13.0	2.2
Latvia (LV)	12.2	1.8
Netherlands (NL)	12.0	1.9
Estonia (EE)	11.8	1.4
Finland (FI)	10.6	1.6
Poland (PL)	10.3	2.3
Norway (NO)	9.7	1.3
Sweden (SE)	9.4	0.4
Austria (AT)	8.6	3.2
United Kingdom (UK)	8.1	2.5
Slovakia (SK)	7.2	3.4
Greece (EL)	7.2	1.4
Spain (ES)	6.9	1.5
Lithuania (LT)	6.8	0.7
Slovenia (SI)	6.7	1.9
Germany (DE)	6.7	1.2
France (FR)	5.7	1.6
Cyprus (CY)	5.7	0.0
Luxembourg (LU)	4.8	0.0
Ireland (IE)	4.2	0.5
Hungary (HU)	2.8	0.5
Romania (RO)	2.5	0.7
Italy (IT)	2.3	0.5
Portugal (PT)	1.8	0.4
Bulgaria (BG)	1.6	0.0
Malta (MT)	0.0	0.0
EU27	7.0	1.7

Figure 1. Telework development in EU in 2000 and 2005

Figure 2. Telework by sector and occupation in EU

Figure 2 [1] reflects the use of teleworking in industries, occupations and the educational level of the teleworkers. The figures show that teleworking is used intensively in real estate, financial intermediation and education. More than 15% of the workforce is engaged in teleworking at least a quarter of their worktime. The figures also show that senior managers, professionals and technicians are more than 10% engaged in teleworking activities.

4. Teleworking in Romania

As a result of the studies, analysis and evaluations from 1996 to 1999 Western IQ company established the first experimental Telework Center in 1999. In its early stages the telework center had 3-5 telework positions, a website for telework promotion, a database for customers, training section, international contacts with telework organizations experts and practitioners from Europe. The first telework activities were:

- Data and image processing;
- Translating services;
- Training courses.

From 2001 to 2003 Romania contributed to the E3WORK international project with its expertise. E3WORK project had France as coordinator and Poland, Latvia, Hungary, Lithuania and Romania as members. The project had its main objective: supporting and promotion of teleworking in the project's member countries organizations.

In Romania there is no agreement signed between social partners on teleworking and there is no official act to define telework. Also there is no official statistics concerning teleworking in Romania. The National Institute of Statistics published in 2006 data about workers and their

workplace. According to the statistics mentioned, in 2005 there were 13.7% people working at home. The age distribution of the people working at home was: 16.4% of the 15-24 age group, 8,8% of the 25-49 age group, 25.8% over 50 age group. There is no statistic of the percentage of teleworkers but the 15-24 age of group is more likely to be envolved in teleworking activities than other groups [3].

Romania has no regulatory framework on teleworking. The rules that can be applied for teleworking are mentioned in the Labour Code article 106 (“Work at Home” chapter).

5. Conclusion

Teleworking has multiple benefits. Key benefits of teleworking include:

- Reduces commuting time;
- Reduces pollution;
- Reduces fuel consumption;
- Reduces unemployment rate for people with disabilities;
- Allows employees to work in remote areas far from the central offices of the company.

US and Western European countries have developed a coherent policy for telework development. The figures show that the percentage of teleworkers who spend most of their time in teleworking activities is above the european average level.

Romania has made vital steps in IT infrastructure development. According to statistics, the number of internet users has

increased from 800,000 in 2000 to 12,000,000 in 2008 (see table 2). The price for a teleworking post is now affordable for the average romanian. All this data show that teleworking has a certain future in Romania.

Table 2. Statistics on internet users from Romania

Year	Internet Users [mil]	Populati on [mil.]	% populati on	Statist ic source
2000	0,8	22,217	3.6 %	ITU *
2004	4,0	21,377	18.7 %	ITU *
2006	4,94	21,154	23.4 %	CI Alma nac
2008	12,0	22,246	53.9 %	ITU *

The external competitiveness of the New Member States

Ciurilă Nicoleta
Academy of Economic Studies, Bucharest
nciurila@yahoo.com

Abstract

The present paper analyses the export performance of the New Member States in terms of export growth and market share in the period of 2000-2009. Also, the main factors that prompt the external competitiveness in these economies are determined. The results show that the most dynamic New Member States (NMS) in terms of market share and export volumes are Poland and the Czech Republic followed at some distance by Hungary and Romania. While Hungary and the Czech Republic have improved or maintained their price competitiveness throughout the analysed period, a few countries like Romania and Lithuania suffered a serious deterioration in this area due to increases in labour costs. After the onset of the international financial and economic crisis price competitiveness has been partially restored. In the case of non-price competitiveness, the most dynamic NMS is the Czech Republic. Romania is ranked quite low in this area and has experienced small improvements in the analysed period.

Keywords: external competitiveness, New Member States, export volumes, market share.

JEL Classification: F14, F15, F17, F41, O24

1. Introduction

Competitiveness is defined ([5]) in a broad sense as “the set of institutions, policies and factors that determine the level of productivity of a country”. In a restricted sense however, the level of competitiveness is determined by a country’s ability to achieve economic growth through exports.

The present paper analyses the developments in the competitiveness of the NMS and the factors which prompted these developments. The study is conducted for the period of 2000-2009 and is based on quarterly data collected from the Eurostat.

Data shows that Hungary, Czech Republic and Poland have posted the highest yearly growth rates throughout almost the entire period analysed (figure 1). Also, the commercial balance has been positive in case of the Czech Republic, and had only a small negative value as a percent of GDP in Hungary and Poland. Romania has constantly increased its exports until the onset of the international financial and economic crisis. The exports’ growth rate has however slowed down during the year 2007 but rebounded to high values in the beginning of 2008. The onset of the international economic crisis led to a strong decrease in exports in the case of all NMS, but Romania was the country that experienced the smallest decline.

Figure 1. The development in real exports’ growth rate in the NMS

Source: Eurostat, author’s calculations

In terms of the market share held in the European Union, Poland and the Czech Republic clearly dominate, while the third and fourth performers are Hungary and Romania. Although, all countries have improved their market share throughout the analysed period in detriment of the euro area countries, Poland and the Czech Republic appear to be more dynamic.

The following sections elaborate on the determinants of external competitiveness and their developments in the NMS in the

analysed period.

2. The determinants of external competitiveness

The literature regarding the determinants of external competitiveness is quite vast and international organizations use a number of different indicators to assess a country's level of competitiveness.

The World Economic Forum takes into account when constructing their Global Competitiveness Index ([1]) a number of twelve categories of factors: institutions, infrastructure, macroeconomic stability, health and primary education, higher education and training, goods and market efficiency, labour market efficiency, financial market sophistication, technological readiness, market size, business sophistication and innovation. While macroeconomic stability and labour market efficiency could be connected with competitiveness through prices, the other categories are related more to non-price determinant factors.

Other institutions like the European Central Bank ([4]) and the OECD ([2], [3]) distinguish clearly between two main categories of determinants:

a) price competitiveness determinants. These refer to factors such as the real effective exchange rate and unit labour costs. The real effective exchange rate should ideally be computed using all the trading partners of an economy and the price indexes of only tradable goods. This is a computationally intensive task and taking into account the fact that the main trading partner of all NMS is the euro area, we will use the bilateral exchange rate against the euro and the prices of the euro zone to compute the real exchange rate. In order to include only the prices of tradable goods, we compute the real exchange rate based on the export deflators.

b) non-price competitiveness determinants (technological and structural competitiveness). This category focuses on factors such as product quality, innovation (measured by research and development expenditure, number of patents etc), the structure of exports on products (concentrating on the technological intensity of products) and geographical destination, the flows of foreign

direct investments and so on. In case of the technological intensity of the products, the exports are divided into three broad categories: low, medium and high-tech products. A country is considered more competitive if it focuses more on medium and high-tech products and less on low-tech ones.

The next section will focus on the main developments in these fundamental factors of competitiveness in the NMS.

3. The developments in the determinants of competitiveness in the New Member States

The Global Competitive Index published by the World Economic Forum ([5]) places Romania on the 64th spot out of 132 countries. Out of the NMS the best performer is the Czech Republic, followed by Poland and Hungary, while the worst performers are Latvia and Bulgaria. Romania scored particularly poor at two categories (institutions and infrastructure) and received the best scores in case of higher education and training and market size.

Empirical studies ([1]) have shown that in the case of the NMS, their competitiveness has improved in the detriment of the euro area countries, in complete disagreement with the evolution predicted by the real trend appreciation of their currencies. The analysis was based on the development of the real effective exchange rate computed using unit labour costs, the consumer prices index, the GDP deflator or the industrial producer prices index. However, using the exports' deflator, the real appreciation of the exchange rate is smaller in countries like the Czech Republic and Poland, indicating only a small deterioration of the price competitiveness in the case of these two countries in the period of 2000-2008 and a rebound starting from the last quarter of 2008. Moreover, Hungary seems to have improved its price competitiveness throughout the period. The countries which have experienced the most severe reduction in price competitiveness are Lithuania, Romania and Bulgaria. All NMS seem to

have regained their price competitiveness after the onset of the international financial and economic crisis. It is worth noting however, that the correction in price competitiveness was higher in case of the countries with flexible exchange rates which suffered a sizable nominal depreciation of their currencies. In case of the countries with a currency board or pegged exchange rate, the adjustment of the real exchange rate was prompted by an important decrease in nominal labour costs.

Figure 2. The real exchange rate against the euro based on the exports deflator

Source: Eurostat, author's calculations

Regarding the labour costs, these have systematically increased in all NMS; this is to be expected considering the low level of nominal wages existing in these economies compared to the euro area average. The highest increases in the analysed period were clearly experienced in Lithuania and Romania, while increases in the all fixed currency regimes countries have also been important. This has impacted severely on price competitiveness as we have already concluded by analysing the developments in the real exchange rate (figure 2). However, countries like Lithuania, Latvia and Estonia rate have experienced a sizeable adjustment in labour costs during the economic crisis, attempting to regain their competitiveness without devaluing their currencies. Despite the important increases in labour costs in Romania, the average wage expressed in euro is still the second smallest among the NMS. Consequently, we should expect further increases in labour costs in Romania, which, although smaller than those experienced in the past, will erode external price competitiveness in the future.

Figure 3. Labour cost index developments in the NMS

Source: Eurostat, author's calculations

The analysis of the research and development expenditure as a proportion of GDP shows that the Czech Republic is the leader in this area followed, at some distance, by Estonia, Hungary and Latvia. Romania had for a long period the smallest ratio of research and development expenditure to GDP out of all NMS, but has surpassed Bulgaria since 2006.

In terms of foreign direct investments (FDI), the best performer is Bulgaria, which had a ratio of FDI flows accounting for as much as 30% percent of GDP. However, this country has remained the worst performer in terms of external competitiveness out of all NMS. The second recipient of FDI's is Romania, although the inflows have reduced since the onset of the international financial and economic crisis.

Another indicator of the external competitiveness of a country is the technological intensity of its exports. An analysis of the products exported by Romania broken down into eight broad product groups following the Standard International Trade Classification indicate a clear pattern: the exports of equipment and machines (a category of medium tech products) has gradually increased in the detriment of manufactured products (a category of low tech products). In this respect, Romania's external competitiveness seems to have gradually increased.

4. Conclusions

The paper analyses the export performance of the New Member States in terms of export growth and market share in the period of 2000-2009. The results show that the most dynamic New Member States (NMS) in terms of market share are Poland and the Czech Republic, followed by some distance by Hungary and Romania. Also, the main determinants of external competitiveness for these economies are examined. Hungary has benefited from an improvement in price competitiveness, while the trend appreciation of catching up economies has only slightly affected the Czech Republic. On the other hand, Romania and Lithuania are the countries that have lost their price competitiveness the most due to a rapid increase in labour costs. In all NMS, price competitiveness has been partially restored during the economic crisis but the mechanisms have been substantially different: while the countries with flexible exchange rates have benefited from the nominal depreciation of their currencies, the countries with a fixed exchange rate have relied on the adjustment in nominal wages.

In terms of non-price competitiveness, the best performing country is the Czech Republic, a country which is also ranked the highest according to the Global Competitiveness Index. Romania's non-price competitiveness is quite low considering the small amount of

research and development expenditure and the unfavourable scores it received from the World Economic Forum at chapters such as institutions and infrastructure.

As the level of the average wage in Romania is currently smaller than in the other NMS, we would expect it to increase in the future, thus further damaging price competitiveness. In this case, Romania will be able to gain market share and improve its capacity to export only by making progress in non-price competitiveness determinants: the structure of exports, innovation, institutions, infrastructure and so on.

cristina_coculescu@yahoo.com
radudespa@yahoo.com
ofolcut@yahoo.com

Abstract

The consumption economic theory, which was propounded by Ernest Engel (1821-1896), has been substantially improved over time, by the contributions of the modern economists. However, the extensive themes of the studies about the euro-atlantics populations' consumption models (as well as populations from other geographical areas) still remain a domain relatively less explored and known.

At present, no appreciable understanding of the consumers' behavior exists and especially of the real motivation for adopting certain consumption practices. Although in this domain a lot of studies, observations and investigations had been conducted.

In this paper, the authors analyzed the change impact of the consumption models in the context of a sustainable development. The analysis follows the evolution of the phenomena, as well as it concerns the general characteristics at the global level.

Key words: consumer behavior, consumption models, sustainable development, efficiency, sufficiency

JEL Classification: D01, D11, Q01, Q57

1. Introducere

Even in the last years, there were many institutions and large companies who initiate scientific investigations on the consumption model belonging to different populations. The existence of a relatively small number of researches using sample comparable methods complicates the integration in a unitary item of knowledge.

At present, there is no exhaustive comprehension of the consumption behavior and especially of the real motivations in adaptation of consumption practices. Even in this domain, there are a lot of years of searching, studies and observations. But, in every situation, the searching does not delimit the investigation area using only a peculiar method. No one can, however, investigate in a satisfactory manner, the field of consumers' reason and impulses which are at the base of the effective consumption behavior.

Anyway, the socio-economic consumption theory has evaluated the relationship between rational and emotional feelings. It has often been observed that the universal human needs are generally satisfied only by certain attributes of the products or services image.

The dynamics of change which occurs on different market of the goods and consumer services attained a high level during the last decades [1].

In any market economy, the elastic demand profile responds to changes in some elements of the methods and techniques for research of the consumption models.

2. Sustainable Consumption – Sustainable Development

The sustainability principles designate the gearing of three dimensions: ecology, economy and social area. In combination with the consumer behavior, the ecological dimension of the sustainability becomes more and more important. The economic development and the social welfare are not possible on long term, particularly in a well limited environment, which arise the nature to the rank of vital element. On the other hand,

the economical and social aspects enable the trial of making ecology workable. The ecological production and consumption are elements which can be realized if the consumer can afford it and if both the consumption and the production are based on acceptable social auspices [2].

The sustainable consumption is a field of activity that is explicitly stated and is interdisciplinary. The change of the consumer behavior is a process involving a large number of social groupings. Apart from households, the biggest consumer grouping, are the authorities, the economy, educational institutions, Non-Governmental Organizations, and more other. This is why the authorities need to create a proper legal frame so as to protect and sustain the style of consumption of the consumers.

The consumption and production, short sustainable models, represent an important cause of the environment issues at all levels – from the local level to the global one. Therefore, there are intensive preoccupations about “the changing of the consumer’s custom” subject. Additionally, the “sustainable consumption” issue - also like “sustainability” issue in general - is linked by other subjects as justice (at global level), distribution or globalization. Especially in the rich industrialized countries this prevails as a rule customs underlined by the exaggerate consumption. When in some world parts, people consume in a wasteful manner, there are other poor areas of the world where people cannot satisfy even the basic needs. For this reason, a change in consumption and production models requires the planning of a strategy which should take into account the disequilibrium observed above [2,4].

2.1. The change of the consumers’ customs

First of all, the change of the consumers’ customs supposes a fundamental change of the values and the life style. The consumers’ change in the way of thinking and to action cannot be imposed by the authorities. For this reason, the occurrence of new and sustainable customs in the consumers’ behavior needs a comprehensive, informative and consultative campaign. Concerning the consumer, the

products and the mode of transportation must become transparent, the “right ecological” price must be known and the alternatives which should protect the environment must be revealed [3].

Only in a second stage one question occurs: which should be the concrete measures through a sustainable comportment concerning the consumer be implemented?

Taking into account the consumption complexity phenomena, even at the level of relatively small population group, the steps of empirical study often enforce the effectuation of methodological adaptation, based on the rigor of standardisation of research methods.

The indicators used by the United Nations Organization, for evaluate the consumption model dynamics make up essential instruments in monitoring the changes which occur in the volume and the intensity of the exploitation and use of natural-economic available resources, as well as in the formulation of the profile politics [9].

The social politics specialists from different countries had tried to identify series of indicators to signify the welfare and the wealth of a nation and its sustainability. An indicator of high accuracy in this sense is the gross domestic product; even it presents a lot of limitation concerning the comprehensive formulation of the population, access to the goods and consumption of the products.

The UNO Commission on Sustainable Development has instituted an international working schedule on the indicators concerning the sustainable development. An element of this program consists of the identification of a set of basic indicators for changing measurement on consumption/production models.

The exigencies imposed on the consumption indicators, for their admission into this set must be simple, attractive and accessible. From these points of view, the GDP/inhabitant presents relevance, relatively high at the level of inferences, which can be made on the peculiarities (quantities) of the consumption models [6].

The UNO distinguished between two large categories of relevant indicators for studying the consumption model: the key-resources and the principal group consumers. The indicators concerning the key-resources aim at the

energy, the materials, the water and the land. The indicators concerning the principal group consumers aim the mobility, consumption of goods and services, buildings, savings, foods and at entertaining activities.

The selection of such indicators takes into account the perspective of designing of sustainable production and consumption models. The differences between these indicators and classical indicators express, on one hand, the impact of the use the key-resources on the environment and on the other hand, reflect the type of concrete nature of the adopted decisions, of both the producers and consumers of goods and services. In order to build and to develop such indicators, the governments of developed and in transition countries can use a wide range of indicators based on the peculiarities, needs and national priorities.

Since 1992, many institutional groupings of big affairs interests in industry, non-governmental organizations or large academic communities have made effort in order to classify the concepts regarding the engagement of long-term sustainable production/consumption models. This is relevant in determining the responsibilities which accrue to the different economical, social and political actors in this domain and implicitly orient the scientific research in the sense of investigation the premises of sustainable production/consumption models.

Many factors/indicators of the sustainable development are correlated with the consumption/production models. One of these factors influences the consumption/ production models, others factors are influenced by the existing models, but for most of factors/indicators, the causal relations function in both ways [5].

One factor which has a high influence on the consumption/production models is the poverty phenomena. The families with low incomes activate in the low productive and ecologically fragile environments, which they used to exploit in an unsustainable manner in order to survive. Such families have a reduced access to the capital flow, to the production means, to the promotion opportunities on the social-economical stair, to the cheapest energy distribution, to the public services and even to some social services, to other types of

resources which are capable of alleviating/eliminating their poverty status.

The UNO working schedule with the sustainable development indicators has proposed the control keeping of a large number of poverty indicators. These include: the poverty rate, the at-persistent-risk-of-poverty rate, the inequality of income distribution ratio (Gini coefficient), the gender pay gap in unadjusted form ratio, the access to the wealth, the access to the education, indicators of sanitary assistance, etc.

The consumption/production models are also influenced by the migration of population phenomena, by the goods, capital and information movement. The rural-urban migration and the international migration determine the changing of the consumption models of the ones involves and often the ones existent in the start/destination area of the migration flow. The consumption models for the different geographical areas are reciprocally influenced by some commercial practices and by the realization of some investment.

The promotional phenomena, the television and other mass-media means, as tourism or other way of trip, also constitute sending opportunities of some consumption models, especially from the developed countries to the ones in transitions.

The consumption/production models influence many domains as natural resource availability like water, land, green areas, etc. These influence also the population health, the development of human settlement and wasting resource patterns. All these influences have become very relevant in the last decades, having an important contribution to the globalization phenomena.

2.2. The efficiency strategy and sufficiency

There must be settled principles in order to open the way for a long sustainable society. A lot of courage and creativity are needed to put into practice these principles.

The efficient strategy is meant to drastically reduce the consumption through the technical progress redirection. In the center there is the resource productivity growth. A reduction of the natural resource

consumption to its tenth part is a big challenge for all creative and enterprising human beings. It is considered to represent a “new technological revolution comparable to Industrial Revolution”. This courageous project is still less litigious comparable to other projects [7].

The efficiency strategy is just a passing level to a sustainable development. This level must be completed and sustained by another dimension, called by the Wuppertal Institute authors “The Sufficiency Strategy”. It is about the necessities and life styles and a redefinition of life quality. This does not mean the end of a well-being.

3. Conclusions

There is not only one principle available for the future consumption. The characteristic feature of consumer’s decisions is an integral component of the modern, democratic, pluralistic society which is not doubted by the scenarios which anticipate new, sustainable life styles. The consumer's decisions are and will be strongly influenced by the frame-conditions such as: political decisions, prices, available technologies, incomes and their distribution, social rates and the principles which guide the different existing groups in the society, the advertising and marketing influence.

The adoption of long sustainable consumption processes assumes the usage of assets and correlated services which guarantee the satisfaction of basic necessities, with the condition of playing down the exploitation of natural resources and toxic substances, avoiding the wastage of resources and pollution, among a whole life cycle so that this will not jeopardize the existence of future generations.

As a result of the new exigency assessed by the production processes, the desirable changes of the consumption models features assume [10]:

- the promotion of the examination of consumption behaviors, which brake the sustainable growth, as well as the examination of possibilities of changing these behaviors at the global population's level and especially at the level of populations with consumerist type;
- the identification of the most efficient policies and dissolution instruments of the

unsustainable consumption/ production models, inclusively through information dissemination and ecological warnings;

- the achievement of the equitable distribution of development resources, inside and between countries.

To have a sustainable existence means having a healthy living, in partnership and in a tolerant way, to admit the value of things, to enjoy and use them with pleasure. It also means to attach much value to quality, not to run for every fashion tendency, but follow some of them. To consume in a sustainable manner means to remember that “better” is the enemy of “good”, not “cheaper”; it means to remember that the community and the individuals are parts of society [9]. The sustainable life style is the art of knowing how to behave honestly in fake structures. So we need both of peak policy and our basic actions to do that. Only acting together will ensure a long sustainable economic, production and consumption structures.

Application Integration - Financial Accounting Model in Applications *Enterprise Resource Planning*

Codreanu Diana-Elena,
Popa Ionela,
Marin Camelia

“Constantin Brancoveanu” University of Pitesti
codreanudia@yahoo.com
popainela80@yahoo.com
cameliamarin81@yahoo.com

Abstract

Most specialists believe that there is no Enterprise Resource Planning without any financial and accounting information in the operations they administer in these systems.

A financial-accounting pattern gathers and strengthens information related to all the activities of a company thus allowing unitary management to be possible. A financial-accounting pattern itself is not the most important but it is necessary when implementing any ERP application. All the data in a system are centralized in such a financial-accounting pattern, therefore providing the support for various reports.

The word integration is very common nowadays, whether we talk about integration in the European Union or other structure, whether we talk about economic integration applications.

Key words: Enterprise Resource Planning (ERP), management system, financial and accounting information.

JEL Classification: M41;

Global economic development, competitiveness, have led to organizational information systems solutions in models of increasingly complex.

Currently, due to progress in information technology and telecommunications, access to data and information is easier, and so the question is to know more and more, and know how to use the maximum information that you have to a time.

Ours is a country highly skilled human capital in terms of professional accounting and computer but internationally recognized. Also, there is continued interest of IT specialists to offer the best possible solutions in terms of accounting.

An integrated computer system to be the answer for any company that needs a modern computer system to automate processes internedin organization, or relations with customers, partners, suppliers.

Application integration and organizational expertise is called in the language of EAI (Enterprise Application Integration). In companies shows that there are fewer computer to carry out design and write applications and increasing number of applications that integrate computer. Be integrated entity is not represented by an object or a software component, but is a software application.

Application integration is present in two forms:

- Intense integration applications - company-wide application integration

- External integration applications - integration of business-to-Business applications.

Among the advantages of integration can be mentioned[9]:

- *Scalability* - replacing all with a single interface that provides all access points to the information system, their ease of administration and the possibility of adding other tools or applications;

- *Performance* - software package provides full data security;

- *Ease of deployment* - the ability to change parameters (source name, target name) is essential;

- *Centralized management* - interfaces are automatically managed from a central point;
- *Accuracy in processing / zero errors* - the ability to deliver data to the target immediately after reading the source is very important;
- *Heterogeneity of sources* – the process of transforming data into information involves the possibility of combining heterogeneous data source;
- *Centralized management* - interfaces are automatically managed from a central point;
- *User groups* - organizing a database of users, sharing of experiences and dissemination of best practices and successful cases of failures;
- *References* - obtaining an integrated platform is the best recommendation in electronic business world;
- *Security* - Security applications require high standards;
- *Quality of technology partners* - large projects requires companies to develop business relationships only with partners who are already integrated;
- *Training* - conduct training programs for groups of users;
- *Unlimited Support* - 24 hours in 24, seven days in July, Web and telephone support with easy access to company knowledge base for fast resolution of problems;

An integrated computer system to be the answer for any company that needs a modern computer system to automate processes internedin organization, or relations with customers, partners, suppliers.

Financial system - accounting plays an important role in any organization because it involves all activities that ensure the financial resources necessary to achieve organizational objectives and track while its heritage value of the entire movement.

Also reflected in other economic activities taking place in economic organization.

Integrating software applications is a complex activity that brings together people, equipment, programs, and management practices.

One of the main problems facing IT managers is to develop an effective integration of information systems and organizational.

Information from economic integration organization strongly influence the organization's financial accounting. Different information sources should always work with

financial accounting system to collect the necessary data recording operational accounting transactions.

An ERP management system of a company means planning the four major factors in successful business: human, financial, technical and resource factors (the four M's – Man, Money, Machines and Materials) [6].

Due to the progress of information systems, the study of accounting trends pursues three aspects:

- *accounting as a descriptive and modelling instrument of an enterprise*, thanks to the enterprise's and its economic, social and technical environment's evolution. In this context, there are attempts to identify the evolution directions which occur within a modern enterprise;

- *accounting as a system processing the necessary information in enterprise modelling*. The American Accounting Association sees accounting as an information system since the latter comprises the general aspects of information theory as well as typical features of systems' general theory;

- *accounting as a social practice in a network of regulated restrictions* taking into account the strong relationships among an organization, accountants and users.

At present, accountants benefit from new information means that help them gather, process, manage and analyze both the concrete data resulting from certain processes, and those referring to knowledge, an enterprise's tangible assets which are possible due to the following applications: the Intranet, knowledge bases, data mining, especially the Electronic Data Interchange.

Finding new solutions to integrate certain dissipated informational sources within an enterprise which should collaborate with the financial-accounting system has become a must. At present, an idea is stated about complete integration which is a major goal of managing informational resources which are getting more and more complex and numerous and therefore it is necessary to accomplish and implement integrated information systems.

A primary sense of the information system notion is provided in Government Decision no. 841/1997, where it is stated that an integrated information system is one that meets the following requirements:

- it uses a unitary data base;
- comprises information programmes which include the activities of all company functional departments according to its organization chart;
- there is a security plan of the information system which includes proper technical and organizational steps.

ERP Systems emerged in company applications in the context of the information boom and the extraordinary growth of information technology and communications in the early 1990's.

An ERP (*Enterprise Resource Planning*), "seen as the best way to express the interdependence between the economic field and information technology, is a software multi-modular infrastructure which provides management and coordination support of various structures and processes in a company with a view to achieving business goals" [1]. The main goal of an ERP system (*business processes' integrated management system*) is to accomplish better communication within a company, to improve the cooperation and interaction among various departments such as production planning, acquisitions, production, sales and customer relations.

Davenport T.H., one of the famous specialists in the fields of management and information systems for business, suggests the following definition of an ERP: "a package that promises the complete integration of all the information within an organization" [1]. This concept is illustrated in **Graph 1**.

Graph 1. The conceptual scheme of an ERP system (abridgement of [5])

Front-office applications
Back-office applications

An ERP system is a complex software solution based on the customer-server architecture whose elements are integrated within an ordinary platform in order to manage a company's resources, process transactions and facilitate the integration of all the necessary processes in business centralizing them, making data dissemination easy and removing redundancy [1].

The ERP systems developed until now include a set of elements: schedules, money collecting and payments, salaries, human resources, planning and production, project management, production monitoring, consumption and cost planning and supervision, along with the *financial-accounting element or general book-keeping*.

The main functions of these elements are the following: the automation of financial-accounting data entries taken from primary documents; the accomplishment of full accountancy at analytic and synthetic level. More often than not, this element achieves only the functions of financial book-keeping namely getting the synthesis accounting documents required by the legislation in force (accounting balance sheets, VAT reporting, taxes and fees for the budget) and the accountancy documents (accounting notations, day books, account cards, cash books, sale and acquisition books, trial balances etc.). This element can be associated to an analysis module just like an instrument panel (typical of a MIS or even EIS system) which provides synthetic and operative information about company performance necessary to a manager when making decisions. According to the accounting data, various indicators are calculated which show the financial results of a company such as: revenues and expenses for products/services, the status of financial availability etc.

The Financial-Accounting Module is the central element of any ERP application. All the data in the system are centralized in the financial-accounting module and they provide the support of various legal reports. As far as small companies are concerned, the investment in a financial-accounting solution is a primary step; yet, as they grow, resorting to an ERP

solution to integrate all the business processes becomes a compulsory request”, stated Raluca Ioana Komartin, Managing Director, LLP Bucharest in review ”Market Watch”, February 2010, no. 122”[7].

The specialists in the field believe that a financial-accounting pattern manages information which in their perspective is central to any company.

Implementing an ERP system often takes place in two stages in order to diminish the impact upon the entire activity of a customer and also to reduce the stress in an organization after changing the work methods. Therefore, the first stage includes the implementation of the basic modules, namely: Production, Financial-Accounting, Fixed Assets, Commercial and the additional patterns subsequently. Implementing the Financial-Accounting module should be part of the first stage of an ERP system implementation due to the overall picture it provides to the management.

Along with integrating the data and achieving full reports about organization activities which are major advantages of an ERP implementation, the Financial-Accounting module has as a principal strength the automation of specific operations up to 95% according to the customization degree of an application. Operations’ automation is possible due to the high repeatability of financial-accounting operations and implies some models already present in an application or predefined when implementing. Along with the increase in the operation speed, automation allows people who do not have too much accounting knowledge to work with this application and it

also does not allow human errors in certain operations.

The Financial-Accounting Department is very important in any organization as the main goal of any organization is to make profit and this is what the department takes care of, watching the money of all the departments in a company.

The Financial-Accounting model in ERP systems allows other departments in the organization to function at a high efficiency level and provides those in charge with company management the support, the right and timely information they need to make the right decision. It is believed this model should be the first step in the implementation of an ERP system and it should be granted much attention both when developing a software product, and during implementation project.

m_ellysa@yahoo.com

Abstract

Access to information technologies and INTERNET create prerequisites for building information systems to serve the interest of individuals or entities. In this regard it is notable European initiative and is currently Romania to implement e-services as a solution to solve e-governance bureaucracy and inefficiencies that affect the government.

This study reviews the benefits of implementing e-government system in government, barriers affecting the implementation and development of e-government systems and elements of cost-benefit analysis to be undertaken any project before and during implementation to become a successful example.

Keywords: e-government, cost-benefit analysis, information services, Internet network, ITC

JEL Classification: L86

1. Introduction

Accessible "on-line public service through information technology, via the Internet was an important and significant step made by the European countries in recent years. Governments of various European countries have become aware of the importance of Internet and information technology as the optimal channel, efficient

and effective promotion of the interests of both rulers and citizens interests.

In general, the term e-governance means use of IT, particularly Internet services, as a tool for better governance, good governance through better understanding of public policy outcomes, high quality services provided a greater commitment from the public [9]. The e-governance can be seen as a permanent commitment by the government to improve relations between citizens or private sector on the one hand and public sector on the other hand, having to the lower cost, providing efficient and quality services, providing information and knowledge [5].

In a broader definition of e-government includes the use of all information and communication technologies, from simple fax machines and finishing with the sophisticated systems used by different ministries or government apparatus, to improve citizen access to government information and services, and monitoring satisfaction, commitment and participation of citizens on the process of government [10].

In another narrower definition, e-government is the production and delivery of government services through IT applications used to simplify and improve communication, collaboration and transactions between government and the various elements of the apparatus of government, between different ministries, various government agencies, between private and public sector [1].

The purpose of the paper is to highlight the following aspects related to the use of e-government in public administration:

- Benefits arising, for citizens and the private sector through the implementation of e-governance in public administration;
- Factors and barriers affecting implementation and developing e-governance ;
- Efficiency investments in new public service.

2. Implementing e-governance in public administration

The relationship of public administration - citizens has always been a rather controversial, both sides having quite a lot of the other accused. Lack of professionalism of civil servants, excessive bureaucracy, corruption that reigns over all but officially there, going slow administrative procedures, lack of professionalism in public relations, congestion, confusion or employee errors, lack of awareness among the public are largely matters Management involved in this relationship-manage.

A modern government requires overcoming all these problems with the emphasis not only on maximizing the efficiency of public services but also the layout and the provision of such services on their quality. This is to make everything transparent, to provide equal services to all who request it, Fast and the highest quality. Using information technology offers the possibility of changing the quality of government services citizens and social and organizational entities.

Information technology can help public institutions in two ways:

- Implementation of programs undertaken in the administration processes - helps to conduct internal business, data processing and management, the design of different systems and different analysis. This is the "invisible" to the public.
- Use of Internet domains - allows the display of information on the institution and its services and collect feedback from users, various other information about them

or proposal for electronic services that can be used much faster and far more comfortable citizens, only the computer.

In public administration, both at local government level and at government agencies, e-government involves the interaction of central government / local citizens to provide quality services and by their use of electronic means to communicate with other fellows, to discuss problems and complaints regarding the operation of this administrative system

To summarize what was said above, the main objectives of using information technology in the public sector are:

- free access to information and exchange of information;
- development of democracy offers citizens the opportunity to express opinions;
- opening the public sector to be more transparent, efficient, rationally organized, able to offer better service [2];
- measurement, monitoring and performance reporting, efficiency and effectiveness of public institutions.

Viewed in terms of benefits to citizens and private sector, implementation of "e-government in government sector can contribute in many ways:

- More efficient public sector organizations;
- Increase accessibility of citizens to public services and public databases;
- Decrease various costs and waiting times for customers of various public services;
- Improving the quality of public services;
- Building trust between public organizations and citizens;
- Increasing monitoring and surveillance of public service to the community.

It also benefits [3] to both citizens and the private sector resulting from the very characteristics of this new type of specific service digital economy:

- opening and participation: opportunity to express your opinion and to have greater control over decisions affecting you;
- accessibility: lower costs and access for all citizens;
- ease of use: language simple and easy steps to follow;
- availability: all they want people, whenever and wherever;

- speed: discounts or gain time.

In Romania the way government institutions, with very weak links between institutions and lack of understanding of common elements with integrated institutions and real joint is mediated by the Agency for Information Society Services (ASSI) [11] and is supported by four large pillars:

- Central Supply - providing back-office systems for central administration. This is intended implementation of elements of common knowledge, reducing costs, improving simultaneous analysis and enhanced security areas;

- Data exchange administration - Using position which he created by operation of only portal (www.e-guvernare.ro) for the provision of e-government by central government institutions and Memorandum for the implementation of electronic portal as a personal contact, ASSI agent data can become public institutions. However, law enforcement may be insufficient and more actions would be necessary. The main challenge is to become ASSI trusted partner for other institutions. Cultural barrier can be overcome mainly by cultural means, and confidence is one of the most important means.

- Unified methodology - To obtain a synergistic effect among public institutions in terms of improved outcomes of IT & C should be used a common methodology. Here, ASSI has, by law, the authority to regulate / govern the field of e-government.

- Standardization - Some of the main targets are: development of an architectural basis of government and methodology for business processes.

Agency ensures the smooth functioning of some of the e-government systems critical:

- National Electronic System is the law, the official portal for central government services. This gives companies greater opportunity to file tax returns online. The system also centralizes all official forms from central government so that citizens can download them free and they can send you only completed by the institution simply by accessing;

- Electronics in Transportation System Award is a two-way transmission licensed under the criteria set by Romanian authorities for Transport and the Ministry of Interior. Shipping companies introduce their offers complete vehicles (engine type, number) and the desired path and the Romanian authorities of Transportation or local authorities introduce other criteria (experience in transport, etc.) And finally, to designate the winners of each range.

- Electronic Procurement System is the most important component of the Agency. One of the three e-procurement systems in Europe has been developed since 2002, and 2008 will be fully subject to all EU rules.

All systems, as some staff have belonged to another government body, which had as main task to supervise and manage the frequency spectrum. Their main challenge was to provide quality services and even though their movement has been newly created agency, the challenge remained the same. Agency is another organization more "service oriented" than "customer oriented" and based on principles of governance will remain an indefinite time, maybe with minor changes according to the specific new services.

3. Impediments to deployment of the system e-governance in public administration

In most cases, strategies and plans for systems implementation "e-government in developing countries, is based on the theories and experiences of developed countries [4]. Feeling the pressure of requests from citizens to provide public services on-line type e-governance, developing countries have no other way than to take the perfect model of implementations of e-government in developed countries [5].

Implementing a system of e-government in developing states, and particularly in our country is influenced by major factors.

Center for International Development of Harvard University, identified four factors impact on the implementation of systems e-governance, describing in terms of implementing the system of e-governance gap between the developed and developing

countries [6]. The four factors mentioned can be synthesized as follows:

- Accessibility to the Internet - includes communications infrastructure development, resource allocation and support of information technology and communications;
- Learning and using the Internet - including the extent to which the education system fails to integrate information and communications technology in a process to help improve education, the existence of common training programs for the purpose of training people in information and communications technology (the digital sample of the baccalaureate examination, or obtain the ECDL certificate);
- e-economy development - including the use of information and communications technology by private firms and public sector to interact;
- A legislative framework for the Internet - including policies to promote or discouragement on the use and / or implementation of information technology and communications

If some experts have focused on factors influencing the deployment of e-governance, other professionals focused on another aspect of the implementation of this, namely the barriers that lead to systems incomplete e-governance or hold back the development time of systems already.

In general, if the government in implementing or developing a system for e-governance not takes account of the influence and impact of various factors mentioned above, these factors become real return from deployment to exceed the barrier pretty hard by the government.

According to the OECD Observer publication [9], the barriers that may arise regarding the implementation of the system of e-governance can be summarized as follows:

- Legislative barriers - lack of a clear framework to clarifying government agencies or any public organization about what can and cannot be included in the e-governance, particularly in areas which require security of data or technical standards may be a major barrier against

the implementation or development systems;

- Budgetary constraints - budgetary allocations for the e-governance;
- High cost IT investments, that massive allocations of budget funds cannot be supported or not present, for some reason, the budgets. In many cases the structure and the design of the budget act against the deployment of e-governance in that by not recognizing that budget expenditure on e-government as being in fact a cost-effective and efficient investment.
- A barrier of technology and implementation solutions adopted - investments in e-governance IT and involves high costs, costs borne by the budget. In general, the higher a country's technological level is higher - I refer here to a well structured IT market, IT major indigenous producers, there are strong centers of research in the IT field, the more country first has a much faster access to information and cutting-edge IT technologies and on the other IT technology acquisition costs are lower.

Another classification of barriers affecting the implementation of systems e-governance is presented below [7]:

- Legislative barriers - on the existence of laws, procedures, regulations and specific directives to allow or facilitate the development of electronic services.
- Administrative barriers - on the existence and assignment of qualified personnel, the personalities of the public service mentality and the need and desire for structural reform, lack of funds necessary to purchase IT technology;
- Technological barriers - associated with the availability of IT infrastructure, there are many and varied applications, standards and safety standards;
- Cultural barriers - public attitudes associated with IT technology, degree of openness that society has to technologies such as IT, the level of information and findings on the use of population information and communication technologies, the degree of trust / mistrust of people in solutions Proposed by IT systems, the costs that users generate in the use of electronic services;
- Social barriers - associated with impediments to the social status of users and / or staff use of e-governance (fear of job loss or

degradation of social status, resistance to change of personnel because of how slow to adapt to new IT technology).

4. Efficiency investment in e-governance

Creating and implementing a system of e-governance involves serious investment so that it is essential to Cost - benefit from expected costs and benefits of the project, taking into account also the risks and the project.

The main elements [8] of such an analysis include:

- A. Costs
 - Domestic investment needed to shift from traditional to electronic services;
 - The costs of establishing an electronic government portal;
 - Administration and maintenance.
- B. Benefits
 - Benefits for the institution;
 - Benefits for citizens (or other beneficiaries);
 - Overall benefits.
- C. Risks
 - Political risk;
 - Organizational risk;
 - Technological risk.

Such analysis is based on principles of assessment of any proposed business and eliminates those investment projects in electronic government services consuming public funds and not makes anything. As a negative example can be given to e-government system in a developed European country where 23 of the 60 services have not been used ever in the last 5 years and the number of electronic transactions is less than 0.1% of the total.

Following a cost benefit analysis of such investment in electronic government services can be outlined the following recommendations

- Make a detailed and rigorous analysis - to determine the actual project, it should be considered in detail. Part of planning is essential in providing the information necessary to evaluate the project. The institution must establish

detailed objectives, milestones and success criteria in time for the projects it proposes.

- Assessment project during implementation and after completion - this approach allows you to tailor and improve underperforming areas, which will increase the chances of success of the project. However, this assessment will determine the initial assessment and effectiveness, enabling better planning of projects next. It is appropriate to create a working group to assess and monitor (which can be composed of representatives of all those affected by the project: government, community, companies, experts)

- Taking measures to increase the impact of the project:

- Reducing costs by:
 - Technological leap - the choice of the most modern and comprehensive solutions;
 - Focus on actions to maximize impact: offering the required services and delaying others until users are ready (there are many studies on the use of Internet by citizens that can be used for this);
 - Management contracts with major hardware and software bidders, whereby payment is made according to the results, to reduce initial investment and risk.
- Increasing impact by:
 - Enlarging the target group - the creation of service in order to be used by a wide range of clients;
 - Stimulating the use of Internet and computer - creating public access points, facilities for investment firms offering IT / Internet;
 - Developing new services, making links to other indirect services to extend the offer and get any additional income (must be borne in mind that the gates of public institutions generally attract a huge number of visitors).

5. Conclusions

The implementation of e-governance is clearly for the government sector as an important step to increase efficiency of public services and in terms of increasing customer satisfaction (categories of citizens who call a particular type of public services).

While the benefits of using this type of systems are major implementation of these systems is not easy, it involves detailed and

serious analysis of the various and multiple aspects that may influence the success / failure of implementation and further development of the system.

Also ignoring or non-analyzing factors have a major influence in the implementation and development of systems for e-governance drive to transform these factors into genuine and serious "barriers" barriers that work against the implementation of e-governance and are in fact responsible for going slow or failed implementations of this.

Finally any plans to create a system of e-government budget include the allocation of significant amounts of money. As the economic environment where investments are planned and analyzed in detail to serve the best interest of the trader and the public system such projects should be subject to a cost-benefit analysis to highlight the need or otherwise of such a project.

Access Customized Forms

Cosma Emil
Jeflea Victor
"Ovidius" University of Constanța,
ecosma@univ-ovidius.ro,
jefleavf@yahoo.com

Controls group) – Fig. 1:

Abstract

By using *Word*, *Excel* or *PowerPoint* one can automate routine operations using the VBA language (*Visual Basic for Applications*). This language is also used in *Access*, allowing access to data stored in tables or queries. Thus, Access and VBA resources can be used together. Access is designed for programming forms and reports (among other things), so there won't be found any of the VBA editor's specific forms.

Keywords: Acces, programming forms, reports

JEL Classification:H2

1. Introduction

Access Forms is primarily a way to input a more friendly data introduction way than the classic method of grid operation with rows and columns in *Datasheet* view mode.

One form *includes controls* that are related or unrelated to fields (of one or more tables or queries) which allow the definition of a graphical interface with the user: labels (*Label*), text boxes (*Text box*), buttons (*Button*), lists (*Combo Box* or *List Box*), radio buttons (*Option Button*), check boxes (*Check Box*), images (*Logo*), graphics (*Chart*), etc. These controls may be assigned code sequences (*Visual Basic* instructions).

In the *Forms* group one chooses the *Form Design* button, while controls can be inserted in the form (in the *Design* tab,

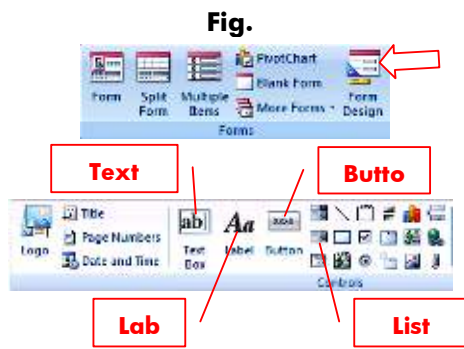

× **Button.** From the *Command Button Wizard* window select a *system button* specific to a category (associated with a code) or a *user button* - which the programmer can edit and to which a personal sequence of instructions can be assigned (in this case, click on *Cancel*) - Fig. 2:

× **TextBox,** related with a field in the data tables (**Bound Control**) or *unrelated* (**Unbound Control**). The unrelated text box also contains a label which prefixes it. This label can be edited or removed (when it is not necessary) – Fig. 3:

× **Label,** text displayed on the form (controlled via software) - Fig. 4:

× **ListBox, ComboBox**, list of one or more elements. If the total number of items exceeds the number of those that can be attached, a *scroll bar* is automatically added to that control. These boxes may be populated with data from tables - Fig. 5:

In order to edit forms, it is necessary to carry out specific operations such as:

- × controls' movement and dimensioning;
- × controls' properties modification (in *Property Sheet*);
- × controls' appearance modification through borders, shades and text effects (*Bold, Italic*);
- × introduction of new controls.

Controls included on the forms are of three types: *Bound Controls*, *Unbound Controls* and *Calculated Controls*.

- **Bound Controls** are data fields within a table or a query. A form must contain a control related with each field you want to appear in the form. *You cannot insert calculation within a related control.*

- **Unbound Controls** are controls that contain a label and a text box. Normally, unrelated controls are used to identify other controls or areas of the form. *Calculations can be inserted into an unrelated control.*

- **Calculated Controls** are all calculated values of the form, namely totals, subtotals, averages, percentages, etc.

⇒ Controls included in the forms have properties that may be fixed in the

Property Sheet window (corresponding button is included in the Design tab).

⇒ Forms edited in *Design view* are running in Form View - Fig. 6:

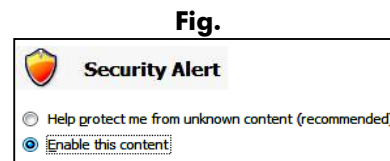

⇒ While testing code sequences, there often occurs syntax or logical errors caused especially by beginners. In order to solve them, a **Reset** is necessary (in the **Run** menu of the *VBA*) – Fig. 7:

⇒ In further exemplifications it is necessary the running of some code sequences, so for the message - Fig. 8:

one selects *Enable this content* through the *Options* button operation - Fig. 9:

It is possible the invalidation of the message: *Click on the Office Button, Access Options, Trust Center, Trust Center Settings ..., Macro Settings, Enable All Macros (not recommended; a potentially dangerous code can be run).*

Calculates payment for a loan based on constant payments and a constant interest rate.

IPMT(rate, per, nper, pv, fv, type)

Determines the payment of interest rate on a given period for an investment based on constant periodic payments and a constant interest rate.

2. Financial functions

Financial functions perform normal calculations for business, such as determining a loan payment, future value or current net value of an investment and bond or coupon values.

Common arguments for financial functions include:

- ✓ *Future value (fv)* - the amount of investment or loan after all payments are made.

- ✓ *Number of periods (nper)* - total number of payments or periods of an investment.

- ✓ *Present value (pv)* - the value of an investment or loan at the beginning of the investment. For example, the current value of a loan is the basic capital that is borrowed.

- ✓ *Rate (rate)*- the interest rate or discount rate for a loan or investment.

- ✓ *Type (type)* - the period in which payments are made during the period of payment, such as at the beginning of the month or at the end of it (0 or 1, implicit 0).

The most important financial functions are:

FV(rate, nper, pmt, pv, type)

Calculates future value of an investment based on periodic and constant payments and a constant interest rate.

PV(rate, nper, pmt, fv, type)

Returns the present value of an investment. Present value stands for the amount that represents in the present a range of future payments. For example, for a loan, the amount borrowed is the present value for creditors.

NPER(rate, pmt, pv, fv, type)

Provides the number of periods for an investment based on constant periodic payments and a constant interest rate.

PMT(rate, nper, pv, fv, type)

↓ Example

One may define a customized form for performing financial calculations using VBA programming language

- × In the form are introduced three *TextBox* type controls, three *Button* type controls and a *Label*. Fig. 10:

Fig.

- × Controls' properties set in *Property Sheet*:

Name	Control
Interest Rate	a1
Number of Periods	a2
Value	a3
Show Results	r
bFV	
bPV	
bPMT	

*For buttons at the *On Click* property,  the following statements are written:

```
Private Sub bFV_Click()  
r.Caption = FV(Val(a1),  
Val(a2),  
Val(a3))  
End Sub  
Private Sub bPV_Click()  
r.Caption = PV(Val(a1),  
Val(a2),  
Val(a3))  
End Sub  
Private Sub bPMT_Click()  
r.Caption = PMT(Val(a1),  
Val(a2),  
Val(a3))  
End Sub
```

*In *Form View* the form will be displayed as follows - Fig. 11:

One can enter (from the keyboard) calculating values – with point instead of decimal point as the programming language requires. Calculations are made by clicking the buttons (for example for *FV*) - Fig. 12:

Fig. 12

Example ↑

Landmarks in Ecological Economics

Cosma Sorinel
„Ovidius” University of Constanta
sorinelcosma@yahoo.fr

Abstract

While numerous criticisms of economic theory and thought have been expressed over time, ecological critiques of economics are relatively new in broader discourse, becoming more prevalent in the past thirty to forty years. But ecological economics has historical roots as long and deep as any field in economics or the natural sciences, going back to at least the 17th century. Nevertheless, its immediate roots lie in work done in the 1960s and 1970s. Ecological economics as such was founded in the works of Kenneth E. Boulding, Nicholas Georgescu-Roegen, Herman Daly, Robert Costanza, and others.

Key words: ecological economics, Nicholas Georgescu-Roegen’ theory

JEL Clasification: Q01, Q57

1. Introduction

While it appears that critiques of economic thought on ecological grounds have arisen relatively recently in response to global environmental and sustainability issues, a review of historical thought back to the eighteenth century reveals otherwise. Research illustrates both economists and natural scientists discussed, debated and held different perceptions on the relationship between the human economy and the environment, particularly energy flows, in the origin of economic thought; indeed, it is argued that a body of ecological economic thought has objectively existed since the 1880s. Pre-classical, Physiocratic and early nineteenth century classical economists gave attention to the physical side of economic activity (i.e. the treatment of natural resources and

the physical assumptions of production theory), and early work also discussed issues of ecological energetics of human economies.

An abrupt change occurred in the mid-nineteenth century, as theorists in economics shifted from studying production dynamics to the adoption of the maximization model from analytical mechanics, thereby moving away from physical realities towards an analysis of exchange value. A static optimization theory resulted, concerned primarily with efficiency and equilibrium, and inputs, tastes, drives and preferences of consumers were given: material and energy resources thus disappeared from theoretical view.

2. The physiocrats and early classical economists

The classical model found its origins in a physiological analogy, which **Thomas Hobbes** had taken over from **Aristotle** and **Harvey**, where a model of the circulation of ‘nutriments’ by the blood was used as an analogy for the materials foundation of the commonwealth. While this source was forgotten, the classical model subsequently developed by **Petty, Cantillon, the French Physiocrats, Smith** and **their nineteenth century classical successors** continued to embody this materials-based approach to production and prices, embedded in physical reality where only land could produce food and materials.

The first school of economics is attributed to the **Physiocrats**, a French school of social philosophy writing in the mid-eighteenth century, a group believing in the principle that natural resources, and fertile agricultural land in particular, were the source of material wealth. Land was seen to work alongside the laborer in

production and the surplus product was considered to result solely from the contribution of land.

Although the Physiocrats never identified exactly how their belief that the rule of the universal laws of physics extended to create a natural social order, their way of thought, in regard to thinking of mechanics, was duplicated in its pattern and conception of market interactions. While the influence of the Physiocratic school peaked in the 1760s and declined rapidly thereafter, their importance in regard to ecological economics lays in attempting to base economics in physical reality, and tracing the origin of all wealth to the land.

An element introduced into economics by the **Physiocrats** which has endured until the present is their insistence of treating individuals as sovereign entities, like atoms. This perception of individuals was embedded in **Adam Smith's** work, and hides ethical issues of whether the pursuit of individual greed is in the interest of society as a whole. Such 'an atomistic view of individuals and mechanistic view of a social system contrasts sharply with the more organic, or ecological, view that community relations define who people are, affect what they want, facilitate collective action, and have a historical continuity of their own'.

This suggests a divergence in regard to humans as a larger part of the ecosystem from the origins of economic thought.

3. The classical approach

Such ideas are carried through in the subsequent development of the classical approach, whose starting point was a theory of production. The capital stock, following Smith, was divided into two broad, physically complementary categories: fixed capital, consisting of machines and structures, and circulating capital, including food, fodder, raw materials, working finance and so forth. Essentially, it was explicitly noted that there was no production without appropriate tools, materials, food and fodder, and a crucial distinction was made between land and

industrial machinery. Subsequent theorists continued such ideas: Malthus (1815) argued that only 'the machinery of the land' could produce food and raw materials, and Ricardo (1817) similarly wrote of the 'original and indestructible powers of the soil'.

Classical economists, explicitly expressed by **John Stuart Mill**, saw a temporary phase of growth that must culminate in a new steady-state economy, recognizing that the laws 'governing' the economic system change as the system changes. In essence, the Classical school held a dynamic and steady-state conception of the economy which was consistent with the natural world. **John Stuart Mill** hypothesized that the „stationary state” of an economy might be something that could be considered desirable, anticipating later insights of modern ecological economists, without having had their experience of the social and ecological costs of the dramatic post-World War II industrial expansion.

The Earth's carrying capacity is a question that was first examined by **Thomas Malthus**, and more recently in an MIT study entitled *Limits to Growth* (1972). Although the predictions of **Malthus** have not come to pass, some limit to the Earth's ability to support life are acknowledged.

The models of **Malthus**, who expressed concerns over population, and **Ricardo** led to economics being called the 'dismal science', as the carrying capacity limits in Malthus's model and the lower quality of the next available resources in the Ricardian model conflicted with the beliefs in progress so prevalent during the nineteenth century.

4. The emergence of neoclassical theory

Neoclassical economics lacks any representation of the materials, energy sources, physical structures and time-dependent processes that are basic to an ecological approach, and is inconsistent with the physical connectivity and positive-feedback dynamics of energy and information systems. The essential

problems is due to the fact that modern economic theories have neglected the implications of basic physical principles governing material and energy use for an economic theory of production, for the operation of a production-based price system, for macroeconomic (disequilibrium) dynamics and for longer run growth processes and prospects.

This negligence undermines the long-term perspective, steady-state and planetary scale-focus of ecological economic thought, and points in essence to the divergence in paradigms between conventional and ecological economics.

Walras, in his *Elements of Pure Economics*, undertook to do for economics what Newton had done two centuries earlier for celestial mechanics, a view with which **Jevons** agreed, with his preoccupation over the mechanics of utility and self-interest. Thus a wholesale shift occurred from a production and growth approach to a static analysis of an exchange economy, with a rejection of the classical cost-of-production theory of value and a new formulation centered around scarcity and diminishing marginal utility.

The mechanistic reduction began as **Jevons** took the approach of defining fixed capital as a version of circulating capital, thereby eliminating materials, fuels and fixed capital as direct inputs in production. This is surprising when one considers his recognition of the critical importance of energy and coal reserves in *The Coal Question* (1865), and discussion of concepts of sustainability: other countries lived on the annual regular income from harvest, but Britain lived on capital, 'a capital which would not yield interest because once it was turned into heat, light and power, it disappeared forever into space'.

In relation to **Jevons'** disregard of such issues in his formulation of neoclassical theory, the marginalist program appears to have created a conceptual blindness in a scientist who well understood the physical significance of energy in production activity.

Menger and **Walras** were also influential in the further elimination of raw

materials from production, where the latter made the fundamental step of arguing the independent contribution of individual inputs to output: just as a field will grow us a crop year after year, so machines, instruments, tools...engender incomes in the same way. **Walras** eliminated raw materials by vertically aggregating production into an instantaneous one-stage transformation of original factors into final output. Items of fixed capital are assumed to yield flows of producer and consumer goods, yet he did not appear to question how a machine produces physical flows of output independent of material feedstocks and the energy required to do work

Neoclassical theorists' neglect of time, raw materials, energy carriers and complementarity in production sets the stage for such formulations in the 1890s: **Wicksteed** assumes the existence of variable proportions in the short run, which is then extended to the long run to provide a general theory of substitutability between inputs. Such ideas are advanced without any discussion of relevant physical features of production activity.

The emergence of the sub-branch of **environmental economics** during the middle and latter part of the twentieth century continued within this neoclassical framework, i.e. with theorists such as **Pigou** and **Hotelling**. While these theorists have contributed some tools to ecological economic analysis, i.e. environmental valuation, efficient resource use over time and so forth, their background is fundamentally neoclassical and reductionist.

5. Early twentieth century ecological critiques of economic theory

While the specialization of economics and formulations of pure theory intensified, the early twentieth century was concurrently characterised by a growing body of literature devoted to the analysis of the role of energy and natural resources in human affairs, and particularly in economic production. One of the first realistic studies of the carrying capacity of the earth was published by **Pfaundler**, a professor in

physics in Austria and Rector of the University of Innsbruck, in 1902. His main thesis was that the carrying capacity of the earth was not determined by the availability of materials but by the availability of free energies, since materials could be recycled due to the law of conservation of matter, and furthermore suggested that the Law of Entropy was needed in order to be able to understand the economy.

A decade later, the Austrian physicist and engineer **Popper-Lynkeus** made a fundamental contribution to **ecological economics**, presenting a significant (utopian) proposal to decrease the use of exhaustible resources in order to make the economy permanently viable, rather than increasing capital accumulation and economic growth. He drew a long, detailed portrait of the economy, and also carried out an in depth analysis on the possibility of substituting renewable energy for coal energy.

Popper-Lynkeus influenced the Vienna Circle and particularly Otto Neurath, who proposed the integration of all sciences into a 'unified science' that would include, as in an encyclopedia, all the propositions of 'universal history.

Perhaps one of the most significant contributions made to ecological critiques of economic theory in the early to mid twentieth century was the Nobel Prize winning chemist **Frederick Soddy**, whose critiques were based on a rationalist approach to economic categories. He appeared to be motivated by a conviction that looking for solutions to the human predicament was of utmost significance, and came to believe such predicaments were not located in the physical or chemical world but in human social interactions, particularly in the sphere of the economy.

Soddy's main idea in his critiques of economic theory was that economists were mistaking real capital for financial capital – in other words, mistaking chrematistics for economics – and took direct issue with Keynes' view on long-term growth. According to **Soddy**, real wealth came solely from the flow of energy from the sun; it was therefore a flow that could not

be saved, only spent. He believed that capital could thus not really be stored, as in reality it was energy embodied in certain objects, subject to the law of entropy. **Soddy** therefore saw the accumulation of capital as an impossibility due to the physical absurdity of mistaking the expenditure of energy for the accumulation of productive capacity: 'Plants accumulated solar energy, whereas man expended it. Coal burned was burn forever. It cannot be burned and kept in the cellar at the same time, and still less can interest continue to be accumulated on the value of burnt coal; this is precisely what happens with the economists' and entrepreneurs' so-called 'capital'. That wealth has not been saved, but spent, with a counterpart in the form of a receipt, and whose holder could go on earning interest every year on the amount of the debt: this was purely a social convention'.

Soddy thus believed in a science of economics that would not study the economy as regulated by the price system (which could be called the study of chrematistics), but as an analysis of the provision of the common wealth with the means of life which modern science made possible. He also saw a fatal flaw in economics as the confusion of wealth, which had a direct physical dimension, with debt, a purely imaginary mathematical quantity with no physical dimensions. Soddy wished to obtain a physical conception of wealth that would obey the physical laws of conservation. He derived a crude energy theory of value and also illustrated the existence of monetary divergences from those value principles.

It is important to note that while **Soddy** was considered one of the precursors of the technocracy movement, developed in the United States in the 1930s, his views and perceptions of the world were quite different to those of this latter group: 'Technocracy claims that by the use of the inanimate energy of Nature and by means of machines and mass production, man had become independent of his own physical exertions for his maintenance'. Soddy did not emphasise the impossibility of capital accumulation as based on lack of effective

demand, as did the technocrats, but rather the long run question of whether the increase in productive capacity which the economists attributed to investment was not a mirage.

Writing at about the same time as Soddy was the physical chemist **Alfred Lotka**, whose broad interests in chemistry, physics, biology and **economics** led to a far-reaching synthesis of these fields together with thermodynamics in his *Elements of Physical Biology* in 1925. He asserted that the goal of his research was to lay bare the 'biophysical foundations of **economics**', with energy being the fundamental underlying principle, and was the first to attempt an integration of **ecological** and economic systems in quantitative and mathematical terms.

6. Ecological critiques of economics: mid/late twentieth century

While many ideas were developed in the mid twentieth century regarding open-access resource management and commons institutions (i.e. Pigou, Hotelling, Hardin and others), the final critical foundations in **ecological** economic thought which heed discussion arose in response to the resource crisis and limits to growth debate in the late 1960s and early 1970s.

The ecological critique of economics experienced a minor boom a few years before 1973: **Kenneth Boulding's** *The Economics of the Coming Spaceship Earth* (1966) set the stage for **ecological economics** with its description of the transition from the 'frontier economics' of the past, where growth in human welfare implied growth in material consumption, to the 'spaceship economics' of the future, where growth in welfare can no longer be fueled by growth in material consumption. Daly (1973) further elaborated on this theme with his work on steady-state economics, building on the work of John Stuart Mill, over a century ago, where he discussed the implications of acknowledging that the Earth is materially finite and non-growing, and that the economy is a subset of this finite global

system. He explicitly indicated the logical inconsistencies between the emphasis placed on economic growth and the energy and environmental realities confronting humankind, and outlined institutions and efficiency issues that must be addressed in the move toward a steady-state economy. These two critiques on economists' perception of ecological and global systems imply a shift in what Schumpeter (1950) calls 'pre-analytic vision', where a fundamental change is suggested in the *perception* of the problems of resource allocation and how such problems should be addressed (Costanza et. Al. 1997).

7. The Romanian economist Nicholas Georgescu-Roegen

The Romanian economist **Nicholas Georgescu-Roegen** made significant contributions to the mathematical refinement of standard neoclassical economics during the post World War II period, yet later in life also heavily critiqued economic theory in regard to entropy and economics.

The Romanian economist **Nicholas Georgescu-Roegen** (1906-1994), who was among Daly's teachers at Vanderbilt University, provided ecological economics with a modern conceptual framework based on the material and energy flows of economic production and consumption. His *magnum opus*, *The Entropy Law and the Economic Process* (1971), has been highly influential.

Georgescu-Roegen's work on entropy and economics still stirs considerable controversial discussion among economists perhaps in part because it conflicts with beliefs in progress that are still strongly held by economists, and also because it does not us inform us of how quickly the transition needs to be made from stock to flow energy resources.

Georgescu-Roegen forcefully pointed out what he terms the 'philosophical bareness of standard economic theory': every subsequent development in thermodynamics and the physical sciences has lent additional proof of the bond between the economic process and physical

laws, yet such a view is entirely missing from standard economic theory (Cleveland 1987). He discussed the critical role of energy, described the fallacies of reducing the economic process to a self-sustained mechanical analogue and outlined the significance of second law of thermodynamics, the Entropy Law, for economic thought: 'The significant fact for the economist is that the new science of thermodynamics began as a physics of economic value and, basically, can still be regarded as such. The Entropy Law itself emerges as the most economic in nature of all natural laws. It is in the perspective of these developments in the primary science of matter that the fundamentally nonmechanistic nature of the economic process fully reveals itself' (Georgescu-Roegen 1971: 3).

He implacably stated that 'the value of the standard form of the production function as a blueprint of reality is nil' (see Georgescu-Roegen 1971: 244), and that it is therefore absurd to hold onto such theory in practical applications (Mirowski 1988). Perhaps the most significant, explicitly stated notion **Georgescu-Roegen** made clear was the inherent problem in conceptualising the economic process as a mechanical analogue: the view of an isolated, self-contained and a-historical economic process, a circular flow between production and consumption with no outlets and no inlets, is ignorant of any qualitative or quantitative change in the environment into which it is anchored (Georgescu-Roegen 1971). He emphasised the uni-directional, irreversible nature of the economic process: what goes in is valuable, low-entropy energy and matter, and what comes out is valuable goods and services plus valueless high-entropy waste heat and degraded matter (Cleveland 1987). Daly (1995) sketched the changes that would occur if one attempted to rewrite a basic economic principles text incorporating the paradigm shift expressed in *The Entropy Law and the Economic Process*. Once one introduces the concept of entropic flow, so many revisions would be required as to make the text no longer standard (Daly 1995).

8. Conclusion

This review has illustrated the existence of tangible theoretical roots to the discipline of **ecological economics**, from the Physiocrats and the Classics in the eighteenth century through to ecological critiques of economic thought at the end of the twentieth. Beginning with the Physiocratic conception that the ultimate source of wealth laid in the physical world, expressed in the productivity of agricultural land, the early classical writers carried through such ideas in the first theories of production. This latter school held a dynamic and ultimately steady-state conception of the economy; the economy was naturally situated in time, with decisions to consume today analysed in the light of their consequences for the future (Foley 1989), an idea consistent with natural world phenomena.

Concurrent to the ecologically based critique of economics, neoclassical theory began to emerge with a new vision based on analytical mechanics; the physical approach to production, capital goods and manufacturing as a materials-processing activity thus disappeared. A wholesale shift occurred from a dynamic production and growth approach to a static analysis of an exchange economy. The neglect of time, raw materials, energy carriers and complementarity in production paved the way for such formulations in the 1890s, and economics continued to increasingly become pure and mathematised in nature. Furthermore, the neoclassical vision was reinforced as professionalisation, specialisation and immanent standards in the sciences intensified, and the disciplinary nature of university departments reduced cross-discipline communication.

Economics witnessed a growing isolation from its natural resource component and the natural sciences, and a homogenisation of these elements.

Ecological critiques of economic thought continued in the early to mid twentieth century with Pflaunder, Popper-Lynkeus, Soddy and Lotka. These theorists

recognised and proposed ideas such as: calculations for the carrying capacity of the earth; a utopian vision of a sustainable economy; the problems of mistaking chresmetics for economics and the integration of ecological and economic systems in quantitative and mathematical terms respectively. The concepts presented by Boulding, Daly and Georgescu-Roegen, among others, along with the increasing recognition of global environmental problems and sustainability issues, served to push the emergence of the discipline of ecological economics in the past thirty years.

Smart Grid Technology

Cosma Sorinel
„Ovidius” University of Constanta
sorinelcosma@yahoo.fr

Abstract

The largest interconnected machine on Earth, the century-old power grid is so massively complex and inextricably linked to human involvement and endeavor that it has been called an ecosystem.

To meet sustainability requirements, the electric industry is poised to make the transformation from a centralized, producer-controlled network to one that is less centralized and more consumer-interactive. This move promises to change the industry's entire business model and its relationship with all stakeholders, involving and affecting utilities, regulators, energy service providers, technology and automation vendors and all consumers of electric power.

Efficient transmission and distribution of electricity is a fundamental requirement for providing citizens, societies and economies with essential energy resources.

In the short term, a smarter grid will indeed function more efficiently, enabling it to deliver the level of service we have come to expect more affordably in an era of rising costs, while also offering considerable societal benefits – such as less impact on our environment. In the longer term, we should expect the Smart Grid to spur the kind of transformation that the internet has already brought to the way we live, work, play and learn. And certain veteran observers within the technology space maintain that the Smart Grids represent an opportunity to technology providers larger than the internet.

Given new awareness, understanding, tools and education made possible by a smarter grid, all consumers will be able to make choices that save money, enhance personal convenience, improve the environment – or all three.

Key words: efficiency, energy, smart grid,

JEL Classification: O13

1. Definition and structure

There is no fixed definition for a Smart Grid. It is perceived as a highly automated and interconnected intelligent electricity delivery system through which energy suppliers and consumers are interconnected in a bi-directional information network. It involves implementing a network that parallels the electrical one and transitioning from a commodity broadcast delivery to a two way information highway. To address these challenges, the industry has to accelerate adoption of information technologies.

A Smart Grid delivers electricity from suppliers to consumers using two-way digital technology to control appliances at consumers' homes to save energy, reduce cost and increase reliability and transparency. It overlays the electricity distribution grid with an information and net metering system.

Such a modernized electricity network is being promoted by many governments as a way of addressing energy independence, global warming and emergency resilience issues.

Businesses and homes begin generating more wind and solar electricity, enabling them to sell surplus energy back to their utilities.

Islanding is the ability of distributed generation to continue to generate power even when power from a utility is absent. Combining distributed resources of every description – rooftop PV (solar), fuel cells, electric

Vehicles – the community can generate sufficient electricity meet their essential

needs in case of an event that can isolate the community or the region, such as an unusually strong storm.

Smart Grid infrastructure consists of electronic meters at each residence and business, an information network to carry data from the meters to the utilities in near real-time and to bring information on the instantaneous price of electricity back to consumers; gadgets which help us automatically adjust our electrical use to prices in whatever way we want to do that; and lots of electronics and other devices in the electrical grid itself, which let the grid use the information on usage to adjust transmission and supply and accommodate the varying output from alternative energy sources.

2. Future electricity markets

The liberalization of electricity markets is an important factor to take into account. It affects the business framework of companies in a fundamental way and, when implemented well, it can bring the benefits of competition, choice and incentives for an efficient development. The change might be better described as a revision of the traditional monopoly-based regulation of electricity supply. It has been accompanied by a trend towards an open market in power, meaning free choice of power supplier by electricity consumers. In addition, liberalization has separated the responsibility for the secure transmission and distribution operation from the electricity generation business.

Liberalization is not the only challenge for how networks will evolve in the future. The organization of the network in the future will be affected by the dynamics of energy markets. Scarcity of primary energy sources on one hand and climate change on the other is likely to greatly affect decisions on new investments in generation. It is not so much the case of playing central versus distributed solutions, but much more to take advantage of a wide energy technology portfolio and the coexistence of many possible solutions.

The costs and prices of electricity will suffer alterations.

To reduce demand during the high cost peak usage periods, communications and metering technologies inform smart devices in the home and business when energy demand is high and track how much electricity is used and when it is used. To motivate them to cut back use and perform what is called peak curtailment or peak leveling, prices of electricity are increased during high demand periods, and decreased during low demand periods. It is thought that consumers and businesses will tend to consume less during high demand periods if it is possible for consumers and consumer devices to be aware of the high price premium for using electricity at peak periods, this could mean cooking dinner at 9pm instead of 5pm. When businesses and consumers see a direct economic benefit of not having to pay double for the same energy use to become more energy efficient, the theory is that they will include energy cost of operation into their consumer device and building construction decisions.

Supporters of renewable energy favor Smart Grids, because most renewable energy sources are intermittent in nature, depending on natural phenomena (the sun and the wind) to generate power. Thus, any type of power infrastructure using a significant portion of intermittent renewable energy resources must have means of effectively reducing electrical demand by „load shedding” in the event that the natural phenomena necessary to generate power do not occur. By increasing electricity prices exactly when the desired natural phenomena are not present, consumers will, in theory, decrease consumption. However this means prices are unpredictable and literally vary with the weather, at least to the distribution utility.

The price could be changing in seconds and electric equipment is given methods to react on that.

As customers can choose their electricity suppliers, depending on their different tariff methods, the focus of transportation costs will be increased. Reduction of maintenance and replacements costs will stimulate more advanced control.

A Smart Grid precisely limits electrical power down to the residential level, network small-scale distributed energy generation and storage devices, communicate information on operating status and needs, collect information on prices and grid conditions, and move the grid beyond central control to a collaborative network

Real-time pricing is a central concept of this new grid. These are energy prices that are set for a specific time period on an advance or forward basis and which may change according to price changes in the market. Prices paid for energy consumed during these periods are typically established and known to consumers a day ahead (“day-ahead pricing”) or an hour ahead (“hour-ahead pricing”) in advance of such consumption, allowing them to vary their demand and usage in response to such prices and manage their energy costs by shifting usage to a lower cost period, or reducing consumption overall.

3. Costs and benefits of Smart Grids

While much has been written about the potential benefits of the smart grid, less has been written about its costs. It is difficult to find studies that quantify the benefits and costs because they can be computed only on a utility by utility basis. One way of looking at benefits is to calculate them as avoided costs of new generation, transmission and distribution.

Undoubtedly, smart grid technologies do come at a cost, representing significant investments. Greater investments are being made in regions of the country that have high electricity costs, are thermal power based, have peak energy challenges, and have deregulated retail markets. These regions have more incentive to invest in smart grid technologies that help them identify system inefficiencies and manage daily peak demand. For all their promise, however, smart grid technologies have not been fully implemented anywhere. Utility analysis shows that nearly all utilities will save enough in avoided costs with a comprehensive smart grid deployment to at least cover smart grid development and

deployment costs; however, many utilities barely break even.

Transformation of the current grid into a Smart Grid is a vision to make it more reliable, more secure, more economic, more efficient, more environmental friendly and more safer. These values could be realized through the applications of digital technologies including sensors, communication links, computing technologies and controls. It will allow for active participation of the customers, accommodate all generation resources and storage, provide for power quality, anticipate and responds to possibilities of blackouts, manage and utilize physical assets efficiently.

The implementation of a Smart Grid provides direct benefits to the end consumers of the electricity. However, these types of benefits accrue to society in general and are not just limited to the end consumers. Therefore, it is important to make a distinction between “consumer” benefits and “third party societal benefits”. An example of a consumer benefit would be the economic loss a consumer can prevent with better outage management provided by the Smart Grid. In other words, outages may cause consumers to dispose of food in the refrigerator because it gets spoiled due to the electricity outage. If a Smart Grid helps in reducing the frequency and/or duration of the outage, then the avoided economic loss (food costs in this example) is termed as a consumer benefit of the Smart Grid. By comparison, an example of a “third party societal benefit” would be a decrease in environmental degradation because of better electric demand management that results from a Smart Grid. Note that the societal benefits impact everybody regardless of whether an entity is a direct customer of the utility.

Smart Grids provide the infrastructure to facilitate load reduction and demand management programs. Each participating customer in this program creates a positive consumption externality that helps in reducing peak loads coincident with the utility’s system peak. Utilities can take advantage of this condition to displace

generating units' run-time, thereby decreasing the amount of pollutants discharged by peaking units. In addition, by automating certain field operations, manual field trips can be avoided, further reducing tailpipe emissions associated with these vehicular trips. Of course, reductions of pollutants have many other benefits that include health benefits and reduced cost.

Benefits that accrue from enabling the efficient and flexible connection of distributed energy resources (DER) devices to lower voltage distribution grids. DER devices include renewable energy (low or zero carbon impact) generation such as wind and photo-voltaic cells and also bulk electricity storage devices that are now becoming available. DER devices break the pattern of 'economy of scale' that for 50 years has led to generation connections migrating to central power plants connected to high-voltage transmission grids. Many DER sources are of a scale that makes it economic to connect to distribution grids directly at the distribution voltage level, provided that the existing grids are upgraded to Smart Grids to accept these energy infeeds, collect intelligent information, and handle their variability. The challenge to traditional grid design is most evident where it needs to accommodate microgeneration with its power quality and revenue metering challenges. This aspect is likely to be a key determinant for governments in which carbon reduction targets have been set. Conversely, traditional grids are potentially a significant barrier to achieving such targets if they are not converted to smart operation.

Benefits that accrue from enabling large-scale DER devices (such as off-shore wind farms, marine energy, and storage systems) to connect and operate efficiently and securely. Large scale DER may connect to transmission grids, but in many circumstances it may be economically and technically attractive to connect them to grids located in coastal areas. This, however, places a new duty on distribution grids, requiring them to operate more like transmission systems with new requirements for power flow control,

voltage management, and automatic control actions. Smart Grids architectures and technology solutions are likely to be important enablers here.

Benefits that accrue from enabling plug-in electric vehicles. A Smart Grid infrastructure will be required to support a fully operational practical implementation of plug-in electric vehicles in the near future. Most of these initiatives are presently in the "concept stage" but many automobile companies are becoming increasingly aggressive in their development activities. The principal idea behind plug-in vehicles is to view an automobile as an electric appliance. To make the concept of plug-in vehicles a pervasive, commercially viable, and operationally practical, requires the development of effective markets and a broader access to these vehicles. At this point, the anticipated benefits are plug-in vehicles are enormous, especially when the reduction oil consumption, decreased dependence of foreign oil, and the ensuing national security concerns and environmental ramifications are included in the equation.

The ancillary services hold the potential for storing power and selling it back to the grid when the grid requires it. Enabled by new technologies, plug-in hybrid vehicles are currently scheduled for showroom floors by 2010.

Assuming customer acceptance regarding price, performance and longevity, these vehicles offer consumers the opportunity to shift use of oil and gasoline to electricity – and to power a car for the equivalent of \$.90 per gallon. (As inefficient as the grid is today, it is cleaner on balance than oil and gasoline.) Consumers get far more affordable transportation. Relying more on electricity for transportation and less on fossil fuels increases our energy independence as well as our environmental prospects. PHEVs take advantage of lower cost and off-peak capacity and can provide grid support during the peak periods.

The above benefits provide a sense of the type of societal benefits that are possible in a Smart Grid program. In

addition to these above benefits, there are other, not-so-easily quantifiable benefits. These include benefits like social perception of the utility and the goodwill created in the marketplace. This not only can serve as source of competitive advantage with other utilities, but also impacts seeking corporate funding in equity and credit markets. Typically such benefits create a “bandwagon” effect in the industry that forces other utilities to undertake programs that also create significant economic welfare for the society.

4. Conclusion

Smart Grid benefits to consumers are lower overall rates and the chance to use very cheap way off-peak electricity for charging electric vehicles and appliances, generating and storing heat for later use, and adjustable activities like clothes washing and drying. Businesses have even greater opportunity to reduce energy costs. The benefits for the economy are less money spent on fossil fuel and a better return on alternative energy investments. The benefit for the environment is less use of fossil fuel to generate electricity. Smart Grid deployment is a key tool in addressing the challenges of climate change, ultimately

and significantly reducing greenhouse gases and criteria pollutants. Smart grids are able to accommodate renewable energies. Smart grids are not only interesting from the point of view of renewables. They also offer a way for households to better control their electricity bill thanks to individual metering devices. So there are lots of winners. But above all, developing Smart Grid technology has become an urgent global priority as its economic, environmental, and societal benefit will be enjoyed by generations to come in the spirit of sustainable development.

Aspects Referring to Utility and Risk of Investments Decision Systems

Abstract

The explanation of investment behaviour in the light of expected utility it meant an important step in the substantiation of the theory regarding investment portofolio. It was demonstrated that the linear form of utility function excludes certain decisive decisions (Allais's paradox), so that in a short period of time from Neumann-Morgenstein's hypotheses specialists' attention directed to finding a utility function that would explain as well as possible the relationship with the risk in investment behaviour. The most important contributions on this issue are more recent, from 1980: The hypotheses of „expected diminished utility” of MacCrimmon (1979) and Machina(1982), the hypotheses of „ non-linear expected utility” of John Quiggin (1993), the hypotheses of „ conditional expected utility”, sustained by Chew, Karni si Safra in 1987, the hypotheses of „non-additivity expected utility” of Fishburn (1988) or the hypotheses of „expected utility based on investment behaviour”, brought by Machina (1988).

Keywords: investment behaviour, expected utility, risk, investors' preference axiom

JEL Classification: D03, D81, D92, G11

1. Introduction

At present, the notion of risk seems to be synonymous to that of activity. Although omnipresent in the business environment and not only, risk is often relatively difficult to

detect or anticipate. The events that may affect the income and subsequent performances of investment are so numerous and varied, that their identification is a challenge even for the most experienced investors, since future remains unknown to a great extent. Many business decisions are made starting from future forecasts. Making a good decision bas don estimates, presumptions, expectations, forecasts of future events involves a reasonable amount of risk, sometimes quite difficult to define and, in most cases, impossible to quantify with accuracy, given the abstract nature of the concept with uncertain outcomes or consequences [1].

Generally, the concept is used to describe situations or events with uncertain outcomes or consequences. In fields such as statistics, financial and investment management, risk, as a notion, sends to the possibility and probability of a result variations as to the initially estimated values or levels.

2. Traditional approaches to risk and usefulness

Risk and its consequences have been the preoccupations of economists, mathematicians, engineers in all economic fields. Interesting definitions and approaches were given to it by significant analysts, especially in the second half of last century. For such approaches ad studies, Nobel (Markowitz, Sharpe) prizes have been awarded or theories that meant a revolution to investment management were discovered.

An important step forward in the traditional risk theory was performed by Morgenstern and Neumann (theory of expected usefulness - 1944). They approached risk from a different perspective than Knight's, for example, based on the ability to associate relevant probabilities of a sequence of events [2].

The starting point in Morgenstern and Neumann's design of a new vision on risk in economic decision-making was the "expected usefulness hypothesis" issued by Daniel Bernoulli as a solution to the famous St. Petersburg paradox (Nicholas Bernoulli in 1713). The St. Petersburg paradox started from the idea accepted up to that moment that the investment decision and the behaviour of market operators are directly linked to the expected profit. The paradox proposed the following situation: a game in which a coin was used for which an amount of money was paid to the players the moment the coin indicates one of its facets. Which would be the maximum amount an operator was willing to pay for such a game?

Taking into account that at the moment n the coin indicated one side (the one side that the player chose initially), the expected profit is calculated using the formula $1/2^n$ - the probability that at the n moment the coin indicate the initially chosen side, 2^n - the paid sum if at the n moment the coin should have fallen on the initially chosen side):

$$E(r) = \sum_{n=1}^{\infty} \frac{1}{2^n} \times 2^n = \left[\frac{1}{2} \times 2 + \frac{1}{4} \times 4 + \frac{1}{8} \times 8 + \dots + \frac{1}{2^n} \times 2^n \right]_{n \rightarrow \infty} = \quad (1)$$

$$[1+1+1+\dots]_{n \rightarrow \infty} = \infty$$

The Paradox lies in the fact that such a game generated an expected and infinite profit and, consequently, the sum of money the players wanted to invest was infinite. The solution forwarded by Bernoulli to solve this paradox was based on 2 ideas which practically revolutionized the theory of the investment decision:

- the utility of a revenue/income $u(w)$ as the result of the investment does not rise in

direct proportion with the w income. In this case $u'(w) > 0$ and $u''(w) < 0$.

- the sum that an operator wants to invest does not depend on the expected profit (productivity), but on the expected utility. Mentioning again the formula of the expected profit, this is the result [3]:

$$E(r) = \sum_{n=1}^{\infty} \frac{1}{2^n} \times u(2^n) = \left[\frac{1}{2} \times u(2) + \frac{1}{4} \times u(4) + \frac{1}{8} \times u(8) + \dots + \frac{1}{2^n} \times u(2^n) \right]_{n \rightarrow \infty} < \infty \quad (2)$$

where: $u'(w) > 0$ and $u''(w) < 0$.

In these circumstances, the expected profit from an investment has a finite value (its utility does not depend directly on the income, even more, it goes down in comparison with a factor of variation α). In the original form of Bernoulli's hypothesis, this one used a logarithmic function of utility:

$$u(w) = \alpha \log(w),$$

later demonstrating that this situation characterizes the investors who don't like taking risks. To sum up, the expected profit proposed by Bernoulli as solution to St. Petersburg paradox, has the following form:

$$E(u | p, X) = \sum_x p(x)u(x) \quad (3)$$

where: X - does not represent a set of variants of profit, $p(x)$ - the probability of getting those profits and $u(x)$ - the utility of the x profits.

Bernoulli's hypothesis has revolutionized the area of the investment decision in risky situations, offering a new perspective with the solution that he forwarded to an apparently paradoxical problem. This new approach has led the way to the modern theory of the portfolio, the expected utility being more relevant for the investment decision than the estimated profit.

3. The theory of the expected utility Neumann-Morgenstern

The new theory in the domain of financial investments of high risk was based not on the capacity of association of some relevant probabilities to a decisional situation but on the expected utility of the gains generated by the investment [4]. This approach makes reference to Bernoulli's hypothesis, the contribution brought by Neumann and Morgenstern dealing mainly with the lottery axiom and the axiom of the operators' preferences towards different investments which offer aleatory ways of gains.

The axiom of the composed lottery

Any alternative of investment generates with a certain probability p a gain x .

We note by X the set of gain variants x_i obtained using a probability $p(x_i)$ (where $\sum p(x_i)=1$ and $p(x_i) \geq 0$ for $i=1, \dots, n$) and $\Delta(X)$ a set of simple probabilities of X , we call *lottery* a point p within this set $\Delta(X)$.

A first captious problem connected with the lottery concept refers to what the specialists call composed lotteries. Neumann proved for the first time that such a lottery can be separated into a sum of simple lotteries. Let us assume the following example: a lottery composed r which provides a 50% probability gain to the lottery p and a 50% probability gain to the lottery q . The lottery p provides the players the following gain sets: $(x_1, x_2, x_3)=(0, 1, 2)$ with probabilities $(p_1, p_2, p_3)=(0.5, 0.3, 0.2)$ and the lottery q provides the players the gain sets of: $(y_1, y_2)=(2,3)$ with the probabilities $(q_1, q_2)=(0.6, 0.4)$.

Generalizing the example above, a composed lottery is a set of K simple lotteries $\{p_k\}_{k=1}^k$, connected between them through probabilities $\{\alpha_k\}_{k=1}^k$, to each simple lottery p_k a α_k probability corresponds [5].

Such a composed q lottery, formed as $q = \alpha_1 p_1 + \alpha_2 p_2 + \dots + \alpha_k p_k$, can be reduced to a "simple" lottery, formed as: $q(x_i) = \alpha_1 p_1(x_i) + \alpha_2 p_2(x_i) + \dots + \alpha_k p_k(x_i)$. From the equation of the composed q lottery the sum of the

probabilities of the gain variants p_1, p_2, \dots, p_k provided by the simple lotteries is equal to:

$$S = \alpha_1 \sum a_i + \alpha_2 \sum b_i + \alpha_3 \sum c_i + \dots = \alpha_1 + \alpha_2 + \alpha_3 + \dots = 1^3$$

This is a simple lottery because:

$$\left\{ \begin{array}{l} p_1(x_i) = \sum a_i p_i \text{ (unde } \sum a_i = 1); \\ p_2(x_i) = \sum b_i p_i \text{ (unde } \sum b_i = 1); \\ \dots \\ p_k(x_i) = \sum k_i p_i^{(k)} \text{ (unde } \sum k_i = 1); \end{array} \right. \Downarrow$$

$$q(x_i) = \alpha_1 p_1(x_i) + \alpha_2 p_2(x_i) + \dots + \alpha_k p_k(x_i) = \alpha_1 \sum a_i p_i + \alpha_2 \sum b_i p_i + \dots + \alpha_k \sum k_i p_i^{(k)}. (\#)$$

From this example we get to the following axiom:

If $\Delta(X)$ is a set of simple lotteries X , any compound lottery $r = \alpha p + (1-\alpha)q$, where $\alpha \in (0,1)$ belongs to $\Delta(X)$ (can be reduced to a simple lottery).

According to the two, the probabilities associated with the different variants of winning are considered "objective", i.e. they are determined exclusively by exogenous factors (the economic operators had no significant influence). *The only role played by the operators who were working in an uncertain environment was to choose the winning possibility (lottery) that offered a better option of winning from all the winning possibilities.* Morgenstern and Neumann explained the different options for a "lottery" coming from economic operators by associating a utility function U_i with every lottery p in $\Delta(X)$. Like Bernoulli, the two believed that winning itself was not taken into consideration when operators chose one "lottery" over the other (proceeding from the utility associated with this "game). For example, if operators were to choose between winning \$10 and \$20, they would most certainly choose the second option. If they were to choose between two "lotteries", one giving them the possibility to win \$10, with

probability 20%, respectively \$20, with probability 80%, and another one giving them the chance of winning \$10, with probability 40%, respectively \$20 with probability 60%, operators would obviously choose the first placement variant. Preferring one “lottery” or another doesn’t aim for profit, but for its distribution probability. *In this case, the utility function is not associated with the profit from placement variants (Bernoulli), but with the profit determined by means of distribution probabilities.* This new approach resulted in a better understanding of investors’ behavior with respect to different placement variants [6].

Investors’ Preference Axiom

$F \succeq \text{pref}$ is a binary relation defined on $\Delta(X) \times \Delta(X)$, which helps us explain the preference for a lottery p in $\Delta(X)$ over a lottery q such that: $p \succeq \text{pref } q$. If $p \overset{1}{\sim} \text{pref } q$ and $q \overset{1}{\sim} \text{pref } p$, then $p \sim \text{pref } q$ (the two lotteries are equivalent). For such a binary relation that defines investors’ preference for a lottery or the other, there are the following axioms (the investors’ preference axiom) [3]:

A.1. The complementarity of investors’ preference: if $p \succ \text{pref } q$, then $q \succ \text{pref } p$ for any “lottery” $p, q \in \Delta(X)$.

A.2. The transitivity of investors’ preference: if $p \succ \text{pref } q$, and $q \succ \text{pref } r$, then $p \succ \text{pref } r$ for all the “lotteries” $p, q, r \in \Delta(X)$.

A.3. Archimedes’ Axiom: if $p, q, r \in \Delta(X)$ such that $p \succ \text{pref } q \succ \text{pref } r$, there is an $\alpha, \beta \in \Delta(0,1)$ such that $\alpha p + (1-\alpha)r \succ \text{pref } q$ and $q \succ \text{pref } \beta p + (1-\beta)r$.

A.4. The axiom of the independence in investors’ preference: for any lottery $p, q, r \in \Delta(X)$ and any $\alpha \in [0,1]$, then $p \succ \text{pref } q$ iff $\alpha p + (1-\alpha)r \succ \text{pref } \alpha q + (1-\alpha)r$.

The axiom of Archimedes is also known as the axiom of continuity in investors’ preference. This axiom proves that if a lottery p is preferred over a lottery q that is in its turn preferred over a lottery r , then the most preferred lottery (p) may be combined with the least preferred lottery (r) by means of a variable $\alpha \in (0,1)$ such that the compound lottery $\alpha p + (1-\alpha)r$ is preferred over lottery q . Nevertheless, there is a $\beta \in (0,1)$ for which investors prefer lottery q over the compound lottery $\beta p + (1-\beta)r$.

The independence axiom is a little more complex and proves that the preference between two lotteries p and q is not altered if both lotteries are combined with a third lottery r to the same extent. This axiom precedes a series of theories regarding the choice between two pairs of lotteries [7].

These axioms, as presented, had not been entirely completed by Neumann and Morgenstern, a significant role being played later (especially with regard to the axiom of independence) by I.N. Herstein and J. Milnor (1953), N.E. Jensen (1967) or Peter C. Fishburn (1970-1988). The axiomatization regarding the investors’ preference for a certain earning form represents, beyond doubt, an important step in what concerns the portfolio choice.

4. Conclusions

Beyond doubt, the implementation of the expected usefulness of the profits granted by a title portfolio (regardless of its location) within the investment decision equation represents a step further in understanding the investment behavior and the functional mechanisms of the financial markets. Taking into account only the profit, without considering its usefulness for the person interested in investing in the financial markets, has proved to be an incomplete and insufficient hypothesis in terms of investment decision.

The meaning given by Neumann and Morgenstern to the conceptualization of the investment decision in conditions of risk and incertitude has proved to be a good one, with a few exceptions and adjustments. The psychological and behavioral features subsequently associated to probabilities (deemed as partially objective) have completed and added new perspectives to the investment theory. Unanimously accepting the idea that the expected usefulness is important for the investment decision, the experts’ subsequent efforts have focused on finding new forms for the usefulness function, which would explain better the behavior of the people making decisions when facing the risks undertaken.

In conclusion, drafting a set of realist alternatives regarding the risk decrease and control depends, mainly, on a comprehensive and thorough analysis, and on the behavior of the person making the decision, of the people involved in the business' fulfillment on the decision-making level. Although, they require a large amount of time and a systematic procedure, the risks' identification and quantification are highly useful.

The Competitiveness of the Romanian Tourism within the European Market

Dodu Silvia Patricia
Patrichi Ioana Crsitiana
Romanian-American University, Bucharest
patricia_dodu@yahoo.com
ioanapatrichi@yahoo.com

Abstract

Within the context of the globalization of the social-economic life, tourism becomes a factor promoting a country's national identity and its unique position within the marketplace, competing against all the other countries that are marketing their own natural and cultural strengths in an attempt to attract domestic, regional, and international travelers. The market conditions are expected to become even more competitive, as more and more tourism destinations will be added to the global travel map, resulting in significant changes to today's national and international flows of tourists and resources. Therefore, it is imperative that Romania establish clear social-economic development goals that rely on tourism as a key sector that can contribute to its efforts to build a modern and prosperous image among the European countries and civilizations.

Key word:tourism, market, competitiveness

JEL Classification: L83

1. Introduction

Like the majority of the economic sectors in 1989, tourism was deeply impacted by the realities of the communist regime, being improperly managed and misaligned with the market requirements and expectations. Its target markets were mainly consisting of the Eastern block countries, as well as domestic tourists – who, unable to travel abroad – were providing sufficient levels of demand for the then-available tourism infrastructure. The development of the mass tourism in the '80s led to the significant issues observed during the transition to the

market economy: low quality of facilities and services, concentration of most hotels in a limited number of high-potential destinations filled with massive, aesthetically unattractive tourist structures, crowded destinations, with architecture styles, dining hall-like restaurants, totally disconnected from the requirements of the tourism international markets.

Major investments in tourism and tourism structures were made in the '60s, especially on the Black Sea seaside, followed by another wave of investments in the 1970-1985 timeframe, when tourism was considered a vital economic sector and a key source of foreign currency; however, the development efforts lacked a well-established strategy, correlated with the trends in the international tourism & travel markets. This approach generated a legacy of rich resources that – despite its obvious shortcomings – could have become a valuable launching pad for a new and competitive Romanian tourism.

The political instability of the '90s, the lack of decisive actions and strategic development strategies, combined with the serious legislative and managerial errors and mistakes, were the main factors that led to the failure of this economic sector.

During the very same period, other ex-communist countries such as Hungary, Poland and the Czech Republic quickly recognized that tourism is a key component of the new economic reality and they subsequently granted it the attention required, turning it into a highly functional and productive sector.

2. Tourism Competitiveness Index

Currently, Romania is ranked no. 66 out of 133 countries (second-lowest ranking among

the ex communist countries) based on the Travel & Tourism Competitiveness Index published by the World Economic Forum in 2009, a counter performance that illustrates the inability of the post-1989 governments to turn a high-potential sector into a source of economic growth and development.

While the top ranked countries in the Travel & Tourism Competitiveness Index are those with long traditions in the tourism industries (Top 3 spots being taken by Switzerland, Austria, and Germany, closely followed by France, Canada, Spain, Sweden, and the United States), other former Communist countries (such as Czech Republic, Hungary, and Croatia) also show high levels of competitiveness. In recent years Romanian tourism has started to show signs of improvement, moving up from no. 76 (2007), to 69 (2008), and even higher, to no. 66 in 2009, with a total score of 4.04 points (see Table 1.).

Table 1. Travel & Tourism Competitiveness Index Ranking for the Former Communist Countries (2009)

Country	2009 Ranking		2008 Ranking
	Rank	Score	
Czech Republic	26	4.86	30
Croatia	34	4.54	34
Slovenia	35	4.53	36
Hungary	38	4.45	33
Slovakia	46	4.34	38
Bulgaria	50	4.30	43
Montenegro	52	4.29	59
Poland	58	4.18	56
Russian Federation	59	4.14	64
Romania	66	4.04	69
Ukraine	77	3.84	77

Source: World Economic Forum, *The Travel & Tourism Competitiveness Report 2009*.

It must be stressed that – despite the opinion of some Romanian specialists who think that our tourism has sufficient strengths to perform competitively at regional and international levels – Romania still faces serious issues in adjusting to the requirements of the international markets (as evident from its position in the Competitiveness Index).

Tourism infrastructure, as well as human,

natural and material resources are key determinants of the tourism' competitiveness, a fact that underlines the need to identify Romania's rank among the other Central and Eastern European countries.

Table 2. Travel & Tourism Competitiveness Ranking on Key Components (Select Countries)

Country	Legal env.	Infrastructure & business env.	Human, cultural and natural resources
Czech Republic	16	36	24
Croatia	43	37	43
Slovenia	38	33	61
Hungary	26	42	59
Slovakia	34	54	55
Bulgaria	56	48	46
Montenegro	50	66	35
Poland	72	68	29
Russian Federation	79	61	38
Romania	61	64	77
Ukraine	62	72	103

Source: adapted from World Economic Forum, *The Travel & Tourism Competitiveness Report 2009*.

The key issues facing the Romanian tourism, as described in the 2009 "Travel & Tourism Competitiveness" report, include the lack of sustainable development (ranked 121st out of 133 countries), lack of transparency related to the government decisions (126th), quality of the natural environment (110th), road quality (126th, down from 124th), price competitiveness, openness (118th), and efficiency of the branding and marketing policies (119th).

The decline in rankings (from 119th to 121st) for the importance placed by the government on the tourism-related strategies is further proof that the deficiencies seen in this sector are mainly caused by the state authorities' inability to properly assess the importance of tourism for the overall economy and to act accordingly by supporting it. To put things in perspective, Romania is the second from bottom among the countries ranked (with Spain ranked 13th; Austria 15th; Greece 20th; Croatia 44th; Hungary 71st; Bulgaria 101st; only one country is ranked lower, Poland 126th).

Among all criteria considered, Romania's

highest ranking is obtained for its legal environment (61st); our tourism-related resources are ranked 76th among all countries considered, the lack of trained human resources, the lack of openness, and the quality of the natural environment being listed among the factors contributing to this poor performance.

Comparisons between Romania and its neighboring countries reveals Romania's lack of competitiveness, with rankings of 10 (resources), 8 (infrastructure and business environment) among 11 countries included in the analysis.

In terms of investments in hotels and restaurants, the analysis reveals a similar picture – very low interest in investing in tourism compared with other economic sectors.

Data in Table 3 show tourism investments of under 2% of total investments in the overall economy, despite a recent boost in investments mainly associated with building and renovating hotels in various urban areas.

The OECD report (using data from the Romanian Association for Foreign Investments) considers that “the fact that only 2% of the foreign investments in Romania are allocated to the tourism sector is proof of an overall low productivity of Romanian tourism”. [1]

Table 3. Investments in Hotels and Restaurants (2000-2007)
-Billion ROL

Year	Total Investments	Investments in Hotels & Restaurants	in %
2000	12.498,7	109,8	0,88%
2001	20.419,5	274,6	1,34%
2002	27.173,5	331,5	1,22%
2003	35.651,2	481,5	1,35%
2004	44.869,9	750,4	1,67%
2005	54.566,0	936,6	1,72%
2006	72.891,0	1.249,2	1,71%
2007	98.417,7	1.600,9	1,62%

Source: Romanian Statistical Yearbook 2008

According to WTTC statistics, total 2008 tourism investments (including investments in hotels, restaurants, tourism facilities, infrastructure, etc) reached 3.26 billion USD, with 3.04 billion USD expected for 2009.

Lately, Romania has become a more attractive target for investors interested in the tourism sector, a sector long ignored by

them. Romanian tourism appears to be on an ascending trend, with increased interest manifested by international hotel chains (many of them, such as J.W. Marriott, Howard Johnson, Crowne Plaza, Golden Tulip, Hilton, Ibis, Inter-Continental, Novotel, Ramada, Best Western, Radisson SAS, and the newly-launched Pullman already present on the Romanian market). Most of these hotels are located in Bucharest (due to the high demand from business travelers and – as a result – occupancy rates higher than those in other European cities), with very few of them located outside the capital city.

According to a market study completed by Trend Hospitality [2], at the end of 2008 there were 122 hotels (with a total of over 10,000 rooms) located in Bucharest, fewer than in other European Capitals, such as Warsaw, Budapest, or Prague. During 2008, the number of available rooms has increased by 25%, due to grand openings of some major hotels, such as Rin Grand Hotel (1,400 rooms), Ramada Plaza (302 rooms), and Radisson SAS (424 rooms), boosting the percentage of 4-star rooms to 47% of the total number of rooms available.

Trends in the Romanian tourism market mirror those witnessed by the other Central and South-Eastern European countries, expecting major tourism investments in the coming years. Bucharest – as a key destination for business travelers – appears as the European city with the highest expected rate of growth for the number of available rooms, a trend that will continue in the short and medium term, provided only a mild impact of the current economic crisis on the region's tourism industry.

Figure 1. Investments in Tourism Infrastructure in Select European Countries (Semester 1, 2008)

(Source: Jean-Francois Laporte)

We can expect Bucharest to continue to

attract international hotel chains interested to enter the market in 2010. The major investments are expected to focus on larger 4- and 5-star properties (150+ rooms each) targeted at business travelers.

3. Conclusion

The integration of Romania within the European Union brought an investment strategy in agreement with the development plans and goals of the common European market, within which Romania is an active member. Before the integration, Romania received UE assistance through various development programs (such as PHARE and SAPARD) that focused mainly on investments and marketing and training initiatives. Today, Romania is granted assistance through operational programs part of the European Union Structural Funds.

Figure 2. Number of New Hotel Rooms Planned in Select CEE Capitals (2008-2010)

(Source: Jean-Francois Laporte, "Hospitality Business Environment Overview", 2008)

The National Strategy for Regional Development, based on the Regional Development Plans and the 2007-2013 National Strategic Reference Framework, has identified tourism as a regional development priority, considering the tourism potential and resources available in all regions of the country. This existing potential justifies granting financial support to rehabilitate the tourism infrastructure, to take advantage of the country's natural resources and to improve the domestic and international marketing of the tourism sector.

Abstract

During the last 20 years, Romania has been passing important social and economic transformations and it is considered today as a developing country aiming to adjust its processes and features to those of UE countries. The significant increase in the number of bachelor programs supplied by various faculties is one of the issues we can refer to in order to explain the great interest paid to a proper economic education. The aim of this paper is to argue that, despite the big number of the economic programs, the Romanian curriculum is structured such that students can't benefit from a proper understanding of Economic Behavior. The authors argue that Behavioral Economics should be included in curriculum as being the trigger in students' awareness in respect to integrating some weaknesses of making economic decisions process.

Key words: economic education, Romanian curriculum, behavioral economics, bounded rationality

JEL Classification: D03, D79, D81, D83

1. Introduction

During the last 20 years, Romania has been passing important social and economic transformations and it is considered today as a developing country aiming to adjust its processes and features to those of UE countries. Passing from a controlled economy toward a market economy resulted in many challenges that

Romanian people had to face, and the process of integration of new values and practices, like for example free competition, less protectionist regulations, increasing income inequality, products diversification and the pressure of the free choice, led to an increased demand for economic education.

Based on ARACIS report, during the last 20 years the number of faculties which offer economic programs has constantly been increasing and in our days there are about 300 master programs in economic domain. The deep interest manifested in this field and the attention paid these years to the Economics is normal, if we think on the shift the economists had to face after December 1989.

Among various transformations this country has been facing in the recent years, the changes in consumers' attitudes, practices and mentalities, the challenges that stress producers' priorities and strategies are some of the issues that must be now studied by the Romanian economists. There is a wide literature that helps producers to understand how to deal with the new economic conditions. However, the individual as such benefits from less information in respect to the exposures he faces, even in case he is in process of graduating from an economic bachelor program.

There are, of course, important contributions that specialist provide us with in order to make more understandable the new problems that individuals face and their specificities (see for example [1], [9] or [10]) but most of them are focused on developed

countries case, as for example [2], [4], [7] or [13] and even in this international framework some protests can be found against a lack of interdisciplinary approach in dealing with individuals' attitudes and acts.

This paper aims to focus on the gap between the current economic education and some improved interdisciplinary approaches that can help individual in understanding the challenges he faces under Afluenza society. The remained part of the paper is structured as follows: the second section aims to emphasis the importance of education in general and economic education in special, while the goal of the third section is to explain that, despite the increase in the interest for economic specializations, students are not aware of some basic weaknesses of their own economic behavior. The fourth section aims to describe some of the general features of the new field of Behavioral Economics and to stress the idea that a proper economic preparation would greatly benefit from including this discipline in the curriculum.

2. Understanding the Importance of Economic Education

Based on statistic evidences, Philip Stevens and Martin Weale (see [14]) indicate that it is generally accepted that life standards are increasing due to education. People are the beneficiary of education and in the same time are responsible for its existence and improvement. Secondly, econometric studies indicate that the level of education and the income of an individual seem to be directly correlated. The conclusion of this issue is a logical one, in the sense that a country could became richer based on a high level of education, as well as any individual in that country could increase his or her income based on the same education.

A wide range of studies and papers argue the strong existing connection between education and economic growth. Since 1974, when Jacob Mincer's model was accepted as a proper framework used to estimate returns to schooling, to

schooling quality or to measure the impact of work experience on male – female gaps, economists have agreed with the existence of this relation. Despite the fact that today the Mincerian model seems to be an old fashion one, there are others models which try and succeeded in detecting the measure of the impact of education over economic growth.

To conclude, we have to take into consideration on the one hand the evidences according to which education and economic growth are strongly connected to each other and on the other hand the widely accepted opinion that the role of higher education in a knowledge driven economy has never been more crucial (see [11]) than today.

According to Evoh [3]: „Poverty in all its manifestations – hunger, illiteracy, sickness, unemployment, political disengagement – are directly or indirectly associated with lack of information.” Understanding the basic principle of Economics, being able to deal with its main mechanisms, and graduating from a program which offer all the opportunities for such preparation in Economics seems to be for many students today the core of a future welfare. This paper aims to focus on understanding the differences between the information provided by the Standard Economic Model and the information which is provided by Behavioral approaches and seeks to explain the main issues that coming from the same Standard Economic Model make students less aware of when acting as individual economic agents.

3. Understanding Our Own Economic Behavior Triggers

As a matter of studying individual risks coming from less discussed social and economic exposures, in the early of 2010 students of the Faculty of Business and Administration within University of Bucharest were subjected to a study based on two questionnaires provided by James [5, p.7]. The aim of the first study was to test whether students have already been infested with “Afluenza” virus, resulting in hyper – consumerist behavior, and the

second study aimed to test the level of “infection”. The two questionnaires were applied both at master and at the 3rd year of bachelor level, and the samples size were 32 for the master level, and 54 for bachelor level.

From the results we obtained, we could observe that the level of infection is approximately normal distributed, showing that the age segment between 26 and 42 is mostly affected, while the other age segments show less or no infection at all. Those master or bachelor students who have been getting in touch for a while with labor market as well as with the consumption as a social signal, displayed more confusion in consumption behavior and in the values they perceived as being important in life.

The size of the samples used in this study is not very large but still the results raised some questions in respect to how well the triggers of the economic behavior are perceived by students and how well protected are the students we are preparing for graduating from an economic program, against the main challenges a market economy impose.

In an attempt to check whether some information coming from Behavioral Economics side will change students’ approach in judging economic problems, another study was conducted – this time at bachelor level only. Some aspects were discussed, coming from the remarkable contributions of Daniel Kahneman works. The first issue comes from [6] and refers to the following questions:

“Question 6. Imagine that you are richer by \$20,000 than you are today, and that you face a choice between options:

6. receive \$5,000 or B. A 50% chance to win \$10,000 and a 50% chance to win nothing.

Question 7. Now imagine that you are richer by \$30,000 than you are today, and that you are compelled to choose one of two options:

7. lose \$5,000 or D. A 50% chance to lose \$10,000 and a 50% chance to lose nothing.”

The second issue comes from the “Asian disease” Problem [16] and refers to the following two step choice that should be

done:

“People are informed about a disease that threatens 600 citizens and asked to choose between two undesirable options:

Option 1. (a) saving 200 lives with certainty and (b) one – third chance of saving all 600 and two – thirds chance of saving nobody

Option 2. (c) 400 people dying with certainty and (d) two – thirds chance of 600 dying and one – third chance of nobody dying.”

In the control group, students were asked to make the choice in the first problem, and after a week they were presented the “Asian disease” problem and invited to make a choice again. In the treatment group, students were asked to make the choice in the first problem, and then they were explained the framing effect. They were told that the two questions are in fact similar in terms of financial state and that only emotional factors lead to inconsistent choices as for example A – D or B – C. Next week, the same students were asked to make a choice in “Asian disease” problem.

The result of the study shows that the students coming from the control group were unable to recognize that Option 1 and Option 2 in this problem are identical in terms of objective results, in the same proportion as they were unable to recognize similar facts in the previous problem where the financial states were the same. The same inconsistency in making choice was found in “Asian disease” problem to a similar degree as in the previous week example. However, most of the students coming from the treatment group were able to isolate the framing effect in the “Asian disease” problem and their choices were consistent. The same students coming from the treatment group were able to observe and manage the fact that they were inclined to make inconsistent choice once they were confronted to the negative frame of the Option 2.

Again, the authors of this paper admit that the size of the samples used in this second study is not very large but still the results raise again some questions in respect to how much informed students can become

aware of their behavior and of the determinants involved in making economic choices.

4. Standard Economic Model versus Behavioral Economic Approach in Economic Education

As we have already mentioned in the introductory section of this paper, the dynamic of the interest that students manifest for economic education has been increasing over the last 20 years, fact reflected by the impressive number of bachelor and master programs that got authorization from ARACIS. Thousands students apply yearly for economic programs and thousands graduate from such institution hoping in obtaining a good job and a decent position in society. Soon after December 1989, as a natural consequence of, to the one edge, failure of the command economy and, to the other edge, the start of the transition toward market economy, the Romanian scholars begun to rethink the information that was supposed to be taught in faculties. The curricula and the syllabus were changed according to the new requests of the economic development and some of the cores of international academic models were used in designing the new approaches. Yet, many Romanian scholars had to informally admit after some years that the past habits lie heavy on Romanian education's shoulders. In spite of the new curriculum design and the new disciplines description, many professors continued actually to teach the same out of date information and to use the same concepts as before.

A new approach in teaching Economics could be discussed? A new understanding of the models and a mature acceptance of an interdisciplinary approach could have been brought into discussion? The authors of this paper repeatedly tried to signalize some weaknesses of the programs in Economic field and faced resistance from people too much in habit with certain information and with certain approaches.

The attitude is somehow easy to be understood. Taking into consideration aspects coming from Sociology, Anthropology or Psychology is an attempt that received much resistance even in academic communities having a long tradition in dealing with market economy. In the same time, there are institutions all over the world which pay considerable attention to the impact of emotions on economic behavior and a new field in Economics emerged in the early '60.

The authors of this paper have the intention to discuss in praise of Behavioral Economics as being one of the disciplines which should be included in curriculum for each economic domain, either at bachelor level, or – in the worse case – at master level.

Of course that some readers would argue that economics, in any form it takes, is about behavior and that once we refer to Economics we implicitly take into consideration human perspective. Is this true? Or is this the reason why the Behavioral Economics has been changing, during the last decades, the way economists transformed world into concept? Let's be fair and admit that the behavioral approach tends to focus on a different framework than the standard economic model did before and this is why some relevant features of human behavior tend to enlighten sides of economic decision making process never took into consideration before. We authors of this paper believe that actions like underlying the standard economic model anomalies, exploring alternative models, describing and testing these models in real world, are valuable aspects used both in normative and positive economic attempts.

The Behavioral Economics would be valuable in teaching students about their own boundaries that are systematically ignored in the standard economic model. The rationality hypothesis, the lack in self – control and self – interest are part of the classical triad discussed in Behavioral Economics. Our previous experience in teaching students about these issues proves that there is a considerable interest

in understanding the hidden part of their personality.

During the sixth semester of the Business Administration program in Faculty of Business and Administration within University of Bucharest, the Risk Economics discipline is part of curriculum. Among much information about risk factors in any economy, the three above mentioned economic agent boundaries are discussed. As part of bounded rationality, students are taught about their incomplete information processing ability, about their random approach in making decisions, about their loss aversion profile as well as about anchoring and frame effects they are subjected to. Once the bounded rationality is fully understood, students are able to realize that they are inclined to biased probabilistic biased and that the hypothesis of utility maximization that is so much promoted in standard economic model has almost nothing to do with their own approach.

It is also of great help for our students to learn about things they are doing against their own “long – run” interest. Concepts like, for example, diagnostic utility make clear to them that the tendency of ignoring the “long – run” effects is the core of addictive behaviors like for example drug and alcohol consumption, of under-savings or procrastination. Students are taught not only that the neoclassical view stating that “the more alternatives for choice you have, the more sovereign you are” is somehow against the brain tendency of getting blocked the minute it has too many alternatives [15].

Both the effects of the lack of self – control and bounded rationality described above are perceived by our students as being spectacular and unexpected, but the third part of the triad is even more of interest for them. The lack of self – interest, translated into words as being our willingness to act according to others expectations and values, leads us to preferences having pronounced social features. Instead maximizing our own interest, it seems that we are more inclined to feed others well – being

especially when those are fair with us. The economic agent seems to be either nicer than the standard economic model claims or worse (when the fairness condition is not matched) than expected, but in any case the economic agent doesn't follow the neoclassical assumption of being fully rational.

5. Conclusions and recommendations

From what we authors are aware, there is no economic program in Romania including Behavioral Economics in its curriculum. Even it is impossible to speak about the advantages of understanding the behavioral perspective in few pages of a paper; there is a wide literature in this field. One can find behavioral approaches in marketing, finance, microeconomic and macroeconomic level, and even managerial accounting started using the new interdisciplinary approach as specific tools. The authors tried to introduce some of the core concepts and tools of Behavioral Economics in the process of students' preparation in Faculty of Administration and Business within University of Bucharest. After becoming aware of effects like for example framing effects, anchoring, arousal impact, overconfidence in assessing probabilities and so on, students were much more able to recognize when their own emotions made the decision and not their rationality and they benefited from a better self control in decision process. The paper aimed to argue that, based on the increasing interest that students have been manifesting for economic programs during the last 20 years, the specific curriculums should include Behavioral Economics as a factor of informing young economists about the interdisciplinary approach of the studies that aim to explain the making decisions process using human behavior features.

Finding a Minimal Transport Cost for a Transport Problem

Dumitru Ileana

Teodorescu Ana-Maria

Petroleum-Gas University of Ploiești

Ilenush2003@yahoo.com 80ro@yahoo.com

Abstract

This paper is about finding a solution to a transport problem, using visual programming applications, with one of the specialty software – Visual Basic. Among company's spendings there are product transport spendings supported by economic agent in his way from each producers to beneficiaries.

We presented the transport problem under the form of a table which contains entry data: producers (ex. București, Ploiești, Arad, Pitești), beneficiaries (ex. Metro, Kaufland, Carrefour, Sellgros) and transport costs from each producers to beneficiaries.

We used the minimum cost line method and north-west corner method as economic mathematic methods for determining a minimal transport cost.

Key words: transport problem, transport cost, solution, visual programming application;

JEL Classification: C61;R48;

1. Introduction

In market economy in order to maximize a company's profit you to first have to lower the expenses as much as possible.

A transport problem is represented under the form of a table which contains entry data: producers (ex. București, Ploiești, Arad, Pitești), beneficiaries (ex. Metro, Kaufland, Carrefour, Sellgros), the producers available quantity, consumer demanded quantity of goods and transport costs from each producers to beneficiaries. As you know, a balanced market means equal offer and demand. In a transport

problem, the offer is represented by the available quantity of products on the

market, and demand is represented by the quantity of products the beneficiaries need. The quantity of produced goods will have to be equal to the quantity of needed goods. Although the transport problems are not only balanced problems (there are transport problems which are not balanced – the offer is not equal with the demand), this article presents a balanced market (the transport problems which are not balanced will be discussed into another article).

One of the economic mathematic method for determining a minimal transport cost is the minimum cost line method; this method will offer a value of transport cost for the product from producer to consumer.

The minimum line cost method, the minimum table cost method and N-W corner method are some of the initial transport methods.

Table 1 presents the transport problem, for what we realised an application in Visual Basic. In this table we have a entry data as: -producers (București, Ploiești, Arad, Pitești); -consumers (Metro, Kaufland, Carrefour, Sellgros); -values of transport cost for the product from producer to consumer; -available quantity of products – disponibile; -demanded quantity of consumers – necessary;

	Me tro	Ka ufl and	Ca rre fou r	Sell gro s	Dis pon ibil
<i>București</i>	X_{11} C_{11}	X_{12} C_{12}	X_{13} C_{13}	X_{14} C_{14}	D₁
<i>Ploiești</i>	X_{21} C_{21}	X_{22} C_{22}	X_{23} C_{23}	X_{24} C_{24}	D₂
<i>Arad</i>	X_{31} C_{31}	X_{32} C_{32}	X_{33} C_{33}	X_{34} C_{34}	D₃
<i>Pitești</i>	X_{41} C_{41}	X_{42} C_{42}	X_{43} C_{43}	X_{44} C_{44}	D₄
<i>Necesar</i>	N₁	N₂	N₃	N₄	Tot al

Table 1 – The transport problem presentation

were: X_{ij} – quantity goods that producer i „loads” to consumer j , $i, j = \overline{1,4}$;

C_{ij} – transport cost from producer i to consumer j , $i, j = \overline{1,4}$;

D_i – producers available quantity i , $i = \overline{1,4}$;

N_j – consumer demanded quantity of goods j , $j = \overline{1,4}$;

After we applied a minimal cost transport method, we used the objects function for determine transport cost.

$$f_{ob} = \sum_{i=1}^4 \sum_{j=1}^4 (X_{ij} * C_{ij})$$

(Formula 1)

The minimum cost line method is one the other initial methods for finding initial solution in transport problems. In economic mathematic, this method is presented:

-we select minimum transport cost on first line (C_{1j});

-in suiting cell we “load” possible product quantity corresponding available quantity of goods (D_1) and demanded quantity of

goods (N_j) – minimum product quantity D_1 and N_j ;

-in case available quantity of goods was not used up on first line (for first producer-Bucuresti) we stay on same line and we select next minimum transport cost ;

-we keep “loading” on first line until available quantity of goods D_1 is finished (for first producer-Bucuresti);

-when first producer’s available quantity of goods is finished we continue with second line – next producer – Ploiesti;

-the algorithm keeps going on the same reasoning until all available quantity of goods is finished.

If transport problem is balanced (equal offer and demand), available quantity of goods and demanded quantity of goods are finished in the same time. Transport problem finalization is made when objects function will be induced.

North-west corner method is presented

-we start from cell (1,1) related first producer (București) and first consumer (Metro) collating producer available quantity D_1 and consumer demanded quantity of goods N_1 ;

-we “load” possible product quantity according to necessary and available quantity;

- if after the “loading” the available quantity is not finished, the next cell to “load” will be (1,2), contrariwise – when demanded quantity of goods is not finished, we start loading cell (2,1) ; when producers available quantity and consumer demanded quantity of goods will be finished, we will „load” cell (2,2)

- we proceed the algorithm until the product available quantity and demanded quantity of goods are finished.

Using the minimum cost line method, we obtain an initial solution. Optimum methods for finding minimal transport cost require more time and fund, but offer the minimal transport cost (optimum). The authors of this article propose an application wherewith we obtain a solution for transport problems using initial methods: line and N-W corner. In this situation a motivation of this choise is required. Why N-W corner mehtod and not another (minimum column, minimum table)? The N-W corner method is about the

geographical position of the consumers and the producers (unlike the other methods). The result obtained by this method is biggest, therefore an economist does not approve it.

2.The Visual Basic application

The application realised in Visual Basic is based on the unreal example in which we consider as producers București, Ploiești, Arad, Pitești, and as beneficiaries (Metro, Kaufland, Carrefour și Sellgros) malls that need product quantity put on market by producers.

The financial economic mathematics gives us initial and optimised methods that help us determine the value of the transport cost supported by producers in the product way to beneficiaries.

This application, based on the minimum cost line method and N-W corner method, will visually realise a product „load” from producers to consumers to obtain a minimum cost.

In Visual Basic we put over a form on which we add visual objects as ComboBox, CommandButton, Label and TextBox. In the application, ComboBox objects will be used to select the producers and beneficiaries for which will be introduced producers available quantity, consumers necessary quantity and transport cost from each producer to consumer with the visual object CommandButton.

Another visual object: CommandButton („Calculul costului minim de transport pentru cantitățile de disponibil introdus”) enables the loading of products in the transport problem and transport spendings estimate (objects function).

The visual objects Label were used to introduce the name of the imaginary producers and consumers in the Form. TextBoxes were added to show available and necessary product quantity and transport costs from producers to consumers.

Figure 1 presents the Form with all visual objects under discussion

Figure 1 – The visual object introduced of the initial Form

Figure 2 shows that by using the “Introduceți disponibilul pentru” button, a value equal to the available produced goods will be assigned to the ComboBox object.

Figure 2 – Selection the producer for add available funds

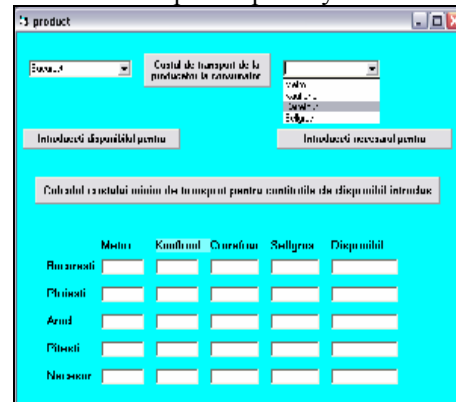

Figure 3 shows that when we select one consumer from a visual object ComboBox, we will be able to assign a value that represents the demanded quantity of goods – using the „Introduceți necesarul pentru” button.

Figure 3 – Selection the consumer for add required quantity

The CommandButton visual object „Costul de transport de la producător la consumator” will let you assign values of the transport cost from one selected producer (first ComboBox) to one selected consumer (second ComboBox) – figure 4.

Figure 4 – Introduction of transport cost from producer to consumer

Figure 6– User’s message in case the market is stable

This application works for both cases: when there is a stable or unstable market situation. When the sum of available quantity is not equal to the sum of required quantity, an error message will be displayed: „Piața nu este echilibrată!!! Programul nu poate fi rulat.”(figure 5). In this case, the user will have to introduce other transport costs, available and demanded quantity values.

Figure 5 – User’s error message in case the market is not stable

Figure 7 show the result of pressing the button “Calculul costului minim de transport pentru cantitățile de disponibil introdus”. The issue of this stage will be adding transport costs, available and demanded quantity.

Figure 7 – Displayed introduced data

Whereas the authors proposed to determinate a minimal transport cost for available goods quantity from producers to consumers, figure 8 and figure 9 show that introducing available, demanded product quantity and costs, a transport cost will be obtained. A message box „Valoarea costului de transport este” will appear and the obtained cost will be write here.

Figure 8 – The result– the transport cost value with line method

When the transport problem is balanced the sum of produced goods is equal to the sum of demanded goods, the user will receive a message „Piața echilibrată...Calculăm costul minim de transport”(figura 6). He will add transport costs, available and necessary quantity introduced in visual objects TextBox, by pressing the button “Calculul costului minim de transport pentru cantitățile de disponibil introdus”.

Figure 9 – The result – the transport cost value with N-W corner method

3. Conclusions

Finding a minimal transport cost for a transport problem is useful in economy for the profit increase. This paper suggests reader an imaginary transport problem for which the application achieved in Visual Basic determine a minimum transport cost. As we know, any application is achieved using an algorithm that has as principal characteristic – generality.

Corresponding this characteristic, the program (application) will handle the problem generally, not particularly, so the application proposed by authors can be applied by many economic agents what

have four production centres and four distribution centres.

The realised application can be useful for each economic agent who has branches in Bucureşti, Ploieşti, Arad and Piteşti and transports products to centers such as Metro, Kaufland, Carrefour and Sellgros for a product transport spendings prevision.

The neural model of the European Union (EU-27) annual growth rates

Elefterie Liana
Tudoroiu Nicolae
Spiru Haret University of Constanta
elefterieliana@yahoo.com
tnicolae@excite.com

Abstract

The EU statistics reveal over 19 million active enterprises within the EU-27's non-financial business economy (defined as industry construction, distributive trades and services, and therefore excluding financial and public services) in 2004. About one third (32.5%) were active in the distributive trades sector which were also relatively labor-intensive activities, accounting for almost 25 % of the EU-27's non-financial business economy workforce in 2004. In this work we develop a study of the impact of the annual growth rates for industry of the European Union countries on the global annual growth rate of the European Union-27 using neural models between 2004-2008. This research work investigates the possibility to apply neural network modeling for simulation and prediction of the EU-27 global index of production and domestic output price index behavior due to the impact of the same indices of different EU-27's countries. Therefore we will explore this modeling technique to build the neural model of this complex dynamic economy system. The results obtained by using neural models are more accuracy compared to those obtained by regression methods, and the performance of the neural networks is audacious.

Key words: neural modal, enterprises, non-financial business economy, index of production, domestic output price index;

JEL Classification: C61;O52;

1. Introduction

Macroeconomic growth simulation has great importance in economic developments and policies, but there have not been any effective methods of simulation. For this purpose could be used several architectures of neural network (NN) to construct the neural models simulating the complex dynamics of the overall economy system, in general, or particularly the relations of GDP (Growth Domestic Product), financial revenue, work force and price on industry structures of the economy.

In financial theory, the efficient market hypothesis (EMH), in its weak form, predicts that analysis of time series data alone will provide no excess return over a simple buy and hold strategy and the data contained in the time-series has no economic value unless the data leads to a transaction [9].

Noticeably, the economic processes of both the national and the global economies could be multivariable (Multi Input-Multi Output, MIMO) and nonlinear, with variable gain and variable time delays [11]. It is very well known that in industry to control such processes, self-adaptive, model-based artificial neural networks (ANN), is very complex task, using multi-variable control strategies. Self-teaching ANN algorithms are trained off-line on past history of the economic process (the measured data set of the last decades of operation of the process). In our research we will consider a realistic approach based on the fact that any economy is a multivariable dynamic economic process. The block scheme of the overall economy system is presented in Figure 1.

„Figure 1. The dynamic complex economy system-Block scheme”

The controlled variables (the set points) of this process could be the GDP and the leading economic indicators (LEIs) of the economy. Different nation's economies might distribute the resulting production differently among the population, but the manipulated and disturbance variables in all economic processes are basically the same. The only difference is that inside of the free societies, most of the variables are allowed to float freely, while in totalitarian societies some of the variables are arbitrarily constrained.

The goals of both economies (the set points in the block scheme shown in figure 1) are to keep their Leading economic indicators, LEIs, and their GDP reference variable at some desirable values or to keep raising these targets [2], [9], [17]. As shown in the block scheme presented in figure 1, the relationship between manipulated variables, for instance the interest rate, taxation, trade or energy policy and controlled variables (GDP or LEIs) are functions of the "gains" at the nodes in the "hidden" layers of this self-learning ANN model of the economic process.

To overcome the deficiencies of the linear economic processes modeling, in the recent economic research are adopted neural networks models to forecast business cycles. The decision to focus on neural networks arises directly from the features of these models. First, neural networks are data-driven, can "learn" from experience during the training process, and are well adapted to, underlying relationships. This property makes the neural networks an ideal modeling method whenever exists a

little prior knowledge about the appropriate functional representation of the input-output economic process relationship. Second, once the neural network architectures are suitably specified they are capable to approximate every functional representation to any given degree of accuracy. Finally, neural networks are nonlinear representations and predict, with high accuracy degree, the future value of the reference series, and consequently they are very useful to model a broad variety of macroeconomic time series.

2. Neural networks description

The Neural networks, called also Artificial Neural Networks (ANN), were introduced by McCulloch and Pitts in 1943, and complex dynamical systems by Forrester in the 1950s [17]. The ANN is capable of learning the relationships between inputs (manipulated and disturbance variables) and outputs of the economic process based on its past history.

Recent work in computer science has shown that these networks are more capable than digital computers. Once the neural model of the economic process is build, off-line trained, it can be continuously on-line updated, in real-time, by minimizing the difference between its predicted output value, Y , and its target value \hat{Y} . Their architectures are presented in Figure 2-3 [15] and represent computational models that consist of a number of simple processing units (neurons), placed in layers (input, hidden, output) that communicate by sending signals to each other over a large number of weighted connections. The simplified network diagram 3-4-2 shown in Figure 2 is a full-connected, three layers (input, output and one hidden) feed-forward, perceptron neural network. Fully connected means that the output from each input and hidden neuron is distributed to all of the neurons in the following layer and feed-forward means that the values only move from input to hidden to output layers; no values are fed back to earlier layers as a recurrent network does.

„Figure2. 3-4-2 neurons detailed multilayer perceptron architecture”

All neural networks have an input layer and an output layer, but the number of hidden layers may vary. When there is more than one hidden layer, the output from one hidden layer is fed into the next hidden layer and separate weights (matrix W) are applied to the sum going into each layer. The processing units transport incoming information on their outgoing connections to other units. The signal information is simulated with specific

values stored in those weights w^{ij} that make these networks have the capacity to learn, memorize, and create relationships among experimental input-output data set. Each unit j can have one or more inputs, but only one output. An input to a unit is either the data from outside of the network, or the output of another unit, or its own output. The total input to unit j is simply the weighted sum of the separate outputs from the connected units plus a threshold or bias term $(\theta_1, \theta_2, \dots, \theta_n)$. Most units in neural network transform their net inputs by using a scalar-to-scalar function called an activation function σ (sigmoid function), given by:

$$\sigma = \frac{e^{\lambda x}}{1 + e^{\lambda x}} \quad (1)$$

where λ represents the learning rate of the neural network scheme [17]. Many natural processes and complex system learning curves display a history dependent progression from small values of the learning rate λ that accelerates and approaches a peak over time. For lack of

complex descriptions a sigmoid function is often used. A sigmoid curve is produced by a mathematical function having an "S" shape [15]. Recently, empirical economic models derived from neural networks have been shown to offer advantages in both accuracy and robustness over more traditional statistical approaches (regression methods).

3. Back propagation (BP) training scheme

The experimental input-output data set will be used to train feed-forward neural networks using an error back-propagation algorithm. We will focus our attention on matching model predictions with measurements for network learning and generalization. For this purpose we investigate the simulation with neural networks consisting of three layers (input, hidden, output) or more, configured in different architectures trained by the Levenberg-Marquardt back-propagation error algorithm [1], [10]. Even though a simple steepest descent gradient algorithm can be efficient, there are situations when moving the weights within a simple learning step along the negative gradient vector by a fixed proportion will yield a minor reduction of error. For flat error surfaces for instance, too many steps may be required to compensate for small gradient values. Furthermore, the error contours may not be circular and the gradient vector may not point toward the minimum. To avoid these situations one may we replace the gradient descent method by the Gauss-Newton optimization method, which uses the second derivative of the error function E , namely its Hessian matrix $H(w) = \Delta E = \nabla(\nabla_w E)$. To update the weights, a recursive Gauss-Newton optimization algorithm may be expressed in the following matrix form [10]

$$w^i = w^{i-1} - \gamma [H(w^{i-1})]^{-1} (\nabla_w E) \quad (2)$$

Because the Hessian matrix may be singular, it can be made invertible by using the Levenberg-Marquardt relaxation as follows:

$$H(w^i) = H(w^i) + \mu I_n$$

(3) where μ is a relaxation parameter and I_n is an identity matrix. The Levenberg-Marquardt algorithm is preferred for a small number of weights because the computation speed of the inverse Hessian matrix decreases when the number of the weights increases. Otherwise, the steepest descent optimization algorithm is preferred.

The number of hidden neurons and layers are varied to provide optimal network performance. The development of an optimal neural network structure is complicated by the fact that back-propagation networks contain several adjustable parameters for which the optimal values are initially unknown. These include structural parameters (such as the number of hidden layer neurons, initial weights and biases) as well as learning parameters (such as the learning rate, momentum, and error goal). The learning rate determines the speed of convergence by regulating the step size. However, the network may settle far away from the global minimum of the error surface if the learning rate is too large. On the other hand, smaller rates can ensure stability of the network by diminishing the gradient of noise in the weights, but result in longer training times. For this reason the algorithm could be improved by introducing an adaptive learning scheme which decreases considerably the training time.

A smaller training tolerance usually increases learning accuracy, but can also result in less generalization capability as well as longer training time. Conversely, a larger tolerance enhances convergence speed at the expense of accuracy in learning. It is shown in the literature that a single hidden layer is sufficient for learning any function, but the number of hidden neurons can grow without a bound. This of course, may result in a network with a large number of connections which defeats the main purpose of having an accurate prediction. By increasing the number of hidden layers, each consisting of sigmoid nodes, the complexity of the network can increase more rapidly than the number of connections. The optimum network architecture should have a minimum number of connections and produces a low cross-validation error.

Network performance is measured by the root mean squared error [RMSE], which is given by [10], [15].

$$\sigma = \sqrt{\frac{1}{n-1} \sum_{i=1}^{i=n} (y_i - \hat{y}_i)^2} \quad (4)$$

where n is the size of the test set, y_i is the measured value of the output, and \hat{y}_i is the estimated response provided by the neural networks. All these neural network architectures have to be trained on the experimental data set to earn the mapping from inputs to outputs of the process model. However, sometimes a network with small number of hidden neurons could be sufficient to generate this mapping. To avoid over fitting it is recommended to limit the number of neurons to the fewest as possible, as long as the network converges to the desired error level, and cut off the training once that error was met, i.e., for example, such in figure 5.

One of the most problems that occur in many applications could be the over-fitting. The error on the training set is driven to a very small value, but when new data are presented to the network, the error is large. The network has memorized the training examples, but it has not learned to generalize to new situations. One method for improving network generalization is to use a network that is just large enough to provide an adequate fit. If we use a small enough network, it will not have enough power to over-fit the data. Since we do not know how large a network should be in our application, we will select regularization. This technique of regularization encourages smoother network mappings by adding a penalty to the error function to give.

4. The neural model of the European Union annual growth rates

We will start to build several architectures of neural networks in different successive layers with each layer having fewer units than the previous layer. Every time a new layer will be build, a single unit, called the master unit, will be added. Then step-by-step additional units will be added. At every step the neural network will be trained and the forecasting performance will be estimated. The whole process will

be repeated until a larger network did not sufficiently contribute to the forecasting performance.

In the process of network design selection, we will test every neural network structure for different forecast horizons, all calculations will be performed by using MATLAB 7.5 (R2007b) software, Neural Network TOOLBOX. We will use the back-propagation algorithm that automatically supervise the testing and record the neural network performance.

After extensive testing of possible structures of neural network designs we will select the best neural network architecture that performs very well. The layers of a multilayer network play different roles. Multiple-layer networks are quite powerful. For instance, a network of two or maximum three layers used in our research, where the first and second layer are sigmoid (tansig) but the third layer is pure linear (purelin), can be trained to approximate any function (with a finite number of discontinuities) arbitrarily well. A single layer neural network with linear activation function has the same properties as the linear regression model. The sensitivity analysis suggested that there are some nonlinear relationships between the reference variable and selected leading indicators. This explained why we were able to improve the forecast performance of the original model. We underlined one important contribution of neural networks--namely their elegant ability to approximate arbitrary nonlinear functions. This property is valuable in time series processing, especially in the forecasting field. However, it should be noted that nonlinear models are not without problems, both with respect to their requirement for a large database and careful evaluation, and with respect to limitations of learning or estimation algorithms. All the neural network architectures proposed in this section will be trained on the experimental data set to learn the mapping from inputs to outputs of the economic process model. To avoid over fitting we will limit the number of neurons to the fewest as possible as long as the network converges to the desired error level, and cut off the training once the error was met. Our proposed neural model

structure (26-10-6-1, 26 input neurons assigned to all 26 EU-countries, 10 and 6 hidden neurons and one output neuron assigned to the global index of the EU-27) for the EU-27 economy system integrated with the neural controller is a nonlinear static model integrated in a feedback closed system neural control strategy well described in [15]. The neural network objective is to represent a static model of the economic process which is assumed to be expressed as a nonlinear function \mathcal{G} :

$$\hat{Y}(k) = g(U(k)) \quad (5)$$

Before training the network weights and biases off-line they are initialized using Nguyen-Widrow, initial conditions (small random values). From the preliminary simulation results in our research, the network parameters could be very well initialized, for example, to the following values: error goal = 0.025, learning rate = 0.02 and momentum = 0.95. The number of epochs to reach the error goal depends on the initial conditions for the weights and biases and the number of hidden neurons. The back-propagation algorithm attempts to minimize the error between the output of the network and the target or desired response in weight space, using the method of gradient descent in conjunction with Levenberg-Marquardt relaxation [10]. The simulation results are presented in Figures 3-4. In Figure 3 are represented the neural models of the EU-27 growth production index (a) and domestic production price index (b) based on the experimental input-output data set provided by EUROSTAT, during the years 2004-2006. In Figure 4 are represented the same neural models of the EU-27 that include also the results predicted for the 2007-2008 period. These simulation results reveal a very good capacity of learning input-output map of the experimental data set, and a very good capacity of generalization.

5. Conclusions

This research work is dedicated to investigate the possibility of applying neural network models for simulation and prediction of the dynamic performance of the complex economic processes such as alternative to the linear regression models. Therefore we explore the proposed neural network architecture to build the neural models of this complex dynamic economy system. It is our opinion that the lack of economic structure is the main weakness of neural networks in forecasting applications. Due to the black box nature of neural networks, users of forecasts may feel some discomfort if they are unable to give proper economic interpretation to the estimated relationships. Economic theory does not always yield a specific functional form that is to be used for empirical verification of the theory. In such cases, neural networks have a great advantage over traditional methods. A researcher can start with a large network and prune it to the most efficient form.

Considerations Regarding The Methodology Of Analysis And Performance Evaluation For Modern Romanian Small And Medium Enterprises

Enuși Mariana
Academy of Economics Studies, Bucharest
marinusa@hotmail.com

Abstract

The key-factor in profitability of the small and medium modern enterprises is the intellectual capital and non-corporal actives of those. The empirical formers studies confirm that the intellectual capital has a great impact to the performances of the small and medium modern enterprises.

The aim of this article is to exam the inter-relations and inter-actions between the components of the intellectual capital and the non-corporal actives in the process of evaluation the performances of the modern enterprises that is a competitive sustainable advantage. These are basic for help the decisions of the management o allocate resources and the decision of the investors regarding the correlation between value and price.

Key words: SME, intellectual capital

JEL Classification: D21, L25

1. Introduction

The globalization and acceleration the technological changes stress inside the economical medium the importance of the ongoing the activities making the differences between the modern and classical enterprises in allocation the resources and the decision of the investors about the correlation between the value of the modern enterprises and the price of the non-corporal actives (intangible actives).In this context, there are new opportunities (or threatens) for business.

They can observe the real growth of the incorporate knowledge in human capital and also in the intellectual capital of the modern enterprise and opening the new contradictions between the liberty of the

immaterial labor and its disciplinarian, between the creativity of the intellectual labor and control.

2. Intellectual capital

In 1990's there was developed the concept of the intellectual capital, when the managers realized that the two problems regarding the company management and the evaluation are only the two sides of one coin."-what you want to lead you must measure" and" what you want to measure you can lead". The intellectual capital represents the fusion between the two flows of thinking. (Roos et al., 1997).

In Romania, since 2000,they have stressed these two flows and the two problems regarding the management and both the evaluation determined some companies to evaluation the intellectual capital and non-corporal actives.

According to the Minister of Public Finance of Romania, no. 306 of 2002 for approval of simplified accounting regulations harmonized with European Directives, intangible assets include:

- formation expenses;
- development costs;
- concessions, patents, licenses, trademarks, rights and other similar values;
- goodwill;
- other intangible assets, and
- intangible assets in progress.

The structure of the intellectual capital is deeply rooted , was the first time that the economist John Keneth Galbraith in 1969, and Peter Drucker talked about "knowledgeable workers".

The intellectual capital is an intellectual material - knowledge, information, intellectual property, experience – these may be put to increase the welfare (Stewart,

1997) of modern enterprises.

Intellectual capital and major components

Potential asset value	Asset value	
Human capital	Intellectual asset	
- Experience	• Programs	• Methodologies
- Know-How	• Invention	• Documents
- Abilities	• Data base	• Drawings
- Creativity	• Projects	
	Intellectual Assets	
	• Patents, Copyrights	
	• Trade Secret factory	

In the context of modern business is important to understand the entire company as a business value as the sum of all assets (tangible and intangible).

A classification of the assets of modern business, as follows:

- Differentiable Assets- this class of assets is often unique and includes assets such as production, processing and distribution, which are similar between companies, but still different in some respects from those of competitors

The following figure present market value of a company from liquidation value of the generic assets and market value of assets plus market value a generic intangible assets.

Figure no. 1 Market value of a SME's with intangible assets

Source: I., Anghel – Theoretical and Applied Economics, Editura ASE 2004

In the context of current economy, the management role is to establish modern enterprise value than generic asset value. The performance depends on today's modern enterprise knowledge and ability of human capital (potential value) in intangible assets of the organization (such as trademark, patents, licenses, goodwill, trade secrets, copyrights, intellectual property, etc.).

Figure no. 2 The components of a SME's with intangible assets

Source: Author's owner

3. Evaluation of intangible assets (intangible) under financially Reporting Standards (IFRS)

Through the performance evaluation methodology of the modern enterprise they answer questions such as:

- What is the real value market of the enterprise
- Is this value satisfactory or not?
- How did they get the results?
- Which are the wanted performances and also the results and what is the level of the performance?
- What have they do for get the wished performance?
- What is the intangible value indicated (not shown in the balance sheet)?

The general aim of the evaluation methodology consists in a continuous training and the most important think is to help the evaluators of he non corporal actives regarding in the ownership and use recognized assessment methods appropriate for determining market value or fair value of intangible assets separately, both required for carrying out transactions based on market value and requirements for financial reporting under International Financial Reporting Standards - (IFRSs).

The five recrecognized methods of evaluation of separated intangible assets entered into the three traditional evaluation approaches are:

- II.1. Transactional method
- II.2. Relief from Royalty Method
- II.3. Premium Profit, or Incremental Income Method
- II.4. Multi-period Excess Earnings Method
- II.5. Replacement Cost Method

The forecast period of financial indicators used in applying the five methods above, is shorter than the remaining economic life or equal with legal life. The economic life is defined as the period in which intangible

assets are expected to generate an economic benefit for their owners. Legal life is the period in which intangible assets are protected by law.

The six stages of implementation of these methods are:

- a) estimate the remaining economic life of the intangible asset ;
- b) forecast net turnover achieved by using the intangible asset;
- c) determining the appropriate royalty rate (the market);
- d) determining the discount rate specific intangible asset under evaluation;
- e) calculating the present value of net charge economy;
- f) calculating the depreciation tax benefit - but where is assessing the initial recognition of an intangible asset in the financial statements.

Classical sources of profit or cash flow are either extra an excess of selling price (premium price) reduction of expenditure items (variable or fixed-economies of scale) or a combination of the two sources above.

Comparing the flow of income or cash flow forecast can be made:

- be between the entity using intangible assets and other similar entities without an intangible asset. If a brand is product evaluation. Applying this procedure is subject to credibility than they can forecast revenue or cash flow that is not feasible to use similar entity. If there is sufficient information to make such a credible forecast, additional profit method should not be used, either between that of the entity, in two ways: with and without the use of that intangible asset. It is the evaluation of a patent and a non-compete agreement.

Always preferred result of the assessment, based on direct knowledge of the market, is where intangible assets are trade on a market, or are the current trading prices of similar intangible assets, either current trading prices of some similar intangible assets, in the second case of being necessary, some corrections to reflect differences between selected elements of comparison (respectively the differences between intangible assets and intangible assets valued comparable selected as appropriate).

The initial evaluation of identifiable intangible assets with finite economic life, so liquidated, following a business combination,

fair value of these will include the tax benefit resulting from the amortization of intangible assets.

Form for calculating the tax benefit (BF) is:

$$BF =$$

$$\text{Estimated value} \times \frac{n}{\{(n - F_{cap}) \times S\} - 1}$$

where:

Estimated value = total economy or discounted fee, or replacement cost of internal generation identified with the cost of an intangible asset similar or identical;

n = number of years for amortization of intangible assets;

F_{cap} = capitalization factor and required update rate;

S = tax rate.

4. Assessment of intellectual capital and intangible assets in a modern business. Case study at S.C. Arobs Transilvania Software

S.C. AROBS Transilvania Software has recently turned 11 years:

S.C. AROBS Transilvania Software partner becomes Microsoft Gold Certified Partner

On July 1, 2009, S.C. AROBS Transilvania Software (AROBS) has acquired the status of Microsoft Gold Certified Partner - the highest form of partnership between Microsoft and companies operating in IT & C Achieving.

Segment-sized GPS and PDA S.C. Transilvania AROBS 2010 estimate for growth this year lower than that recorded last year in 2009 to a figure approaching 5 million and estimated a forecast for market share between 20 and 25%.

An estimated 2 million revenues from outsourcing services company, approximately 20-30% of the total business of SC AROBS Transilvania.

The modern enterprise management, internally generated computer programs are also an advantage for the organization and ensure long term sustainability of the company are internally generated for the skills and knowledge that group of authors who contributed to making them part of the company's intangible assets.

Internally generated computer programs to describe their functionality to address the cost of historical costs for generating computer programs, if these expenses are not shown separately requested:

- a. number of man-hours required for recreation program;
- b. the categories of personnel needed;
- c. employee wages in section b., and
- d. share information to determine administrative costs or overheads;
- e. the registration fees.

But especially for the income approach:

1. income / savings to the historical software;
2. forecast revenue from licenses including values for the remaining life of the software;
3. direct expenditures related to income forecast point b.;
4. forecast expenditure (eg. maintenance costs).

Remaining economic life to meet the following requirements:

- i. which was originally expected economic life and that is the date of valuation;
- ii. when it was put into service program;
- iii. description of internal development that could prolong the economic life;
- iv. description of internal development to replace the computer program that could reduce its economic life, and
- v. description of external factors that may affect the economic life remaining.

6.	Replacement cost (€)	1.17.101
7.	Net replacement cost (rounded off)	617.000

5. Evaluation of a method patent economy / fee exemption

For the value of a patent application involves:

- List of patents for which protection pay legal fees;
- List of patent applications;
- The case of patents, the economic effects achieved;
- R & D spending to generate historical patents.
- Identification of patents and products share the administrative costs or overheads;
- Identification of patents and related products are expected to have commercial life;

a) estimates of income from patent over the remaining economic life;
b) estimates of direct costs related revenue in a.

- Feedback about the possibility of extension of patent protection legally provided over the life;
- Details of possible transmission of economic rights through patent license agreements or assignment.

Under assessment is a patent for a new product, the company used SC AROBS Transylvania Software, owner of the patent, which is acquired by the company Mio.

To assess the balance sheet is a patent by the method of acquisition, that company's acquisition by the company Mio SC AROBS Transylvania Software.

Type the requested amount is fair value.
Date of assessment: January 10, 2009
Assumptions for assessment are:

- useful life of the patent was estimated to be 5 years
- sales for products manufactured using patent was as expected:

- thousand.Euro-

Year	Amount
2009	4.400
2010	4.840
2011	5.227
2012	5.541
2013	5.818

- fee turnover rate, the field was set at 4%;
 - company profit tax rate is 16%;
 - economic discount rate (exemption) of net charge was set at 16%.
- Calculation of Tax Benefit due to the deductibility of depreciation, is:

Indicators	2009	2010	2011	2012	2013
Net turnover	11,00	18,00	22,27	23,1	23,8
EXPENSES	1,70	2,5	2,78	2,16	2,27
Profit	2,2	3,5	3,7	3,0	3,2
Net income	1,3	2,5	2,5	1,8	1,9
Net income	0,852	0,773	0,671	0,582	0,708
Depreciation	2,7	20,3	2,5	1,27	7,8
Intangible	556,4				
Net income					
Depreciation	0,13				
Tax	0,10				
Depreciation	2,57				
Intangible	65,1				
Tax benefit	621,5				

For assessment was to highlight the difference between book value figures of the company acquired its real market value through intellectual capital and intangible assets owned by default

Tax benefit of depreciation is worth € 651,000 and the fair value of the patent was calculated to € 6,215,000.

The difference between the two values is the subject of our study, by default of intangible intellectual capital of SC Transylvania AROBS maintains financial goal for this year 2010 and aimed at business between 7 and 8 million €, an increase over the previous year in 2009 with 30% for 2011 and plans to achieve a figure of up to 10 million € .

6. Conclusions

In practice evaluation of intangible intellectual capital of the firm's default to normal traditional highlight of the five methods with rigorous approaches. Evaluation methods of intangible intellectual capital default of modern enterprises in Romania meet international standards.

The investigation conducted by the author with reference to intellectual capital market has allowed the establishment of fundamental issues related to the formation of intangible intellectual capital implication of modern enterprises

Among these are:

- a) the state has relegated many market institutions;
- b) the scarcity of specialists for the "production and marketing knowledge;
- c) reduced integrity of the national economy in the world economy;
- d) lack of incentives to professionals able to create and invent states tend to conceal innovations and know-how;
- e) the inventors migration abroad;
- f) lack of financing sources of business innovators, etc. ...

According to research conducted at the micro level analysis has shown that driving out local businesses need and opportunity rather than actual market cost of the product via appropriate intellectual and rational management of intangible assets, and in particular, intellectual property default.

But once the assessment bears a theoretical and practical, roll the balance sheet as at most companies, these intangible assets are not indicated.

Research results showed that in practice, local businesses face a number of problems associated with managing intellectual capital, intangible assets, including the highlight:

- a) lack of sources of funding for both development and for recording intangible assets;
- b) lack of knowledge needed in the recording of intangible assets;
- c) moral rapid aging of intangible assets;
- d) lack of incentives from the state enterprises for the creation of intangible assets;
- e) non-recovery of costs for creating and recording of intangible assets related to small volume production;

f) unenhancing the legal framework protecting intellectual property.

Suggestions:

1. Today, innovation is needed and setting up infrastructure. Achieving that goal is only possible as a result of carrying out state policy innovation active mass use of various levers and instruments.

Basic tasks that faced Romania in the formation of innovative system is derived first, the formation of normative-legal basis favorable to innovative activity, above all in matters of protection, disposition and use rights to the intellectual capital (starting point should be to enact law on intellectual property), and secondly, building an infrastructure developed to support the intellectual activity and rapid transmission of the results of scientific research that has commercial potential, business sector for production and removal market innovations in the form of goods and services.

2. A major innovation in creating infrastructure has training infrastructure. In Romania it is necessary to form an effective system of financing of innovative activity, both at the expense of budget resources and extra budgetary funds account. State funding for innovative scope should be oriented in the following areas: capital injection (partially without being paid) for innovative projects that have a high commercial potential able to become the "locomotive" to increase innovation, innovations in financing off-budget funds, full state funding irreversible and innovative projects, which bears the national character, but of interest to private business.

3. It requires the protection of local

entrepreneurs by providing innovative risks and other risks related to intellectual property objects.

To address this problem, the state must ensure market transparency and stability of national security, contribute to implementation of international standards in insurance business and supervisory standards, to continuously improve insurance legislation, to create conditions for integration Romania's insurance market in insurance and reinsurance schemes.

Justifications for Intervention in the Marketplace in Favor of Consumer Protection

Abstract

Economic reality of everyday life places the consumer in an objectively unbalanced report in favor of the producer/trader, even if the first, with his needs, should be both the origin and the final point of production activity. In this context, the present paper contains an analysis of the reasons behind the intervention in the marketplace in favor of consumers. Each one with its advantages and its limitations, these reasons have allowed the development of comprehensive national systems for consumer protection.

Key words: consumer protection policy, competition policy, market failures, economic power, information, measures

JEL Classification: D18

1. Introduction

Consumer protection policy has an ancient genesis, dating back at least to Roman times with the adoption in Roman law of various implied warranties against latent defects in the sale of goods, and evolving in the latter part of the last century to encompass weights and measures legislation, regulations dealing with adulterated food, dangerous drugs, and various forms of "quackery" on the part of suppliers of goods and services. However, the current legislative and regulatory consumer protection framework developed by the world's states largely finds its genesis in the consumer and more general policy activism of the 1960s and 70s, during which period most of the major national consumer protection statutes were first enacted or extensively elaborated.

The traditional justification of consumer protection is founded on the notion of

restraining the monopoly power of huge companies and the potential that they possess to influence consumers via advertising that limits consumers' ability to verify what is in their own best interest. This theory refers not to the individual consumer in a concrete situation, but stresses a general economically weaker position of the consumer *vis-à-vis* the suppliers. Consumers are seen as less knowledgeable and as economically inferior to producers and traders. So a large deviation between the ideal of consumer sovereignty and reality is presumed. Producers are seen to possess "sovereignty," corporations are powerful and able to bring their goods onto the market and they can manipulate the consumers to buy them. Disadvantageous transactions are thought to result from the exploitation of a seller's bargaining advantages *vis-à-vis* the individual consumer. There is a widespread chance of exploitation as a consequence of the discrepancy between the economic power of the producer/dealer and that of the consumer.[1]

The power imbalance on the market ("countervailing power") leads to demand for market reconciliation, compensation or balancing. According to this conception the state must support the consumers as weaker market participants during the counterweight formation.

2. Competition Policy as a Valuable Instrument for Consumer Protection

In well-functioning markets, supported by general contract law, competitive pressure means that only those firms which give consumers what they want can prosper. There is little role for any intervention to protect the consumers when all product attributes and prices are easily observed and evaluated at

the time of sale, when search cost are not significant, when consumers sample offers from multiple suppliers, and when most consumers are capable of making reasonably good decisions concerning the product in question.

But many, perhaps most, products do not satisfy these restrictive requirements and some consumers might not always obtain a good deal, even when substantial competition is present. In such cases additional policies to aid consumers have a role to play.

In fact, what prevents markets from delivering good outcomes to consumers? Familiar reasons include, as we mentioned earlier, abuse of dominance and collusion between suppliers, and these fall broadly within the domain of *competition policy*. However, there are several other reasons why competition need not work well, especially because of imperfect information about product attributes or market prices, consumer high cost of obtaining market information, supplier significant costs of advertising, or consumers possessing imperfect information about their own needs. These features fall broadly under the heading of *consumer protection activities*. [2]

These activities can be divided into two categories: (a) *consumer protection policy*, properly speaking, which is designed to modify the status quo in terms of the information available to consumers; and (b) *consumer promotion*, geared toward education and the creation of institutions and associations for consumer protection advocacy.

Consumer protection and promotion policies are generally introduced by the government, either through public consumer protection agencies, through different measures designed to reduce the transaction cost of litigation, or through the creation of alternative mechanisms for dispute resolution. But, there are also private-sector initiatives such as the creation of customer services centers by corporations and consumer affairs columns in the media that can be designed to protect consumers' interests. [3]

Competition policy and consumer protection policy share the common purpose to facilitate the exercise of *consumer sovereignty* defined as a state in which consumers can freely take decisions based on their individual interests and in which markets will respond to the collective effect of those decisions. But competition policy is mainly intended to ensure that a range of options is available to consumers through market competition, while consumer protection

seeks to protect the ability of consumers to freely choose among such options without their critical faculties being hampered by such violations as deception or omission of material information. Together these policies function to protect a free economy. [4]

However, while the objectives of both policies are essentially the same, competition policy is more a proactive policy that attempts to promote consumer interest in the marketplace, whereas consumer protection policy puts forward mainly a reactive agenda to protect the interests of consumers and provide access to redress for abuses. [5]

Both competition policy and consumer protection policy are theoretically justified on the basis of the possible occurrence of "market failures", such as abuse of economic power, asymmetrical information transaction costs, externalities, entry barriers and natural monopolies. In this context, the market failures can be divided into two categories: (a) those *external to consumer relations*, comprised of restrictions to the range of consumer choices which can be corrected within the sphere of competition policy; and (b) those *internal to consumer relations*, comprised of restrictions to the consumer's ability to choose freely from among the options available which can be corrected within the sphere of consumer protection. [6]

Thus, market imperfections such as imperfect information and irrecoverable entry costs, or anticompetitive conduct such as price or reputation predation, price fixing, horizontal restrictions, mergers and vertical restrictions, fall within the exclusive remit of competition policy.

On the other hand, the sphere of consumer protection covers cases involving complaints relating to product features, warranties and contractual clauses associated with market failures whose impact harms four types of consumer: those whose freedom of choice is subject to some form of coercion; "vulnerable" groups (such as children); victims of misleading or incomplete information; and consumers who have to deal with information that may be difficult to understand. There are also certain "hybrid" cases that involve constraints on both consumer choice and the effectiveness of choosing among the existing options. This is the case, for example, with conduct that results in higher search costs, tied sales or

resale price fixing.

Being justified on the same basis, the competition policy and consumer protection share the common purpose of guaranteeing the consumer sovereignty in the marketplace, and, in practice, both functions converge. Moreover, they stimulate each other reciprocally, so that the level of competition in a market may affect the level of consumer protection required. If a competitive market is seen as delivering choices in terms of prices and quality, regulatory intervention on behalf of consumers may need to be strategically targeted so that there is little, if any, negative impact on the competitive process. It is important that consumer protection not hinder competition by, for example, imposing excessive compliance costs on businesses, which are likely to be ultimately passed on to consumers.

3. Main Reasons for Consumer Protection Policy

Therefore, as a distinct aspect of social protection that a democratic society must promote, *consumer protection policy involves, in practice, a set of measures belonging to public or private initiative and adopted in order to ensure and improve, on a continuing basis, the interests of consumers in the marketplace.*

The development at national level of a coherent consumer protection policy is justified from *various reasons*.

- Under *efficiency reasons*, all people should get what they want, so even the individual interests of consumers should be satisfied. In this respect, it is assumed the rationality of human behavior, which is why government intervention in favor of consumers is justified for reasons of developing their ability to satisfy their individual interests, seeking to achieve the overall economic efficiency by correcting, in particular, the market failures that jeopardize consumer sovereignty in the marketplace, such as, for example, prohibiting misleading advertising.

This efficiency considerations, as rationales for consumer protection, may be challenged for several reasons. Thus, first, their adoption requires proper identification of costs and benefits involved, action that it is not always very easy, for the decision made to be the most efficient in practice. Second, measures taken for efficiency reasons not necessarily take account

of specific complex economic, social and legal factors which influence the relationship between the consumer and the producer/trader and make the exercise of power in those relations. Also, the rationality behavior assumption, underlying these reasons, ignores how consumers mostly make decisions and effectively conduct themselves in the market.[7]

- Taking measures to protect consumers can be justified also for *paternalistic reasons*, which are based, most often, on the premise of challenging the rationality assumption of certain categories of consumer behavior - such as minors, the elderly, the sick people and low income households, considering that, for some reason, they are unable to pursue their own interests, so as to justify intervention for their protection. For example, measures targeting minors may include: setting strict rules that their consumption products must meet; banning the sale of alcoholic or tobacco products; banning advertising that can exploit the psychological vulnerability of children etc.

But even this paternalistic attitude towards some consumers may be challenged especially in liberal societies that emphasize individual freedom and autonomy, such as when people are in a terminal stage of disease causing death and up which is assessed that decision should be allowed to have access or not to some experimental drugs with an increased risk to human health.[8,9]

- Because the measures taken to protect consumers from efficiency reasons have often been criticized that they mostly ignore such issues as equal or fair distribution of resources in society, it has been supported the promotion of measures based on considerations regarding *distributive justice*. Adherents of this point of view argue that one source of concern and, indeed, of failure in the transactions between consumer and producer/dealer is the unequal distribution of bargaining power between the two parties, situation which motivates the adoption of measures to protect the weaker party against the abuse of the strongest partner.

And how, almost every time, it is considered that the difference related to size and available resources are detrimental to the consumer, it is required the appropriate

intervention in his favor to restore the same footing as its partner, by promoting measures as: correct definition of the terms of sale contracts; prohibiting the use of unfair terms; providing legal mechanisms available to consumers to offset any damage etc.

These measures adopted from distributive justice reasons may also be challenged on the grounds that, in general, consumer location in a weaker position compared with its transaction partner is especially true for companies that are in a monopolistic or dominant position, who have the power to manipulate consumers in their own profit, issues that fall under competition policy and should be regulated specifically by it.

As another source of inequality in bargaining power are the informational asymmetries, so that the producer/dealer may exploit the available information to the detriment of consumers, it is also considered that a transactional balance can be accomplished through fair distribution of information between partners.[10]

- The advantages, and especially the limits of the reasons categories analyzed above led to the adoption of consumer protection measures from an *eclectic mix of reasons based on certain information principles*. [11, 12]

Thus, it is considered that to be truly useful for consumer decisions, information must meet several criteria: the consumer has access to a sufficient volume of information to take the best decision; the information content is right; the information is easy to understand, allowing those who use it to process towards relevant comparisons between consumption alternatives available to them; the information comes from a reliable source, otherwise being ignored by the consumer.

When one or more of these criteria are not met, it is necessary to adopt measures aimed at protecting consumers in order to reduce the cost of obtaining and processing information or to improve consumer assessment of the information value by making him aware of hidden risks involved in certain activities, or both.[13] In response, the specific measures that can be taken include: the obligation of producers to disclose certain information about their products through labeling or advertising; the introduction of certain provisions in sale contracts to benefit the consumers; establishing standards that products or services sold in the

market must meet, regulating liability for defective products.

4. Conclusions

Government intervention in the marketplace for consumer protection reasons should be taken only to the extent that solutions based on market mechanisms is not working properly. Such situations may occur when: reduced repetition of transactions or their absence does not allow consumers to receive performance incentives created by repeated transactions that can be achieved from some satisfied customers; the costs of entry and exit from the industry are very reduced, allowing the manifestation of a large number of operators with transient existence, not always the most reliable; reduced value transactions discourage consumer to seek compensation, after its completion, for any damage incurred through legal action etc.

Abstract

The economic literature and practices show that an efficient service sector, with a high level of quality, is a decisive factor of the sustainable economic development and competitiveness of modern economies. In this paper we would like to highlight, through a statistical-economic analysis, the importance of the service sector in the process of economic growth and job creation, compared with other sectors of Romanian economy in the period 1990-2008. For Romania, the existence of a constant concern for efficiency and services quality is imperative both at the national and regional level in order to accede to the status of a country with a developed economy, a knowledge-based economy.

Key words: service sector, services quality

JEL Classification: L80, P44

1. Introduction

Developing an economy based on knowledge and innovation (smart growth), promoting a more efficient, greener and more competitive economy (sustainable growth) and fostering a high-employment economy delivering social and territorial cohesion (inclusive growth) represent the three mutually reinforcing priorities stipulated in “Europe 2020 Strategy” [1] so that Europe should emerge from the stronger economic and financial crisis. Therefore, through this strategy, the major role that the service sector should have at the national economy level and implicitly on the UE economy is acknowledged at a European level.

The growing share of services in global output, employment and international

transactions has brought to the forefront the issue of the role played by services in the national economy.

As far as the concept of “service sector” and the role of the structural changes in economic growth are concerned, the contributions of authors like Fisher A.G (*The Clash of Progress and Security*, 1935), Clark, C.A. (*The Conditions of Economic Progress*, 1940), Chenery H.B. (*Comparative Advantage and Development Policy*, 1960), Fuchs, V. (*Economic Growth and the Rise of Service Employment*, 1980) need to be pointed out. These studies have noted and documented the positive association between growth and share of services in the industrial-distribution of the labour force based on Petty’s Law which states that in the course of economic growth there will be a shift of population from agriculture to manufactures and from manufactures to services.

There are a lot of studies that have theoretically argued and empirically estimated the link between performance of service (or tertiary) sector and economic development. For example, B. Eichengreen, P. Gupta (2009) considers that one of the most striking regularities of the growth process is the massive reallocation of labour from agriculture into industry and services [2]. One of the stylized facts of economic development is that the share of services in GDP and employment rises as per capita incomes increase [2]-[5].

In our paper we aim to identify the connection between service sector and employment, on the one hand and service sector and economic growth, on the other hand, based on the statistical data in Romania, between 1990 and 2008. Moreover, we intend to show the connection between economic growth and employment, in the tertiary sector context.

2. The role of the service sector in the economic growth process

In the economic theory it is stipulated that economic growth precedes service sector growth. But along with the growth of service sector, growth in manufacturing sector also takes place and the two-way spillover effect induces growth in the economy. Therefore, there is a causal relationship between economic growth and growth in the service sector.

Transition economies, including the Romanian economy, have inherited a deformed economic structure, where the forced development of the hard industry affected the increase in the service sector and convenience goods sector. After 1989, the commerce and prices liberalization have opened the way to a resource reallocation and a *change of the economic activity's structure on sectors, branches and domains, according to the market's needs*. In order to present these changes we have to start with the gross value added (GVA) evolution, but mainly with the evolution of the changes in the structure of the GVA, on categories of resources.

In the first transition year – 1990, out of the GVA total 50% was achieved in industry and constructions, 23.7% in agriculture and the rest in services.

Figure 1. Share of GVA by Sector (%), 1990-2008, in Romania”

(Source: Own calculations based on data contained in the Statistical Yearbook of Romania, National Institute of Statistics (NIS), 2009)

This situation changed during the transition period and in 2008 out of the GVA total only 37.6% was achieved in industry and constructions, 7.5% in agriculture (including hunting, forestry, fishing and fish breeding) and the rest in services and assimilated activities (54.9%), according to the data in figure 1.

As far as the contributions of the tertiary sector to the formation of GVA are concerned, these are very different.

„Figure 2. The GVA structure and Employment structure, in the tertiary sector, in 2008, in Romania (%)”

(Source: Own calculations based on data contained in the Statistical Yearbook of Romania, NIS, 2009)

Within the service sector the highest contribution to the achievement of gross value added, in 2008, pertains to the activity of *real estate transactions, renting and service activities mainly rendered to enterprises*, 39.6% respectively, followed by the *trade activity* (22.3%) and the *transport, storage and communications activity* (21.3%), according to fig. 2.

Although the service sector developed, between 1990 and 2008, in comparison with the countries of the EU we are still behind. In order to support this statement we present the following data in the table figure no.3 In the EU countries- 27, according to the information provided by Eurostat, out of the GVA achieved in 2008, only 1.8% was achieved in agriculture, 26.5% in industry and constructions and in services 71.7%. In Romania, in the same year, out of the total GVA nationally achieved, 7.5% was achieved in agriculture, 37.6% in industry and constructions and 54.9% in services.

„Figure 3. Share of GVA by sector in 2008, Romania and EU (%)”

(Source: http://epp.eurostat.ec.europa.eu/portal/page/portal/national_accounts/data/main_tables)

The change of the economy’s structure allowed the following situation, beginning with the year 2000 until now, the sustained economic growth process in Romania has led to the doubling of the GDP per capita (calculated on the basis the Purchasing Power Parities), from 4900 in 2000 to 11800, in 2008 [8] reducing the gap compared with the EU 27. Nevertheless the level of GDP per capita achieved in Romania in 2008, represents only 45.8 % from the EU 27’s average.

In Romania, between 1990 and 2008, based on the Spearman correlation coefficient of 0,693 (fig.4), a direct correlation between the share of services in GVA and GDP per capita was identified, fact that highlights the decisive role of the service sector in the process of economic growth.

„Figure 4. Correlation between share of GVA by sector (%) and GDP/capita, 1990-2008”

Note: GDP/capita is calculated and expressed in constant prices (1990)
(Source: Own calculations based on data contained in the Statistical Yearbook of Romania, NIS, 2009)

On the other hand, it can be noticed that also between the contribution of the primary sector to GVA and GDP/capita as well as between the contribution of the secondary sector (industry and construction) to GVA and GDP/capita there is an inverse relationship.

The statistical data prove, in this way, that in Romania the service sector has a higher contribution, as compared to the other sectors, to the economic growth. The economic and the social role is acknowledged in this sector, paying special attention to the tertiary sector within the sustainable development strategies of the Romanian economy.

3. Employment and service sector in Romanian economy

The gradual focusing process of the employed population in services is usually considered a positive historical process of social and economic progress.

The structure on sectors of employment differs in space and time. Within the *pre-industrial* companies most of the people worked in the primary sector. Together with the *industrial revolution* and by moving from the natural economy to the barter one, the favourable environment was created so that employment would be oriented toward the secondary sector to the

detriment of the primary one. The second stage of labour force reallocation took place by moving this toward the service sector, conditioned by the existence, on the market, of the demand for various services and the access of an increasingly category of economic agents to the services provided by this sector.

The service sector in Romania proves to be the only sector where an increase of the employed population is registered. Between 1990 and 2008, 742 thousand jobs were created in the tertiary sector (the employed population in this sector increased from 2,985 thousand in 1990 to 3,727 thousand in 2008), the ratio of the employed population in services, out of the total number of employed population, recording an increase of 15 percentage points (from 27.5% in 1990 to 42.6% in 2008, according to the data in the figure below).

„Figure 5. Employment structure, by activity sectors (%), 1990-2008”

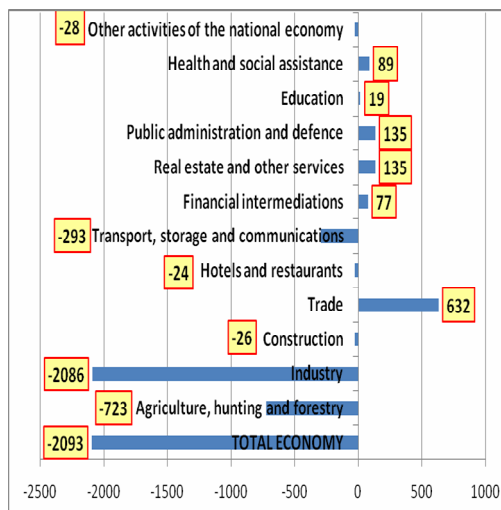

(Source: Own calculations based on data contained in the Statistical Yearbook of Romania, NIS, 2009)

Due to the fact that within the service sector different changes of the jobs took place, according to the economic activity, it has to be mentioned that the highest job increases were recorded in the activity of *trade* (+633 thousand), followed by *public administration and defence* (+135 thousand), *real estate and other services* (+135 thousand), etc. (fig.6) accounting for 1,087 thousand jobs. On the other hand the employed population in the following activities was reduced: *transport, storage and communications* (-286 thousand),

hotels and restaurants (-30 thousand) and *other activities of the national economy* (-3 thousand) with 345,000 people (see figure 6.)

The apparent prevailing employment in the tertiary sector in Romania is not the result of job transfer from the first two sectors to the service sector, but it represents the effect of diminishing industrial activity, with all its implications, fact that resulted in reducing the global income and consequently, as has been stated above, in lowering the number of jobs even in the service sector. This sector has not proved the role of job generator and absorber of people laid-off from industry.

„Figure 6. The evolution of employment, by activity of national economy 1990-2008 (thou persons)”

(Source: Own calculations based on data contained in the Statistical Yearbook of Romania, NIS, 2009)

We mention that although 742 thousand jobs were created in 1990-2008 in the tertiary sector, these were not enough to take over the labour force laid-off from the primary sector (723 thousand people) and the secondary sector (2112 thousand people), creating by 2836 thousand less jobs in 2008 compared to 1990 [according to fig. 6]. Agriculture was the „outlet” for laid-off people, a refuge zone. The economic reality proved that subsistence agriculture is inefficient and effects are quite dangerous both in the short term and in the long term.

In 2008, out of the 3,727 jobs created in services, 31.4% are in the trade activity, 14% in the real estate and other services 12.6% in transport, storage and communications. In the *hotels and restaurants* activity and the *financial intermediations* activity fewer jobs were created, according to the data in the figure 2.

In order to outline the place where Romania is, in relation to the EU, concerning the structure on sectors of employed population, the differences between Romania and EU-27, EU-15 respectively are shown in line with data included in fig. no.7.

Reviewing data in the below figure it is noticed that concerning the structure of employed population on sectors of activity, Romania has a particular situation within the EU’s Member States, with an extremely powerful economic and social impact, characterized by much disequilibrium, first of all due to the extremely high proportion of employed population in agriculture and its maintaining during a relatively long period (1990-2008), to the detriment of services. Beside Romania, the countries in EU-15 have lower shares that are much below the Romanian level.

„Figure 7. Employment structure, by activity sectors (%), in Romania, EU-27 and EU-15, 2008”

(Source: Employment in Europe, 2009, for Romania -Statistical Yearbook of Romania, NIS, 2009)

It should be mentioned that the low level of employed population in agriculture reached by EU-15 and EU-27, is the result of a long historic process of transferring employed people in agriculture, firstly to the secondary sector, particularly to the processing industry, and then to both secondary and tertiary sectors.

To reduce the gaps in the field of employment it is necessary to emphasize the rise of the employment rate in the tertiary sector because at present, a prevailing employment in the tertiary sector is the most important factor of changing the structure of employment [6].

In Romania, the change of employment structure much as difficult and costly seems to be, is more than necessary. It must be done in order to shift from poverty to economic welfare.

4. Correlation between employment and economic growth in the service sector

The transition from the centralized economy to the market economy has generated significant modifications both in the economic structure and also regarding the sectors composition of the employed population [3]. In most countries of the Central Europe, the decline of the employed population from industry and agriculture was accompanied by significant increases recorded by service sector, a valid statement both from the GDP proportion of the tertiary sector perspective and as regarding its specific share among the employed population.

In Romania, the correlation between the employment structure and the contribution of the employed population to the creation of the Gross Value Added allows us to state the following: The rise of the proportion of the employed population in services out of the total employed population with 15 percentage points (from 27.54% to 42.6%) has determined between 1990 and 2008 a rise of the contribution of this sector with 30.2 percentage points (from 26.3% to 54.9%).

„Figure 8. Direct correlation between employment in services (%) and GVA in services (%), 1990-2008, in Romania”

In the economic theory it is stated that most of the countries with a small share of agriculture (primary sector) in the employment structure usually have a high level of GDP per capita and vice versa.

Between these two indicators there can be determined a statistically significant correlation because there can be recorded a direct, strong relation between the proportion of the employed population in services and the contribution to GVA, fact pointed out by a 0.893 Pearson's correlation coefficient.

„Figure 9. Correlation between the employment share by sector (%) and GDP/capita, 1990-2008”

From the calculations made, in order to establish the intensity of the correlation between GDP/capita and employed population share in the three sectors, between 1990 and 2008, it results that

between the employed population share in the primary sector and the level of GDP/capita a significant inverse correlation can be established (the correlation Spearman coefficient is -0.619). Also, between employment in secondary sector and the level of GDP/capita the relationship is indirect, but low. In the tertiary sector a strong, direct relationship is identified (the correlation Spearman coefficient is -0.789), thing that reflects that in Romania, the growth in the employed population in the tertiary sector has positively influenced the GDP/capita growth.

The service sector producing services (“intangible” goods) tends to require relatively less natural capital and more human capital than producing agricultural or industrial goods. As a result demand has grown for more educated workers, prompting countries to invest more in education-an overall benefit to their people. Another benefit of the growing service sector is that by using fewer natural resources than agriculture or industry, it puts less pressure on the local, regional, and global environment, the conditions for *sustainable development* being assured.

5. Conclusions

Services represent one of the most dynamic areas of the modern economy, the research of the services quality from an economic as well as social point of view is mandatory. The normalization development in the sector of service activities can be a considerable trump both of competition and growth of consumers’ life quality.

The economic reality of Romania reveals the direct relation between the

proportion of the employed population in services and the contribution to gross value added, proving, through statistical data, that in Romania, the service sector has a higher contribution to the economic growth compared to the other sectors.

For this reason we consider that this sector should be acknowledged the economic and social role, giving higher importance to the tertiary sector, under the quantitative, qualitative and structural aspect, a special attention within the sustainable development strategies of the Romanian economy.

Evolution of Fiscal Pressure in Romania Compared to other European Union Member States

Iacob Mihaela Ioana
Boglea Vanina Adoriana
Universitatea „Aurel Vlaicu” of Arad
mihaiacob1976@yahoo.com
vanina.boglea@yahoo.com

Abstract

This article analysis the concept of fiscal pressure and fiscal optimum. A comparative study of the fiscal pressure between Romania and the other EU member states has also been made. The academic literature analyzes the specific problem of the fiscal pressure from all points of view and the problem which pressed upon the theoreticians and also the practitioners of the last decades remains the fiscal optimum. The difficulty in resolving the problem consists in opposite interests: on one hand, the government is willing to acquire the highest level due to the ascendant tendency of public expenses; on the other hand, the tax payers long for a much reduced level in order to dispose of more financial funds.

Key words: fiscal pressure

JEL Classification: H25, R11

1. Understanding the fiscal pressure

Although at the tax payer's level the tax seems a necessary evil, by virtue of honesty and good citizenship, he agrees to pay it as long as this tax won't affect his normal behavior in economy and society. That is why it is considered that the purpose of the fiscal system consists in realizing some financial objectives (financing the budgetary institutions), economical objectives (stabilizing the economical cycles) and social objectives (acting upon the system of distributing welfare) and for qualification we use the concept of fiscal pressure.

An efficient tax policy is the one capable to offset the following two trends: on one hand, the state wishes to have a high level of taxes, as it needs to finance the growing

public expenditures, whereas, on the other hand, the tax payers wants as low a tax level as possible, which trend is caused by the degree of bearability of a high fiscal pressure.

Fiscal pressure is generally given by all the obligatory tax bites which are calculated by reporting the total sum of obligatory tax bites (taxes, social insurance contributions) in a given period, usually one year, to the size of gross domestic product achieved during the same period by a national economy.

Besides the fiscal pressure technically determined, at a macroeconomic level, there is also a psychological fiscal pressure that measures the tax threshold of tolerance of each taxpayer and that, most often, takes the form of individual fiscal pressure determined as a ratio between the total extent of mandatory levies paid by a taxpayer and his total income before tax.

The specific problem of the fiscal pressure generated a series of attempts of the American theoreticians, and not only, to rethink the problem of the fiscal optimum.

Thus, in 1974, Arthur Laffer transposed graphically (Laffer Curve) an idea expressed in 1776 by Adam Smith, according to which too high tax rates destroy the basis on which taxation acts.

Arthur Laffer believes that there is a threshold of maximum fiscal pressure to which any increase generates a reduction in the tax capacity, because a too high fiscal pressure will discourage the taxpayer to invest, save, produce and work.

Laffer Curve illustrated in the form of a graph relationship between tax rate and income level of taxes.

Graph 1: Laffer Curve

According to Laffer Curve, the amount of obligatory tax bites is a increasing function of the fiscal pressure rate, but only until a certain maximal board, marked by M point, which corresponds to the maximal level of the curve, then it becomes an decreasing function of this rate, going until the cancellation if the rate would reach the theoretical level of 100%.

The relationship was the theoretical argument for showing the opportunity of the reduction of the marginal taxing rates which had arrived at very high levels during the application of the keynesist economic policies and of the development of the state's welfare. An important diminution of the direct taxes and an attenuation of their progress are to be wanted also because the people with larger incomes are those who invest and save more. The reduction of taxation must come along with the public consumptions diminution, in order to liberate the necessary resources for restarting the production.

2. Analysis of the Romanian fiscal pressure

As for Romania is regarded, the fiscal political measures that are promoted by the fiscal authorities, other factors come into sight, such as the quality of administrating the fiscal debts of the state and the level of compliance with the tax, all these have influenced the volume and structure of compulsory drawings, as well as the fiscal pressure they put.

Graph number 2 shows the dynamic of the fiscal pressure in Romania between 1990 and 2008.

Graph 2: Evolution of fiscal pressure in Romania 1990-2008

The analysis of the statistic data from Romania shows the fact that the pressure of the compulsory taxes/drawings, calculated through taking into consideration all the taxes and social contributions collected by the public budgets, have been reduced from 35,5% in 1990 to 27,7% in 2008. Much of the interval we have analyzed, the pressure of compulsory taxes/drawings has been oscillating around the value of 27%, registering a small increase in 2008, compared to the level registered in the previous year.

Our country, with a fiscal system under 30% is situated in the category of the countries with an average fiscal obligation, in which, although the pressure of compulsory taxes is not an exaggerated one, and in some situations even unbearable, especially in the conditions in which the gross domestic product on an inhabitant is relatively small. The practical experience has shown that, an approximately equal level of pressure of the taxes, this is easier to bear in a country where the gross domestic product is higher than in a country in which the GDP is lower.

This big discrepancy between the moderate fiscal system in Romania and the tax payer's perception upon the almost unbearable level is explained through the fact that the level of the fiscal tolerance doesn't depend on the absolute level of the fiscal obligations, but as well as on the size of its tolerance.

For accrediting the idea that in Romania there's a high fiscal system, a great part has been played, along time, by the existence of a large number of compulsory taxes, charged both to legal and natural persons as well as the legal instability which has characterized the Romanian fiscal system. In our country, there wasn't a strategy of the fiscal evolution; the fiscal system has functioned under the form of a mechanism with deranged movements, without having the capacity to orientate the economic development towards performance.

3. Comparison to the member states of the European Union

Compared to other European countries, members of the European Union, we can observe that the level of this indicator in Romania puts our country on the 1st place among the European countries. On the first places, together with Romania, we can find Slovakia, with a similar weight-under 30%-as well as other two Baltic states: Lithuania and Latvia. The highest share of taxation in GDP has been recorded in Denmark, Sweden, Belgium, France, Italy and Finland.

We can appreciate that, outlying countries (except the northern countries) tend to practice a lower fiscal system Great Britain and Ireland, Spain and Portugal, Cyprus and Malta, The Baltic States and Poland, Slovakia and the newest member states Romania and Bulgaria, have a lower fiscal system, while the "continental countries" (France, Benelux, Germany, Austria, Hungary, The Check Republic and Slovenia) either overpass the European mean or are close to this.

This wide variety of tax ratios in the Union is not new. Even before the 2004 enlargement, the EU included a number of member states with tax ratios close to the 50% mark, such as the Scandinavian countries, but also several low tax member states, such as Ireland, Greece, Spain and Portugal.

There are substantial differences not only between the UE15 and the new member states but also amongst the latter. One may distinguish two groups of countries: a smaller one composed of three countries (Cyprus, Hungary and Slovenia) with tax levels exceeding the EU-27 average (37.5%) and

the remaining new member states with lower tax ratios: from the Czech Republic (36.9%, less than one percentage point below the average) to Romania (27.7%, with 9 percentage points below the average).

We have to take into account that the comparison of the pressure of compulsory taxes in Romania, with the levels registered in other states, is not very conclusive, because the fiscal systems have different structures and the levels of economic development are different.

Making a comparison between the pressure of compulsory taxes in the European member states and appreciating the level of pressure in the European Union, in general, confront many difficulties determined by the influence of a variety of general and specific factors for each country such as [1]:

- differences in accounting periods and methods;
- voluntary social security contributions, which are fairly large for some countries (including Germany), are included as tax revenues in the national accounts but not in the revenue statistics; so are the employer social security contributions for government employees;
- imputed government contributions are not included in the revenue statistics;
- inheritance and gift taxes are not considered as taxes in the national accounts while they are included in the revenue statistics;
- for EU countries, VAT and customs revenues are shown net of the amounts transferred to the European Commission in the national accounts while the revenue statistics show gross data.

In underlying the restrictions determined by the use of the pressure indicator of compulsory taxes, we can also add the opinion according to which "this indicator is somehow limited as a comparison measure between countries along time. Among the factors that can influence the level and tendency we can enumerate: the extension of some counties through expenses for social and economical security, rather than through direct governmental expenses, even if social transfers are or not subject of taxation"[2].

The deficiencies of this indicator are also presented in the work "The Fiscal System and Prices in the Market Economy"[3] where it is appreciated that "the differences between countries, most of them established in time,

have to be interpreted carefully, because they can reflect either differences of institutional type regarding the social protection systems, being able to be explained through the weight of the social dues in the total of compulsory taxes, or as a certain policy regarding the budget deficit." It is also shown that "the level and structure of compulsory fiscal taxes depend on the number of factors out of which some have an evolution that doesn't depend on the state's will: it's the case of the demographic structure of the country, especially the weight of the older persons."

The pressure of the compulsory drawings must be analyzed in a larger frame, not through limitation at the appreciation of the level of pressure but through its linking with the influences of some factors such as:

- the purchasing power of the net profit-the level at which the remained profit after being taxed ensures the needs of sustenance, of spending the spare time as well as of saving the housekeeping;
- the compensations the budget flows financed through taxes induce;
- the level of the tax benefits and the payers to which they refer;
- the existence of a fiscal moron of proportions;
- the evolution of the gross domestic product and of the fiscal incomes.

4. Conclusions

The level of this indicator in Romania puts our country on the 1st place among the member states that have reduced fiscal pressure. On the 1st places along with Romania, there are several other countries

with a similar weight-under 30%-Slovakia as well as other two Baltic states: Lithuania and Latvia. The highest share of taxation in GDP has been recorded in Denmark, Sweden, Belgium, France, Italy and Finland.

The downward trend of the level of taxation manifested in Romania can be considered as an effect of the general trend of fiscal loosening, resulting in reducing the rate of corporation tax, starting from the 1st of January 2000 from 38% to 25% and then to 16% starting with the 1st of January 2005, the general tax rate reduction of VAT from 22% to 19% followed by the introduction of the reduced rate of 9% and 5%.

This large discrepancy between moderate taxation in Romania and the level of perception of the tax payers upon the hardly bearable level is explained through the fact that, the level of supportability of taxation depends not only on the absolute level of tax obligations, but also on the size of its bearing base (GDP)

Moldova Republic's Gross Domestic Product Prevision Using Artificial Neural Network Techniques

Ilie Constantin

Ilie Margareta

„Ovidius” University of Constanta,
ilie.ctin@yahoo.com

Abstract

Considering the present economical status, it is necessary to efficiently manage the Gross Domestic Product (GDP) especially for developing countries. Thus, it will be advantageous to have some knowledge about future trends or specific values of the GDP in accordingly to the dynamics of certain economics indices such as Investment in fixed capital, Imports from other countries etc. The present paper contains the basic research to determine the possibility of using artificial intelligence for the prevision of future GDP. In order to determine the GDP of Moldova Republic the following data were considered: Imports from other countries, Investment in fixed capital, Retail trade and Industrial production. A feed forward artificial neural network (ANN), with 10 hidden neurons, was trained and tested. After 590 iterations a maximum training absolute error of 0.008983 was obtained. Also the absolute validation error was 0.012664 and the network error was 0.000248. The final testing errors belongs to the [0.00; 2.47] interval of absolute values and to the [0.00; 0.23] interval of relative values. The results offer the bases for the future researches.

Key words: Gross Domestic Product, artificial intelligence, prevision, Imports, Retail trade;

JEL Classification: C82

1. Introduction

The Artificial Neural Networks are used in several domains such as the card fraud detection, the prevention of stock exchange, the effects of decision making etc. Their capabilities emerge from their possibilities to simulate nonlinear systems and processes and give tendencies and previsions in fields (like economics) where, currently, the variables are more nonlinear and unpredictable.

Predicting the GDP can be very useful for decision making in order to initiate and develop decision in order to influence the regulation of GDP.

The survey of input and output data correspond to the monthly 1995-2009 timetable. For the processing and construction of the feedforward ANN the Alyuda NeuroIntelligence was used [1].

2. Experimental research

The research was developed regarding to the phases of artificial neural network use:

- Data analysis;
- Preprocessing data;
- Neural Network design;
- Neural Network training;
- Training testing - Final query.

The testing and final query will be presented in the Results and Discussions section.

Data Analysis

The data analysis is very important because it prepares the grounds for the entire following procedures and any error in the data values will be perpetuate in all the next phases and will affect the results (“garbage

in, garbage out”). The values analyzed are presented in table 1.

From the basic data set, that contains 7 numeric columns, 3 of those columns were disabled: Agricultural production, Cargo, Consumer price indices, as the result of the influence that those data had over the output. The remaining 4 numeric columns: Industrial production, Investment in fixed capital, Imports from other countries and Retail trade (In% to previous year) were accepted as input data.

The entire data set consisted from 28 series from which 3 were used for the testing process. The remaining 25 data series were organized as follows: 22 records to Training set (88%), 2 records to Validation set (8%) and 1 record to Test set (4%).

Table 1: Data values analyzed [4]. (Example)

Producției industriale	Investiții în capital fix	Importurile din alte țări	Comerț cu amănuntul	PIB-ul
96.00	84.00	268.00	112.0	98.60
85.00	110.00	176.00	88.00	93.50
88.00	78.00	114.00	73.00	96.60
116.0	107.00	274.00	118.0	106.6

Preprocessing data

In order to get an efficient and easier training, in several occasions, methods or techniques of data values preprocessing are used. This is applicable in our case and the method was: Scaling Numeric Columns. The result is in table 2.

Numeric columns are automatically scaled during data preprocessing. By default numeric values are scaled using the following formula [1]:

$$SF = \frac{SR_{max} - SR_{min}}{X_{max} - X_{min}} \quad (1)$$

$$X_p = SR_{min} + (X - X_{min}) \cdot SF \quad (2)$$

where:

X - actual value of a numeric column

X_{min} - minimum actual value of the column

X_{max} - maximum actual value of the column

SR_{min} - lower scaling range limit

SR_{max} - upper scaling range limit

SF - scaling factor

X_p - preprocessed value

Table 2: Data values preprocessed.
(Example)

Producției industriale	Investiții în capital fix	Importurile din alte țări	Comerț cu amănuntul	PIB-ul
-0.29	-0.73	0.92	0.27	98.60
-1.00	0.42	-0.22	-0.50	93.50
-0.80	-1.00	-1.00	-1.00	96.60
1.00	0.28	1.00	0.47	106.60
-0.29	-0.73	0.92	0.27	98.60

Preprocessing report:

Input columns scaling range: [-1..1];

Output column(s) scaling range: [11.84..17.96].

Neural network design

Considering the values, the numbers and the type that defines the data, the feedforward artificial neural network was chosen to be used. The number of hidden neurons and layers was obtained through the search of several architectures and due to the past experience. So the final architecture used is presented in figure 1.

The architecture search report was:

- Architecture was selected manually
The architecture selected for training is [4-7-1]- had the best fitness;
- Fitness criteria: Inverse Training error;
- Hidden layers activation function: Hyperbolic tangent;

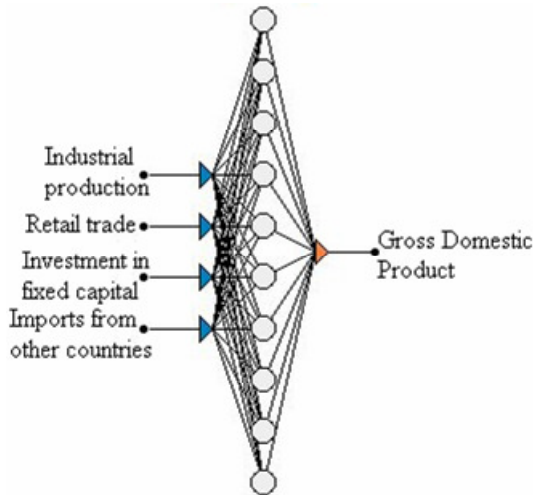

Figure 1: ANN architecture [4-10-1].

- Output data: Gross Domestic Product (GDP) [ln% to previous year];
- Output error: Sum-of-squares;
- Error function: Sum-of-squares;
- Activation function for the output layer: Linear.

The usual training algorithm for the feedforward neural network is back propagation algorithm, in this case the Levenberg-Marquardt algorithm.

Levenberg-Marquardt is an advanced non-linear optimization algorithm. It is the fastest algorithm available for multi-layer perceptrons. However, it has the following restrictions:

- It can only be used on networks with a single output unit.
- It can only be used with small networks (a few hundred weights) because its memory requirements are proportional to the square of the number of weights in the network.
- It is only defined for the sum squared error function and therefore it is only appropriate for regression problems.

The results of the training session can be visualized in figure 2 as the network error.

Neural Network training

Figure 2. Network errors. Error improvement vs. iteration number.

The training conditions were:

- Quick propagation coefficient: 0.5;
- Learning rate: 0.1;
- Number of iterations: 590;
- Stop training conditions: Desired error achieved value: max AE=0.0001, track on training set.

Where: *Quick propagation coefficient* - Quick propagation coefficient is additional training parameter for Quick propagation algorithm. This parameter is used to control magnitude of weights increase in some cases.

Learning rate - A control parameter used by several learning algorithms, which affects the changing of weights. The bigger learning rates cause bigger weight changes during each iteration.

AE - Absolute error. An error value that indicates the "quality" of a neural network training. Calculated by subtracting the current output values with the target output values of the neural network. The smaller the network error is, the better the network had been trained.

Iterations - A single complete presentation of the training set to the neural network during the training process. After 590 iterations a maximum training absolute error of 0.008983 was obtained. Also the absolute validation error was 0.012664 and the network error was 0.000248.

Figure 3. Network' weights after training session.

In figure 3 it is shown the weight distribution for the neural network used, after the training phase.

3. Results and Discussions

In order to see that the training was successful and the ANN was ready to prevision the sales values from the input data: Industrial production, Investment in fixed capital, Imports from other countries and Retail trade (In% to previous year), it was necessary to take a final testing. This the final query that uses data unrevealed to the ANN until then. If the ANN offers results values very closed to the real data, then the training was successful and it can be use in the future prevision. In order to validate the research results an interval of difference between the real and simulated data was imposed: [-3; 3] absolute value and [-5; 5] % relative values. The comparison between the real data and data simulated by the ANN is presented in table 3.

Table 3: Gross Domestic Product (GDP) [In% to previous year].

Real data	Simulated data	Absolute value difference	Relative value difference [%]
102.10	102.10	0.00	0.00
107.20	104.73	2.47	2.30
93.50	93.42	0.08	0.09
	MIN	0.00	0.00
	MAX	2.47	2.30

As can be seen in table 3, the results of the testing not only that comply with the imposed condition but the error are smaller than those expected.

4. Conclusions

Having in mind the results presented above we can say that this first phase of the research was a success.

The next phases imply adding new input data that influences the Gross Domestic Product and also the effects that those data have over the major economic dynamics. Also, future research must be modified for the use by the small and medium business, in order to modify the acquisition, stock and flow management for the products and/or raw materials.

pusa.tapliga@yahoo.com

Abstract

Organizations now have the opportunity to fulfill most of their information system requirements through software packages, rather than building bespoke solutions. The advantages of this approach, particularly the perceived cost and time savings, appear self-evident. However, there are disadvantages, which must be carefully understood and evaluated before selecting and purchasing a software package. The organization must also be aware that it is probably entering a long-term commercial relationship with a supplier. It may be costly and difficult to end such a relationship, as converting data from one product to another may be prohibitively expensive. Hence the risks of the software package approach must be identified and appropriate risk avoidance and mitigation actions developed.

Key words: software packages, time savings, risk, financial activity

JEL Classification: Q33

1. Introduction

The need for an accountant to have specific competencies in information systems is one of the modern world's demands, which doesn't operate anymore without IT. These days an employee in the financial field must be able to: explain how to effectively use information systems and information systems resources in an organization; identify and apply methods of organizing and accounting

for information systems delivery and information systems projects; explain the principles of initiating, planning and controlling information systems projects; participate in the definition and specification of user and system requirements; describe how an appropriate solution might be defined to fulfill the specified user requirements; participate in the implementation, monitoring and maintenance of an information systems solution; participate in the quality assurance of an information systems project; identify how computer software can assist effective information systems management, development and quality assurance.

There is a strong tradition of bespoke systems development in information systems delivery, where 'in-house' analysts and programmers develop systems to meet the specific requirements of an application. In the formative years of computing there was little alternative to this approach because generalized software packages did not exist and the fragmentation of the hardware market reduced the viability of such an approach.

For many years the marketplace was:

- supported by the notion that systems developers had to be part of the company (like production staff, catering staff and cleaners) and located in an identifiable IT department;
- dominated by mainframe and minicomputer manufacturers delivering expensive and non-standardized technology. The hardware spend (both for purchase and

maintenance) dominated the IT department's budget;

- restricted to a limited set of software packages, usually framed to follow legislative requirements (such as integrated accounts) and only available on a restricted number of hardware platforms.

2. Benefits of the software implementation in the financial activity of the firms

Quality benefits. A further perceived advantage of the software package solution is hinted at in the previous point – the absence of unit and systems testing. The software package is a proven product that has undergone systems testing (in development) and user acceptance testing (by the users who have already bought and used the package). Hence the product should be relatively error-free, as well as fulfilling most of the functional requirements of the application. The implementation should not be affected by the programming errors and misconceptions that can bedevil bespoke systems development.

Time savings. The bespoke systems development needs to be tightly specified, designed, programmed and tested. This part of the lifecycle is very time-consuming and during this period requirements may change, so complicating the process even further. The software package is a product that already exists. It can be purchased and implemented almost immediately. There is no requirement for design, programming, unit and systems testing.

Cost savings. The most quoted advantage of the software package approach is reduced cost. The purchase of a software package is perceived as significantly cheaper than developing a bespoke alternative. In a bespoke system the cost of systems development is borne completely by the organization commissioning the system. In a software package solution, the cost of the systems development is spread across all the potential purchasers of the system. For example, a building company estimating, accounting and job control system that currently costs \$4,000 to purchase, actually cost \$500,000 to develop. This cheapness is

usually an important factor in deciding to pursue the software package approach.

Available documentation and training. In the software package approach the documentation can be inspected and evaluated before purchasing the product. The documents (such as user manuals and HELP systems) are usually of high quality because they represent an important part of the selling process. In contrast, the documentation supporting a bespoke systems development is not available until very late in the lifecycle and is often sub-contracted to users who do not have the time to do the job properly.

A similar principle applies to training. Prospective purchasers can attend a course prior to buying the product and so further evaluate the suitability of the package. Similarly, economies of scale allow the software vendors to produce and provide high quality training courses, supported by professional trainers, at a relatively cheap price.

Organized maintenance and enhancement. Software products are usually supported by a formal maintenance agreement. Although this agreement costs money, it usually provides:

- unlimited access to a help desk, where experts can sort out user problems;
- upgrades to the software that correct known faults and also include new functionality defined and agreed with the user community.

The cost of this support and enhancement is again spread across a number of users and so can be offered relatively cheaply to each individual customer. The cost of providing such services would be extremely expensive if they were borne completely by an organization commissioning a bespoke development. The upgrade issue is particularly significant to organizations purchasing accounts and payroll packages. The functionality of such systems is affected by legislative changes made by government. These changes are frequent and unpredictable. It is comforting for the customer to know that all amendments are covered by the agreed software contract.

3. The negative effects of IT in the activity of the firms

Financial stability of the supplier. Internal Information Systems (IS) departments do not go out of business. However, external software suppliers are subject to the vagaries of management and the markets. There is a risk that they may go out of business, or experience financial problems that affect the quality of their support and development services. It is possible to reduce these risks (through ESCROW agreements) but the disruption likely to accompany the enactment of such an agreement should not be underestimated.

The changing nature of requirements. There is plenty of evidence to show that requirements change during the lifetime of a system. These changes are due to a number of factors:

1. Users change. New managers arrive who have a different perception of requirements and the business process. They demand new output reports to support their particular management information requirements.
2. The business changes. The business may decide that it wants to operate in a different way. This may be led by new product and marketing initiatives or may simply be a reaction to changes in the business environment that force the company to re-think its organization, products and services.
3. Changes due to:
 - actual experience: using the software may lead to a realization that functional requirements were not quite correct.
 - emergent hardware and software technologies: bespoke systems can usually be amended to reflect these changes. However, software packages may or may not. The problem is still one of control. It is not possible for the software supplier to predict or to cope with changes in a particular business implementation. Some of the changes may not be incorporated into a future release but, at the outset, there is no guarantee of this.

Competitive edge. Many organizations claim that they use (or wish to use) IT and IS as a competitive edge in the market place. They develop bespoke systems

to give them that edge. In the software package approach, the software solution (or product) is open to all competitors and potential competitors. It is difficult to see how such a solution can provide a competitive edge, as all potential competitors have access to that solution.

Ownership. In the bespoke systems development approach, the ownership of the software usually resides with the purchaser – the customer, not the supplier. This is particularly clear if the development is undertaken ‘in-house’, because the ownership of the code clearly resides with the organization, not the IT department or individual programmers. Even if an external software house produces the code, the contract usually specifies that the source code belongs to the commissioning agent (the customer) and not the supplier.

In the software package approach, the ownership of the software usually remains with the supplier. Customers are licensed to use the product, but they never own it. This ownership issue has a number of implications:

The supplier decides the future development of the package. Hence, future functionality is not in the control of the customer – although of course they can lobby for certain features to be included in future releases.

The software supplier can make decisions about the ownership and support of the product. For example:

- The software supplier may decide to withdraw support from earlier versions of the package. Hence customers may be forced into unnecessary (and potentially expensive) upgrades. This may involve hardware upgrades.
- The software supplier may decide to sell their product to a third party. Individual customers may be unnerved or inconvenienced by such a move. For example, a few years ago a popular package was sold to a large industry player with a reputation for aggressive customer relation. Many customers of the package were worried by this move (despite assurances from the new owner) because they were more comfortable with the ‘laid-back’ approach of the former owner. Some began to make plans to move their systems to a rival product.

The key issue here is that the software purchaser has little control over the future direction and ownership of the product they are buying. This is not the case with a bespoke development.

We are increasingly comfortable with all things internet. We love to Google, we book our holidays online, buy our groceries, apply for jobs, administer bank accounts, file tax returns, and e-mail has become the primary form of business communication for many. From here, the move to equally widespread online bookkeeping is not exactly a giant leap - and software suppliers seem to realize this.

Accountants who want to exploit the benefits of online accounting are literally spoilt for choice. But it is worth wading through the various possibilities in search of something that will suit your business, whether you are employed by a small enterprise or run your own accounting firm because, in both scenarios, the online approach to accounting and bookkeeping can offer advantages over the more traditional approach.

When a bookkeeping application is provided online using the 'software as a service' model, you do not need to install and maintain the software on a PC, network multiple PCs together to enable them to share data, upgrade to the latest and greatest hardware or remember to backup your data. Anyone can gain tap into bookkeeping software and the company's financial data using a browser, as long as they have permission to do so, plus a PC, a telephone and an account with an internet service provider.

With an online bookkeeping system business users can work on their accounts any time it suits them, from anywhere with internet access, and their accountant can do likewise, making clients easier to manage and support.

By reporting financial information through the standard, investors, regulators, analysts and companies can benefit from increased transparency and usability of the information, and faster access. The way information is formatted today, in paper and electronic-paper form, it would take five or six hours to get information on the five

largest semiconductors companies and put it into an analytical application of any kind.

4. Conclusion

The recognition that IT may be best organized as a procurement, rather than development, department. There has been a trend towards outsourcing as companies have downsized to concentrate on their core business. Consequently, the number of developers left to produce the in-house solutions has reduced significantly. IT is not the only function to be affected in this way. Cleaning and catering, once provided by local employed labor, has now been outsourced by many companies.

The reduced cost and standardization of hardware has meant that fewer organizations are tied into a manufacturer's strategy. Software is available across a limited set of dominant platforms and the cost of moving from one platform to another has considerably reduced. Software (or more accurately the people who develop it) is now the most expensive part of systems development. As a result, the cost of software production is closely monitored.

Finally, the passage of time has led to more software products being made available. This has strengthened particular market sectors (for example, there are many integrated accounts packages available in the market) as well as broadening the scope of package solutions. There are packages for golf club administration, patient records, marketing, family tree construction, etc.

As a result, many organizations have focused more on fulfilling their requirements through the purchase of an appropriate software package. The perception is that this is a cheaper, faster and more reliable approach to systems development. Hence the task is to find a package that fulfils user requirements or to differentiate between competing packages that all appear to do the job. This article looks at some of the perceived advantages and disadvantages of the software package approach to information systems delivery.

Tourism in Romania

Ioneci Mihaela

„Constantin Brâncoveanu” University of Pitesti
ioneci_mihaela@yahoo.com

Abstract

Currently, when surpassing the economic crisis is being prefigured, tourism has an important role in economy. This role must draw the governors' attention on tourism in order to create a favourable environment for development. The development of tourism in the immediate period following the economic crisis leads to the creation of new jobs, to the reduction of poverty and to the increase of the gross domestic product. Nevertheless the strategies for tourism development adopted at global level must be adapted to each country or region.

Key words: tourism, the economic crisis, Romania's economy

JEL Classification: E00, E20

1. Introduction

Romania's economy was based in the recent years on gross added value obtained in the following sectors of activity: trade; hotels and restaurants; transport and telecommunications; automobiles repair and household goods (23.2%); industry (22.8%); financial activities; real estate; renting and business services (12.6%); agriculture; forestry and fishery (6.4%); constructions (5.1%).[4]

Among the services offered by our country, a special place is occupied by tourism. Tourism has been considered even since 1989 the area in which Romania could be competitive, being subject to the development and improvement of the conditions offered to the potential tourists. In time, tourism began to grow, attracting tourists both from the country and from abroad.

2. Content

To produce an analysis of this sector, the tourists arrived in the tourist reception structures in the last four years are shown in table number 1.

Table no. 1 Arrivals in the tourist reception structures

	(thousands persons)			
	2006	2007	2008	2009
Romanians	4836	5421	5659	4865
Foreigners	1380	1551	1466	1276
Total	6216	6972	7125	6141

Source: Monthly Statistical Bulletin December 2009, 2008, 2007, 2006

The evolution of the number of persons registered in the tourist reception structures increased in the first three years analyzed, but the figure dropped sharply last year, being lower than the valued recorded in 2006. The evolution of the number of persons registered in the tourist reception structures increased in the first three years analyzed, but the figure dropped sharply last year, being lower than the valued recorded in 2006.[1]

The year 2007 recorded a total of 6,972 thousand tourist arrivals in the tourist reception structures, with 756 thousand tourists more than in the previous year, representing an increase of 12.2%. In 2008 the peak of tourist arrivals was recorded for the period examined, reaching the figure of 7,125 thousand people, increasing as compared to 2007 by 153 thousand people, representing an increase of 2.2%. In 2009 the tourists registered in the tourist reception structures were of 6,141 thousand people, decreasing as compared to 2008 by 984

thousand people, which in relative figures means 13.8%.

The number of tourists registered in the tourist reception structures as averaged for the four years shown in Table number 1 is of 6,6135 thousand people.

These tourists mostly consist of Romanian tourists, the foreign tourists representing about one quarter of the Romanian tourists. The Romanian tourists have recorded the same evolution as the total number of tourists, rising in the first three years and falling in 2009. The number of the foreign tourists has increased during the first two years, 2007 recording the highest number of 1,551 thousand people. The reduction of the number of foreign tourists in Romania started a year before the general trend; that is to say from 2008 this number decreased by 85 thousand as compared to the previous year.

The evolution in percentage of the number of Romanian and foreign tourists is presented in table number 2.

Table no. 2 The structure of the tourists in Romania

	2006	2007	2008	2009
Romanians	77,8	77,8	79,4	79,2
Foreigners	22,2	22,2	20,6	20,8
Total	100	100	100	100

Source: Calculations made using the data from table number 1

The relative sizes of structure do not show considerable changes between the years analyzed, the percentages being relatively close. In 2006 and 2007 the corresponding percentages to the Romanian and foreign tourists are identical, even if in absolute sizes there are differences. It should be noted that in the first two years, the share of foreign tourists is higher than the other two years, being consistent with the recorded absolute values. Over the past two years the share of the Romanian tourists increased at the expense of the foreign tourists by approximately 2%.

The net usage index, the arrivals of the foreign visitors in Romania and the

departures of the Romanian visitors abroad are indicators that record the same trend of reduction as in 2009. It should be noted that a number of the Romanian tourists prefer as final destination other countries to the detriment of Romania.

Table no. 3 Specific indicators of tourism in Romania

	2006	2007	2008	2009
Net usage index (%)	33,6	36	35	28,4
Arrivals of foreign visitors in Romania (thousand persons)	6037	7722	8862	7575
Departures of Romanian visitors abroad (thousand persons)	8905	10979	13072	11722

Source: www.insse.ro

The fact that tourism, both the national and the international one is dependent on what happens in the world economy has been fully demonstrated by the economic crisis, by reducing the number of tourists in the recent years, 2009 representing a real decline in this sector. It should be noted that in 2009, except Africa, all the other regions recorded negative results compared with 2008: Europe (- 6%), Asia and the Pacific (- 2%), America (- 5%), Middle East (- 6%) and Africa (+ 5%).[3]

Chart no. 1 The evolution of international tourism

Source: <http://www.unwto.org> (2010 - prevision)

The evolution of tourism in our country is not unique, fitting in the global situation. The worldwide decline began in 2008, representing 4.4% compared with the results from 2007. In 2009 the global tourism was severely affected, the results recorded being negative.

An explanation of these results is given by the Secretary General of the World Tourism Organization, Taleb Rifa, who declared that 2009 was a difficult year for tourism, because of the economic crisis, but also because of the uncertainty related to the flu A(H1N1) pandemic.[6]

The forecasts for 2010 are more than optimistic, anticipating a revival of the world tourism. Globally, tourism recovery measures address the following issues: integrating tourism in the infrastructure and recovery programs; examination of the fees and dreams hampering tourism growth; better promotion of tourism also by using major events; creating new jobs, especially in Small and Medium Enterprises; considering tourism as a development and trade aid.

Concerning the domestic tourism, the trend for 2010 is presented with the help of the research report "Tourist services consumption in Romania" conducted by INSOMAR in November 2009.[2]

INSOMAR conducted a survey using a sample of 2,504 persons, representative for Romania's population aged 18 years and over that age. The sample also includes individuals from all the counties and the 6 districts of Bucharest, namely 55 urban areas and 43 rural areas. The survey generated results with a maximum permissible error of 2%, the probability being of 95%.

Chart no. 2 The share of the people who intend to go as tourists in a place other than the one where they live

Source: Research Report "Tourism services consumption in Romania", INSOMAR, November 2009

The results obtained using the survey showed that 44% of our population considers to spend a tourist holiday tour in 2010, while 56% do not intend to spend a holiday tour. Of those wishing to spend a holiday tour in 2010, 22.2% want a stay of maximum 5 days, 35.1% between 6 and 10 days, 24.5% over 10 days and 18.2% do not know exactly the time they will spend as holiday tour.

Females are those who hold the largest share both among those who intend to go as tourists and among those who do not have this intention. According to age, those between 18-34 years old and 35-49 years old record percents of 31.7% and 34.1%, and for the other age groups the shares are of 23% and 11.2%.

Table no. 4 The structure of potential tourists in 2010

	Age groups				Sex	
	18-34	35-49	50-64	65 și peste	M	F
Intend to go as tourists	31,7	34,1	23	11,2	48,6	51,4
Do not intend to	12,6	24,1	31,1	32,2	46,8	53,2

go as tourist s						
-----------------------	--	--	--	--	--	--

Source: Research Report “Tourism services consumption in Romania”, INSOMAR, November 2009

Depending on the level of education among those who intend to go as tourists, the largest share of 44.3% has completed high school or post-secondary school. Surprisingly, the lowest percentage is recorded by the people who have higher education, only 25.4%. Among those who do not want to spend a holiday in 2010 those with higher education represent 6.7%. The people who will spend a holiday tour in 2010 come from urban areas in a percent of 68.2%, while those who do not intend this are arranged roughly equally between the urban and the rural areas. [5]

3. Conclusions

The year 2010 for the tourism in Romania is not envisaged to be within the optimistic trend found worldwide. The reduction of the number of tourists in the last year finds its explanation in the economic crisis that has affected our country since 2009, its effects being felt in Romania later than in the U.S. In 2009, in general, the keeping of the prices from 2008 were announced, but this strategy did not represent a strong enough momentum to attract tourists. Feeling the effects of the economic crisis in Europe and implicitly in our country has led people to be more careful with leisure expenses.

Cultural Strategizing: Shadows of IT Governance

Iorga Oana
Soş Cristina
“Al Cuza” University of Iasi
iorgal_a@yahoo.com
cristinasoos@yahoo.com

Abstract

In the emergence of information economy and the global discourse of the new era of Knowledge Based Society, not only organizational culture debates, but also the information technology topic find their ways to the management concerns and initiatives.

Thus, the general level being management and corporate governance, the specificity (locally applied action of global discourses) is preoccupation for performance, which wears the cloths of “cultural decoding” and “IT governance” – the last being also a strategic management view, which can not be included in technical studies.

We prospect tow of the means of Agency theory: Multinationals (thorough organizational culture) and Higher education programmes (through Strategic management programmes). The challenge is fostered by the process of adaptation to performance measures for Romania: a premise for success.

Key words: globalization, knowledge based society, IT Governance.

JEL Classification: D 83

1. Introduction

Information and information technology (IT) are the least understood of the key assets on many enterprises, but looking ahead, the influence of IT on enterprise performance will continue to grow. IT supports standardized process components, shared knowledge, instantaneous communication, and electronic linkages – the foundations for new business strategies.

While there is a variety of a discourses present globally, only some of those ideas

will result in local activity. Romanian high education system should, thus, percuss, through both practice adoption and university programmes, to these new IT-related subjects, as a premise to survive and succeed in a global competitive knowledge based environment. It’s genuinely accepted that the way in which people “implicitly define the content of strategy” makes the real difference between them.

Teaching and researching on IT governance stresses out the importance of harmonization of the “Enterprise Strategy & Organization” with “IT Organization & Desirable Behaviors”.

Thus, the topic of STRATEGY is among the ones of most importance. Considering the fact that there are by now some general areas of agreement about the nature of strategy, it still requires a number of different definitions before we can elaborate and build upon it. Especially since it can be seen as a: *plan, pattern, position, perspective, or a ploy*, in an environment demanding faster responses and increasing agility, management teams must ensure that **IT is an enabler of**, not an obstacle to, **organizational change**.

2. Lenses from organizational theory

One of the causes of the so well known “*informatic paradox*” (performance from IT investment doesn’t pay off) could retrieve its explanation in Mintzberg observation: “pervasive strategic failure in many large corporations may well be attributed to the army of business schools graduates who have been sent out with an incomplete tool kit” [1].

A more critical perspective (for the academic side, this time) is offered by the same authors through their recommendation, coming form a critical review of 10 schools of management: (schools should) “open up the range of

perspectives by providing a more varied set of ideas for (such) students as well as practicing managers”- towards a synthesis, a corroboration of particular aspects into a *holistic vision on the topic*, more than a re-compound of the whole by its parts, but critically considering each of them .

Thus, the theoretical foundation of our discourse (a field review, not a literature review) is getting closer to the concept of „*strategy-as-practice*”, which rapidly and recently developed into a robust field of research. The key challenges underlying the strategy-as-practice agenda may be examined empirically using an overarching conceptual framework of praxis, practices and practitioners.

The field of “strategy-as-practice” does not require ‘new’ theories per se, but to draw upon a range of existing theories to explore the strategy problems defined within our conceptual framework, to develop novel methods and research designs for their study (Balogun et al., 2003), and to advance explanations of how strategy is accomplished using these different levels and units of analysis [2].

3. Conceptual delimitation

“It is in the way actors connect with such processes that it becomes possible to better assess and understand institutional *stability and change that often stretches over considerable periods of time* (Mutch,2006)

OECD articulated two complementary sides of governance:

- Behavioral side of corporate governance: “Corporate governance encompasses the relationships and ensuing patterns of behavior between different agents in a limited liability corporation; the way managers and shareholders but also employees, creditors, key customers, and communities interact with each other to form the strategy of the company.”

- Normative side of corporate governance: “Corporate governance also refers to the set of rules that frame these relationships and private behaviors, thus shaping corporate strategy formation, the company law, securities regulation, listing requirements, also be private, self-regulation.”

The more we experience the new information economy’s materialization in practice, the more critical become one of the levels and unit of analysis: that in relation to the information technology. In fact, IT governance is frequently defined as a component of the corporate governance.

IT (and information systems refers to many categories of resources (people, software, hardware, time, relationships, financial) and the governance of them can not be study or conceptualized outside the organizational environment and theoretical discourse

- “The behavioral side of IT governance defines the formal and informal relationships and assigns decision rights to specific individuals or groups of individuals.
- The normative side defines mechanisms formalizing the relationships and providing rules and operating procedures to ensure that objectives are met.”

Fortuitously or not, the previous text seems to match the culture and quality rhetoric “that *strong cultures can be consciously designed and manipulated ... not only formulating value systems, but also instilling those values in their employees*”.

IT governance is seen as “specifying the decision rights and accountability framework to encourage desirable behavior in the use of IT” [3], thus, the answered question of “What does an analysis of strategists and their doings explain?” is valuable in the context of IT domain researchers and practitioners interests in terms of: “What content characteristics of formal IT strategy predict the extent of plan implementation?”

An important practical contribution can be derived from here. In practice, the CIO (Chief Information Officer) is often responsible for the IT strategy process, as well as the IT strategy topics and the IT strategy plan (Gottschalk, et al., 1995).

Fig. 1 Graphical representation of IT Governance’s position in a company [3]

Source: Weill, P., Ross, J. –IT Governance [3]

An IT department and CIO team have to deal with practice-oriented approaches in distinguishing between an information, information systems and information technology strategy, as “strategy, according to this view, is ***not something that an organization has but something its members do***¹.”

- An Information strategy details the information needs of the organisation and processes necessary to collect, produce, store and disseminate information.
- An Information systems strategy consists of a specification of the information systems needed to support organisational activity in the areas of collection, storage, dissemination and use of information.
- An Information technology strategy consists of a specification of the hardware, software, data, communication facilities and IT knowledge and skills needed by the organisation to support its information systems

In Jarzabkowski’s article, ‘practice’ refers both to the situated doings of the individual human beings (micro) and to the different socially defined practices (macro) that the individuals are drawing upon in these doings”, “what doing strategy involves and, most importantly, how that doing shapes strategy” [2].

¹ An initial special issue on micro-strategizing (Johnson et al., 2003) took up this challenge, ***emphasizing the myriad micro-actions through which human actors shape activity in ways that are consequential for strategic outcomes***

“When CIO sits down to produce the formal, broadly understood, IT strategy, this research provides clear priority on what to include in the plan document to increase the likelihood of its implementation; description of (a) responsibility for implementation (on time, within budget, intended benefits, step-wise implementation of large projects, high priority projects and short-term benefits from initial projects), (b) of user involvement during the implementation (user training, understanding, participation, operation, development and support)”.

Remember the behavioral aspect in the definition of IT governance and we will be enabled to see that without a cohesive IT governance design, enterprises must rely on their CIOs to ameliorate problems through tactical solutions, rather than position IT as a strategic asset. This statement of Peter Weill and Jeanne W. Ross maps on the perspective of Jarzabkowski et. al.: “in order to understand human agency in the construction and enactment of strategy it is necessary to re-focus research on the actions and interactions of the strategy practitioner”[2].

Being a subset of corporate governance [4] and the only predictor for the valued added by using IT in the business, the Information Systems Science research has also approached IT governance from organization theoretical perspective: IT governance structures, IT governance processes. Several ***IT governance methods*** have been developed or been relabeled as IT governance methods. These methods such as CobiT and ITIL have been developed by IT professionals and experts within a certain issues, whereas academic researchers have been in lesser roles.

Thus, we are sure not to be mistaken when we argue that, from a “strategizing in practice” solution and challenge, pursuing and adopting IT Governance within a company offers already-elaborated and tested, “best practices” oriented and reliable tools and instruments to IT strategizing for successful **performance**.

4. Further remarks

Reflecting on the transformations that are brought into debate when talking about the “information era”, “knowledge based society” as opposed to “industrial society” (and so on), one of the possible hypothesis that pay off to be tested is the fact that in some countries the institutional level is already influenced (and changed by the use of IT in socio-economical life) in such a manner that can and does influence other national business systems (and social) through international flows and processes that are taken place in the IT domain.

While institutional entrepreneurship literature has been able to cast light on the various roles active agents play in the emergence of new field, it still falls short on explaining how institutional entrepreneurs act at the intersection of local institutional and global-macro discourses in the field emergence. The term „institutional entrepreneurship is not restricted to the administrative structures that get to have economic initiatives, but in exchange, it focus on individual and organizational level activity (skills, activities, positions) through which involved actors are able to initiate and maintain the processes of **collectively take part in framing emerging fields**, preceding any governmental level legitimacy. Nina Granqvist’s research studies identifies that „scientific and other epistemic communities and various globally operating organizations mediate global trends to localities” [5]

5. Multinationals

Agency theory, as opposed to classical view, for which a firm is a unified profit-maximizing identity and the operations of a market are costless for a it), sees Firm as an agency relationship on a set (nexus) of contracts, with divergences between principal and agents.

There are many forms of entities that can take the role of “actors” when it comes to locally dissemination of global ideas, especially on the management topics (strategy, culture, IT), but two of them we refer more in this paper, mainly as institutional entrepreneurship instances:

multinational companies (MMC) and higher educations systems. MNC can be seen as:

–‘transmission mechanism’: how processes and practices get transferred from one institutional context to the other and what the impact of this is.

– as in the ‘bridge’ metaphor, MMC relates to how new connections are made and new complementarities developed.

MNCs became a source of diversity inside institutional contexts. They engage in new ways with institutions, local firms and local actors, in some cases reshaping them, in others reinforcing them and in others undermining them. Their existence is not simply absorbable into these different settings; they constitute a new form of organizational reality.

Placing these ideas in the Romanian context, we conducted research activities and elaborated two study cases on the management and cultural diversity topic:

~ “C Retail” company which has a 5 year activity in Cluj on the market of food and non-food retail products and

~ “T En-gros” company which has a 14 year activity on the market of fruit and vegetable wholesalers (en-gros)

They are both multinational companies that perform economic activity in Romania.

The conclusions drawn on the cultural decoding incentives that were performed upon, remain under the sign of performance and elements of cultural specificity.

With this study we tried to present several **models used to measure performance** (one of which is visualized in Fig. no. 2), the familiarization with the dynamics of a multicultural team and the particularities of multinational teams, some of the difficulties specific to the on site research work and along with them, some of the methods used to gather, analyze and interpret data.

Our success resides in providing proves of organizational culture that are well correlated to elements of team performance. As we know, they are not always easy to observe and isolate from other economic and technical dimensions or cultural clichés.

Through this study we intended, firstly, to bring in the Romanian cultural context

the research regarding the impact of culture on performance, both at the organizational level, and at the team level. Secondly, another objective that we reached was to decode the manager's perception on this so much controversy dimensions that company's performance stands for along with the performance assessment practices.

Fig. no. 2 Schein's cultural model
The Cultural Dynamics Model

Source: Hatch, M., J., - "The Dynamics of Organizational Culture", *The Academy of Management Review*, No. 4., 1993, p. 660

The results of the comparison we enacted between the 2 study cases facilitated the identification of a certain number of characteristics specific to each factor used from the theory to compose our research framework (eg. Organizational structure and its impact, the culture generated by the leadership style, strategic management, the performance management system (PMS), the impact of strategy an of the (PMS), the teams features, the team and the manager's perception on performance, team development and formative process, performance assessment system, rewards and recognition, the impact of the teams).

Each one of them has a certain impact on performance. However, measuring the intensity of this correlation was not among the aims of our study, so that it remains to be treated in further research

Organizational culture, as expression of "practice-side" in the business area, mediates the movement across boundaries of different ideas and topics related to management domain.

6. Higher education programmes

"Because the national business systems approach has developed a deep understanding of organizations in their

national contexts, it is well placed to consider how increasing international flows and processes are impacting on this"[6]

Higher education institutions should, thus, consider, in their own strategy - when designing their programmes for the education on Management and Business Information Systems – that they are, undoubtedly, the site where the inherent tensions in the processes of reception, translation and transmission of emergent discourses, such as that of Organization Culture and IT governance, are experienced.

In regard to the "tensions" (positive or not), we would like to signalize the existence, mostly in UK and USA, of Critical Management Studies as the academic project that challenges the idea that management is a disinterested technical process by applying analytical perspectives from critical and postmodern theorists to management as social and economic practice [7].

We, as researchers, all are acquainted to the academic desiderate for the results of scientific research of "better way to understand the phenomenon and through the ability to forecast, to make life better".

As the debate in our present article exposes, there are no reasons to see both Organization Culture and IT Governance as scientific subjects: its concern (related how people work and how management should be done) goes far ahead from a simple "best seller" of a "good practice" and an efficient "strategy framework". Getting closer to the IT domain is realized through "grounded theory" coming from other research fields (which have their own practice-theoretical "issues", problems, concerns). This is a special way of dynamics.

However, Barley and Kunda observe that "in the past, studies of work provided an empirical foundation for theories" and discuss the "reintegration of work studies into organizational theory, indicating what the conceptual payoffs might be [8].

On the other hand, in real society and in that of scholars, the research field of information technology is too broadly seen as a cumulus of "instruments or tools" in the first place.

Means for the incentives to work with them and manage IT do *come from* the

practice, and from what happens in the reality when people use IT (computers, software, policies, standards and so on) – mainly, as a “Caesar’s right”: tribute to “user involvement” phase of the information system lifecycle, but also as reflecting and studying on the interaction of humans with IT.

Acknowledging how CMS academics in the US and the UK have used education as an entry strategy into wider critical debates about the nature and purpose of management, the article explores the subject on a more specific and narrower niche, that of Strategic Management of IT.

Since higher education institutions occupy an interesting role in relation to management practice and theory, we argue that the faculty and scholars are simultaneously recipients and translators of mainstream (IT) management ideas and producers of critical research on it.

We can not have a complete view on neither learning about research, nor learning for research if we ignore one of the two approaches: theoretical or practical.

7. Conclusions

In this article we have prospected on the two topics that answer the challenges localities (such as Romania) usually face in the context of globalization and knowledge based society: cultural decoding and IT. Our proposal benefits from grounded theory approach on organizational theory issues, but combined them to more practice-emerging concepts: organizational culture (assessing the performance of multicultural teams) and IT governance (assessing the performance of IT investments and the desirable behavior in relation to IT).

In the adaptation process, an important role is played by uncertainty, coming mostly from the question of resources (all types), but also as a result of the fact that while there is a variety of discourses present globally, only some of those ideas will result in local activity. The power to explain this phenomenon is provided by the Agency theory particularized on the institutional entrepreneurs (both individuals and organizations) who act at the

intersection of local institutional and global-macro discourses in the field emergence, initiating and maintaining the processes of *collectively take part in framing emerging fields*.

In this context, Romania, represented by organizations and higher education system should, thus, percuss: adopting new concepts like IT Governance will suppose a cultural decode, apart from the “best practices” and “imported frameworks” due to the fact that, in spite of being a board responsibility and a means to measure the performance of IT use, it implies collaboration (and not only control), communication between stakeholders and team work. Thus, at this top strategic level, the human factor is more evident than in other IT management issues, being, as in the case of corporate governance and cultural management, one of the independent variables that influence and determine the dependant variable (the success of company’s investments and actions).

Going back to academic world, the other point we aim to touch in our essay is related to the idea that any university programme should be able to cope with both theoretical foundations and impulses from practice in an “engaged scholarship” manner and fulfill the aim of „scientific and other epistemic communities and various globally operating organizations that mediate global trends to localities” .

Data Preprocessing in Web Usage Mining

Istrate Mihai

„Constantin Brâncoveanu” University of Pitesti
mihaifrance@yahoo.com

Abstract

Data collected from Web in the first stage of data mining are usually diverse and voluminous. These data must be assembled into a consistent, integrated and comprehensive view, in order to be used for pattern discovery. Like in most applications of data mining, data preprocessing involves removing and filtering redundant and irrelevant data, predicting and filling in missing values, removing noise, transforming and encoding data, as well as resolving any inconsistencies. The task of data transformation and encoding is particularly important for the success of data mining.

Key words: data preprocessing, data filtering, user identification, users session identification.

JEL Classification: L 86

1. Introduction

In Web usage mining, data preprocessing includes the identification of users and user sessions, which are to be used as the basic building blocks for pattern discovery. The accurate identification of users and user sessions is particularly important for Web personalization, because the models of individual users are based on user behavior encoded in user sessions and associated correctly with the corresponding users.

The data preprocessing step is to some extent domain-dependent, e.g. the content and the structure if a Web site affect the decision about which data are relevant. It is also strongly dependent on the type and the quality of the data and thus, it constitutes a hard engineering task in the Web usage mining process. Moreover, there is a compromise between insufficient preprocessing, which will make the pattern discovery task more difficult and affect its results, and excessive preprocessing that may result in removing data with useful, but implicit, knowledge [1], [2].

2. Data filtering

The first step in data preprocessing is to clean the raw Web data. During this step the available data are examined and irrelevant or redundant items are removed from the dataset. This problem mainly concerns log data collected by Web servers and proxies, which can be particularly noisy, as they record all user interactions. Due to these reasons, we concentrate here on the treatment of Web log data. Data generated by client-side agents are clean as they are explicitly collected by the system, without the intervention of the user. On the other hand, user supplied data (e.g. registration data) need to be verified, corrected and normalized, in order to assist in the discovery of useful patterns.

Significant redundancy in log files is caused by the specification of the HTTP protocol, which requires a separate access request to the server for each file, image, video, etc. that is embedded in a Web page. Usually entries in log files that refer to image, sound, video files, CGI scripts and image map files are considered redundant. These files are downloaded without a user explicitly requesting them and thus, they are not part of the user's actual browsing activity. Therefore, these entries are usually removed from the log files [3]. However, as mentioned above, the data preprocessing task is domain-dependent and removing those files may, sometimes, cause the loss of valuable information. This is the case, for example, when a site consists mainly of multimedia content.

In addition, log entries corresponding to requests that have not been satisfied, e.g. requests that received HTTP error responses, are filtered out of the log file, though they may correspond to information that is needed by users. In addition, records created by spiders or crawlers, i.e., programs that download complete Web sites in order to update the index of a search engine are also removed, since they are not considered usage data.

Crawlers and spiders can often be recognized through the User Agent field of the server logs, since most crawlers will identify themselves using this field. Another technique is to look at the pattern of track of a particular visitor. If the visitor is retrieving pages in an exhaustive pattern of following every hyperlink on every page within a site, then it is a crawler. Tan and Kumar propose a method for identifying spider sessions based on a variety of features that are extracted from access logs such as percentage of media files requested, percentage of requests made by HTTP methods, as well as features that are showing the breadth-first searching behavior of the spider [4]. Data referring to other Web sites, over which the site administrator has no control, are also considered irrelevant and are usually removed.

3. User identification

The identification of individual users who access a Web site is one of the most important issues for the success of a personalized Web site. Many of the existing commercial personalization systems require the users to identify themselves, by logging in before using the system. However, this process introduces a burden to the user that is not acceptable for many Web sites, e.g. the average e-commerce site. For this reason, a number of studies have proposed various approaches to automate the process of user identification. The most important of these are presented here.

The simplest approach is to assign a different user to each different IP identified in the log file. Several of the Web usage mining tools adopt this approach, despite its high degree of inaccuracy, due to the use of proxy servers. Cookies are also useful for identifying the visitors of a Web site by storing an ID, which is generated by the Web server for each user visiting the Web site, but since they are considered a security and privacy threat, users may disable or delete them. Furthermore, if a user connects to the Internet using different machines, then that user cannot be identified correctly.

Due to these problems, other heuristic techniques have been proposed. One of these techniques is the use of special Internet services, such as the *inetd* and *fingerd* services [5], which provide the user name and other

information about the client accessing the Web server. One problem with this method is that these services may also be disabled for security reasons. In addition, if the users operate behind proxy servers it is impossible to identify them with the use of the *inetd* and *fingerd* services, since the proxy server corresponds to one host IP address for many users.

Two more heuristic methods to overcome user identification problems are presented in [3]. The first method performs an analysis of the Web server log file in Extended Log Format, looking for different Web browsers, or different operating systems, in terms of type and version, even when the IP remains the same. This information suggests the existence of different users. The second method presented in the same work combines the topology of a site together with access log referrer entries. If a request for a page originates from the same IP address as other already visited pages, and no direct hyperlink exists between these pages, then it is suspected that a new user is accessing the Web site. These two methods are also not without problems. Apart from their cost in terms of computational effort, there are also many cases where the heuristics fail, e.g. when a user opens different browsers or more than one browser window visiting different pages from the same site that are not directly hyperlinked. A further problem with the second heuristic is that it does not help in identifying the user fully, i.e., relating different visits of the same user to the site, at different times.

Schwarzkop employs a different technique for user identification [6]. A unique ID, generated by the Web server for each user, is included in the URL of the Web pages delivered to the users. Instead of storing this ID in a cookie file, the user is asked to create a bookmark for one of these pages, which includes this ID as part of its URL. The ID is used to identify the user, whenever the user returns to the site, via this bookmarked page, and is stored in the log file replacing the IP address of the user. This is a very simple technique, avoiding several problems that cookies have, such as the blocking of cookies by the user. However, this technique is also problematic. The main problem is that the identification process is only semiautomatic as the user must bookmark

a page and use that page to access the site, otherwise the user's ID will not be used. Furthermore, the situation of a user accessing the Web site from different machines, also affects this technique.

4. Users session identification

The identification of user sessions has also received significant attention in Web usage mining projects, as sessions encode the navigational behavior of the users and they are thus important for pattern discovery. A user session is a delimited set of pages visited by the same user within the duration of one particular visit to a Web site

Various heuristic methods have been used to identify user sessions. Spiliopoulou divides these methods into time-based and context-based [7]. Examples of time-based heuristics are the use of an upper limit to the time spent on a page, or an upper limit to the total duration of a session. Access to specific types of page, or the completion of a conceptual unit of work can be considered context-based methods.

Time-based methods have been used in most of the specific literature. According to these approaches, a set of pages visited by a specific user is considered as a single user session if the pages are requested at a time interval not larger than a specified time period. This period, also known as page viewing time [8], varies from 25.5 min to 24 h, whilst 30 min is used as the default [3]. However, this heuristic is not very reliable since the exact actions of a user are not known and may vary considerably, e.g. a user may be reading the same page for a long time, or may have left the office for a while and return to reading the page, etc. In addition, the value of this timeout depends largely on the content of the site being examined.

An important problem with the common time-based methods is the use of the cache, which may lead the system to the conclusion that a session has ended, while the user is still retrieving pages from the cache. This problem can be alleviated by the introduction of special HTTP headers. Shahabi propose an alternative method of measuring the viewing time for a page, using Java agents, that send back to the server the client's system time each time a new

Web page is loaded or unloaded at the client's browser [8]. However, external factors, such as network track and the type of browser, used by the visitor, introduce important obstacles to this method. Furthermore, the use of Java agents or JavaScript may be disabled by the user.

Yan identify user sessions by modifying the NCSA httpd server, in order to include session identifiers in the Web pages [9]. The first time a Web page is requested from a specific host-IP address, an identifier is embedded in this page corresponding to the start of a user session. This identifier is kept in subsequent requests coming from the same host, and a timeout mechanism is used to separate different session identifiers. However, caching mechanisms, affect the accuracy of this approach, since pages that are retrieved from caches are not included in the sessions.

User sessions are sometimes processed further to provide more useful entities. One such example is the concept of a transaction, a term derived from data mining and used mainly in market basket analysis. A transaction is a subset of related pages that occur within a user session. In order to identify transactions, Cooley made the assumption that transactions have a strong relation to the browsing behavior of a specific user, and can thus be identified using contextual information [3]. Based on this assumption, the pages of a site are divided into three types: navigational or auxiliary pages, containing primarily hyperlinks to other Web pages and used only for browsing, content pages, containing the actual information of interest to the user and hybrid pages, combining both types of information. Although, there are pages on the Web, which belong clearly in one of the three categories, such as index or home pages, this context-based classification is not very strict and depends on the users' perspective. A navigational page for one user may be a content page for another.

In [3] transactions are classified to content-only transactions, corresponding to the content pages that a user has chosen to view within a Web site and auxiliary-content transactions, corresponding to the paths to a content page. Two methods for identifying transactions of these two types are described: the reference length, and the maximal

forward reference. The reference length method examines the time period that a user spends visiting a Web page. If this period is greater than a certain threshold, the page is assumed to contain useful information, i.e. it is a content page, and is added to a content-only transaction. Otherwise the page is considered navigational, and is added to an auxiliary-content transaction. Auxiliary-content transactions are 'closed' with the questionable assumption that the last page a user visits is always a content page. Any interruption to the browsing sequence caused by external factors may erroneously lead to the identification of a content page. Another problem with this method is that the definition of the appropriate threshold is strongly dependent on the content of the site.

The maximal forward reference method has been proposed by Chen [10]. According to this approach, a transaction is defined as the set of pages visited by a user from the first page, as recorded in the log file, up to the page where the first backward reference has occurred. A backward reference is a page that is already included in the recorded transaction. The next transaction starts with the next forward reference, i.e. a new page that is not included in the recorded transaction. Using the classification of pages into content and navigational ones, maximal forward references are content pages, while the pages leading to the maximal forward references are navigational (auxiliary) pages. This method has an advantage over the reference length method since it is independent of the site content. However, it also suffers from an important problem, which is the caching of Web pages that prevents backward references to be recorded in log files. Cache-busting can solve this problem, with the cost explained above [11].

Finally, Ardissono and Torasso [12] also employ contextual information to identify a sequence of actions, in a user's browsing sequence, that are related to a certain item, defined as the Current Focus of Attention. The actions that are performed without changing the 'browsing' focus, constitute the local

history, which is used to analyze the user's behavior.

Data Collection in Web Usage Mining

Istrate Mihai

„Constantin Brâncoveanu” University of Pitesti
mihaifrance@yahoo.com

Abstract

The first step in the Web usage mining process consists of collecting the relevant Web data, which will be analyzed to provide useful information about the users' behavior. There are two main sources of data for Web usage mining, corresponding to the two software systems interacting during a Web session: data on the Web server side and data on the client side. In addition, when intermediaries are introduced in the client-server communication, they can also become sources for usage data, like proxy servers and packet sniffers. We will consider each of these sources in the following paper. Also we are trying to associate the data collection methods with the requirements imposed by different classes of personalization functions.

Key words: Web usage mining process, client-server communication, cookies, external data, and intermediary data.

JEL Classification: A12, C88, Y80

1. Server side data

1.1. Server log files

Server side data are collected at the Web server of a site. They consist mainly of various types of logs generated by the Web server. These logs record the Web pages accessed by the visitors of the site. Web servers have the ability to log all requests. There are two Web server log formats.

Most of the Web servers support as a default option the Common Log File Format, which includes information about the IP address of the client making the request, the hostname and user name, if available, the time stamp of the request, the file name that is requested, and the file size.

The Extended Log Format (W3C), which is supported by Web servers such as Apache and Netscape, and the similar W3SVC format, supported by Microsoft Internet Information Server, include additional information such as the address of the referring URL to this page, the Web page that brought the visitor to the site, the name and version of the browser used by the visitor and the operating system of the host machine.

Web usage mining tools use Web server log files as the main data source for discovering usage patterns. However, log files cannot always be considered a reliable source of information about the usage of a site. The problem of data reliability becomes particularly serious for Web personalization, where it is important to identify individual users, in order to discover their interests. There are primarily two sources of data unreliability: Web caching and IP address misinterpretation.

The Web cache is a mechanism for reducing latency and track on the Web. A Web cache keeps track of Web pages that are requested and saves a copy of these pages for a certain period of time. Thus, if there is a request for the same Web page, the cached copy is used instead of making a new request to the Web server. Web caches can be configured either at the users' local browsers, or at intermediate proxy servers. The obstacle that is introduced is the same for both types of cache. If the requested Web page is cached, the client's request does not reach the corresponding Web server holding the page. As a result, the server is not aware of the action and the page access is not recorded into the log files. One solution that has been proposed is cache-busting, i.e., the use of special HTTP headers defined either in Web servers or Web pages, in order to control the way that those pages are handled by caches. These headers are known as Cache-

Control response headers and include directives to define which objects should be cached, how long they should be cached for, etc. However this approach works against the main motivation for using caches, i.e., the reduction of Web latency.

The second problem, IP misinterpretation in the log files, appears for two main reasons.

The first reason, also known as the „AOL effect”, is the use of intermediate proxy servers, which assign the same IP to all users. As a result, all requests from various host machines that pass through the proxy server are recorded in the Web server log as requests from a single IP address. This can cause misinterpretation of the usage data. The same problem occurs when the same host is used by many users (e.g. members of a family). The opposite problem occurs when one user is assigned many different IP addresses, e.g. due to the dynamic IP allocation that is used for dial-up users by ISPs. A variety of heuristics have been employed in order to alleviate the problem of IP misinterpretation.

Finally, information recorded at the Web servers' log files may cause a privacy threat to Internet users [1], [11], [12]. Especially the referrer field is considered private information and according to the Request for Comments (RFC) on Hypertext Transfer Protocol - HTTP/1.1 2616, the user should have the option to transmit or not the referrer field through the Web browser. Unfortunately, most browsers do not conform currently with this recommendation.

1.2. Cookies

In addition to the use of log files, another technique that is often used in the collection of data is the dispensation and tracking of cookies. Cookies are short strings dispensed by the Web server and held by the client's browser for future use. They are mainly used to track browser visits and pages viewed. Through the use of cookies, the Web server can store its own information about the visitor in a cookie log at the client's machine. Usually this information is a unique ID that is created by the Web server, so the next time the user visits the site, this information can be sent

back to the Web server, which in turn can use it to identify the user. Cookies can also store other kind of information such as pages visited, products purchased, etc., although the maximum size of a cookie cannot be larger than 4Kbytes, and thus it can hold only a small amount of such information.

The use of cookies is also not without difficulties. One problem is that many different cookies may be assigned to a single user, if the user connects from different machines, or multiple users may be using the same machine and hence the same cookies. In addition, the users may choose to disable the browser option for accepting cookies, due to privacy and security concerns. This is specified in HTTP State Management Mechanism which is an attempt of the Internet Engineering Task Force to set some cookie standards. This attempt is formalized in the Request for Comments (RFC) 2965 [2], [11], [12]. Even when they accept cookies, the users can selectively delete some of them. Cookies are also limited in number. Only 20 cookies are allowed per domain, and no more than 300 cookies are allowed in the client machine. If the number of cookies exceeds these values, the least recently used will be discarded.

1.3. Explicit User Input

Various user data supplied directly by the user, when accessing the site, can also be useful for personalization. User data can be collected through registration forms and can provide important personal and demographic information, as well as explicit user preferences.

This is the case for some applications (e.g. online banking) where fairly detailed user data are available. However, this method increases the load on the user and it is generally considered a serious disincentive for visiting the site.

Furthermore, we cannot always rely on user-supplied information, since it is often incomplete and inaccurate. Users tend to provide as little as possible personal information for reasons concerning their privacy.

Another type of user data collected at the server side is the query data to a Web

server that are generated on e-commerce sites, portals and digital libraries [3]. These data are provided to a local search engine, when the user is trying to identify specific information within the site. However, free-text data are particularly rich and there is no formal standard for describing them. As a result, it is difficult to make use of these data.

1.4. External Data

Finally, user data providing demographic information [3] can be acquired from third party suppliers who maintain user databases for various reasons. However, privacy concerns have led to the introduction of legal obstacles in the distribution of these data. For instance, the European Union's Directive (EU Directive) on Personal Data, which took effect on October 23, 1998, restricts the transfer of personal data to a non-EU country.

2. Client side data

Client side data are collected from the host that is accessing the Web site. One of the most common techniques for acquiring client side data is to dispatch a remote agent, implemented in Java or JavaScript [4],[5]. These agents are embedded in Web pages, for example as Java applets, and are used to collect information directly from the client, such as the time that the user is accessing and leaving the Web site, a list of sites visited before and after the current site, i.e., the user's navigation history, etc. Client side data are more consistent than server side data, since they overcome caching and IP misinterpretation problems. However, the use of client side data acquisition methods is also problematic. One problem is that the various agents collecting information affect the client's system performance, introducing additional overhead when a user tries to access a Web site. Furthermore, these methods require the cooperation of users, who may not allow an agent running on their side. Web users often activate security mechanisms for restricting the operation of Java and JavaScript programs from their browsers,

in order to avoid running hazardous software. The result is the ineffective operation of agents collecting client side data.

An older technique used to collect data at the client side was through a modified version of the Mosaic browser [6], [7]. This modification allowed the browser to record the Web pages that were visited by a user and send that, together with other information, such as time of access, and time of response, back to the server. Browser modification is not a trivial task for modern browsers, even when their source code is available, like Netscape Navigator. Furthermore, modified browsers that record the behavior of users are considered a threat to the user's privacy and thus it is difficult for users to accept their use.

3. Intermediary data

3.1. Proxy Servers

A proxy server is a software system that is usually employed by an enterprise connected to the Internet and acts as an intermediary between an internal host and the Internet so that the enterprise can ensure security, administrative control and caching services.

Despite the problems that they cause, which were mentioned above, proxy servers can also be a valuable source of usage data.

Proxy servers also use access logs, with similar format to the logs of Web servers, in order to record Web page requests and responses from the server. The advantage of using these logs is that they allow the collection of information about users operating behind the proxy server, since they record requests from multiple hosts to multiple Web servers [9], [13], [14]. On the other hand, the problems of caching and IP address misinterpretation that were mentioned above, are also applicable to proxy server data.

3.2. Packet Sniffers

A packet sniffer is a piece of software, or sometimes even a hardware device, that

monitors network traffic, i.e., TCP/IP packets directed to a Web server, and extracts data from them. One advantage of packet sniffing over analyzing raw log files is that the data can be collected and analyzed in real time. Another important advantage is the collection of network level information that is not present in the log files. This information includes detailed timestamps of the request that has taken place, like the issue time of the request, and the response time, as well as whether or not the user has cancelled the request, by pressing the Web browser's stop button. The complete Web page that has been requested can also be included in the sniffed data [8], [10].

Although, the use of packet sniffers also has important disadvantages compared to log files. Since the data are collected in real time and are not logged, they may be lost forever if something goes wrong either with the packet sniffer or with the data transmission. For example, the connection may be lost, the packet sniffer may lose packets, or the packets may arrive in a disordered state, and hence it will not be possible to process them correctly in real time. In addition, especially for e-commerce sites, TCP/IP packets are increasingly transmitted in encrypted format, reducing the ability of packet sniffers to extract useful information. Finally, since packet sniffing tools operate directly on the data transmitted over the Internet, they are considered a serious threat to the users' privacy, especially when used by intermediaries like Internet Service Providers.

Financial Calculations in Access 2007 (SQL)

Jeflea Victor
Cosma Emil
"Ovidius" University of Constanța
jefleavf@yahoo.com
ecosma@univ-ovidius.ro

Abstract

Many *DBMS* producers have expanded the support for *SQL* by adding instructions to that particular language. The role of these extensions is to provide additional functionalities and simplified methods to perform certain operations. Although they are often very useful, these extensions have the tendency to be specific to a particular *DBMS* and are rarely supported by many producers. The standard *SQL* is controlled by the *ANSI* standardization committee, which is thus known as *ANSI SQL*. All important databases management systems, even those who use their own extensions, support *ANSI SQL*. In most cases, the *SQL*, which is submitted as an annex to the *Microsoft Access DBMS*, is *ANSI SQL* and applies to any database management system.

Key words: Acces, reports

JEL Classification: H2

1. Creating and running a *SQL* script

In the *Microsoft Access* editing environment, in order to introduce text to a *SQL* statement, which is a **Query object**, it is necessary to follow the following steps:

✦ In the *Create* tab click (with the mouse) on the *Query Design* button **Fig. 1**:

✦ Close the *Show Table* window that appears and in the *Design* tab select the *SQL View* button **Fig. 2**:

✦ The instruction text should be edited in the *SQL* view on the *Select* word area (the most common instruction used in *SQL*) – **Fig. 3**:

✦ Running is made by pressing  by **Run** button.

➔ It is advisable to use the **right mouse button** to display some contextual menus, relative to the objects concerned (*Table* or *Query*). In the left side of the screen (*Navigation Pane*) one can see the list with names of objects, these could be displayed (*View*). Tables may be presented in *Design View* or *Datasheet View*. To view current *SQL*

scripts the current view is *SQL View*.

➔ Views may be closed (right-click on view and *Close*), while the objectives in the *Navigation Pane* can be removed from the database (right-click on object and *Delete*).

2. The syntax of SQL statements

SQL statements are composed of simple terms in English. These terms are called keywords, each *SQL* statement being composed of one or more keywords. A keyword is a reserved word which is part of the *SQL* and is used exclusively to describe the instructions (for instance, one can never name a table or a column using a keyword).

Each instruction begins with a *name*, followed by other words called *clauses* and user words. The name of the instructions and the clauses are keywords (reserved). **Spaces utilization.** All spaces included in an *SQL* statement will be ignored while processing that particular instruction. *SQL* statements can be specified in a single line or may be divided on several lines. Splitting statements on multiple lines make them easier to read and troubleshoot.

Statements completion. *SQL* statements can be concluded by a semicolon (;). Most DBMS programs do not require the mandatory utilization of this character.

Capitalized/lowercased letters. It is important to note that *SQL* statements do not distinguish between capital letters (uppercase) and lower-cases (small letters). By convention, for a better explanation of edited statements, upper case letters are used for all *SQL* keywords and lower-case letters to name columns and tables.

3. Data types

Types of data are basically rules that define data which can be stored in a column and the effective way to store them.

Data type specification is made for several reasons:

➔ Allows limiting the type of data that can be stored in a column. For example, a column of a numeric data type will accept only numeric values.

➔ Data types allow a more efficient internal storage. Numerical values and those

of date/time type can be stored in a more condensed format than text strings.

Numeric data types store numbers. There are accepted more types of numeric data, each with a different field of numbers that can be stored. Obviously, the bigger the field, the more increases the required storage space.

Most DBMS type programs accept a particular numeric data type to store *monetary values*. Usually called **MONEY** or **CURRENCY**, these types of data are essentially **DECIMAL** types with well-defined intervals, which are recommended for storing monetary type values.

4. Fields with calculated value

Besides already the existing fields in tables, one may create new fields, called *fields with calculated value (aliases)*. These fields do not actually exist in data tables. In this case, the **Select** instruction has the following syntax:

```
SELECT
AS expr calculated field [,]
[AS expr calculated field,]
...
FROM name
[WHERE condition]
```

expr	Relation calculation.
calculated field	Name of the calculated field.
name	Name of the table from which calculations are extracted.
WHERE	Horizontal selection.
condition	Condition according to which horizontal selection is made.

5. Calculation Functions

Functions used in *SQL* statements are grouped into two categories:

- **Aggregate Functions**, specific to *SQL* (e.g. **COUNT**, **MIN**, **MAX**, **SUM**, **AVG**)
- Functions for data handling specific to Access (**VBA functions**)

In the second category falls **FORMAT** function to specify the way numbers are

specified:

FORMAT(expression, strFormat)

expression	May be a variable, a constant or an expression derived from them.
strFormat	Display format defined as a string. Each character # indicates a number, and 0 specifies if there appear zeros for completion, at the beginning or at the end.

↓ **Example**

SELECT FORMAT
(10000, "###,### lei") AS Expr1

Example ↑

6. Financial functions

Financial functions perform normal calculations for business, such as determining a loan payment, future value or current net value of an investment and bond or coupon values.

Common **arguments** for financial functions include:

- ✓ *Future value (fv)* - the amount of investment or loan after all payments are made.
- ✓ *Number of periods (nper)* - total number of payments or periods of an investment.
- ✓ *Present value (pv)* - the value of an investment or loan at the beginning of the investment. For example, the current value of a loan is the basic capital that is borrowed.
- ✓ *Rate (rate)* - the interest rate or discount rate for a loan or investment.
- ✓ *Type (type)* - the period in which payments are made during the period

of payment, such as at the beginning of the month or at the end of it (0 or 1, implicit 0).

The most important financial functions are:

FV(rate, nper, pmt, pv, type)

Calculates future value of an investment based on periodic and constant payments and a constant interest rate.

PV(rate, nper, pmt, fv, type)

Returns the present value of an investment. Present value stands for the amount that represents in the present a range of future payments. For example, for a loan, the amount borrowed is the present value for creditors.

NPER(rate, pmt, pv, fv, type)

Provides the number of periods for an investment based on constant periodic payments and a constant interest rate.

PMT(rate, nper, pv, fv, type)

Calculates payment for a loan based on constant payments and a constant interest rate.

IPMT(rate, per, nper, pv, fv, type)

Determines the payment of interest rate on a given period for an investment based on constant periodic payments and a constant interest rate.

↓ **Example**

a) For 13 monthly deposits, to 100 monetary units with 10% annual interest, the balance achieved can be calculated as follows:

SELECT FV(10 / 100 / 12,
13, -100) AS Expr1

b) Calculation of bank deposit for monthly return of 150 monetary units (9.5% annual interest, 12 years):

SELECT PV(9.5 / 100 / 12,
13 * 12, 150) AS Expr1

c) Number of months needed to achieve a balance of 2,000 monetary units (monthly deposit of 100, 9.5% annual percentage rate):

```
SELECT NPER(9.5 / 100 / 12, -  
100, -2000) AS Expr1
```

(rounding is required, $18,63... \approx 19$)

d) For a bank loan of 13,000 branches, in 12 years, 9.5% annual percentage rate, monthly payments are:

```
SELECT PMT(9.5 / 100 / 12, 12  
* 12, 13000) as Expr1
```

e) Interest rate owed in the second year, for a loan of 13,000 monetary units, for 12 years, (9.5% annual percentage rate):

```
SELECT IPMT(9.5 / 100, 2,  
12, 13000) as Expr1
```

Abstract

Number of theories and opinions regarding globalisation is overwhelming. Economically approaching this matter it may be said that globalisation is the opposite of protectionism and economic nationalism manifesting a good relationship with the free market and neo liberalism having common characteristics with internalisation. A new dimension of globalisation is represented by development of the electronic commerce in the latest time becoming a leader factor of businesses success in the 21st century. Infrastructure of the electronic commerce- the internet- offers instantaneously an open communication environment for all participants. This new dimension offers to the companies the opportunity of improving their processes but there is still one problem to be settled-that of data security -this involving efforts aimed to support all actors of this market in order to diminish the risks. Within this context of globalisation there are pertinent the tendencies of common ,public and private preoccupations too for the security of the global cybernetic space .In order to achieve the potential of the electronic commerce all over the world it is necessary a global equilibrated informational infrastructure .Electronic commerce carrying on involves approach and settlement of a multitude of technical and juridical problems regarding monitoring and crypt of the informational flows , transfrontalier financial transactions ,global fraud

Key words: globalization , commerce, data security, information

JEL Classification: P25 C88

1. Introduction

A characteristic of new economies is the globalization phenomena this one affecting the whole world. Globalization brings additional competition that has as result a better quality of the goods and services and therefore a better quality of life. Increase of life quality is completed by another dimension of the globalization consisting in the access that everyone has to the information existent in the internet network irrespective of the geographical location. As internet has not been conceived as a business environment ,proliferation of electronic trade has as effect intensification of the security and protection actions regarding the transactions carried out by the means of this environment .

2. Globalization general concepts

Globalisation is one of our days large circulation terms . The complex process of globalization was launched at the end of the ‘80’s and may have an economic, political, electronic, cultural and even a social meaningful approach. It may be stated that we are the witnesses of a global civilisation with common interests and values and common efforts serving a common cause of the humanity occurring the idea that the world will become a kind of a global village(McLuhan)

Anthony Giddens points out the social and economic elements defining globalization as “messengers of social and economic relationships development that expand in the whole world.A key aspect of the

globalisation study is the apparition of a global system this meaning that to a some extent we have to consider the world as forming only one social order .”

The most synthetic expression of the globalization process is given by “Strategy of National Security of The United Nations : a new “era” that defines this “as a process of acceleration of the economic , technological ,cultural and political together with the democratic government , market economy ,observance of human rights ,economic dynamism and revolution of communications “.

Roland Robertson appreciates that “globalization concept is referring to world decrease and world awareness degree as a whole”.

Globalization also includes some complex processes with a variable dynamic reaching different fields of a society ;it may be a phenomena ,an ideology ,a strategy or all these altogether. Globalisation may describe increase of commerce and investments as a result of barriers fall and interdependence between states . Within the economic context it is found the reference to the effects of the commerce in general and liberalization of commerce or free exchange in particular .

Supporters of globalisation do not deny competition sharpening as long as economies become more and more connected but they argument that this one is positive as businesses efficiency is achieved within a background that creates equal chances for more and more inhabitants of the planet .On the other hand we are aware of the anti globalisation measures that become obvious in some countries on the occasion of the high level meetings or other international forums .

3. Globalization index

Globalisation established domination of market economy . Besides GDP(Gross Domestic Product) index that is mentioned in all kinds of governmental announcements ,index of globalisation internationally gains more and more ground .Every year A.T.Kearney Company publishes in the famous magazine Foreign Policy the top of

world states on the basis of the globalisation index. Globalisation index is calculated for 62 countries that achieve 96% of the world GDP. The globalisation index synthesizes economic development level, level of interpersonal contacts ,technological connection level , level of commitment and political integration of the country in different international bodies and organisations. The report regarding the globalisation index reveals that the most intense globalization is that in the countries in which people live more and have a better health .

Most of the analysis regarding the globalisation process focus on the necessity of the diminishment of the economic development gap between the states of the world.

Bodies like The World Bank, The International Monetary Fund , World Trade Organisation supported by the interests of some large companies that own the control in different markets administrate the circulation of the strategic economic resources and, therefore, development of more countries of the world .

Globalisation plays an important role in the economic changes of our country pointing out the manner in which our government tries to attract foreign investments that should generate an economic increase

Globalization and its connections with the e-commerce

Globalisation is tightly connected with the world trade . Trade occupies an important role in promoting and maintaining an equilibrated community life being well known that almost everywhere same types of goods are produced . This makes that the more the globalisation process is consolidated the more it is outlined the necessity of specialisation of the production

profiles of the states. Globalisation leads to increase of the commercial activity in a larger extent in comparison with the increase of the output this generating in a country the presence of more products that come from other countries.

Within software field, globalisation is the technical term that combines internalisation and localisation processes. The negative effects upon the multinational companies by the usage of some sophisticated financial methods in order to reach the limits of local standards and laws aim to control the balance between labour and services of some regions unequally developed .

A new modality of commercial transactions performance and a new way of economic activity carrying out due to the rapid and strong development of the information and telecommunication technologies is represented by the electronic trade. The electronic trade offers the possibility of configuring products or services and having immediately their real prices comparatively with the prices of more offerors assuring thus a higher carrying out speed of the commercial transactions and allows the simplification of the procedures used in transactions leading to the increase of competitiveness of the company and implicitly of the country, determines the increase of transactions value by stimulating the buyers .

Electronic commerce is an integrated concept that reunifies a large variety of services in this field of businesses using electronic means .The problem that occurs from the first click for internet connection is that of data security menace .The present development of the electronic businesses will revolution business conduct and commerce too the latter one globalising more and more .

Within this context attacks to security are preponderantly manifesting by the following ways :

- Communications interception. Such a kind of attack may lead to theft of some important information belonging to the customers such as number of the credit card, account number or other important data that may bring prejudices to customers ;

- Stolen passwords . Such thefts may move the tack of the attacks from the trials of breaking the protocol to those of trying to obtain these information clearly ;

- Modified data . This manifestation may lead to the modification of the content of some transactions ;

- Registration . Such an attack can modify the identity of the person allowing her to present as another person ;

- Repudiation . Due to this type of attack it is possible to appear the refusal of recognising some transactions done by network .

In order to diminish the security risks in the utilisation and administration of the systems that participate in the achievement of the transactions by electronic trade the best strategy is the aggregate one. This involves the aggregate evaluation of IT infrastructure and classification of exposures to the risks of security .For every identified risk there has to be issued plans of measures either to diminish the exposure to those risks or to decrease the impact of the produced risk .

Data security and counteract measures

Internet has been created as an open environment but not necessarily a safe one ,the TCP/IP protocol missing basic security services .

We have to admit that at least till now we can not state that there are perfect security solutions. In order to assure the success of the business within an organisation it is necessary to allow the permanent access of the employees ,customers and business partners to the electronic resources either the access is achieved by internet(the most frequent method) or not . These accessions automatically create risks and the success of a business is determined by the balance between the existent and assumed risk and profit of the organisation .Presently world expenses for the technologies for data security exceed 13 billions of dollars .

The space of the millions of computers interconnected by a global informatics infrastructure is called Cyberspace. Security of this space represents a major priority of the specialists and users ,too. The analysts of this concept noticed an apparent

contradiction between communications needs and connectivity on one hand and necessity of data confidentiality and authenticity to the computers and networks on the other hand .Cryptography is the science of secret writings. A cipher is defined as the transformation of a clear message or text in a ciphered message or cryptogram. The process of transformation of a clear text in a ciphered one and inverse transformation of the cryptogram in a clear text is named deciphering or decrypt. Both ciphering and decrypt are controlled by one or more cryptographic keys .

There are more methods and algorithms for ensuring data security. The cryptographic asymmetrical methods use crypt with public keys utilising distinct keys for messages ciphering and deciphering .Communication may be achieved when correspondents know the public key of the other one .There are more cryptographic methods with public keys : RSA ,Diffie-Hellman,the cryptographic method based on mathematical operations on the elliptical curves ,methods based on crypt probabilistic algorithms . These methods bring a security increase due to elimination of transmitting the private key to that with which communication is done but crypt speed is lower in comparison with the method with secret keys and is vulnerable to personalisation.

An important moment of modern cryptography evolution is that when Whitfield Diffie and Martin Hellman researchers at Stanford University of California settled the basis of a different principle from that of asymmetrical ciphering : instead of using one secret key there are used two different keys ,one for ciphering and another one for description .The first key-the private one- is kept in secret and it is known only by its owner and the public key may be publicly known .

Cryptographic methods use crypt with secret keys known as transmitter and receiver. The transmitter chooses a ciphering algorithm and a key that are communicated to the receiver in a safe way. A classic cryptographic system has five components :messages with clear text,messages with ciphered text ,the keys, ciphering and deciphering transformations. The main

cryptographic symmetrical methods are: LUCIFER cipher, Data Encryption Standard cipher Japanese Data Encryption Algorithm cipher ,multilevel ciphers, proposed Encryption Standard cipher, Kerberos scheme.

More and more organisations want to offer WEB pages and FTP servers for the public access from Internet. The companies that carry out activities of electronic trade by internet have to control the access from her own network towards internet and vice versa. The most frequently used solution for providing security to such a network is the so named firewall this signifying a system that imposes a control policy of the access between two networks. A firewall is a system placed between two networks that have the following properties:

- the whole traffic from interior towards exterior has to pass through this one ;
- it is only allowed the passage of the authorised traffic by the local security policy
- the system itself is immune to the trials of penetrating its security.

Assurance of an adequate security level for an organisation is achieved by the elaboration of a security policy in order to prevent the unauthorised access to resources and information .A firewall is not only a combination of devices that supplies security to a network .Firewall is a component of a general security policy playing the protection role of the informational resources of the company.

Data security assurance have to consider the following fundamental security demands:

 Confidentiality sometimes named secrecy protects the content of the transactions against the unauthorised reading by other persons than the receivers specified by transmitter. Confidentiality represents the supreme aim of the computers security and it gains new dimensions as control measures .The developed countries regulated by law control of confidentiality

 Integrity sometimes named accuracy supplies to the receiver of a transaction the security that the received message is identical with the message issued at origin .This service aims that the data stocked in the computer or being in transit in the network not to be altered or modified.

 Availability involves that data and information stocked in the memory of the computer to be accessed by authorised persons. Persons that have access to data are grouped in two categories: system administrators and general users the latter one having access only to certain available data for them.

 Non repudiation supposes confirmation of the addressee of an electronic message this meaning that the message is written or sent by persons who claim they sent .Non repudiation lays at the basis of the electronic signature assuring authenticity of this one.

Implementation of security on levels in the computers network is achieved with the help of the protocols that may be grouped in the following classes:

- identification and authentication protocols;
- protocols for data transfer protection ;
- protocols for ciphering keys administration;
- protocols for present time verification .

According to The National Security Strategy of Romania our country confronts with risk factors too of which there are pointed out the following:

- ✓ trans national and international political terrorism;
- ✓ illegal access of informatics system;
- ✓ economical-financial aggression.

The main types of vulnerabilities regarding information and informational systems for which prevention measures have to be taken are: low level of the informational structure and delays in its achievement at the standards imposed by dynamics of globalisation ,deficiencies of the protection of classified information.

4. Data security in Romania

At The European level it was established The European Agency for Security of

Information Networks that has as main target to help The European Commission ,the member states and business community to treat, answer and prevent information and networks security matters .Following the legal background of European Union within the field of data security Romania adopted national legislation in this area starting with 1st of January 2007 ,our country having a representative in The Administration Council of ENISA participating directly in the decisions taken in the field of data security at EU level.

Representatives of Bitdefender declared that Romanian market for security solutions reached last year a value of 10 millions of Euro this representing an increase with 20% in comparison with 2006 and they also estimate a 20-25% increase for 2008. Their expectations concern not only the increase of antivirus and firewall area but the increase of other segments less protected too Starting with 2004 Romania has implemented the standard 3D secure - the most modern and safe method of electronic payment- in order to allow the electronic commerce operations to be carried out fully safe.

Specialists of this field consider that the majority of The Romanian companies are not enough precautious and appeal to security services after they are already attacked by hackers, crackers, spies , vandals or other bad intentioned persons.

This year for the first time Romania will participate in “The Day of Internet Safety” organised by The European Network “Internet Safety”.

5. Conclusions

Due to permanent change and adaptation of development opportunities and risks too the process of information security has to be an incessant and dynamic one .Today no organization can perform her activity without a security policy, time demonstrating that there is a predisposition that all resources to be attacked .On the other hand an excessive preoccupy for large investments in the surveillance and monitoring systems may capture attention

of hackers who stake on profits achievement using virus methods.

Most of the time there are received answers to the eventual cybernetic attacks from the private sector and less from the public one. Governments intervene with security measures in this space in order to provide the security of their own cybernetic infrastructure and thus to be able to reach the missions and proposed targets .

Impulse-Response Analysis in a Simple DSGE Framework

Leonte Alexandru

The Academy of Economic Studies, Bucharest
alexandruleonte@yahoo.com

Abstract

This paper intends to perform a simple impulse-response analysis on the Romanian economy with the help of a DSGE model. The DSGE methodology has its origins in the Real Business Cycle Theory, and recently it became quite popular, especially after the seminal contribution of Smets and Wouters ([8]). I use a model with a single stochastic variable, namely technological progress, and focus on the response of the main macroeconomic variables to a technology shock. This endeavor is a first step in developing a DSGE model that can be used for policy purposes.

Key words: DSGE, impulse-response analysis, real business cycle.

JEL Classification: E22, E32.

1. Introduction

This paper aims to perform a simple impulse-response analysis with the help of a DSGE model. These models have become quite popular in recent times. Their main advantage is that they offer microeconomic foundations for the neo-Keynesian mathematical relations between macroeconomic variables. The use of a simple model to observe the responses of these variables to a stochastic shock can be regarded with suspicion. Still, it has been shown that simple models can perform as well or even outperform more complicated models, especially in the case of emerging economies, for which long time series are not available, and so parsimony is a highly welcomed feature of a model. This analysis is a first step in the endeavor of building a DSGE framework for the Romanian economy that includes staggered price and wage setting, liquidity constrained consumers, etc., fiscal and monetary

authorities, non-Ricardian fiscal setting, etc., that can be used for policy purposes and that account for the stylized facts that characterize the macroeconomic variables.

2. Literature review

DSGE models have their origins in the Real Business Cycle Theory pioneered by Kydland and Prescott ([7]). A large number of recent contributions to the literature that analyze emerging economies follow the approach described in [8]. In the paper, the conceptual framework that characterizes the micro-founded general equilibrium models is enriched with rigidities that are due to the way in which firms set their prices (like those that feature in [2]) and with rigidities due to the structure of the labor market (following [3]). The authors contribute by placing a significant number of stochastic shocks to observe their effects on the macroeconomic variables. Jakab and Vilagi ([5]) build a DSGE model for the Hungarian economy, which features besides agents that maximize their utility function with respect to their budget constraint, liquidity-constrained agents (the so-called *rule of thumb* consumers, first introduced in [4], that fall into two categories: wage-earners with little income and pensioners. A simplified version of this model is used for Hungary in [6] to evaluate monetary policy. In what regards determining values for the parameters, a general tendency of using Bayesian estimation can be distinguished, combined with calibration. The Bayesian techniques (well described in [1]) result in statistically significant coefficients that can be interpreted, even in the case of small samples. Finding arguments (usually from the microeconomic theory) for fundamenting a certain value of a coefficient (in the case of calibration) or a certain distribution with its parameters (in the case of Bayesian estimation) remains a constant preoccupation.

3. The model

The model represents a basic DSGE framework. The economy is populated by agents with infinite lives. The representative agent maximizes the following utility function:

$$U_0 = \max \sum_{t=0}^{+\infty} \beta^t \left[\frac{C_t^{1-\sigma}}{1-\sigma} - \frac{L_t^{1+\varphi}}{1+\varphi} \right] \quad (1)$$

where C represents consumption, L represents the amount of time spent at work, σ is the elasticity of inter-temporal substitution, φ is the inverse of the Frisch elasticity of labor supply, and β is the subjective discount factor.

The agent has the following budget constraint:

$$C_t + I_t = W_t L_t + R_t^K K_t + \Pi_t \quad (2)$$

where I represents investment, W represents the wage rate, K represents capital, R^K is the return on capital, Π is profit.

Capital has the following rule of motion:

$$K_{t+1} = (1 - \delta)K_t + I_t \quad (3)$$

where δ is the capital depreciation rate.

Profit is calculated as production minus production costs:

$$\Pi_t = Y_t - W_t L_t - R_t^K K_t \quad (4)$$

The production function is of the Cobb-Douglas type:

$$Y_t = A_t K_t^\alpha L_t^{1-\alpha} \quad (5)$$

where α is the elasticity of capital.

Finally, the real interest rate is defined:

$$R_t = R_t^K - \delta \quad (6)$$

All the variables are expressed in real

terms, the price index is normalized to 1.

The necessary condition for inter-temporal optimality is derived using the Bellman principle. We get the Euler equation:

$$E_t \left[\left(\frac{C_{t+1}}{C_t} \right)^\sigma \right] = \beta(1 + R_t) \quad (7)$$

The intra-temporal optimal choice between consumption and labor is:

$$C_t^\sigma L_t^\varphi = W_t \quad (8)$$

The profit-maximization necessary conditions are:

$$\alpha \frac{Y_t}{K_t} = R_t^K \quad (9)$$

$$(1 - \alpha) \frac{Y_t}{L_t} = W_t \quad (10)$$

The model has no closed-form solution. I follow the standard approach and log-linearize it around a non-stochastic steady-state (I use a first-order approximation). Here is the complete list of log-linearized model equations (the small letter represents the log-deviation of the variable from the steady state, namely $x_t = \ln X_t - \ln X$, where X is the steady-state value of the variable):

$$E_t \left[\frac{1 + \sigma \cdot c_{t+1}}{1 + \sigma \cdot c_t} \right] = 1 + (\beta - 1) \cdot r_t \quad (11)$$

$$\sigma \cdot c_t + \varphi \cdot l_t = w_t \quad (12)$$

$$y_t = w_t + l_t \quad (13)$$

$$y_t = r_t^K + k_t \quad (14)$$

$$r_t = (1 - \beta + \beta \cdot \delta) \cdot r_t^K \quad (15)$$

$$y_t = a_t + \alpha \cdot k_t + (1 - \alpha) \cdot l_t \quad (16)$$

$$y_t = (1-h)c_t + hi_t \quad (17)$$

where $h = \frac{\alpha\beta\delta}{1-\beta+\beta\delta}$.

$$k_{t+1} = (1-\delta) \cdot k_t + \delta \cdot i_t \quad (18)$$

The model is closed with the standard dynamic for technological progress:

$$a_t = \rho \cdot a_{t-1} + \varepsilon_t^a \quad (19)$$

where $0 < \rho < 1$ in order to ensure a positively correlated process which converges, and ε_t^a is a normally distributed stochastic shock with 0 mean and constant variance.

I calibrate the parameters using standard literature values and steady-state conditions. The subjective discount factor $\beta = 0.97$ which corresponds to a quarterly real interest rate of approximately 3,1%. The capital depreciation rate is set to 2,5% per quarter, and the elasticity of capital is set to 0,33. The intertemporal elasticity of substitution is set to 0,5, corresponding to a square root utility function in consumption, and the inverse of the Frisch elasticity is set to 2, following the literature. Finally, I set $\rho = 0,95$.

4. Impulse-response analysis

We get the following responses to a technological shock:

Figure 1: Consumption response to a positive technological shock

Figure 2: Investment response to a positive technological shock

Figure 3: Production response to a positive technological shock

We observe that a positive technological shock leads to an increase in production (according to equation (16)), which in turn leads to an increase in both consumption and investment (according to equation (17)).

A critical parameter which determines the shape of the responses is the inverse of the Frisch elasticity. For $\varphi=0$ and $\varphi=+\infty$ we get the following responses:

Figure 4: Real wage response to a positive technological shock ($\varphi=0$)

Figure 5: Real wage response to a positive technological shock ($\phi=1000$)

Figure 6: Labor response to a positive technological shock ($\phi=0$)

Figure 7: Labor response to a positive technological shock ($\phi=1000$)

5. Conclusions

The simple DSGE framework that has been used facilitated a micro-founded impulse-response analysis which allowed the observation of macroeconomic variable

behavior. Parameter values have a large influence on the responses, so there is need for extensive micro-evidence in order to calibrate a parameter or specify a prior distribution, in the case of Bayesian estimation.

6. Note

This article is a result of the project “Doctoral Program and PhD Students in the education research and innovation triangle”. This project is co funded by European Social Fund through The Sectorial Operational Programme for Human Resources Development 2007-2013, coordinated by The Bucharest Academy of Economic Studies.

A Rescue Plan for the Finances of Consumer – the Incomes and Expenses

Lupaș Ioana
Lupaș Adrian
Zamfir Cristina Gabriela
“Dunarea de Jos University” of Galati
ioanalupasc22@yahoo.com
alupasc@ugal.ro
cristinapisica@yahoo.com

Abstract

The crisis is now a big problem all over the world. The impact of economic global problems over euro zone is very powerful, especially on the lay-off. The most danger for the common people in periods of recessions is the unbalance between the charges and revenues. For balance his expenses and incomes, a person needs to find different solutions. In this work, we have analyzed the budget of the household and then, we tried to give solutions for common people to survey the crises; we made a rescue plan for consumer's finances. Among the first steps of the rescue budget are: to analyze of what you have now, not what you had; make a plan with stages and objectives, then chose the most suitable modality to save the money, and always keep an historic of the incomes, expenses and saving money.

Key words: economic global crisis, population expenses and incomes, plan for consumer's finances.

JEL Classification: D12, D14, G01

1. Introduction

A big problem in nowadays for all over the world, especially in the industrial countries is the recession. The most danger for the common people in periods of crises and recessions are the unbalance between the expenses (charges) and incomes (earnings, gains, revenues). For balance his expenses and incomes, a person need to apply to extern sources.

But, the impossibility to applying to the extern sources because their cost is high or the lay-

off, may lead to the forced execution by creditors and finally to personal bankruptcy and the lost of proper goods. Romania needs a law for person's bankruptcy, to protect persons against forced execution.

On the other way, in such periods, many opportunities come into view, especially for the acquisitions for homes and cars, because their price is low.

2. Steps to secure the consumer's financial future in the US

After Suze Orman a recession rescue plan should have five steps²:

Step1: Live on half

Whether someone is single or in a double-income household, the person needs to live only half of what he is used to, and to put the rest in the bank. If all of a sudden he fined himself without a job – or his partner fined themselves without a job – he is now going to have his income cut by 50 percent almost immediately.

By living on half now, the person will know whether he can really afford to pay his bills if the worst happens. When a person is freaked out, that is no time ...and it's never too early to start formulating an unemployment action plan.

This step is the first to use and cut expenses as necessary.

Step2: Stash your cash

In today's economy, cash is the king and the credit could be shrinking daily.

If the credit card is no longer available, what does the consumer do if he loses his job and

² Book: Suze Orman's 2009 Action Plan, Keeping your money safe & sound.

have no savings? He will be in serious trouble. Before this recession, credit cards could always be used in case of emergency. Now, credit card companies are making it more difficult for people to use their cards.

Therefore, a good advice is to pay for things in cash.

Each month can add up to big savings and a person can increase his savings even more if he finds the right account, if he compares the interest rates of savings accounts, CDs and other bank products.

Step3: Make the stimulus package work for you

In US, the new economic stimulus package changes the rules for tax credit for first-time home buyers.

Part of the intention behind the economic stimulus plan passed by US Congress is to create millions of jobs for Americans, but it's also designed to lend a helping hand to those out of work.

If it happens to get laid off, to lose the job, a person has 18 months where that company has got to cover him with health insurance.

Step4: Make your home affordable

The loan modification program is designed to help families dangerously close to foreclosure. The US government estimates it could help 3 to 4 million homeowners keep their monthly mortgage payments if and only if they are qualified in this program.

Step5: Look at what you have, not what you had

Things will get better, get worse ...in the next three or four years, it will start to turn around. But there are a few years until every single person feels a hope again.

This is why it is so important to look at what you have and be grateful, instead of looking at what you have lost and feel angry.

After Jean Chatzky there are 5 steps to secure your financial future:

- build a cushion
- pay down debt
- rebalance your portfolio
- keep your job

- work on your credit score.

Also, according to them, there are essentials things that a person in US can't afford to skimp on, because sooner or later will affect them, such as:

- retirement planning
- insurance
- exercise
- healthcare
- charity.

3. A recession rescue plan for consumer's finances in Romania

In generally, and also in Romania, we should follow the next steps for success:

- Find a motivation for savings
- Make a plan with stages and objectives
- Chose for the most suitable modality to save the money
- Make the saving money before the spending money
- Keep an historic of the incomes, expenses and saving money.

These are the steps we must follow to succeed. The necessity of having saved money is obviously: the risk of losing the job, the risk of unwanted events, medical surgery etc.

Also, we can see some opportunities offered by the crisis if we have savings and as a paradox to save more money. An example is a person who searches to rent a house; the market price is 500 euro; he finds an owner who needs liquidities and agreed to negotiate at the price of 400 euro, 20% under the price market, with a period condition: one year or half year. In this case, the person save 1200 euro per year and the owner is satisfied to have fast liquidities.

A Romanian in media spends from 100 lei, 71, 5 lei for consumed food or goods, 15, 6 lei for taxes, contributions, dues and fees. According to the National Statistic Institute, they spend over 90% of theirs incomes.

Table1-b. Total expenditure of main household categories in 2008

Table1-a. Total expenditure of main household categories in 2008

Total expenditure of main household categories in 2008	Total households Trim 4 lei	Total households (percentage)
1. Money expenditure of which, for:	1753,97	84,28%
-purchasing of consumed food and beverages	1282,02	61,6

Source: *Population income, expenditure and consumption, bulletin INS, 2009 and my calculation*

In 2008, the final trimester, the income of household was 2318,52 lei (increasing 23%, towards 2007, and 59% towards 2006) and the expenditure of household was 2081 lei. (89,8% from total income)

A study made in January 2009 shows that many of the Romanians have the strict necessary goods, 35% of the interviewees, but almost of them are dreaming to buy cheap goods en rates or to take a loan. Third of them intend to spend their holidays in the country and half out. Half of the consumers do not intend to reduce money expenditure for purchasing of consumed food and beverages, but 30% intend to reduce the budget for clothes because of the crisis.

4. Conclusions

In conclusion, how to escape from the dates? The consumer needs a plan for debts management. First the person should make a budget:

- -Total income: 100%
- -Total expenditure: 20% debts (for example), 80% money expenditure for purchasing of consumed food, beverages and non-food goods etc.

If for example, there are 30% debts, a person should reduce the expenses and he will have 70% money expenditure for purchasing of consumed food, beverages and non-food goods etc. and has to identify not necessary expenses. A person can reduce the expenses by organizing the bills, not making any more

debts, changing the companies who offer utilities (e.g. the phone, TV), changing the bank or the credit card etc. Some acquisitions can be postponed and it is advisable to buy cheap things.

The first priority is the financial stability.

One of the rules is to keep more liquid money in bank products. We have to be preoccupied by the safety of money.

Regarding the financial behavior, a person must have in mind that the money mustn't been wasted. The money should covered rational and adapted charges because of the crisis. Also, the buying capacity of Romanian is going down. *It is necessary more then ever to think positive, to stop spending and to start saving and try to consume Romanian products.*

Abstract

The Information and Communications Technology (“ICT”) industries have come together as a dynamic ecosystem. Networks, devices, content and applications increasingly rely on each other to innovate and generate new value, providing multiple benefits to the economy.

Key words: Information and Communications Technology, economic growth, technology progress, educational burden.

JEL Classification: L86, M15, O31, O33, O53

1. Introduction

The purpose of this paper is to analyze the impact of investment in Information Technology and Communications (IT&C) equipment and software on the recent resurgence in world economic growth. The crucial role of IT investment in the growth of the economy has been thoroughly documented and widely discussed.

In just a few years, the Internet has had a visible impact on the daily lives of many – at work, at home and how they communicate with one another. But a key policy question for the future is: How will the Internet affect the performance of the economy and the standard

of living of average people? In particular, is the Internet just a different way to communicate or will it be a significant factor in sustaining the remarkable increase in productivity recorded since the mid-1990’s, as many executives and venture capitalists in the industry, and some economists, seem to believe.

Jorgenson has shown that the remarkable behaviour of IT prices is the key to understanding the resurgence of American economic growth. This behaviour can be traced to developments in semiconductor technology that are widely understood by technologists and economists. [1]

The growth of IT investment jumped to double-digit levels after 1995 in all the G7 economies – Canada, France, Germany, Italy, Japan, and the United Kingdom, as well as the United States. These economies account for nearly half of world output and a much larger share of world IT investment. The surge of IT investment after 1995 resulted from a sharp acceleration in the rate of decline of prices of IT equipment and software.

This was traced to a drastic shortening of the product cycle for semiconductors from three years to two years, beginning in 1995.

After 1995, IT&C grew constantly, this being in close relationship with the growth of the Internet. (see Table 1)

Table 1: Internet Users and PCs¹

Year	Personal computers (millions)	Internet users (millions)
1997	325	117
1998	375	183
1999	435	275
2000	500	390
2001	555	489
2002	615	616
2003	650	721
2004	775	867
2005	808	989
2006	n/a	1168
2007	n/a	1344
2008	n/a	1542

2. Sources of Potential Cost Savings

Whether, and at what pace, the potential cost savings and thus productivity improvements will be fully realized depend on a series of factors. In principle, the Internet has the potential to increase productivity growth in a variety of distinct, but mutually reinforcing ways:

- by significantly reducing the cost of many transactions necessary to produce and distribute goods and services;
- by increasing management efficiency, especially by enabling firms to manage their supply chains more effectively and to communicate more easily both within the firm and with customers and partners
- by increasing competition, making prices more transparent, and broadening markets for buyers and sellers, which puts pressure on suppliers to adopt techniques that translate into cost savings.

The cost savings are largely projected to be one-time savings for each firm that achieves them, although in practice, such savings may be spread over time in individual firms, while at the sector level a process of diffusion from first-adopters to followers should generate the

pattern of annual productivity savings we estimate.

However, the limited available evidence suggests that successful implementation of Internet-based cost-savings strategies requires far more in the way of organizational commitment, than actual investment spending of capital. [2]

3. Transactions - Cost Savings:

The potential for transactions-cost savings from transition to the Internet is especially high in the health-care sector, because it is so large (for example, in the U.S. in 2007, health care and insurances represented almost 14% of GDP)².

The health care system is so information-intensive, and so dependent on paper records. Moving health-insurance claims processing to the Internet would require aggressive efforts to standardize claims formats, but savings could be large.

Web-based processors may be able to deliver the same quality of service. The Internet also offers great potential in the area of managing medical records, not only for cutting costs, but also for improving the quality and effectiveness of care. Assuming that privacy concerns can be adequately addressed, patients and providers would benefit enormously from conversion of current, mostly paper, medical records into electronic medical records in a standard format. Providers would then be able to access the patient's full medical history quickly and enter their own observations and treatments.

Transactions are the bread and butter of the financial-services industry, and so it is not surprising that the Internet already is leading to lower transactions in this sector in the developed countries. In the mortgage lending industry, customers are using the Internet to shop for information and compare rates, although only a tiny fraction of mortgages now originate on-line, where it is cheaper to process them. This should change over the next few years as consumers grow more

¹ Source: ITU World Telecommunication/ICT Indicators Database. [5]

² Source: U.S. Department of Commerce Bureau of Economic Analysis, USTelecom Analysis

comfortable using “digital signatures,” now legal under laws.

The Internet can reduce transactions costs at all levels of government. In particular, the Internet has enormous potential, now only beginning to be realized, for dispensing information to citizens less expensively and more accurately than telephone inquiries. Filing tax returns or applications for permits and licenses on-line, for example, cuts costs both to the government and to taxpayers.

In Romania, the Ministry of Communications wants that in five years all the taxes to be paid online, calling this 500 million Euro project “eRomania”. All the employees now hired will be replaced by online portal access sites and this will reduce the costs with up to 35% out of the total GDP of Romania¹. The eRomania portal, aimed at simplifying the interaction of the business world and of citizens with state institutions by creating up to 600 online public services by 2013, is a controversial one, with the amount allocated for it, almost half a billion Euros, considered to be too high. The amount may not be efficiently spent, because the amount allocated seemed to be rather high, considering that a website does not cost more than 1 million Euros. [3]

But if we regard the figures from the United States two years ago, we can see that almost the same amount was invested only by the Private Sector Invests \$455 Billion Annually in ICT and Infrastructure. (Figure 1)(Figure 2)

Figure 1: Private Fixed Investment in Software and Equipment 1990-1999 (\$ billion)

Figure 2: Private Fixed Investment in Software and Equipment 2000-2008 (\$ billion)²

In 2008 ICT accounted for:

- 22% of U.S. capital investment
- 43% of U.S. non-structure capital investment

4. The Internet and Efficient Management

The use of the Internet as a management tool may have considerable potential for improving efficiency in many sectors of the economy and may cause significant restructuring of those sectors in the process, especially in the manufacturing sector. Many of the potential efficiency gains come from use of Web-based technology to manage supply chains more effectively, reduce inventory, and cut customer-service costs.

These savings should show up within the firm and arise from better scheduling for information sharing across the company, more efficient interaction with other firms in the supply chain, and elimination of some intermediaries' altogether.

Cisco Systems, for example, has been a leader in dealing with suppliers on the Web to enhance efficiency of its procurement and in monitoring the company's extensive outsourcing of its manufacturing operations. The Internet is also being used effectively in a number of industries to link partners in joint enterprises across large distances, enabling them to share production schedules and integrate their operations. [4]

The Internet is also being used effectively in a number of industries to link partners in joint enterprises across large distances, enabling

¹ GDP estimated for 2010

² Source: U.S. Department of Commerce Bureau of Economic Analysis.

them to share production schedules and integrate their operations.

There are numerous potential opportunities also in the auto industry for Internet-aided increases in efficiency, product development, procurement, and supply, and in various aspects of the manufacturing process itself. They suggest the applicability to automobiles of the “Dell model,” under which customers specify exactly what features they want and buy a product that is built to suit their tastes. The Internet driven automobile sector of the future could thus involve far fewer dealers and salesmen than it does now. And considering the auto industry crisis, this may come as a solution for large corporations like GM.

Personal Consumption Expenditures (PCE) for Communications Services, between 1990 and 2008, shows that the mix is shifting to broadband, mobile, and entertainment, however broadband access remains a small portion of overall spending.

5. Non-measured Benefits

It is vital not to overlook the variety of benefits to end-users of the Internet, including added convenience, wider choice, and customization, that are not and probably will never show up in the productivity statistics.

Internet will continue to provide customers with wider choices among customized products and services (ordering Dell computers on-line is a perfect demonstration).

Distance learning, while perhaps not adding much in the way to productivity, is being used by firms and an increasing number of colleges to deliver education at times convenient to students, without having them physically attend the courses. An increasingly Internet-based medical system will save lives by, among other things, cutting down on errors in transmitting prescriptions to pharmacies. [6]

6. Leading Roles

Directly or indirectly, ICT contributes up to half of U.S. Productivity Growth. As a key driver of productivity, ICT is a critical source for:

- GDP growth
- Rising living standards
- Government fiscal resources

- Global competitiveness

World economic growth, led by the industrialized economies and Developing Asia, experienced a strong resurgence after 1995. Developing Asia accounted for an astonishing 60 percent of world economic growth before 1995 and 40 percent afterward, with China alone responsible for half of this, but output per capita remained well below the world average. Sub-Saharan Africa and North Africa and the Middle East languished far below the world average.

Eastern Europe and the former Soviet Union lost enormous ground during the transition from socialism and have yet to recover completely.

The growth trends most apparent in the U.S. have counterparts throughout the world. Investment in tangible assets, including IT equipment and software, was the most important source of growth. However, Non-IT investment predominated.

The leading role of IT investment in the acceleration of growth in the G7 economies is especially pronounced in the U.S., where IT is coming to dominate the contribution of capital input. The contribution of labour input predominated in the Non-G7 industrialized economies, as well as Latin America, Eastern Europe, Sub-Saharan Africa, and North Africa and the Middle East.

All seven regions of the world economy experienced a surge in investment in IT equipment and software after 1995. The impact of IT investment on economic growth has been most striking in the G7 economies.

The rush in IT investment had especially taken part in the U.S., but jumps in the contribution of IT capital input in Canada, Japan, while the U.K. were only slightly lower. France, Germany, and Italy also experienced a surge in IT investment, but lagged considerably behind the leaders. [7]

The greatest impact may not be felt in e-commerce, but rather in a wide range of “old economy” arenas, including health care and government, because of changes to the way information flows.

As a result of the Internet, there is considerable scope for management efficiencies in product development, supply-chain management, and a variety of other

aspects of business performance, encouraged by enhanced competition.

The penetration rate of Internet access, especially broadband, will affect the extent to which firms face intense competitive pressure to change existing management methods, among other practices. In addition, policy will play an important role. [8]

7. The Burden of Knowledge

Another aspect, somehow hidden behind all the benefits, is that if knowledge accumulates as technology progresses, then successive generations of innovators may face an increasing educational burden. Innovators can compensate in their education by seeking narrower expertise, but narrowing expertise will reduce individual capacities, with implications for the organization of innovative activity - a greater reliance on teamwork - and negative implications for growth. The knowledge burden mechanism suggests that while the nature of innovation is changing, negative implications are recorded for the long-run economic growth.

Physical stocks can be transferred easily, as property rights, from one agent to another. Human capital, by contrast, is not transferred easily. While one generation may rather effortlessly bequeath its physical assets to the next, with human capital stocks, this is fundamentally not the case. Technology tends to reinvent itself time and time and again during history.

The vessel of human capital – the individual – absorbs information at a limited rate, has limited capacity, and has limited time on earth. The difficulty of transferring human capital and full comprehension of previously technology gained knowledge has broad implications in economics. The total stock of knowledge and the sentiment that knowledge begets new knowledge, with implications discussed extensively in the growth literature and in the micro-innovation literature, suggests a different, indirect implication of Newton's observation: if one is to stand on the shoulders of giants, one must first climb up their backs and the greater the body of knowledge, the harder this climb becomes. If technological progress leads to an accumulation of knowledge, then the educational burden on

successive cohorts of innovators will increase. Innovators might confront this difficulty by choosing to learn more. Alternatively, they might compensate by choosing narrower expertise.

Choosing to learn more will leave less time in the life-cycle for innovation. Narrowing expertise, meanwhile, can reduce individual capabilities and force innovators to work in teams.

Related to this point, the efficiency of education — the rate at which we transfer knowledge from one generation to the next — becomes a policy parameter with first-order implications for the ultimate organization of innovative activity and for growth. Future improvements in the knowledge transfer rate could potentially overcome growth in the knowledge stock. While this transfer rate probably faces physiological limits, policy choices in education take on further importance.

8. Conclusion

One of the major features of the Internet revolution is its potential to make the whole economic system, nationally and internationally, more competitive by bringing many markets closer to the economists' textbook model of perfect competition, characterized by large numbers of buyers and sellers bidding in a market with perfect information. The results should be lower profit margins, more efficient production, and greater consumer satisfaction. In particular, added competition in supplier and product markets should place increased pressure on firms to use the Internet to introduce the cost-savings techniques.

Much of the benefit from the Internet is likely to show up in improved consumer convenience and expanded choices, rather than in higher productivity and lower prices.

In particular, measures to improve privacy protection for Internet users generally would increase the volume of e-commerce and thus reinforce competitive pressures on firms to adopt cost-saving technologies, while delivering non-measured gains in convenience and customization at a faster pace.

A rising burden of knowledge is an inevitable by-product of technological

progress. Even if the stock of knowledge is accumulating over long periods of time, a possible may be that some future revolution in science can reset and simplify the knowledge space, causing a fall in the burden of knowledge.

The causes of the 1997 Asian crisis. The start of subprime crisis

Mihuț Marius

“Babeș-Bolyai” University of Cluj-Napoca
mihut.marius@econ.ubbcluj.ro

Abstract

This article was started with the theoretical approach of the general economic crisis, the increase/decrease model, by using the process of the money becoming, merchandise money and fiat money. During the time of fiat money there was a break between the material substances from the symbolic value. There was the break when the credit function appeared, because the money and the merchandise cannot circulate simultaneously. The credits have two aspects: a positive one, because it multiplies the possibilities of financing with the same quantity of money; and a negative one, because there is the danger of multiplying of fiat money who will bring increasing value, or much more a symbolic one, of the economy over its inner value, and when trust is lost, there are no money anymore to sustain the growth and the economy will crash.

We have presented the Asian Crisis from 1997 and made a debate on the foreign debt of those countries, the high return rates of investments and the bad allocation, the decreasing rhythm of the exports, the lack of commercial law and of course the huge sums of money taken as loans by the South Eastern Asian countries before the crisis, for investments that had profit rates below the capital cost.

At the end of paper, we tried to present two figures showing and explaining the mechanism of forming and bursting of the speculative bubble.

Key words: increase/decrease model, Asian Crisis, foreign debt, investments, exports, profit rates, speculative bubble.

JEL Classification: E32, G01, G14, G18

1. The theoretical approach of economic crisis. The increase – decrease model

In this attempt of explaining the model increase-decrease we wish to start from the beginning of money. In the evolution process there were two important steps: 1. money as merchandise and 2. fiat money.

1. In this first step money had the function of measurement of value. Money had an intrinsic value. Money and goods are moving simultaneously. It was necessary to pass to next step because gold would have been suffering a depreciation of its physical value if the goods would have been changed for gold.

2. The second step in which money has the function of mean of exchange, and further function of payment. If they are moving with a pushed, imposed value, this value would have been not covered. Without being covered, it becomes fiat money that will work on trust. It would be as if we would take a copper coin and would put a nominal not real value of 1000 \$, but it is not the real value! So those “imposed money” not covered in money as merchandise will not be able to fulfill their main function of unit and measurement of value. “It is the same like in the case in which we cannot measure weight is the gram has no weight itself; the same we cannot measure value if money has not inner value” [7].

In this step the money and the goods are not moving simultaneously. It will be a separation in the material value and symbolic value of the merchandise. If before buying an object the payment would be on the spot, so that money and merchandise would be simultaneously, now we are in the situation in which the merchandise will be on the property of the client when only a percentage will be paid. So we achieved the credit system! The seller credits the client, so that the client will be able to use the money till

the maturity, till it is necessary to pay the seller. So the money will be available in the economy so transactions can be made with them in this period. There will be individuals, entities that will need that money. So the credit can be defined as being a temporary need of money that is temporarily available in the economy. This is also the possibility in which the client pays a certain good and does not receive it but after a period of time. In this case the client credits the supplier, the money being at the availability of the second one in order to be used.

The credit – supplier of supplementary profit but also uncertainty

The credit has two economic consequences: a) a positive one and this because it multiplies the possibilities of financing with the same quantity of money. This financing situation multiplies also the rentability of the investments, and this because the profitability brought is higher than the interest, because otherwise investments will not be made anymore. “The cost and the availability of the credit become important elements of influencing the level of the economic activity; they are probably the most important influence factors in determining the asymmetric shape of the increase/decrease model. “ [9] ... and b) a negative one, because in the real economy fiat money are not fully covered by money as merchandise; there is the danger of multiplying money that will bring increasing value, or much more a symbolic one, of the economy over its inner value. ...the monetary signs without coverage that feeds the over value, and that have as necessity more and more sums of money till we reach paroxysm and to crisis. By cheap credit all the time we had an increase of the symbolic side of the economy, and due to the fact that in some situations in which the hopes of the economic companies are far away from reality, and in spite to converge they are furthering away.

When it is about fiat money, being a convention that it is good as long as exists enough capital to sustain the economic increase. When the players are understanding that the trees cannot grow till the sky, and they are wondering till where can they go, it

is the moment that I like to call it “attention”, after which decrease is coming; so that the trust has a fantastic role in the credit systems... there it is the root of the problem. We will see that this phenomenon happened in Asia in 1997.

The sum of the fiat money should be equal with the sum of goods and services. Everything that it is in plus creates inflation, macroeconomic disequilibrium. That means, as we know it, that the relative value of money is decreasing in comparison with the other merchandises, so that the purchasing power.

Renouncing at the full coverage in gold for money was decided in 1976 in Kingston. From that moment on “there is no need for money guarantee in gold, but with all merchandises of each country” [7]. This is impossible to be put in practice. So was the start for money not covered in real economy.

It is quite true that with the help of the credit, the savings are increasing much more easy and faster, but it is also true that if the trust vanishes than a major decrease can happen.

Once in crisis the banks, trough their representatives, will become more strictly in crediting, saying that will make no exposure once again. And they are not doing it, until they will hold major liquidities. Then they will let money flew, and a new cycle begins. This happened in the '70, and in 1882, than a follow up in Mexico in '94, than the Eastern Asia crisis in 1997, and the crisis of today so called « subprime ».

2. Causes of the Asian crisis

Japan, the wealthiest country was not the only one to increase in such a spectacular way. It was followed by the South Eastern Asian countries, so called dragons (South Korea, Singapore, Hong-Kong and Taiwan). As the figures are showing those countries had a annual average economic increase of 8% from 1970 till 1996.

Table 1. The economic increase of the South Eastern Asian countries, 1970-1998, (in %)

	1970-1996	1997	1998
Singapore	8.2	7.5	0
Hong Kong	7.5	5.2	-4.5
South Korea	8.4	5.5	-6.5
Taiwan	8.3	6.8	4.5
Malaysia	7.4	7.4	-4.7
Indonesia	6.8	6.8	-15.5
Thailand	7.5	7.5	-7

Source: [3]

Those incredible performances were called “the Asian miracle”. But in 1997 this Asian miracle let place to the Asian crisis, and in the majority of cases it was the pass from strong economic increase to devastating recession. The causes of this crisis will be analyzed as follows.

The Asian countries were the victim of the speculative unjustified attacks? The crisis was the consequence of those speculations? The currencies and the stock markets were victims or causes? Are some of the questions that lead to many speculations along the time, without achieving consent? Some economists considers that this crisis was obvious because the economies of those countries had structural problems that sooner or later should have been shown or the other size of the economists front that sustains that there were no reason to panic, and that the only cause of the crisis was panic for the investors in special the foreigners.

2.1. The deficit of the balance of trade and the investment rate

One of the macroeconomic disequilibrium’s of the South Eastern Asian countries was the trade balance deficit. A high trade balance deficit and a deficit of the current account, it is commonly considered as being a problem, because it needs an adjustment, a macroeconomic one, but, before the crisis, at the Asian countries was understood as a sign of the forced that they have had. For a better understanding we present you the trade balance equation:

$$NX=S+(T-G)-I. [3]$$

The trade balance is equal to private total savings (S), and public savings (T-G), minus investment (I). From here results the fact that a deficit can have three causes: a weak

degree of private savings, a budgetary deficit (T-G<0), or a high return on investment rate. So before concluding that a foreign deficit is a positive situation, we must know the source of it. Generally speaking, if it is the cause of a high investment rate, it is not a concern, because they are invested money of today that will bring money in future to cover the deficit. If there is another cause then the foreign trade is concerning.

In the table below there are macroeconomic indicators that have been characterizing the most affected economies in 1996, in % of GDP:

Table 2. Trade balance, current account, investment rates and government fiscal balances (in % of GDP), South Korea, Malaysia, Thailand, Indonesia, Philippines.

	South Korea	Malaysia	Thailand	Indonesia	Philippines
Trade balance	-4.3	-4.9	-8.1	-3.4	-4.8
Current account	-4.8	-3.7	-8.5	-3.3	-4.7
Investment rates	38.4	41.5	41.7	30.8	24
Government Fiscal Balance	0.5	0.8	1.0	1.3	0.3

Source: [8]

From this table we can see that the governments had budgetary surplus, so the foreign deficit was due to the high rate of investment; and how investment had a low profit rate, sometimes below the capital cost⁷, this was one of the causes of the Asian crisis. In order to observe better the efficiency of the investments we will present the ROIC indicator that is relation between the investment rate and the output growth rate.

Table 3. Incremental Capital Output Ratio (ICOR) in 1993-1996

South Korea	Malaysia	Thailand	Indonesia	Philippines
4.9	4.8	5.1	3.9	5.5

Source: [6]

⁷ For example, in Korea, 20 of the highest 30 conglomerates had results below the capital cost in 1996

The investment rate and the inflow of capital continued the rally even after the negative signs that low return rate brought, only hurrying crisis.

We need to take into account also another aspect of the investment, which means their lack in the technological progress. It is a fact that an increase can be sustained without technological progress only for a limited period of time and this because we use the capital for each worker till the investment achieves 100% from the production. [3] This scenario was at the bases of the Asian miracle, high returns of investments, without technological progress, so the increase should end sometimes.

2.2. The exports and commercial law

It has been seen that the slowing increasing growth of exports. The Asian economies had a average growth is only 5% in 1996, while the increase of approximately 20% in 1994 and 1995. The reasons are many between of: the long economic stagnant increase of the Japanese economy after 1990, the decrease of prices for products for IT (for ex. DRAM) that have been a major part of the exports of that specific country, devaluation of the Chinese currency, the appreciation of the US dollar in comparison with the Japanese currency, etc. The massive inflow of capital together with the decrease of the exports leads to the increase of the trade balance deficit.

One cause of the Asian crisis can be the commercial law that had a lack of knowledge. For instance the bankruptcy law. In Malaysia there is no legal matter on such a thing. One bankrupt company can continue the activity. If the creditor wishes to have the money back there was no legal tender to force the borrowed to pay the debt, the assets cannot be liquidated.

2.3. Formation and splashing of the bubble

At the beginning of the 90 there was the financial market liberalization. Many countries from South East Asia eliminated the control on capital movement, opened the markets for foreign investors, and lifted the

restrictions in the banking activities and insurance. In addition those states established an agreement that linked their currencies to the US dollar. Those aspects encouraged the business world and domestic banks to loan in foreign currency in order to invest or to lend locally in real estate business and capital market. As a follow up in each phase of expansion, the prices of the real estate and shares increased rapidly bringing more capital in this part of the world, especially as banking loans and short term investment. Also in the favor of bringing capital the projects were guaranteed by the states. The pressure to guarantee the projects were made by big corporations in order to maintains the increase. The risk payments attached to those international loans made by Asian States diminished by the beginning of 1997, and rating agencies did not conceived the risk till June 1997 [2]. The market operated with the idea that the return on investment was ensured against shocks. These pressures and credits were simultaneously brought with capital accumulations that lead to a strong deficit of the current account.

As Paul Krugman said: "value – Pangloss: in the situation of the government guarantee, the banks are used to follow the future value, the most optimistic in order to evaluate the investment projects, that will lead to over-evaluation of the projects." [5]

The institutional investors (funds) «are measuring the activity by comparison between others, that will make them like a and makes them follow each other...When one of the markets is increasing value, they must increase investments onto that market, otherwise they become thin and backwards»[9]. Those institutional investors are using other people money and between them there is a huge competition being a fight for clients; and they must report results better and better, so they must go there where capital is having a very high return rate. But when problems appear in order not to report a decrease in the portfolio, the funds are hurrying to sell and this huge supply of value titles will lead to decreasing prices.

Some American fund managers understood the disequilibrium's for those countries and

at the beginning of 1997 started to sell in margin⁸ the Thai baht and Malaysian ringgit. Coincidence or not, according to Bijan Aghevli, the former vice-director of adjunct Department for Asia- Pacific of IMF, the organization that put on guard on the local authorities at the beginning of 1997 (without making public), but «it was difficult to convince them of the gravity of the future problems».[1]

Understanding that will follow a depreciation of the local currencies, the institutional investors withdraw largely in the summer of 1997, fact that brought dismantle of the fixed exchange rate with the US dollar. As an immediate consequence was the devaluation of the national currencies, that led to increasing crisis, because the loans were in the majority large, and short loans in US dollars, fact that led to external shocks. Together with the depreciation of the currencies in link with the US dollar the debts were much more burden.

The biggest problem connected to the loans taken was bad internal allocation of these funds brought from foreign markets, and this from many reasons between we can mention: „lax supervision and weak regulation, law capital adequacy ratios, lack of incentive-compatible deposit insurance schemes, insufficient expertise in the regulatory institutions , outright corrupt lending practices”[8], bad credits⁹, the lack of a governmental strategy that will make entrepreneurship to have wished results¹⁰, etc.

If we take the example of South Korea we should talk about their conglomerates, so called chaebols. These were huge family companies that would benefit from the State help. The link with the power brought

banking credits even that they could have no guarantee.

Table4. Financial conditions that most companies had at the end of 1996 (in hundred million won and %).

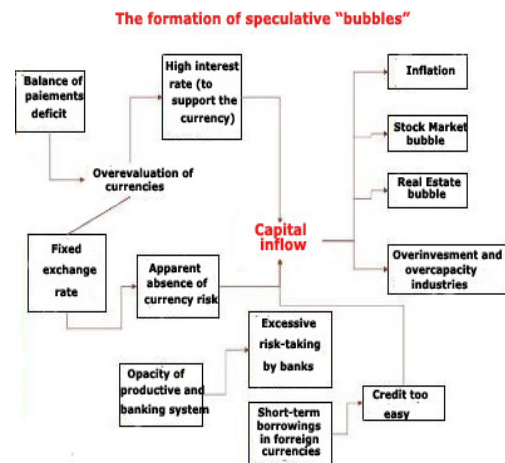

Chaebol	Total Assets	Debt	Sales	Net Profit	Debt/Equity ratio
Samsung	509	370	601	1.8	268
Hyundai	532	433	680	1.8	439
Daewoo	342	264	382	3.6	337
LG	371	288	467	3.6	347
Hanjin	139	118	87	-1.9	557
KIA	142	119	121	-1.6	524
Ssangyong	158	127	195	-1.0	409

Source: [4]

In USA this Debt/Equity rate had an average of 70% in 1996. So that, in 1996-1997, eight from the biggest chaebols were destroyed by the huge debts that were contracted. So from 1996 were sent alarm signals regarding the imbalances of firms.

Before the conclusion, we want to expose the mechanism of formation and bursting of speculative “bubbles”.

Figure 1. The formation of speculative “bubble”

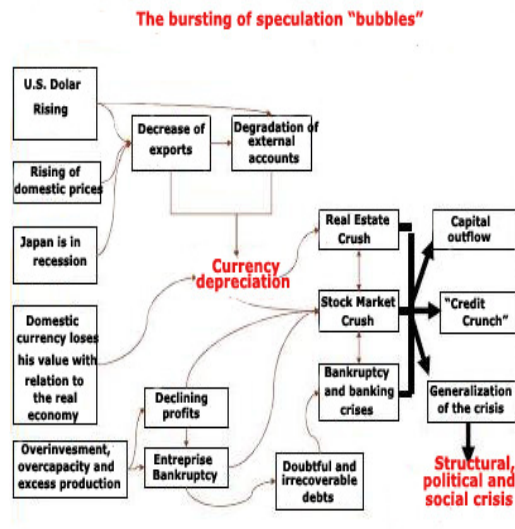

⁸ Short selling means the selling of a security that the seller does not own, or any sale that is completed by the delivery of a security borrowed by the seller. Short sellers assume that they will be able to buy the stock at a lower amount than the price at which they sold short

⁹ By some non official sources quoted by World Bank, bad credits were in South Korea approximately 70% of the own capital of the banks

¹⁰ Starting with 1994, over 40% of the new investment were made in the real estate business, that we cannot say that it is not productive but for sure less productive «a la long» than investment in research and development or why not developing new industries

that are seeing this Asian crisis as being one that started from fundamental problems; from here started the legitimate panic of the foreign investors.

Figure 2. The bursting of speculative “bubble”

3. Conclusions

In conclusion, those being the causes presented, we are closed to those economist

Human Development and Romania's Position in the World

Moise-Țiței Adina
Ovidius University of Constanta
adinatitei@yahoo.com

Abstract

The purpose of the present paper is to make a brief presentation of what human development means in Romania. There are a variety of approaches to measure and monitor different aspects of poverty and human development in general, for our purpose we selected the synthetic indicators proposed by United Nation Development Programs, we will analyze the trend recorded by them and we will compare the position of our country in the European and global scale in terms of development.

Key words: human development, synthetic indicators, UNDP

JEL Classification: O15

1. Introduction

Human development must be seen as a new medium where people can fulfill their entire creative potential, they base their existence on needs and interests, with multiple choices- this is more than national income growth or other traditional indicators. Everyone is entitled to a long and healthy life and we all deserve to be informed, to access the resources necessary for a decent standard of living, but also the right to participate in the community life and in the decisions concerning them. The ultimate goal is to create an opportunity for all the members of society while respecting human rights, thereby, increasing respect for self and others.

2. Measuring Human Development

Measuring human development is part of the concern of numerous experts, and the results of their studies arouse public interest, especially in the current context, of

globalization, and competition among nations.

Of the many ways, we stopped to that used by Human Development Rapport (HDR), annually published by United Nation Development Program (UNDP). In these rapports we found many indicators, but we focused on those discussing Human Development Indices (HDI), which combine indicators of life expectancy, educational attainment and income. The HDI sets a minimum and a maximum for each dimension, called goalposts, and then shows where each country stands in relation to these goalposts, expressed as a value between 0 and 1.

The educational component of the HDI is comprised of adult literacy rates and the combined gross enrolment ratio for primary, secondary and tertiary schooling, weighted to give adult literacy more significance in the statistic. The life expectancy component of the HDI is calculated using a minimum value for life expectancy of 25 years and maximum value of 85 years and for the wealth component the goalpost for minimum income is \$100 (PPP) and the maximum is \$40,000 (PPP). The HDI uses the logarithm of income, to reflect the diminishing importance of income with increasing GDP.

Given the imperfect nature of wealth as gauge of human development, the HDI offers a powerful alternative to GNP for measuring the relative socio-economic progress at national and sub-national levels. Comparing HDI and per capita income ranks of countries, regions or ethnic groups within countries highlights the relationship between their material wealth on the one hand and their human development on the other. A negative gap implies the potential of redirecting resources to human development.

Table 1 – The trend of Human

Development Index for Romania

Year	Life expectancy index	Education index	GDP index	HDI value
1998	0.753	0.886	0.673	0.771
1999	0.747	0.883	0.684	0.771
2000	0.747	0.884	0.695	0.775
2001	0.758	0.881	0.679	0.773
2002	0.758	0.875	0.698	0.777
2003	0.772	0.889	0.716	0.792
2004	0.775	0.899	0.741	0.805
2005	0.783	0.907	0.781	0.824
2006	0.788	0.915	0.794	0.832
2007	0.792	0.915	0.804	0.837

Sources: HDR, 2000-2009

The table data shows us the dynamic components of the HDI index for a period of 10 years, from 1998 until 2007. For each of them, like access to education, life expectancy and the possibility of having a decent life trend is highlighted. Their contribution to Romania's development level change during is equal, because HDI is calculated as the simple arithmetic average of the other three indices.

Figure 1 – Components Evolution of the HDI for Romania

Analyzing the graph we noticed that all three indicators have a tendency to

increase, the most pronounced being the index of living standards. It is not either negligible the positive evolution for the education index, which is due to the increase registered at various levels of schooling.

Regarding life expectancy index, it has an average of 0.7673 units for the period under review, with a mean absolute increase of 0.0043 units per year and an average relative increase of 0.56% annually. *Education Index* has an average of 0.8934 units, an absolute average increase of 0.0032 units annually and the relative average increase of 3.16% annually. Also, the standard of living index has an average of 0.7265, an absolute average increase of 0.0145 units, and the relative average increase 1.99% annually. Therefore, the mathematical observed values, register the positive trend of all components of the HDI index.

To make a forecast for the next period values we assume that all the components will follow the same linear upward trend. Thus, we have long linear features such as: $Y_t = a + bt$, where a and b are function parameters, t represents time, and Y_t are projected values for selected indicators.

- for the life expectancy index the linear function that describes the evolution of the indicator is: $Y_t = 0.7673 + 0.002675 t$;

- for the education index the linear function that describes the evolution of the indicators is: $Y_t = 0.8934 + 0.002024 t$;

- for income index the linear function that describes the evolution of the indicator is: $Y_t = 0.7265 + 0.007827t$;

Table 2 - Projected values for HDI components

Extrapolation	Year		
	2010	2011	2012
Life expectancy index	0.802	0.812	0.818
Education index	0.923	0.927	0.931
GDP index	0.843	0.859	0.875

Note: Extrapolation was made without taking into account the negative effects that the current economic crisis will have on parameter values and in particular on GDP

Figure 2 – Evolution of the HDI

HDI values recorded during the analyzed period placed Romania among the countries with medium level of development until 2003 including, but since 2004 our country is located in the developed countries group, in which case the HDI value exceeds 0.8.

HDI is calculated as the simple arithmetic average of the three indices previously analyzed. It is recorded an upward trend for the period 1998-2007, as can be seen from the chart.

The average HDI value for the period under consideration is 0.7957, the average absolute increase of 0.0073 units annually and the relative increase is 0.91% annually.

For the next period the indicator values can be estimated using a linear function of time: $Y_t = 0.7957 + 0.004172t$. Thus, the project values for HDI are as follows:

Table 3 - Projected values for HDI

Extrapolation	Year		
	2010	2011	2012
HDI	0.858	0.866	0.874

The upward trend of the HDI will continue for the next years, the component that will constantly increase is the level of education, because enrollment in secondary and tertiary education system is in fashion. Unfortunately, the GDP per capita growth captures only the mean change in real disposable income for the lower level of the hierarchy can decrease, while for the rich it will increase.

3. HDI and Romania's Position in the World

As following, base on the available data, we tried to illustrate Romania's position in relation to other European countries or with other countries of the world in terms of human development.

Of the multitude of statistical information provided HDR 2009 published by UNDP we took into consideration several indicators which we considered relevant to our approach, namely: GDP per capita (PPP US\$), life expectancy index, education index and human development index (HDI). We considered highly relevant the information corresponding to 2007.

Table 4 - The Hierarchy after HDI

Economic landmark	HDI 2007	GDP per capita (PPP US\$)	Life expectancy index	Education index
<i>Very High Human development</i>				
1. Norway	0.971	53433	0.925	0.989
2. Australia	0.970	34923	0.940	0.993
3. Iceland	0.969	35742	0.946	0.098
4. Canada	0.966	35812	0.927	0.991
...				
9. Switzerland	0.960	40658	0.945	1.000
10. Japan	0.960	33632	0.961	0.971
...				
36. Czech Republic	0.903	24144	0.856	0.938
37. Barbados	0.903	17956	0.867	0.975
38. Malta	0.902	23080	0.910	0.887
<i>High Human Development</i>				
39. Bahrain	0.895	29723	0.843	0.893
40. Estonia	0.883	20361	0.799	0.964
41. Poland	0.880	15987	0.842	0.952
...				
63. Romania	0.873	12369	0.792	0.915
...				
83. Lebanon	0.803	10109	0.781	0.857
<i>Medium Human Development</i>				
84. Armenia	0.798	5693	0.810	0.909
...				
158. Nigeria	0.511	1969	0.378	0.657
<i>Low Human Development</i>				
159. Togo	0.449	788	0.620	0.534
...				
182. Niger	0.340	627	0.431	0.282
OECD	0.932	32649	0.900	-
Europe	0.902	24775	0.832	0.954
EU27	0.937	29956	0.899	-
World	0.753	9972	0.708	0.784

Sources: HDR 2009

Analyzing the above table, we stopped to some issues that show Romania's position regarding human development.

Compared to the European Union, a community of countries with high human development, Romania, as a full member, registered an HDI of 0.837 for 2007 and is situated on the list of countries with a high degree of human development.

In terms of GDP indicator per capita, our country has a value of 12,369, of 2.42 times lower than the European average. Life expectancy index is less than the European average of 1.13 times and the average of life expectancy is only of 70.5 years. The education index is 0.915, slightly lower than the European average which shows Romanians' appetite for diplomas.

If we compare the values of indicators registered for Romania with the values recorded for OECD countries, the differences are even greater, which indicates the low level of human development for our country. Significant differences were recorded for GDP per capita and life expectancy at birth.

In order to illustrate Romania's position in terms of human development we also used in our comparison the values of indicators such as Norway, which is placed on a well deserved top position, and Switzerland, situated on the 11th position; it is worth mentioning the fact that both countries are not members of the European Union.

5. Conclusions

Romania's desire to become a modern, inclusive society, cannot ignore the aspects concerning life quality and human development in general. The calculation of indicators and international comparisons

can provide us information on the progress of Romania in developing multiple perspectives and helps us in taking action to achieve our goals.

Thus, analyzing the HDI calculated values using the method UNDP, we can conclude:

- for the period 1998-2007 it has been considered an assessment of the human development index and its components, with a small decrease in 2001 compared to 2002;

- since 2002 HDI recorded a significant increase from year to year, as higher levels of education and increase GDP per capita;

- all three components of HDI records a positive contribution for the period under review, significant is the average GDP per capita and less important is the life expectancy which increased slightly from 70.2 years to 70.5 years.

Romania's position after HDI ranking, according to HDR 2009, is 63, which places it on the top of the list, but international comparisons with other European Union countries or with other Europe countries, show us a disadvantage in sustainable development in general and especially in human development.

Things are even more worrying, as our position is after the countries that have a potential much more modest than ours. Unexploited potential is one of the causes of "backwardness" and among the culprits are the deficient political management and the ineffective governance.

Economic Behavior According to the Principles of Sustainable Development

Moise-Țiței Adina
Bacă Eleonora
“Ovidius” University of Constanta,
adinatitei@yahoo.com
eleonorabaca@yahoo.com

Abstract

Today, sustainable development is a global responsibility, as long as phenomena such as poverty, hunger, poor access to medical services or pollution accompany permanently the life of billions of people. Therefore, we in what follows we will try to make a brief presentation of some possible solutions, in accordance with the principles of sustainability, which could make a better life for all of us. The solutions we are thinking about are not only related to a new way of consumption, but also, to a new mode of production. We took into consideration proposals which respect freedom, fairness and human values.

Key words: sustainable development, economic growth, consumption

JEL classification: Q01

1. Introduction

The economic dimension of sustainable development means the dematerialization of the economic growth. It also requires focusing on competitiveness, particularly through the dissemination of efficient technologies. Increased competitiveness is the result of a number of factors which target a new structure for the economy. The activities of research and innovation increase the share of services and activities with high value added, a “clean” life in terms of environmental, labor skills to ensure growth, labor productivity growth, etc.

Especially for the developing countries, there is a strong need of targeting tech investments, of reducing energy consumption—the goal of these actions is to decrease the gap

between different national economies. Thus, all these become necessary in order to modernize the existing production capacities, to improve energy efficiency, to offer renewable energy resources, and also for the investment in research that may offer new technical and technological solutions. As for this last point, the poor links with the economic sector caused delays in the technologic transfer of research results and reduced the recovery.

2. A New Way of Consumption and the Reconsideration of Needs

The action plan for sustainable development adopted at the Earth Summit, held in Rio de Janeiro in 1992, mentioned as major cause of continued deterioration of global environment the deficit model of consumption and production, particularly in industrialized countries [1]. The message reflected the complexity of the problems we are facing: poverty as well as excessive consumption by affluent populations places a damaging stress on the environment.

According to statistics 15% of the world population living in developed countries accounted for 56% of global consumption, while the poor, representing 40%, accounted for only 11% of this. Current consumption exceeds the planet's ecological capacity, leading to erosion of natural capital at a significant rate.

Sustainable development calls for a review of the consumption in accordance to the finite quantity of resources. All these determine us to reconsider the wastage and the false needs, to rationalize the consumption and rethink the concept of need. The minimal bioeconomics program proposed by N.G.Roegen urges us to

give up fashion, and to think that actions such as: changing the car every year or housing redevelopment every two years is a bio-crime [2].

In his actions the man uses all his abilities to obtain maximum and immediate benefit. The increases in the extraction of energy and mineral resources, create a larger capacity of production. This ultimately proves to be a behavior that ignores long-term adverse consequences. It is specific to the postwar period, when economic growth was sustained by a stimulated demand.

If we consider the sovereignty of the consumer as being the most important concern, the pollution and environmental damage are not part of industry concerns and the damage costs of air, water and ambience will be immediate consequences we will all have to face. If we consider the sovereignty of the manufacturer, it will assume responsibility for those taken, without ascribe to consumers, especially in the context of their manipulation. *Galbraith* explains that the need to manage, lead and influence consumer behavior is dictated by the circumstances of modern industrial life which through the use of sophisticated technology and large investments generates large organizations inflexible and vulnerable.

An intensely debated question is whether today's society belongs to the consumer or deals with a consumer society. The producer's attitude is characterized by an excessive advertising that removes consumers' reticence and the show is directed by publicity campaigns and financed by the producers of goods.

The freedom of consumers is also restricted by the show offered to him. The purchases we make highly depend on the social category to which we belong or rather that which we would like to belong, thereby, increasing the social role of consumers in accordance with their incomes and developing an unnecessary and ostentatious consumption.

Natural needs have limits, but the potential for consumer goods is high once the goods acquire social significance. Income becomes the main factor determining the dynamics of consumption and individual behavior is influenced by a number of subjective factors.

Keynes, in his book "The General Theory of

Employment, Interest and Money", mentions eight "mobiles" which determine people to spend: foresight, prudence, calculation, thirst for prosperity, independence, business spirit, pride and avarice and six other "mobiles" that stimulate the appetite for consumption as thirst for satisfaction, myopia, generosity, recklessness, ostentation, extravagance. According with this, the real result of economic process is the pleasure to exist[2].

The goal of sustainable development is human development first, although it should be not done at any price. The satisfaction of needs must contribute to the affirmation of human personality in economic, social, political, cultural sphere.

3. A New Mode of Production

The classical type of economic growth is based almost entirely on non-renewable resources such as fossil fuels or others. This attracted severe criticism from economists and especially from environmentalists, sociologists, philosophers or human rights defenders.

Moreover, the branches of production are autonomous and divided; creating problems to the recycling of waste products. Thus, an entire branch of industrial production that can be used in agricultural production remains unused.

One of the proposals for a new mode of production is the "trivalent enterprise" concept developed and supported by the researcher Maria Popescu. She proposed to integrate the production vertically and horizontally, which would enable a system of operation without any waste, according to nature's model [3]. In this way all material's components and energy resources will be treated, to obtain larger quantities of goods and services with the same quantities of raw materials. The enterprises will produce the goods required on the market, the companies will be downsized, reorganized and restructured according to the overall development prospects and these will be integrated into the local context. The companies should "live as a network", closed in a circle and creating goods without pollution and unemployment.

A new mode of production also means cleaner production, with fewer pollutants

discharged into the natural environment and less waste. There are serious attempts at replacing the fossil fuels with clean renewable resources like biomass, solar, wind, tidal power.

Eco-industry produces not only goods aimed at preventing pollution, but also property intended to measure, limit or correct environmental pollution. The machinery and equipments will be used for water treatment, waste, air protection, beginning on the premise that a once polluted environment cannot be "cleansed" as in the initial phase. All these are possible under severe legislations which could govern, manage and save the environment. There should also be severe rules concerning the incineration, transport and storage of the dangerous waste.

If we take into consideration a new mode of production, we cannot forget biological agriculture. The greed and desire for progress, the intensive management of this sector the desire to achieve performance comparable to that used in industry, have produced changes with adverse effects on human life, the environment, the quality of land, water or forests.

It is assumed that agriculture, forestry and fish are part of the natural environment and, in this spirit, we consider important the cultivation of resistant pest varieties, increase soil fertility through the use of natural fertilizers made in close circuit of the farm, proper crop nitrogen fixation in soil, the use treatment and spray preparations produced from vegetable etc.

In our opinion, the mode of production that characterized the last century cannot continue, we must reconsider the system of needs, and it will be necessary to change the consumption and the production in the above mentioned direction, so that the economic policies implemented can be a real response to the sustainable development aspirations.

4. Conclusions

The criticism brought to production and consumption from different positions all validate the same conclusions. Thus, the waste of any kind becomes hard to tolerate, the

poverty placed on the background of an apparent wealth, the damages brought to the environment, the suffocation of overcrowded and over-polluted cities etc. Under these circumstances it becomes necessary to replace the type of growth with a rational one, based on matrix of values and a technical one based on production and consumption. The new way has to be rational in terms of the use of all types of resources (financial, human etc), to be based on clean industries, biologic agriculture, it should also marginalize 'heavy' industries and it should promote information based industries.

All the countries of the world, irrespective of their development need a durable development: the developed states need to keep their standards in terms of their quality of life, the less developed ones need to eliminate their delay. The amplitude and the peculiarities on national economies impose a different approach even if the initial starting point is represented by unanimously-acknowledged requirements.

In the case of Romania, for example, durable development represents the way through which the inherited economical deficiencies can be diminished. The problem is far from being simple, the instability of economic processes and the deep crisis from which it started make things more difficult. However, even under these circumstances we believe that durable development is a viable alternative capable to give birth to useful ideas and actions for such a vital concern.

"Ovidius" University of Constanta

Ph.D Student Mihailescu Emil Raul

Abstract

Law 273 of June 29, 2006 on local public finances establishes the principles, the framework and the procedures regarding the formation, administration and utilization of local public funds, as well as the responsibilities of local public administration authorities and of public institutions involved in the local public finance domain. This law also clearly stipulates the coordinates of budget execution at local level, to which we will be referring. Local budgets elaboration stands for a complex process, and at the same time, a strict regulated process in the Romanian public financial law.

Key words: budget programming, amount limits, public investments, budget execution.

JEL classification: H6

1. Local budgets - procedural steps

According to the Law on local public finance, Ministry of Public Finance shall transmit the general public finance departments, the county councils and the General Council of Bucharest, until June 1 of each year, a framework-letter which will specify the macroeconomic context on which the forecasted budget projects will be created, their elaboration methodologies, the limits of amounts recouped from some state budget incomes and from consolidated transfers throughout Bucharest, in order for credit officers to elaborate budget projects.

The credit officers of the state budget or other budgets, budgets in which are stipulated transfers to local budgets, send to local public administration authorities

the amounts within 10 days of receiving receipt of the expenditure limits approved by the Government, in order to encompass them within the budget projects. The same officers, while considering the limits of the received amounts, prepare and submit to the general directions of public finances, until July 1 of each year, balances local budgets projects and their annexes, as well as the estimations for the next 3 years, and thereafter they sent the local budget projects throughout Bucharest at the Ministry of Public Finance until July 15 each year.

Within 5 days after publication of the state budget law in the Official Gazette of Romania, Part I, the Ministry of Public Finance shall transmit to general departments of public finances the amounts deducted from certain incomes of the state budget and the consolidated transfers approved by the budget law state. The general departments of county public finances, namely Bucharest, as well as the county councils and the General Council of Bucharest, allocate on administrative-territorial units within 5 days of notification, the amounts deducted from certain incomes of revenue, as well as the consolidated transfers for the completion of local budget projects by the credit officers.

Taking into consideration the individual incomes and the distributed amounts, the credit officers within 15 days after publication of the state budget law in the Official Gazette of Romania, Part I, completes the local budget project, which will be published in local newspapers or will be displayed at the administrative territorial unit's main office. Administrative territorial unit's residents can lodge complaints on the budget project

within 15 days after its publication or display.

Within 5 days after the deadline for submission of appeals, the local budget project, accompanied by the credit officer's report and the complaints made by residents, is subject to the approval of authorities, namely the credit officers.

Deliberative authorities, not later than 10 days from the date of submission for approval of the budget project, pronounce the result of litigations and adopt the local budget project after it was voted on chapters, subchapters, titles, articles, paragraphs and annexes.

The budget projects are approved by the authorities no later than 45 days after the publication of the state budget law in the Official Gazette, Part I.

If authorities do not approve the local budget projects within the legal time, the general departments of public finances order the suspension of supplying quotas, namely amounts deducted from certain incomes of the state budget and of consolidated transfers until they are approved by authorities. In this case, out of the local budget there can be made payments only to the extent of the other incomes' limit.

Under this law, the credit officers are required to submit the approved local budgets to the general departments of public finance within 5 days from their approval. The general departments of public finance prepare and submit within 10 days to the Ministry of Public Finance the budgets throughout each county, respectively Bucharest, that are grouped within each county and within Bucharest into villages, towns, cities, sectors of Bucharest and county, taking into consideration the budget classification structure.

Note on the budget process in case of non-approval by Parliament

- If the state budget law has not been adopted by at least 3 days before the end of the financial year, the previous year budgets will continue to apply until the approval of the new budgets, the monthly expenditure limits usually exceeding 1/12 of the previous year budgets, with the exception of special cases that are solidly justified by

credit officers, or, where applicable, 1/12 of the amounts proposed in the budget project, if these are lower than those of the previous year.

- Public institutions and new-approved measures in the current year, which start with 1 January of the next budget year, will be funded until the budget approval, up to 1 / 12 of their provisions included in the budget project.

- The general departments of the public finance will grant administrative-territorial units amounts deducted from certain budget incomes and consolidated transfers of 1/12 of the previous year's budgetary provisions within the monthly limit.

- If the amounts deducted from certain state budget revenues and consolidated transfers exceed a monthly limit of 1 / 12 of the previous year budgetary provisions after the full use of incomes and allowances deducted from certain state budget incomes, the general departments of public finance may approve their supplementation based on analysis and substantiations presented by credit officers.

- If the amounts shown above (section 4) are proposed in the state budget project as lower than the previous year, monthly limits are given to the quota of 1/12 of the amounts proposed by the state budget project.

2. Local public investments

Based on the public investment program of each administrative-territorial unit, public investment expenditures and other investment expenses financed by local public funds are included in the budget projects made by the credit officers, which are also presented in section D as annex to the initial budget, and respectively, corrected and approved by the authorities.

The credit officers of the local budgets annually create the public investment program on a functional classification. For each object included in the investment program are presented financial and non-financial information.

The technical-economic documentation of the new investment objectives, whose finance is fully ensured or supplemented from the local budgets, as well as those financed from internal and external loans, contracted directly or guaranteed by local administrative authorities, are approved by the authorities, while those of new investment objectives, which are financed from external loans and, in addition, from transfers from the state budget and other sources, as well as those financed integrally or supplemented from external contracted loans or guaranteed by state regardless of their value, are subject to Government approval.

The technical-economic documentation for investments designated to prevent and remove the effects of accidents or natural disasters, as well as the consolidated notes regarding other investment expenses included in the global position which are developed and approved according to law, are approved by credit officers while immediately inform the authorities.

The credit officers update and approve on their own responsibility the value of each new or continued investment objective, regardless of funding sources or the competence of their approval, taking into account the evolution of price indices. Investment objectives and other investment charges on investments are included in the annual investment programs, being annexes to the budget only if the technical-economic documentation and the consolidated notes regarding the necessity and opportunity of making investment charges have been previously developed and approved under law.

Obviously, all the credit officers are the ones who determine the priorities in the allocation amounts for each objective registered in the investment program within the limit of funds included in the budget project for this purpose, while ensuring accomplishment of investment objectives within the approved execution term.

The investment objectives are nominated into investment categories within the investment programs as follows: continuing investments, new investments and the "other investment

expenditures" global position. Investment costs are detailed in separate annexes by the credit officer, based on consolidated notes, which will include elements referring to the necessity, the opportunity and to other indicators characteristic of such investments, and are approved by the authorities together with the local budget.

If the case when during the budget implementation, for objective reasons, the implementation of an investment project can not be achieved according to the budget projection, the local budgets' credit officers may propose authorities, until October 31, the approval of funds redistribution among investment projects included in the program.

3. Progress of budget implementation. Specific principles

The progress of budget execution is based on some specific principles:

- Incomes and budget appropriations are approved and included in the budget classification structure through local budgets;
- Budget appropriations are authorized during the budget year;
- Approved personnel costs can be increased by budget appropriations transfers;
- Transfers of budget appropriations from one chapter to another chapter of the budget classification and from one program to another must be approved by the authorities, based on appropriate justifications of the credit officers, and may be made before expenditures are running;
- Transfers of budget appropriations within the same budget chapter, including between same chapter's programs, that do not contravene with this Article, the state budget law or the law of rectification, are the responsibility of each credit officer for the individual budget and the budgets of institutions and subordinated public services and may be made before expenditures are running;
- Proposals for budget appropriations transfers are accompanied by justification, particularization and the

need for implementation of budget classification subdivision and chapter until the end of the budget year, as well as of the program from which it dismisses, and of the chapter and the budget classification subdivision on which budget provisions are supplemented respectively;

- Transfers of budget appropriations under the conditions specified in section (4) and (5), may be made starting with the 3rd trimester of the budget year.

Incomes and budget expenditures' allocation on trimesters

Revenues and expenditures approved by the local budgets are distributed in trimesters, according to the legal terms of revenue collection and the period during which expenditures are necessary.

Endorsements shall be issued by:

a) the Ministry of Public Finance, for amounts deducted from certain incomes of the state budget and for transfers from this budget, based on proposals of the local budgets' credit officers, transmitted by the general departments of public finances within 20 days from the publication of the state budget law in the Official Gazette of Romania, Part I. Thus, the approved amounts shall be allocated on administrative-territorial units by the general departments of public finances;

b) the local budgets' credit officers, for budgets available to them within 15 days after approval of the amounts referred to in points. a).

Transfers' repartition on trimesters, as well as their modification shall be notified by the credit officers of the state budget or other budgets to the local public administration authorities within 10 days after the approval by the Ministry of Public Finance of budget credits repartition on trimesters.

Budget appropriations approved by local budgets can be used through open credits made by their credit officers while considering the approved amount limits, according to the specified destination and in compliance with legal provisions governing such expenditures.

Budget appropriations openings for transfers from the state budget or other budgets to local budgets within limits set

by that respective budgets, are carried out by the Ministry of Public Finance through the general departments of public finance, at the request of local budgets' credit officers, according to the needs of budget implementation concerning its destination, or by other credit officers for legal transfers.

Budget expenditure is made only based on justificatory documents confirming contractual commitments, receiving of material goods, provided services, works executions, payment of salaries and other entitlements, payment of budgetary obligations as well as other obligations.

In the case when during the budget year, based on legal provisions, there happen to exist transfers of institutions, actions or tasks to the concern of local administrative authorities, the Ministry of Public Finance is authorized to introduce appropriate changes in the state budget's volume and structure, without affecting the budget balance.

Budgetary appropriations related to non-refundable external funds have a predictable character and run under agreements concluded with foreign partners. Non-refundable external funds will be collected in a separate account outside the local budget and will be spent only within the limits of this account and for the purpose for which they were granted.

4. The main coordinates of budget execution

In the budget execution process, budget expenditures go through the following phases: commitment, validation, authorization and payment. Budget execution in towns, cities, sectors of Bucharest, counties and in Bucharest is based on the principle of separation of power between persons having the quality of credit officers and persons who have the quality of accountant.

Operations specific to expenses' employment, liquidation and ordination are in the attribution of credit officers and are executed based on notifications of public institutions departments.

Expenses payment is provided by the financial-accounting chief while considering the limit of available funds. Payment instruments must be accompanied by evidence. These justifying documents must certify the accuracy of paid amounts, receipt of goods, execution of services and others alike under legal commitments. Payment instruments are signed by the chief accountant and the chief of financial-accounting department.

Payments execution within the approved budget appropriations limit shall be made solely on the basis of documentary evidence made in accordance with laws, and only after they have been committed, liquidated and passed.

Payment expenses at villages and at public institutions, on which the financial accounting department has a staff number of less than 5 persons, are provided by the credit officer and the authorized person responsible for accounts in compliance with methodological norms regarding the organization, recording and reporting of budgetary and legal commitments.

For certain categories of expenditures there can be made advance payments up to 30% under the law. Amounts representing advance payments that are unjustified through delivered goods, works executed or rendered services until the end of the year will be recovered, under the contractual provisions, by the public institutions that have granted the advances and will be returned to the budget which gave the credits.

In the case of failure to deliver goods, execute works or render services for which advances have been paid, that particular public institution can recover the amounts by perceiving price increase for delay at the level of the existing revenue, being calculated for the period since they have been granted and until they have been recovered.

5. Annual execution account. Budget surplus or deficit

(1) The credit officers shall elaborate and submit for approval by authorities, until May 31 of the next year, annual accounts of budget execution having the following structure:

a) at revenue section: initial budgetary provisions, permanent budgetary provisions and incomes;

b) at costs section: initial budget appropriations, permanent budget appropriations and payments made.

Quarterly and annually, the credit officers prepare financial statements on budgetary implementation which are submitted to the general departments of the Ministry of Public Finance. After verification, they prepare and submit to the Ministry of Public Finance the centralized financial statements regarding budget execution on the whole county, according to established norms and deadlines. Then, the Ministry of Public Finance transmits the Ministry of Administration and Interior a centralized financial situation of the local budgets' execution.

Note: Annual financial statements, including their annexes, are presented by the credit officer to authorities for approval.

Annual surplus of the local budget, resulted at the end of the budget year after adjustments are made in the limit of amounts deducted from certain incomes of the state budget, as well as of transfers consolidated from the state budget other budgets, are usually used for:

a) reimbursement of any outstanding loans, interest payments, commissions, expenses and other related costs;

b) establishing the working capital.

The available circulating assets bear interest rates, are kept in a separate account opened on behalf of each administrative-territorial unit, at the territorial units of the State Treasury outside the local budget, and can be temporarily used to cover deficits from gaps between revenue and expenditures in the current year, as well as for a definitive cover of the possible

deficit budget resulted at the end of the budget year.

The working capital can be used to finance some investments attributed to the local administrative authorities or to develop local public services in the interest of the community.

Note: The use of the working capital and of its execution account is approved by authorities outside the local budget.

6. Some specifications regarding the final execution of local budgets

Local budgets cash execution is carried out by territorial units of the State Treasury, being highlighted in separate accounts:

- a) budget revenues collected on the budget classification structure;
- b) payments made by public institutions' authorized persons, within both the limits of budget appropriations and destinations approved under law;
- c) charges and payments on domestic and external public debt, which resulted from contractual loans or loans guaranteed by the state, as well as those contracted or guaranteed by local administrative authorities, including those relating to reimbursement maturity rates and payment of interest rates, commissions, charges and other related costs;
- d) other financial transactions made in the local administrative authorities' account;

e) keeping and utilisation of non-reimbursable available external funds or their equivalent in lei, which received on the basis of agreements, governmental understandings and from international bodies, according to approved budgets.

Note: For contracted loans, other than those from the availabilities of the current Treasury General Account, local administrative authorities may open accounts at commercial banks, in order to run them.

In the execution process, the allocation of amounts deducted from certain incomes of the state budget is monthly made by the general departments of public finances, on the basis of substantiations made by credit officers.

Obviously, as in the previous legislation, budget implementation shall end on 31 December of each year. Then, any un-received income and any expenditure that is incurred, liquidated and passed under budgetary provisions and which is unpaid until December 31 will be cashed or will be paid in the budget account for the next year.

Recent Macroeconomic Developments in the New Member States

Murarașu Bogdan
Academy of Economic Studies, Bucharest
bogdan.murarasu@fin.ase.ro

Abstract

Recent monetary and fiscal policy measures in response to the macroeconomic developments in the New Member States, in the context of the international financial and economic crisis during the years 2008 and 2009 which prolonged further in 2010 were characterized by heterogeneity and asymmetries. The macroeconomic imbalances characterizing the recent evolution of these economies are different from country to country as a result of diverse factors such as the excess demand magnitude at the onset of the crisis, the importance and structure of the commercial flows, the external financial indebtedness or the different contribution of the economic sectors to the economic growth.

Also, the monetary and fiscal measures implemented before and after the onset of the crisis are important. In particular, in the countries with a fixed exchange rate, monetary and fiscal policy measures have been limited by the additional constraint of maintaining the confidence in the domestic currency. In countries such as Hungary and Romania which have an inflation targeting regime, the interest rate reductions have also been limited by the liquidity problems on the interbank market as well as by a high level of the inflation rate that existed in these economies at the onset of the crisis.

Key words: financial and economic crisis, economic growth, fiscal policy, liquidity problems

JEL Classification: G01, G15, G18, O49

1. Introduction

The macroeconomic developments in European Union (EU) countries in the context of the international crisis that became manifest mainly during 2008 is characterized

by heterogeneity and consequently by different responses of the monetary, fiscal and revenues policies mix. In the European Union economies, especially in case of those countries which aren't members of the euro area yet, the general perception is that the return of the aggregate demand and supply to the levels which existed before the onset of the crisis will be a gradual one and the effects of the uncertainties will be felt with a heightened persistence in all sectors of the economy.

The macroeconomic imbalances of the last decade and the international financial and economic crisis are tightly linked ([1]). The worldwide small real interest rates, the distortions persisting on the credit market, financial innovations and the loose exchange rate and monetary policy of some emerging markets such as China, have contributed to the onset of the financial crisis in the USA and to its propagation on a global scale. The main determinants of the financial crisis in the USA and its evolution to a global economic crisis are the loose monetary policy of several central banks which have fuelled real estate bubbles, excess savings, inappropriate quantification and hedging of counterparty risks, as well as unsuitable measures taken immediately after the onset of the financial crisis ([2]). With regards to the solutions of the crisis, the implementation of a substantial financial stimulus packages will help through the recession without causing significant aggregate demand pressures ([3]).

Regarding the new EU member states, the effects of the economic crisis as well as the measures taken by each government are significantly different in exchange rate targeting countries as opposed to inflation targeting countries. The difference resides in the fact that exchange rate targeting countries have had few options in case of monetary policy measures considering their commitment in insuring the stability of the

exchange rate. An example is given by the economic development of the Baltic States during 2008 and 2010 as they have undergone a serious economic adjustment accompanied by the deterioration of the labour market, by additional constraints on the financial markets and a decrease in the sentiment towards the stability of the domestic currency. In this context, the main challenge of the monetary policy was to maintain the confidence in the fixed exchange rate system. The inflation targeting countries which have a flexible exchange rate regime have been affected by low transmission of the interest rate decreases on the financial markets. This development was mainly triggered by heightened risk aversion and low liquidity on the financial markets. From the inflation targeting New Member States' category we have included in our analysis the following: Czech Republic (CZ), Hungary (HU), Romania (RO) and Poland (PO) and from the exchange rate targeting ones: Estonia (EE), Latvia (LV), Lithuania (LT) and Bulgaria (BG). We have also added in our analysis three developed economies which are not members of the euro area: Denmark (DK), Sweden (SE) and the United Kingdom (UK).

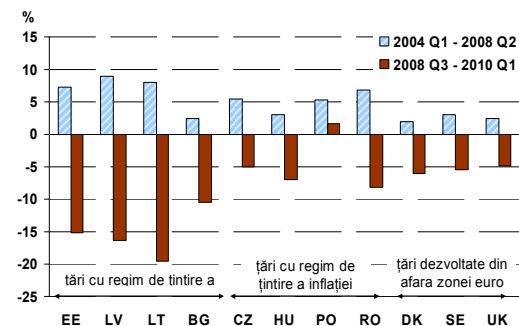

2. The impact of the financial crisis on the economies of the New Member States

The impact of the international economic crisis was experienced with different strength in the New Member States and the three developed economies which are not members of the euro area. While some economies like Poland and to a certain extent the Czech Republic have passed this recession without experiencing a major contraction of the economic activity, other countries such as the Baltic States have suffered decreases of the real GDP of more than 10% in the period of 2008 Q2 – 2010 Q1.

As we can notice in Figure 1, the countries which have grown at a high rate in the years before the crisis have also been those who have experienced the most severe decline in the economic activity. The different impact of the crisis can be highlighted through the reaction of the labour market in the analyzed

economies. Regarding the changes in the unemployment rate and the real wages growth rate, the most affected countries are the Baltic States, followed by the central and south eastern European countries and then by the developed countries which are not members of the euro area (see Figure 2). This development of the labour market is tightly linked to the economic developments but also reflects the flexibility of these markets and the efficiency of the policies implemented by the governments.

Figure 1. The economic growth before and after the international economic crisis (average year on year growth, quarterly data)

Source: Eurostat, authors' calculations.

In countries such as Hungary, Romania and the United Kingdom the adjustment of the labour market wasn't achieved by the adjustment of wages which can suggest a delayed response of these economies to the effects of the crisis mainly in case of the public sector.

Figure 2. The change in the unemployment rate and the wage growth rate (2008 Q3–2010 Q1)

Source: Eurostat, authors' calculations.

Regarding the different sectors of the economy, it is obvious from Figure 3 that the

industry has contracted the most in all economies but its contribution to the total gross value added (GVA) is different in each economy, depending both on the relative dimension of this sector and on the degree of reliance of each economy on exports.

Source: Eurostat, authors' calculations.

3. Possible causes of the heterogeneous macroeconomic developments during the crisis

A first explanation for the different responses of the European economies to the international economic crisis can reside in the different cyclical position of these economies in the period before the crisis and in the unlike effects of the financial crisis on the aggregate supply and the potential output. As it is visible in Figure 1, the decline of the economic activity was more pronounced in the economies which have grown mainly based on excess demand. This was in most cases accompanied by inflationary pressures and important appreciation of the domestic currencies which has led to major external imbalances expressed thorough important current account deficits. The causes which have lead to this aggregate demand imbalance are the excessive growth of real wages and loans which have fuelled the growth of unit labour costs and asset bubbles especially on the real estate market.

In order to quantify the magnitude of the disequilibrium between aggregate demand and supply at a certain point in time, the main method is represented by the decomposition of the GDP in potential level and output gap. We can hence determine how much of the GDP change is due to the modification of the

production capacity in the economy (capital stock, labour force) and to the modification in the demand excess/deficit.

Figure 4. The annual growth of the potential GDP in 2008Q2 and 2009Q4 (% yoy)

Source: Eurostat, authors' calculations.

For all the 11 analyzed countries, this decomposition was performed using univariate filtering methods: Hodrick Prescott filter, band-pass filter and the univariate Kalman filter. The data regarding the seasonally adjusted GDP are taken from the Eurostat database for the period of 1998Q1 – 2009Q4. The potential GDP and the output gap is obtained as a weighted average of the series resulted using the three different filtering methods, while the weights are inversely proportional with the volatility of the potential GDP. Figures 4 and 5 present the annual growth rate of the potential GDP and the output gap in 2008Q2 and 2009Q4.

The potential GDP growth has decreased in all countries and the biggest reduction is the one in Lithuania. However, the negative evolution of the real GDP growth rate was mainly due to the transformation of the excess demand of the 2nd quarter of 2008 in a demand deficit in the next four quarters.

Figure 5. The output gap in 2008Q2 and 2009Q4 (percent of the potential GDP)

Source: Eurostat, authors' calculations.

The countries which at the onset of the crisis had the largest aggregate demand disequilibria are also the ones which suffered

the biggest corrections – this is the case of the Baltic States, Bulgaria and Romania. However, it is clear that Romania's economy had the largest excess demand, but the correction that followed the onset of the international crisis was only the fourth largest. The difference between Romania and the Baltic States resides in the exchange rate regime – in Romania the depreciation of the domestic currency has partially absorbed the shock generated by the reduction in external demand, and hence the decrease in the economic activity was smaller.

Another possible explanation for the different macroeconomic reactions to the effects of the crisis is the degree of economic openness of the economies. Taking into account the high degree of commercial openness of almost all EU member states, the commercial channel represents a major cause for the spread of the effects of the economic crisis in all EU economies. The structure of imports and exports in the EU member states is another source of divergence in the macroeconomic evolution. Recent analysis has shown that the countries with a significant weight of intermediary and capital goods in their commercial flows have been aggressively affected by the worldwide decline in economic activity following the important reduction of investments at producers' level. On the other hand, the countries with a high weight of consumption goods in the commercial flows have suffered less from the effects of the crisis as the reduction in the consumption of this type of goods has been moderate.

Tightly linked to the degree of openness is the interconnection of the European financial markets. In the countries with a high degree of financial intermediation the effects of the crisis have been more severe. On the back of the increase in risk aversion, the amplification of the financial disintermediation process and the reduction of the economic agents' revenues, the financing requirements of the economies with high degree of intermediation have increased substantially. Following the reduction of the external financing sources, on the back of the increase in the risk premium associated with emerging markets, a substantial correction of the current account and private sector economic activity took place. In case of the

Baltic States, Bulgaria and Romania, the most important reductions of the financing resources came from the other investments' (especially financing lines extended by foreign banks to their subsidiaries) and foreign direct investments' side; in case of Hungary, Denmark or Sweden the significant reduction corresponded to portfolio investments.

4. Response of the fiscal and monetary policy to the effects of the international crisis

Except for Denmark and Sweden, all the countries analyzed had an unfavourable fiscal position before the onset of the crisis. In Romania for example, during the year 2007, fiscal policy was expansionary on the back of a favourable economic cycle which subsequently lead to an increase in the budget deficit at around 5.4% at the end of 2008. The main challenge for the fiscal policy since the onset of the crisis was to keep the budget deficit at sustainable levels while also implementing measures to stimulate aggregate demand and supply. Countries such as Latvia, Romania and Hungary which have closed financing agreements with the international financial institutions (The International Monetary Fund, the European Union and the World Bank) will have to implement a series of strict measures convened with these institutions in order to reduce their budgetary deficits. Among these measures we can mention on the public expenditure side: the reduction of the public sector, the reduction of the costs related to pensions and capital expenditures and on the revenues side mainly the expansion of the taxation base. The aim of these measures is the reduction on a three years' horizon of the budget deficit to GDP ratio below 3%. In countries like Lithuania and Estonia the measures regard the reduction of public expenditures such as capital ones and social transfers but also the increase of the taxation rate. In the Czech Republic and Poland fiscal policy measures weren't specific to a recession as automatic stabilizers have adjusted these economies. An example in Poland's case is the reduction in labour taxation in 2007, a measure which has

worked during the crisis as a financial stimulus for both employers and employees.

The uncertainty regarding the evaluation of the fiscal policy measures resides in the difficulty of estimating the degree in which aggregate supply has been affected by the economic crisis and the decrease in the potential GDP growth rate as these two issues relate to the structural position of the budget balance. Figure 6 presents the fiscal position of the economies relative to the degree of public indebtedness. The least favourable combination is the one in which a high budget deficit is accompanied by a high level of public debt situated close to the Maastricht criteria value of 60%. In such a situation are countries like Poland, Hungary and the United Kingdom which are on a different level of economic development suggesting that crisis effects on public finance don't depend very much on the level of development.

In case of Romania, the excessive budget deficit recorded in the second half of this year was accompanied by a moderate public debt expressed as a ratio of GDP. This makes possible the increase in the public financing needs without jeopardizing the Maastricht criteria regarding public debt.

Source: Eurostat, authors' calculations.

Regarding the response of the monetary policy to the current macroeconomic problems of EU countries, their effectiveness was determinant to the different evolution of these countries. In those economies in which there is an exchange rate targeting regime, monetary policy decisions were confined by the necessity to ensure a stable value of the

domestic currency with respect to the euro. This limitation has affected the real economy as it wasn't sustained by monetary policy measures. Also, in most of these countries, in the period before the onset of the crisis the level of the real interest rates was extremely low and that fueled a sizeable excess demand and an unsustainable economic growth.

One can notice in Figure 7 that in the countries with a pegged or fixed exchange rate, the reduction of the interest rates was smaller compared to other economies while the real GDP decrease was larger but accompanied by a more sizeable reduction of the annual inflation rate. In countries such as Hungary and Romania which have an inflation targeting regime, the interest rate reductions have also been limited by the liquidity problems on the interbank market as well as by a high level of the inflation rate that existed in these economies at the onset of the crisis. Also, the unfavourable perception regarding the risk of the investments on emerging markets determined an increase in the risk premium and the maintenance of interbank interest rates higher than the monetary policy rate.

Figure 7. The development of the main monetary indicators (2008 Q2 – 2009 Q4)

Source: Eurostat, authors' calculations.

5. Conclusions

The macroeconomic developments of the EU New Member States in the context of the international financial crisis in the years 2008 – 2010 were characterized by heterogeneity and were accompanied by distinct economic policy measures. The different impact of the economic crisis on these economies can be explained by the different position of these economies in the business cycle at the onset of the crisis but also by factors such as the

different structure of the commercial flows, the distinct external financing dependency or by the different contribution of the economic sectors to the formation of gross value added. Also, the monetary and fiscal measures implemented before and after the onset of the crisis are important. In particular, in the countries with a fixed exchange rate, monetary and fiscal policy measures have been limited by the additional constraint of maintaining the confidence in the domestic currency. Also, in the Baltic States, Bulgaria and Romania, the expansionary fiscal policy before the onset of the crisis has affected the functioning of the automatic stabilizers which in recessions should stimulate

aggregate demand by reducing the impact of taxation on the disposable income of economic agents.

Abstract

In our world the large amount of existing data and the need to convert and analyze this large amount of useful data has led to the concept of data mining.

Using data mining techniques is driven by the urgent need, common to many fields, to store, access, describe, model, and especially to understand and effectively use of the large amounts of data.

Lately the use of data mining in the field of academic analysis has proved particularly useful.

This paper presents the concept and architecture of data mining systems, and also, is presented some of its applications in the field of university to study students' behavior.

Key words: data mining techniques, effectively use, data, student performance;

1. Introduction

Knowledge acquisition is one of the priority areas of artificial intelligence research. Extraction techniques and methods consistent and relevant knowledge from large empirical data, obtained either by total research, either by selective survey, based on a representative sample, have developed and improved significantly, with the exponential growth in technology information.

Development in recent decades, information technology has fostered the creation and implementation of complex algorithms to extract knowledge from large databases. These techniques are today the

basis for a particular area, and growing, that of artificial intelligence: data mining.

2. An overview; concept and stages

Extracting information from data is, as is well known, a concern for centuries in science, and more. Bayes' theorem (1700s) and regression analysis (1800s) are examples of these concerns long before the emergence of computer science.

The emergence and development unprecedented since the second half of the twentieth century, computers and information technology has facilitated the development of new techniques such as neural networks, clustering, genetic algorithms (1950s), decision trees (1960s) and Support vector machines (1980s). In the new context, is crystallized area today called data mining. So, *data mining is the process of applying these methods to data with the intention of uncovering hidden patterns* [12].

Unlink information extraction, whose goal is to automatically extract structured information from unstructured documents, data mining is a data processing using sophisticated data search capabilities and statistical algorithms to discover patterns and correlations in large preexisting databases; a way to discover new meaning in data[18].

A synthetic definition of data mining is provided by Wikipedia[17]: *Data mining is the process of extracting patterns from data.*

Commonly, data mining, involves four classes of tasks: classification, clustering, regression and association rule learning.

These steps can be developed to enable better practical application of data mining processes. In this sense, stress contribution

Irina Tudor, one of the first Romanian specialists who developed this area that the main stages in the process of data mining are [15]:

- Problem definition
- Database construction,
- Use of data (data is understanding, their view, create pivot tables that provide a clear picture of consistency of the database);
- Data preparation (selection of variables to be predictive model components)
- Model building
- Evaluate model
- Interpretation of results and improved model

Data Mining involves the integration of techniques from different areas of both storage and processing, and artificial intelligence and representing an interdisciplinary field, the main disciplines wherewith it crosses are those technologies, generic named, as the data warehouse and database systems, automation learning and statistics.

3. The architecture of Data Mining Systems

Data mining system is a computer system consists of all hardware and software components that interact and communicate with each other for finding data models (knowledge) from a data warehouse.

Data mining system architecture consists of the following components [6]:

- Databases, data warehouses or stores of information are represented by one or more databases, data warehouses, spreadsheets or any other information storage;
- Server database or data warehouse is responsible for extracting relevant data based on user demand for data mining;
- The knowledge base contains domain knowledge which is used to guide the search or to evaluate the significance of patterns obtained. Knowledge can be represented by a conceptual hierarchy is used to organize attributes or attribute values on different abstraction levels, user experience (heuristics) that can be used to assess the

significance of patterns, restrictions or limitations and significance of the metadata.

- data mining engine and consists of a set of functional modules for tasks such as: characterization, association analysis, classification, evolution and deviation analysis;
- pattern evaluation module uses a series of indicators and interact with data mining module so as to guide the search to those significant patterns.
- User interface provides communication between users and system. It allows users to travel patterns or data structures of databases or data warehouses, to assess patterns and to visualize patterns generated in different formats.

4. Using methods and data mining techniques to analyze the behavior of students

Although using data mining techniques in higher education is an area of recent research, there are many works in this field. Studies conducted between 2000-2009 led to the conclusion that using data mining techniques in education is a promising area of research and have specific requirements.

One recent study based on using data mining techniques has been developed at the Faculty of Information Technology and Computer Science from Yarmouk University [14]. This study sought to highlight factors that determine the performance of students in the Computer Programming (C++) and predicting the exam performances.

The data analyzed were collected using a manual acquisition system by interviewing based on questionnaires.

As environmental data mining was used Weka platform. The methods used are algorithms ID3, C4.5 and Naïve Bayes classification by decision tree, classification algorithms and attributes. Were generated decision trees, sets of rules and was performed sensitivity analysis of factors.

Were initially identified 12 attributes according to attribute purpose to test scores. Following classification, were determined nine significant attributes for student performance (Table 1). Classification was

performed on four classes: A (9-10), B (8-9), C (7-8) and D (5-7).

By applying decision tree method was found that the greatest influence on student performance on the course of Computer Programming (C++) is the profile of graduate school. This attribute is considered as the root node of the decision tree. Also were resulted a set of 41 production rules. Some general rules, the longest usually consists of 9 attributes, while the shortest rule covers only 2 attributes.

Table 1 Attributes for student performance

	Attribute	Possible values
9.	Profile graduated high school	A, B, C, D
8.	Form of financing	No fee, duty, an employee of the university
7.	Current chair holder	CIS, CS, MIS
6.	Function of the teacher	Lecturer, Lectured, Professor
5.	Family environment	Family, Friends, Single
4.	Type studies	Normal, Parallel International
3.	Teacher sex	M, F
2.	Specialization followed by the student	CIS, CS, MIS
1.	Student sex	M, F

Of production rules discovered, the most representative are:

- *If the student is female and graduated high school profile is A, then note that you will get to the C++ is C (between 7 and 8).*
- *If the teacher is female and the student is employed at the university and graduate school is C then note that you will get to the C++ is A (between 9 and 10).*
- *If specialization followed by the student is the CIS and the type of study is parallel and chair holder of course is CIS or CS and profile college graduate student is B*

or D then note that you will get to the C++ is D (between 7 and 8).

To obtain accurate classification model was tested three different classification methods: ID3, C4.5 and Naïve Bayes. The results obtained (ID3 = 28.32%, C4.5 = 38, 05% and Naïve Bayes = 38.05%) indicates that samples collected and attributes are not sufficient to generate a high quality classification model.

A second study, on which we stop, was made by P. Haddawy and N. Hien [9] to Technology Institute in Asia (TIA) use data mining techniques at predicting success in relation with students graduated college, and other information extracted from registration dossiers.

Data used in the study covers the period 2003-2005 and data are available at registration. These data are from 1386 graduate and 212 graduate students.

Were used attributes, namely: age, sex, marital status, nationality, English language test result, the institute where he obtained his diploma earlier specialization, average graduation, field of study and type of diploma (Masters or PhD), the average obtained in TIA. . Nationality attribute values were determined according to classification made by World Bank country against Inter gross product. Attribute institute where he obtained his diploma have values between 1 and 10 and represents its position in the ranking institutions. This ranking was made on the basis of the Asian Institute of Technology, obtained by foreign students admitted prior to the institute.

The tend, that is found after analyzing the values of dispersion, is that the doctoral students receive higher marks than those who attend Masters.

Also, PhD students are older. Because of these differences have been created two separate prediction models one for master and other for doctoral students.

Using a bayesian network for analysis and reasoning based on cases, the technique can be applied to any higher education institution which has a database of students and has good information on applicants.

Finally, another interesting study was conducted at the Islamic University of Gaza [7] and sought to analyze the learning behavior of students. They used data from

151 students who were in the database during the first semester of the academic year 2007-2008. Data sources were:

- E-learning course that used to (Moodle) from which data were extracted on resources utilization provided by the e-learning system: courses (e-books), exercises (e-exercises), homework (e-homeworks) and the results of students in solving exercises available in the system.
- The faculty database from where they collected data on GPA score (ratio between the number of credits obtained and the number of exams passed) obtained by students, the final score in that discipline.
- Information held by teachers in relation to attendance of the students in courses and intermediate scores obtained.

Were identified the attributes: attendance, GPA score, number of hours that the e-learning system is used, and utilization of resources: e-resources, e-exercises, e-homework, term marks obtained, laboratory marks obtained and the final mark.

KNIM data mining system was chosen for this study, an open source system developed by the University Kontanz from Germany.

Classification was used to predict the student's final mark at the database course. It was generated a decision tree using J48 algorithm, which the following production rules were separated:

- *If the intermediate mark and the presence score is good then the final mark will be excellent.*
- *If the term mark is a failure and the lab mark is a failure too, then the final mark will be a failure.*
- *If the term mark is medium and GPA score is lower then the final score is low.*
- *If the term note is medium and GPA score is good, and then utilization of e-homework resources is small then the final score is low.*
- *If the term note is medium and GPA score is good and then utilization of e-homework resources is average and is present score is medium then the final score is good.*
- *If the term mark is medium and GPA score is very good then the final score is very good.*

The advantage of using this model is that the smaller notes can be predicted. The teacher can now predict which students will not pass the exam before the end of the semester.

Group data was performed with Expectation-Maximization algorithm (EM-clustering). EM-clustering algorithm is a mixture of maximum probability estimates based on the parameters of stochastic models.

Students were grouped according to their performance in five classes (groups). Outlier analysis was used to detect data that are significantly different from the rest of the data. Each of these knowledge obtained from the outlier analysis can be used to improve student performance. For example, students can be identified with learning problems.

In addition, similar studies with significant results among the studies conducted by Varsha Namdeo, Anju Singh, Divakar Singh, Dr. RC Jain [11] at a technical college profile in India, the study at the Faculty of Electrical Engineering, Eindhoven University the Netherlands [3] which aimed to identify students who need assistance to continue their studies, and the study by Bodea, V, Rosca, I at the Academy of Economic Studies [2], which among its main objectives aimed to identify the most important attributes on student performance, identification of the evolution of student performance and the analysis risk of the lack of integration in the academic work for the first-year graduate students.

5. Conclusions

Growing interest in data mining site may be motivated simply by the urgent need, common to many fields to store, access, describe, shape, and especially to understand and effectively use the large amounts of data.

Data-mining is a powerful analysis tool that provides to the institutions of any kind, whether governmental, non-governmental, or any other field, for example, general education, the opportunity to be able to allocate better their human and material resources, and to achieve a better management.

Data Mining introduces new concepts and methods in the academic environment.

However, this is a new type of predictive analysis, with a large scope for research and education.

Data mining techniques are suitable for marketing applications at university level, and analysis on how to improve the quality of education. In addition, IT systems orientation to data mining applications was observed because they offer a good decision support in the educational environment. This is just one of the many applicability areas of these data mining techniques, with the best results for the university-level management.

G. Mladenatz and his Writings: the International Echo of a Romanian Co-operative Theorist

Păiușan Robert
Academy of Economic Studies, Bucharest
office@arse.ro

Abstract

The present article focuses on the international echo enjoyed by the writings of Gromoslav Mladenatz (1891-1958). He was in the interwar and immediate postwar period a distinguished professor at the Commercial Academy of Bucharest, a research fellow and mentor in the field of co-operation. His internationally most quoted work was *History of co-operative doctrines*, which was published successively in Romanian, French, Italian, Serbo-Croatian and Spanish.

Key words: co-operation, interwar period, co-operative movement

JEL Classification: B31

1. Introduction

Gromoslav Mladenatz (1891-1958) belongs to the hall of great professors and scientists honoring the Commercial Academy of Bucharest, dating from interwar and immediate postwar period, that have become known worldwide.

2. Mladenatz work

Mladenatz is the author of a work totaling 8 books and dozens of studies, articles and didactic materials that were published not only in Romanian but also in many foreign languages.

His writings include:

- *Istoria doctrinelor cooperative*, (History of the Co-operative Doctrines), Bucharest, 1931. Better known is the French version, which enjoyed a world wide recognition of the still young economist: *Histoire des doctrines*

co-opératives (History of co-operative doctrines), Presses Universitaires de France, appeared in Paris in 1933 in the well-known collection “La Bibliothèque Économique Internationale” of great economic and social-politic doctrines, with a very courteous foreword of the French specialist in co-operative issues Bernard Lavergne. He wrote that Mladenatz’s entire life, dedicated to the study and practice of co-operative movement, entitled him to write an objective and documented book. “Briefly, it is impossible to tell more and better things in such a restrained number of pages” [1], wrote Lavergne. The book was put in print due to the special request of the economist Charles Gide, in his capacity as president of the International Institute for Co-operative Studies.

- The same work was later translated into Italian, Serbo-Croatian and Spanish in Mexico and in Argentina. The Mexican edition *Historia de las doctrinas cooperativas*, which appeared in 1944, was commented by Luis Nuevamana, a specialist in the field. The Argentinian edition, translated after the French version, appeared in 1969 with the comments of B. Lavergne;

- *Problema concentrării întreprinderilor cooperative* (The Problem of the Concentration of the Co-operative Enterprises), The National Office for Co-operatives, Bucharest, 1932;

- *Tratat general de cooperatie* (General Treaty of Co-operation) Ed. Muguri, Bucharest, 1933. It included most of his lessons held at the Commercial Academy and the Higher School for Co-operation, both in Bucharest, and at the International Co-operative School in Basle – Switzerland;

- *Asociațiile cooperative de consum* (The Co-operative Consumption

Associations), The National Office for Co-operatives, Bucharest, 1933;

- *Istoria gândirii cooperative* (History of the Co-operative Thought), The National Office for Co-operatives, Bucharest, 1935, was a completed version of his 1931 Romanian book;

- *L'économie coopérative* (Co-operative Economy), in "Revue des Études Co-opératives", 2, 1933, in which he presented a genuine opinion on organizing a socio-economic system of co-operative orientation. This paper established the place of Mladenatz as a co-operative theorist in the French speaking area. The Romanian version *Cooperația în economia agricolă* was published in "Independența economică", Bucharest, 1935;

- *Gândirea cooperativă în România* (The Co-operative Thought in Romania), Independența Economică, Bucharest, 1939.

In Mladenatz's opinion, the co-operative system would not abolish property and freedom, but put them in the hands of the masses, as producers and consumers, leading to the expansion of the social basis of a democratic society. The co-operative action is developed in line with three sets of basic principles, on an economical, social and ethic level.

In its organization, the cooperation is obliged to respect the unity in interest and refraining political engagement of the participants. According to the definition of Mladenatz, the co-operative represents a free association of a number of small producers or consumers, who chose to establish a common enterprise, through which they would exchange services between the associates.

3. Points of view of other economists

Mladenatz is among those economists who were in favor of the third economic way, between the free-market and the central planned economic systems. For instance, Romanian economist Virgil Madgearu favored a peasant agricultural state, Manoilescu a corporatist industrial order, other Romanian economists a solidarity solution. For

Mladenatz, *the social co-operative economy* was offering a new perspective for bringing together the work and the results of the work. The fundamental principle of the social co-operative economy is the specific way of the social product repartition, which take the character of an economy pursuing the general interest [2].

The agricultural cooperative, associative form of performing common work represented for Mladenatz the only social and economic organization, through which the peasant could combine the individual ownership of a land with the collective ownership of the inventory of modern agriculture [3]. As the prices of Romanian agricultural products fell on the international market during the economic crisis in 1929-1933, he would recommend the involvement of co-operatives in the trade of grain with the purpose of removing the intermediaries and adopting a production structure that would prove itself to be much more productive.

The co-operative units would show differences in comparison to capitalist enterprises on different levels such as: the purpose of forming, means of action, position towards capital and labor, economic results and others. The principles of a co-operative organization were the following: self help, solidarity, predominance of labor interests, profit distribution to those directly involved, autonomy in relation to the State. These principles made it possible to put this method in practice, because it was considered fair in distributing a social product- establishing an adequacy between the incomes and the personal contribution into achieving those incomes.

4. The co-operative movement

Going through a wide bibliography on this subject, Mladenatz basically put together a synthesis of the most important characteristics of the co-operative movement:

- The co-operative movement is the action of emancipation of the working classes, that has as starting point the *idea of organizing working interests*;
- The action of emancipating the working classes comes from the *genuine*

initiative of those interested. It is an action of self help, different from a charitable action as from the one started by a political authority that has as purpose helping and defending the interests of those economically weak.

- The co-operative sets in power stage the spirit of solidarity and not the one of competition of those associated. It crowns the principle “comprehend to live” and not the one of “fight to live”.

- The co-operative pushes people towards associating with those of his kind. It doesn't search for winning but for bringing *services* to those associated. It is not a creation of selfish purposes, but it is *open for all* than can be used through their participation at the association, respecting the rules.

- The co-operative represents a *collective economy*. All or only parts of the economic functions of adherents pass to the task of the common enterprise.

- Each co-operative unit is not considered an isolated institution, but a cell of a great confederate organization that has as main purpose the public interest.

- This organization is considered to be permanent. By gathering funds from different institutions throughout the years, they aim at building common funds which will further serve to develop the movement even more in the future [4].

Mladenatz got involved in developing the co-operative movement at an international level by serving different functions: as member of the International Office for Labor, International Co-operative Alliance, International Institute for Co-operative Studies, as well as a plain participant (representing Romania or a personal level) at international gatherings that had as theme co-operative issues. He was for cooperation between national co-operative organizations and according to his opinions, this would lead to mutual knowledge, exchange of experiences but was also a doctrinal necessity, no one could organize a cooperative by himself [5].

Emphasizing the ideas of the historic German school (which influenced his development as an economist) he considered that the laws and trends in economy, in the extent in which they were actually validated by real life, had a historical and fleeting character [6].

5. Mladenatz studies

The writings of Mladenatz, beginning with those published in French, were very well received and appreciated in the specialized international literature. This fact is confirmed by all the favorable reviews of his books. Moreover, they generated study concerns on the problem of co-operatives in Romania reflected in PhD thesis, books, studies and reflections on this topic. There are worth mentioning the following studies:

- R. Kamil, *La coopération en Roumanie*, PhD Thesis, Paris, 1930;

- J.G. Polinet-Charron, *Les coopératives rurales et l'Etat en Tchécoslovaquie et en Roumanie*, Paris, 1932;

- A. Chabert, *La coopération en Roumanie*, PhD Thesis, Paris, 1940.

This last work, written towards the end of the 30's, enhances a rich Romanian bibliography, beginning with the most important writings of Mladenatz. The author refers to the topic from three different perspectives: historical (it reflects the evolution of the Romanian co-operative, starting with the first organization forms till the late 30's), legal (studies of the legislation of co-operatives) and economic (analysis the credit cooperative separated from the co-operatives for consume, supply and production) [7].

6. Conclusions

In line of these considerations, Mladenatz formulated some interesting reflections about the place of economic science and the mission of an economist. The economic science was considered a social science, and the studied object was not the individual, but *socetas oeconomica*, the entire world of acts and ideas in the economic domain.

The Improvement of the Performance of the Public Administration in Romania

Panea Ionuț Valentin
Academy of Economic Studies, Bucharest
ionut_panea@yahoo.com

Abstract

The present article focuses on the role and the importance of the Human Resource Management as a whole in a public organization and also some pieces of advice for the improvement of its performance in the Romanian Public Administration.

Key words: human resources, management, public administration, civil servants

JEL Classification: H50

1. Introduction

Within organizations, people are the key and vital resource, today and tomorrow, ensuring the survival, growth and competitive success. All the organizations have established links between them and all of them constitute the modern society.

Human resources are considered to be the first strategic resources in an organization [1], are unique in terms of their potential for growth and development and their ability to meet and overcome their limits to meet new challenges and demands of present and, why not, for the future.

Because of their peculiarities, human resources are the only inexhaustible resource of creative solutions and new ideas, original and valuable ones, which can lead to the development of organizations and society as a whole, but may equally well destroy it and cause disaster or big problems. Therefore, means for forming organizations concern human resource quality, considering that people are most valuable asset.

2. The importance of human resources

Human resources are one of the most important investments of an organization. There is evidence that investing in people is the surest way to guarantee the survival of an organization or to ensure the development, competitiveness and its future.

Naisbitt and Aburdene states that: "The new information society, human capital has replaced financial capital as a strategic resource." [2] Management of human resources decisions are among the most difficult, because they link the individual factors, organizational and situational influences which are reflected in these decisions. They need to always be taken according to the person referred to in its personality.

Personnel decisions vary from one organization to another, from one subdivision to another, from one country to another, because such decisions must be tailored to their needs and their importance is not the same in all cases. Personnel decisions must evaluate dual-looking statements, which are morally or ethically and legally extremely complex. They must be very responsible in terms of social responsibility, developed and evaluated in terms of social impact.

Man by nature, mentality and culture forms a biological entity that, even for the genetic revolution, remains a great unknown variable. Human potential differs from an individual event in other genetically influenced, by biological, social, cultural, educational and other factors specific to each individual and each activity or each organization. Therefore, human resources is a great human potential, to be understood, motivated and trained in order to involve full employees to achieve organizational objectives.

Taking into account all aspects that define human personality: skills, knowledge, aspirations, character and temperament traits, resource management can harness the most demanding, valuable, rare, difficult to imitate, relatively irreplaceable, unique resource equipped with the ability to create to produce and use all other resources available to an organization [3].

3. The importance of the civil servants

The increased interest in human resources does not mean an undervaluation of the material, financial or informational resources. Systemic design approach involves the organization of human resources in close interdependence with other resources, from the fundamental objectives, whose achievement compete together. Human resources at the expense of other pressures affect the dynamic balance that makes the organization function and its development [4].

The establishment of the rule of law in Romania has imposed the need for employment relations of civil servants to be established by specific legislation, unlike the other categories of employee status. As stated in government programs, public administration reform in Romania is based, with priority on those legislative initiatives that can provide real government autonomy and a high degree of professionalism.

The Romanian Constitution stipulates in art. 72, par. (3), letter i) that the status of civil servants is regulated by organic law, which highlights the importance given by the fundamental law of this country's social categories that resume the proper functioning of the rule of law.

In the draft of the statute, there were considered European Community standards in this area, aiming at forming a career civil servant, politically neutral, able to fulfill the duties of the public authorities and institutions as part of a body of public officials consistent with similar structures in countries with extensive experience in the field of democracy.

In my doctoral thesis, I tried to analyze two important institutions, one in Bucharest, The General Directorate of Public Finances and one in the nearby Ilfov county, The Ilfov County Council. At the end I tried to formulate

some general advice regarding the improvement of the Human Resource Management processes involved in the functioning of the two institutions.

In the Directorate of Public Finance of Bucharest I appreciate that we cannot speak about the existence of human resource management policies, representing those carried out by specialized divisions to ensure the recruitment, selection, development and personnel necessary to achieve conservation objectives. Being a public administration, it is subject to hierarchical forums like the Ministry of Finance and Tax Administration Agency, in the scheme of organization and staffing. Thus there are certain restrictions on the number of personnel in public institutions in terms of reducing the overall number of civil servants.

4. Conclusions

After analyzing the way people work in the evaluation of the performance of human resources in the Directorate General of Public Finance of Bucharest, there are to be drawn the following conclusions:

- The performance evaluation system represents the base reward/punishment system for employees based on individual contribution to organizational goals;
- The results of the performance evaluation of individual professional human resources is to identify those with potential promotion, but also those with professional or integration issues;
- The results of the performance evaluation process will identify the individual needs of individual professional training and professional development of staff;
- The current system has a somewhat formal character, the lack of a specific evaluation system of public servants engaged in finance and taxation, and more detailed assessment of professional performance. Methodology for assessing the professional performance is a general applicable to all civil servants regardless of the operating field. Public Finance General Directorate of Bucharest has a specific task on which would be to set their own criteria and to determine their weight in the completion of each activity.
- Has an annual character and becomes a routine activity to be carried out at regular

intervals, without taking into account the objectives underlying this activity and its achievement;

- There are certain restrictions practiced by the evaluation system, which cannot allow the sharing of personnel tasks, functions or positions, which are somewhat rigid in application. For example, if for the evaluation of individual job performance was assessed a civil servant with a grade of "exceptional" under the law and could promote a higher level, it will not if the institution had no job vacancies;
- Lack of an evaluation grid established on the bases and rules of modern science to ensure greater relevance assessment;
- Use the same performance criteria for civil servants implementation without making a distinction of importance criterion in the functions of each position in the party. If for the assessment of a civil servant in charge of execution that will collect taxes from the

taxpayers, "creativity and initiative spirit" is not a relevant criterion, for working to support other taxpayers, it is essential.

- The evaluation system is quite complex, cumbersome and difficult to maintain because of the way of scoring and making calculations for the final verdict and abstention of the multitude of performance criteria and individual goals;
- The current HR performance evaluation only put emphasis on trial managers, the evaluator's perception that any person has a value system or is subject to their own limits.
- The absence of a scientific assessment process and specialists, to apply these methodologies on the basis of modern science. We believe that individual job performance evaluation results would be significantly different if it were made Teams of specialized assessors to sit next to psychologists, sociologists and other specialists in fields studying human behavior.

Data Warehouse and Business Intelligence Components

Păunescu Loredana-Maria
Petroleum&Gas University, Ploiesti
loredana.paunescu@yahoo.com

Abstract

Management information systems are now essential tools of the modern manager, the vast majority of routine decision making, decision-making process with the necessary information search and retrieval techniques of information was completely taken by these systems.

In addition, their improvement continues, accompanied by improved performance computing provides increased opportunities for acquisition of segments of the increasingly comprehensive reasoning activity will be produced by human decision-maker. The category of systems that provide support in decision making can be defined. The term business intelligence. It covers all informational tools that provide a more "intelligent" business process.

Key words : data warehousing, information system, decision process, expert systems.

JEL Classification: M10 ;

1. Introduction

Information systems to assist decision and business intelligence tools tend to become ubiquitous elements within companies. Dynamics of contemporary economic life and the information explosion makes use of different types of systems to assist decision-making process despite the limitations imposed by an inability necessity. In perfect reproduction of human reasoning by computer, management information systems are now essential tools of the modern manager, vast majority of routine decision making, decision-making process with information necessary techniques.

The search and retrieval of information being taken over entirely by these systems. In addition, their improvement continues, accompanied by improved performance

computers, offers greater possibilities of taking over segments of increasingly comprehensive reasoning of activities carried out by human decision-maker . The category of systems that provide support in decision making can be defined by the term business intelligence. It covers all informational tools that provide a more "intelligent" business process. Integrating traditional applications, operating with a range of programs or data analysis category expert systems provide a basis to assist effective decision making.

In terms of making decisions based on business intelligence solutions, have been identified these basic steps:

- Analysis - filtering data from many useful information according to business model and identify performance indicators. Analysis of information in different contexts to identify trends Business intelligence means the information available to all company departments so that every manager to carry out its own analysis and be able to monitor performance indicators on the segment that is interested;
- The discovery of causes - explain the causes of certain phenomena which do not correspond with the business model;
- Action - making decisions based on information analyzed. These decisions are based on protecting the future effects it will have an action (eg, increased sales to a particular product as a result of promotions). Again, the human component plays an important role: it estimates that the variants of action will result. Business Intelligence assist in decision making by being able to simulate the effects (what if analysis);
- Measuring outcomes - in this last stage we can see if the decisions were correct or if the results are not exactly those expected, indicating the direction in which we must act to improve them.

2. Designing Business Intelligence Solutions

When we want to implement a Business Intelligence solution must start from the needs of users will use. Should not be taken into account only the management team here, but any user will need, in one form or another, the information in this system to operate. Users can share a system of Business Intelligence:

- Users of information - they need only report or specific performance indicators. They use standard reports and have no capacity to review;
- Consumers of information - they need opportunities to analyze information in various contexts and seek functions for dynamic data queries;
- Analysis and experts - those who are multidimensional analysis is required to identify trends and to take major decisions. They need ad hoc analysis and access to any information in the system. In order to get a more correct the categories of system users and to meet their requirements, design solutions should consider the following two elements:

a) locating information on which the analysis is done

b) these data will be present, usually in various existing operational systems: applications Line of Business (LOB) systems, Enterprise Resource Planning (ERP), Customer Relationship Management (CRM), human resources (HR) management network Distribution (supply chain). All these systems have some common characteristics, among which are the most important is that transactional systems. Another aspect, which usually prevents the use of data for analysis, is that the systems are isolated and little communication with other systems and data are not correlated. When you wants to achieve a solution to review must find a way to integrate data from these systems.

c) Users of the system and the types of information needed

Will be created for user profiles, later to be developed and planning system design based on these requirements. The systems' capacity for business intelligence focus on improving access and delivering useful information to

both consumers and information to those providing information. A computer system for business intelligence needs to offer scalability and be able to support and integrate software tools from several manufacturers. A data warehouse[1] is a data source of a BI system. There is also a large amount of information on the Intranet web servers on the Internet and in paper format. Computer systems for business intelligence are designed to allow access to all forms of information, not just those stored in a warehouse of a company data[2]. Inside a firm we collect large amounts of data on daily transactions: data about orders, inventories, invoices, Sales, Customer, etc..

Also, companies also external information (eg demographic information). Being able to consolidate and analyze this data can often lead to a competitive advantage (increase sales, reduce production costs, improving sales, finding new sources of income, etc.).. All this is possible if there is appropriate applications and tools needed to analyze the data and whether data is in a format suitable for analysis.

The main objectives of a BI system are:

- to allow low-cost solutions that offer advantages to the company;
- to allow quick and easy access to company information for a large number and variety of users;
- to provide support for modern technologies (complex analysis techniques, tools, OLAP, data mining tools, etc.)[3]
- to provide an open and scalable operating environment.

Note that the computer systems for business intelligence are actually modern decision support systems-level organization that uses new information technologies. The term computer system for business intelligence is actually a term "umbrella" used by experts to a wider class of decision support systems[4], integrating all the features of data warehouses, OLAP tools, data mining tools, web, etc. .

Depending on the complexity of decision making at the organization, the number of users, organizational requirements, the amount of information necessary for decision-making process and other factors, modern decision support systems will employ and integrate one or more of new technologies current information. If you use the data warehouse /

data center and query and reporting tools then we have a decision support system with data warehouses.[5]

If you integrate data warehouse with OLAP tools are obtained so-called ROLAP systems, and if it is used and facilities offered by the Web get oriented decision support systems Web. Many companies prefer to build a separate system for BI applications, either security reasons or for reasons of performance. Nowadays there is a variety of tools and methodologies available to develop BI solutions:

- applications such as IBM's DecisionEdge for customer relationship management, Oracle Sales Analyzer for analysis of marketing activity, Oracle Financial Analyzer for analysis of financial activity, etc.. ;
- query tools such as Cognos Power Play, Business Objects, Business Objects, IBM's Query Management Facility etc.. ;
- OLAP tools such as Essbase, Arbor Software, Express Analyzer, Express Objects, Oracle, etc.. ;
- statistical analysis tools such as SAS System, SAS Institute, etc.. ;
- data mining tools such as IBM's Intelligent Miner.

Many of these applications and tools have web facilities. OLAP tools are used frequently in decision support systems, they enable interactive analysis of multidimensional data. Their main merit is that they are close to analysts' mode of thinking and improve execution performance of applications.[6]

Consequently, multidimensional database technology won lately attention from manufacturing companies and researchers. Whatever type of architecture implemented OLAP tools shows the user data in a multidimensional data model and applications are made using multidimensional paradigm. Yet many of the existing OLAP products have certain limitations:

- does not provide a query language similar to SQL;
- treats asymmetrical dimensions and measures,
- there is no widely accepted conceptual model for multidimensional databases.[7]

Multidimensional modeling is a conceptual modeling technique used by OLAP applications. However, multidimensional data

modeling is not a problem specific to OLAP systems. Statistical databases, geographic and time databases are related to multidimensional data.

Data models proposed in the field of statistical databases, spatial, temporal models have many common points with OLAP data. For example, temporal database rows and columns of relational tables are viewed as two dimensions, and time appears as the third dimension, creating what is called the cube of time (time cube).[8]

All views, reports and analysis are made in terms of hypercubes (n-dimensional cube). A three-dimensional matrix can be visualized as a cube with each dimension forming a face of the cube. Typical dimensions of an enterprise data are time, measures, products, geographical regions, distribution channels etc. Underlying all activities of a firm stand processing. This includes collecting, storing, transmitting and manipulating data.[9] The importance of good information can be viewed as the difference in value between the correct and wrong decisions, where decisions are based on information. The greater the difference between good and bad decisions, the more important to have good information. Most companies invest more in information technology. Good information must be accurate, current, complete and easily understood. The first functional requirement OLAP systems appears from these general requirements for data processing: to provide accurate, current, complete and easy to understand. The activities and operational decision-oriented analysis is a core business activity, regardless of its size, area activity, legal form.. Buying, selling, manufacturing and transportation are examples of operational activities. Information on sales, production and costs may be recorded and managed in one or more databases, used for operational purposes. Operational activities are performed at a relatively steady. Data is read and updated frequently and is an actual photo of what happens in business. Each application uses a small amount of information and its nature is generally predictable. Monitoring, evaluation, comparison, strategic planning and resource allocation are examples of analytical work. The information generated by the activities of decision analysis is oriented as it is in a form

that makes it immediately usable in decision making. Orientation is essential for decision analysis.[10]

Many activities are focused on operational decision without relying on analysis. Less frequently, managers and analysts can ask: « What is the difference in profit between one trimester and other from the last year? ». The answer to such questions is information that is based on analysis and decision-oriented. The data is more read than updated to these activities. Applications using the derived data and analytical nature is not always predictable. Most companies use different tools two types of activities:

- to ensure maximum efficiency in both activities
- to achieve fast update transactional and account activities quickly in OLAP systems is an important category of decision support systems-oriented companies must have quickly date. Nowadays, the firms must use rapidly the applications, offering users quick and easy access to information to reflect changes in business environment. BI systems focus on quick delivery and access to user informa A data warehouse is not yet a complete solution for the needs of managers. A weakness of the solutions using data warehouses is that specialists focus less on technology and management solutions (Business Solutions). Although manufacturers offer powerful data warehouse for building and accessing a data warehouse, these tools require a significant amount of work for implementation. It also puts too much emphasis on the store building process and less on Many organizations believe that if you build a data warehouse and provides users with the correct tools, the problem is solved. In fact it is just the beginning.[11]

Although information from the warehouse is fully documented and easily accessible, the complexity will limit the use of store managers, the main beneficiaries. Business intelligence systems focus on improving access and delivering useful information to both consumers and information to those who provide information. A computer system for business intelligence needs to offer scalability and be able to support and integrate software tools from several manufacturers. A data warehouse is a data source of a BI system.[12]

There is also a large amount of information on the Intranet web servers on the Internet and in paper format. Computer systems for business intelligence are designed to allow access to all forms of information, not just those stored in a data warehouse. One company is collecting large amounts of data on daily transactions: data about orders, inventories, invoices, sales, clients, etc.. Also, companies need and external information (eg. demographic information). Being able to consolidate and analyze this data can often lead to a competitive advantage (increase sales, reduce production costs, improving sales, finding new sources of income, etc.)..

All this is possible if there is appropriate applications and tools needed to analyze the data and whether data is in a format suitable for analysis.

3. Conclusion

Integrating traditional applications, operating with a range of programs or data analysis category expert systems provide a basis to assist effective decision making.

Ph.D Student Teliceanu Claudiu

Abstract

A modern public service requires changing organizational culture, the transition from personnel management to human resources management being accomplished through a strategic modernization of the first. Moreover, the issue of leadership in public administration has raised many and profound debates in the specialty literature, very often public institutions being perceived as unable (as opposed to private organizations) to implement and promote a competitive leadership style. Human Resource Management in Romanian Public Administration is much less visible in public institutions, while at the National Agency of Civil Servants (NACS) there is only a HUMAN RESOURCES MANUAL with indicative value for these institutions.

Key words: public service, human resources management, single salary, assessment procedures review, continuous training of personnel, administrative decentralization.

JEL Classification: H61, H68

1. Introduction

Both in Romania and other Eastern European countries the administrative reform has been often understood only at the level of new laws and regulations adoption, the only administrative changing tool being located in the law. There have been taken and put into practice ideas, policies, procedures and laws without taking into account well grounded prior studies and without being adapted to the Romanian reality.

Different administrative systems, different cultures, different legal systems and practices have created or create different conditions compared with other countries in the world, especially as the public management functions (forecasting, organization- coordination, management, motivation, evaluation and control) have been ineffectively implemented year after year, while some were missing altogether. Thus, there have emerged such new structures, which were incapable though to implement change and achieve optimum level of effectiveness and efficiency.

With regard to Human Resource Management in Romanian Public Administration, we can mention that it is *scarcely visible* in public institutions, and there is a HUMAN RESOURCES MANUAL with an indicative value for these institutions at the National Agency of Civil Servants (NACS) [1]. This manual we refer to provides information on the principles and practices governing human resources management in Romanian public administration, being mainly based on legal rules (rules which often create difficulties in their application).

Considering the presented points, as well as the characteristics of personnel management against the human resources management, we may rather define within public institutions staff management characterized by [2]:

- short- or medium-term developed strategies as comparing with long-term ones that are specific to human resources management;
- acceptance of subordination and not of psychological reasoning based on occupational dedication;
- identification of bureaucracy and not of some organic links at an organizational level;

- a criterion of unconditional subordination integration and not of integrative participation;

- a vision in which staff is included in labour costs, etc. without being regarded as an investment.

A modern public service requires changing *organizational culture*, the transition from personnel management to human resources management being accomplished through a strategic modernization of the first. Moreover, the issue of *leadership in public administration* has raised many and profound debates in the specialty literature, very often public institutions being perceived as unable (as opposed to private organizations) to implement and promote a competitive leadership style [3]. Leadership and organizational development must be the focus of Public Administration in Romania. As an example among the instruments that could show efficacy in this regard, *Blake Mouton Managerial Grid* is found, representing a two-dimensional model of leadership styles in the way that it uses both personnel concern as well as tasks concern in order to identify the leadership style practiced by a person occupying a leading position. [4]

2. Range of issues on public function

Taking into consideration the development level of public function in Romania and the impact of Romanian economic current affairs in this area, we identify the main existing problems, as follows:

- **Numerical reduction of human and financial resources in the budget sector**, as a main result of the economic crisis, is one of the problems faced by the Local Public Administration in Romania at this moment [5]. The efficient use of public funds based on the application of vigorous public financial management and the employments made as a result of real analysis of needed staff related to the organizational and divisional strategic objectives [6] wouldn't lead to the necessity of applying this measure.

- **Poor implementation or inappropriate applicability of motivation, including the wage system** [7], by referring to human resources performance. Lack of transparency of the wage system or motivation in general, correlated with the absence of some effective human resources policies, lead to *personnel demotivation increase* and thus to the stagnation and/or *decrease of their professional performances*.

As an example: Although an assessment of how public officials perform their duties and of the training level is necessary especially when it is sought to form a professional body of civil servants, the real problem lies on how well this assessment reflect reality.

Even if there are set clear criteria for each category of civil servants, the evaluator's subjectivism is more difficult to be removed, at least for now. *Civil servants must be motivated, according to established criteria and not based on subjectivism of the evaluator or of the halo effect. Proper evaluation of human resource brings performance within organization and indirect recognition of human capital* [8].

We estimate that, under these conditions, it is/will be imperative to analyze and review the applicability of civil servants' performances evaluation system and of local administration contracted personnel. Therefore, it is aimed that *human resource motivation should be based strictly on real professional results* and competences that lead to achieving project or organizational objectives as a whole, while meeting defined performance criteria.

Systems of public sector performances measurement is still in a transition phase, transition which is identified (in a higher stage) even in countries where these systems have been used at all administrative levels. However, procedures and performances measurement tools suffer continuous changes, being neither exhaustive nor truly systematic... [9]

- **Poor development of human resources departments** within public authorities and institutions or their **lack** in some public

organizations (such as City Halls in rural areas). *Responsibilities of such a department are usually laid upon one of the civil servants, who is not always professionally trained to the exercise such powers.*

A first effect of this problem is the *non-unitary application and/or breach of current legislation relating to the public function*; a second effect is the *faulty application or administration of human resources*; and not least, the lack or, *in the case when these are formulated, the faulty application of human resource management strategies*. In order to solve this problem, we consider useful the analysis of each entity that identifies these deficiencies and the development of an action plan related to the complexity of each situation.

• **Weak system of continuous training.**

In this case, we have identified public administration personnel training without always taking into account the deficit or training related to the objectives or responsibilities of the occupied position, as well as the existence of a reduced number that should bring additional theoretical and practical knowledge in specialty fields required by public institutions. Until these weak points we plan to study in this project will be resolved, we believe that development of a work environment that facilitates learning with continuous assessment of results is really useful. [10]

• **Damaged image of civil servants** (and contractual staff) research is another strong research point in the project. *Image of civil servants and public administration is determined by the citizens' perception about the evolution of the - corruption - factor, as well as their connectivity to it.* Therefore, reduction of quality, efficiency and timeliness of service delivery to citizens reflect in their opinion a *less favourable image that is associated with public institutions employees.* [11]

• **Lack of direct, strengthened collaboration of the National Agency of Civil Servants (NACS) with local public authorities and institutions** leads to limitation of the NACS' role in the public

function's management process. We may also mention the lack of institutional capacity of NACS related to the nature and volume of task it must perform.

On the other hand, NACS does not take into consideration contractual personnel or personnel having special status in public institutions. We consider necessary the existence of an authority to administrate both civil servants and other personnel we have referred to.

• **Necessity to:**

a. obtain structural and process-related improvements of public policy cycle management in central and local public administration,

as well as

b. improve quality public services delivery, with emphasis on the decentralization process.

By carrying out *Operational Programme for Administrative Capacity Development*, public institutions and authorities, as well as stakeholders interested in this area can access various local funds in order to diminish/eliminate the presented weak points.

Administrative Capacity Development/modernization of the Romanian public administration is an approach which aims at creating a more efficient and effective public administration with a body of competent civil servants for the socio-economic benefit of Romanian society. This stands for another point to solve current problems of the public administration amid European concerns of administrative cooperation under the Treaty of Lisbon. [12]

We believe that through research that we propose we will help achieve these national and local objectives.

The issues presented here are recognized by the National Agency of Civil Servants, to a greater or lesser extent, as being problems confronting Public Administration at the moment.

On the other hand, since the implementation of Decision No. 699 of 2004 for the approval of the updated Strategy of the Romanian Government on speeding up the reform in public

administration from 2004 to 2006, we are not aware of another strategy that had the same status and same legal value. Exceptions and given only by:

- **National Reform Plan 2007-2010** [13], a document that shows a *low concern for human resources actions in public administration*, as according to content of chapter on Public Administration;

- **Strategy for better regulation at the central public administration level 2008-2013** [14], which the executive would adopt a bit later; obviously, it includes neither local public administration, nor concerns about the human component that should provide performance based on decentralization in public administration.

Therefore, local authorities may allow limited *formulation of strategies at local institutional level in the absence of a framework strategy for Romania*.

Moreover, at the local administration level we can identify poor financial decentralization, in many cases existing only transfer of organizational tasks and some public services administration from the central level to the territorial one, without a sufficient financial support.

- **Government Programme 2009-2012** [15] in Chapter 19 - Public Administration Reform includes *Human Resources Management* section, which aims at *implementing the single salary law, review of assessment procedures and continuous personnel training*, but it also covers the issue on *Improving the efficiency and transparency in the activity of public administration institutions, Administrative decentralization and local administration efficiency increase (section that brings as novelty the elaboration of a project on Romania's administrative-territorial reorganization) and Financial decentralization*.

Moreover, according to the latest studies of public polling institute, the civil servant in Romania is perceived as an almost negative manner.

Thus, the following negative aspects have been identified:

- The fairly high score obtained by human relationships and attention paid to

the chief denotes the application of professional promotion practice based on *knowledge* (preferred, nepotism), although the related persons are not sufficiently competent;

- The perception of the degree of corruption at the direct chief level - only 55.4% say their boss is correct;

- Discontent manifested towards their income - 48% of respondents say they are pretty unhappy or deeply unhappy, and for 67% it meets minimum requirements;

- In terms of initiatives prevention, only 51.8% believe that their ideas are promoted to the management sector in the organization they are working for;

- Management instability of public functions which are under the influence of changes in the political sphere - 48% of respondents indicate device management change as a consequence of interchanging political parties in power;

- *Public* behaviour (physical and verbal violence; rules of conduct in public spaces are not followed);

- Less annoying is the lack of information (on certain issues, the overall level of training or lack of civic culture).

3. Conclusions

To conclude with, after years of accelerated reforms in public administration, civil servants' perceptions and values reflect as well some positive effects in the process of modernization, but these are at a considerable distance from public demands, as contrasted with good practice standards of developed countries and theoretical and practical study of international literature in the field.

Advantages and Disadvantages of Globalization

Podașcă Raluca
“Petro&Gas” University, Ploiesti
raluca.podasca@yahoo.com

Abstract

Globalization has become one of the most debated issues of our times. Considering that many of the approaches to this phenomenon do not have an answer yet, we are still dealing with multiple interpretations, some even contradictory. The globalization of the world economy entails common standards and values; it can generate both global balance and imbalance having both winners and losers. Failure to adapt to the globalization process brings along a series of disadvantages that lead to poverty and economic crisis. Every country must confront and adapt to this inevitable and irreversible process that is globalization.

Key words: globalization, poverty, economic crisis, competitiveness, labor productivity index of economic globalization.

JEL Classification: F02, F15, F41.

1. Introduction

The phenomena from the past decade that mark the evolution of the world economy are a sign of globalization, of interdependencies, and of interaction. Any event from whatever corner of the world affects more or less the entire world economy. The globalization phenomenon is relatively recent. It appeared after World War II and it developed stunningly in the past few years.

The scope of globalization is to create a network of the world's economic life. The network, as a development and communication level, gains multiple dimensions, guaranteeing the complex relationships between the micro, macro and world economic levels. Therefore, Philip Kotler considers that “the companies that will succeed in business will be the ones that will

manage to create the most efficient global networks.”

The revolution in communications contributed decisively to the globalization of production and competition, changing unfalteringly the way businesses were initiated and developed. Therefore, the transnational companies decentralized their production processes, creating the goods in countries where the costs are minimal. The globalization of production created jobs and offered higher salaries to workers from less developed countries, increasing the competition between the workforce demanders[1].

The national identity of a nation will disappear as an effect of globalization. The role of the state tends to decrease in favor of the transnational companies.

Globalization is an unprecedented world scale revolution, a new era. Defining globalization is extremely controversial. Globalization may be considered to be the process of expanding transactions between people across country borders, of accentuating the interdependencies between states, as a result of an unprecedented development of the cash flows of goods and services, information, capital. It implies the internationalization of commercial exchanges, of production, and in the past decades of capital markets.

2. Measuring globalization

The degree to which a country is connected to the world represents a new issue that has recently caught the attention of specialists. They intend to compute an index which reflects as accurately as possible the degree of globalization of an economy. “Foreign Policy Magazine” computed a globalization index which is a compound, multidimensional index that includes four dimensions:

- the integrating dimension which determines the degree of interdependency

of the respective economy to the other countries: commercial flows, external payments, foreign investment flows;

- the political dimension which represents the degree of international political commitment of the state: number of foreign embassies of each country, number of attendances in international organizations, participation in UN peace maintenance missions;
- the technological dimension which reflects the degree of IT connectivity of a country (the weight of Internet providers from the total population, the weight of Internet users from the total population, the number of Internet servers with high performance standards);
- the personal dimension that concerns international tourism, international telephone traffic[2].

Table 1. Country Classification according to the compound index of economic globalization, 2009

Rank	Country	Global ization Index 2009	Global ization Index 1995
1	Singapore	7.29	6.04
2	Hong Kong (SAR)	6.90	5.50
3	Ireland	6.87	5.08
4	Belgium	5.82	4.51
5	Sweden	5.77	4.00
6	Denmark	5.77	4.36
7	Switzerland	5.62	3.93
8	Netherlands	5.45	4.62
9	Israel	5.16	4.67
10	Finland	5.14	3.76

Source: Ernst & Young, "Redrawing the map: globalization and the changing world of business", January 2010

The compound index of economic globalization offers the opportunity to actually compare the states of the world.

In the Ernst & Young classification Romania holds the 30th position out of 60 countries included, with a globalization index of 4.00 in 2009 as opposed to 2.65 in 1995. It is noticed

that the small countries dominate the globalization index classification which is measured through their integration in the world economy, as they are focusing more on international markets for growth and economic prosperity. Unsurprisingly, the classification is led by Singapore which is extremely dependent of international trade: the aggregated imports and exports represent over 300% of the country's GDP. Only a small correlation was noticed between a country's size (economic power) and its degree of globalization, statistically speaking. However, economic intuition suggests that small countries have a stronger tendency towards globalization. The globalization index marks two major trends:

1. The economic crisis slowed down the globalization process but it is estimated that as the economy recovers, the globalization index will rise again although at a slower pace than in the beginning of the year 2000.

2. Technology will remain the main engine of globalization. Without the technological innovations like mobile telephony and the Internet, globalization as we know it would not have been possible.

Culture remains the most visible form of the modern world's globalization and measuring the flows of trends and ideas is much more difficult than of measuring cultural, financial, or population flows. The cultural globalization index takes into account statistical data regarding the import and export of books, periodicals and newspapers, data gathered by UNESCO. All these indicators are computed based on the number of people, starting from the assumption that the higher this is, the higher the probability that a person has access to foreign cultural products. Another indicator that should be introduced is the movie flow but data is available only for a small number of countries [3].

Table 2. Internet Users Percentage in September 2009

Area	Internet Users Percentage out of the total area population	Internet Users Percentage by area out of the total number of users
Africa	6.8%	3.9%
Asia	19.4%	42.6%
Europe	52.0%	24.1%
Middle East	28.3%	3.3%
North America	74.2%	14.6%
Latin America/ Caribbean	30.5%	10.3%
Oceania/ Australia	60.4%	1.2%
Total	25.6%	100.0%

Source: www.internetworldstats.com

As presented in the above table, Asia, Europe and North America hold 81.3% out of the total of Internet users. This means that at this moment these areas are the most favored to a rise in the Internet economy. Furthermore, there are clear discrepancies between the developed and the less developed countries in terms of technologic and informational levels necessary for the existence and functionality of the new economy. These differences will slow down the creation of the new global economy.

3. The advantages of globalization

The goal of globalization is profit and maintaining the companies' activity. Considering that R&D expenses increase rapidly and the life span of products has drastically diminished, a denser network of partners was in order. The internationalization of production, the introduction of technical progress, the reduction of transport costs, they all contribute to the decrease of production costs which allows a cut in the prices of goods and services and the access of the population to cheaper goods. Globalization also brings an

increase in competitiveness which has a positive effect on production by increasing the diversity of goods and services. Also, the companies' productivity as well as their efficiency increase which lead to a better customer demand satisfaction. Local companies deal with international economic agents and in order to survive, they need to adapt quickly to the market's demand, to increase the quality of its products and to decrease the prices.

International regulations concerning the free movement of goods and services facilitate the access to more and more markets. During the past few years, the custom duties for most of the industrial products decreased continuously and a lot of developing countries changed their orientation from countries exporting mainly primary products to countries exporting processed products. The globalization phenomena is an advantage mainly for the countries with developed economies that have a greater economic competitiveness: high labor productivity, very advanced technologies, skilled workforce, reduced production costs.

Globalization offers unlimited possibilities for a real global development but it progresses unevenly across regions. Certain countries adhere to the global economy much faster than others and they enjoy consistent economic growth and poverty reduction. For many East Asian countries, the politics toward global integration led to economic growth and prosperity.

During the past few decades, the political, economic, technological, social, cultural and psychological trends have managed to radically change the world. The speed at which the global economy has been transforming at the brink of the two millennia was unimaginable half a century ago. The third millennium brought along a richer world, a world in which life expectancy and the standard of living increased, a world characterized through more freedom and the possibility to choose between more options.

4. The disadvantages of globalization

Apart from the advantages related to the phenomenon of globalization presented mainly from the point of view of the transnational corporations, there are a series of

opinions that consider that this irreversible process generates a series of dangers that should not be overlooked.

Globalization tends to suppress the cultural traditions of the nations. The cultural specificity is diminished and the mass culture appears. It tends to overpower the other cultures ending up in replacing them. Mass culture becomes a universal culture with a strong consumerist character. Some voices that criticize capitalism consider that certain dominant cultures, like the American one, tend to overwhelm the other cultures, globalization becoming a process of domination of the weak by the strong corporations of the world. As such, the gap between the rich and the poor increases and the countries with a less performing economy start being overlooked. For these countries, the consequences of globalization are reduced exports and close to zero attractiveness for foreign investors [4]. Some authors consider that the price paid for globalization surpasses the advantages that it brings: the corruption took over the political life, the environment was destroyed and the speed of change did not offer enough time for the countries to adapt culturally. Globalization generated economic crisis that led to the increase of mass unemployment.

The leaders of Third World countries believe that their destinies are determined by the forces of globalization and they hope that “this tsunami will transform into a positive force of reconstruction and development and not into a menacing force of destruction and destabilization”. Africa is the most disfavored area of the world due to the lack of economic cooperation from globalization.

The developing countries are disregarded because they cannot keep up with the rapid process of globalization and fall into the abyss of poverty and disintegration.

Favored by globalization, the underground economy increased. Great fortunes are created many times as an effect of drugs and weapons traffic, prostitution, smuggling, money laundering, all under the mask of corruption. The world market was liberalized before the creation of the necessary global institutions for control and supervision of corruption and the opportunity to exploit the system was never greater.

5. Conclusions

The main losers of the globalization process are those countries that cannot join this growing phenomenon. They are left behind because of a lack of trustworthy political, juridical, economic, and social institutions. They have rejected the international economic ties like in the case of the African countries. The winners are the nations that drew commerce, capital and high technology (Japan, Korea, and Ireland). Therefore the losers are not really victims of globalization but more of the lack there of.

Environmental ethics

Popa Cristina

Ministry of Environment, Forest and Sustainable Development

cris20072002@yahoo.com

PhD Candidate Maricescu Liliana Denisa

“Valahia” University of Targoviste

Abstract

Respecting environmental constrains has a long history in humans' behavior and contributed in the development of the value systems that guide our behavior. In the last decades, these constrains are somehow differently shaped and understood since humans' technological capacity increased well beyond the limits of natural systems. These developments and the natural dynamic create premises for undesired processed to be unleashed. Are these changes mirrored in our value systems and how could they be integrated in these systems in order to shape a sustainable human behavior are the questions addressed by our paper. It is found that it is necessary to introduce new values in order to reflect some important environmental changes.

Key words: ethics, sustainable development, behavior, environmental change

JEL Classification: Q50

1. Introduction

Ethics means several different things, including systems of value in the customs and practices of human beings; those aspects that constitute moral behaviour; and the philosophical study of moral principles. Environmental ethics takes into account the fact that an individual has the moral obligations that go to the moral obligations of all ecosystems. The paper bring in discussion the ethic problematic of environemt, start from the manifestation of environemnt actions and goes further to normative principles of environmental ethics.

Environmental ethics is a new sub-discipline of philosophy that deals with the ethical problems surrounding environmental protection, has emerged as a new discipline that joins the world of natural ethical values (Van de Veer and Pierce, 1994, Armstrong and Botzler, 1998). Even now is recognized the universality of human rights, the reports of society with environment are contradictory, we discuss three manifestation of environmental actions: deep ecology, intermediate ecology and shallow ecology.

2. Deep Ecology

Philosophical belief system that holds that all forms of life—plant, animal, human—have an intrinsic right to exist in the natural environment and that humans have a direct responsibility to maintain the environment for all life forms. Is ecology that placing humans within ecosystems, different but not better or more valuable than other species or other "beings". With deep ecology, all beings have inherent value, apart from their usefulness or interest to humans, and people do not have a right to kill other creatures wantonly, destroy their habitats or cause pollution of the air, land or water on the basis that human need and human want is more important and powerful than any other creature's right to exist.

Deep ecology has led to a new system of environmental ethics. The core principle of deep ecology as originally developed is Arne Dekke Eide Næss doctrine of biospheric egalitarianism — the claim that, like humanity, the living environment as a whole has the same right to live and flourish.

3. Shallow Ecology

Philosophical belief system that holds that humans have a responsibility to protect the environment so it can support human life both in the present and in the future. With shallow ecology, people start from an assumption, often unexamined, that human beings are the central species in the Earth's ecosystem, and that other beings and parts of systems are of less importance or value.

In its extreme manifestations, shallow ecology views other beings and features of the Earth as resources for human use, and fails to see their intrinsic value or their value to each other.

Box 1. Case study

Suppose a mining company which has performed open pit mining in some previously unspoiled area.

Does the company have a moral obligation to restore the landform and surface ecology?

And what is the value of a humanly restored environment compared with the originally natural environment?

It is often said to be morally wrong for human beings to pollute and destroy parts of the natural environment and to consume a huge proportion of the planet's natural resources.

If that is wrong, is it simply because a sustainable environment is essential to human well-being?

Or is such behaviour also wrong because the natural environment and/or its various contents have certain values in their own right so that these values ought to be respected and protected in any case? .

4. Intermediate Ecology

In which humans have greater value but efforts are made to extend value to nature, usually other animals. Natural items have some intrinsic value, but wherever they conflict with human interests the latter must take precedence. Wilderness preservation, for example, is defensible in these terms as the preservation of something which does indeed have some intrinsic value which also meets some human needs; where oil, minerals and

other apparently vital needs are concerned, however, the former must give way.

Today, face with problems such greenhouse effect, the destruction of the ozone layer, and the presence of toxic and nuclear waste, the growing disappearance of wilderness areas, a steady loss of biodiversity among living things, and even the actual extinction of some species, more and more it is recognized that we have environmental obligations. Moreover, the massive destruction of the environment caused by military actions across the world, the military industry is among the most heavily polluting industries. The arms race not only wastes Earth's limited resources, but also leads to a lack of trust among nations. Some countries have annual military budgets of more than 40 billion US dollars, while to save the tropics, where 70 per cent of non-human species live, would require only 30 billion US dollars.

Once we recognize the environmental obligation all areas of ethics are affected, including just war theory, domestic distributive justice, global distributive justice, human rights theory and many others. Take global distributive justice as an example: if one considers how climate change will affect people throughout the world so differently – affecting individuals' homes, sanitation, resistance from disease, ability to earn a living and so on - it is clear that consideration of the environment is essential to such questions of justice. Part of the job of the environmental ethicist will thus be to give such disciplines the benefit of his or her expertise.

Finally, environmental ethics will be informed by our scientific understanding of the environment. Whether it be changes in our understanding of how ecosystems work, or changes in the evidence concerning the environmental crisis, it is clear that such change will inform and influence those writing on environmental obligations.

5. Principles Of Environmental Ethics

The environmental ethics concern is to outline our moral obligations in the face of such concerns. Environmental ethics extends the scope of ethical concerns beyond one's community and nation to include not only all people everywhere, but also animals and the whole of nature – the biosphere – both now

and beyond the imminent future to include future generations. There are many overlapping concerns and areas of consensus among environmental ethics, environmental politics, environmental economics, environmental sciences and environmental literature.

An environmental ethic is typically a global ethic with a global perspective, environmental pollution does not respect national boundaries. No country can deal with this issue alone. To cope with the global environmental crisis, human beings must reach some value consensus and cooperate with each other at the personal, national, regional, multinational and global levels.

Three normative principles of environmental ethics

(1) Principles of environmental justice

Environmental justice is the minimum ethical stance of environmental ethics. There are two dimensions to environmental justice. Distributive environmental justice concerns the equal distribution of environmental benefits and burdens, whereas participatory environmental justice focuses on opportunities to participate in decision-making. While domestic environmental justice is easily understood and accepted, the institutionalizing of global environmental justice remains a challenge to global society.

(2) Principle of intergenerational equality

The principle of intergenerational equality is an extension of that of equality. Equal rights constitute the core of the principle of equality. The rights to life, liberty and happiness are basic human rights shared by everyone, future generations as well as the present generation. Every generation should leave the following generation an equal opportunity to live a happy life.

(3) Principle of respect for nature

Though they may come from different perspectives, most environmental ethicists agree that we have a duty to conserve and protect the integrity of the ecosystem and its biodiversity. No one doubts that the prosperity of human beings depends on the prosperity of nature. Human beings are part of nature, and the human economy is a sub-system of nature's economy.

Environmental justice is the priority issue of environmental ethics. Unjust social frameworks maintain and reinforce

environmental injustice, with the result that the privileged permanently enjoy the benefits of the environment while the disadvantaged bear disproportionately the burdens of the environment. A right to the environment is one of the basic human rights, and everyone and every state has a duty to protect it. International environmental injustice is especially worrisome today. The developed countries should change their policies of transferring heavily polluted industries to developing countries, stop exporting hazardous waste to developing countries and adjust the high-consumption lifestyle of their population, these require better environmental policies.

Most policies have environmental and normative implications. Therefore, environmental ethics plays a great role in decision-making. Decision-makers are often ignorant of, unclear about or unable to deal with the ethical elements of their decisions. Policies involving prevention and control of pollution, or preservation and restoration of natural areas, are evaluated in terms of economics, politics and ethics. The environmental ethical dimensions of any given policy should be systematically explored, political powers should be urged to pass environmental protection laws, and people should be encouraged to engage in environmental protection campaigns.

Environmental ethics needs to be and will be informed by changes in the political efforts to ameliorate environmental problems. While this enterprise can be, and often is, quite abstract, it is also meant to engage with the real world. After all, ethicists are making claims about how they think the world ought to be. Given this, the effectiveness of states and governments in "getting there" will affect the types of ethics that emerge. For example, the Kyoto Protocol might be regarded as the first real global attempt to deal with the problem of climate change. However, without the participation of so many large polluters, with the agreed reductions in greenhouse gas emissions so small, and with many countries looking like they may well miss their targets, many commentators already regard it as a failure. Ethicists need to respond not just by castigating those they blame for the failure. Rather they must propose alternative and

better means of resolving the problems we face.

6. Conclusions

Given the increasing concern for the environment and the impact that our actions have upon it, it is clear that the field of environmental ethics is here to stay. If contemporary society adhere to the principles of environmental ethics, environmental protection and maintenance of biological diversity will become fundamental priorities, known as the ethics encourages social responsibility and the use of natural resources ensuring a sustainable development.

In the context of sustainable development, the business community acknowledges and accepts the need to gradually implement a social and environment police. Environmental protection is no longer regarded as an area reserved exclusively for government and community, but rather a shared responsibility of several interest groups: companies, financial institutions, managers, creditors, contractors, customers. The financial consequences, environmental responsibility and the risk to damage the reputation of a company is important for the adoption of standards of ethics and responsibility of environmental protection in each company.

Additional, civil society required to be consulted by the industry actors, and organizations are asked more and more to make public its standards of ethical conduct. Currently, external partners are more interested in the manner in which managers run their businesses. Some industries in particular are very sensitive to public opinion, in a world where communication is instantaneous and global. Following ethics in protecting the environment, companies react by social responsibility activities, environmental ethics is visible through the actions of corporate social responsibility, it calls on us to think and act locally as well as globally.

Automatic Detection of Common Long-Term Monetary Policies on Global Exchange Market Using Gabor Analytic Phase Binary Encoder

Nicolaie Popescu-Bodorin
Spiru Haret University, Bucharest, Romania
<http://fmi.spiruharet.ro/bodorin/>

Abstract

An application of Signal Processing to time series data analysis is presented here. Gabor Analytic Phase Binary Encoder (GAPBE) is used to retrieve the phase information from the long time series of currency exchange rates. As a result, a binary code is generated for each currency. Then the (dis)similarity between the local trends of any two different currencies is expressed through Hamming distance. A common policy for two different currencies is found when the Hamming distance between the binary codes representing the two given currencies is sufficiently small, but exact interpretation of the similarity scores obtained is left to the specialists. And this is all from the economist's point of view.

On the other hand, those interested in iris recognition should read this paper because the same procedure can be used to encode images of human iris. In this case it is worth to give an example of cheating iris recognition by finding two different irides having too similar iris codes. From this perspective, we show here that the exchange market provide us with such an counter-example in which two different exchange rate variation curves are encoded as too similar binary codes.

1. Introduction

This paper aims to present an application of Signal Processing to time series data analysis. Even if the examples here are based on time series reflecting currency exchange rates, an informed reader will be able to replicate the results using other particular data sets. If someone is interested in automatic detection of (dis)similarity between the local trends of some time series, the approach presented here is suitable for achieving the goal, regardless the particular nature of the data. When the time series contain the currency exchange rates for a long period of time, the similarity between the local trends of two different currencies is called a *Common (Shared / Mimetic) Long-Term*

Monetary Policy (CLTMP). This paper shows how to recognize automatically such a policy regardless if it happens intentionally or not.

Gabor Analytic Phase Binary Encoder (GAPBE) was originally introduced in [2] under the name of Gabor Analytic Iris Texture Binary Encoder (GAITBE) and used to encode images of human irides as binary iris codes. As is shown here, it can be also used to encode other signals (exchange rate time series in this case) very different from those for which it was originally designed.

For each currency, GAPBE is used here to retrieve the phase information from each exchange rate variation curve (Fig.1) as a binary code. Then the (dis)similarity between the local trends of any two different currencies is expressed using the Hamming distance between the corresponding binary codes generated for those currencies. A common policy for two different currencies is said to be found when the Hamming distance between the binary codes representing the variations of the two given currencies is sufficiently small, but the exact interpretation of the similarity scores obtained here will be left to the specialists

2. The test data set

The test data set used here comes from European Central Bank [1] and contains the exchange rates between euro and the other convertible currencies for a period of eleven years (1999-2010). Just for unification, the old ROL currency is expressed as RON. The appreciation / devaluation curves in Fig.1 are obtained as follows:

- All currencies use EUR as reference (an

Figure 1. Currency exchange rate variation (appreciation/devaluation) curves for the last eleven years (1999-2010). The data originated from [1].

imaginary horizontal line at the height of one should be interpreted as being the euro reference

- The second reference value is computed for each currency as being the average currency-euro exchange rate on the first 1.4 years (between 1999/01/04 and 2000/06/01)

The two references defined above allow us to analyze exchange rate variations against the euro - as an external reference, and against a virtual auto-reference value computed for the early history of each currency. They also allow us to represent currency devaluation / appreciation curves in a horizontal narrow band around 1, regardless the big differences between the nominal values of different exchange rates (for example, see the following two average exchange rates: 0.6954 for GBP-EUR and 130.87 for JPY-EUR).

3. The phase of a time series

The concept of *phase* comes from Signal Processing where is generally used to express information about the local variations within a signal, where '*local*' means that the variations are measured within a

neighborhood of the current point. The neighborhood is usually called a *window* and its extent is referred as the scale at which the signal is analyzed. And nothing changes if the analyzed signal is a time series of exchange rates.

When thinking about windows and scales, consider the following example: using a big window will enable us to find the roads within a satellite image but only a small window will allow the selection of a certain car from a certain road matching a given set of criteria. Here, the phase of a time series is computed as follows: for a given signal v , the corresponding strong analytic signal is computed:

$$a = v + jH(v),$$

where H denotes the Hilbert transform [5] computed using a certain window of size s (here we will use windows of one, two, or four weeks) and j is the complex unit. Then the phase information contained in v is retrieved as the instant phase P of the complex signal a :

$$P = \text{atan}(\text{imag}(a) / \text{real}(a)),$$

Figure 2. Uint8 quantization of three currency variation curves (HUF, GBP, PLN) and their corresponding binary codes (generated using GAPBE).

where the division by zero is considered a legal operation and the notation ‘./’ indicates component-to-component division. Gabor binarization (Fig.2) of initial signal \mathbf{v} is then defined as being the logical index (binary code):

$$B = \text{logical}(P > 0),$$

also regarded as a relation between the components of \mathbf{B} and \mathbf{P} , respectively. In short, the above three operations define what we called Gabor Analytic Phase Binary Encoder (GAPBE). More details about the encoder can be found in [2]. Also, a demo program will be available for download as soon as possible [6].

In Fig.2, three variation curves from Fig.1 (HUF, GBP and PLN) are quantized as uint8 (unsigned 8-bit integer) row vectors and replicated (32 times each) to form a visible image. The same type of replication is done with Gabor binarization codes in order to obtain big enough images illustrating exchange rate variations in 8-bit and 1-bit domains.

4. Gabor-Hamming indicators

Let us consider n currencies C_1, \dots, C_n and their Gabor binarization codes B_1, \dots, B_n . Hamming similarity between two binary codes B_i and B_j , denoted h_{ij} , is the ratio between the number of the corresponding bits that agree and the common length of the codes:

$$h_{ij} = \text{sum}(\text{logical}(B_i == B_j)) / \text{length}(B_i)$$

Such similarity coefficients computed for eight currencies are presented below, in Table 1 and Table 2, as percents.

Gabor-Hamming indicators of common long-term monetary policy for a certain set of n currencies are defined here as being the

biggest values found within the lines and columns of h_{ij} matrix, excepting - of course - the elements within the first diagonal.

In Table 1 and Table 2, *Gabor-Hamming indicators* are marked in bold. The coefficients marked with gray background tell us that the compression practiced by applying GAPBE can lose enough information such that the similarity between two very different variation curves (Fig.1 RON-HUF, RON-PLN) to be scored almost identical or even better than the similarity between two curves that really look alike (Fig.1, CZK, HUF, PLN).

Table 3 shows the correlation coefficients c_{ij} computed for all pairs of currencies (i,j). *Correlation-based indicators* of common long-term monetary policies are defined here as being the most extreme values found within the lines and columns of c_{ij} matrix.

From all *Gabor-Hamming indicators* (Tables 1, 2), those marked with underline have the highest level of confidence because they are also confirmed by the *correlation-based indicators*.

Table.1. *Gabor-Hamming indicators* of common long-term (2006/02/13 - 2010/02/16) monetary policies computed using a window of two weeks.

%	USD	GBP	JPY	CHF	CZK	HUF	PLN	RON
USD	-	<u>58</u>	<u>66</u>	54	45	38	39	44

Table 2. *Gabor-Hamming indicators* of common long-term (2006/02/13 - 2010/02/16) monetary policies computed using one-week, two-weeks and four-weeks windows.

%	USD	GBP	JPY	CHF	CZK	HUF	PLN	RON
USD	-	60	67	53	45	39	39	46
GBP	60	-	52	50	51	51	52	53
JPY	67	52	-	67	47	37	38	41
CHF	53	50	67	-	46	40	42	42
CZK	45	51	47	46	-	65	67	58
HUF	39	51	37	40	65	-	75	68
PLN	39	52	38	42	67	75	-	65
RON	46	53	41	42	58	68	65	-

Table 3. *Correlation-based indicators* of common long-term (2006/02/13 - 2010/02/16) monetary policies.

%	USD	GBP	JPY	CHF	CZK	HUF	PLN	RON
USD	-	36	36	16	-78	-38	-42	19
GBP	36	-	-69	-75	-56	50	47	92
JPY	36	-69	-	93	1	-78	-74	-80
CHF	16	-75	93	-	17	-73	-67	-86
CZK	-78	-56	1	17	-	26	39	-38
HUF	-38	50	-78	-73	26	-	88	69
PLN	-42	47	-74	-67	39	88	-	65
RON	19	92	-80	-86	-38	69	65	-

5. Conclusion

From the economist's point of view, the facts presented above tell that *Gabor-Hamming indicators* of common long-term monetary policy are suitable tools for economical analysis but they should be used in conjunction with other indicators of other type (*correlation-based indicators*, for example).

The same recommendation is theoretically advisable when using GAPBE in iris recognition, but unfortunately it is unpractical because, in iris recognition, supervising Hamming similarity with other parameters inevitably leads to an important

loss of speed.

The automatic analysis of the sub-market containing those eight currencies considered in Fig.1 and Tables 1-3 reveals a cluster of three Central and South-East European currencies which behave unitary, as a single currency (CZK, HUF and PLN).

It can be also seen that RON currency is the big loser on this sub-market because, excepting a positive trend in between 2005-2007, it always failed to integrate with the common long-term regional monetary policy of its stable neighbors.

Bioeconomics – the Essence of Nicholas Georgescu-Roegen’s Legacy

Popovici Veronica
„Ovidius” University of Constantza
verovnp@yahoo.com

Abstract

The ever augmenting climate debate nowadays sent us back on the field of research to one of the first economists that truly understood the devastating effects of human activity over our planet – no other than the founding father of bioeconomics, Nicholas Georgescu-Roegen. Reflecting upon all the factors that contributed to the tremendous insightfulness and incredible topicality of his convictions, we embark on a synopsis of the great Romanian economist’s lifetime work and on an analysis of his fundamental heritage for the human kind, fitting it in the pattern of the main biographical circumstances which influenced his academic development and interests.

We will try to outline the key moments which determined the transition from a purely mathematics-driven formation to an authentic interest for the economic science, its social character and the fitting of the bio-physic setting in this context, only to end up analysing the multiple layers of bioeconomics and to further canvass the different acceptations of what we proudly consider to be the essence of Nicholas Georgescu-Roegen’s message for posterity.

Key words: Nicholas Georgescu-Roegen, bioeconomics, entropy law.

JEL Classification: A 12; B 29; B 31.

1. Introduction

The innovative economist genius Nicholas Georgescu-Roegen has brought a contribution of an unquestionable value to science, being the first scholar who recognized the economic relevance of the thermodynamic principles and, especially, of the entropy law.

For almost half a century he has been inner critic of the neoclassic theory, outlining its

alternatives and insisting on the fact that the pure quantitative arithmomorphic standard economic theory eliminates MAN with all his characteristics and influential environmental factors from science, this approach offering a truncated image of reality.

In this context, Nicholas Georgescu-Roegen adopts a different angle for the economic science, but also for the political economy, with respect to the thermodynamic evolution. His revolutionary ideas involve a transformation of economic values through an authentic reconciliation between modern economics and biology as science of life, the result of this reconciliation being bioeconomics.

With a comprehensive embedment of economic, social and bio-physical constraints, the subject matter of economics becomes more than a simple description of the changes which take place within the markets, gaining multidisciplinary valences, the true purpose of economics being to produce an immaterial flow – the pleasure of living.

A raised awareness of the interdependencies between resources limitation, social instability and social organisation of the economic activity is becoming more and more recurrent nowadays, which makes our attempt to revise the underestimated contribution of Nicolas Georgescu-Roegen to this polemic even more justified.

The work of Georgescu-Roegen is however much more ample, being usually perceived through two registers, the first including articles on consumer theory or the production theory, written in the first stage of his career and following especially the tendency of that time to intensely use mathematics in economics, and the second one emphasizing his deep interest for what, thanks to him, has become known under the name of bioeconomics, interest which marked the rest of his academic efforts in the last part of his life.

Hence the very contradictory appreciations of his contribution, a large part of economists validating the early writings on pure economic theory and ignoring his late work, very criticized by neo-classical economists.

On the other hand, the pleaders of the latter consider Georgescu-Roegen a real pioneer in the sustainable growth and development field, giving up the neo-classical paradigm in the '60s in order to dedicate his entire attention to the issue of limited resources and social institutions.

In spite of these conflicting opinions about the work of this great economist, there were nevertheless voices claiming for coherence and logical evolution in its path from the system of values that accompanies the economic activity's point of view, starting from the hedonistic one of the neo-classical economics, then to the conflict between neo-classicism and the system of social values in the agrarian economy and culminating the '70s-'80s with the examination of the conflict between individual, social values and environment.

This article aims therefore at taking a brief glance at the entire work of the great Romanian economist and an analyzing his fundamental legacy, fitting it into the pattern of the main biographical circumstances which influenced his academic development and interests.

Thus we will try to outline the key moments which determined the transition from a pure mathematical development to an authentic interest for the economic science, his social character and the fitting of the bio-physic setting in this context, in order to stress in the end upon bioeconomics and to debate more widely the different meanings of what we proudly consider to be the essence of Nicholas Georgescu-Roegen's message for posterity.

2. Biographical and scientific marks

Professor Nicholas Georgescu-Roegen was born in a modest family with Greek descent in Constanta, on February the 4th 1906.

A brilliant young student, he took mathematics and statistics courses in some of the top elite schools of Europe: he attained a bachelor in mathematics from the University of Bucharest in 1926 and a PhD in mathematic statistics at Sorbonne in 1930, at the age of only 24.

He then continued his postgraduate studies at the College University of London, under the

guidance of the renowned statistician Karl Pearson. After a relatively short experience as a lecturer at the University of Bucharest, during which he also married Otilia (a mathematician colleague with whom he shared many interests), he was offered a Rockefeller researcher scholarship at Harvard between 1934 and 1936. Here he had the chance to work closely with the great Joseph Schumpeter, presiding the long weekly meetings of economic debates of the European researchers at Harvard, gatherings that represented maybe the most remarkable reunion of economists who ever worked together in the same place (and consisting of famous names such as Oscar Lange, Fritz Machlup, Gerhard Tintner, Nicholas Kaldor, Wassily Leontief, Ed Hoover and Paul Sweezy – all of them becoming afterwards great economic scientists).

This 'apprenticeship' in the economic science, as Georgescu-Roegen himself described it, meant a period of intense intellectual activity for him, in which many of the significant ideas that marked the second part of his career were born and found a rich soil to flourish.

Thus, under the close guidance and sympathy of the mentor Schumpeter, who shared his vision according to which the most important changes in economics are of qualitative and not of quantitative nature, his work at Harvard strengthened his belief that the economical processes, as well as the historical ones, are unique and impossible to accurately describe by any mathematical formulas.

In this short defining period, Georgescu-Roegen wrote four papers, out of which the last one – an original and pioneering contribution to the consumer choice theory, named '*The pure theory of the consumer's behaviour*' (Quarterly Journal of Economics, August 1936) – brought him fame and launched his international career.

Schumpeter would have wished to have Georgescu-Roegen as co-author for one of his books, reason why he invited him to join the group of professors at Harvard at the end of the scholarship; however this offer was turned down, Georgescu-Roegen preferring to return out of patriotism in his native Romania where he occupied different governmental positions and endured four dictatorships.

In 1948, under the threat of being arrested by the communist régime, Georgescu-Roegen managed to leave Romania, returning in the

end in the United States, where he became a professor at Vanderbilt University in 1949, position he kept until he retired in 1976.

For an economic thinker less gifted, such a decision to isolate himself from the revolutionary intellectual changes taking place in the USA would have been fatal. But not for Georgescu-Roegen who, although distanced from the economic activity for 12 years, following the voice of his heart and putting an ocean between his reality and the one of the burning revolution of the new economy, thanks to his extraordinary talent and strong mathematical base managed to recover the 'lost' time extremely quick, with the advantage of having enlarged the perspective over the institutions' importance for the economic development, gained throughout the time spent in his native country.

His first book – '*Analytic Economics*' (Cambridge, MA: Harvard University Press, 1966) – contains twelve articles published between 1935 and 1960 in different journals, some of them being considered even by the author among his fundamental contributions to the economic theory.

However, starting with this very book, Georgescu-Roegen already shows his disapproval regarding the growing tendency of excessively mathematizing economics, of the technology supremacy over reality and of disregarding the true economic life.

His specialization in mathematical statistics, the ideas highlighted mostly on the subject of economic utility and the experience gained in the governmental economic planning during the 'Romanian exile' were the essential elements allowing Georgescu-Roegen to have an overview of economics and offered him the pillars of critical argumentation to the classical economic theory, in the entropy and bioeconomics papers. One of these main pillars is to be found in his insistence upon the fact that economic phenomena are dialectical by nature and are based on the bio-physic reality of the environment.

Moreover, the original approach of the choice process, determined by the ranking perspective of the human needs, also determined him to emphasize the differences between '*homo oeconomicus*' described by the neo-classical theory and the active people within a social context – differences very well synthesized in the period during which Georgescu-Roegen

drew his attention towards the agrarian economy.

The two articles written on this subject and published in 1960, respectively 1965 draw from a number of economists the merit of forming the point of complete detachment from the neo-classical theory in Georgescu-Roegen's work and moreover, announced a fundamental change in his orientation as an economist.

In spite of a real interest for the underdeveloped and overpopulated agrarian economies and a deep understanding of their evolution displayed in these articles (unfortunately completely out of the current scientific focus areas), they formed the foundation of the emergent ecological economy, serving as a preamble for his future papers and constituting an ideal mean to display some of the most significant ideas which form the basis of bioeconomics.

Thus, in examining the agrarian life, Georgescu-Roegen outlined the obvious dependency of the peasant upon the biological and seasonal cycles, immediately emphasizing the fact that these do not lend themselves to the economic theories derived from an analogy with mechanics (the classical theory).

However, the impact of the biological processes upon the economic activity does not limit itself only at the level of the rural communities; therefore, appealing to the second law of thermodynamics, Georgescu-Roegen inserts the idea of entropic degradation as a fundamental constraint of all economic activities.

Then, he delimitates the economical effects of low entropy in the reduction of the stocks and the rising of the flows, idea which formed the basis of his fundamental paper – '*The law of entropy and the economical process*', published in 1971.

The fundamental message towards economists was that of recognizing the humans as a biological species, constrained by bio-physical processes and as social beings 'moulded' by institutional patterns.

3. Georgescu-Roegen's entropy and bioeconomics

The use of the second thermodynamic law – the entropy law – as a metaphor for economical activity is for sure the main scientific step

associated with the name of the great Georgescu-Roegen.

A few characteristics specific to thermodynamics, such as the qualitative change, irreversibility, inter-determination, limitation as a basic condition, are in complete antagonism to the mechanic model associated with the standard economical process, producing a very different image of the economic activity compared to the simple classical circular model which did not present the influence of any exterior systems or resources.

Georgescu-Roegen highlighted the fact that humans, as all biological beings in fact, depend upon the energy available in usable form, this being one of the essential distinctions on which he repeatedly insisted – the one between the free or available energy, and the ‘bound’ or unavailable energy. The entropy measures the unavailable energy of a system, and the human race unfortunately has the ‘merit’ of being at this time the most significant factor which contributes to entropic degradation through the rising of the extraction rate of natural resources and the elimination of the waste in the environment.

In the ‘70s Georgescu-Roegen invented the term ‘bioeconomics’, adopting a new approach to economic science; as he himself says, the term has the purpose of always making us think of the biological origin of the economic processes and thus bringing in foreground the problem of humankind’s existence with a limited stock of accessible resources, located and attributed unequally.

This last and most important part of the Romanian-American economist’s work integrated best the social and environmental components of the economic activity. He employed the term of *exosomatic organs* (borrowed from the biologist Alfred Lotka) in order to name the apparently unlimited variety of ‘detachable limbs’ developed by men in order to extend their range and field of activities.

Moreover, he also ascribed the current state of turmoil for humanity, characterized by ecological disasters on a wide scale and by ‘malignant inequality’ due to this exosomatic evolution.

The long history of humankind in the use of these ‘exosomatic organs’ has created dependence on the comfort and pleasure that they bring. The difficulty occurs however in

their process of production, very dependent at its turn on the finite stocks of energy and matter, bringing the obsession of our species for *more* and *better* on a path of collision with the imminent bio-physical limits.

Another feature of this exosomatic evolution represents the emphasis of social conflicts. Georgescu-Roegen perceived the division in social classes as a function of the production process which divides people in ‘governors’ and ‘governed’, a division which continues in the same direction in the sphere of distributing production’s fruits, as well as in the use of these exosomatic organs.

Thus Georgescu-Roegen criticized the neo-classical pure mathematical paradigm regarding the market equilibrium, arguing the oblivion of an essential detail, namely that the Walrasian equilibrium presumes the existence of an initial distribution of revenues and that this distribution is determined by the division in social classes.

The logical course on which Georgescu-Roegen gradually integrated the institutional and bio-physical component in his papers culminated with the personal model of the production activity presented for the first time in 1965 and then more detailed in ‘*The entropy law and economical process*’ and other papers. In this model he defined the technologization trend as being viable only if it can simultaneously maintain the adequate material structure and its functions forming the basis of the resource flows necessary to produce technology and, consequently, can serve the human species for an infinite period of time and in the current environment conditions.

This viability imposes therefore that the natural, terrestrial resources funds remain unchanged after the production process. Without sustaining all the necessary conditions in order to maintain these material funds, the ability of the economical process to produce energy flows cannot be perpetuated – therefore, the system of funds has to remain non-degraded within a viable production process.

In addition to that, according to Georgescu-Roegen’s opinion, the sustainability of any system should be evaluated on the sustainability of the whole system, not just on that of a part of it at a time. Without maintaining and sustaining the functions of the fund’s elements, an economic process cannot continue to produce economic flows in time. That is the reason why Georgescu-Roegen

always insisted on the fact that time should be a parameter in any production function, having a strong influence on the viability concept which forms the basis of its bioeconomical program.

In strong relation with these strong ideas was born also the fourth law of thermodynamics, the indisputable merit of this discovery being entirely attributed to the Romanian economist. Georgescu-Roegen had the brilliant idea to generalize the entropy law for matter. Thus, the fourth law doing nothing else but proclaiming for matter exactly what the second law of thermodynamics proclaimed for energy: «The same quantity of matter and energy can only be used once» or, «The same quantity of entropy can only be use once».

When matter is concerned however, an essential difference occurs, namely that instead of the tendency towards zero temperature, when the entire energy has become unusable, the tendency towards chaos occurs, when the entire matter has become unusable after its use, hence the irreversibility of this process.

This epochal discovery led Georgescu-Roegen to the developing of a program of bioeconomical measures in order to stop humankind's hustle towards disorder and chaos. Under the conditions of only a very small part of the used energy being able to become usable again through recycling, the only viable way to stop this imminent process, in his vision, is to find ways of freezing the terrestrial resources fund at its current stage, through rationalization, moderation, mutual help and returning to a precedential stage of development of the human society.

4. The bioeconomical program of Georgescu-Roegen

The economical and political recommendations detached from his bioeconomical approach were often catalogued as unrealistic, even utopian, demonstrating once again the universal rigidity associated with the consideration of a revolutionary paradigm.

Another cause would also be the incision with which Georgescu-Roegen claimed that the inhabitants of the developed countries should accept a lower standard of life if there was a wish for third world countries to ever get out of poverty.

Because of the rapid growth of global population, its unequal distribution, as well as that of the natural resources in the entire planet, and the monopsony power exerted by the developed nations over the resources of the world, he did not see another solution but slowing down the economy in some parts of the world so that the poorer nations could catch up and reach a 'modest' level of development, level which gradually would impose itself as a general standard.

Ultimately, his vision dictated the complete change of direction for the global economy, from one based on terrestrial resources funds to one based on solar energy flows.

'The minimal bioeconomical program' developed by Georgescu-Roegen in 1976 offered eight recommendations to head the human society in the opposite direction, including the gradual decrease of the population until it reaches a level which can be sustained just by organic agriculture, avoiding to use polluting energy sources (and employing regulating measures if necessary), giving up extravagant fashion, equipment and machines, producing goods which can be used longer and repaired easier, and rediscovering the equilibrium between labour and spare time, a transformation which would come naturally under the implementation of the rest of the measures.

In spite of the relevance and necessity of implementing many of these measures, even the most enthusiastic supporters of Georgescu-Roegen remain speechless in front of political and social obstacles raised by the desideratum of these kind of drastic changes.

Even the great economist himself revealed often scepticism about the human race's power of acceptance of any program which would presume the reduction of our material comfort, admitting sadly and sarcastically that we are maybe fated to have 'a short, but intense and extravagant life rather than a long, vegetative existence, without many remarkable events'.

The core of the bioeconomical paradigm consists therefore in the imperious change of our values system, so that decisions would be made based on the idea that the available matter and energy resources of the Earth are actually the legacy of mankind and should be preserved as much as possible for the future generations.

The implications of this kind of behaviour are naturally of biological, economical and

political nature, but any sacrifices should be made in the vision of Georgescu-Roegen on behalf of the greater good, of the posterity's protection, abandoning the maximization of the utility principle in favour of a more sensible principle – the one of minimizing the regrets.

The problem is not that people would be insensitive or incapable to act in a rational way regarding future generations, but the fact that, although no one is immortal, the entire humanity acts as if it would live forever and, consequently, values welfare without moderating itself and without abstaining from the things assuring it.

And however natural this reasoning might seem, this does not mean that a program which tends to treat all generations as being equal in rights in inheriting our planet is less rational, on the contrary.

5. Conclusions

Concluding our remarks, we cannot wish for more but to strengthen Georgescu-Roegen's message which, although needing an implementation much more adapted to nowadays reality, it remains as important and moreover, in our opinion, will become more and more relevant with the passing of time. The oppressive questions remain, of course, how much time will it need to pass before it receives the value it deserves and if the time that would have passed shall not eliminate the advantage of its existence?

The polemics around some of the most important ecological problems our species is confronted with, like losing biodiversity and global warming, have had as a result the display of policies based on the classical economical theory disadvantages, namely on the personal interests of some singular individuals belonging to every generation.

The economic discipline has much to gain from Georgescu-Roegen's contribution, whose ideas can revive and enrich these debates reappeared in the last years between economists and philosophers regarding the notion of rationality of an individual, notion which forms the basis of the neo-classical theory of utility.

The nature of the values defining us and the essential role of time are recurrent subjects in the works of Georgescu-Roegen, putting him always outside the static, strictly quantitative

and monist approaches of the neo-classical economy.

His heretical insistence on the fact that all markets, societies and ecosystems share a general dependence on energy and the inexorable laws of thermodynamics brought him to the entirely disagreeable conclusion that modern human society is not sustainable.

Maybe his message has persisted to always being as rigid and misfit to the comprehension power of a society blinded by consumerism and infatuated with slogans, sophisticated equipment and speed.

For Georgescu-Roegen, a realistic vision of the entropic nature of our existence would simply translate itself into a wise use of the resources; by their useless and ignorant dissipation we do nothing else but annihilate our chance for future choices, shortening the life of our species.

He even reaches that point of invoking capital commandments, where "Thou shall not kill!" or "Love your neighbor as yourself!" would transform under these dark perspectives into "Love your species as yourself!".

If we wish the human race to persist on Earth, our values system has to evolve farther than integrating the market values, even farther than the one of human communities' traditional values.

Such a 'viable' system of values has to take into consideration the limitation of resources on this unique planet, our dependence and vulnerability towards the fragile equilibrium of the live network surrounding us.

What is sad is the observation that at the present level of mankind development, such a conscious position regarding the dramatic role which we all play in our own elimination continues to be ignored, underappreciated and interpreted in distorted manners.

We can say that we are in an obvious deadlock when even the contemporary substantial literature on subjects of sustainability does not do anything else but underline the very difficult position, politically speaking, of the entire movement against the polluting the environment; this happens while all the professional reports on the other hand manage to describe in a worrying manner the effect of human activity on the planet, only to conclude with the same encouragement towards bigger economic growth as a solution for sustainable development.

Georgescu-Roegen's position and the solutions proposed by him can really be considered drastic and not easy to digest for a society arrived at a high degree of complexity, from all points of view.

However, not taking them into consideration or categorically discrediting them is for sure an equally reckless choice, especially now when all signals point out that we cannot continue to avoid addressing the crucial choices we must make.

Because, in the end, as the great economist also said, the human species will be the one defeated in this fight – “the planet Earth has went through much more difficult periods of time than the one it faces right now because of humans' activities, it had a very good life without us for the most part of its existence and it will continue to live exactly the same after we will cease to exist”.

Innovation as a competitive weapon in the uncertain service economy

Abstract

In this paper we want to demonstrate that nowadays - innovation is one of the key components of the service economy. Innovation today is not just a simple option for any service company, each and every one should use innovation to ensure revenues, profits and why not – survive on a more dynamic and evolving market. Starting from Peter Drucker's theory we can consider innovation one of the specific tools of the entrepreneurs, the means by which they can exploit changes as an opportunity for another business or another service.

Innovation is one of the key elements to make a business successful and help existing companies to face the challenge of globalization – the new economy. Using innovation is a must for a company that wants' to have a competitive advantage.

New service delivery models are essentially created after working closely with customers to provide innovative and unique solutions that can satisfy the consumer ever-changing needs.

Key words: service innovation, knowledge economy, technology, service systems, creativity.

JEL Classification: L80, O31, O33

1. Introduction

Innovation is one of the major driving forces - alongside skills, investment, enterprise and competition - that improves the productivity increases of organizations, and is therefore responsible for significant profit gains in the service sector. It is capable to create the conditions for business success and

help companies and countries to respond to the challenge of globalization. Innovation can be defined as the successful exploitation of new ideas – this definition applies to all firms in the economy and is equally relevant to services innovation. In the UK's Innovation Report 2003 were identified seven success factors for the country's innovation performance: sources of new technological knowledge; the capacity to absorb and exploit knowledge; access to finance; competition; customers and suppliers; the regulatory environment; and networks and collaboration [3].

In the knowledge economy, cleverness and dynamism, innovation and technology are considered to be essential instruments. These challenges created by „the new economy” are affecting all management areas that must align to these changes and must use the essential instruments (cleverness, dynamism, innovation and technology), without that, the failure is sure.

Innovation can take several forms: product innovation – changes in the things (products/services) which an organization offers (for example, a new design of car, a new insurance package for accident-prone babies and a new home entertainment system); process innovation – changes in the ways in which they are created and delivered (examples: change in the manufacturing methods and equipment used to produce the car or the home entertainment system, or in the office procedures and sequencing in the insurance case); position innovation – changes in the context in which the products/services are introduced (examples: the creation of a new market segment around low-cost flying, the development of a wide range of new media applications across both the internet and mobile delivery platforms); paradigm

innovation – changes in the underlying mental models which frame what the organization does (the shift of mainstream customers to low-cost airlines, the provision of online insurance and other financial services [8]).

A wide number of factors are impeding firms' commitments to innovation, with none of these standing out as markedly more important than the others. These barriers to innovation can be classified into three groups. The first relates to demand – customers do not want and/or cannot pay for innovations; customers are unresponsive to innovations; and previous innovations make further innovations unnecessary. The implication here is that firms do not innovate because they perceive no need to, and/or no reward for innovation. The second set of barriers relate to the firm's own abilities and internal impediments to innovation – the firm lacks the required technologies; the firm lacks the key staff necessary to innovate; organizational rigidities make innovation difficult; and the firm is too busy to innovate. The implication here is that firms would innovate more if they had more resources (including time) to do so. The third set of 'other factors' includes firms feeling regulations inhibit innovation; innovations are too easily copied; and the costs and risks of innovation are too high. It is notable that the top factor was customers' unwillingness or inability to pay for innovations, whilst the factor least likely to be identified as an important impediment to innovation was a lack of required technologies.

The old innovation theories, the researchers say, are flawed because they have focused almost solely on products and have ignored service offerings. They've also recognized firm-level innovation - the work of R&D departments, for example - while ignoring the value-added contributions of customers. In a new paper that challenges some long-standing theories about both what innovation is and how it's achieved, Stephen Brown and co-authors Stefan Michel, and Andrew Gallan, argue that the time has come for companies to rethink the ways they approach the innovation process. Innovation, according to Brown, Michel and Gallan, is no longer solely the domain of techniques or engineers working in isolation in a lab. Innovation now includes the collaboration of creative customers, who find ways to address their own wants and needs in the product or service. Customers are not just the receivers of value, they are the ones co-

creating the value in what companies and firms offer. They are not passive recipients of value [1].

The role of clients in the co-production of services and service innovations needs to be examined and conceptualized. The client is often especially critical in services innovation, so questions arise about: How to understand and assess the role of clients in innovation processes, to measure the co-production of innovations, the exchange and fusion of knowledge that goes on here? How to understand and assess the "impact" of innovation on service firm, client, and the service-client relationship? How to understand changing division of labor between the client and provider (as exemplified by self-service and user-driven innovation strategies, and as confronted in make-vs. -buy choices)?

Management and decision-making issues do not solely arise in the service organization, in many of these cases. This means that further questions arise concerning client decisions as to evaluating service propositions (especially given the difficulty of assessing services in advance of their production), and estimating the inputs required from the client (how is risk assessed and shared? How is trust established in innovation contexts?) How do customer perceptions of project success vary during the course of one or more services engagement (and associated learning effects)?

2. Towards innovation and competitive advantage with the Science of Service Systems

Driven by today's new business environment that includes advanced telecommunications, accelerated business globalization, increased automation, and rapid technology innovations, emphasis in the service sector has evolved from a traditional labor-based business to sources of innovations, collaboration, and value co-creation, driving the emergence of service-value networks at a pace never before seen in history. It is obviously a trend that leading and competitive services are all remarkably delineated with information-driven, customer-centric, e-oriented, and satisfaction-focused characteristics.

A variety of services enabled through service-value networks in the high value areas have been emerging recently, such as online information and knowledge service, IT

outsourcing to post-sales training, on demand innovations consulting (e.g., work helping customers reengineer products, automate business processes, improve goods and services delivery efficiency, and design and deploy supportive IT systems). By all means the networks must be built carefully, by developing adequate infrastructure based on workers and partners engagement. The partnerships – based on utility exchange – are developing in connection with organization's capabilities, with its valuable propositions, offered through appropriate channels, as solutions in relation with its target market. The success implies action capacity based on connections that allow these effective co-operation arrangements.

The competency of service providers to deliver superior outcome to the end user inevitably relies on the capability of engineering, performing, and managing quality of services throughout the entire service-value network. No matter what service is provided for whom, an entity of individuals or businesses, whether the need is fully met and the customer completely satisfied relies on the efficient and effective operations of the service-value network. Entities in the service-value network are service providers and clients; they could be individuals or businesses (e.g., companies, institutions, governmental agencies). It is widely recognized that competitive service systems are value coproduction configurations of people, technology, internal and external service systems connected by value propositions, shared interest and information (languages, customs, regulations, and metrics)[6].

With the help of on-going "industrialization" of the information technologies, enterprises must aggregate products and services into total solutions by implementing integrated and complete value chains to deliver their service-oriented solutions. The essential goal of applying total solutions to service-value networks is to enable the discovery, design, deployment, execution, operation, monitoring, optimization, analysis, transformation and creation of coordinated business processes across the whole value network. Ultimately, the profit across the whole service-value network can be maximized as it becomes the top business objective in today's global business environment [6].

Services specialists consider that the key to creating optimal service-value networks and

measuring service productivity, quality, compliance, operations, and innovations to gain competitive advantages is Service Science. Despite the recognition of the importance of service research, the shift to focus on disparate and global-scale services in the information era has created a research gap due to the overwhelming complexity of interdisciplinary issues across service marketing, service-oriented business modeling, information technologies, and workforce management. Filling the gap is essential. It is required to move the field forward not only by understanding and serving the customer but also by designing efficient systems of service delivery; training and motivating service providers; using new service technologies; and understanding how service affects the marketplace, the economy, and government policy.

A service system is a system that consists of people, technology, infrastructures, and processes of performance, which must be people-centric, IT-powered, and market-driven. The success of establishing service systems capable of delivering competitive and satisfactory services substantially relies on the following factors:

1. Service demand/marketing: varieties, market acceptance, penetration, and potentials, competitiveness and economic benefits - not just revenue (cost, price, inventory), but also beneficial opportunities in the long run.
2. Service environmental settings: service consumer's environmental setting (customs, languages, cultures, and regional regulations); service provider's environmental setting (workforce management, human behavior, skills training, knowledge transfer); human interfaces and interactions (psychological and physiological).
3. Adaptable and sustainable service engineering process: operations function and value, hybrid designed (artificially) and evolved (naturally) to meet the diverse needs of service environmental settings.
4. Large-scale information infrastructure: a complex and integrated system that can evolve over time to optimally support the defined service engineering processes, aimed at the delivery of needed data and information to the right user at the right time.
5. Effective management and efficient organization: planning, design, execution, and reengineering of the defined complex and adaptable services systems.

Science of Service Systems can be defined as a general theory of services that consists of

three bodies of knowledge: 1. Service systems and their services: understand the origins of new service systems and new services. Understand what is and is not a service system, and what services are produced and consumed. The role of people, technology, shared information, as well as the role of customer input in production processes and the application of competences to benefit others must be defined as well. 2. Service system improvements: Understand the ways a service system improves or can be improved over time through investments, including improving efficiency, effectiveness, and sustainability. 3. Service system scaling: Understand the ways improvements (new competencies) in one service system can be spread (scale out and scale up) to other service systems, both within and between types of service systems. Because of the nature of customer input in the production process, scaling the distribution of competences is a challenge in service systems. Unless the new competence can be reduced to a simple list of instructions that the receiving service system can implement through self-service, a more complex transformation service is required to spread the competence. [4]

Innovations are the key to stay a step or two ahead of competitors. New service delivery models are essentially derived by working closely with customers to co-create innovative and unique solutions best meeting customer inevitably changing needs. According to some specialists, a service innovation framework is critical for service businesses to stay outperform. "The framework can guide the creation of customer value and demand, and the processes and organizations that deliver services successfully - all of it catalyzed by emerging technologies." [5]

In summary, to help service providers maximize the profit across the whole service value network with a competent configuration by employing materialized and concrete service innovation framework, Services Science should be comprehensively studied, aimed at scientifically facilitating crafting and measuring service productivity, quality, compliance, operations, and innovations. As we mentioned before, Services Science is the key to creating optimal service-value networks and measuring service productivity, quality, compliance, operations, and innovations to gain competitive advantages.

3. Creativity, as a key component of service innovation

The service industry demands innovation in the coming decades; this innovation will come from companies that foster creativity and communication. Service innovation has many inherent risks from both customers and competitors, but wise management of these risks can lead to increased profits and a stronger long-term position. Creativity is a term that gets thrown around a lot but is sometimes difficult to define. Specialists consider that creativity is: "the habit of continually doing things in new ways to make a positive difference to our working lives". The following trend was mentioned in Business Week: "The Knowledge Economy as we know it is being eclipsed by something new - call it the Creativity Economy" [2].

While creativity shouldn't be limited to a few elites at a company, some discipline is required in order to make creativity useful and valuable for a business. Specialists consider that creativity and innovation are distinct entities, but the two words are often interchanged in the business world. Creativity plays a role in all the aspects of innovation, beginning with the generation of ideas. "You have to be creative in where you go to get your insight", appreciates Dave Lewis. If a firm consults the same research all the time, it comes up with the same insight.

Businesses need to give employees the skills and structure to bring change to marketplace. Creativity in the business world is a habit that can be practiced and honed. The practice of creativity in business should not be limited to so-called "creative types". Everybody in the company has the ability to be creative and should be encouraged.

We consider that Vaillant is an outstanding example of performing service innovation based on creativity. Today, Vaillant provides heating, air conditioning and ventilation in a perfectly coordinated system. They offer tailor-made room climate systems for the most demanding applications. The Vaillant success story started more than 110 years ago with a fundamental innovation (they introduced hygienic hot water convenience to the home with his gas bath boiler as a closed system). Since then the Vaillant brand has influenced global heating technology by a large number of innovations as today new visions are required. Their innovation is implemented in three directions: comfort, intelligent service

and design. Comfort innovation: their aim is to offer a perfect room climate - pleasant temperature, comfortable humidity levels and optimum air quality: a heating/air conditioning system that produces the ideal climate, a perfectly coordinated room climate that adjusts itself automatically. Intelligent service: the Vaillant Service Partner keeps his eye on the heating system – with the internet technology of vnetDIALOG. The technician is not on site but still keeps an eye on the heating system. Design innovation: their aim about design is to create user-friendly, perfect technology. Good design makes performance and quality noticeable. Vaillant understands that design is not just a means of making products attractive to touch and look at. Vaillant combines intuitive operation, good ergonomics and the consideration of future customer requirements with new product concepts, which means that the customer can feel the high quality in every sense. Vaillant is working with universities to develop concepts which look a long way into the future of modern domestic comfort. Young designers and architects develop a personal image of how customer requirements could change and what customers will consider to be domestic comfort in the future, and how products will meet these requirements. Customer can therefore enjoy an optimum level of safety and energy efficiency, combined with the highest level of comfort. This is the future of service at Vaillant, and it is already available today. [9]

A performing management of innovation requires finding answers to the following questions:

- How do service organizations (of different types) manage innovation processes in practice?
- How do these organizations capture intelligence on innovation so as to make it more reproducible (this may be referred to as "knowledge management") and why is this apparently often lacking? How can matters be improved?
- What is the role in services of traditional innovation activities (R&D, design, sourcing information from professional networks and from contract research and universities, acquiring equipment and software, training)? What other mechanisms and practices are involved?
- How are these activities planned, implemented, monitored, evaluated? Are there roles for better policy support, better metrics, etc?

In the 1990s, innovation was about technology and control of quality and cost. Today innovation is more about reinventing business processes, collaborating and integrating within the firm, and creating entirely new markets to meet various customer needs. Increasing globalization, the growth of the Internet, and more demanding customers are forcing marketers to find innovative ways of conducting service business. Understanding the connectedness of the external environment is vital to enhanced innovation in all domains.

4. Conclusions

Innovation has always been important to companies, especially with respect to developing new products. What has changed, however, is the focus of innovation in most companies. The twentieth-century model of innovation was about quality control, cost reducing and operational efficiency. Today, innovation is about taking corporate organizations built for efficiency and rewiring them for creativity and growth.

Through increased growth, better collaboration, and a broader product mix, the most innovative companies can pull their products out of commodity status and increase their profit margins. It is clear that innovation has become a source of revenues and profits and also a key driver of competitive advantage and success in today's uncertain economy.

And let's not forget one of Jon Spolestra's main themes from his famous book - "Ice to the Eskimos" - telling us that the companies have to innovate, innovate, and when they get tired they have to innovate some more so their success is certain.

cris2001vl@yahoo.com

Abstract

Information security is a broader concept which refers to ensuring the integrity, confidentiality and availability of information. The dynamics of information technology to induce new risks to which organizations must implement new measures of control. Technological development has been accompanied by security solutions, equipment manufacturers and applications including technical methods of protection performance. However, while in information technology change is exponential, the human component remains unchanged. Information security can not be achieved solely by technical measures, is primarily a human problem. Most security incidents are caused by inadequate management and organization, rather than because of deficiencies in security mechanisms. This paper presents the use of firewall security systems.

Key words: security, information, technology, development;

JEL Classification: Q32;

1. Introduction

Dependence on increasingly large information systems increase the vulnerabilities typology which organizations must face. Moreover, the issue of protection should consider private networks often interconnect with public services. If this issue add to the problem of information sharing is shaping a rather complicated picture in which the implementation of effective controls is a difficult task for the specialist IT & C.

Many of the systems on the market were designed as structured methodology but did not have as primary objective and ensure a degree of security because at that time technology was not nearly as developed nor as accessible to beginners. With the proliferation of the Internet but as important means of modern communication mechanisms need proactive security became a certainty. In practice note that many institutions turn to external technical solutions to solve their security problems without seeking to identify specific needs and requirements. Identification of internal controls to ensure an appropriate degree of security of an institution's information assets requires a thorough planning and precise identification of the objectives of this institution.

Financial institutions, industry, defense, aerospace, information technology industry, electronics industry sectors with the greatest risk in terms of information security. Also in this category of risk within government institutions, which is why the adoption of an organizational culture based on ISO / IEC 17799 is key.

It is important that each organization could to identify their security requirements. To do this it must appeal to three main sources:

- risk analysis;
- existing legislation;
- standards and procedures.

Using an appropriate methodology to analyze the risks the organization can identify its own requirements relating to security. Such a process generally involves four main steps:

- Identification of assets to be protected;
- identifying risks / threats specific to each asset;
- Risk ranking;
- identify checks that are removed / reduced the risks.

In this respect, ISO / IEC 17799 offers a number of security objectives and controls from which professionals can select those that match

the operating business. Furthermore this standard should not be considered a panacea of information security as long as it only provides advice to those responsible for implementing and managing a security system within an organization. A control mechanism should not cost more than good organization to be protected.

The security of a company shall be subject to the constituent elements, namely: making software security structure, defining security policies, standards, rules and procedures. Without stringent policies, security programs will be close without support, inefficient and will not align strategy and organization objectives. Policies, standards, rules and procedures are the foundation of the organization's security program. Effective, clear out, will serve the process of auditing and potential litigation. Combining elements specified, an entity may implement specific controls, processes, awareness programs and more, just to bring a touch of tranquility.

2. Use firewalls on intranets

A firewall is a hardware or a permanent filter that monitors and data transmissions made between your PC and Internet or local network, to implement a filtering policy. This policy could mean:

- protect network resources from other users of other similar networks - the Internet.
- Control resources they will access local users.

A firewall, working closely with a routing program, examines each data packet network (either the local or the view) that will pass through the gateway server to determine if it is sent on to destination. A firewall also includes or works with a proxy server which calls the package on behalf of workstation users. The most common protective cases these programs are installed on computers that meet only that function and are installed in the routers.

Firewall solutions fall into two broad categories: first is the professional hardware and software solutions dedicated to protecting all the traffic between an enterprise network and the Internet, and the second category is the personal firewalls on personal computers dedicated to traffic monitoring.

Although not a very proper distinction, firewalls can be divided into two main

categories according to the mode of implementation:

- dedicated device running the filtering software is dedicated to this operation and is virtually inserted into the network (usually even after the router). It has the advantage of increased security.
- combined with other networking facilities.

For example, the router can serve as a firewall, and for small networks the same computer can play at the same time the role of firewall, router, file / print server, etc.

The walls of protection plays a significant role in security management of an intranet. A shield is a device or application that controls the communication between the internal network and an external network such as the Internet. A shield (Figure 1) serves several purposes:

- acting as input filter for Internet traffic to the servers of the organization, preventing unauthorized reaching package of Web servers and applications;
- provide connections to the Internet via proxy maintaining internal user authentication;
- traffic logs, providing audit support, reporting, as for planning.

Figure 1. Location Firewall.

Firewalls do not work without risk. They are generally difficult penetrated, but it has been exceeded, the internal network is open to intruders. In addition, a firewall can not resolve internal network compromise. Approximately 70% of security breaches occur within the company, that are created by people across the wall of protection. An example may be using a modem and a dial-up connections.

In practice the following risks were observed on firewalls:

- ports - filter rules are based on source and destination ports. A machine that uses TCP / IP has 65,535 virtual ports, some of which are used by certain services;
- routing - this option allows users to define how IP routing package.

- SOCK - is a library of application proxies used to allow certain services to be used to keep intruders out;

- Scanning direct PRC – port-mapping is a service that allows users to identify ports that reside on remote procedure calls ;

- scan hidden - not an intruder tries to establish a connection but use package at an interface. These packages give us different answers, depending on the quality of the port (open or not).

- connectionless protocols - firewalls have difficulty in detecting packages used in services that do not require establishing a connection, and UDP, for intranets is necessary to have a intrusion detection system in order to protect the network perimeter attacks.

Intrusion detection systems can be installed as probes or agents. Probes are more efficient in terms of intrusion detection because it minimizes the impact on existing systems by passive hearing and reporting to the central console, without interruption.

Intrusion detection services running on a network device following functions:

- inspect string of data that passes through the network, identifying signatures of unauthorized activities and working procedures of defense;

- generates alarms when detecting events, notifying appropriate personnel security;

- activates an automatic response to certain problems.

In addition to intrusion detection can be considered a proxy for TCP aggregator that will improve security by restricting firewall ports exposed.

Tunneling and encryption are used to create point-to-point networks generally being used protocols and Layer 2 Tunneling Protocol (L2TP), Point-to-Point Tunneling

Protocol (PPTP), IPSec and encryption standards such as DES, MD5, Triple DES, etc..

Mobile code such as Java and ActiveX program creates a growing threat. Applications to inspect the content must:

- provide control over Java mobile code, ActiveX or another;

- prevent attacks by mobile code;

- enable the safe navigation using both Java and ActiveX features.

3. Conclusions

Finally, security management is a necessity in the increasingly high, both in intranet network type and other types of networks together, because the multitude of network access points. At the same time need new tools and techniques and a combination thereof to provide maximum safety possible.

Abstract

The core activities in systems development are system analysis, system design, programming, testing, conversion, and production and maintenance. Systems analysis is the study and analysis of problems of existing systems and the identification of requirements for their solution. Requirements must consider economic, technical, and temporal constraints, as well as the goals, procedures, and decision processes of the organization. There are various systems-building alternatives: the traditional systems life cycle, prototyping, application software packages, end-user development, and outsourcing.

Key words: *systems development, users, data planning and modeling methodology, database technology and management, data administration;*

JEL: O10;

1. Introduction

Wherever their origin, new information systems are an outgrowth of a process of organizational problem solving. A new information system is built as a solution to some type of problem or set of problems that organization perceives it is facing.

The resulting information systems is the product of a series of activities called **systems development**. Systems development is a structured kind of problem solving with distinct activities, as is illustrated in Figure 1 [3]. Each activity involves interaction with the organization.

Figure 1. The systems development process

2. Database Trends

Recent database trends include the growth of distributed databases and the emergence of object-oriented and hypermedia databases.

Beginning in the early 1970s, information processing became more distributed with the growth of powerful telecommunications networks and the decline in computer hardware costs.

The dispersion and use of computers among multiple geographically or functionally separate locations so that local computers handle local processing needs is called *distributed processing*. Although early distributed systems worked with a single centralized, over time the smaller local

systems began to store local databases as well. A *distributed database* is one that is stored in more than one physical location.

There are several ways of distributing a database:

a. the central database can be partitioned so that each remote processor has the necessary data on customers to serve its own local needs; changes in local files can be justified with the central database on a batch basis, often at night;

b. the central database can be duplicated at all remote locations; also require updating of the central database after hours;

c. another possibility is to maintain only a central index distributed database and to store complete records locally; a query to the central name index identifies where the full record can be found; there are no central database and no updating costs.

d. an "ask-the-network" distributed database, the network polls its remote processors to locate a record and transfers the complete record to whatever processor requests it.

Distributed systems have *benefits*: reduce the vulnerability of a single, massive central site; permit increases in systems power by purchasing smaller, less expensive minicomputers; they increase service and responsiveness to local users; and *drawbacks*: are dependent on high-quality telecommunications lines, which themselves are vulnerable; local databases can sometimes depart from central data standards and definitions and pose security problems by widely distributing access to sensitive data.

For large national organizations working in several regions, the question is no longer whether to distribute but *how* to distribute in such way to minimize costs and improve responsiveness without sacrificing data and system integrity.

Conventional database management systems (DBMS) were designed for homogeneous data that can be easily structured into predefined data fields and records. Conventional DBMS are not well suited to handling graphics-based or multimedia applications. An *object-oriented database*, on the other hand, stores both data and procedures as objects that can be automatically retrieved and shared. The *hypermedia database* approach to information management transcends some of the

limitations of traditional database methods by storing chunks of information in the form of nodes connected by links established by the user. The nodes can contain text, graphics, sound, full-motion video, or executable computer programs. Searching for information does not have to follow a predetermined scheme; the user can choose his own path to move from node to node. For each node displayed on the screen is shown the links between the node depicted and other nodes in the database.

3. Management Requirements for Database Systems

Perhaps the most difficult task of the systems analyst is to define the specific information requirements that must be met by system solution selected. Requirements analysis carefully defines the objectives of the new or modified systems and develops a detailed description of the functions that the new system must perform. Requirements must consider economic, technical, and temporal constraints, as well as the goals, procedures, and decision processes of the organization.

Much more is required for the development database systems than simply selecting a logical database model: the database is an organizational discipline, a method, rather than a tool or technology. It requires organizational and conceptual change.

The critical elements [3] in management requirements for a database environment are:

a. *data administration*: data planning, information policy, maintenance of data dictionaries, data quality standards;

b. *data planning and modeling methodology*: enterprise analysis, which addresses the information requirements of the entire organization is needed to develop databases; the purpose is to identify the key entities, attributes, and relationships that constitute the organization's data;

c. *database technology and management* refers to the more technical and operational aspects of managing data, including physical database design and maintenance; these functions are performed by **database administration**;

d. *users*: a database serves a wider community of users than traditional systems; more resources must be allocated to training end users.

Techniques used in requirements determination have involved over time to become more structured and increasingly rely on computer support. The more traditional requirements determination methods include interviewing, observing users in their work environment, and collecting procedures and other written documents. One of the current method is Joint Application Design (JAD); CASE (Computer-aided software engineering) tools are useful in requirements determination; prototyping has become a key tool for some requirements determination efforts.

4. Different Approaches to Improving Development

In the continuing effort to improve the systems analysis and design process, several different approaches have been developed. Attempts to make systems development less of an art and more of a science are usually referred to as system engineering or software engineering. As names indicate, rigorous engineering techniques have been applied to systems development.

The *system life cycle* is the oldest method for building information systems and is still used today for medium or large complex systems projects. This methodology assumes that an information system has a life cycle similar to that of any living organism, with a beginning, middle, and end. The life cycle methodology has a very formal division of labor between end users and information systems specialists. Technical specialists such as systems analysts and programmers are responsible for much of systems analysis, design and implementation work; end users are limited to providing information requirements and reviewing the work of technical staff.

The systems life cycle is still used for building large transaction processing systems and management information systems where requirements are highly structured and well defined. However, it is costly, time-consuming and inflexible. Volumes of new documents must be generated and steps repeated if requirements and specifications have to be revised.

CASE Tools is software that provide automated support for a wide variety Systems Development Life Cycle (SDLC) activities. An integrated and standard database called a

repository is the common method for providing product and tool integration, and has been a key factor in enabling CASE to more easily manage larger, more complex projects and to integrate data across various tools and products.

The term CASE is now extended to includes all types of computer tools from business modeling and requirements capture to implementation tools.

The general types of CASE tools are:

- diagramming tools enable system process, data and control structures to be represented graphically;

- form (computer display) and report generators that make it easier for the systems analyst to identify data requirements and relationships;

- automatically check for incomplete, inconsistent, or incorrect specifications in diagrams, forms, and reports;

- a central repository enables the integrated storage of specifications, diagrams, reports, and projects management information;

- documentation generators produce technical and user documentation in standard formats.

Joint Application Design is a process for collecting information system requirements and reviewing system designs. The basic idea is to bring structure to the requirements-determination phase of analysis to the reviews that occur as part of design. Users, managers, and system developers are brought together for structured meeting run by a JAD session leader. By gathering all the people directly affected by an information system to agree on system requirements and design details, time and organizational resources are better managed.

In many organizations, end users are developing a growing percentage of information systems with little or no formal assistance from technical specialists. This phenomenon, called end-user development, has been made possible by fourth-generation software tools: query languages, report generators, graphics languages, application generators, application software packages, very-high-level programming languages, and microcomputers tools (general-purpose application packages that have been developed for microcomputers).

Prototyping is less formal than the life cycle method. Instead of generating volumes of detailed specifications and documents,

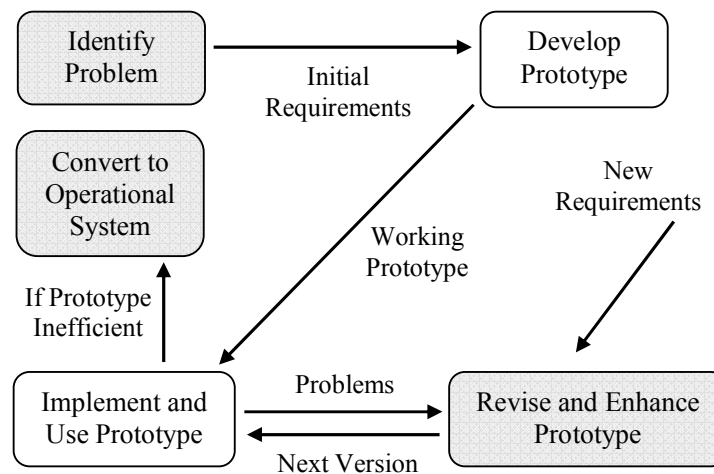

prototyping rapidly generates an experimental working model of a system for end users to evaluate. This method is most useful when some uncertainty exists about requirements or design solutions; it is especially valuable for the design of the *end-user interface* of an information system. Prototyping is best suited for smaller applications - large systems would have to be subdivided so that prototypes can be built one part at a time.

Prototyping consists in designing and building a scale-down but functional version of a desired system. A prototype can be built with any computer language or development

tool, with query screen and report design tools of a database management, and CASE tools.

Using prototyping as a development technique, the analyst works with users to determine the initial or basic requirements for the system; once the prototype is completed, the users work with it and produce feedback to improve the prototype; this iterative process continues until the users are satisfied with it. The advantage of this technique is that involves the user in analysis and design and its ability to capture requirements in concrete, rather than verbal or abstract form.

Figure 2. The prototyping methodology [6]

If one organization develops or runs a computer application for another organization, that practice is called outsourcing: a firm develop and run your application on its computers, so all you do is supply input and take output.

5. Sources of software

The specialists group the sources of software into six major categories: information technology services firms, packaged software producers, enterprise-wide solutions, application service providers, open source software, and in-house developers.

Information technology (IT) services firms help companies to develop custom information systems for internal use, or they develop, host, and run applications for customers.

On the top of global software companies is IBM who has been moving away from a

reliance on hardware development towards services and consulting: middleware software and application server, Web server, system integration services, IT consulting. Some of the largest computer companies in the world produce software exclusively, like Microsoft, the top in operating systems and its personal productivity software (Microsoft Office Suite).

Software companies develop what are sometimes called prepackaged software or off-the-shelf systems: Microsoft's Project is popular example of such software. The packaged software development industry serves many market segments.

Some off-the-shelf software systems cannot be modified to meet the specific, individuals needs of a particular organization. Such application systems are sometimes called turnkey systems. The producer of a turnkey system will only make changes to the software when a substantial number of users ask for a

specific change. Even though many organizations perform similar functions, no two organization do the same thing in quite the same way. A turnkey system may be good enough for a certain level of performance, but it will never perfectly match the way a given organization does business.

More and more organizations are choosing complete software solutions, called enterprise solutions or enterprise resource planning (ERP) systems, to support their operations and business processes. Each module supports an individual, traditional business function, such as accounting, distribution, manufacturing, human resources. The difference between the modules and traditional approaches is that the modules are integrated to focus on business processes rather than on business functional areas. Using enterprise software solutions, a firm can integrate all parts of a business process in a unified information system. The benefits include a single repository of data for all aspects of a business process and the flexibility of the modules. a single repository ensures more consistent and accurate data, as well as less maintenance; the modules are flexible because additional modules can be added as needed once the basic system is in place.

Another method for organization to obtain applications is to rent them or license them from third-party providers who run the applications at remote sites. Users have access to the applications through the Internet or through virtual private networks. The companies that host the applications are called application service providers (ASP). As a business grows or changes, using an application through an ASP becomes limiting. Responding to the need for growth and flexibility is a new generation of providers called managed service providers (MSP). An MSP can offer customized applications and also include business processes, engineering, security and maintenance.

Although exist several different types of external sources of software, in-house development remains an option, when resources and staff are available and system must be built from scratch.

6. Paradoxes of information systems development methods

Despite the efforts in method development and research, the question "are methods actually used in practice" is more often raised. It is a contradiction between the great efforts made to promote text-books methods and their surprisingly low use in practice. The companies still use empirical researches, or develop their own variants. Thus, there is a paradox between the claimed advantages of methods, which should indicate high use, and the empirical observations revealing low acceptance of methods.

It was identified some major benefits and drawbacks of method use [4].

Major benefits include enhanced documentation, systematized information systems development process, meeting requirements better, and increased user involvement.

Organization which do not use methods consider that these are labor-intensive, difficult to use and learn, and as having poorly defined and ambiguous concepts. The methods are also seen as limiting and slowing down development, generating more bureaucracy and being unsuitable. Most methods are proposed as universal, therefore the methods is not to apply them as given.

The local methods are more popular than their commercial counterparts; this explains the low acceptance of CASE tools which normally necessitate the use of fixed methods.

To sum up, many of the organizations which apply methods do not use totally the methods propose by other: commercial methods are modified, simplified or combined them with other methods, or organizations develop their own methods.

The development of the local method is relatively high costs and requires significant expenditure of resources, but they consider more applicable for the organization.

Abstract

Managing risks become a very challenging task for any organization and one of its priorities. The rising complexity of modern business processes, the globalization and the IT business perspective determined important changes in making business approach bringing opportunities but also increasing risks. Recent years have emphasized concern and focus on risk, and it became increasingly clear that a need exists for a robust framework to effectively identify, assess, and manage risk. COSO response to this need was materialized in its Enterprise Risk Management – Integrated Framework providing key principles and concepts, a clear direction and guidance in managing risks. The financial and economic crisis showed the importance of a strong risk management process and the need of important changes in order to improve the risk management process in each organization. Romanian companies were strongly affected by the crisis. One of the most important reasons is the ineffective risk management system in the company.

Operational risk is complex and its impact on companies' activity and financial results is high. Its complexity makes more difficult the effort to define dedicated models for its measurement. Modeling and better managing the operational risk is one of the priorities in all big organizations.

The present paper focuses on the main issues on operational risk management implementation and presents the authors' research results regarding operational risk management as an important part of the risk management process.

Key words: risk management, operational risk, financial and economic crisis

JEL Classification: D03, D81, G01, L20, M19

1. Introduction

Managing a multitude of internal and external risks is one of the most significant challenges facing global organizations today. Minimizing losses, maximizing organizational efficiencies and increasing incomes have always been high priorities for executive management and boards of directors. Increasing transaction volumes and the globalization of business, together with a larger reliance on IT, have induced high risks to organizations. In order to maintain a competitive advantage and to improve overall performance, organizations are seeking a way to understand and proactively manage the risks that can impact the business. The risks must be managed in a holistic approach and their independence action must be understood and treated accordingly. The banking industry is the most advanced in risk management as a result of a strict regulatory environment and supervision. This accumulated experience together with COSO recommendations must be valorized in any industry.

2. Risk Management Process

According with the governance principles, risk management and internal control system design and implementation are two linked and very important attributions of senior management. Risk management represents a process directed towards the assessing, mitigating (to an acceptable level) and monitoring of risks.

In COSO definition, internal control "system is a process, affected by an entity's board of directors, management and other

personnel, designed to provide reasonable assurance regarding the achievement of objectives” [3]. Control activities include also the policies and procedures maintained by an organization to address risk areas. The organizations’ objectives can not be achieved if the risks are not identified, assess, control and monitor in an appropriate manner.

The risk management goal is to maximize the operational capability of the organization, ensuring an efficient use of resources, valuating the existing opportunities in order to maximize the gain. To reach this goal it is necessary to have a good and profound understanding of the existing risks, to implement an efficient internal control system in order to prevent or mitigate the risks.

The management must focus on two issues: risks and opportunities emphasize COSO document [3]:

- Identifying and assessing risks in order to implement adequate controls over the processes and activities so that to obtain the risks’ mitigation;

- Identifying and evaluate the opportunities ensures the needed framework to optimize gain.

Risk management must accomplish the following tasks [9]:

- Identify risks
- Evaluate the risks as to likelihood and consequences
- Assess the options for accommodating the risks
- Prioritize the risk management efforts
- Develop risk management plans
- Authorize the implementation of the risk management plans
- Track the risk management efforts and manage accordingly

The process starts with risks identification. The significant risks must be identified and then assessed. Knowing the impact and likelihood for each risk, management must decide which are the unacceptable risks, the acceptable risks and their acceptance level (in other words the risk appetite must be established). In order to maintain the risks at the accepted level, management must decide the measures to control and monitor risks. The priorities are established and the risk management plan is prepared. It is very important for the management to monitor the

results of its risk management policies and plan.

Risk assessment is an ongoing process that includes identifying risks to achieving organization objectives, analyzing the risks, and deciding how to respond to the risks. External risks arise from activities outside the organization. These external risks may not be directly controllable by the organization or they may constrain the way in which the organization is permitted to take or address risk. Technological developments, changing public expectations, changes in the legislative and regulatory framework, natural catastrophes, extreme natural phenomena and economic changes all have the potential for creating external risks in an organization. Internal risks arise from activities inside the organization. No matter of the nature of risk (internal or external) the process of identifying risks should consider the following characteristics and attributes: type of risk, source of risk, areas the risk impacts, and level of ability to control the risk.

3. How to Manage Operational Risk?

Operational risk is not new, but the oldest risk which organizations face. Operational risk is defined as "the risk of loss resulting from inadequate or failed internal processes, people and systems or from external events" [2]. In Basel Committee approach, this definition includes legal risk, but excludes strategic and reputational risk.

Each organization’s operational risk profile is unique and requires a tailored risk management approach appropriate for the scale and materiality of the present risks, and the size of the organization. Each organization will need to consider its complexity, range of products and services, organizational structure, and risk management culture as it develops its operational risk management.

The operational risks can be generated by different causes as for example: business disruption and systems failures, processes failure, compliance gaps, failing controls, people behavior, damage to physical assets, employment practices and workplace safety, internal and external frauds, clients, products and business practices. The definition of operational risk incorporates the risks

stemming from people, processes, systems and external events.

Each company is a dynamic organism, knowing permanent growth, developing new products and services more and more complex and using more sophisticated IT infrastructure, operating in a dynamic regulatory, financial and economic environment. All these elements are source of potential operational risks. In this respect there can be identified some areas where operational risks are emerging:

- Extend use of automated technology mapping the potential of manual processing errors into system failure risks. It is also necessary to emphasize the great reliance placed on globally integrated systems;
- Proliferation of new and complex products;
- Extend of e-business and e-government transactions needing related business applications exposing the companies to potential new risks (internal and external fraud and system security issues);
- Need for continual improvement of internal controls and back-up systems;
- Usage of risk mitigation techniques;
- Outsourcing arrangements of all kinds. It is important to emphasize that the management remains responsible for risk management even for outsourced activities.

To make operational risk management effective in the business units it is essential to understand that operational risk is integrated to all other risk types and to understand the overlaps that occurred in particular with credit and market risk for example.

When working effectively, operational risk processes can provide coherent approach to managing risk and control, ensuring the embedding of operational risk into managing the business.

The implemented policies, processes and procedures should include principles for how operational risk is to be identified, measured, monitored, and controlled across the organization. It is important to mention that line of business management is responsible for the day-to-day management of operational risk within each business unit. Business lines' management must ensure that internal controls and practices within their line of business are consistent with the organization policies and procedures to support the

management and measurement of the organization's operational risk. But the awareness of the risks in general and operational risk in particular, must characterize each member of the staff. Implementation of the operational risk framework within each line of business should reflect the scope of that business and its inherent operational complexity and operational risk profile. It also must facilitate the collection of data on operational risk events.

We can conclude that the key elements in the operational risk management process include:

- Appropriate policies and procedures;
- A strong knowledge of the implemented processes in the organization and the existing weakness;
- Efforts to identify and measure operational risk;
- Effective monitoring and reporting the operational risk events and their impact;
- A sound system of internal controls ensuring the limitation of the operational risk events. This implies periodical review of the existing controls in order to ensure their effectiveness;
- Adequate testing and verification of the operational risk framework and continuous improvement of the operational risk framework.

In the authors' opinion, these elements can be put in practice by:

- Creating a system for collecting data related to incidents;
- Establishing a set of key operational risk indicators;
- Establishing the potential operational risk that can occur;
- Analyzing relevant external loss data to understand industry experience with respect to large losses;
- Designing and implementing adequate controls for the potential operational risk;
- Periodical test on the implemented controls, reporting controls' failure and taking measure for controls' improvement.

As figure no. 1 shows in all risk models is important to imbed relevant experience and knowledge and to value the existing information on potential loss events. All these operational events must be reported and retained in dedicated databases. All this

information will be analyzed and the response action will be decided accordingly.

Information related on operational risk must be summarize and reported periodically. Events with high financial impact will be reported at the moment of discovery. Being part of the risk management process it is also object of the internal audit assessment.

Operational risk management reports should summarize:

- Operational risk loss experience at the organization level, business lines, and event-type basis;
- Operational risk exposure;
- Changes in relevant risk and control assessments;
- Management assessment of early warning factors signaling an increased risk of future losses;
- Exception reporting;
- Operational risk causal factors.

Figure no. 1 Incorporating all available knowledge in risk model [6]

Sound internal controls will reduce the possibility of significant human errors and irregularities in internal processes and systems, and will assist in their timely detection when they do occur. Operational risk inputs play a significant role in both the management and measurement of operational risk. Operational risk inputs help the organization in identifying the level and trend of operational risk, determining the effectiveness of risk management. That's why each organization must define and implement its policy that identifies when an operational risk loss becomes a loss event and must be added to the loss event database. The organization must be able to capture and aggregate internal losses that cross multiple business lines or event types. In this respect, creating and implementing application that can be accessed by all the staff in order to input the loss events is critical. In the same

time, the employees must be encouraged to report this kind of events. This is also a corporate governance issue that must be put in practice.

The information input in the loss event database refers to the followings:

- Loss amount;
- Description of loss event;
- Where the loss is reported;
- Loss event type category;
- Date of the loss;
- Discovery date of the loss;
- Event end date.

The authors consider that, in designing operational risk process, can be used AMA approaches defined for the banking institutions, consisting in ensuring [7]:

- An independent operational risk management function.
- An operational risk measurement system that is closely integrated into the day-to-day risk management processes of the bank.
- Regular reporting of operational risk exposures to business units, senior management, and the Board, with procedures for appropriate action.
- The operational risk management system must be well documented.
- Regular reviews of the operational risk management processes/systems by internal and/or external auditors.

4. Conclusions

Risk management is a challenge for all the organizations. The organization, being a dynamic organism and operating in a changing environment is exposed to increasing and diversified risks. To reach the established objectives it is compulsory to ensure an efficient use of resources and monitor the risks. There is no predefined solution for risk management in general and operational risk management (ORM) in particular. Each organization must tailor and permanent improve its risk management process. What is essential is to make all employees aware on risk issues. Risk management must be understood and perform as an ongoing process.

Managing IT Risks

Stanciu Victoria
Academy of Economic Studies, Bucharest
stanciu victoria58@hotmail.com
Bran Florin Paul Ph.D
BCR Erste

Abstract

At a time when the importance of information and technology is obvious in every aspect of business, the need to manage more appropriate the IT risks has never been so important. IT is not just widely present in all organizations but complexly interconnected inside and outside the organization. As organizations' dependence and interdependence on IT have increased, the consequences of IT risk have increased as well. Technology has increased the amount of data and information being processed and it has significantly impacted the control environment and business itself. IT is now a key component of the business activities in any organization. In the same time IT risk management became a key component of the corporate governance. More and more organizations are aware that an effective and efficient IT risk management is vital to their success and reputation. Securing and operating today's complex systems is challenging and demanding. The increase of the cybercrime imposes more complex security solutions and higher costs.

The present paper presents the authors research results regarding IT risk management underlying the impact of the inadequate IT risk management on the organizations' activity, the necessity to build a global IT risk solution and manage all the risks, no matter of their nature, in a holistic approach.

Key words: IT risk management, technology, cybercrime, security;

JEL Classification: M15;

1. Introduction

The risk management process must take into consideration the fact that risks action is interrelated and their consequences must be evaluated in a holistic approach. Risk travels through the organization in an interdependent and connected way.

Risks must be recognized and managed holistically across the entire organization. Risks of all kind exists by the organization activity its self. IT risk always exists, whether or not it is detected or recognized by an organization. Not long ago, IT risk occupied a small corner of operational risk. Now, it is time to change this approach and treat IT risk as a significant risk and manage it accordingly. Due to the importance of IT to the overall business, the IT specific risks can induce failure to achieve strategic objectives.

In their work the authors opt for a mixed research methodology, including deductive positive research, as well as inductive critical interpretative research. These two approaches are able, in the authors' opinion, to offer a strong interconnection of theory and research work, merging quantitative and qualitative research methods.

The methodological approach was mostly positive and required the following steps:

- The selection of the research area.
- Research area literature review: The main source of information was represented by IT Governance Institute and ISACA documents.
- Delimitation of the conceptual framework boundaries which included the specialists' points of view regarding fundamental concepts and the relationships arising among these concepts. At this level,

descriptive, exploratory and evaluative research techniques were used.

- Decisions regarding key questions/areas.
- Defining the starting hypotheses to be verified through empirical research.
- Performing the research: carrying out interviews with IT managers and specialists, documentation on risk management processes implemented in Romanian organizations and conducting analysis on these IT risk management solutions.
- Final conclusions formulation.

The authors started their research from the requirements of the IT governance principles and IT security standards and intended to emphasize the impact of the IT risks the organization is exposed to if there are not implemented adequate IT security strategies and policies. The research outcomes were materialized in authors' recommendations regarding approaches to be used in IT risk management and means of correlation of IT, business and risk strategy.

2. Needing a holistic approach in risk management

IT has become an integral part of the business. With IT so intrinsic and pervasive within organizations, governance needs to pay special attention to IT. In this respect, IT governance became an integral part of organization governance. In this new approach, the business strategy and the IT strategy become interrelated. Risk strategy is also built in correlation with business and IT strategies. Now, more than ever, the executives understood how strongly the enterprise relies on IT and how critical IT is for the execution of the business strategy. As a result, the sets of objectives for business and IT strategies are interconnected and the monitor over the objectives fulfillment must be done for both sets - business and IT.

The figure no. 1 emphasizes the linkage between business, IT and risk strategies. The business strategy can't be established without taking into consideration the risks involved by the organization processes, products and its operating environment. The business objectives must be based on the defined risk profile (the present one and the targeted one) and the organization tolerance at risk. In order to accomplish the business strategy objectives

IT strategy will provide the frame and requirements for IT developments so that the technical solutions (hardware, software and communication) to support the business lines ensuring in the same time the needed security.

Figure no. 1. The interconnection between business strategy, IT strategy and risk strategy

Based on the IT strategy, the IT plans will be drawn ensuring the IT solutions' implementation. A key to successful IT performance is the optimal investment, use and allocation of IT resources (applications, technology, facilities, data, and people). In this respect, the IT strategy and plans must be tailored based on the business plans and projects and their schedule must be aligned to the business plans and deadlines.

The value that IT adds to the business is a function of the degree to which the IT organization is aligned with the business and meets the expectations of the business. These expectations can be reflected in some indicators and requirements as for example:

- Meeting business requirements
- Flexibility to adopt future requirements and ensuring permanent compliance with legal requirements
- Time response
- Ease of use and security
- Integrity, accuracy and disponibility of information
- Limits regarding downtime caused by IT dysfunctions
- Limits regarding the number IT events/losses from IT events
- Number of users.

But how IT can support risk management and why risk strategy is linked with IT strategy? Risk management process needs consistent databases and dedicated applications in order to offer accurate and

consistent risk information. As a result, based on the risk models, risk scenarios and stress tests designed by chief risk officer (CRO), the organization will develop/acquire the IT dedicated solutions so that in day-to-day activity to be implemented the risk strategy. It is also necessary to notice that IT risks are subject of risk management assessment, monitor and reporting. In this respect, risk limits must be established for IT risks too so that their control to be effective. This IT risk acceptance levels imposes adequate IT solution, security solution inclusively. In this respect, IT strategy will be tailored based on this IT approved risk profile.

3. IT risks and consequences

Today, the success of organizations may hinge on mastering a broad landscape of IT risks. According with IT Governance Institute documents “**IT risk** is the business risk associated with the use, ownership, operation, involvement, influence and adoption of IT within an enterprise. IT risk consists of IT-related events that could potentially impact the business. It includes both uncertain frequency and magnitude, and it creates challenges in meeting strategic goals and objectives as well as uncertainty in the pursuit of opportunities” [8]. IT risk encompasses the full spectrum of risks that may affect or result from IT operations: natural disasters or changes in government and/or supervision bodies’ regulation, internal processes that affect product or service quality, IT organizational and datacenter performance, loss of intellectual property, supervisory or legal controls, and much more.

In the authors’ opinion, many managers do not yet understand the full implications of IT risks. IT risk, in many organizations, is still approached as a technical issue and is not approached linked to other specific risks. That is why IT risks are considered to be just on IT specialists’ responsibility and there is no adequate implication of other senior executives.

Our research emphasize that most IT risks arise not from technical or low-level people issues but mainly from the failure of the organization’s oversight and IT governance processes. IT risk results from decision-making processes that ignore the full range of potential business consequences of IT risk.

Such failures produce a series of inadequate decisions, inadequate structured IT assets that are manifested as ineffective IT governance. Best practice recommends integrating the management of IT risk into the overall enterprise risk management (ERM). IT risk must be managed as any other significant risk. In this respect the organization must prepare and approve:

- Clear strategy and policies. The IT strategy must be correlated with the business strategy. The IT assets and support can potentate the business and create new opportunities, can improve the organization image and reputation.
- The risk profile and the processes for its monitor, IT risk being part of them.
- Procedures for risk response.

Because IT risk is now a business risk, with business consequences, enterprises must change the way they manage it. They must replace technology-driven approaches and fragmented views of IT risk with an integrated view that starts with an understanding of the business risks and consequences that generated by IT decisions.

We must understand IT in a dual approach: risk and opportunities. IT demonstrated that it is a progress vector for any organization: enables the use of the business opportunities and enhances values through optimal use of IT resources. At the same time IT, by all its components, can induce vulnerabilities and expose the organization to adverse events. In this respect, the dedicated processes for IT risk identification, assessment, monitor and report need periodically review and improvement.

IT environment is very dynamic. It is characterized by permanent changes and developments. As a consequence, new vulnerabilities and threats can occur. In this respect, the IT risk identification and monitor is an ongoing process.

Every organization has a unique IT risk profile that can register changes in time. These changes are determined by the new risks tolerance and IT infrastructure and components. The organization security strategy and policies must be tailored on its characteristics, complexity and demands.

4. Responsibilities on IT risks

While risks like market, credit, liquidity and other operational risks than IT risk have long been incorporated into corporate decision-making processes, many executives tend to relegate IT risk to technical specialists. According with IT Governance Institute (ITGI) document on IT risk framework, “responsibility belongs to those who must ensure that the activities are completed successfully. Accountability applies to those who own the required resources and have the authority to approve the execution and/or accept the outcome of an activity within specific risk IT processes”. In this respect ITGI presented its recommendations on the attributions and responsibilities related to risks, IT risks inclusively [9]:

- Board has the accountability on common risk view and integrating with Enterprise Risk Management (ERM).
- Chief executive officer will have both responsibilities and accountability on common risk view and integrating with ERM.
- Chief risk officer will have responsibilities and accountability on all ERM areas: risk governance, risk assessment, risk response.
- Chief financial officer will have responsibilities on common risk view.

It is the first time when an organization as ITGI is providing such detailed requirements on this subject. All these recommendations aim at ensuring a strengthen governance and risk management by clarifying main responsibilities on risk area.

It is important to emphasize the place of business management and business process owners in this matrix of responsibilities and accountability related to risk. Business management is responsible on: common risk view, integration with ERM, risk analyze, maintaining risk profile, managing risk and risk response. The business process owners get responsibilities on all risk governance, risk assessment, risk response issues.

In risk management process are implied risk committees being responsible on common risk views, risk-aware decisions and risk analysis. As best practice requires (ITGI), “for larger enterprises, it is necessary an IT executive committee (often referred to as the IT strategy committee) acting on behalf of the board and

chaired by a board member. This committee is a very effective mechanism for evaluating, directing and monitoring the use of IT in the enterprise and for advising the board on critical IT issues”. [9]

A strong internal control system implies three functions: risk control, compliance and internal audit. All these three functions present responsibilities on risks:

- Risk control function gets responsibilities on all risk governance, risk assessment, risk response issues;
- Compliance and internal audit are in charge with common risk view and event response issues.

The common users, accidentally or not, can induce IT risk events. In this respect there are required several response actions from the organization part:

- enforce a risk culture, and place IT risk in the appropriate place. A risk-aware culture starts at the top with business executives who set direction. The goal is a culture in which risk is discussed openly across the organization and actively managed to tolerable levels.
- ensure continuous training on risks’ procedures, IT inclusively;
- implement adequate controls and perform their periodically review.

Having an excellent IT staff is not enough to control IT risk. Managing IT risk requires everybody involved to think differently. The CIO must make the business consequences of IT risk clear to business executives and provide a decision-making environment in which those executives can discuss and make decisions about IT risk in business terms. Business executives must ensure that the CIO has implemented risk management and must actively participate in the decisions and culture changes that IT risk management entails.

Many of the risk factors are generated by ineffective IT governance. It is important to notice that inadequate IT governance is characterized by the absence of appropriate structures and processes for business involvement in IT investments and decisions.

5. Risk mitigation action points

In order to mitigate risks, it must be identified the systems’ vulnerabilities and their threats source. Each identified risk must be

analyzed from likelihood and impact points of view and delimited to acceptable risks from those considered unacceptable. The IT risk “appetite”, mining IT risk levels assumed by the management decision, is used in the acceptable and unacceptable risks delimitation. Risk mitigation activities imply several steps to be followed [3]:

- Actions prioritize: in this stage the risk levels established in the risk assessment activity are used. The result of this step is the actions ranking (the ranking levels are: high, medium, low);
- Evaluation of the recommended control options: the starting point is the risk assessment. The step result is the list of possible controls;
- Cost-Benefit analysis. This step ensures the assessment of the impact of implementing and not implementing the controls and the associated costs. In accordance with the risk appetite a certain level of risk is accepted by the management. All IT risk solutions will have to ensure this risk acceptance and face with an agreed cost;
- Selecting the needed controls. The implemented controls must be permanently assessed so that their effectiveness is ensured. In time, the existing controls can impose improvements or new controls can be added so that the risks to be mitigated.
- Responsibilities assign;
- Develop safeguard implementation program which include: risks and associated levels, actions prioritization, recommended controls, selected controls, responsible persons, timings, maintenance requirements.

The organization must establish the needed controls for the IT risks. According with Symantec IT risk report the key controls for managing IT risk are [5]:

1. Strategic controls implying:

- IT policy, strategy, and architecture
- Organizational structure, roles, and responsibilities
- Governance, compliance and continuous improvement
- Data lifecycle management

2. Support controls

- Asset inventory classification and management
- Physical and environmental management
- Configuration, change and release management

- Incident, response and problem management.

The effectiveness of the implemented controls must be permanently checked, and if needed additional controls must be implemented. The IT environment and systems are in a permanent change and development in the effort of better sustain the organization needs. All these changes can be source of new vulnerabilities. This is why risk identification and assessment process must be considered as an ongoing process. Independent opinion on IT security and IT risk management is needed on periodically bases. This is why IT audits are periodically performed.

6. Conclusion

IT risk management is more than using technology to solve security problems. Implementing an adequate IT function and ensuring a strong IT risk management the organizations can gain competitive advantage from its competitors. But IT must be understood and managed in its dual approach: risk and opportunities.

Adopting an integrated view of IT risk represents a milestone of the risk management process. All senior managers must be aware of the importance of an adequate IT risk management and allocate the needed resources for the IT function and security solutions in order to keep IT risk at an acceptable level.

The business strategy must be designed in correlation with risk strategy and IT strategy. Without these correlations, the strategic goals can't be accomplished under a consistent risk control.

IT risk management must be an ongoing process, starting with risk assessment, paying an important attention to the cultural and training issues and addressing long-time improvements.

Risks, of all kind, must be managed in a holistic approach being known their interrelation. The board must approve an appropriate risk profile. An early warning system must be put in place so that the organization reacts in time in case of registering increasing levels of risks.

Responsibilities on risk management must be clearly assigned and ensured in day-to-day

activity impaling all senior managers and process managers.

Data and Information Exchange via the Internet

Stancu Ana-Maria Ramona
Academy of Economic Studies, Bucharest
ana_maria_ramona@yahoo.com

Abstract

In connection with the exchange of data and information on the Internet talking about EDI, XML and UDDI. I can say that EDI is international standard for exchanging documents and computerized and appeared through the years 1960 and can be considered the ancestor Electronic Commerce and also talk about the benefits of it. Descendant of SGML and XML was developed for the construction of languages of any domeniului. Vorbesesc and characteristics and advantages and can say that format is flexible, open standard that can be accessed by many applications on multiple platforms, and UDDI provides a mechanism for registration and classification of web services that you offer web services and show you want to eat.

UDDI is itself a Web service and users communicate with UDDI SOAP measaje used. A UDDI registry contains information about businesses and services you offer. UDDI can be used to record any type of service not only web services.

Key words: EDI, XML, UDDI

JEL Classification: A12, C88, O33

1. EDI (Electronic Data Interchange)

EDI represents the international norm for the computerized exchange of documents (data). The EDI acronym comes from the English language: Electronic Data Interchange which means "Exchange of electronic data". EDI is defined as: „*the exchange of computerized information from one application to another, in a structured data format, through a telecommunications network*". The EDI standard approved by ONU is called EDIFACT meaning: EDI for Administration, Commerce and Transport. In essence, EDI

allows the exchange of electronic documents eliminating the printing and handling of paper. This exchange is not practically limited in time and space.

EDI – Electronic Data Interchange) emerged in the 60's and could be considered the ancestor of the Electronic Commerce – EC. EDI gives to commercial companies the opportunity to exchange business documents into a standard format by using electronic means for their processing and transmission.

Towards the end of the 70's a new model emerged related to business computerized systems- *the reciprocal exchange of Electronic Data* (EDI - Electronic Data Interchange).¹

EDI specifically refers to structured messages. Non-structured messages could be sent in several ways, for instance, by means of electronic mail (e-mail).

EDI technology reduced the costs incurred both by producers and by suppliers (wholesale or retail). Also, it led to the substantial improvement of acquisition processes (optimisation of stocks and their correlation with the demand). However, due to implementation costs and incompatibility issues between different EDI versions, the real penetration power estimated on the market has never been achieved.

The use of EDI at an international level has been imposed by the requirements of the complex exchange of commercial documents and by sophisticated relationships between companies

The advantages provided by EDI are the following:

- Increase of competitiveness
- Increase of customers' number;
- Increase of information reliability;
- Easy access to computer statistical data;
- Increase of personnel efficiency.

¹ <http://www.ledisource.com/information/beginner>

2. XML eXtensible Markup Language

XML (eXtensible Markup Language), descendant of SGML (Standard Generalized Markup Language) is a meta-language used in the activity for structural marking of documents whose specification has been developed beginning with 1996 within the Consortium entitled World Wide Web (W3C), by a research group led by Jon Bosak from Sun Microsystems, to which subsequently adhered a series of expert groups from academic (Text Encoding Initiative, NCSA, James Clark) and industrial communities (SUN, IBM, Netscape, Oracle, Adobe etc.). The first XML version was standardized in February 1998; this standard has been subsequently revised twice in October 2000 and February 2004 respectively.

The functions designed for XML range as follows:

XML should be easy to use on Internet.

- XML should be compatible with a wide range of applications.
- XML should be compatible with SGML.
- It should provide facile programs which will further process XML documents should be written.
- The number of optional facilities from XML is reduced to a minimum, ideally to zero.
- The XML documents should be readable by users and clear in realistic terms.
- The XML design should be prepared fast.
- The XML design should be formal and concise
- The XML documents should be easy to create.
- The lapidary character from XML markings should bear minimum importance.

XML has been elaborated in order to:

- Separate the syntax from semantics in order to provide a common framework for structuring the information
- Elaborate mark-up languages for application in any field
- Ensure the future structuring of information
- Provide the independence from platform and support for internationalisation

Ever since its appearance, the XML language has enjoyed sustained popularity, even greater than Java and HTML languages, being considered the most advanced web technology. The increased level of flexibility and its simplicity are the two characteristics which make it so wanted. XML gained ground when Internet Explorer 5 and Netscape 6 browsers were launched and quickly became the solution for companies which intend to automate and connect their systems and data basis.²

A XML document is an ordered labelled tree:

- **character data** – leaf nodes containing data
- **elements** nodes tagged by
 - a name (often call the element type) and
 - a multitude of attributes each having a name and a value; these might contain one or several children.

Main characteristics of XML are:

- it is a markup extended language, similar to HTML;
- it has been designed for data writing;
- XML tags are not predefined but they could be created by the user on the basis of some predefined rules;
- XML contains a reference to a Document Type Definition (DTD) in order to describe the way in which data are being formatted;
- XML is used in conjunction with a DTD in order to be auto-descriptive.

XML advantages

- XML describes the contents and the display modality of the respective contents;
- The information is easier to find and handle in XML-based format;
- XML provides multiple facilities which are improved by presentation (for instance by using browsers)
- XML supplements HTML: XML data could be used within HTML pages.

XML provides the ideal methodology for electronic business as it permits the makers of type messages to clearly identify the role and syntax of each element related to variable data

² PC Romania Journal,
http://www.pcmagazine.ro/pcmag3-3/timpul_liber3.shtml

using a definition which is both automatically workable and automatically interpretable.

XML could extend existing EDI applications as it permits the creators to add data specific to the application.

The XML language represents a flexible format, an open standard which could be accessed by numerous applications on multiple platforms. This means that applications could be conceived faster and could be solidly-built and easier to service.

3. UDDI (Universal Discovery, Description and Integration)

In order to solve the issue related to the discovery of Web services and to the ways communication is achieved with them the technologies developers and the business leaders gathered their efforts and coordinated with a view to develop the UDDI [17] specification. UDDI represent a common effort for the integration of business-to-business transactions so as to reach industrial proportions. This Web service defines a set of standard interfaces for accessing data bases by creating an open framework, independent from the platform which gives the companies the opportunity to accomplish several objectives at the same time.

Currently, **UDDI** specifications reached version 3 which tries to constitute **UDDI** as a huge „meta service” intended for searching web services.

UDDI allows the companies operating via the Internet two things:

- To discover one another;
- To define their interaction modality via the Internet.

4. Conclusions

International standard for electronic document exchange, EDI contains functions necessary to carry out specific electronic data interchange. Software establishes connection with computer communications partner, and receives transfer data confirms and completes the connection, according to communication protocol. Need to communicate with all devices connected via Internet required to create a universal language. This language is XML, which facilitates the exchange of data

between different devices: computers, cell phones, PDAs, etc.. By combining EDI with XML to create a powerful new tool Internet applications. UDDI is a directory that is intended to be complete all companies that have presence on the Internet, and Web services that provide them. Through UDDI creates a standard interoperable platform and applications that enable businesses to quickly find and use the dynamic Web services provided by the Internet.

Support provided by SQL Server for XML language

Stancu Ana-Maria Ramona
Academy of Economic Studies, Bucharest
ana_maria_ramona@yahoo.com

Abstract

This paper aims to provide support offered by SQL Server for XML. Languages run server-side scripting (ASP, ASP.Net, PHP or JSP), are already mature technology today, providing an opportunity to develop complex applications for Web ului. Necesitatea can communicate with all connected devices via the Internet has required the creation of a universal language that is understood by all devices and applications located on the server must be able to prepare data for transmission. XML makes its presence felt in this area mainly because of its flexibility in WML (Wireless Markup Language), an XML application for mobile dizpositive.

Key words: information exchange, Internet, XML, server, WEB, ASP, ASP.Net, PHP, JSP;

JEL Classification: O33, A12, C88

The very fast development of the Internet has helped the main trend related to the development of applications after the 90s to consist in the provision of support and accessibility for clients connected to the Internet, either via computers or through some other devices (intelligent mobile phones, PDA, etc.) which could be connected to the Internet. The large number of languages and technologies which permit the facile development of applications related to the exploitation of existing databases by means of a simple Web browser. To this end, the scripting languages run on server-side (ASP and its successor ASP.Net, as well as PHP or JSP) are presently mature technologies which represent a further opportunity to develop some complex Web-dedicated applications.

Bearing in mind the need to be able to communicate with all devices connected through Internet the creation of a universal language understandable by all equipment, no matter how various, has been imposed. XML

proved to be the response to all these needs, forming a new period – a superior stage from all points of view – during the evolution of informational era and facilitating the exchange of data between various equipments. XML also emerged as a consequence of the limitations of the Hypertext Mark-Up Language (HTML). The latter could not provide the necessary flexibility for using data within other applications.

Taking into account all these considerations I shall present bellow some of the facilities provided by the *SQL Server* environment for the *XML* technology and the modality it integrates with the Web Server - Microsoft Internet Information Server (IIS), explaining at the same time the most significant among the most recent options, specific for the SQL language and capable to provide support for *XML*.

The server-side applications should be able to prepare data for transmission. These applications should provide XML documents with extended or fixed DTD validation pointers and towards one or several styles specifications. We need to convert the XML to server-side objects in order to publish certain information, in order to create services and to improve the manner in which businesses are being managed via the Internet.

There are several server-side technologies which cannot be divided as easy as the Client Technologies. The HTTP protocol is being used by the client browser with a view to transport data processed on the server-side before these are sent from HTTP to the client. The procedure involved for transferring and processing of data is very simple: the client browser requests an URL from the server. The DNS (Domain Name Server) determines the IP server address and redirects the Web server request which carries out a new session for the client.

The electronic publishing for the purposes of direct marketing is one of the most usual forms of promoting businesses through the Web and companies could obtain significant sales increases only by using it.

Web Servers could provide information to users in two different ways: static files and dynamic-generated files.

The first situation refers to the use of existing XML files which one can create by extracting information from within a database and by generating the XML file which will be stored on the server.

Its displaying is performed by means of XSL-extensible Style sheet Language.

The second possibility is constituted by the dynamic generation of XML files due to server-side languages - JSP, ASP, CGI, PHP, etc.

The configuration of the support for XML as far as SQL Server is concerned supposes the following operations:

A. By means of the *SQL XML Support* application in IIS the option *New – Virtual Directory* is being selected. Subsequent to the carrying out of this operation an assistant (wizard) will be available who will facilitate the determination of interaction between the data base server and the Web server.

B. *The creation of the virtual directory*, establishing its name (which shall be used within the URL component module for selecting the Web pages) and of the physical directory where Web pages or other specific elements will be stored. Supposing that the virtual directory has been called XML, the Web pages or SQL interrogations based on XML technology could be accessed through the browser, using the following address: http://nume_server_web/XML.

C. By means of the *Security section*, a user name and a valid password are being introduced in order to access the SQL Server and the data base which we intend to operate through the XML technology. Moreover, in the event we determined the mixed authentication mode we could access the data base both through an SQL Server user account and by using a standard user account of the Windows operating system.

D. The *Data Source* section allows for the determination of SQL server to be accessed and of the data base to be used. In the event the server is accessed within the local network the appropriate IP address needs to be specified; if these settings are intended for testing at a local level, the identifier (*local*) shall be specified for the SQL Server field.

E. By means of the *Settings* the way in which the interaction between the data base server and the Web server would be made is therefore set, through XML technology.

Therefore, two important options could be established:

- *Allow URL Queries* – through this option SQLXML interrogations might be performed directly through the introduction of the SQL interrogation as an additional parameter to the URL address. *Allow Template Query* – through this option interrogations might be performed while using a series of predefined XML templates.

Also, configuration options are accessible allowing the setting of directories where the templates and configuration schemes of XSL files would be stored.

The advantages of using the XML-XSL combination are as follows:¹

- It is easier in terms of site management
- XML separates the formatting contents
- XML represents an open standard

The advantages of using XML within the electronic business are the following:²

- *Simplicity*-it could be easily understood by computers and by people

- *Extensibility* –it gives us the opportunity to create our own tags closely related to the business specificity

- *Maturity* – the XML specification appeared in February 1998 but this language represents a simplification of SGML – a language which made its appearance long before and which proved its usability in business environment.

A new business pattern is mentioned, that is mobile businesses which in fact represent an extension of businesses for wireless devices.

The XML currently emerges in this area due to its flexibility especially through WML (Wireless Markup Language), an XML application for mobile devices.

Conclusion

The most convenient practice management databases is provided by modern DBMS SQL Server 2005, which was created by Microsoft and the company integrates advanced analysis tools and security in conditions of high reliability. Every copy of SQL Server 2005 comes with a suite of Business Intelligence services and facilitățile autooptimizare dynamic, self and allow administrators database to focus on strategic business

¹ <http://www.106.ibm.com/developworks/library/>

² xml and b2b

requirements. User access Internet require collaboration between database server and web server, leading to exploitation of centralized database of customers that are provided only data they require aceștia.Platforma. NET technologies together with other host applications designed to be run Web - Microsoft Internet Information Server - and management system database SQL Server 2005 is the most modern, fast and efficient way for a firm to be a good presence on the web.

A Risk Correlation Model for an European Emerging Country and its Integration in a Global Macroeconometric Model

Stoenescu Cimpoeru Smaranda
Academy of Economic Studies, Bucharest
smarandacimpoeru@yahoo.com

Abstract

In this paper we construct and estimate a country-specific macroeconometric risk driver engine which is compatible to the GVAR model and framework developed by Pesaran, Schuermann and Weiner, methodology that makes use of cointegration techniques to link the cyclical or systematic components of firm credit risk with the firm's own idiosyncratic credit risk. As the general framework in PSW, 2004 lacks a Central-Eastern European component, we propose an extension of the model in order to incorporate a Romanian element. We adapt the Romanian variables and data to the particularities of an emerging economy. The results show that the new estimated component can be use as a theoretically consistent correlation model within a Romanian specific credit portfolio management tool.

Key words: GVAR model, emerging economy, Central-Eastern European component.

JEL Classification: C51, O40

1. Introduction

The recent challenge in the credit risk modeling refer to the linkage of the the cyclical or systematic components of firm credit risk with the firm's own credit risk. Credit risk refers to risk due to unexpected changes in the credit quality of a counter party or issuer and its quantification is one of the major frontiers in modern finance. Credit risk is a key element in portfolio management, bank capital regulation and credit derivatives pricing. Recent years have witnessed significant advances in the techniques,

design, calibration, implementation of models for assessing credit risk.

Considering its important place in the country specific and world economy, we can view the credit risk as one of the causes and the effects of the economy's status. In order to sustain this comment, we argue that the economical environment has a major influence on the asset value of companies (the "effect" implication), but also that the credit activity of banks, based on their assessment of credit risk is a lead factor in the development/drawback of an economy (the "cause" implication)

The "cause" implication is also stated by Carpenter et al. (2001): "the credit supply behavior of banks may affect the cyclical of economic activity for a variety of reasons, including factors that are unrelated to capital requirements, such as time-varying perceptions and aversions to risk among loan officers." The latter part of the statement refers to the judgemental assessing of credit risk, which is indeed a subjective component of lots of rating models of banks in Romania. In the same paper, Carpenter explains the feedback effect between capital requirements and business cycle: in case the general economic climate deteriorates to a certain level, a significant number of loans would have to be reallocated to a higher risk category, which means that capital requirements could rise noticeably. As issuing new equity is rather difficult on short term, banks will not choose to raise capital, but instead will opt for shifting assets away from the higher-risk loan categories or reducing the growth of their overall balance sheet. Therefore, credit supply conditions might become more restrictive as an economy is falling into recession, especially considering the new capital requirements under Basel II. As the purpose of the paper is not to

assess the effect of credit supplies on the business cycle, we will not go further with this analyze and focus on the influence of macro-economical context in the credit risk modeling.

Commercial banks would largely benefit from a global macroeconometric model capable of generating forecasts for a core set of macroeconomic variables taken for a set of region and countries, thus considering the interdependencies that exist between worlds' economies – all put together in a consistent, cohesive methodology.

This idea was developed by Rae and Turner (2001) – they constructed a small forecasting model covering the US, the Euro area and Japan; another model structure across OECD countries, China and other regional blocks was incorporated in the NiGEM model (National Institute's Global Econometric Model). However, although these models provide significant contributions to the inter-linkages that exist among major world economies and proved good forecasting results, they are difficult to use for risk management (due to their size and lack of financial inter-between world's economies).

The methodology proposed by Pesaran, Schuermann and Weiner (2004 – PSW) and Pesaran, Schuermann, Treutler and Weiener (2006) has the advantage of linking an adjusted structural default model to a structural global macroeconometric model (global vector autoregressive – GVAR model), thus providing the context for estimating the conditional credit risk. The PSW methodology is comprised of two steps: first – a macroeconomic simulation engine is estimate and then the specific default firm models are estimated in order to translate the macroeconomic conditions into credit risk outcomes.

The paper has the following structure: the first three sections are dedicated to the methodology and framework proposed by PSW (2004), followed by Section 5 where we propose a methodology for constructing a vector error correcting Romanian model which can be linked to the original model.

2. The PSW GVAR model

The macroeconomic risk-driver model (GVAR) used in PSW (2004) is comprised of 7 developed economies, USA, Germany, France, Italy, U.K., Japan, China and 20 other countries aggregated in 4 regions: Western Europe, South East Asia, Middle East, Latin America. The output for these countries accounts for 70% of world GDP. They were chosen based on the size of their GDP, basically G-7 countries – considering that major banks have most of their exposure in these set of countries. In the case of Romania, the GVAR model lack applicability since it does not include an east European region. However, the approach is general enough so that country-specific cointegration models can be linked into the global and already established GVAR model, as already did by Wet et al. (feb.2009), which successfully included a South African component into the model. In this section of the paper we present the core elements of the GVAR models, as stated in PSW (2004).

The N+1 countries/regions considered in the global economy, are indexed by $i = 0 \dots N$, country "0" taken as referenced country. The country specific variables are related to the global economy through the vector of foreign variables (constructed with inter-country trade weights), the "starred" variables. The equation for the vector of specific variables can be written as a VARX(1,1) :

$$x_{it} = a_0 + a_{1t} + \phi_{11}x_{it-1} + A_{10}x_{it}^* + A_{11}x_{it-1}^* + \varepsilon_{it}, t = 1, \dots, T; i = 0, \dots, N \quad (1)$$

Where x_{it} is a $(k_i \times 1)$ vector, x_{it}^* - $(k_i^* \times 1)$, Φ_i - $(k_i \times k_i)$ matrix, A_{i0} , A_{i1} - $(k_i \times k_i^*)$ matrix. Please note that if $A_{i0} = A_{i1} = 0$, the model reduces to simple VAR(1).

We make the following notation: $\Sigma_{it} = (\sigma_{it,ls})$ the covariance matrix of the residuals, $\varepsilon_{it} \sim i.i.d. (0, \Sigma_{it})$, where

$\sigma_{it,ls} = COV(\varepsilon_{ilt}, \varepsilon_{ist})$, thus only lag dependent, time invariant.

The global variables used in the model can be summarised as follows:

$$y_{it} = \ln\left(\frac{GDP_{it}}{CPI_{it}}\right), \quad p_{it} = \ln(CPI_{it}), \quad q_{it} = \ln\left(\frac{EQ_{it}}{CPI_{it}}\right),$$

$$m_{it} = \ln\left(\frac{M_{it}}{CPI_{it}}\right), \quad q_{it} = 0.25 \ln\left(1 + \frac{R_{it}}{100}\right) \quad (2)$$

Where “i” stands for the index country and the variables are: nominal gross domestic product (GDP), consumer price index (CPI), nominal money supply (M), nominal equity price index (EQ), nominal rate of interest per annum in % (R).

3. Solution of the GVAR model

In order to solve the GVAR model, we define the vector:

$$z_{it} = \begin{pmatrix} x_{it} \\ x_{it}^* \end{pmatrix}, \text{ of dimensions } (k_i + k_i^*) \times 1 \quad (3)$$

By using (3) in (1), we get:

$$A_i z_{it} = a_{i0} + a_{i1}t + B_i z_{i,t-1} + \varepsilon_{it} \quad (4)$$

Where $A_i = (I_{k_i} - A_{i0})$, $B_i = (\Phi_{i1}, A_{i1})$, both A_i, B_i are matrixes of $k_i \times (k_i + k_i^*)$ an rank k_i .

We collect all variables in a global vector:

$$x_t = (x_{0t}, x_{1t}, \dots, x_{Nt}) \text{ of dimensions } (k \times 1),$$

where $k = \sum_{i=0}^N k_i$

thus, we will have:

$$z_{it} = W_i x_t, i = 0, \dots, N \quad (5)$$

where W_i is a $(k_i + k_i^*) \times k_i$ dimensions matrix of fixed (known) constants defined in terms of the country specific weights $w_{ij}^y, w_{ij}^p, w_{ij}^q, w_{ij}^e, w_{ij}^r$ and w_{ij}^m . W_i can be viewed as the “link” matrix that allows the country-specific models to be written in terms of the global variable vector, x_t .

Replacing (5) in (4) we obtain:

$$A_i W_i x_t = a_{i0} + a_{i1}t + B_i W_i x_{t-1} + \varepsilon_{it}$$

where $A_i W_i, B_i W_i$ are $k_i \times k$ dimensional matrices. The above equation can be written as:

$$G x_t = a_0 + a_1 t + H x_{t-1} + \varepsilon_t \quad (6)$$

both G, H are $(k \times k)$ dimensional matrices. Then, we find the solution of the GVAR model by multiplying (6) with G^{-1} :

$$x_t = G^{-1} a_0 + G^{-1} a_1 t + G^{-1} H x_{t-1} + G^{-1} \varepsilon_t \quad (7)$$

4. Estimation of the GVAR model

So far, we have presented the solution for the GVAR model, a very elegant and natural

solution proposed by PSW (2004). As it has been observed, the general model allows for interaction amongst countries and economies through three channels: contemporaneous dependence between the endogenous (domestic and foreign) variables and their own lagged values; dependence of country-specific variables on common global effects (oil prices were chosen in the GVAR model); weak cross-sectional dependence of the idiosyncratic shocks between countries.

These particularities provide a complete system of N+1 country-specific variables which can be estimated simultaneously. However, the number of parameters that need to be estimated in such a global model is often higher than the number of data available. In order that the model wouldn't become unusable, PSW (2004) make a significant enhancement to the framework and prove that the model can indeed be estimated by estimating step-by-step the country models, rather than simultaneously, thus making it feasible for large values of N.

Under weak exogeneity conditions the parameters of the country specific models can be estimated using the reduced-rank regression approach introduced by Johansen (1989, 1995). As such, one allows for the possibility that the levels of the macroeconomic variables might be cointegrated in the long run, this being one of the main reasons for choosing the reduced-rank regression instead of ordinary least squares. Although a simpler technique, OLS wouldn't have allowed for the fact that one or more of the six factors used in the model might have unit roots, or that the variables might be cointegrated (e.g. the levels of the variables might be “tied” together in the long-run). As the method developed by Johansen assumes that all variables are endogenously determined and of order I(1), a modified method for estimating reduced rank regression is used, method that permits weakly exogenous regressors, which has been developed by Harbo, Johansen, Nielsen and Rahbek (1998) and Pesaran, Shin and Smith (2000).

Therefore to estimate the country-specific models subject to reduced rank, we shall firstly consider a generalized version of the global model that allows for “common global

variables” such as oil prices. The augmented VARX* model in this case is given by:

$$x_{it} = a_{i0} + a_{i1}t + \phi_i x_{it-1} + \lambda_{i0} x_{it}^* + \lambda_{i1} x_{it-1}^* + \psi_{i0} d_t + \psi_{i1} d_{t-1} + \varepsilon_{it} \quad (8)$$

For $t=1,2,\dots,T$ and $i=0,1,2,\dots,N$, where d_t is an $s \times 1$ vector of common global variables assumed to be weakly exogenous to the global economy. The error-correction equation for the above model is written as follows:

$$\Delta x_{it} = a_{i0} + a_{i1}t - \Pi_i v_{i,t-1} + \lambda_{i0} \Delta x_{it}^* + \psi_{i0} \Delta d_t + \varepsilon_{it} \quad (9)$$

where:

$$\Pi_i = (A_i - B_i, -\Psi_{i0} - \Psi_{i1})$$

A_i, B_i as defined in equation (4) and:

$$v_{i,t-1} = \begin{pmatrix} z_{i,t-1} \\ d_{t-1} \end{pmatrix}$$

Π_i is a $k_i \times (k_i + k^* + s)$ matrix and provides information of the long-run level relationship that may exist amongst the variables of the model. In the case where all the variables, z_{it} and d_t , are I(1) and are not cointegrated, then Π_i will be equal to zero and equation (9) becomes a first differenced model:

$$\Delta x_{it} = a_{i0} + \lambda_{i0} \Delta x_{it}^* + \psi_{i0} \Delta d_t + \varepsilon_{it} \quad (10)$$

Where $a_{i1}t$ is no longer part of the model, as in order to avoid the problem of quadratic trend, a supplementary restriction was imposed, that is:

$$a_{i1} = \Pi_i \kappa_i.$$

If $\Pi_i = 0$, then we will have random walk models (augmented by oil price changes) for the global variables, z_t . If we use the solution technique presented in the previous section, we get the following form for the GVARX* model:

$$G \Delta z_t = a_0 + \Psi_0 \Delta d_t + \varepsilon_t \Leftrightarrow \Delta z_t = G^{-1} a_0 + G^{-1} \Psi_0 \Delta d_t + G^{-1} \varepsilon_t$$

The important conclusion one can draw from the above equation is that if in the regional models there are no long-run relationships (e.g. no cointegration), then there will be no long-run relationship in the global model.

But, as outlined by PSW (2004), “in general due to long-term inter-linkages that exist between domestic and foreign variables themselves one would expect Π_i to be non-zero but rank deficient”. We note that the rank of Π_i equals the number of cointegrating relationships between variables in country i . The rank deficiencies appears when $rank(\Pi_i) = r_i < k_i$. In case where Π_i is non-zero but could be rank deficient, the error-correction form of the country-specific

model will be estimated considering the reduced rank restriction:

$$H_{r_i} : rank(\Pi_i) = r_i < k_i$$

If $rank(\Pi_i) = r_i$, we can write:

$$\Pi_i = \alpha_i \beta_i'$$

Where α_i is a $k_i \times r_i$ matrix of rank r_i , β_i a $(k_i + k^* + s) \times r_i$ matrix of rank r_i

Identification and estimation of β_i and other parameters, is carried out in two steps: first the rank of Π_i is determined (using the maximum eigenvalue or the trace statistics). Then, β_i is estimated by imposing the suitable exact or possibly over-identifying restrictions on the elements of β_i .

5. Extending the original model with a Romanian component

Using the methodology outlined above, the original GVAR model incorporates seven country-specific and four region-specific models, capturing the dynamics of 25 countries' macroeconomic developments. However, since the GVAR model lacks an East-European, emerging country model, in this section we begin the challenging task of adding a East-European component to the GVAR model, which is believed to be compatible to the general model.

Firstly, we will argue the need to incorporate a East-European component in the general model. As also stated before, the original GVAR models (PSW, 2004), is comprised only of developed countries/regions. However, considering the expansion of the European Union towards Central and East Europe in 2004 and 2007, we believe that including the mentioned component is a natural and necessary development of the model. We note that in 2004 a large group of 10 countries were included in UE, out of which: Poland, Slovenia, Hungary, Czech Republic, Slovakia and others; in 2007 Romania and Bulgaria were also accepted in UE. All mentioned countries come from the communist regime that shadowed Europe after World War II until the early 1990. After 1989, year of violent changes of power, all countries

faced the problem of turning to a market economy, after over 40 years of command controlled economy. The transition period was not an easy one, phenomena like hyper inflation, privatization, high volatility of exchange and interest rates were problems that had to be overcome in order to implement the principles of capitalism. In the last 10 years, all mentioned countries tried to “grow” from emerging countries to developed ones. However, if 2007 was a promising year for all Europe, the effects of the global economic crisis cut the rapid pace of growth of these economies. Even so, the Central and East European economies remain an important component of the World economy that cannot be neglected in a GVAR model.

The second issue was to choose between a country specific model (Romania would seem an obvious choice as we could use the results to further develop the model into risk correlation matters) or a regional model that would incorporate several central and eastern European economies. We have opted for the first version because the degree of development in the chosen region varies very much from one economy to the other. For instance, based on the GDP in 2008, the emerging economies have dispersed ranks: Poland is rated best on 18, followed by Czech Republic (40), Romania (43), Slovakia (57), Bulgaria on 72. This is an empirical prove of the different stages of development for these countries and an argument that supports our option of estimating a country rather than a regional specific model for the Central-Eastern side of Europe. The somewhat middle position owned by Romania between similar economies leads us to think that it is a reasonable choice and a good exponent for the selected region.

The third issue we have to deal with is the choice of the variables and the construction of the data series. Since this paper is focused on adding a Romanian component to the PSW (2004) GVAR model, it is advisable to use, as far as possible, the same underlying data during construction so that one could link this model to the outcomes generated by the original PSW (2004) model in a dynamic global simulation and forecasting framework. Therefore, in order to construct the global macroeconomic data, we have tried to use the same variables and time

interval for the data series, but we have come across some difficulties. First, we will not include two variables: interest rate and equity price index, thus for the Romanian component we will have $k_t = 4$. The reasons are basically data unavailability: for the interest rate, the treasury bill reference rate is available starting with 2002, while for the equity index, the Bucharest Exchange Trading Index (BET) was first listed in 1997, and in the first years of operation, the capital market was very volatile and its stabilization occurred somewhere in 2004-2005. In this case, the variables we use are: GDP_{Rt} the nominal gross domestic product for Romania, CPI_{Rt} the consumer price index, M_{Rt} the money supply (M2), and E_{Rt} the domestic currency/USD exchange rate

From here on one can construct the foreign/starred variables and test the integration properties of the series. The results of the unit root tests are in line with the a priori expectation and the general results found in the literature. Given the unit root results, we acknowledge that the VECM approach is appropriate within the Romanian context.

6. Conclusions

Based on the methodology proposed by PSW (2004) this paper proposes a new component that could be linked to the original model proposed by PSW, component that represents a group of European countries that are not represented in the current form of the GVAR model. We propose the framework for constructing a Romanian-specific credit-market correlation model based on a Vector error-correction model which includes both domestic and global economic variables. The challenge of the estimation process is the construction of the variables and data sets for an emerging economy. As results obtained from estimates are in line with the ones delivered by PSW (2004), one can argue that the correlation model could be employed as a stand-alone model within a Romanian-specific credit portfolio management tool.

This paper is a result of the project „Doctoral Program and PhD Students in the education research and innovation triangle”. This project is co funded by European Social Fund through The Sectorial Operational Program for Human Resources Development 2007-2013, coordinated by The Bucharest Academy of Economic Studies.

Abstract

Evolving of models for realizing an economical-ecological balance for accepting or rejecting investment projects should be increasingly from practical viewpoint, implying a more elaborate theoretical approach and scientific fundamented. Even if we have pertain to an economical approach and aim a level of updated real net income fairly high for each accepted project, the model also includes ecological component monetary tackled, but fundamented from welfare viewpoint. Proposed model proves practical utility and has the ability to generate individual and social welfare.

Key words: investment project, economic value, ecologic criteria

JEL Classification: L19, Q57

1. Investment projects and pollution

Investments represent an important factor of economic and social development. There are many situations when investments and investment projects with major environmental impact especially, such as those from energetic field, chemical industry, mining or ferrous metallurgy, besides bringing about benefits they lead to appearance of externalities pollution likeness or significant deterioration of environment, even if it is not felt directly and actively as a high pollution. How much

deterioration of environment is, for investment projects represents a problem which neither theory, nor economical practice or policy-makers can neglect anymore. Lasting development involves efficient and responsible decisions, in order to achieve a dynamic economical-ecological equilibrium.

When taking decisions on an investment object is important to compare the investment (project cost), net profit (gain) and total economic value which is lost because of the project.

Figure 1 The evolution of investment process and pollution

These are shown in Figure 1 where the following symbols were used:

- C - Cost of production during objective operation;
- Q - Output value during objective operation;
- D - Objective economic lifetime;

D_f - Objective physical lifetime;
 T - Duration of investment recovering;
 S_1 - Total investment value;
 S_2 - Value of benefit for investment recovery ($S_2 = S_1$);
 S_3 - Amount of net profit (gain) obtained by objective operation during economic lifetime
Based on presented relations can be established:
1. If $S_3 - B_c > 0$ investment project is realized or modernized
2. If $S_3 - B_c < 0$ investment project is not realized or modernized

where:

B_c - Benefit obtained as a result of environment preservation and therefore of investment project unfulfilment or area development

Total economic value represents actually measurement unit for preservation benefit B_c , meaning of total amount for asset remained as natural environment.

Benefits and costs of the project can be measured relatively easily because they are presented as data based on market prices. This is not the case for total economic value and so it is necessary to investigate ways for measuring the components of total economic value.

Such an assessment represents a practical and theoretical particularly complex problem which has not been fully clarified till present. Importance of techniques' elucidation for establishing the total economic value is that decisions for investment or function maintenance of various economical objectives are based on it.

Total economic value of natural environment is the main element also for both benefit measurement of environment improvements and measurement of environment damages.

If consider one development project whose total economic value lost due to this project or gained because of its unfulfilment must be calculated (Fig. 1), it can be concluded that losses and benefits are opposite sides of the same concept.

2. Environmental issues

Nature and living creatures (including humans), considered from their interdependence perspective, are driven by distinct laws ensuring a natural dynamic balance between different ecosystems.

Along with the development of economic activities, the natural balance of different ecosystems was affected.

We can affirm that nature regenerates itself or has the ability to create a new balance between ecosystems and economic activities, but this ability is constrained, and economic activities determine a constantly growing accumulation of polluting factors in the environment, making impossible their annihilation. Finally, the environmental balance is affected, with undetermined extraeconomic and economic effects, influencing even the human race existence. Starting from this statements, Dansereau formulated in 1957 a series of rules for interaction between man and environment. Reversion law – the environment tends to regain the lost positions right after the ceising of humn economic activities. The cultivated land, abandoned from various reasons, is spontaneously reintegrated in the nature; Irreversibility law – certain renewable natural resources becomes unrenearable when humans, through irrational economic measures, interrupt them or the conditions in which the cycle takes place; Reversed action law – Any environmental change as a result of human economic activities has consequential effects on economy, social life and even health. Massively cutting forests in ancient Italy had fatal consequences on agriculture.

Summarizing, the human action on the environment results are: disturbance of bio-geo-chemical cycles – through removing materials from the cycle and transforming cyclical processes in acyclical ones; change of environment's chemical composition – through discharging waste on rivers; replacement of natural interaction systems – with human social-economic activity determined interaction systems; replacement of environment's natural

components with artificial ones (for example: earth crust completely human controlled).

Regarding the interaction between humans and nature, Vemadski and Teilhard de Chardin introduced the concept of noosphere (deriving from the greek noos = brain, intelligence, intellect). Noosphere means human rational, conscious control of the environment, based on ecological principles. This is a necessity for ensuring the existence of future generations. One of the basic conditions to be met is to control and maintain the environment pollution in acceptable limits in order to ensure the conditions for sustainable functioning and development of the society.

These concerns regarding the human rational, conscious control of the environment (ambient) materialized in the 80s and 90s in a new interdisciplinary science, environmental economics, that intends to identify the relationship and the methods for rational environmental management, condiered an economic resource, on the basis of the hedonistic principle of achieving maximum social satisfaction with a minimum of insatisfactions.

Returning to ecology, we can say that pollution has a totaly different meaning than the economic one, in any ecosystem pollution being a shock that detonates a growing imbalance as the polluters quantity increases. The balance is decisively broken when the polluters quantity exceeds the environment's capacity of absorption.

In figure 2 the horizontal line AA' is the environment's absorption capacity; the line OP is the pollution level. The balance is broken when pollution exceeds E.

Figure 2 – Pollution and environment's absorption capacity

We can say that Q_E^* is the „optimal” level of activity from an ecological point of view, of course if the absorption capacity is not exceeded but for an activity level above Q_E^* . In reality we cannot speak of an optimal Q_E^* representing the maximum flow of activity accepted by the receiving environment during a certain period of time. We notice that curve AA is just an approximate representation; it is not easy to precisely determine the extreme environment capacity, we can identify an undetermination area (the drawing area).

We cannot state that pollution is present only from a starting point. It is obvious that as soon as it becomes positive, it generates imbalances in ecosystems, and when it reaches the maximum tolerable ecological level (E), it becomes harmful and implies a social cost from the economic point of view. The point E in figure 2 is an ecological ceiling, and an economic doorstep.

3. Comparative analysis of economic and ecologic criteria

The comparative analysis of economic and ecologic criteria allows us to state that ecology and economics are two different and antinomic fields. The analysis purpose is not to determine which of these two fields must prevail, but to identify guidelines for solving the economic-

ecologic balance. As the society will have a certain protection of the environment as a goal, it must accept that only the economic criteria are not sufficient for adopting decisions.

Finally, the problem regards the environment's absorption capacity, including the capacity to recycle the waste, the crowding limits, the ecological processes and space covering.

We cannot conclude that economic activity must be ceased or limited, it would be a nonsense, but if the society decides that environmental protection is important, it must limit certain activities to a level that does not exceed the environment's absorption capacity. The cost-benefit analysis itself cannot identify such a purpose. Usually, a „good” analysis must involve a proper cooperation between the involved factors: public administration (government), companies and community members. This means to get over the fact that economic analysis is not capable of measuring everything in monetary units, and accepting the fact the cost-benefit analysis is unable to evaluate ecological phenomena and the risks associated. This perception deficiency makes the existing generation to undertake risks for the future generations, and from this must come at least the carefulness, if not the thoughtfulness. More than ever, the environmental issues remind us that economics cannot manage everything and that J. St. Mille's statement - „he is a poor economist who is just an economist” is more actual than ever.

4. Updated total net income - decision criteria

For accomplishing economical-ecological equilibrium for an investment project it can be used a model based on estimation of updated total net income. This model requires a comparison of incomes total amount in their updated form and costs and damages produced by investment objective during conception, operation and sometimes after its closing. Main income categories on the one hand and losses, damages on the other hand are:

A. REVENUES

1. Updated net incomes obtained as a result of investment objective operation - VNA
2. Updated net wage incomes - VSNA;
3. Updated state incomes - taxes, social insurances, etc. - VASTA;
4. Incomes involved by investment objective existence and operation - VAA;
5. Incomes resulted from residual sale - VRA.

B. LOSSES, DAMAGES, COSTS

1. Environmental damages produced by objective accomplishing - DMA;
2. Pollution produced during lifetime - PDVA;
3. Pollution generated by manufactured and sold products, performed services; updated - CHDPA (updated remediation costs);
4. Updated costs for natural environment restoration after economical activity - CRMA.

One first model which can cause updated total real net income without taking into account the social component and state incomes would be possible starting with all previous indicators. Updating can be done when making an investment decision or at the time of objective commissioning.

$$Vn_{rta} = \sum_{h=1}^T Vn_{ah} - \sum_{h=1}^{T_1} Pn_{ah} - \sum_{h=1}^d Dn_{ah} + Vn_r$$

where:

T = lifetime of investment objective;

P_{nah} = updated net losses since "h" year produced by environment deterioration because of objective operation, which can be determined by impact studies;

V_{nah} = updated net income since "h" year obtained through objective operation;

D_{nah} = updated losses produced by environment deteriorations during "h" year due to environment damages during objective construction;

Vn_r = residual net income obtained by removing the use of objective;

V_r = residual income obtained from the goal out of service;

Vn_{rta} = total real net income, which represents the total real benefit of the community obtained as result of objective operation.

second model involves an extension of the calculation and financial analysis to an economic analysis, according to a model similar to World Bank where in addition to issues strictly related to company's cost-benefit analysis there are quantified also private social benefits and state incomes. Such a model also based on updated total actual net income is:

$$Vn_{rta}=VNA+VSNA+VASTA+VAA+VRA- \\ -DMA-PDVA-CHDPA-CRMA$$

Measurement and monetary assessment of pollution and damages caused to natural environment come under the concept of total economic value, of finding a market value for environment resources and measurement of losses due pollution generated by investment objective or investment project variant, respectively. It represents a permanent research field, but also the reason of many controversies among economists and ecologists. From economical viewpoint, one project is realizable if updated total real net income is positive and large enough and minimum benefit principle is applied. In this case, minimum benefit represents an opportunity cost.

5. Conclusions

The economic-ecologic balance is a major concern of our days for a sustainable development. The issue of this challenge can start from the investments projects and the decisions makers how can except or reject a harmful project or less useful for the society or community.

To put together economic criteria with economic criteria is not an easy task from many points of view. According to this objective a theoretical and practical proposal is to be use for decision the indicator named real net present value. This indicator aggregates in general and practical way the economic and ecologic criteria the benefit on a project end the losses for the environment caused by the realization of the investment project. This method is also acceptable from accounting and banking perspective and generated if is necessary a hierarchy of the project and their alternatives.

Implementation of Best Sustainable Practices in the Hospitality Industry

Sztruten (Lefter) Gina Gilet
*Academy of Economic Studies, Bucharest and
Romanian- American University, Bucharest
lefter_gina@yahoo.com*

Abstract

Following passage through times of global economic crisis, also called "resource crisis", and due to the extremely advanced level of development of hotel industry globally, it is becoming appropriate and necessary to implement ecomanagement systems for the hotel business, as currently there are no alternative economic recovery plans. Subordinating under the requirements of sustainable development planning, hotel development and management activities must be conducted only in terms of environmental compatibility.

Key words: global economic crisis, "resource crisis", hotel industry, eco-management systems

JEL Classification: L83, M19, Q01, Q57

1. Introduction

Hotel ecomanagement process comprises several stages (initial, interim and final) and implies a certain order in actions taking place in space and time, mainly aimed at increasing economic efficiency, environmental, social and cultural rights of all activities taking place within the hotel unit.

In the practice of firms and institutions, the concept of sustainable development is correlated with the concept of ecomanagement (environmental management). The concept of hotel ecomanagement applies all rules, beliefs and values operating in any successful environmental organization.

2. The Hotel Eco-management System

Hotel eco-management is still widely regarded as a special hotel species that requires a whole set of measures more or less charged with marketing messages. But someone who seeks global trends, notices that major international chains are very seriously concerned about this issue and announces an entire series of measures to limit the polluting effects of the existence of their hotels.

Taking into account the resources needed to develop eco-hotel business, as pillars of the ecomanagement hotel system, we can still speak of certain raging necessary measures to implement, which must become part of the hospitality industry best practices. These measures should cover the location, architecture, energy, water materials, noise, air quality and carbon emissions, design and performance measurement.

Location as a ground element for new projects. For exclusively natural environments it is very important the development of a study of environmental impact to identify solutions and how the development will fit in that location. A study correctly done, in order to identify the most appropriate measures, means something else than getting a merely formal environmental notice.

Architecture and its role in reducing environmental impact. The aim of sustainable design lies in finding constructive solutions, which is reflected in hotel construction characteristics, ensuring first the well-being and second the coexistence of three groups making up the overall ecosystem (inorganic elements, living organisms and humans).

Energy - global urgency of the third millennium. Energy is used in the processes of heating, cooling, lighting, water movement

within the building and indoor comfort. But its use has environmental impact.

Natural gas, are preferable to any other fossil resources due to lower emissions of CO₂ and lack of other toxic fumes arising from burning other fuels such as LPG, diesel oil, etc..

Whenever it is financially feasible it should be used a building management system BMS (Building Management System). Another important element in the building's energy efficiency are the heating, ventilation and air conditioning systems (HVAC - Heating Ventilation and Air conditioning). By careful design it can get higher efficiency.

Water - main wealth of the planet. Widely used devices can reduce water flow in high consumption places such as shower heads, flow aeration devices for water in sinks batteries, low volume toilet tanks, batteries and sensors in baths urinals, rainwater collection systems and moisture sensors for irrigation systems. In areas where water is a precious resource, can be used waste water recycling systems, so-called gray water (Grey-Water).

Waste - the result of a consumer society. A "green" management requires effective staff training and implementing best practices such as selective waste collection and maximize the use of retail potential to recycling systems available in the area. The most common categories are: white glass, colored glass, metal, office paper and newspapers, cardboard, plastic, cooking oils, organic waste.

Materials used - careful selection in a hotel ecomanagement. It is recommended to reduced the use of materials that cannot be reused (ex: marble) and promoting producers with environmental consistent policies. Main construction materials used are adhesives, aluminum, cement, concrete, flooring, glass, insulation, masonry, metal, plaster, paint, steel, finishes, wood, wiring, removing toxic substances (acrylic, asbestos, epoxy resins, lead, etc.).

Noise - the comfort factor of influence. Noise is a factor that must be controlled inside the hotel in order to grant hotel guests the comfort desired. The architect, the installations designer and the manufacturer must work together to fit in the standards generally accepted for hotel industry in the following

areas: windows, room-room, bathroom-bathroom, bathroom-room, room-corridor, fans, divisions, kitchen- restaurant, kitchen-halls, partitions- halls, equipment.

The carbon footprint of a hotel and air quality in eco-hotel spaces. Hotels must have non-smoking rooms. A smoking room is harder to clean in terms of clean air having a negative impact on people suffering from allergies or asthma.

Desirable emission levels and solutions shall be developed after a study of environmental impact. Another aspect to be considered in a Green Hotel is the use of substances that endanger the ozone layer. CFCs and HCFCs are no longer acceptable substances. HFCs do not endanger the ozone layer, but contribute to global warming effect. They are in the process of substitution with ecologic refrigerants (ammonia, propane, butane, etc.). Indoor air quality is an equally important issue pertaining to the quality of building design.

Ecological interiors aided by appropriate design. The choice of options for wall finishes, floors and ceilings, modern solutions are preferably involving recycled materials. Therefore a green room must begin with motion detectors for lighting in the corridor / entrance saver, energy-efficient lighting, appropriate colors, a heating system, ventilation and efficient air-conditioning, ecological materials, TV and mini bar must be efficient and meet the ozone layer requirements, in the bathroom should be mounted cosmetics dispenser and water consumption control systems, noise must be controlled and why not guests are taught to sort themselves the garbage in categories.

Ecomanagement measured performances. Applies to each hotel management system, it is to plan, to implement and also to continuously monitor the implementation plan. It is indicated to permanent report to indicators that are used to relate (benchmarks), such as: kWh/m², CO₂/yr tons, liters water/m², tons waste per year, amount recycled waste, etc.

3. Case study: NH HOTELES SA

NH Hoteles Group ranks 8 in the top 10 hotel groups in Europe and ranks 22 in the Top 300

Corporate - global hotel group with 347 hotels in 22 countries. NH Hoteles offer high quality services and facilities, boasting a great setting to receive guests. Provides high technology to enable customers to communicate, work and relax.

Briefly, NH Hoteles aims to maintain the status of European leader in hotels specialized on the business travel segment, satisfying guests, having locations in Latin America and Europe. The hotel group organizes many charitable events and launched a program with a strong impact on the public, namely environmental protection and promoting healthy tourism. By this program NH Hoteles will implement ecomanagement modern systems.

Environmental Strategic Plan 2008-2012 was launched in 2008. It is based on a thorough environmental impact of groups businesses in terms of energy and water consumption, CO₂ emissions and reduced waste. Targets have been set to achieve overall reduction of these indicators, based on measurements taken in 2007 and were designed, of course, policies and procedures to reduce them. Thus, NH Hoteles has established a set of ecomanagement objectives for 2012:

- Reduce energy consumption by 20%,
- Reduce water consumption by 20%,
- Reduce CO₂ emissions by 20% ,
- Reduce waste by 20%.

Figure 1.1. Reducing energy consumption

With the launch in 2008 of the Sustainable Development Strategy following the implementation of new methods of management at central level, 2009 meant the first big leap in reducing consumption. Thus, energy consumption decreased by 8%, because

percentages thereafter referred to diminish from year to year and 7%, 4%, 3%.

Figure 1.2. Reducing water consumption

Refurbishment, a judicious maintenance, customers and employees co-participation in this program led to savings in water consumption during the first year after launching the program with more than 9%. Target site be dropped from 8% in 2010 to 2% in 2012.

Figure 1.3. Reducing CO₂ emissions

Regarding the CO₂ emissions, while carbon footprint is relatively small compared to other companies, in NH Hotels a room produces on average 12 kg of CO₂, the program targets a reduction of over 7% in 2010 to reduce by 4% in 2011 and the 2012 target is 3% in CO₂ emissions reduction.

Figure 1.4. Reducing waste

Over the life time of a hotel, international experts say that the hotel produces large quantities of waste for construction, during the whole life cycle activity, and for the closure or recovery. Because of these large quantities, waste has become an important indicator and easily measurable. For the first 2 years after the launch of the sustainable strategy, NH Hotels have proposed to reduce by 7% the amount of waste, so that for the next two years to reduce to about 4%.

4. Conclusions

In hotels departments procedures and processes can be achieved with immediate actions and activities on one hand, with minimum cost, but also with activities that require changes, reorganizations and new technologies involving large expenditure on a larger time horizon.

As long-term actions, equipment with minimal energy consumption can be acquired, eliminating carpet surfaces, painting with organic materials, furniture made from recycled materials, solar panels, drainage systems and waste water purification, etc., considered interdepartmental investments.

All these elements form the basis for a sustainable development strategy in a hotel. In other words, a strategy is not "a great project, nor a set of plans, but rather a set of tools and actions that are reflected in a coherent and dynamic way the challenges of sustainable development.

Budgetary Procedures in the Administrative-Territorial Units

Teliceanu Claudiu
Bujdoveanu Aurica
"Dunarea de Jos" University of Galati
Mihailescu Emil Raul
Academy of Economic Studies of Moldova, Chisinau

Abstract

According to Law no. 273 of June 29, 2006 on local public finances, the elaboration of local budgets projects pertains to credit officers. They must however take into account the main macroeconomic and social forecasts for both the budget year for which the budget project is elaborated and for the next 3 years, those being developed by the empowered bodies and fiscal and budgetary policies that are both national and local. There should be also taken into consideration provisions of concluded internal or external loan agreements, memoranda of funding or other international agreements that are signed and/or ratified.

Key words: budget structures, financial indicators, shares, transfers.

JEL classification: H60

1. Advance details

In terms of content and structure of public budgets, thus including local budgets as well, we stress that revenue and expenditures are grouped (into budget) based on approved budgetary classification of MPF. Therefore revenue will be divided into chapters and subchapters, while expenditures will be divided into parts, chapters, subchapters, titles, articles, as well as into paragraphs. Obviously, as it is known, this was stipulated in previous regulations as well. What is now precisely and distinctly stated refers to the tax payers that have stable working places with minimum 5 employees working in that particular place, and who are obliged to require these employees' tax registration, as taxable income from wages, at

the fiscal body where the working point exists. The request should be made within 15 days of its foundation for the newly established offices and the fiscal body is required within 5 days from the tax registration to make a written notice of this to the mayor.

The above mentioned tax payers are required to hold the corresponding accounting in order to determine income tax from wages that is calculated, withheld and paid, while the mayor, through specialized bodies, can check at fiscal authorities the tax registration of payers from both the main headquarters and secondary offices. We underline that the mayor is required to bring any deficiencies to fiscal authority of the Ministry of Public Finance.

2. Regulation of local budgetary procedures

Article 26 of Law no. 273 of June 29, 2006 on local public finances stipulates that all expenditures found in chapters and articles have a targeted and limited destination, while the permanent and temporary staff number, as well as the basic wages fund is approved separately by the annex to each public institution's budget.

The operating and development sections are used to substantiate the local budgets and are approved as annexes to them respectively:

- The operating section includes current expenditures for the functioning of responsibilities and competences approved by law, which are specific to each administrative-territorial unit;
- The development section includes capital expenditures.

Non-reimbursable external funds and domestic and foreign loans are included in

annexes to local budgets and are approved at the same time.

Competences regulation in setting local taxes requires that they be approved by the local and county councils, as well as by the General Council of Bucharest.

A special aspect is given by the regime of amounts resulted from the assessment of fixed assets and some material goods, as well as revenues resulted from leasing or rental of several goods or the recovery of confiscated properties. The amounts received from sales or from the exploitation of materials resulted from demolition, dismantling or decommissioning as provided by law, from assets or sale of material assets belonging to public institutions, financed entirely by the local government, constitute local budget revenues.

The same sort of amounts received by other public institutions stands for their budget, while revenues resulted from leasing or rental of property owned by the private or public domains of the administrative-territorial units are local budget revenues.

Note: The proceeds of confiscated goods are turning to local budget revenue, according to the subordination of the institutions that have ordered their seizure. Under law, proceeds of sale of goods belonging to the private domain of administrative-territorial units are full local budget revenues.

New rule (Article 30) refers to special taxes for the operation of some local public services, as follows. Thus, for the operation of local public services created in the interests of individuals and legal persons, local and county councils and the General Council of Bucharest approve special taxes. The amount is determined annually, while the incomes derived there from are wholly used to cover expenses paid for setting up local public services and to fund ongoing maintenance and operating costs of these services.

Through regulation approved by deliberative authorities are established the activity areas and the conditions under which special taxes can be introduced, as well as the organization and functioning way of local public services for which that particular taxes are proposed.

Special fees shall be collected only from individuals and legal persons who use the local

public services for which that particular taxes were imposed, in a separate account opened outside the local budget, being used for the purposes for which they were created while their execution account is approved by deliberative authorities.

Note: According to law, local public services performing economic activities are required to calculate, record and recover the physical and moral wear of fixed assets related to these activities by tariff or price. The depreciation amounts for these assets are collected in a separate account opened at State Treasury units, are used exclusively for investments in that area and are distinctly highlighted in the investment program as their funding source, with exceptions regulated under loan or security agreements made with international financial institutions.

3. Mechanism of income tax shares

Public (territorial) financial practice implies that out of the income tax charged to the state budget in each administrative-territorial units, to allocate monthly within 5 working days from the end of the month when this tax was collected, a rate of 47 % to local budgets of villages, cities and municipalities on whose territory the taxpayer operate; a 13% share at the county's local budget and a share of 22% in a separate account at the Treasury, opened on account of general directions of the county public finances.

The execution rate of 22% is allocated by the General Directorates of the county public finances in the period mentioned within, for balancing the local budgets of villages, towns, municipalities and county, being proportional to the amounts allocated and approved for this purpose in the respective budgets.

82% share of income tax for Bucharest is distributed as follows: 23.5% to local budgets of the sectors of Bucharest, 47.5% to the local budget of Bucharest and 11% in a separate account opened on behalf of the Public Finances General Directorate of Bucharest to the Bucharest Treasury for balancing sectors of Bucharest's local budgets.

11% quota is allocated by the Public Finances General Directorate of Bucharest to

balance local budgets of sectors and municipality of Bucharest, in proportion to the amounts allocated and approved in the respective budgets.

The practice of consolidated transfers to local budgets include amounts' movement from the state budget to the local budgets for investments financed from external loans, the Government contributing to its accomplishment, and it is approved annually at a global level through the state budget law.

Out of the state budget, through the budgets of some credit officers, as well as out of other budgets, there can be granted transfers to local budgets for financing some development of social programs of national, county or local interest.

Deliberative authorities may approve collaboration or association for carrying out local public works and services. Collaboration or association shall be based on contracts of association in which are stipulated the funding sources, representing the contribution of each local government authority involved, the contracts being concluded by the credit officers under mandates approved by each local council involved in cooperation or association.

The same authorities may decide on participation with capital or assets in the name and on behalf of the interest of local communities they represent, on the formation of companies or on the establishment under the law of local or county public services as appropriate.

They may also decide to purchase, on behalf of local interests they represent, the shares in the companies in which they participated with a share of capital and they can increase or decrease their social capital under the law.

The above mentioned normative act stipulates that the associations of communitarian development are financed by contributions from local budgets of territorial-administrative member units, from other project based sources and from loans or public-private partnerships, under the law.

4. Final provisions

Government run national development programs to stimulate the association of

administrative territorial units and the increase of their administrative capacity; these programs being annually funded by the state budget through the Ministry of Administration and Interior.

In all cases the financial obligations arising from agreements of cooperation, twinning or accession of the administrative-territorial units to internal associations organized at national level or to international organizations with legal personality, determined by deliberative authorities under the law, are paid from their local budgets.

We also stress that part of local budgets is the budget reserve fund available for the local and county council and for the General Council of Bucharest and its sectors, representing a share of 5% of the total amount. This is used on the credit officers' proposal, based on the respective councils' decisions to finance urgent or unforeseen expenditures rising during the year, to eliminate the effects of natural disasters, as well as to grant aid to other administrative-territorial units in situations of extreme difficulty at the request of the mayors of these units or on own initiative.

Integrating in the EU or in the World?

Urziceanu Ramona-Mihaela
"Agora" University of Oradea
ramona.urziceanu@univagora.ro

Abstract

Economic theory suggests that the degree of cyclical synchronisation is related to the degree of economic integration and structural similarity between countries. In gauging changes in the synchronisation of countries' business cycles and the underlying driving factors, it is important to distinguish EU-specific developments from worldwide integration tendencies, i.e. globalisation.

The effects of goods and capital market integration on business cycle synchronisation are theoretically ambiguous. The net effect is composed of a synchronisation-enhancing effect on the demand side of the economy, and a synchronisation-diminishing effect on the supply side resulting from increased incentives for specialisation.

Key words: economic integration, business cycles, synchronisation-enhancing effect, synchronisation-diminishing effect

JEL Classification: E00, E32, E39, O47, P52

1. Economic integration, structural similarity and specialisation

Openness to trade is a key element in measuring the degree of integration of the new Member States in the EU. The higher the degree of openness, the more any changes in international prices of tradable goods are transmitted to domestic prices and the cost of living. Furthermore, as indicated by Frankel and Rose (1998, 2000) [1], a high degree of trade openness is likely to lead to more synchronous business cycles via a symmetric propagation of common demand shocks. Yet, as argued by Krugman (1993) [2], this is to be expected only to the extent that trade is dominated by intra-industry trade, whereas inter-industry trade would favour sectoral specialisation, and thus a

desynchronisation of cycles.

Trade integration. The new Member States are characterised by a high and rising degree of trade openness. Measured by the average of exports and imports as a percentage of GDP, openness in the EU-12 has increased from 42% in 1999 to 58% in 2007. Looking specifically at new Member States' exports to EU-15 countries, the share in total exports was fairly stable at around 68% between 1999 and 2003, but has decreased since then to just below 60% in 2007. Exports between new Member States have gained in importance since 2004, with their share in total new Member States' exports rising from around 14% in the pre-accession period to close to 20% in 2007. The share of exports to former USSR countries (CIS) has increased since 2004, while the rest of the world has slightly lost ground as a trading partner.

Overall, it appears that while new Member States' trade openness has increased over time, the share of exports going to the old Member States, though still high, has been falling. The rest of the world, including the US, does not play a big role. Looking at flows from the old Member States, however, the share in total exports going to the new Member States has risen steadily over the past decade (to 7.5% in 2007).

Structural similarity. The similarity of economic structures has a direct and an indirect link to cyclical synchronisation. The direct effect works through the symmetric impact of common shocks and the decreasing likelihood of idiosyncratic shocks in the case of structurally homogeneous countries. The indirect effect operates through trade relationships, where the degree of cross-country specialisation is decisive for whether trade can be expected to foster or reduce business cycle synchronisation.

The composition of output tends to be closely related to the stage of economic

development. Empirically, a higher level of development can be associated with a smaller share of agriculture in aggregate output and a larger share of services, whereas the share of industry typically has an inverted U-shaped relationship to per capita output, increasing first and declining later.

Distinguishing between agriculture, construction, manufacturing, energy/water and services, the shares of the five activities in total value added (VA) at current prices reveal a significant difference in output composition between old and new Member States. Agriculture accounts for a significantly larger share in the new Member States, and services represent a much smaller share. Manufacturing and construction are somewhat larger in the new Member States, and more significantly so the energy and water sector. At the same time, while there are no dramatic changes in the structure of output over the observed twelve-year period, there is nonetheless a trend of convergence of the new towards the old Member States. While the shares of agriculture and manufacturing declined between 1995 and 2006, the services sector increased. However, since around 2003/4, these trends appear to have come to a halt or even been partly reversed in the services and manufacturing sectors.

The distance indicator points to a diminishing distance between new and old Member States between 1995 and 2002, but to a renewed pick-up around 2003/4 and a stabilisation thereafter. A broadly similar picture emerges for the comparison with the US. Owing in particular to the significantly larger services sector in the US (above 78%), the structural distance between the new Member States and the US is appreciably larger than with the EU-15-countries. While the distance measure declined steadily until around 2000, there is a stabilisation thereafter.

To examine whether the movements as described are due to real output redistribution, changes in relative prices or both, the same measures can be computed on a real basis, i.e. using value added data at constant (2000) prices. In principle, one would expect both price and quantity changes to occur. Productivity growth in the tradable sector should raise the relative prices of (less traded) services in the new Member States via the Balassa-Samuelson effect. Changes in consumption patterns linked to an increase in living standards should also drive up prices of services and lower demand for

agricultural products. At the same time, real output redistribution would imply real resources flowing from the stagnant activities to the growing activities, i.e. presumably services and to some extent industry.

In real terms, the changes in output composition point to slight structural divergence rather than convergence. While the real distance index is rather stable between 1995 and 2002, the measure points to mounting structural differences since around 2004. The picture is again similar for the US, but slightly less pronounced. The main reason for the pick-up in structural difference in real terms seems to be a rising share of the manufacturing sector and an again falling share of services activities, contrary to movements in both the old Member States and the US. These trends point to the significance of changes in relative prices rather than real output redistribution in the new Member States (Balassa-Samuelson effect).

Product and trade specialisation. The analysis has so far described developments in broad sectoral composition rather than in actual product specialisation. An analysis using a deeper industrial breakdown into 56 industries broadly confirms the above results for Poland, the Czech Republic, Hungary and Slovakia for the period up to 2003. Comparing export shares for 99 and 158 product categories (CN 2digit and STIC 3-digit breakdown) between old export composition emerges over time, indicative of more homogeneous trade patterns, i.e. increasing intra-industry trade.

Summing up. The analysis sends mixed signals as to the likely impact of trade developments on business cycle synchronisation. Looking at export structure by destination, the share of old in new Member States' total exports has decreased over the last decade on account of stronger intra-EU-12 trade and trade with CIS countries. On the other hand, the share of the new in old Member States' total exports has increased. Measured by output composition in real terms, the structure of new Member States' economies still seems to be significantly different from that of old EU Member States, pointing to further need for structural convergence. However, the quality

of trade flows in goods between new and old Member States seems to have become more homogeneous. Despite remaining differences in non-merchandise sectoral composition, the apparent gain in importance of intra-industry trade would speak in favour of an increasingly homogeneous effect of sector-specific shocks on the two groups of countries, thus fostering the synchronisation of their business cycles.

2. Business cycle synchronisation between new and old member states: the empirical picture

Subsequent to the indirect, theoretically-founded approach of the previous section, this section looks directly at empirical measures of business cycle synchronisation. Cross-country correlations of output fluctuations, measured by de-trended GDP, and other measures of synchronisation are used. To gauge which components of output have the highest degree of synchronisation, a separate analysis is carried out for expenditure and sectoral GDP components.

2.1. Overview of previous findings

Owing to the relatively short data samples and the wide variety of business cycle indicators and de-trending methods used, the literature on business cycle synchronisation of the new Member States has arrived at highly variable conclusions. One rather general result is that synchronisation with the old Member States seems to be present, but at a lower average level than for individual old Member States. Similar conclusions emerge concerning inflation. The results differ considerably across countries, reflecting the heterogeneity of the new Member States and making general conclusions hard to draw. Lastly, most contributions target the degree of synchronisation with the euro area rather than the old Member States with a view to gauging the new Member States' preparedness for EMU enlargement. Analysing synchronisation between the EMU and the eight Central and Eastern European countries, Darvas and Szapary (2008) [3] find that Hungary, Poland and Slovenia have achieved a high degree of synchronisation with the EMU for GDP, industrial production and exports, but not for consumption and services. For the other countries, they find less or no synchronisation. Using impulse response analysis, Slovenia and

Poland are found to be most sensitive to euroarea shocks. Eickmeier and Breitung (2006) [4] use a large-scale structural factor model to analyse the variance shares of output and inflation explained by common euro-area factors. The proliferation of euro-area shocks appears rather similar for new and old Member States, masking, however, a considerable degree of heterogeneity across the new Member States. Covering all twelve countries, Afonso and Furceri (2007) [5] find Cyprus, Hungary and Malta to be highly synchronised with EMU countries. At the same time, synchronisation seems to have increased over time overall. On a sectoral level, their results suggest that the industry, building and agricultural sectors are the main driving forces of synchronisation, while the services sector is characterised by a low level of synchronisation. Artis, Marcellino and Proietti (2004) [6] find that cyclical synchronisation with Germany is large for Poland, Slovenia, Estonia, Hungary and the Czech Republic. In a meta study, Fidrmuc and Korhonen (2006) provide a comprehensive overview of the literature on business cycle synchronisation and the (a)symmetry of macroeconomic shocks between new Member States and the euro area. Analysing 35 studies, the highest average estimates of business cycle correlation with the euro area are found for Hungary (0.36), followed by Slovenia (0.26) and Poland (0.25). In several studies, the cycles of one or more new Member States are found to be correlated more closely with the Euro area than one or more peripheral Euro area economies (Portugal, Ireland and Finland). It has to be noted, though, that the study summarises findings that are based on data samples typically ending in or before 2002, i.e. not covering developments over the latest six years.

2.2. Empirical analysis

2.2.1. GDP-based synchronisation

Following established practice in the literature, filtered GDP series are used to measure countries' business cycles. Four measures of synchronisation are calculated on the basis of the derived series. Given the interest in the temporal development of

business cycle synchronisation, the measures are calculated for sub-periods and, in the case of the correlation measure, also using a four-year rolling window. Given that in the early 1990s several new Member States were in "transitional recession", the analysis excludes pre-1995 data. The total sample from 1995 to 2008 is divided into the sub-periods 1995 to 2001 and 2002 to 2008. The slight deviation from the natural division into pre- and post-2004 data is warranted by the need for robust estimation results in the sub-periods, where five years of quarterly data would constitute an unreasonably small data sample. Moreover, given that economic agents are forward-looking, it can be argued that the synchronisation-enhancing effects of EU accession were already largely contained in the data two years before actual accession took place. Apart from old and new Member State data, OEE and US data are examined with a view to separating European integration from broader globalisation trends.

Correlation. The first measure of synchronisation is the contemporaneous correlation between the EU-15 and new Member States' cycles. This measure is widely used in the literature, providing a simple, robust and intuitive measure of cyclical comovement. Over the full sample, only Cyprus, Latvia and Slovenia display a bilateral correlation with the EU-15 aggregate in excess of 50%, with Poland and Bulgaria scoring just below that threshold. On average across countries, correlation is at 0.30 over the full sample, and has risen significantly from 0.23 in the first to 0.51 in the second sub-period. To put this into perspective, the average correlation of individual old Member States with the EU-15 aggregate is as high as 0.77 over the full sample, with a minimum value of 0.61 attained for the peripheral countries Finland and Portugal. The rather steep increase in correlation of the new Member States on average in the second sub-period is due to increases in all countries but Poland and Hungary, where correlations decreased from above-average values in the first sub-period. In the post 2002 sample, correlation is clearly above average for Bulgaria, Cyprus, the Czech Republic, Estonia, Latvia and Slovenia, average for Malta, and below average for Lithuania and Slovakia, but also Poland and Hungary. The development of average synchronisation over time demonstrates that the message depends

crucially on whether individual correlations are weighted with countries' GDP shares. While the un-weighted average displays a clear upward trend, with a temporary dip in 2003/4, the case for increased synchronisation is less clear when looking at the weighted average of individual correlations. This mainly reflects the high degree of EU-15 correlation of the Polish cycle before 2002, followed by the temporary decline in 2003-2004. Looking at very recent developments, upward trends in synchronisation are evident for all three Baltic countries, Malta, Poland, Slovakia and, to some extent, Slovenia. Cyprus clearly shows the highest and most stable level of correlation with the EU-15 cycle. Taking the US cycle as a reference for the world cycle, average correlation of the new Member States with global cyclical conditions proves to be significantly lower than with the EU-15. Over the 2002-08 period, average correlation with the US cycle is at 21 %, up from 8% in the 1995-99 period, but markedly lower than the 51 % EU-15 benchmark. In contrast to the EU-15 results, Hungary and Poland (with Cyprus) stand out as countries with the highest bilateral correlations with the global cycle measure.

Leads and lags. The second synchronisation measure is based on the lead or lag for which the correlation between two cycles is maximised. Thus, a value of zero indicates that correlation is highest for contemporaneous relationship, while negative values indicate a lead and positive values a lag of new Member States' cycles with respect to the EU benchmark.

On average, new Member States' cycles appear to be in sync with the EU-15 cycle, particularly in the more recent sub-period since 2002. Focusing on this latter period, significant time shifts (more than two quarters) are perceivable only for Hungary (leading the EU cycle), Lithuania, Malta and Slovakia (lagging). With respect to the US cycle, the countries are on average lagging slightly behind, increasingly so in the second sub-period. This indirectly confirms the common finding that the US is leading the EU cycle. Together, the analysis of leads and lags provides further evidence of a stronger business cycle synchronisation with the old

Member States than with global developments.

Volatility of cycles. Business cycle volatility is measured by standard deviations, expressed in relative terms to the EU15 aggregate. A decrease in the relative volatility can be interpreted as a diminishing role of country-specific disturbances. In line with global and European trends, there has been a trend towards less volatility in the majority of countries, with the average volatility measure declining from 275 in 1995-2001 to 199 in 2002-08. Over the full sample, relatively low volatility is observable for Cyprus, Hungary, Poland and Slovenia. Over the more recent sub-period, Bulgaria, the Czech Republic and Malta likewise display below-average volatility. In interpreting the magnitude of the values, it has to be borne in mind that a single cycle is (almost) necessarily more volatile than an aggregate of several country cycles. Looking at some individual old Member States for comparison, the relative standard deviation of Germany to the EU-15 is 136, while for Belgium it is 272 over the full sample. On average across all EU-15 countries, it is 159. Between the first and the second sub-period, the distance between old and new Member States' cyclical volatility has shrunken, indicative of a diminished role of country-specific shocks. While, since 2002, the volatility of many new Member States' cycles is about the same as in EU-15 countries (Cyprus, the Czech Republic, Malta, Poland, Slovenia), it remains significantly higher on average.

Persistence of cycles. The last measure is the first-order autocorrelation coefficient of business cycles, used as a rough but straightforward summary measure of their persistence (OECD, 2002). The rationale for this measure is that the dynamic effect of any shock depends on the degree of persistence of the series, with shocks having a longer-lasting effect on highly persistent series. Consequently, a similar degree of persistence is important from the perspective of business cycle synchronization. Furthermore, noisy series tend to show lower autocorrelation. Therefore, low persistence compared to other countries can also point to the relative importance of country-specific shocks. The persistence measures of new Member States' business cycles shows that from 1995-2001 to 2002-2008, cyclical persistence appears to have increased slightly on average. While average persistence across new Member States was slightly lower than across EU-15 countries in the first sub-period, it rose to the average EU-15

level (of 0.89) thereafter, implying that the aggregate effect of symmetric shocks and their transmission has become more similar. Given that the degree of persistence in a given economy is linked to underlying structural features such as size and openness, it is difficult to draw country-specific conclusions from the table. One remarkable development seems to be the significant increase in persistence of the Polish business cycle in the second sub-period, indicative of the diminished importance of country-specific disturbances.

3. Estimating the relationship between synchronisation and economic integration

Following the seminal paper by Frankel and Rose (1998), many studies have confirmed the finding that countries with more intense trade ties have more similar business cycles. However, to disentangle the effect of inter-industry trade from that of intraindustry trade, a measure of specialisation has to be added to the equation. Imbs (2004a) concludes that the overall effect of trade on synchronisation is strong, but a sizeable part is found to work through intra-industry trade. Moreover, similar specialisation patterns are found to have a sizeable direct effect on business cycle correlation. Fidrmuc (2004) finds that the link between cyclical synchronisation and trade intensity becomes insignificant once regressions are augmented by additional structural variables. In a similar vein, Inklaar, Jong-A-Pin and De Haan (2008) [7] find that the effect of trade intensity on synchronisation is much smaller than previously reported, with other structural variables such as trade similarity, similarity of monetary and fiscal policies and degree of financial integration having an effect at least as strong. Artis, Fidrmuc and Scharler (2008) conclude that, while trade and financial flows tend to increase business cycle co-movements between countries, divergent fiscal policies and labour market rigidities delay the synchronization of business cycles. Most of the literature analyses the determinants of business cycle synchronisation using a crosssection of

OECD or euro-area countries. Traistaru (2004) [8] analyses the transmission channels of synchronisation in a hypothetical euro area, enlarged by the eight Central/Eastern European countries. She finds structural similarity and bilateral trade intensity to be significantly and positively related to business cycle synchronisation. However, these results apply to country pairs including within-euro area and within new Member States combinations. The explicit determinants of synchronisation between old EU Member States on the one hand and the new Member States on the other have not yet been sufficiently addressed. The estimation results are based on 165 crosssection observations of bilateral correlation coefficients between new and old Member States. Bilateral trade intensity turns out to be insignificant in explaining pair-wise output correlations. The results suggest that the Ordinary Least Square estimation is consistent and close to the Instrumental variables results *Co*). The trade specialisation measure is significant at the 10% level in the Instrumental Variables estimation approach. Differences in monetary policy appear to have a significantly negative impact on synchronisation, even after correcting for the markedly lower level of synchronisation of Lithuania and Slovakia with ED-15 countries via a dummy variable. While financial integration likewise seems to be significantly (positively) related to output correlation, this result is not robust to the inclusion of the dummy for the two least synchronised countries. Finally, differences in fiscal policy are estimated to have a significant negative impact on output synchronisation, at least after correcting for the low level of synchronisation of Lithuania and Slovakia.

The Concept of Intellectual Capital in Maritime Transport

Utureanu Simona
“Ovidius” University of Constantza
Nistor Cristina
Maritime University of Constantza
simona_utureanu@yahoo.com

Abstract

In the Knowledge-Based Society, not financial assets, but knowledge and competencies have become the most important resources for most companies. This paper objective is to make an initial critical exploration of the essential condition of intellectual capital in maritime transport and it starts with defining what intellectual capital is. In this paper there are also discussed means of stimulation of intellectual capital within the maritime company.

Key words: maritime transport, intellectual capital, strategy

JEL classification: K11, F41

1. Defining Intellectual capital

We currently live in a period when knowledge and competencies have become strategic resources that brings a company's success. The company's ability to use intellectual capital and proper technologies is what makes it competitive on market and makes it able to develop innovative integrated solutions that create value for customers.

Intellectual capital in maritime transport represents the knowledge and brain-power capital that makes a maritime company benefit. Intellectual capital includes essential skills and strategic knowledge that a maritime company has developed and the needs to make successful transport of cargo or passengers. It also referees to documents about transport processes, customers, research results, harbour activity and other information that gives competitive advantage.

Examples of intellectual capital are the following: knowledge, competent employees, reputation, brands, customers, R&D,

innovation, patents, IT, workplace organisation and management systems, networks and relationships.

The term “intellectual capital” was firstly mentioned by John Kenneth Galbraith, in 1969 in a letter to Michael Kalecki, a Polish economist with contributions to macroeconomics. In 1980, the Japanese specialist Hiroyuki Itarni studied the effect of *invisible assets* on the management of Japanese corporations. After that, Thomas A. Stewart, Editor-in-Chief of Harvard Business Review, approached intellectual capital to products, processes and people in order to obtain and manage profit. In 1991 in the article *Brain Power - How Intellectual Capital Is Becoming America's Most Valuable Asset*, published in Fortune magazine, he defines intellectual capital as “the sum of everything everybody in your company knows that gives you a competitive edge in the market place”. In 2001, he considers that today's companies are applying the concept of intellectual capital into day-to-day operations to dramatically increase their success.[1] Nick Bontis of McMaster University in several academic papers considers that intellectual capital includes *human capital, structural capital and relational capital*. Human capital refers to the skills and knowledge that make value for an organization. The origin of this concept comes from Adam Smith who defined four types of fixed capital: machines, buildings, land and human capital. The second element of the intellectual capital is structural capital and it represents formulas, information, patents, processes etc., that result from the products or systems the firm has created over time and not from the heads of the employees and remains with the organization even when they leave. Relational capital, the third component of the intellectual capital is represented by good relationships with stakeholders (clients, employees, suppliers, government agencies,

competitors and other organizations that come in contact). Leif Edvinsson, a Corporate Director of Intellectual Capital function at Skandia AFS, a Swedish insurance company, developed an intellectual capital “hidden values” management model for the firm.[2]

In European countries, a large importance is given to concepts like knowledge and intellectual capital in private and public economic sector. The Northern countries made a tradition in developing the intellectual capital concept in all the fields, including in the maritime domain. For example, the Danish Ministry of Science, Technology and Innovation republished and distributed since 2000 a guideline for the Intellectual Capital Statements [3].

An intellectual capital statement is an integrated part of a maritime company knowledge management. It identifies the company’s knowledge management strategy that refers to the identification of objectives, initiatives and results, application and development of the company’s knowledge resources. It also communicates this strategy to the company and to the external environment. Intellectual capital statements regard the improvement of the knowledge resources management.

The guideline says that intellectual capital can be understood as a relation between four elements:

(1) A knowledge strategy, which defines how knowledge can make a difference to the firm’s activities regarding its users.

(2) A business model of knowledge that identifies the relatively durable problems facing the management of the firm in order to develop the usefulness of knowledge.

(3) A set of actions, which point out how knowledge is to be managed concretely as a set of activities.

(4) A series of indicators that monitor whether the actions are implemented. Together, this model allows the institutions to appreciate how their activities develop and use knowledge are helpful to their services [4].

Several companies managed to establish a way of accounting intellectual capital, in order to establish the value of knowledge that is owned by the organisation.

Authors Garavan, Morley, Gunnigle and Collins review definitions of intellectual and human capital. They consider human capital

from individual (employability, performance and career development) and organization (investment, ownership, skills and knowledge management) perspectives and highlights the implications for human resource development, both at individual and organizational levels.

Author	Definition of Intellectual Capital
Edvinsson (1997)	Intellectual capital is structural and human capital, thinking and non-thinking assets and it requires a different management approach.
Sveiby (1997)	Intellectual capital is represented by invisible assets of an organization: employee competence (skills, education and experience) and their capacity to act in a wide variety of situations; internal structure (management, structure patents, contracts, concepts, models, research and development capability, software); and external structure (image, brands, customers and supplier relations).
Stewart (1997)	Intellectual material is intellectual material – knowledge, information, intellectual property and experience – that can be put to use to create wealth
Edvinsson and Malone (1997)	Intellectual capital consists of humans, system and market components. Employees and managers in the organisation represent human capital. Human capital refers to what people can do individually and collectively. The system component represents the knowledge in the firm which is independent of people and includes patents, contracts, data bases, and information and production technology. The market component consists of the relationship between the organization and outsiders, e.g. suppliers, distributors and customers.

Kaplan and Norton (1992)	The intellectual capital component of the balanced scorecard consists of three linked perspectives: customers, internal business processes, learning and growth.
Sullivan (1999)	Intellectual capital is knowledge that can be converted into profits. It comprises two elements: human capital and intellectual assets. Human capital consists of the firm's individual employees who possess skills, abilities, knowledge and know-how. Within each employee resides the tacit (not codified) knowledge the firm seeks to utilise. Intellectual assets are created whenever human capital is codified.
Mayo (2000)	This author focuses on a definition of human capital: a capability, knowledge, skill, experience and networking, with the ability to achieve results and the potential for growth; individual motivation in the form of aspirations, ambition, drives, work motivations and productivity; work group effectiveness in the form of supportiveness, mutual respect sharing and values; leadership in the form of clarity of vision and ability to communicate that vision; organisational climate in the form of culture particularly the freedom to innovate, openness, flexibility and respect for the individual.
Haanes and Lowendahl (1997)	A distinction is made between the intangible resources of competence and relationships. Competencies are conceptualised as the ability to perform. They are manifested at the individual and organisational levels. Relationship-type intellectual capital is manifested in the reputation if the company and customer loyalty.

Source: Garavan, Morley, Gunnigle and Collins (2001).[5]

2. Stimulating the intellectual capital in a maritime company

For a maritime company, the intellectual statement is to create values for its customers like making competitive shipping services, high levels of safety, health and qualifications for employees and responsible attitude towards suppliers and other stakeholders. In order to acquire such values, maritime company have to use IT to support production and knowledge management internally and externally, it must be able to retain and attract highly qualified personnel and be a permanently attractive workplace.

For stimulating the intellectual capital, the maritime company has to train employees to use IT and proper communication equipment, both at the organization quarters and on sea, it has to develop and use system supporting knowledge management by being user-friendly and accessible to all and to share knowledge internally and externally.

For a maritime company to attract, retain and develop intellectual capital and highly qualified employees, it has to make and analyze employee satisfaction surveys. The results should be noted in employee satisfaction polls. According to such surveys, the company should give a prior interest to the employees needs and to act accordingly. The management have to identify new methods for development of knowledge competencies. In order to develop the intellectual capital, the employees and the crew must be sent to technical and for personal development trainings and seminars. The working time policy should be flexible, especially for the crew members that stay a long tome on sea.

The efficiency of the simulative practices will be measured with the help of some indicators like competency development activities, number of employees who are active in experience groups/project groups externally, evaluation of workshops and professional courses, or staff turnover. After each management challenge has been reviewed, conclusions can be drawn on the objectives achieved in the current year and in the next year will be proposed other objectives and special initiatives.

A critical aspect of a maritime company that develops the intellectual capital is the open

attitude towards innovation. Innovation is a must if the company wants to deliver tailored integrated solutions and to meet the most demanding customer requirements. The company should also understand the value of win-win partnership.

In Nordika – a project on intellectual capital initiated by the Nordic Industrial Fund – in collaboration with a task force of government representatives and a round table drawn from business and professional associations in the Nordic countries it is considered that IC management and reporting is about the non-physical and non-financial resources of a maritime company, how they are built and retained, how they contribute to value creation. Knowledge, expertise, stakeholders, customer relations, brands and other intangibles are the basic factors for identifying and analysing the maritime company's key values [6].

3. Trends in Maritime Intellectual; Capital Development

According to S. Mthethwa and P.C. Zandee in „Transformation in the South African Maritime Industry – a BEE Case Study” [7], maritime industry is one of the oldest industries and the community is international in flavour and very traditional. It is an industry for people who are seeking a long-term investment and appreciate the value of personal relationships. It is important to invest more time and resources in fewer investments and cultivate strong relationships than spread oneself too widely too quickly. To function effectively at board level without any maritime knowledge or insight creates a lack of ‘value-adding’. This is as much a prerogative of the established business as it is for the Board members/investors/shareholders.

In maritime transport, ships are multi-functional systems that require highly information processing and management systems.

Major changes are taking place in maritime markets and influences intellectual capital. Changes in demography and energy consumption are key factors. Global companies tend to focus on their core-business. Logistics services and transportation are likely to be increasingly outsourced. Some shipping companies, notably amongst container lines and specialised carriers, will

expand their scope of operations and develop into logistics providers, not merely delivering transport services in the logistics chain. [8]

The nowadays technologies send and receive fast and easily large quantity of information inside each maritime company or between company and ship. They will influence both the markets and the shipping industry and the organisation of the work in the companies. These kind of changes will modify the structure of intellectual capital inside shipping companies.

Recruitment of qualified officers and acquiring proper intellectual capital is a major challenge for most shipowners and maritime managers world-wide. A similar need is identified for shore-based functions. In the major labour supplying countries, the demand for officers is increasing faster than the supply and some owners are compelled to look for alternative labour supplying countries. It will take time to develop alternative labour supplying countries. An overall shortage of qualified officers in the coming decade can be anticipated and is to be addressed. Career paths must be developed in order to be attractive for the competent human capital.

4. Conclusions

Intellectual capital represents a strategic asset for maritime business. Several specialists made definitions for this term and as a common characteristic of all definitions, intellectual capital consists of essential skills, knowledge, documents about transport processes, customers, research results, harbour activity and other information that can give competitive advantage. In generally, intellectual capital is formed by human capital, structural capital and relational or customer capital. Human capital refers to the skills and knowledge that make value for an organization. Structural capital represents formulas, information, patents, processes etc., that result from the products or systems the firm has created over time and remains with the organization even when employees leave. Relational capital, the third component of the intellectual capital is represented by good relationships with stakeholders (clients, employees, suppliers, government agencies, competitors and other organizations that come in contact).

For a maritime company, intellectual capital involves making value for customers. Intellectual capital is responsible of making competitive shipping services, and for taking into account the measures of safety, health and qualifications for employees. Suppliers and other stakeholders must be treated appropriately.

Technologies of today evolve so quickly and they influence markets, the shipping industry and the organisation of work in the maritime companies. These kind of changes will modify the structure of intellectual capital inside shipping companies and will accentuate its vital importance.

The Statistical Analysis of the Consumer Attitudes toward the Hospitality Services from Romania

Vasilescu Ramona

Saierli Olivia

“Tibiscus” University Timisoara, Romania

ramonavasilescu@yahoo.com

saierli_olivia@yahoo.com

Abstract

In this paper, we have statistical analyze the consumer attitudes toward the hospitality services from Romania. We have developed a questionnaire which was answered by 83 people. Based on these responses we have made a top of the hospitality services in terms of respondent. Then, we applied the Helmer univariate test to show that these results can be generalized. Also, we asked respondents to give a note for each service of hospitality from our country (for the past two years). We calculated the average of these notes for each service of hospitality separately, and we generalized the results for the entire population by computing for each the corresponding confidence interval, with a 95% of probability.

Key words: consumer, hospitality services, Helmer unvaried test

JEL classification: C32

1. Introduction

It is said that Romania is a beautiful country with a high tourist potential. The Carpathian Mountains are known for their unique species of animals. About 5.18% of the area of Romania has a protected status: three biosphere reserves (Danube Delta, Retezat and Rodna), thirteen national parks (Domogled-Valea Cernei, Cheile Nerei-Beuşniţa, Semenice-Cheile Caraşului and Defileul Jiului), thirteen natural parks (Porţile de Fier – Iron Gates, Grădiştea Muncelului-Cioclovina, the Ţara Haţegului dinosaur geo-park, the Mehedinţi Plateau geo-park), etc. The

mentioned examples are in the vicinity of the Banat region, where we have completed our study.

The rising of the living standards is reflected in many aspects of life; among them is also reflected on the tourism. Until the appearance of the economic crisis, the statistics have revealed that Romanians are increasingly willing to spend significant amounts of their income to travel abroad and in our country for tourism. But this economic crisis has reduced the number of trips, following the global trend.

Despite all these opportunities, tourism and hospitality in Romania have met with little success and popularity; the failures in these areas have been the subject of many debates and research. Unfortunately, the answers given so far have failed to elucidate the most common causes.

2. Material and Methods

To analyse the characteristics of hospitality that make the Romanian destinations attractive, we designed a questionnaire to obtain the data necessary to study the consumer attitudes toward the services of hospitality in our country. In order to determine the correct sample, we have used the data provided by the National Institute of Statistics, the 2008 Yearbook, with regard to the population of the Banat region. The sample has been computed by using the Decision Analyst STATSTM 2.0 software for a desired confidence level of 95%. Following this computation we have obtained a sample volume of 73 respondents. For one week, this questionnaire was answered by 83 people, including 32 men and 51 women aged 19-58

years. Respondents were randomly selected from the counties of Timis and Caras-Severin.

We also used data provided by the National Institute of Statistics, Statistical Yearbook 2008 – chapter 20 Tourism.

For the data obtained we used:

- **The ordinal scaling method** to determine the place of hospitality services (the room, the restaurant, the bar room, the recreation and the SPA center) of the accommodation units (the respondents were given a place from 1 to 5 for each of these services, 1 representing the best place).

- **The interval scaling method** to determine the overall score provided (in all the trips in the last 2 years) (respondents were given a point from 1 to 10, where 10 is the maximum score).

- **The Helmert (χ^2) test** to determine if the classification of the hospitality services, in terms of their importance to respondents, corresponded to the reality.

3. Results and Discussions

Starting from the data offered from the National Institute of Statistics, the evolution of the autochthonous tourists in Romanian between 2000 and 2007 is illustrated in Figure 3.1.

Figure 3.1. The evolution of the autochthonous tourists in Romania according to the National Institute of Statistics

In this study, 83 people are interviewed about their attitudes relative to hospitality services. Survey results are in table 3.1. and to obtain them we used **the rank order scale** which implies that the respondent establishes a hierarchy of the hospitality services analyzed according to their importance, indicating the place occupied by each of them.

Thus, if among the respondents there isn't a particular preference for a certain hospitality service, then the survey results would be, theoretically, those of the table 3.2.

But, we can say with a 95% probability that the survey reflects the actual preferences of consumers in the market?

Table 3.1.

The classification of hospitality services by the place occupied by the respondent's view (only 75 of 83 people responded to this question)

<i>The service</i>	No. (O_i)
<i>The room</i>	40
<i>The restaurant</i>	13
<i>The bad room</i>	4
<i>The recreation</i>	13
<i>SPA Center</i>	5
<i>Total</i>	75

From Table 3.1. we can see that the room seems to be the top preference, followed by the restaurants and entertainment, then the SPA center and on the last place is situated the bar room. But who can guarantee that these results correspond to the reality and that they are not only due to the sampling fluctuations?

To answer this question we apply the Helmert unvaried (χ^2) test. This test compares an observed distribution (actual) with a known theoretical distribution and determines whether there are significant differences between them or not. For this we note the observed frequencies whit O_i , and the theoretical one whit T_i .

Table 3.2.

The theoretically results of the survey

<i>The service</i>	No. (O_i)
<i>The room</i>	15
<i>The restaurant</i>	15
<i>The bad room</i>	15
<i>The recreation</i>	15
<i>SPA Center</i>	15
<i>Total</i>	15

Thus, we formulate the null hypothesis (H_0) under which the observed and real frequencies are equal (i.e. $H_0 : O_i = T_i$) and the alternative hypothesis which denies the null hypothesis (i.e. $H_1 : O_i \neq T_i$) and we determine the computed value of the Helmert test as

$$\chi_c^2 = \sum_{i=1}^n \frac{(O_i - T_i)^2}{T_i} = 56,93.$$

From the statistical tables relating χ^2 test for a confidence level of 95 % (i.e. $\alpha = 0.05$) and for $n-1=5$ degrees of freedom we determined its critical value as $\chi_t^2 = 9,488$. As $\chi_c^2 > \chi_t^2$ we conclude with a 95% of probability that the null hypothesis is rejected and that the survey results correspond to actual consumer preferences.

Also, the respondents had to evaluate the services of Romanian hospitality by giving each a score from 1 to 10. Of the 83 respondents to the questionnaire, only 75 have traveled in Romania in the last two years. Thus, computing an average grades for each hospitality service, we obtained the following results:

Table 3.3.

The top of the hospitality service in Romania, in terms of grades given by respondents

The service	The grade	The place
The room	6.93	III
The restaurant	7.32	I
The bar room	6.82	V
The recreation	6.85	IV
SPA Center	7.08	II

Still, we want to extend the results in Table 3.2. for the entire population made up of Romanian tourists. For this purpose is used most often the direct enlargement process. By applying this procedure is estimated the **confidence interval** for the general community average and the limits that will fit the characteristic of the whole community totaled.

Since the sample size is greater than 30, we apply the Laplace function. Thus, the interval in witch the average of the general community is given by the formula:

$$\bar{x} - z_\alpha \cdot \frac{s}{\sqrt{n}} \leq \mu \leq \bar{x} + z_\alpha \cdot \frac{s}{\sqrt{n}},$$

where μ represents the average of the general population, \bar{x} represents the sample average, s represents the standard deviation of the sample and n represents the sample volume.

Table 3.4.

The confidence intervals for a confidence level test of $\alpha = 0,5$ (i.e. with a 95% probability)

The room	
Mean	$\bar{x} = 6.93$
Standard Deviation	$s = 1.841$
The critical value of the test	$z_\alpha = 1.96$
Confidence interval	$6.52 \leq \mu \leq 7.35$
N	75
The restaurant	
Mean	$\bar{x} = 7.32$
Standard Deviation	$s = 1.717$
The critical value of the test	$z_\alpha = 1.96$
Confidence interval	$6.93 \leq \mu \leq 7.70$
N	75
The bar room	
Mean	$\bar{x} = 6.82$
Standard Deviation	$s = 2.238$
The critical value of the test	$z_\alpha = 1.96$
Confidence interval	$6.25 \leq \mu \leq 7.30$
N	70
The recreation	
Mean	$\bar{x} = 6.85$
Standard Deviation	$s = 2.111$
The critical value of the test	$z_\alpha = 1.96$
Confidence interval	$6.37 \leq \mu \leq 7.33$
N	74
SPA Center	
Mean	$\bar{x} = 7.08$
Standard Deviation	$s = 2.046$
The critical value of the test	$z_\alpha = 1.96$
Confidence interval	$6.60 \leq \mu \leq 7.56$
N	70

In conclusion, with a 95% of probability we can assume that the hospitality services in Romania are estimated between 6.25 and 7.70.

4. Conclusions and Future Work

Although the five hospitality services occupy a certain place as important to respondents, however, when traveling in Romania, they prefer to receive better services for SPA center and restaurant, making small compromises in the conditions of the room hospitality. In the future, we'll do an analysis in the way of hospitality services are quoted in our country versus abroad, as current statistics reveal that most Romanians preferred to travel in the country.

Applications of the Chunking Technique in Business Communication

Zamfir Cristina-Mihaela
„Ovidius” University of Constantza
cristina_m_zamfir@yahoo.com

Abstract

In Business English, the technique of chunking and its linguistic expression largely contributes to the business model of communication. Precision questions are undoubtedly one of the most powerful tools for enriching the process of communication and identifying people's language preferences. People communicate using different size chunks of information. Knowing whether to chunk up or down – or both – are the key skills in interpersonal communication.

Key words: Business English, technique of chunking, communication.

JEL Classification: M00, A12, D83

1. Introduction

The chunking technique resembles the Specific / General Meta program patterns. Similar to the general meta program style, in that it starts with the detail and chunks up to the big picture, the technique of *chunking up* involves moving to a larger, more general or abstract level of information.

Chunking is based on a twofold interpretation: on the one hand, meaning is given by a continuous cline of frames, from sub-atomic (micro chunks) to universal (macro chunks) and its inverse operation, i.e. from universal to sub-atomic, and, on the other hand, the cline of frames involves an interconnection between the language of the sensory-based real world and the general, vague and metaphorical concepts.

In order to chunk up or down, both wider and narrower frames of reference of the source text need to be established. For example, chunking down aids as a good strategy for componential analysis in understanding the semantic field of individual words.

Clarifying questions represent a good instrument for the chunking down strategy. In cultural mediation, apart from chunking down, the process of stepping upwards, i.e. chunking up, as well as chunking sideways, i.e. chunking laterally, is also required.

In business, we are interested in “how” one can learn to chunk, in other words *how do we acquire the ability to move attention between generalities and details?* The solution is to start asking questions that are specific to each direction of the *chunk size*. According to Katan (2004:201-202), these questions are seen as “a series of formulaic procedural questions” applied to access either general or specific frames.

2. Chunking up

A piece of information can be chunked up when people undertake research by means of the following questions:

- e.g. What is (x) an example of?
- What is (x) a part of?
- What is (x) a type of?

Ellerton (2006:79) enlarges this list by adding two more questions with respect to applying the chunking technique in negotiation and mediation:

- e.g. What is the intention?
- For what purpose?

He points out that far too often “in negotiation, we continue to explore solutions at the level of thought at which we do not agree. The key is to chunk up until you and the other person agree and then to chunk back down to the details only as fast as you both maintain agreement” (Ellerton 2006:81). Thus, with chunking up, we envisage those options that could match our interlocutor's needs and expectations and, more importantly, we offer those solutions that would support a mutual outcome:

- e.g. *You would like to allocate funds to the production of this clothing range – what is your intention?*

Answer: *To attract the customers we both need by opening gigantic stores in my town and in your town, with large economies of scale.*

The manager's purpose is to indicate two objectives, i.e. *to attract customers, to open gigantic stores* behind the action of allocating funds. If uttered in a rising intonation, the open question *what is your intention?* indicates interest and surprise. The use of the modal "we need" makes the other party interested in a common goal, assuming that his business interest also involves increasing market share. Operating on a higher level, the level of expanding the business, the manager establishes a common purpose and avoids possible troublesome arguments.

The chunking technique plays a crucial role in taking the lead in conversation. As Molden (1996:150) points out, "[F]lexible communication requires the ability to chunk up, down or laterally depending upon the situation". His perspective is supported by Molden and Hutchinson who strengthen the idea that people's communication is based on the use of different size chunks of information across a continuum and that one can "use this concept to pace and lead elegantly" (Molden and Hutchinson 2006:59). As a matter of fact, both Molden (1996) and Molden and Hutchinson (2006) see the technique of chunking as essential in developing rapport on different levels, and in influencing people during business relationships.

People's patterns of language place them on different levels of communication. Some prefer to talk in large information chunks, others speak more specifically in small information chunks. Yet, there are contexts in which certain businesspeople deliberately avoid a straightforward answer when confronted with a precise question. If asked, for instance,

e.g. *Have you informed all the shareholders about the disastrous financial situation of your company?*

the businessman might beat around the bush and chunk upward:

e.g. *The financial situation remains one of our primordial concerns, but looking at last year's balance sheet, we feel that our management team will supervise attentively this year's profit growth.*

In the example above, the businessman's evasive response chunks up from the *disastrous financial situation* to *attentively supervising the profit growth*.

In a conversation about the overall performance of a company, a group of accountants offer the financial reporting based on the results of a strict corporate governance. One can detect different levels of communication and draw a chart of the changing levels used by the interlocutors. For example:

e.g. Laurence: *At the end of this year, the profit and loss account looks quite consolidated.*

Jeffrey: *It would look even better if we could slightly reduce marketing and distribution costs by 10%.*

Bruce: *Don't bother about marketing and distribution costs. Do you know how much retained profit will be left when the shareholders have received 50 cents per share?*

Alex: *Retained profits will be higher than expected / carried to next year make us hope for expansion and further investments.*

This chart outlines two different styles of communication. On a scale from small to large, two of the four accountants (Jeffrey and Bruce) prefer to be specific and talk in small chunks of information, whereas the other two (Laurence and Alex) think more globally and reveal a more general perspective on things. As the chart above shows, Bruce and Jeffrey's *patterns of language* include *small chunk sizes* – financial figures: *by 10%, 50 cents per share*, and economic terms: *marketing and distribution costs, retained profit, shareholders*, and avoid generalities. On the

other hand, Laurence and Alex express themselves in *global objectives*.

It appears clear that Alex sidesteps Bruce's probing question which is tied up with specific details and technicalities, and moves up to making future projects given the satisfactory economic situation: *make us hope, further investments*. Therefore, I would associate Laurence and Alex with the general (global) type of meta program, and I would integrate Bruce and Jeffrey into a more specific pattern.

3. Chunking down

Another strategy by means of which one can "follow through" a series of steps to accomplish something, such as a project, is called chunking down.

A very imposing goal, such as <<starting a new business>>, may be chunked into sub-goals, such as *developing a product, identifying potential clients, selecting team members, creating a business plan, seeking investment, etc.*" (Dilts and DeLozier 2000:166). The example given by Dilts and DeLozier could be represented as follows:

Moving from the general to the specifics, i.e. chunking down from whole to part, requires a detailed analysis.

From the chunking language point of view, we chunk down, going from the general to the specific. Thus, questions like the following help us descend to the parts and relate them to the whole:

- e.g. 1) *What is an/a specific example of this?*
 2) *What is a component/part of this?*
 3) *What are the constituent elements of this?*
 4) *What is a specific example of the marketing mix?*

(Ellerton 2006:80; Katan 2004:201-202)

Question (4) starts from the super-ordinate expression "marketing mix" and leads to its four components: *product, price, promotion, place* which make up the mixture of marketing

activities a company uses when planning the products and services it intends to sell. Each component can be further subdivided into micro chunks or smaller constituents. Operating on the micro level is facilitated by questions like:

- e.g. *What are the constituent elements of x?*
What is a part of y?

(Source: Longman Business English Dictionary 2007:344)

A person who chunks down and emphasizes details has a deductive reasoning marked by precision of language in comparison with a person who chunks up and who thinks more inductively.

4. Lateral Chunking

If chunking up and chunking down correspond to inductive and deductive thinking, respectively, chunking laterally ("lateral thinking") involves reasoning by analogy, metaphors and similes, relating to the abductive thinking.

Lateral chunk responds to questions such as:
 e.g. *What is another example of this class of things (in this context)?*

What is at the same level as x?

What does this situation remind you of?

According to O'Connor (2001:204), "[Y]ou chunk sideways by going from one member of a class to another member of the same class, or from one part of the whole to another part of the same whole".

In the context of business, available sources of credit from banking institutions can be classified according to the different types of banks. Thus, I suggest the following diagram:

It is noticeable that the three modes of communication, i.e. up, down and across make up a map that guides a person towards various thinking styles. For example, the exercise of **chunking up** presupposes that all the four types of banks, namely central, commercial, investment and microcredit converge into a single one, i.e. the banking sector. **Moving down** involves breaking each type of bank into its component elements, that is dividing the central bank into “implementing monetary policy” and “fixing interest rates”, or the commercial bank into “making loans to individuals” and “taking deposits to private individuals” and so on. Finally, **chunking sideways (laterally)** links these parallel financial systems – starting from central to commercial to investment to microcredit.

5. Conclusions

The chunking up strategy is well-known for its vagueness and abstract type of language.

Chunking up usually starts from the level of behaviour and may continue up to the level of identity. That is to say, in order to observe an individual’s actions and specific behaviours, one should start with his/her beliefs in response to the verbal question *what?*

a) *What is your intention?*
b) *What strategy is this an example of?*
and then step up to explore who the person identifies with.

Considering the *wh-* questions – *who, what, where specifically?*, we can associate them directly with the chunking down technique.

Rapport can be quickly established by the practical use of chunking up, down or laterally in organizations / in the workplace.

Preciseness and specificity are rendered by asking questions which lead to the micro level: to chunk down from whole to part, ask *What is a part of this whole?*, to chunk down from class to example, ask *What is an example of this class?*, to chunk down from an outcome, ask *What prevents me from achieving this outcome?*

**ECONOMICS AND BUSINESS
ADMINISTRATION**

SUBSECTION

Marketing – Management

The Management of Media Organizations – from Theory to Practice

ANDREESCU (MANOLACHE) Cristina, Ph. D Student
The Bucharest Academy of Economic Studies
andreescu_cris@yahoo.com

Abstract

Media organizations have become a barometer in the development of a society. The way these organizations are managed depends on the context they can be placed in. Media organizations can be assimilated with a social and economic context. I attempted to emphasize the importance of good management that takes into account the basic principles and which can be integrated into a media organization. Leadership should be concerned with combining the specifics of management with those of human nature. The need for management is real. As it is the interdependence between the media organization and an efficient management. Despite their shortcomings, today's managers are able to manage a newspaper, a radio or a television station. They can be divided into three categories, namely: managers of a media organization, having no knowledge of management; managers having the necessary training but unaware of how to implement management rules and finally, managers with very good training but lacking interest, who let things run by themselves.

Key words: Management, media, management style, leadership styles, free market economy, strategy.

JEL classification: M10

1. Introduction

As with most organizations, the media ones are of a bureaucratic nature. In my paper I tried to stress out their characteristics but what really differentiates them is their name of *unbureaucratic bureaucies*. For the manager of a media organization, it is a greater or a lesser effort of management. I mean that in case of a lack of hierarchy the participative management appears, where the employees' need for self-achievement is encouraged. In fact, the leadership style that should

characterize the behavior of today's managers resides in combining the priority of production with the interest for human resources.

The managers in Argeş are highly interested in what is happening in their neighbors' yard, in the publications of the competition as well as in their own profit. This is so because newspapers such as *Societatea argeşeană*, *Observator argeşean*, *Top*, but less in the case of *Argeşul*, are owned by people who are involved in other businesses that can sustain, despite of losses even, the business called newspaper, just for the sake of the social position or other important advantages deriving from it. Such managers are not interested in adding value or improving, meaning that they do not make efforts for improving their leadership style.

Placing a media organization in a suitable environment allows it to develop. The more dynamic the environment the more differentiated its structure should be. The more differentiated the structure of a organization, the more difficult the task of coordinating the employees' work. This shows how important the different aspects are for the management of a media organization.

2. Literature review

Argeşul is the oldest daily newspaper in Argeş area, whose first issue was published on December 23, 1989, continuing the tradition of the first publication, with the same title of March 31, 1876.

The newspaper in tabloid format does not indulge in scandal stories, has a general audience for its general contents, targeted mainly to the rural audience (subscription-based).

The daily offers general political, cultural, sports, miscellaneous and advertisement information. Cultural and political information comes first. Different other types of stories are approached but mainly when the the other types of information are scarce.

The strong point of the newspaper lies mainly in its highly stable pool of editors that write for the paper. It is one of the few publications that did not know major fluctuations of personnel. The professionalism and stability of the editorial group translated into the possibility of assuming and publishing articles that had an unusual impact and were a first for that region.

Argeşul is a serious newspaper brand that does not promote scandal stories, observes ethical principles and has a leadership aware that credibility is one of the greatest assets of the newspaper.

The long-term strategy of publishing only credible information and not resort to sensationalism proved beneficial. On the Argeş area market, *Argeşul* newspaper is considered the most serious as compared to other four existing newspapers which, with almost no exception, compete in promoting on their front pages, information on crimes, rapes, sex, incest, pornography, showing less interest for the major problems the local community faces.

The daily has been given credibility due to the information it offers, the attitude it has and the fact that it is considered traditional, with a balanced but firm voice. It is a daily with a personality that constantly increased the number of its readers.

Top daily, with 6.000 daily issues, is edited by Media PIC, part of the PIC group of Piteşti. *Top* was launched on the market on April 1, 2003 as a weekly publication. Ten issues later it appeared twice a week, Tuesdays and Fridays.

Six months later, the need for information of the people in Argeş area led to the daily publication of the newspaper, starting with October 1, 2003. Everything contributed to an increase in sales. *Top* daily is edited in very good graphic conditions at the Gutenberg publishing house in Craiova. *Top* defines itself as an information and publicity daily, guided by the interests of PIC group. At present, it advertises the products of PIC group. *Top* is a rather new product in the media market. It presents political, social, economic, cultural, sports, society and miscellaneous information.

All categories are treated fairly to cover most of the public's interests.

The editorial policy of the newspaper aims at bringing the readers general information on all aspects of the social life in Argeş County.

The newspaper targets not only the readers interested in local information but also those interested in events in general. For the last category, the paper brings the latest and most important national and international information.

The Argeş County daily, *Observator*, was first published in January 2000; it appeared in an already crowded market strongly inclined to enrich the genre.

Observator is an independent daily of the Argeş County, published in a 16-page format with an additional daily real estate supplement. The Argeş media market can be said to target the lower class of society. Crime is the topic of excellence for all the newspapers in the area, most of the front page features dealing in this subject. Since day one, *Observator* intended to approach the whole range of social topics, focusing on those targeting the largest audience. News in brief are presented side by side with economic, social or political information, each according to importance. This was the way the newspaper tried to get as many readers as possible.

Curierul Zilei is the daily with the largest public in the area. It was established in August 1994, at the initiative of two businessmen in Piteşti, Mrs. Marilena Baraţă and Mr. Constantin Neaguţ. The first issue was published on September 15, 1994. The editorial office started with a team consisting of young people, mostly with no previous experience with the media work. Paradoxically this proved to be an advantage, which soon translated into an increase in circulation.

Mention should be made that at the time of its first publication, on the Argeş media market there was an audiovisual channel, namely STP Piteşti, radio and television station, and *Argeşul Liber* daily. The direct, concise, dynamic language used by the *Curierul Zilei*, alongside its attractive layout, made it a vivid experience that quickly won the sympathy of the local public. Just to show how this worked we shall say that one of the rules in writing the articles was „Write it as you would tell it.”

Curierul Zilei is a daily tabloid, consisting of news that are 99 percent of local interest. Its contents is varied (news in brief, social, economic, political, sports, publicity) with a focus on miscellanea and publicity. The articles are written with professionalism,

easily readable, presented on pages that are modern, clear and attractive.

Its distribution is 91 percent urban and the remaining 9 percent rural, only in Argeş County. Due to its high circulation and lower publicity costs per one thousand readers, *Curierul Zilei* is the best media tool for publicity messages in the Argeş County. This is shown by the fact that *Curierul Zilei* is used as a publicity carrier by famous clients in the area.

Curierul zilei has its own loyal audience, due to the debatable cases it has always presented. At present, this daily is the most popular one in the county, the one with the fastest development after 1989.

Societatea Argeşeană is a complete one, according to its own description. It was first published on December 1, 2003, in an already highly competitive media market. Along the years, the newspaper adopted different editorial policies, according to the other actors existing in the print media market of Argeş.

Societatea Argeşeană grew its own loyal public, very much like the *Curierul Zilei* by publishing debatable cases, original stories and journalistic investigations that have more than once triggered true political and administrative earthquakes in the Argeş County political class.

It created true information breakthroughs in once considered taboo areas, such as police, magistrates, clergy, finances and the business community.

Societatea Argeşeană is a daily bringing a large volume of information, whose management changed quite often, which presents a diversity of political, social, economic, sports, cultural, ads and publicity, miscellaneous information.

The publication is disseminated all over Argeş County, through its own as well as other distribution networks. As a conclusion, Argeş County continues to be a strong economic center still, people afford less and less buying a newspaper. The lack of cash resulted in the print media consumers' desperate ability to cope. People would buy one paper that would be read by several people or they would resort to radio or television.

Of the five daily newspapers we talked about, *Curierul Zilei* and *Societatea Argeşeană* cover mostly miscellanea, tragic and shocking cases, presented with photos. The other daily newspapers do not focus on

this kind of information but it is nevertheless present.

Economy is the less covered topic by the newspapers of the county, while crime takes precedence on the front pages. Integrating a media organization into the free market economy requires both good training in the field and the implementation of an efficient management style. As for the publication management, the only publications that preserved the manager position are *Argeşul* – the oldest daily newspaper in the area, managed by Mihai Goleşcu – and *Curierul Zilei* – with Constantin Neguţ as general manager, as well as Marilena Baraţă, ex-wife of Cristi Neguţ, as founding chairman, which allows us to say it is a family newspaper. *Top* was created for the purpose of promoting the interests of PIC group and not so much for the sake of successful journalism. It was managed by Marian Jinga, who was removed from leadership as he created his own publicity company.

The owners of PIC group considered there was a contradiction of interests and accused the manager of lack of loyalty. At present, manager of the newspaper is Mr. Iustin Angelescu, who does not interfere with the editorial policy of the newspaper, merely managing the business newspaper *Top* represents.

According to the development of the internal life of the newspaper, we can say it was dictated by personal ego and financial interests. The newspaper is meant as a support for the publicity business of the PIC group.

Observer daily has its own publishing house (S.C. Tipcomp S.R.L), just as *Argeşul* (Argeşul Liber S.A.), which is a great economic advantage.

Marcel Proca, chairman and owner of the newspaper does not interfere with the editorial policy. In 2005, Adrian Ştefănoiu was assigned editor-in-chief. He managed the newspaper well, increased the newspaper circulation, won new segments of readers, improved the editorial team and their working conditions and signed monthly publicity contracts of over 50 million lei. At the same time, there are interesting management positions, such as strategy director Cristi Bumbenici, administrative director Roxana Matei. That looks like there is an editor for each director, which may seem quite funny for the editorial office of a local daily newspaper.

Until the fall of 2005, *Societatea Argeșeană* was managed by Gheorghe Smeoreanu. The businessman financing the newspaper dismissed him for abuse and financial disorder, though he was the manager under which the newspaper started its activity. *Societatea Argeșeană* is considered a branch of *Curierul Zilei*, because Gheorghe Smeoreanu was first manager of *Curierul Zilei*. The newspaper focused on topics of local interest and had no characteristic style: it was an odd mixture of miscellanea, political, sports and moral lessons from His Holiness Calinic, Bishop of Argeș and Muscel.

3. Theoretical Background

The purpose of this paper is to identify the context in which managers of local organizations work. I considered them to be the most important actors in the media. The research is based on the results of questionnaires conducted from September to December 2006, addressed to managers of print media publications in Argeș area, a total of 21 managers of the newspapers *Top*, *Societatea argeșeană*, *Argeșul*, *Observer argeșean* and *Curierul Zilei*.

The questionnaires focused on the perception, opinions and management style in terms of media organization treatment.

The questionnaire results correlated with theory led to the following conclusions:

The opinions of the interviewees were objective but their analyses and comments showed they did not have thorough knowledge of the approached topic. I talk here of the management of the media organization, which was treated superficially. This conclusion resulted from the managers' tendency to be more concerned with profit rather than competition. The reason they give is that profit-driven means customer (reader)-driven but this led to bad management. This is not how it should happen, as one of the most important roles of a manager is to translate potential into reality. This means that a manager is expected to always act as a factor of change, progress and innovation and not just to passively react or adapt to what has already happened. All the interviewees promoted the notion that the means of information co-exist peacefully and complementarily for the purpose of information, an idea that should be discouraged. This image should be replaced

by another one taking into account the fact that the means of information are generally the result of another profit bringing business. As for the management style an acute lack of concern for this aspect was noted. The capability to manage a media organization is the capability to efficiently implement one's own management style. Integrating and maintaining, of course, a media organization into the existing media market requires good media training which, at present, does not exist.

Most media organizations in Argeș need certain investments, need exploring new interest areas as well as bring journalists capable of writing with style into their editorial staff.

The editor-in-chief of *Societatea argeșeană* is worried that some newspaper managers, whether local or central, tend to overestimate the way their newspapers sell and to underestimate the competition. This is an observation that makes me state, as in the theoretical part, that management is truly needed. The fact that unimportant things such as overestimating the circulation of a publication are points of concern for a newspaper manager shows that integrating and maintaining, of course, a media organization into the existing media market requires good media training which, at present, does not exist. An optimal motivational climate should be created, in which the interests and needs of each person could be integrated into those of the organization, so that one's own goals should be best achieved.

Interviewed managers tried to define the strategies of the organizations they lead, but it was all talk. Goals were not clearly defined, here and there just the financial ones, leaving the impression they lacked knowledge on strategy.

One of the greatest problems managers of media organizations have to face is the legal framework and there was a consensus in this respect. Economic issues come first with almost all daily newspapers we approached, while the management struggles to get the selling price that makes the newspaper as affordable to the reader as possible. Peaceful and complementary co-existence of the means of information for the sake of information is an idea that should be discouraged. This image should be replaced by another one taking into account the fact that the means of

information are generally the result of another profit bringing business. For any businessman, media should be a profit-oriented business.

Based on the answers I got, I considered the following conclusions should be pointed out:

Societatea argeșeană – the goals of the media organization are correlated with the interests and the respect of the employees.

Top – the newspaper management has a management style that resembles that of other publications and takes into account the employees' need for a social life. Hence, an increased interest in the human factor.

Based on the questionnaire results it becomes apparent that most media organizations in the Argeș region need certain investments, should identify other areas of interest and bring journalists capable of writing with style into their editorial staff.

4. Paper Content

According to editor-in-chief Daniel Barbu, the manager of *Societatea argeșeană* tries to adopt the typical behaviour of today's managers. The goals of the media organization he manages are correlated with an interest and respect of the employees.

The newspaper is not managed in a profit-oriented way, even if profit is one of the main targets.

The interpretation of other newspapers' managers of the competition is criticised and he sustains the idea that the public is the only one aware of how things are and the only decider on the success or failure of a newspaper. An important role in producing information is played by technological change, which goes for most fields of activity. In Daniel Barbu's opinion, today profit is the most important thing. Management and quality depend on the financial resources. Dumping prices of the newspapers (for instance, at one time, *Societatea argeșeană* had the price of 1000 ROL), which was harshly criticized by the most circulated newspaper in Argeș, *Curierul zilei*. On the other hand, Daniel Barbu admits that the journalists' recruiting system plays a crucial role in the success of the business, of the media organization.

Good management should combine readers' satisfaction and profit. Those who hold the secret manage to make a name and maintain it on the market.

Emilian Zamfir, editor-in-chief at the *Top* daily newspaper believes media organization should not be placed in the commercial area where businessmen's ideas and orientations prevail, as this impedes on presenting the true image of journalism. He sincerely admitted that most times, performance translated into survival, meaning you have to continuously adapt to change, to requirements, to the team you're working with. As in Argeș region competition in print media is extraordinary, (six daily newspapers, and four weekly ones) maintaining a direct and objective contact with readers could be the key to market success.

The newspaper manager has a management style that takes into account the employees' need for a social life. So, there is an increased interest of the manager for the human factor. Emilian Zamfir thinks a good worker is the first step to making profit, an idea shared by his colleague at *Societatea Argeșeană*. This means an evolution at managerial level because it requires an integration of the employees' needs with those of the organization. Newspaper self-management means the financial aspect is very important.

The profit is set at the same level of importance as the readers' satisfaction. The leadership of the editorial office also takes into account the tight competition existing on the media market in Argeș. Unlike Daniel Barbu, the editor-in-chief of *Top* thinks the media market is too often seen in terms of commerce and competition.

As for the economy of the newspaper, a balance is sought between the funds from publicity, the costs of production and the newspaper selling price.

He values much the honesty of the publication and of those managing it, as it is crucial that correct and authentic information reaches the public, which would result in the failure of manipulation attempts.

Unlike other newspaper managers, the chairman of the *Observator argeșean* is keen on the economic aspect. He has a higher level management style, where reaching goals takes precedence over the interest for the other employees.

Marcel Proca is politically involved, which has advantages and disadvantages for the newspaper. Nevertheless he tries to keep a balance so that his political activity does not have undesired effects on the publication.

He tried several styles of management; first with management teams consisting of the

journalsits having different positions in the editorial office, but because of misunderstandings he gave it up and assigned one manager, namely Adrian Ștefănoiu.

According to his employment contract, Adrian Ștefănoiu pledged to increase the circulation by 30 percent over the following six months, publicity with 50 percent whereas the editorial team was supposed to write better articles.

On the other hand, notice should be made of the continuous effort to integrate new technologies.

What the management of *Observator argeșean* seems to forget is the competition. The lack of other newspapers that could at least equal the performance of the newspaper made them so sure of themselves that they do not take competition into account.

As for the profit, it can only be said that it has a leading role in a media organization. It can signify the existence and also the development of an organization, even if in local media we talk of small profit. Economic issues are important even if a balance is sought after between expenses and income (mostly from publicity).

All this is important for attracting a larger audience while bearing in mind the needs and requirements of the public.

Mihai Golescu, manager of *Argeșul*, considers as most important the good relationship of the media with the public, as the only one responsible for keeping media alive.

He believes that in today's environment, where the laws of free market economy and the spiral of industrialization rule, a place apart is held by print media. According to the manager of *Argeșul*, a healthy strategy of a media organization lies in its awareness of the role technology plays in its present but also future activity. Today's media is characterized by sensationalism, hence the effects, unprofessional media, lack of objectivity, a false media.

For Mihai Golescu, being competitive means covering information in a correct, accurate and clear manner.

Argeșul has become a natural and normal presence in the media environment of Argeș, to whom everybody resorts.

5. Conclusions and implications

By sheer definition, the strategy of a society consists, in economical terms, in establishing costs that allow establishing the selling price of the newspaper, in setting a price for publicity correlated with the circulation so that by balancing expenses and costs, a minimal profit is obtained so that the organization can function and the reader can buy the paper. If such a strategy does not exist, the rest is just talk.

I wanted to emphasize that free market economy compels media organizations to have not only a good management but also benefit from the new technologies. They do not only reduce the working time but also contribute to simplifying different operations in both print and audiovisual media. The manager has an important role here, knowing how and when to implement technology.

Another aspect of media management is concerned with the legal frame the media organization works in. Most media managers complain of the limits it sets to their activity. Moreover, they accuse the administration and the political class for that!

Different management styles mean augmenting the role of the human factor. Of course, the manager cannot do everything by himself. An efficient management speaks of the manager's capability to integrate and coordinate the efforts of all members of the organization so that to achieve the desired outcome. One can say that the achievements of a leader are a reflection of his own achievements combined with those of his employees.

In sum, media organizations are successful when they are managed effectively. It is only in such circumstances that they can benefit from public recognition. In terms of quality, there can be noted a lack of reference to the managerial context. The image of the organization is mirrored by the manager's achievements.

If he is able to provide the organization with the necessary resources and if he manages the human factor correctly, he should be able to reach his goals. Otherwise, if the media organization is used in the absence of a strategy, of professionalism, he will disappear and so will the respective media organization eventually.

The Trademark and Its Dismemberments

Lecturer, PhD. Constantin Anechitoae

Faculty of Law „Ovidius” University of Constanta

E-mail: anechitoae@yahoo.com

Professor, Phd., Cornel Grigoruț

E-mail: cornel.grigoruț@gmail.com

Abstract

Currently, brand marks and trademarks and service trademarks are used extensively in all countries - whether developing or industrialized, with a market or planned economy – and they play an important economic role in trade marketing.

Trademarks serve both the interests of those providing goods and services on the market - such as industrialists, manufacturers, distributors, retailers and wholesalers - as well as the interests of consumers, public authorities and the economy, in general.

Key words: trademark, firm, intangible elements

JEL classification: K11, M31

1. The Economic Importance of Trademarks

A trademark enables the entrepreneur who uses it to draw the attention to the potential consumers on the existence of products bearing the trademark, to keep the attention of consumers, once they became familiar with these products and, finally, to distinguish them from the products of the same type that are offered on the market. An entrepreneur can thus acquire a reputation for the products offered under a particular trademark [1].

The value of the trademark comes from the association between a trademark and the product which helps to maintain and develop the demand for the products bearing that trademark, and also from the competition with other products of the same type, belonging to other entrepreneurs. Once a trademark has created the reputation of a company, it makes it easier to enter new

markets, thereby stimulating exports¹. Trademarks also meet consumers' interests in different ways, which are not in any case irrelevant.

Using and promoting trademarks help consumers to recognize the existence of goods and services available on the market, to identify more easily their origin and to choose between similar goods and services. These are the factors that stimulate competition. On long term, this may lead to an increase in the number and types of consumer goods and, eventually, to produce lower prices. Using trademarks may also stimulate competition among users regarding

¹ Google is the first trademark in the world whose estimated value exceeded 100 billion U.S. dollars, according to BrandZ 2009 rankings, released on Wednesday; on the second and the third there are Microsoft and Coca Cola, with 76.2 and respectively, 67.6 billion dollars. "In today's business environment where many companies have collapsed, the trademark has become even more important because it can help support companies in difficult times. Those who will continue to invest in the trademark will be better positioned when the economic situation will be improved than those who reduced costs", said Joanna Seddon, President of Millward Brown Optimor - the audit company which made the rankings. Google is, for the third year in a row, on the first place in BrandZ 2009 rankings, with a 16% increase over last year. Also, the estimated value of Coca-Cola trademark increased with 16%, while Microsoft rose with 8%. BrandZ 2009 rankings include the 100 most valuable trademarks in the world, whose total value is estimated at 1.950 billion dollars, according to studies conducted by the Millward Brown. According to information centralized in this ranking, the highest growth was registered by the category of mobile operators (28%), followed by soft drinks, coffee, fast food, beer and luxury goods, while the most significant decreases are recorded in the case of cars (-22%) and insurance (-48%). BrandZ 2009 rankings were made in 2009 for the fourth year in a row. In compiling the ranking, Millward Brown Optimor considers both the data and financial records of companies and the studies on consumers - natural persons and legal persons.

quality, which, on long-term, it can lead to the general improvement of the quality of goods and services.

Also, an effective system of brand marks and trademarks helps to protect consumers against various forms of unfair commercial practices (e.g. the use of trademarks that mislead or cause confusion because of the similarities with other trademarks). Many countries do not have a specific legislation to protect consumers or, even where such legislation exists, consumers are not always in a position enabling them to defend their rights. In such cases, legislation on brand marks or trademarks may be one of the few legal bases for consumer protection.

Trademarks are equally important for national authorities, particularly for those responsible with quality control and with the control of other characteristics of goods and services. The use of trademarks can help these institutions, for example, to identify, as a result of complaints or tests, supplies and services that do not meet the legal requirements of goods and services similar or belonging to the same category. Finally, the registration of trademarks is a useful source of economic and statistical information for national authorities.

Therefore, every country is interested in establishing an effective system in order to ensure the protection and use of trademarks, so as to satisfy the legitimate interests of producers and consumers and allow optimal use of the contribution that brand marks or trademarks can bring to the economic development.

2. The distinction between trademarks and other distinctive signs

The definition of the trademark, in article 3, allows us to distinguish the trademark from other distinctive signs that have similar identification and differentiation functions. We first mention the equivalence between "firm" and the expressions of "trade name" [2] and "social name", accepted by most authors.

The trade name, for the purposes of the Paris Convention, only means the name of the trader as natural person, respectively the trade company name, and it has that same meaning with that of the company, as defined in Art. 30 of Law no. 26/05.11.1990 on the trade register, republished², according to which "the firm" is the name or, where applicable, the designation under which a trader exercises his/her trade and under which he/she signs.

At Community level, the conflict between the trademark and the trade name has been resolved by the European Court of Justice (ECJ), in the case *Budweiser Budvar, C-245/02*, meaning that, under the exclusive right to the trademark, the holder is entitled to oppose the use of a sign as a trade name, provided that its use is subsequent to the registration of the trademark, in trade activities and intended to indicate the origin of products [3].

The emblem is defined in Art. 30 p. 2 of Law no. 26 of 05.11.1990 (r) as it follows: a sign or name that distinguishes one trader from another of the same type. Both the firm and the emblem accomplish the identification function of the trader, while the trademark distinguishes the goods or services of a natural or legal person from those of others. However, the firm, the emblem and the trademark have the same conditions of validity, i.e. they must be distinctive, lawful and available. If the firm can not be alienated separately from the capital fund, trademarks and emblem conveyance can be made, in principle, separately from the capital fund. The firm has a binding nature, while the trademark is optional; the firm can be only a name or a designation; a trader can only have one firm, but he/she may have multiple trademarks; the firm is protected from the illegitimate use by another trader through the action of unfair competition, while the trademark is protected through the action in unfair competition, but especially on an action of counterfeit [4].

² Published in the Official Gazette, Part I no. 121 of 07.11.1990. The Act has been supplemented and amended by Law no. 12/1998, published in the Official Gazette, Part I no. 15 of 19.01.1998, Reprinted in Publication, in Official Gazette, Part I nr.49 of 04/02/1998.

2.1. The trademark vs. the firm

In order to identify it within the commercial activity, any trade company must have a name. This is called the firm [5].

As regards trade companies with foreign participation, [6] there is one condition required: "The names and emblems of the firm are written, primarily, in Romanian language" [Art. 30's. 3 of Law no. 26/1990 (R)].

In the past, the concept of "firm" was reserved for the individualization of trading companies, for the dealer as natural person, the individualization being made by the "trade name" [7].

In order to be registered, the firm³ should present novelty, it should be differentiated from other firms and it should not cause confusion. Under article 25 from the Methodological Rule of the Ministry of Justice no. 773 of April 21, 1998, on keeping trade registers and establishing records⁴, in order to be registered in the trade register, the firm must satisfy 3 conditions cumulatively: to be available, to be distinctive, and to be lawful.

The firm should be obligatorily stated in the company agreement [Art. 7 and art. 8 of Law no. 31/1990 (R)]. In establishing the firm, the associates must comply with Law no. 26/1990 (R), which governs the content of the firm, differentiated by the legal form of the company; in the case of closely held companies, the firm consists of a name, while in the case of business corporations, it consists of a designation.

The link between the trademark and the firm, as intangible elements of the capital fund, can be retained only provided that the firm is registered as a trademark. Both intangible goods are recorded but on different legal basis.

The firm is designated to differentiate traders, while the trademark is intended to differentiate products/services from those of the same type belonging to other traders⁵.

Mathematical Models in Investment Strategies Regarding Portfolio of Minimal Risk

Anghel Panait
Ovidius University
Economic Sciences I,
Univesitatii Street, Constanta
Romania
E-mail: anghel.panait@yahoo.com

Abstract

In this paper we consider continuous-time market models. We can speak here about the theory of portfolio optimization where H. Markowitz had great results on the mean-variance criterion to judge investment strategies in security markets.

Key words: investment strategies, risk, mathematical model, portfolio

JEL classification:. C65

1. Introduction

Markowitz model of portfolio selection shows how mathematics methods in linear or non-linear general form can be used to find the set of portfolio which is efficient. All investors select the portfolio which best satisfies their preferences assuming risk and return. For the first time in this kind of study Markowitz's analysis offer to the investors the possibility to choose the size of the risk securities. The same analysis can be done in a market with homogeneous expectations when the investors have the possibility of investing in a riskless asset yielding the pure rate of interest. This study was made by James Tobin and his paper "Liquidity Preference as Behavior Towards Risk" and John Lintner in "The Valuation of Risk Asset and the Selection of Risky Investments in Stock Portfolios and Capital Budgets" with conditions that the cost of

transactions, information, and management are all zero.

In economical process we recognize different investors with different expectations in different quantities of portfolio securities. They are interested to have maximum profit with minimum risk.

The theoretical results that we use and obtain will represent the support to a varied strategy of investors on world wide markets.

The first argument is the simplicity of the mean-variance approach to the consideration of continuous-time models. This means that decisions on investment strategies are made at the beginning of the period and the consequences of these decisions will be observed at the end of the period.

2. Theoretical Considerations

Some characteristics of model are:

a) $p_1, p_2, \dots, p_n > 0$ means prices of n different securities at the initial time $t = 0$;

b) $P_1(t), P_2(t), \dots, P_n(t)$ are prices at the moment t . If final time is T , security prices are $P_1(T), P_2(T), \dots, P_n(T)$ and not foreseeable.

We have here a non-negative random variables on a probability space (Ω, F, P) .

$$R_i(T) := \frac{P_i(T)}{p_i}, i = 1, \dots, n$$

are the returns of the securities

$$E(R_i(T)) = \mu_i \text{ for } i = 1, \dots, n$$

are variances

$$\text{Cov}(R_i(T), R_j(T)) = \sigma_{ij} \text{ for } i, j = 1, \dots, n$$

are covariances

If we can hold $\alpha_i \in \mathbb{R}$ shares of security we said that each security is perfectly divisible.

The matrix $\sigma := (\sigma_{ij})_{i,j \in \{1, \dots, n\}}$ is positive semidefinite as it is a variance-covariance matrix.

If we have an investor with initial wealth $S > 0$ we can suppose that he assume to hold $\alpha_i \geq 0$ shares of security i , $i = 1, \dots, n$.

Equality $\sum_{i=1}^n \alpha_i \cdot p_i = S$ is recognized that budget equation

We define

$$\pi_i = \frac{\alpha_i \cdot p_i}{S}, i = 1, \dots, n \text{ portfolio vector}$$

$$R^\pi := \sum_{i=1}^n \pi_i \cdot R_i(T) \text{ portfolio return}$$

From the definition of π_i we have

$$\sum_{i=1}^n \pi_i = \frac{\sum_{i=1}^n \alpha_i \cdot p_i}{S} = \frac{S}{S} = 1$$

and further relation is true

$$X^\pi(T) = \sum_{i=1}^n \alpha_i \cdot P_i(T) \text{ where } X^\pi(T)$$

denotes the final wealth.

We can write

$$R^\pi = \sum_{i=1}^n \pi_i \cdot R_i(T) = \sum_{i=1}^n \frac{\alpha_i \cdot p_i}{S} \cdot \frac{P_i(T)}{p_i} = \frac{X^\pi(T)}{S}$$

Last relation offers the arguments to build a portfolio return R^π .

Very important for the study of economical model are the mean and the variance of the portfolio return

$$E(R^\pi) = \sum_{i=1}^n \pi_i \cdot \mu_i$$

$Var(R^\pi) = \sum_{i=1}^n \sum_{j=1}^n \pi_i \cdot \sigma_{ij} \cdot \pi_j$ the variance of the portfolio

With this result we can speak about an optimum problem, because an investor who chooses a portfolio that wishes to have a return as large as possible.

However this could be a very risky action and the return can have big fluctuations. Here we must understand the idea of minimizing the risk

and maximizing of the return. We shall present in this situation two cases:

1) we study the problem:

$$\min Var(R^\pi), \quad \pi \in \mathbb{R}^n$$

with conditions

$$\pi_i \geq 0 \text{ for } i = 1, \dots, n,$$

$$\text{and } \sum_{i=1}^n \pi_i = 1, \quad E(R^\pi) \geq c_2$$

2) the second optimum problem is:

$$\max E(R^\pi), \quad \pi \in \mathbb{R}^n$$

with conditions

$$\pi_i \geq 0 \text{ for } i = 1, \dots, n$$

$$\text{and } \sum_{i=1}^n \pi_i = 1, \quad Var(R^\pi) \leq c_1$$

3. Optimization theorems

The first problem can be solved by using standard quadratic programming algorithms.

The second problem is a linear optimization problem with quadratic constraint. To solve this problem we do not have special standard algorithms but we could approach this problem with general methods of non-linear optimization.

If we note $\mu = \min\{\mu_1, \dots, \mu_n\}$ and $\hat{\mu} = \max\{\mu_1, \dots, \mu_n\}$, very interesting is to find the constant a which satisfies the condition:

$$(1.1) \quad \mu < a < \hat{\mu} \text{ and } b \text{ where}$$

$$(1.2) \quad \min \sigma^2(\pi) \leq b \leq \max \sigma^2(\pi),$$

$$\pi \geq 0$$

In conditions (1.1) and (1.2) we have the following equivalences.

Theorem 1: If π^* is solution for problem (1)

$$\text{with } E(R^{\pi^*}) = \sum_{i=1}^n \pi_i \mu_i = a$$

then π^* solves the problem (2) with $b := Var(R^{\pi^*})$

Theorem 2: If $\hat{\pi}$ is solution for problem (2) with

$$Var(R^{\hat{\pi}}) = \sum_{i=1}^n \sum_{j=1}^n \hat{\pi}_i \hat{\pi}_j \sigma_{ij} = b$$

then $\hat{\pi}$ is the solution for the problem (1) with $a := E(R^{\hat{\pi}})$

Remark: In the following example we shall show that optimal invest can be realized in a seemingly bad security. To show this, we use a model with two security with negatively correlated prices. The parameters we choose here are:

$$\mu_1 = 1, \quad \mu_2 = 0.8, \quad \sigma_{11} = 0.15,$$

$$\sigma_{22} = 0.25, \quad \sigma_{12} = \sigma_{21} = -0.1$$

From the problem (1) we have:

$$\min_{\pi \in \square^2} \text{Var}(R^\pi) = \min(0.15\pi_1^2 + 0.25\pi_2^2 - 0.2\pi_1\pi_2)$$

$$\text{with conditions } \pi_1 + \pi_2 = 1$$

$$E(R^\pi) = \pi_1 + 0.8\pi_2 \geq 0.96$$

We first consider the two portfolios (1,0) and (1/2,1/2).

$$\text{Var}(R^{(1,0)}) = 0.15, \quad \text{Var}(R^{(\frac{1}{2},\frac{1}{2})}) = 0.05$$

$$E(R^{(1,0)}) = 1, \quad E(R^{(\frac{1}{2},\frac{1}{2})}) = 0.9$$

We see that the portfolio return variance (1/2,1/2) is much less than that of (1,0).

If we write the problem using relation $\pi_1 + \pi_2 = 1$ we find the expression

$$(0.15\pi_1^2 + 0.25(1 - \pi_1)^2 - 0.2\pi_1(1 - \pi_1)) = h(\pi_1)$$

hence

$$\min(h(\pi_1)) = \min(0.6\pi_1^2 - 0.7\pi_1 + 0.25).$$

In this case we obtain the minimizing portfolio as $\pi_1 = \frac{7}{12}$ and $\pi_2 = \frac{5}{12}$.

The Influence of Communication in Achieving the Objectives of an Organization

Anghel Stefania Rodica

Town Hall of Constanta

E-mail: anghel.stefania@yahoo.com

Mitu Cristina-Dana

Ovidius University

Modern languages department

E-mail: crisrina_dana.mitu@yahoo.com

Abstract

The reason for choosing this subject is that in general the atmosphere or conditions where the information, ideas and feelings are exchanged determines the extent to which it reaches a negative or positive force in the organization. I argued here on the dependence between an open and cooperative environment and stimulation of cooperation relations and also on the negative influence of a closed and defensive climate.

Key words: communication, organization, objectives

JEL classification: M14

1. Introduction

There have been studies regarding communication climate even since 1961 when Gibb suggested that in an open and cooperative climate people perceive a more important measure of the importance and value of the role that they fulfill. Such an environment stimulates the team members to better understand what they have to do in order to achieve common goals.

For an open and collaborative communication, the following behaviors are particularly important: descriptive, oriented solution, open and honest, careful and well defined, fair, indulgent and the one which provides feedback is regarded as an essential element maintaining good working relationships and a high level of performance.

Managerial style and organizational culture are major factors in determining the climate of an open and cooperative communication. If in the organization's history were cases in which suggestions were received with kindness and followed, also when mistakes led to positive conclusions and crises were solved in an offhand manner, then the staff could give evidence of more openness in communication. Employees feel they are given confidence and gain more confidence about their jobs and the whole organization. Effective team work, flexibility and a sense of involvement contribute to achieving an open and cooperative environment, benefiting from it.

There are some behaviors that may be characterized as: value judgments, exercise control, are misleading, show indifference, tend superiority, are dogmatic, are hostile. It is unpleasant to work in such an environment especially for those who occupy leadership positions. Consequently, managerial effectiveness in communication begins to deteriorate so much that interactions between individuals reach minimum.

2. The importance of communication in achieving organizational objectives

In the evolution of the organization are very important the mission declaration and the organizational objectives. Effective communication allows people to share their views on the objectives they want to achieve and

the reasons for wanting to achieve them. There are two conditions for this:

- organization to express its clear and consistent objectives to which all members can join;
- leadership to be willing to share information they have with the entire staff at all levels.

Sir John Harvey- Jones writes about this: "Focusing (planning strategies) can be made in a considerable extent by a common vision on the place which is occupied by an individual responsibility within the overall direction followed by the company. There could be no doubt that one aspect that differentiates a successful company from one that is less successful is the existing a clear sense of mission existing in the first and the reassuring feeling that everyone knows the goals and recognize their role in achieving them."

An important role in the development of the organization is represented by the formulation of strategic and operational objectives. Strategic objectives refer to the direction of the organization's evolution, and also relates to methods for assessing the success and the time scale provided.

Organizational and strategic objectives have to be fragmented into operational objectives which are usually detailed as you reach the lower levels of the organization. Division, department or team need objectives which are supposed to be consistent with the overall organizational objectives. The success of the organization is possible only if its departments, or teams are able to realize their objectives.

3. Network and information necessities"

Achieving strategic objectives is strictly dependent on the quality of information provided networking and collective information needs.

Good communication usually occurs when people have information they need to operate effectively. This condition is often violated since some people are not even aware of their training needs.

We are sometimes confronted with too much information and people can get into some kind of "paralysis". They are forced to consume too

much time for analysis and material selection trying to choose the most important elements of a cluster of useless details. A more useful and long term solution is to ensure that everyone's information needs are appreciated and understood by others.

Also too small volume of information leads to inactivity because people do not have sufficient data to ensure their safety in what they do. People give their own interpretation of the information they have and nobody is able to form a clear picture of the situation - mistakes being inevitable.

Communication directed wrong, inaccurate and incomplete may not lead to desired results regardless of how good intentions would be, but rather the appearance of errors and invariably cause a low level of performance causing frustration and loss of trust. It is clear that if people do not receive the information they need to operate, they can not achieve performance standards.

A common problem of larger organizations is that messages often have to travel long distances and pass on to many people before reaching its destination. If communication is involved there is the possibility that the received message to be different than initially as participants in the

transmission process inevitably add their own interpretation. This phenomenon is known as chain distortion.

Some points of the message can be enhanced or new information can be added. Some details may be changed and also the order of various details may be changed as well. Some "gaps" can be filled by the speaker in order for the message to appear more understandable and to sound more credible.

There are two ways of communication: by what we say or write and by what we do. Everything you say verbally or in writing is related to language. Communicate when we try to understand each other but also the context in which interaction occurs. For this we make use of verbal symbols – language. Communication is based on the fact that these symbols are understood. Using ordinary words, without any emotions, do not endanger communication. If words are used to convey abstract moods or

emotions their meanings are not easily transmitted.

In a professional environment, using a language with emotions often lead to misinterpretations and misunderstandings. Effectiveness in communication depends on the ability to be on the same wavelength. Therefore accuracy plays an important role. The communication process always involves a transmitter and a receiver regardless of the number of people interested. Any communication model consists of a simple sequence of seven stages:

1. Transmitter wants the receiver to understand something sent as a message
2. The message is encoded by a transmitter and structured in a logical form – language.
3. When the transmitter is satisfied with the message encoding it is submitted - verbally, in writing, electronically.
4. Message passes through the point of transfer from transmitter to receiver.
5. Receiver decodes the message.
6. Receiver understands the idea that transmitter wants to send.
7. Receiver gets into action following the message.

Communication model in seven steps that we described is based on a very simple process in which the role of the receiver is to understand the message and act according to it.

In the evolution of an organization we consider both the internal and external environment. Therefore communication targets communication techniques within organization and determine the most effective ways of communicating inter organizational. In general,

external communication is to increase the visibility of the organization to which we belong, promote its image, finding partners to provide informational support for achieving organizational objectives. When short-term goals, medium or long term targets also the intervention of the public administration system, of local authorities or government, is necessary and legally recognized use of lobbying techniques in view of an argument consistent and harsh.

Lobby is an approach that follows that the decision factors maker not to make decisions against of a social group or economic categories but rather to adopt measures that would serve their interests. Lobby institutionalizes and regulates this attempt. The results depend on good lobbying training, imposed by the representative of the organization which practice it in his environment.

The Role of Human Resources Management within the Romanian Companies

Antohei Ionut

„Ovidius” University of Constanta, Faculty of Economic Sciences

E-mail: antohei_ionut@yahoo.co.uk

Abstract

Human resources management proves its important role within company facing the challenges brought into light by the actual economic background. Specialised studies have revealed new roles that human resources management will play in the future. The strategic role proves to be a real challenge for the companies in different economies. In order to fulfil this new role human resources management has to go through important changes that will ensure a higher level of competitiveness both for itself and for the company. The Romanian companies are relatively still tight to the classical administrative approach, but progress toward the new role has been underline by different studies.

Key words: human resources management, strategic role, Romanian companies

JEL classification: M10

1. Introduction

The human resources represent the most valuable asset of a company within the background provided by the knowledge base economy and information technologies. Thus, the human resources management becomes an important element gaining new roles.

A company success will be granted by its capacity to value the experience and competences of its members in order to generate new ideas and solutions to the problems the company face.

2. The changing role of human resources management at international level

The human resources management needs to play some important roles within the company, such as the one presented below:

- Strategic partner – major contribution to the establishment and usage of the company overall strategy;
- Change agent – it should enable organisational changes through its own changes, it will develop a organisational culture that will enable such changes;
- Employee’s representative – human resources management will ensure a link between management and employees, trying to obtain a greater level of commitment from them. In the same time the company has to offer its employees rewards linked with performances, development and career opportunities;
- Administrative expert – it represents the traditional role of human resources management. Presently, the focus is set on the efficient administration of personnel, than to applying the regulations.

The strategic partner role proves to be the most important one, considering the current international trends. However, this role implies a changing process still going on base on the fact that many companies are still treating human resources management with less importance [1].

Such an approach will represent a central element in order to develop appropriate strategies (win-win type) regarding the relationship between the company and its

employees. This way, the company will benefit from high performances and commitment toward its values, meanwhile the employees will benefit from the opportunities of development and growth offered by the company.

The new role proves to be a difficult task to accomplish. In many cases difficulties

occurred related to the change of the old bureaucratic way of handling things. Such process implies important changes that have to be made, the management having, in some cases, serious difficulties related to what has to be done in this direction. Therefore, many companies have concentrated their efforts on personnel reduction and cutting off the costs, than on rethinking the specific tasks from a strategic perspective. Thus, the human resources management rest on an administrative approach of doing things, rather than a strategic one.

Specialised studies have revealed that the most important companies have started changing processes in order to develop the strategic role of human resources management. Their experience could prove very useful for the other companies when develop such a complex process.

Companies (such as British Telecom, Pepsi) consider that the main competitive advantage they own, on a long term perspective, is represented by the creativity and level of competence of their employees. Therefore, the role of human resources management consists of establishing a correlation between the human resources strategies and the company overall strategy. The starting point of this approach will be the acknowledgment of the fact that the overall performances of the company are tightly connected with the individual performance of its employees.

In the same time it should be noted that such companies grants the appropriate importance to their human resources managers (they members of companies' board). This way the human resources managers could tackle strategic domain such as: change management, organizational development, information management etc. [2]

The strategic role of human resources management is approached in different manner within companies:

- ◆ there are companies that are using on a large scale decentralization and delegation of tasks. In such cases human resources departments are smaller and the human resources policies are applied by the management of the operational units;
- ◆ other companies promote a strong organisational culture, having larger human resources departments that are responsible with the specific activities throughout the entire company.

Regarding the roles of human resources management within the companies a study of Mercer H.R. Consulting in Holland, Germany and France revealed some interesting findings:

- in Holland 4 out of 6 companies that participate within the study have stated that their major objective regarding the human resources management is to consolidate the strategic role. They are trying to reduce from 49% to 29% the time for the administrative tasks in order to increase the time for strategic ones, currently estimated to 11%[3];
- in Germany, 63% from 21 companies that participated at the study mentioned the need to develop the strategic role of human resources management. They are looking forward to increase the time for these activities, currently estimated at 13%. In german companies the roles of administrative expert and employee's representative are still represented at a high level considering the trade union tradition and the legalised system of codetermination[4];
- in France, the study pointed out that the main role of human resources management is administrative expert, duet o the administrative approach that

french companies have developed in time[5].

The strategic role of human resources management proves to be the future challenge, but the process of developing such an approach proves to be a difficult tasks. There are still companies that are attached to the traditional role (the administrative one).

Today's business environment claims a new approach of human resources management within companies. This field

has to become a strategic partner for the company's management.

3. Human resources management role within Romanian companies

In the past few years, the romanian companies have assumed different principles, especially from the theory and practice of angle-saxon countries, regarding the human resources management practices. Many of these principles are used only by a few romanian organization, especially the multinational companies.

Within romanian companies were functioning and still are traditional personnel departments fulfilling administrative tasks. The issues related to the administrative activities of human resource management have been underlined by another study undergone by SMARTREE Romania. The main findings of this study are synthesized below [6]:

- ✓ **Relationship with the authorities** - 75% of the managers that have participated in this study consider that the bureaucracy is the main difficulty that occurs in the relationship with the authorities regarding the human resources administration;
- ✓ **Personnel decisions** - these decisions are made in 78% of cases by the general manager. This reflects a restrained authority of human resources managers.
- ✓ **Payroll issues** - 90% of the companies reported that the calculation of payroll is made by the general manager or chief accountant. In 75% of cases the companies are

using specialized software to administrate payroll issues.
- ✓ **Human resources training** - human resources training is considered a priority by some 30% of general managers and 50% of human resources managers. The most important areas are considered: conflict management – 34%, personnel motivation – 28%, interpersonal communication – 25%.
- ✓ **Outsourcing of some activities** - 68% of the participant managers are aware of this new concept. It is used on a reduce scale, especially for the recruitment and training activities.

These results reflect a major administrative orientation within the human resources management activities in romanian companies. Strategic activities (human resources planning, conceiving human resources strategy, planning the human resources training and development activities etc.) are absent or underdeveloped.

Another study developed by Corporate Dynamics and Business Edu in 2007 revealed similar results to the ones mentioned above[7]:

- ✓ only about 19% of human resources managers are involved in taking strategic decisions regarding HR field;
- ✓ about 72 % of such decisions are taken by the general manager.

The same study pointed out an improvement of the strategic role level, the 19% mentioned above representing and increasing related to previous year (12%). Another improvement refers to the fact that the human resources managers became on a larger scale members of company's board.

The changes of human resources management within the romanian companies towards modernism and an enhanced strategic role require a complex approach. In the new economical context that Romania is facing, that of the european single economical space, such an endeavour is more necessary than ever.

4. Conclusions

Modern companies have to face various changes that have a great deal of influence on their capacity to meet the planned objectives. Such changes can occur both in the internal side and in external environment of the business. Thus, it is necessary a strategic approach on the functional areas of the organization in order to anticipate these changes, to adapt to them and efficiently achieving the organizational objectives.

The human resources allow the company to adapt to the new conditions, thus they are an important source for its survival and success. The people within the organization have become the most important resource, therefore a strategic approach on human resources management it is extremely necessary.

The human potential of the company frequently represent, the main source of competitive advantages but insufficiently exploited. Thus, conceiving appropriate human resources strategies, connected with the overall strategy may prove an important condition in order to obtain performances and success.

Issues Concerning the Transfer Strategies of Human Resources Management Practices within Romanian Companies

Antohti Ionut

„Ovidius” University of Constanta, Faculty of Economic Sciences

E-mail: antohti_ionut@yahoo.co.uk

Abstract

This paper presents the issue of transfer the human resources management practices within the Romanian companies. This proves to be a very complex issue. It is necessary to determine what kind of practices can be transferred, under what circumstances and what the best strategies to do this are. Conceiving the best transfer strategies regarding the human resources management practices is not a simple task. Different matters have to be considered.

Key words: human resources management practice, transfer strategies

JEL classification: M12

1. Introduction

The human resources management has evolved constantly, reaching an international dimension. The human resources management within an international context implies various issues considering that the organizations are characterized by the diversity of their people. Therefore, the companies need to develop the most suitable practices regarding the human resources based on their diversity and different cultural backgrounds they came from.

Establishing a strategy regarding the transfer of human resources management practices is not a simple task. This is due to the fact that the transfer process implies major changes within the organization. The changing processes have always been complex, involving different issues that have to be coordinated in order to ensure a successful change.

2. The approaches on human resources management practices within the international level

The human resources management practices are analysed at the international level based on two major approaches [1]:

- **The rational approach** – the companies will develop the practices that will enable them to fulfil their objectives in a rational manner and efficiently. According to this point of view the managerial practices will be similar within a specific sector of activity for the same country, even for different countries. This approach assumes a high degree of managerial autonomy.
- **The institutional approach** assumes that the companies are influenced in a decisive manner by their environment. Thus, their practices will be adjusted considering the regulations and compulsions of this environment. Therefore the managerial practice will be different not only from a country to another, but from a sector of activity to another. These differences are explained by various elements such as different regulations concerning the business within a country, the relation between unions and management etc.

Based on the above mentioned two model concerning the human

resources management practices have been developed:

- ◆ **The calculative model** – that promotes those practices that aims to enables the accomplishment of the company's activities in an efficient manner. The human resources are seen as any other economical resource that is assessed by the efficiency of use. Therefore, this model proposes some practices such as: the individual performance assessment (for managers and different professional categories), the reward system tightly connected with the performance assessment, the estimation of the training programs efficiency etc.
- ◆ **The collaborative model** – that involves some practices that are focused more on the people. This way, the value of the employees for the company, ethic issues concerning the contractual relationship are pointed out. The employees are seen as an active partner within the organization, due with a high potential of creativity and innovation that should be properly used. These practices are based on mission statement, the official report on the company's strategy at all its levels, the existence of an employee's communication policy.

Human resources management practices are directly related to he peoples with the organizations. They can prove to be the most important barrier for the changing processes. Therefore, the most efficient transfer strategies should be based on human resources training towards the uptake of the new practices.

It is necessary that the strategies combine the specific elements of the human resources strategies (especially the ones regarding the training and development of the human resources) with the ones specific to the

organizational change strategies. The transfer of human resources management practices implies changes for the people and by the people.

There are many issues that are related to the transfer of the human resources management practices. It is necessary to establish in a clear manner what have to be transferred and what can be transferred, what elements can enable or jam the transfer process.

For the Romanian companies, the models offered by the multinational companies acting within our country, represent the most important source regarding the transfer issues.

The transfer process of managerial practices within the subsidiaries implies different issues that have to be considered within such a process. For example, a study concerning the transfer of human resources management practices within the subsidiaries of the multinational companies within Greece has revealed a few interesting points of view [2]:

- the cultural and institutional background have a great influence over the human resources management practices used by the subsidiaries within this country;
- the trade unions can prove an obstacle in the transfer process;
- the interaction with the local companies has a negative influence over the transfer process;
- there are different degrees of transfer for different human resources management practice.

3. Types of transfer strategies

Considering the fact that the main models regarding human resources management practices are offered by the multinational companies that operate within our country the following transfer strategies can be used[3]:

- ❖ A strategy based on the uptake of the models offered by the top companies-the best practice. This kind of strategy can be applied in the following manners:
 - **a mechanical manner, without any adjustments to the particularities of the company or the cultural context of our country.** In such a situation it could be easy to develop new organizational formulas that have no

real support. It is the case of many Romanian companies that have renamed their ancient personnel department as human resources departments without any changes regarding the specific approach of the human resources domain or the change of the specific practices.

- **an adjusted manner which implies that those models are adapted to the specific needs of each organization.** In this case the issues presented above are considered in order to avoid a force uptake of the models that cannot function effectively.
- ❖ **The strategy of adjustment to the changes that occurs within the economical, social, institutional background (a reactive strategy).** This strategy implies the transfer and the uptake of some human resources management practice when the need for change is absolutely necessary. For example, the use of some systems that evaluate the people performances and correlate this with the reward system and also with the needs for training and development will become necessary when our country will become a EU member. The EU companies that will activate within our country will bring such practices that the local companies will have to uptake. Moreover, a common legislation at the EU level regarding the human resources field will impose the change of human resources management practices within the local companies.
- ❖ **The strategy that derives from the human resources strategies (a proactive strategy).** Throughout this kind of strategy the companies aim to create an organizational frame and a adequate organizational culture that sustain the long term orientation within the human resources field. Continuous training and development of the human resources are considered to be the most important issues. The human resources management practiced within the company will be permanently modernized and adjusted.

These companies can offer models regarding the human resources domain to other companies or to society.

4. Conclusions

The transfer of the human resources management practices within the Romanian companies proves to be a very complex issue. This is a very actual issue especially in the context the European integration process.

It is necessary to determine what kind of practices can be transferred, under what circumstances and what the best strategies to do this are. Conceiving the best transfer strategies regarding the human resources management practices is not a simple task. Different matters have to be considered. One of the most important mentioned within this paper is the cultural background of our country.

Transferring the needed human resources management practices represents an important process that will determine the achievement of a higher degree of modernism and efficiency within the human resources field.

Balanced Scorecard vs. Six Sigma Business Scorecard

Prof. Petru Balogh, PhD,
"Dimitrie Cantemir" Christian University
petru-balogh@yahoo.com

Abstract

The Balanced Scorecard has become one of the most popular and successful instrument for managing the organizations' performance. *The Six Sigma Business Scorecard* combines the Six Sigma methodology with the Balanced Scorecard method for achieving financial objectives. The Six Sigma Business Scorecard utilizes strategy to maximize profitability and growth, accelerate improvement, foster leadership accountability, and encourage employee involvement. It builds on proven methodologies and offers a new method for measuring corporate performance.

Key words: performance, management, methodology

JEL classification: M10

1. Balanced Scorecard as part of performance management

Balance scorecard is part of the performance management system focused on managing the important processes within the organization.

Performance management system must allow:

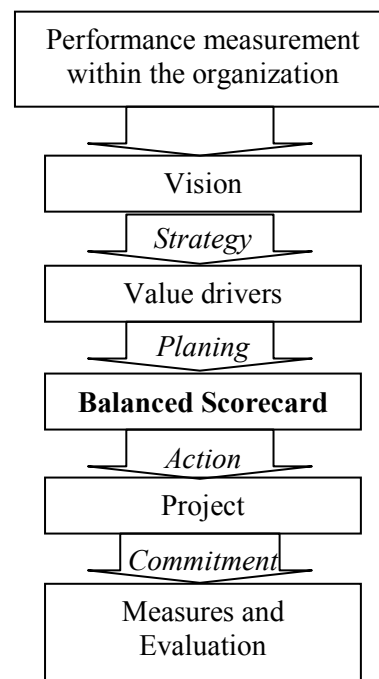

- Striking a balance between the demands of shareholders, employees and customers
- A flexible framework that makes the company aims to be known at all levels of organization;
- Prioritizing real major problems.

Organizations should take measures in accordance with their organizational structure to achieve a balance between different activities.

For the development and / or implementation of a system for measuring the business performances of the organization have taken steps shown in figure 1.

Each organization should develop measures to implement the Balanced Scorecard methodology to assess the improvement of their performances.

Figure 1. Place and role of Balanced Scorecard

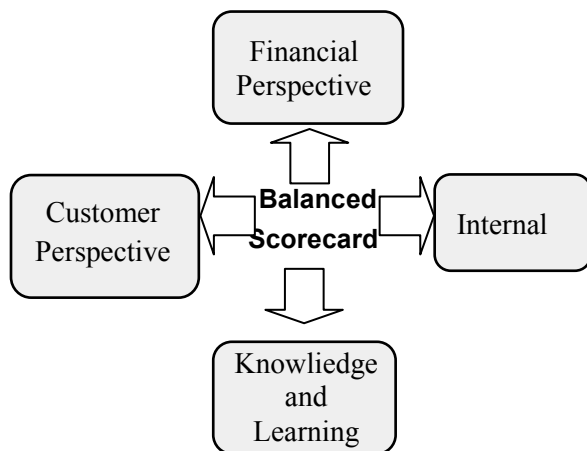

The model developed by Kaplan and Norton, fig. 2, consist of four components:

- Financial: The financial perspective focuses on cost efficiency and set targets for achieving profit within the organization;
- Customers: This view captures the organization's ability to provide quality products and services, the effectiveness of their delivery, and ensure customer satisfaction.

- Internal processes: This perspective focuses on the internal results of the organization, leading to financial success and satisfied customers. To meet organizational goals and customer expectations, organizations must identify key processes in which they must excel. Key processes are monitored to ensure that the results will be satisfactory.

- Knowledge and learning: This approach focuses on staff capacity and quality of information systems. Appropriately skilled and motivated employees, who are providing accurate and timely acquire increasing importance in organizations.

Figure 2. Adapted from material developed by Robert S. Kaplan and David P. Norton

2. The Six Sigma Business Scorecard overview

The Six Sigma Business Scorecard is a complete corporate performance system that requires leadership to inspire, managers to improve, and employees to innovate to achieve the optimum level of profitability and growth.

Considering the business's purpose, its processes, and its total culture, the Six Sigma Business Scorecard combines various measurements into seven elements, as shown in Figure 3:

- Leadership and profitability
- Management and improvement
- Employees and innovation
- Purchasing and supplier management

- Operational execution
- Sales and distribution
- Service and growth

Figure 3. Six Sigma Business Scorecard

With the seven elements or categories of the Six Sigma Business Scorecard defined, it need to look at the measurements associated with them. These measurements are oriented more to process than to function.

3. Comparing Balaced Scorecard and Six sigma Businee Scorecard

Table 1 identifies differences between the Balanced Scorecard and the Six Sigma Business Scorecard. Because of trends in the business environment, market dynamics, the rapid evolution of information technology and the Internet, and competitive pressures, profitability is shrinking. However, businesses have significant opportunities that could improve profitability. Without an integrated measurement system that relates to the corporate culture, vision, and beliefs, identifying what contributes to the loss of profitability and growth can be daunting. Using lessons learned from the Six Sigma methodology, the Six Sigma Business Scorecard offers a method for maximizing corporate profitability. By integrating the

existing quality management system with a performance measurement system, a corporation can aim for dramatic improvement in performance and significant improvement in profitability.

4. Conclusions

Current measurement systems tend to focus on operations, and measurements for the strategic aspects of the business are limited. This leaves leadership unable to relate to the overall performance of the business. The Balanced Scorecard is best deployed at the strategic level and flowed down through the organization. Work groups can devise their own Balanced Scorecards that show their contribution to the strategy of the organization. Action plans and resource allocation can be determined according to the work groups' contributions to the corporate Balanced Scorecard objectives. In theory, if a Balanced Scorecard is created at each department level, it could become a major measurement challenge. People who have experienced the process, however, say that by the time the Balanced Scorecard gets to work groups, the strategy has become unrelated to employees and too much effort is required to maintain the system. As with any new methods and their associated learning curves, challenges are expected.

The Balanced Scorecard has been successfully implemented at hundreds of companies; however, the remaining millions of businesses still need a practical measurement system that will enable them to improve profitability.

Six Sigma Business Scorecard offers a new approach to establishing a corporatewide measurement system that will enable leadership to monitor a company's performance against expected performance. Customers expect better, faster, and cheaper; the Six Sigma Business Scorecard promotes these requirements.

Six Sigma offers a measure of goodness, a methodology for improving performance, a measurement system that drives dramatic results, and a new paradigm that requires a

Table 1. Comparing Balanced Scorecard and Six Sigma Business Scorecard

Balanced Scorecard	Six Sigma Business Scorecard
A strategic management system.	A performance measurement system.
Relates to a longer-term view of the business.	Identify measurements that would drive performance toward profitability.
Designed to develop a balanced set of measurements	Designed to identify a set of measurements that impact profitability.
Identifies measurements around vision and values.	Establishes accountability for leadership for wellness and profitability.
Critical management processes are to clarify vision /strategy, communicate, plan, set targets, align strategic initiatives, and enhance feedback and learning.	Includes all business processes, management and operational, i.e., leadership, innovation, rate of improvement, sales, service, purchasing, and production operations.
Balances customer and internal operations without a clearly defined leadership role.	Balances management and employees' roles; balances cost and revenue of heavy processes.
Emphasizes targets for each measurement	Emphasizes aggressive rate of improvement for each measurement.
Emphasizes learning of executives based on the feedback.	Emphasizes learning and innovation at all levels based on the process feedback.
Focuses on growth.	Focuses on maximizing profitability.
Heavy on strategic intent.	Heavy on execution for profitability.
Management system consisting of measurements.	A measurement system based on process management.

passionate commitment from leadership to

set high expectations. The traditional approach to Six Sigma involves the steps that focus on discovering customers' critical requirements, developing process maps, and establishing key business indicators.

After these steps are completed, the business moves on to review its performance against the Six Sigma standards of performance and takes actions to realize virtual performance.

Innovation Management and Support

Barsan Simona-Clara

Research Institute for Analytical Instrumentation Cluj-Napoca

e-mail: simonaclara_barsan@yahoo.com

Sima Mihaela-Georgia

Bucharest Chamber of Commerce and Industry

e-mail: georgiasima@yahoo.com

Abstract

The article presents the actual state of innovation and the means of supporting it. It starts with a presentation of the main important elements, such as: legislation, innovation, industrial property, its protection, technology transfer, Infrastructure of Innovation and Technology Transfer, competitiveness of SMEs. A case study on innovation's situation within Bucharest-Ilfov area follows, with the purpose of determining the main facts and barriers with regard to this process. In the end of the paper, some solutions to the problems encountered are provided and a part of the benefits recurring from the cooperation with special created structures for innovation, such as Technology transfer Centers, are presented.

Key words: innovation management, protection, technology transfer

JEL classification: O32

1. Introduction

Government policy in the field of research development and innovation aims to enhance innovation processes and increase quality and competitiveness of products and services offered by Romanian companies. Sector with the greatest capacity for innovation, flexibility and orientation towards the market needs is that of SMEs. The success of innovative activities undertaken by SMEs is materialized, both in developing markets through the introduction of new or improved products, as well as improvement and innovation in organizational processes and technologies specific to each company, including the processes of distribution. For SME's innovation is the main instrument of

development. Whether we are talking about developing new products or services or identification of the most efficient already existing methods of accomplishment, innovation brings added value to an organization. In the same time allows it to maintain or improve their market share.

2. Theoretic notions

Innovation represents an activity from which a new or significantly improved product (good or service) launched on the market results, or represents the introduction of a new or significantly improved process in its own unit. Innovation relies on the results of a new technology, of technological development, of new combinations of existent technologies or on using other knowledge obtained.

The object of industrial property (protection) [8] is the: inventions, trademarks and geographical indications, industrial designs and sketches.

Materialization of protection is in the form of **industrial property rights**. These allow the creator or owner of a patent or a brand to benefit from the work or its investment. They are outlined in Article 27 of the Universal Declaration of Human Rights which states that everyone should enjoy the protection of moral and material interests resulting from any scientific, literary or artistic production of which is the author. They reward the effort and creativity that are driving human progress of humanity.

Protection of industrial property is regulated, mainly by the following laws: Law no 64/1991 on patents, Government

Ordinance no 41/1998 on property taxes in

the industry and their use approved by Law No.383/2002.

Ordinance provides a number of fee reductions for the legal protection of objects of industrial property according to the average gross monthly income on the last 12 months of the person either applicant or holder or depending on the turnover of the trader.

In accordance with Law no.64/1991, republished, profit or income through effective implementation in the country by the proprietor or, as appropriate, by the licensees of inventions patented in Romania, including the manufacture of the product or, if necessary, application process is exempt from tax in the first 5 years after the first application, calculated from the beginning of the application and included in the validity of the patent." By the above provisions benefits the patent holder, respectively individuals and / or legal persons exploiting the invention. Income obtained by the holder of the patent from the disposal is exempt from tax.

Technology transfer is the introduction or acquisition in the economic circuit of the technology and specific machines, equipment and facilities resulted from research, in view of new or improved processes, products or services, required by the market that induces an innovative behavior, including the disseminate information, to explain, to transfer knowledge, to provide consulting and communicate with people who are not experts on the issue of basic research, applied and precompetitive research so as to increase the chances of applying such results, provided there was an owner of the results.

This is done by the network of innovation and technology transfer entities (**ReNNIT**).

Infrastructure of Innovation and Technology Transfer was created, is functional, assessed and accredited by the National Authority for Scientific Research under G D no 406/2003 and aims to support economic and social development, foster innovation and technology transfer, attract investment to capitalize results of research and innovation, as well as human resources from the national research and development system.

Their role [5] is to support SMEs and

interface between them, as beneficiaries and producers of innovation "inventors represented by (natural or legal persons), universities, research institutes and companies with research and development activity.

Competitiveness [1] is a complex concept which, at a general level, expresses the ability of persons, companies, economies, regions to maintain competition on the internal and / or especially international scale, and to get, in terms of a specific business environment, economic benefits, resulting in constant increases in productivity and standard of living.

The innovation process, regarded as a company long term risky investment, requires a sustained management effort dedicated to the sector.

We mention as a result of the competitiveness of SME **profitability**. This is a snapshot of economic activity, both at the micro, and macro, and the extent to which companies are the competition and are competitive. Functioning as a binding element and the balance between the potential, resources and costs, research-development networks support SMEs in their efforts.

Part of research and development networks, Technology Transfer Center is the entity whose business is to foster innovation and technology transfer for the purpose of placing into economic circuit the results, transformed into products, processes and new or improved services.

Other results of technology transfer that can help increase the competitiveness of SMEs: the modernization of production, including manufacturing costs and lower economic resources, organization and management, production and services under the ISO quality standards, investment in industries of the future: IT / Hi-Tech; services / consultancy.

3. Innovation situation - case study

To determine the specific of Bucharest – Ilfov Region [7], from the innovation view point, between December 2008 and February 2009, a survey has been made within a representative sample made of 168 SME's. The results have shown that 73, 96% of them

consider that innovation is compulsory for maintaining their competitiveness.

Product-service innovation has been reported in 62% of the cases, process-technology innovation in 32%, organizational innovation in 17% and

marketing innovation in 17%.

Out of 3983 active innovative enterprises, 848 (21%) are in Bucharest – Ilfov Region and the innovation expenditure for the area is 41, 7% of national innovation expenditure. 72.57% are destined to licenses and patents.

The term innovative enterprise covers all type of innovators: product, process innovators as well as enterprises with on-going or abandoned innovations and refers to active enterprises.

Innovation expenditure comprises both expenditure for finalized innovation activities, as well as those for on-going or abandoned innovation activities. The main components of expenditure for innovation activity are: internal and external research – development; machinery, equipment and software acquisition; other external knowledge (licenses, patents, know-how).

The research proved that Bucharest – Ilfov Region has the highest development rank compared to the national average at all levels, offering the biggest opportunities of investment and development. In the same time, it is the centre of research and innovation activities from Romania. There have been identified five activity sectors with high innovation potential: precision mechanics, IT&C, electronics, plastics and construction. To these we add the intensive knowledge-based services sector.

These are the results of the analyzed innovation factors: the potential of innovation management – 76.7%; the potential of creating knowledge – 87.5%; innovation capacity – 75.01%; innovative activities' performance 51.88%; intellectual property – 64.36%.

IN SWOT, the “S” refers to innovation orientation and quality services (49% of answers).

The Romanian labor market is made out of qualified labor force. The effect could be stronger if proper training is provided. This should be permanent, implicate universities, research and companies partnership, so that the results would correspond to the

continuously changing needs of companies and market demands. That would lead to maintaining the competitive advantage and obtain profit.

The “W” or the main obstacles in carrying on innovative activities were: personal fluctuation and material resources. If the personal fluctuation problem can be solved through an elaborate and constant retentions program, based

on proper motivation, the lack of material resources (30% of companies mentioned this factor), detain companies from making the investments that innovative activities require (21% of companies mentioned raised costs as an obstacle in achieving innovation). The major capital source comes from their own income (80%), credits (29%) and other unmentioned sources. The financing from public funds (budgetary) proved to be insufficient and more than that, hard to obtain (72% of companies declared the programs accessing procedure difficult).

4. Conclusions

Innovative ideas used in new products and services [4], by way of intellectual property are essential to business success, increase the ability of businesses to obtain profits, and to discover new opportunities to adapt to rapid change characteristic of globalization. If one would maintain current technological endowment of most SMEs, their risk of becoming uncompetitive quite soon is imminent. A solution is provided by technology transfer centers, which by nature of their activity, as they work with intellectual capital, allow SMEs to access both research results and funding sources for implementation of new technologies / innovations.

Benefits from the cooperation of SMEs with research centers through entities for technology transfer are very high. The effects are observable in concrete economic results achieved by SMEs in the position that they manage to enforce or maintain on the market (the market share, quality of products / services), the positive effects generated in the chain at the level of national economy (raising the living standard of the population, increased exports).

Contribution to increasing awareness and interest towards the development of RDI

activities in the economic agents and legislative level, optimizing the ratio technology transfer / industry, promoting a culture about the importance of technology transfer, increasing added value of production (technological elements and non-technological of innovation: organizational innovation, innovative marketing), promoting a dynamic market-based

knowledge: regional innovation systems, clusters of innovative enterprises, participation in international networks to promote innovation, creating virtual collaborative systems and mechanisms, an integrated information system (web site, portal, database, electronic newsletters), obtaining patents and registering trademarks of, in direct collaboration with OSIM, encouraging public-private partnership to attract capital to technological companies and start-up companies are just some issues that recommend the Technology Transfer Centre as a reliable partner both for the creators of innovation, and its users.

Percentage Programming Approach for Portfolio Optimization

Silviu Bârză

*Faculty of Mathematics and Computer Science
Spiru Haret University, Bucharest, Romania*

silviu.barza@gmail.com

Abstract

In quantitative approach to decision making, a possible point of view for portfolio optimization is to model a portfolio in terms of a linear program. In this approach a linear programming model is in form of continuous non-negative variables instead of integer non-negative variables.

In some earlier paper I introduced one type of combinatorial optimization model named percentage optimization model which it is presented in "Introduction".

Next I will present a linear model for portfolio and possible transformation which produce percentage programming form. For this step I will give a possible example.

In the end I will discuss complexity for an algorithm schema to solve portfolio model in percentage programming form.

Key words: portofolio optimization, linear program, percentage programming form,

JEL classification: C61;

1. Introduction

In some personal studies in combinatorial optimization made in the context of equipment replacement I introduced a particular model of linear programming and I named it percentage programming model.

General form for percentage programming, in matrix expression is:

opt cx

$$\begin{cases} A_1x \leq b_1 \\ A_2x \geq b_2 \\ A_3x = b_3 \end{cases}$$

$$\sum_{i=1}^n x_i = p$$

$$x_i \in \{0, 1, \dots, p\}, i = 1, 2, \dots, n$$

where:

- $opt\ cx$ is the function to be optimized with minimum or maximum;

- $\begin{cases} A_1x \leq b_1 \\ A_2x \geq b_2 \\ A_3x = b_3 \end{cases}$ is the constraints system

- $\{0, 1, \dots, p\}$ is integer and finite set of values for each model variable, with p a non-zero given constant integer;

- $\sum_{i=1}^n x_i = p$ is a special condition named constant sum constraint.

This model can be generalized by modifying variable boundaries to non uniform upper limits. The new form model is named constant sum linear model. Model can be described as:

opt cx

$$\begin{cases} A_1x \leq b_1 \\ A_2x \geq b_2 \\ A_3x = b_3 \end{cases}$$

$$\sum_{i=1}^n x_i = p$$

$$x_i \in \{0, 1, \dots, q_i\}, i = 1, 2, \dots, n$$

where q_i are integers so that

$$\max_{i=1,2,\dots,n} q_i \leq p.$$

In next section of this paper I take a linear model for portfolio and I present the transformation of continuous variable model in percentage programming model, and in constant sum integer model.

Finally, without giving an explicit algorithm for solving portfolio optimization, I will give some consideration about complexity of such an algorithm.

2. Percentage programming approach for portfolio model

In management science, for portfolio is used a linear model which can be presented as:

$$\text{opt } c_1x_1 + c_2x_2 + \dots + c_nx_n$$

$$\begin{cases} A_1x \leq b_1 \\ A_2x \geq b_2 \\ x_1 + x_2 + \dots + x_n = S \\ x_i \geq 0, i = 1, 2, \dots, n \end{cases}$$

where:

- n represent the number of portfolio components;
- $\text{opt } c_1x_1 + c_2x_2 + \dots + c_nx_n$ is the function to be optimized with minimum if c_i are costs or with maximum if c_i represent profits coefficients;
- $A_1x \leq b_1$ and $A_2x \geq b_2$ are upper and lower limitation for different mixture of portfolio component
- S establish total found to be covered by

portfolio

- $x_1 + x_2 + \dots + x_n = S$ indicate that all found must be used in portfolio.

In general, portfolio component are expressed in one currency so that if I take sub-currency I can consider that values for portfolio component are integers. This observation allows me to replace continuous variables $x_i \geq 0$ with discrete variables $x_i = 0, 1, 2, \dots, k, \dots$ and so, continuous linear model turns into integer linear model.

Now I can observe that if one of model variables is greater then S , let say $x_j > S$, while the other remains non-negative, $x_i \geq 0$ for any $i = 1, 2, \dots, n, i \neq j$, then

$$\begin{aligned} x_1 + x_2 + \dots + x_n &\geq 0 + \dots + 0 + x_j + 0 + \dots + 0 \\ &\geq x_j > S \end{aligned}$$

And so, constant sum constraint fails.

Last observation allows me to replace infinite integer variables $x_i = 0, 1, 2, \dots, k, \dots$ with bounded integer variables and to obtain portfolio model in the form:

$$\text{opt } c_1x_1 + c_2x_2 + \dots + c_nx_n$$

$$\begin{cases} A_1x \leq b_1 \\ A_2x \geq b_2 \\ x_1 + x_2 + \dots + x_n = S \\ x_i \in \{0, 1, \dots, S\}, i = 1, 2, \dots, n \end{cases}$$

Which clearly is a percentage linear programming model as it is defined in "Introduction".

As an example let me consider the portfolio linear model:

$$\text{opt } 0.15x_1 + 0.12x_2 + 0.14x_3 + 0.09x_4$$

$$\begin{cases} x_1 + x_2 + x_3 \leq 4000 \\ x_1 + x_2 + x_4 \leq 4000 \\ x_2 + x_3 + x_4 \leq 4000 \\ 3x_1 + x_2 + 2x_4 \geq 6000 \\ x_1 + x_2 + x_3 + x_4 = 5000 \\ x_i \geq 0, i = 1, 2, 3, 4 \end{cases}$$

in which one must place 5000 currency unit (c.u.) in 4 different funds with 15%, 12%, 14% and 9% profit per c.u. so that total sum in any 3 funds must not exceed 4000 c.u. Additional must be fulfilled $3x_1 + x_2 + 2x_4 \geq 6000$.

Using the observations presented earlier, portfolio model from above, which is a continuous linear programming model, it is transformed in a percentage linear model defined as:

$$\begin{aligned} &\text{opt } 0.15x_1 + 0.12x_2 + 0.14x_3 + 0.09x_4 \\ &\begin{cases} x_1 + x_2 + x_3 \leq 4000 \\ x_1 + x_2 + x_4 \leq 4000 \\ x_2 + x_3 + x_4 \leq 4000 \\ 3x_1 + x_2 + 2x_4 \geq 6000 \\ x_1 + x_2 + x_3 + x_4 = 5000 \end{cases} \\ &x_i \in \{0, 1, \dots, 5000\}, i = 1, 2, 3, 4 \end{aligned}$$

3. Constant sum programming approach for portfolio model

The goal of this section is to see if there are any possibilities to reduce variable domains for percentage programming model. This question has a positive answer. To do so I must analyze upper bound constraints identified by system $A_1x \leq b_1$.

Firstly, I consider only one relation from $A_1x \leq b_1$, namely:

$$a_{i,1}^1x_1 + a_{i,2}^1x_2 + \dots + a_{i,n}^1x_n \leq b_i^1.$$

To use properly this relation I specify that all coefficients $a_{i,j}^1$, $j = 1, 2, \dots, n$ must be non-negative and $b_i^1 > 0$. Let consider j for which $a_{i,j}^1 > 0$.

Because $x_k \geq 0$ and $a_{i,k}^1 \geq 0$ for any $k = 1, 2, \dots, n$, $k \neq j$, results that

$$\sum_{\substack{k=1 \\ k \neq j}}^n a_{i,k}^1 x_k \geq 0$$

and so, $a_{i,j}^1 x_j \leq b_i^1$. While $a_{i,j}^1 > 0$ I have $x_j \leq \frac{b_i^1}{a_{i,j}^1}$. Now, because x_j is integer, I

obtain $x_j \leq \left[\frac{b_i^1}{a_{i,j}^1} \right]$, where $[w]$ designate integer part of w . I have also $x_j \leq S$ and so

$$x_j \leq \min \left\{ S, \left[\frac{b_i^1}{a_{i,j}^1} \right] \right\}$$

Now, let

$$q_j^i = \begin{cases} \min \left\{ S, \left[\frac{b_i^1}{a_{i,j}^1} \right] \right\} & \text{if } a_{i,j}^1 > 0 \\ S & \text{if } a_{i,j}^1 = 0 \end{cases}$$

be the upper bound for x_j resulted from the i -th relation in $A_1x \leq b_1$ for which all coefficients are non-negative. If in i -th relation of $A_1x \leq b_1$ there are negative coefficients I consider $q_j^i = S$ for any $j = 1, 2, \dots, n$

If I consider all m_1 relations from the system $A_1x \leq b_1$, let

$$q_j = \min_{i=1,2,\dots,m_1} q_j^i$$

be upper limit for variable x_j , $j = 1, 2, \dots, n$.

In this way, from percentage linear programming model I obtains the model:

$$\begin{aligned} &\text{opt } c_1x_1 + c_2x_2 + \dots + c_nx_n \\ &\begin{cases} A_1x \leq b_1 \\ A_2x \geq b_2 \\ x_1 + x_2 + \dots + x_n = S \end{cases} \\ &x_i \in \{0, 1, \dots, q_i\}, i = 1, 2, \dots, n \end{aligned}$$

Because for all $i = 1, 2, \dots, n$, $q_i \leq S$, it results that

$$\max_{i=1,2,\dots,n} q_i \leq S$$

And so the last model represents a constant sum integer linear programming model as it was specified in “introduction”.

If I reconsider the example from section 2, I can see that every relation produce a upper bound equal to 4000 c.u. in variables. So I have $q_1^1 = q_1^2 = 4000$ and $q_1^3 = 5000$ and then $q_1 = 4000$. Similarly, $q_2 = 4000$ and $q_3 = 4000$. So

$$\begin{aligned} \max_{i=1,2,\dots,n} q_i &= \max \{4000, 4000, 4000\} = \\ &= 4000 \leq 5000 = S \end{aligned}$$

and portfolio new model is:

$$\begin{aligned} \text{opt } &0.15x_1 + 0.12x_2 + 0.14x_3 + 0.09x_4 \\ \left\{ \begin{array}{l} x_1 + x_2 + x_3 \leq 4000 \\ x_1 + x_2 + x_4 \leq 4000 \\ x_2 + x_3 + x_4 \leq 4000 \\ 3x_1 + x_2 + 2x_4 \geq 6000 \\ x_1 + x_2 + x_3 + x_4 = 5000 \end{array} \right. \\ x_i &\in \{0, 1, \dots, 4000\}, i = 1, 2, 3, 4 \end{aligned}$$

4. Consideration about models complexity

Portfolio models in percentage programming and constant sum programming are included in combinatorial optimization. This is why one could think that this kind of models have exponential complexity when are solved. For percentage programming if a model hare n variable with domains $\{0, 1, \dots, S\}$ then the

general complexity is $(S+1)^n$. For constant sum programming complexity is $(1+q_1)(1+q_2)\dots(1+q_n)$.

This value for complexity is bigger then in realty.

For percentage programming model, because all variables are integers, constant sum constraint reduces complexity to the problem of number of partition for integer value S with no more then n non-negative integers. For constant sum integer programming complexity is lower then complexity in percentage programming because of additional upper bound in variable domains.

The goal of this paper is not to present an algorithm for solving portfolio optimization, this problem with exact complexity values will be presented in future paper more dedicated to mathematical aspects.

Abstract

The health system in Romania in a continuous transformation from a centralized system (type Semashko) exists before 1989 year to one based on social health insurance (type Bismark). This paper examines the management and the organizational structure of the health system in Romania, and the relations between them in the context of the Health Reform Law.

Keywords: management, organizational structure, health system.

JEL I 18; M19

1. Introduction

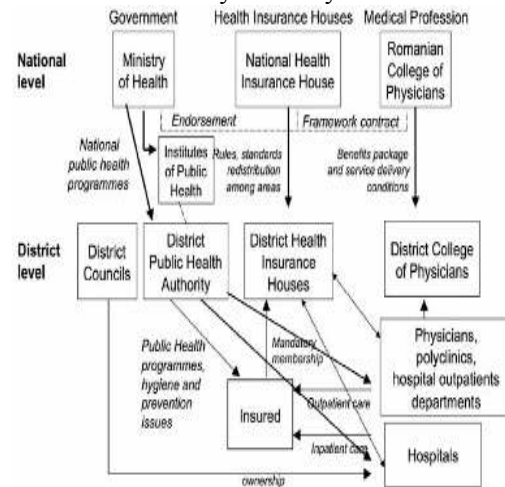

The Romanian health system is in a continuous transformation with the adoption of the law of social security health. For this reason the health system organization in Romania known a number of features that it individualized by the other European countries, but which raises a series of specific problems.

The organization is a primary function of management. The organizational function means establishing the optimal organizational function which enabling the activities, and the implementation of these functions means clear definition of all the elements that determine the organizational function [2].

In health system, the organization has its specific activity due to health specificity. [1].

The Romanian health system is organized at two levels: national (central) and district (judet). At the national level, the organizational structure of the health system is ensured through collaboration of: the Ministry of Public Health, the National Health Insurance House and the College of Pharmacists. At the district level, cross-sector intervention is ensured through District of Public Health [4] (figure 1).

Figure 1. Organizational chart of the statutory health system

Source: Vlădescu C., Scintee G, Olsavszky, V., Allin S., Mladovsky, P., *Romania: Health system review*, Health Systems in Transition, 2008; World Health Organization, vol. 10, no. (3): p.25

The national level is responsible for attaining general objective and ensuring the fundamental principles of the government health policy. The district level is responsible for ensuring service provision according to the rules set by the national level.

The highest authority in the Romanian health system is the government, performing

his role through the Ministry of Public Health.

2. The Ministry of Public Health

The Ministry of Public Health (MPH) apply the strategy and the politics of the Government in the area of ensuring the health of the nation. The Ministry of Public Health organize and coordinate the activities for ensuring the health of the population and prevention (according to the 34 article from Law nr.145/1997) [5].

The Ministry of Public Health has the responsibility to elaborate the national health politics and to solve the problems of public health (according to the 1st article from Law nr.100/1998 concerning public assistance) by prevention, prophylaxis and the control of mass illness [8].

The responsibilities of the Ministry of Public Health consist of [4]:

- Stewardship role in engaging main stakeholders in different types and different stages of health policies and strategies formulation, implementation and evaluation;
- Defining and improving the legal environment in the context of wide public circulation that includes views of stakeholders and of patients;
- Ensuring increased transparency in managing the state's budgetary allocation for health. The Ministry of Public Health retains responsibility for financing and managing the national public health programmes, selected specialty services and investments in buildings and high-technology medical equipment;
- Regulating both the public and the private health sectors and their interface;
- Ensuring leadership in conducting research and developing policy and planning in relation to developing reform policies and monitoring their impact; monitoring the impact of financing reforms; monitoring the need to upgrade buildings, major repairs and high-technology medical equipment; and monitoring the emergence of the private health sector;
- Defining and improving the legal and regulatory framework for the health care system. This includes regulation of the pharmaceutical sector as well as public health policies and services, the sanitary inspection and the framework contract;
- Developing a coherent human resources policy and for building capacity for policy and management of the health care system.

The **SWOT analysis** is a strategic planning method used to evaluate the Strengths, Weaknesses, Opportunities, and Threats involved in a project or in a business venture. As a modern management technique is used with remarkable results in every field, both at the micro and macro level [3]. The SWOT analysis applied at the Ministry of Public Health reveals [8]:

Strengths:

- Existence of competent specialists;
- Existence of a young personal;

- Availability of working across the hours of programs;

- Human resources with preparation in different areas (both medical and other complementary areas), which increase the capacity to solve a complex problematic.

Weakness:

- Different degrees of technical competence for employee with same levels of remuneration;
- Deficiency in responsibility assuming;
- Low motivation, due the low capacities of differentiation between the employees with different productivity;
- An organizational climate which doesn't conducive team working;
- Low capacity to control the task achievement both at individual level and between departments;
- Lack of continuity in task allocating;
- Absence of a career plans for employee and of a coherent politics of training and maintains employee;
- A lots of institution in coordination/subordination.
- Absence of an integrated informational system.

Opportunities:

- The health is an area with social major impact, which maybe delivers arguments for the adoption of a certain politics;
- The UE adhesion enforces the adoption of a new standards and recommendations, which have the finality the rising of the efficiency and quality;
- The status of UE member opens new possibility of finance on projects from European funds.
- The interest of local public administration authorities to took over a part from the ministry's responsibility.

Threats:

- The rising of the patient's informal level, concomitantly with the progress and the diversification of the diagnoses and therapeutics technologies will make a rising of complex medical services
- The freedom of people's circulation enables the utilization of different health services from different countries;
- The development of private health system is an environment competitor for the public system;
- The population ageing and the migration of young labour;

- The rising of the collateral costs inducted by treatment covering of rare disease, but very grave, or due to the price politics of some medicines distributors;

- The lack of preparation in health area at the level of local administrations.

In the minister exists ten structures operates to rank of general direction or direction, as follows: The General direction organization, human resources, professional development and remuneration, Juridical direction, Pharmaceutical direction, General Direction politics, strategies and quality management in health, Authorities of public health, Inspection of state hospital attendant, National agency of programs, Logistics, administrative, public relations and mass media direction, Budget and external credits direction and External relations and European business direction.

The head of the Ministry of Public Health is Minister of Public Health, who is helped by three state secretaries, a state sub-secretary, a general secretary and a general assistant secretary. The minister flow-chart shows a number of 285 jobs.

3. The District of Public Health

The basic administrative unit of health services organization is **District of Public Health** (DPH). These contain administrative units of the Ministry of Public Health, under the authority of the local Prefect.

Public health authorities are administrative units of the Ministry of Public Health under the authority of the county prefect. They are implementing policy and national public health programs locally identified priority local health issues, develop and implement local public health action.

Activities of District of Public Health public health authorities:

- assess the health of the population of the territory surrounding villages;
- identifies the main public health problems and allocate funds and human resources to solve them;
- implementing health programs;
- coordinate the work of health units in the territory;
- provide specialist staff for all county health system structures.

4. National Health Insurance House

National Health Insurance House (NHIH) is a public autonomous institution, of national interest, with juridical personality, that administrates and regulates the social health insurance system applying the strategy and the politics of the Government [7]. The NHIH was established at the 1st of January 1999 by the Law 145/1997 on social health insurance. NHIH operates based upon their statute and is responsible mainly for:

- assuring the logistic of the Romanian health social insurance system;
- collecting the material funds and their proper utilization;
- coordinating and supervising the activity of the District Health Insurance Funds (DHIF);
- elaborating the framework contract and the accompanying norms sets up the benefit package to which the insured are entitled and the provider payment mechanism;
- deciding the resources allocation between types of care.

The NHIH is governing by a Council of Administration from 17 members. The president of the NHIH Council of Administration is appointed by the prime minister at the proposal of the health minister and has two vice-presidents, elected by Council members.

The basic administrative unit of health services organization is District Health Insurance House (DHIH). These contain administrative units of the Ministry of Public Health in every Romanian district (judet).

5. College of Physicians

Romanian College of Physicians [6] – is responsible for regulating the medical profession. The College of Physicians has important responsibilities relating to the preparation and accreditation of medical personal. For the right to free practice, all doctors must be registered with the County College of Physicians and pay a certain fee. Also, new medical organization must be approved locally by the College of Physicians in accordance with a set of national criteria developed by them. The power of the College of Physicians refers to

the medical malpractice trial practices and problems of medical ethics.

In the Romanian health system, College of Physicians shall:

- Ensuring the development and provision of basic health services provided;
- NHHH to ensure that health services meet quality legal parameters;
- Achieve efficient tracking of emergency care;
- Ensuring the medical assistance in the county level;
- Participation in drawing up plans and construction of hospitals equipped with medical equipment of high performance.

6. Conclusion

The organizational structure of the Romanian health system comprise: The Ministry of Public Health, the District of Public Health, National Health Insurance House and the College of Physicians.

The Ministry of Public Health is responsible for national health policy, control and coordination, analysis and evaluation of medical outcomes, national financial and human resource planning. Also, it arranges national and international collaboration in health care. Many of its functions are carried out through its specialized District Public Health.

District Public Health assesses the population's health status and set priorities for health care. They draw up a local health strategy and allocate resources based on national policy and local needs.

The main functions of the National Health Insurance House are to collect and manage funds and purchase necessary medical services insured. Also, National Health Insurance House develop rules on how the collection of contributions to National Health Insurance Fund.

The College of Physicians is involved in contract negotiation framework that forms the basis for all contracts signed between the National House of Health Insurance and health care providers (both individual and institutional). Because of this, the CM has a decisive influence on the contents of the package of benefits for the insured population, the type of drugs that are cleared and in what percentage.

Abstract

The good news is that the Internet keeps on growing. The bad news is that, as a company, it is getting harder to be found.

Key words: internet,digital technology, efficient channels;

JEL classification: M31;

1. Introduction

The telephone took four decades to reach 50 million users. The Internet has managed this within four years from its release as digital technologies provide such efficient channels for business and consumer interactions transactions.

The excitement and anticipation of what a brochure or product-catalogue would achieve for many companies five or six years ago seems nothing but a distant memory when we take into consideration the transactional and multi-dimensional capabilities of most current web sites. The Internet has come a long way in a very short time as a mainstream business tool.

How significant is Internet marketing to businesses? Today, the answer to this question varies dramatically for different products and markets. For companies such as electronics equipment manufacturer Cisco, the answer is

‘very significant’ – Cisco now gains over 90% of its multi-billion dollar global revenue online. It also conducts many of its other business processes such as new product development and customer service online.

Similarly, the low-cost airlines gain 90% of tickets’ sales online and aims to fulfil the majority of its customer service requests via the Internet. However, the picture is quite different for the manufacturers of high-involvement purchases such as cars or fast-moving consumer goods brands. Here the impact is less significant – the majority of their consumer sales still occur through traditional retail channels. However, the influence cannot be described as insignificant any longer since the Internet is becoming increasingly important in influencing purchase decisions – many new car purchasers will research their purchase online, so manufacturers need to invest in Internet marketing to persuade customers of the features and benefits of their brands. [1]

Therefore lots of concepts have emerged in the last decade:

- e-marketing
- c-marketing
- e-business
- e-commerce
- m-marketing (mobile)
- m-commerce, and so on and so forth

There are more and more concepts and we have to learn to swim through them. “The

Internet is a tidal wave. It will wash over nearly all industries drowning those who don't learn to swim in its waves.” (Bill Gates, Microsoft CEO)

2. How big is the Internet

Assessing the size of the Internet is a somewhat difficult proposition, since it is a distributed body, and no complete index of it exists. What we mean by asking how large the Internet is also plays into how we answer the question. [2]

Perhaps the simplest metric is simply how many people use the Internet. This can be viewed as the population of the Internet, and so would seem to be a decent gauge of its size, which continues to grow since forever (Table 3). Many different companies try to measure Internet usage, but the general answer seems to be that just over a billion people used the Internet in 2008 [3]. Of these, about 500 million use the Internet at least once a week, making them more-or-less permanent citizens of the Internet population. (Table 1)

Table 1: Internet Users (2009 Est.)¹

World Regions	Population (2009 Est.)	Internet Users Latest Data	% from World Total Internet Users	% from Population
Africa	991.002.342	86.217.900	4,78%	8,70%
Asia	3.808.070.503	764.433.900	42,41%	20,07%
Europe	803.850.858	425.773.571	23,62%	52,97%
Middle East	262.687.005	58.309.346	3,24%	28,77%
North America	340.831.831	239.561.000	14,40%	76,16%
Latin America/Caribbean	586.662.468	186.922.050	10,37%	31,86%
Oceania / Australia	34.700.201	21.110.450	1,17%	60,84%
WORLD TOTAL	6.767.805.208	1.802.330.457	100,00%	26,63%

It may be that what most people mean when they ask the size of the Internet - is how many bytes it takes up. Estimating that is a fairly difficult task, but one person made an estimate not so long ago who can probably be trusted to have a good idea. Eric Schmidt, the CEO of Google, the world's largest index of the Internet, estimated the size at roughly 5 million terabytes of data. That's over 5 billion gigabytes of data, or 5 trillion megabytes. Schmidt further noted

¹ Internet Usage and World Population Statistics are for December 31, 2009. Demographic (Population) numbers are based on data from the US Census Bureau. Information can be cited given the rights provided by www.internetworldstats.com

that in its first seven years of operations, Google has indexed roughly 200 terabytes of that, or 0.004% of the total size. There are thought to be some 155 million websites on the Internet, but this number fluctuates wildly from month to month, and one runs into a problem of what exactly constitutes a website. Is a person's individual Facebook page its own website? How about their LiveJournal or blog? What if the blog is hosted by a blog service?

Who could possibly tell us how many web pages there are? There are two obvious candidates: Google and Yahoo, the major search engine companies [4]. Visiting, analyzing and indexing the billions of web pages in the world is their business. Unfortunately, neither company currently publicizes the exact size of its index. And they have not done so since August 2005. We can add this to the dimension of all wireless communication or Wi-Fi, which nowadays play also a very important role to transactions and commerce, through smart phones, PDAs etc. (Table 2)

Table 2: World Communications²

Year	Main (fixed) telephone lines (millions)	Mobile cellular subscribers (millions)	International telephone traffic minutes (billions)
1997	792	215	81
1998	838	318	91
1999	904	490	103
2000	975	738	114
2001	1034	961	120
2002	1083	1157	127
2003	1135	1417	141
2004	1204	1763	166
2005	1262	2219	179
2006	1263	2757	183
2007	1278	3305	n/a
2008	1267	4100	n/a

Whereas m-marketing and m-commerce are to be regarded as smaller parts, but not less important than their counterparts on the big World Wide Web, as same principles apply with small differences, in direct relation with particular cases. For instance, m-marketing was

² Source: ITU World Telecommunication/ICT Indicators Database.

Painted an interesting scenario occurring as the next phase of e-business. A driver on the interstate with his car which just passed the 20,000km car-service mileage, receiving a text message notifying him that his car-service is due and the technology could recognise that he will be approaching the city and suggest that he may wish to exit and visit the dealership where a car will be ready to take him on to his office. His car will be returned to him at his office after service and all what he has to do is just to click and confirm.

In 2008, mobile phone penetration in developing countries had reached that of Sweden¹ ten years earlier. Even the country furthest behind (Myanmar) in terms of mobile cellular penetration is where Sweden was just 24 years earlier. By comparison, The Gross Domestic Product (GDP) per capita lag for most of the Least Developed Countries, compared to Sweden, is over 160 years. Therefore technology can overcome GDP statistics and problems as people tend to adopt new technology as a way to progress. (Table 3)

Table 3: Internet Users Growth (since 2000)²

World Regions	Internet Users (Dec. 31, 2000)	Internet Users Latest Data	% of total users in 2000	% of total users in 2009	Growth (2000-2009)
Africa	4,514,400	86,217,900	1,25%	4,78%	1,809.8 %
Asia	114,304,000	764,435,900	31,66%	42,41%	568.8 %
Europe	105,096,093	425,773,571	29,11%	23,62%	303.1 %
Middle East	3,284,800	58,309,546	0,91%	3,24%	1,675.1 %
North America	108,096,800	359,561,000	29,94%	14,40%	140.1 %
Latin America/Caribbean	18,068,919	186,922,050	5,01%	10,37%	934.5 %
Oceania / Australia	7,620,480	21,110,490	2,11%	1,17%	177.0 %
WORLD TOTAL	360,985,492	1,802,330,457	100,00%	100,00%	399.3 %

3. Search Engines and Data Confidentiality

It is considered that 85% of the visitors on a website get there through a search engine. Search engines have spiders that are programmed to go through the Internet indexing key words into a database. Usually the

algorithms are designed to focus on high quality links (sorted by popularity, as in number of clicks). These spiders get only a limited number of pages and search engines leave a large portion of the Internet not-indexed. This can happen because of passwords, subscription logins, or protected databases, which a spider normally cannot enter. This leaves a “dark” part of the Internet, not covered, but sometimes more relevant than the indexed part. These databases or sites that have links which search engines did not cover, may not be indexed with a dynamic algorithm and it will remain “invisible” until human effort will be taken into calculation. This was tried by Yahoo! Where instead of relying only on automation technology to look through the web, teams of surfers were used to follow demands and visualizations, to classify them accordingly to predefined categories and finally add them to the general index. (Figure 1)

Since the beginning, the description of the “Internet Database” was a marketing dream, because the access to the client’s behavior over the Internet is much more complete than in the physical world. Using cookies and behavior patterns, as well as any form of data collection, especially on well-known search engines (e.g.: Google and Yahoo!), can contribute to a very rich database for marketing techniques, which can be used to determine what a client previously buy, his general preferences or the pattern of searches and clicks can suggest favorite domains or subjects. [5]

Figure 1: Search Engines Shares (Est. 2009)³

Confidentiality elements have become an ethics problem as well as a law-enforcement one,

¹ Sweden was chosen as a benchmark as it ranked first in ITU’s ICT Development Index.

² Internet usage information comes from data published by Nielsen Online or International Telecommunications Union on a free of charge basis.

³ Source: Nielsen/Net Ratings MegaView Search

because most cookies policies must be declared, especially third-party cookies, which are often not so trust-worthy. The launch of Microsoft's browser Internet Explorer 8 (IE8) is massively important, since it is the default browser on Windows boxes. And while it may not be as sleek as Google's Chrome or Mozilla Firefox, most consumers will happily muddle along with IE8 oblivious to alternatives. The privacy browsing capabilities of IE8 will have an impact for online advertising if there is widespread usage, since it blocks the tracking cookies at the heart of online advertising and traffic analytics. What Microsoft gives in standards compliance it also takes away in privacy mode. The IE8 privacy mode, which avoids third-party cookies, might cause some initial headaches where advertising and tracking is concerned.

Cookies are basic recordings of user data which is stored on the user hard-drive and which will offer information about the user at his next visit. A simple example is a wine-producer site, which can store information about the preferences of a certain user, recommending types of wine based on previous choices.

Data security and privacy issues are likely to continue to hit the headlines. Data protection is going to be more than just a security issue; it will have huge PR and brand consequences for anyone getting it wrong. The privacy browsing capabilities of Chrome and IE8 will have an impact for online advertising if there is widespread usage as mentioned above. Businesses will need to audit their data handling and security practices and get the right processes in place. Expect to see some major class actions by consumers against businesses that have had their data breached, stolen or lost.

With Google supplying mobile hardware (G1) and software (Android), and bidding on the wireless spectrum, it is clear that the people at Mountain View wish to develop this market to its full potential. 3G smartphones with large-ish screens, such as the iPhone, BlackBerry Storm and G1 all allow mobile users a close-to-normal web-browsing experience. Thus, as mobile usability improves so will mobile Internet use. Google is moving fast to develop, exploit and control mobile advertising by dictating the platforms and mechanisms we use to browse the web on our smartphones, while also leveraging

the mobile wireless spectrum – so the local search or localized services will grow [6]. This is because results are likely to be more relevant and advertising can be more accurately targeted, but this will mean disclosing the location implicitly at every query. Really Simple Syndication (RSS) is an ideal platform for online marketing and communications as it provides marketers with 100% deliverability and a qualified audience and it will move into majority usage thanks largely to built-in support in the new IE 8 browser. Speculation that Google will shift its algorithm to favor more user behavior metrics is growing. In fact, Google has openly discussed these algorithmic approaches in a patent application called "Information retrieval based on historical data". [7]

There are of course methods to act against these intrusions, such as anti-spyware software, local firewalls or manually deleting cookies, but these are only temporary methods in respect with creating giant databases with user preferences and historical data series.

4. From Banner to Viral

At the beginning of the 90's, an American company called Free-PC was offering its clients free desktops given the condition they had to bare a publicity banner on the side of their monitor at all times. The business was buried as a result of lack of user clicks on that banner. Who would've guessed the people will be so cheap regarding the appealing marketing messages. The annoying banner, too loud or colourful, was quickly replaced with more efficient methods of promotion.

- Pay per click – is a promotion system which allows running promotional ads, but the charge only comes when a user clicks the message. The most popular PPC online system today is Google Adwords.
- Pay per action – is a similar system, only it uses a specific action, like completing a form or subscribing to a newsletter.
- Pay per lead – is a system where visitors are given away something for free and the company will be charged only when a good prospect is delivered. An example is CallWave's free software download that allows monitoring users calls when they

are online. Pay-per-lead also lends itself to a wide variety of marketing strategies. Since you are offering your visitors or subscribers something they can receive for free, you can easily position ads as a valuable service to them.

Pay per – methods offer the possibility of complete control over clicks and revenues or costs, furthermore being very easy to analyze and changed on-the-fly in order to optimize. A secondary benefit is that of free display of the brand while the click or the action from the user doesn't take place. [8]

5. C-Marketing

C-Marketing, as a multifunctional concept in nowadays world, defines itself through its main role players:

- Client:

The client must be in the very centre of every organisation which has marketing as a basis for its activities. The activities of marketing must be designed to satisfy the client thoroughly, because satisfaction gives birth to loyalty and from loyalty are generated huge revenues. The client is the king and the Internet gives him even more power through search engines instruments, price comparison sites and all these are coming packed in a user-friendly technology. This is not a client who will likely respond to pop-ups like in earlier days, but a client whom a company has to build his trust and come with personalised offers, thus building his confidence and loyalty.

- Corporate Culture:

Every business which establishes success as an immediate objective mustn't risk a negative attitude towards adopting new technologies. Technological progress requires constant, repetitive and nevertheless expensive investments, as a mean to respond to the client's requirements. This can also be regarded as a mean for cost control and enhancing efficiency throughout the corporation. The organisation has to have a culture for optimisation through technology and this vision goes beyond the simple building of a website and thus considering promoting the brand. The offer has to come with client-oriented innovations. Online vision means actively seeking partnerships and

strategic alliances in order to increase traffic, brand awareness and finally, sales.

- Convenience:

Changing social and economic reasons such as long working hours, increasing divorcing rates and greater geographical mobility all impact modern living. Usually they impact in a negative way, particularly with regard to stress and time, therefore individuals seek out organisations, products and services to help alleviate this and thus leaving them more leisure time. One example may be that grocery shopping for many is a mundane chore. By storing historical purchase data of individual customers, online food retailers remove this chore and allow consumers to spend more time on the more interesting aspects of shopping. Moreover, it is now expected to be flexible with a range of convenient delivery options including evenings and weekends.

- Competition:

Competition has no physical boundaries. The Internet has brought a greater transparency especially in terms of price, promotions, PR and new product development and release. Price comparison sites give consumers more knowledge and power, but don't forget that such information is also available to online competitors. Organisations make investments in acquiring "competitive intelligence" for strategic planning, which should take into consideration any (or all) of the following: traditional competitors moving online, new online entrants from overseas or domestic, alliances and partnerships or revitalised traditional businesses.

- Communications:

The death of mass-media, the paperless office and growth into one-to-one interactions were forecasted years ago. Now the media is fragmented even more than before, we use our e-mails more, but still print and also suffer from SPAM! However, news, PR and online sales promotions come more quickly and more frequently via newsletters and e-mail marketing campaigns, even viral marketing campaigns which can be utilised effectively to improve loyalty. It is wiser to encourage chat-rooms within a corporate web site, so quick responses can be made to adverse comments, rather than leave it to unofficial external sites.

- Consistency:

Consistency is needed across all communications and all channels to ensure that the brand experience is unswerving, especially if the organisation is operating in both the virtual and the physical world. A firm's reputation established over many years in the high street could be tarnished by a poorly performing web-operation.

- **Creative Content:**

If you want to motivate people to return time and time again, then the site content has to be informative, topical, stimulating and of course relevant to the needs of the target markets. Content should be up to date and for larger organisations with extensive product catalogues, rapidly changing prices, massive information and newsletters, this should be done on a daily basis. Well designed responses to Frequently Asked Questions (FAQs) can resolve many customer enquiries.

- **Customisation:**

Relevant customisation should help achieve the aims of the spiral of prosperity, because the more we know about the client, the more we can tailor to their needs. Customisation can also be viewed in respect with processor speeds, style of monitor and resolution or browser. It is wise to adapt systems to cope.

- **Coordination:**

For the effective operation of an e-business, the real-time dissemination of information from the customer finalising the shopping cart and order is crucial. A scalable IT infrastructure is needed throughout the organisation.

- **Control:**

The technologists have provided marketers with the tools to measure just about any online activity. However, many organisations are just collectors of data, but they do not know what to do with it. They either have not clearly defined their objectives or do not know what to measure exactly. [9]

6. Conclusions

Communication Marketing is given by the new instruments of the digital media, which change the consumer's way of life, as well as by the integration of technology and multiple channels of communication which enhance the complexity of the business scene.

We have e-mail questionnaires, web-based questionnaires, chat rooms and groups as well as theme-related public groups. We could go on, but suffice to say that social media has well and truly arrived.

Although the use of IT has been proven to promote economic openness, the advent of cheap information access may yet to carry unlimited capabilities in terms of social openness. Beyond economics: attribution, cultural perception and social ethics cannot be ignored. We become aware of m-marketing, we long know e-marketing, but in the end – how much of these new techniques will come back to manipulate or choices without us even realizing.

Impediments in developing dry ports – A heuristic view

CIORTESCU Cezar-Gabriel
"Alexandru Ioan Cuza" University Iași
gciortescu@gmail.com

Abstract

This paper will describe and review in-depth the impediments in implementing and developing dry ports, from a heuristic point of view. The dry port concept is based on the idea of a seaport directly connected by rail to inland intermodal terminals, where shippers can leave and/or collect their goods in intermodal loading units as if directly at the seaport. With dry port implementation, CO₂ emissions would be decreased, queues and long waiting times at seaport terminals avoided, and the risk of road accidents would be reduced; thus, regional sustainability would increase. As the container industry has gone through a huge boom up to the world economic crisis, the idea of implementing dry ports into international freight logistics, coping with the need for environmental protection and the creation of new jobs, might at least be part of the solution. Methodology used in this paper is based on extended literature review, interviews and case studies, with external validation regarding dry ports implementation, and is primarily meant to highlight the main impediments which may occur not only in terms of the actual implementation of dry ports but also as far as the actors involved in containerized freight trade are concerned.

Key words: dry ports, impediments, heuristic view, waiting times;

JEL classification: R48

1. Introduction

The first shipping container was invented and patented in 1956 by an American named Malcolm Mc Lean. From that moment on, the container shipping industry has improved its performance at an impressive pace, with containers production reaching high numbers, megacarrier container ships reaching 14000 TEU [1] (one freight container standard size = twenty equivalent unit, TEU) and the seaports container terminals expanding capacity increased by existing ones [2]. It has become the backbone of global trade, estimated to account for 13% of seaborne trade in volume and 49% of the value [3]. The maritime part of the intermodal transport chains has employed even larger ships to cope with the increasing transport demand and for facilitating lower unit costs [3]. It has already been shown that seaports produce economies of scale. Therefore, progress in ports and hinterland operations must match [4-5]. Intermodal transport services to the ports' hinterland, which was defined as "the interior region served by the port", [6] are strained by the increasing flows.

Environmental problems have received increasing attention during the last decade and we can consider that logistics systems can play an important role in reducing the environmental impact or at least constitute a part of the solution. However, logistics concepts, as far as their role in decreasing environmental impacts is concerned, have not been extensively researched until recently [7].

One of the issues, which has been neglected for many years or sporadically implemented on different continents, is the dry port concept, which represents the focus of this paper. The concept was recently reborn due to increased interest in environmental issues related to growing containerized maritime transport. Many studies and researches have been made for the

concept to be integrated into world freight trade.

As container transport volume continues to grow, seaport inland access becomes a critical factor for the seaports' competitive advantage. Therefore, progress only in the maritime part of the transport chain and in seaport terminals, without improvements in seaport inland access, is not sufficient for the entire transportation chain to function successfully.

Methodology used in this paper is based on extended literature review, interviews and case studies, with external validation regarding dry ports implementation, and is primarily meant to highlight the main impediments which influence implementation of dry ports and for the actors involved in containerized freight trade, after a proper definition or at least after defining the concept.

2. Defining the dry port concept

The definition of the concept required investigation of previous names for inland intermodal terminals, as there are different names all over the world.: Gueterverkehrszentren in Germany, Plateformes Multimodales Logistiques in France, Freight villages in UK or Interporti in Italy, Inland Port in US, Inland Container Depots in India and Asia, Estacao Aduaneira do Interior in South America, particularly in Brazil, meaning Interior Customs Station. They all provide transshipment from one mode to another as well as auxiliary services such as warehouses, customs, maintenance workshops, insurance offices and other [8].

India introduced Inland Container Depots (ICDs) in 1983 and Indian Customs (2004) bases its definition of an ICD on the UN ECE definition below, but restricts it to containers. India also uses the term Container Freight Station (CFS), which differs from an ICD since containers are stuffed and stripped there. Hence, an ICD is a consolidation node for containers whereas a CFS aggregates individual consignments into containers. A CFS function might be added to an ICD. ICDs are normally located outside the port towns but there are no site restrictions regarding CFSs. In Europe there has been a focus on business areas offering a wide range of logistics services. In a survey [9],

a definition was provided for an Intermodal Freight Centre as a concentration of economically independent companies working in freight transport and supplementing services on a designated area where a change of transport containers between traffic modes can take place.

An Inland Freight Terminal is "any facility, other than a port or an airport, operated on a common-user basis, at which cargo in international trade is received or dispatched"[10]. An Inland Port is located inland, generally far from seaport terminals; they supply regions with an intermodal terminal offering value added services or a merging point for different traffic modes involved in distributing merchandise coming from ports [11]. The term dry port is used synonymously. Finally, according to the Economic Commission for Europe [12], a dry port is simply "an inland terminal which is directly linked to a maritime port". However, a dry port definition that corresponds to the definition of an Inland Clearance Depot - cited above - was used [13]. Since the former definition on dry port is rather broad in its meaning, all above mentioned terminal facilities might use the notion of dry port due to their links to seaports.

Another definition describes a dry port as "an inland intermodal terminal directly connected to seaport(s) by rail where customers can leave/pick up their units as if directly to a seaport" [8]. Despite the fact that the frame of reference is ambiguous, we nevertheless get a general perspective from the above quoted definitions.

Research made in 2007 [8] classifies dry ports as it follows: close dry ports, mid range dry ports and distant dry ports. This classification is based on the distance between the seaports that dry ports are servicing and the dry ports themselves. The figure below illustrates this particular idea:

Fig.1 Transport network with a dry port.

Source: Roso, 2009

However, one such classification could not be sufficient in order to get a clear definition of the dry port concept. There is still a wide area for research regarding the concept and we will mention other criteria of classification as it follows:

- According to size (meaning how many TEU it can handle per year): small, medium, large and mega dry ports, which can be implemented in land-locked countries.
- According to means of access: depending on how many rail tracks and roads are in and out of facility.
- According to value added services: as stuffing / stripping of containers, maintenance of container, handling and storage of refrigerated / frozen and dangerous goods.

A summative definition, as observed from above, is that dry ports, having the word “dry” as a structural part of their name are supposed to be viewed as different from inland intermodal terminals which have, in addition to standard dry port facilities, at least one inland waterway, by means of which goods can also be transferred also by water means: either by barges, tugs, or other navigational equipment; moreover, its handling equipment is at a higher scale than that of dry ports.

3. Main impediments in implementing dry ports

Regarding dry ports, in different parts of the world there has been success and failure in transportation business. We shall show the main impediments in implementing them, from different points of view: infrastructure, business interest, partnership, legislation, regulation and procedures, human resources, software and automation.

For decades, the rail freight transport system in Europe has been an aggregation of separated national systems due to the long established national regime. Rail transport market had primarily a domestic focus and was organised by closed national monopolies. Europe is striving for internal market, without frontiers where, among others, the free movement of goods is to be ensured. Cross-border trade, existing in a fragmented form, different electrified networks

among all national states, of different size and traction types in national railway networks, turns infrastructure into one of the major impediments in implementing and developing dry ports. Fragmentation in the rail sub-systems has led to poor service performance with high costs, low reliability and long transit time. Shippers and logistics service providers are difficult to be convinced of the benefits of the use of rail transport. Fragmentation refers to the varied forms of divergence in the system of the rail freight transport operations, which impedes the cross-border operation from being seamless, resulting in longer transit time, lower reliability, and higher operational costs. In general, fragmentation is presented in the operational, technical, pricing, administrative, and market systems of the rail freight operation. The commercial operation of trains throughout the trans-European rail network requires in particular excellent compatibility between the characteristics of the infrastructure and those of the rolling stock, as well as efficient interconnection of the information and communication systems of the different infrastructure managers and operators. Performance levels, safety, quality of service and cost depend upon such compatibility and interconnection, as does, in particular, the interoperability of the trans-European conventional rail system [14].

The funding of dry port is related to key actors such as the public sector and the private sector, or a combination of both. Many actors are involved in a dry port, each having its own strategy depending on its core business even if vertical integration could lead to some overlapping. At the same time, various functions could be developed in a dry port depending on the actors involved. The most basic dry port is an inland terminal allowing the modal shift of the containers from barges or trains to trucks or vice versa. The warehousing function is almost non-existent. In this case, the inland terminal is a node in a transport chain, with an increasing level of integration due to containerization, but without a direct intervention on the goods being transhipped. Door to door services are provided mostly by freight forwarders through merchant haulage or by shipping lines through carrier

haulage. Trucking companies, rail or barge operators could also theoretically develop door-to-door services even if in fact they are the most basic transport providers, being subcontractors of freight forwarders or shipping lines. The capital structure of a dry port will obviously influence the composition of the controlling body, whether it is a board of directors or some other organisational entity. The controlling body will have to create a framework harnessing many different skills for the successful establishment of the dry port: layout planners and engineers to design the physical attributes of the facility, custom and shipping experts to establish clearance procedures, railway experts for track layout, accountants for managing development resources, etc. The controlling body must therefore create a management structure suited to the size of the facility and one which does not burden it with unnecessary costs; set clear objectives for management and to monitor the management success.

Environmentally, as it results from case studies [8], the implementation of dry ports would guarantee a rise in the CO₂ reduction by 25%. Also, in a press release [15] the European Parliament sends a clear message: "Trucks should pay for the pollution and congestion they cause". The idea that implementing the dry port concept is on the right track is confirmed by the numerous research projects proposed and financed by the EU and Americas, as well as by private-public funding in Asia and Australia.

At the political level, European decision makers have been playing a vital role in governing the EU wide rail freight sector towards liberalisation by way of bringing forward a variety of legal actions to be implemented in all national states. In recent years, a new type of governance approach has emerged next to the existing ones, entailing different principles. In spite of the considerable efforts that have been made in the past two decades, governance in the rail sector has not yet turned the community rail operation into a borderless one. Today, cross border operations are still subject to various national systems and rules.

4. Heuristic solutions

At the global level, efforts are made to synchronize legislation and harmonize all international conventions, including maritime ones for land-locked countries.

Governments will have to make liberalisation of rail networks possible, as with the road transport. By doing so, they would succeed in creating cleaner and safer freight trade by regulation and procedure. The subsequent implementation of schools for training and re-conversion of jobs for helping the road transporters, as stakeholders in services supply chain, to grow into integrated logistics of freight transport, will become a necessity.

Another solution for implementing dry ports is that they be included in the existing interface and in the integrated software of international freight trading. The application of ISO standards as RFID (Radio Frequency Identification) and EDIFACT (Electronic Data Interchange for Administration, Commerce and Transport). The implementation of ASYCUDA (Automated System for Customs Data) software, developed by UNCTAD, will be a future standard for the operation of dry ports. ASYCUDA is a computerized customs management system which covers most foreign trade procedures. The system handles manifests and customs declarations, accounting procedures, and warehousing manifests, as well as suspense procedures. It generates detailed information about foreign trade transactions which can be used for economic analysis and planning [16].

Moreover, solutions for implementing dry ports into international freight trade are: developing systems of integrated logistics of dry ports for reducing waiting times of ships in seaports anchorage, appealing to reversed logistics, technically sizing dry port equipment, adapted to seaport loading/unloading equipment and capacities, introducing and using double-stack trains and long trains, using DSS (Decision Support Systems) models for full and empty containers, implementing electronic seals and GPS tracking and tracing of containers.

5. Conclusion

Dry port implementation is not a straightforward solution for seaport terminal decongestion or for providing easier seaport inland access; it can, nevertheless be part of the solution. The implementation of dry ports would trigger a series of advantages: on the one hand, CO₂ emissions would decrease, queues at seaport terminals would be avoided, and the risk of road accidents would be reduced. On the other hand, durable regional sustainability would evolve, new jobs would be created, costs would be reduced by value-added services, customs and government control would improve by strengthening security and safety. On a different level, competitiveness of importers and exporters would be increased, with or without economic growth, chaotic movements of cargo in hinterland would be eliminated, costs would be reduced and finally, the issue of empty containers would be solved by reallocation. Although it is obvious that the relocation of containers from road to electrified rail would result in lower CO₂ emissions, a dry port is not merely the equivalent of rail implementation – it is a set of efficient services such as transshipment, storage, depot, containers' maintenance, customs clearance, tracing and tracking. Furthermore, the quality of access to a dry port and the quality of the road–rail interface also determines the dry port's performance.

Health Claims and Communication of Benefits of Functional Foods – Way of Ensuring the Success of Those Products on Market and to Protect Consumers against Fraudulent Claims

Abstract

Expansion opportunity of functional foods on market is positive and consumer interest relatively high. The growth of the functional foods market is related to an aging population, increasing consumer awareness of health issues and a rise in lifestyle related diseases. Functional foods and food components may be available in the market place but in order for consumers to access the benefits of functional foods, they must be informed about them.

This study attempted to identify the importance for consumer purchase and consumption of functional foods, but also identify their attitudes about the need for scientific justification and communication of health benefits for functional food. Research results have shown that consumers are beginning to attach greater importance to healthy eating, 32.99% of respondents believing that this criterion is of great importance in their consumption habits. Most consumers have considered it very important to permit health claims for functional foods by authorized agencies (74.29%), the need for scientific support of health benefits (64.94%) and their communication to the public (89.35%).

Key words: functional foods, health issues, health claims, communicating the food health benefits to the public.

JEL classification: N3

1. Introduction

It is obvious that the aspects related to lifestyle, diet and physical activity play an important role in the increase of the incidence of these diseases, and the success of the reduction measures will depend strikingly on the balance between these factors. This lead to the conclusion that food may contribute to maintaining the health on a long term basis, in ways not recognized until now, which means a new dimension of appreciation of how food can positively influence the health and welfare of the people, beyond providing the nutrients needed [4].

Expansion opportunity on market of functional food seems to be quite favorable, and consumer interest is quite high. However, the distribution of these products on the market is hampered by a number of obstacles. Insufficient clarity of information provided by producers is reflected in the difficulty of control of functional foods before marketing. Disinformation of traders and often of consumers may involve a number of risks, especially to the latter, due not only to the deficiencies in the operation of the health benefits of functional foods, but sometimes also due to the affectation of their state of health.

Consumer interest in the relationship between diet and health increased the request for information about functional food. The scientific and technological rapid progress, increasing healthcare costs, changes in food legislation affecting the label and the product claims, an aging population and increasing

interest in providing health through diet are among the factors fueling the interest in the functional food.

Health sells. And health is also a matter of nutrition – which is why the food and beverage industry is interested in labelling products with health claims.

2. The necessity of health claims

The role of dietary active compounds in human nutrition is one of the most important areas of concern and investigation in the field of nutritional science. The findings of investigations on this subject have wide-ranging implications for consumers, health-care providers and nutrition educators as well as food producers, processors and distributors. New evidence concerning the benefits and risks associated with particular aspects of dietary compounds is constantly emerging in both the scientific literature and the popular media. At times, controversies about these findings emerge. Sifting through all the claims and counterclaims, incomplete and incompatible studies, and biases and competing interests for the elements of truth and a prudent course of action is a challenge. However, such discrimination is essential because changing views about the effects of dietary compounds can profoundly influence the consumption of various foods and, ultimately, health and nutritional status, agricultural production, food processing technologies, food marketing practices and nutrition education [5].

The availability of a clear framework for conducting the assessment of scientific support for claims on foods benefits all stakeholders. Consumers have an assurance that claims have been validated and that all claims are assessed according to the same criteria. Food manufacturers and retailers who wish to make claims will know what evidence they must provide to substantiate them. Regulators are provided with a clear understanding of the limits of the validity of any particular claim [6].

Claims made on food labels, and the associated advertising and promotional literature for specific food products, provide the most direct way of communicating the benefits of functional foods to consumers. Of all forms of communication, those related to claims made directly on the label or package of the food, or indirectly through secondary information,

remain a large and current discussion area. The simplest and most direct way in which consumers can learn more about functional foods is through product labelling, but labelling information must be easily understood and trusted. It is essential that these claims should be based on scientific information.

Legislation regulations on food labelling already applied nearly everywhere in the world require that information on food labelling and advertising would be reliable and not mislead consumers. Mostly, these general rules are sufficient to ensure that statements made by labelling and advertising make a fair and adequate information of consumers. However, to submit a health claim on foods there are additional regulations to avoid possible confusion and uncertainty. These new additional regulations are imposed primarily because of the potential overlap between foods with health benefits and drugs. Secondly, an understanding of the meaning and the processes underlying health claims usually requires knowledge of an expert [4].

Consumers worldwide have common interest in identifying accurate information on food safety, on the extension of choice for a balanced diet that can maximize its potential to support good health. In this respect they are becoming more interested in the official statements of the representatives of the Ministry of Health, of the health specialists as well as of the information provided in the media. When new foods or improved products become available on the market, consumers want to be informed on how to include these foods in their own diet. Besides availability of safe and nutritious food, consumers put a growing emphasis on a more equitable ratio quality / price, on the satisfaction of their needs which are constantly changing, on improving their lifestyles.

Incorporation of the concept of food functionality into awareness about nutrition through general education will ensure that consumers are equipped to understand the messages conveyed by claims, both so that they are not mislead and also so that they can take full advantages of the benefits on offer.

Those potential benefits can best be delivered if all stakeholders (commerce,

industry, agriculturists, educators, government and consumers) are sufficiently well-informed to motivate the introduction of functional food products into the marketplace. Food manufacturers, retailers, primary food producers, caterers, health care workers and governments all have roles to play and benefits to gain in ensuring that functional food science becomes part of general knowledge concerning nutrition, in the same way that knowledge about the role of vitamins and minerals in basic nutrition has become part of general knowledge in the past.

3. Some inconvenience of legislative framework on health claims

The idea behind the legislation is that claims made in relation to health benefits need to be backed by scientific evidence. The body that decides whether such claims are indeed backed by credible data is the European Food Safety Authority (EFSA), which provides scientific advice to the European Commission. In July 2008 the Commission asked EFSA to prepare a scientific opinion on health claims that were permissible in the European Union and provided EFSA with a draft list containing 4185 entries that had been boiled down from the 44 000 claims supplied by the Member States.

Part of the problem is the indigestible nature of the inputs it is trying to assess. Thus, in some cases you only have incomplete information as the potential effects have been obtained under experimental circumstances. But then the dose might vary, the compound might vary, and the circumstances of absorption might vary. It will be difficult to evaluate the complexities of the interactions in real diet situations.

Nutrient profiles are being developed by the European Commission and EU Member States; these are the nutritional requirements that food products must meet to make certain health claims. The system is designed to keep consumers from being misled as to the product's overall nutritional value. The application of nutrient profiles as a criterion would aim to avoid a situation where nutrition or health claims mask the overall nutritional status of a food product, which could mislead consumers when trying to make healthy choices in the context of a balanced diet [1]. The World Health Organization (WHO) is also working in this area hoping to develop an international standard for

nutrient profiles that could be used by many countries.

The procedure of obtaining health claim for a certain product is very complex. Lack of ability to make health claims is the main reason why production companies refrain from investing financially in tests done on people, otherwise expensive, tests related to the efficiency and toxicity of the products.

Susanne Döring, director of consumer information diet and health issues of the Confederation of Food and Drink Industries of the European Union (CIAA), believes that uncertainty over the European Commission's nutrient profiles and the list of generic claims that food products are permitted to make, which the Commission and EU Member States are preparing, will "hinder innovation" and lead to fewer products in the market and less choice for the consumer. The regulation places small to medium-sized companies at a competitive disadvantage because – unlike large, cash-rich multinationals – they can not afford to do the research required to design a food product that makes specific as opposed to generic claims, as a full scientific dossier is required. The regulation is too strict, with repercussions for both industry and consumers: Some companies may decide to pull out of the process altogether, anticipating that their products will not fulfil EFSA's requirements for either generic or specific health claims. Other companies plan to resubmit their data when it is clear what EFSA requires. It's also a problem for the consumer, because if the consumer can't read information on the food packaging he or she is not informed about that product. While industry groups say the food claims regulation is too strict, consumer groups say it doesn't go far enough.

In some specialists opinion the challenging legislative environment provides many uncertainties for those companies marketing products with health claims.

4. The analysis of the necessity of scientific justification of the health statement as a mean of a consumer protection

The research was focused exclusively among potential consumers of food in Constanta looking for gathering information

about their perceptions on food with health benefits, on the need for scientific justification on health benefits of food and their public communication.

To ensure the representativeness of the sample it was considered a confidence level of 0.05 (corresponding to a probability of ensuring research results of 95%), a margin of error of +/- 5% and a p-value = 0.5% (assuming that the key attribute rated is buying food with health benefits and that 50% of consumers prefer those products). Sample size was of 385 persons [3].

The interviews took place in supermarkets from Constanta on alternative days of the working week, both morning and afternoon.

Most of the questions had two or multiple responses and some were open questions.

The survey was conducted between 1st and February 28th, 2010. In all cases, the method used to collect information was personal survey (face-to-face).

The sample consisted of 385 respondents, approximately two thirds of whom are women (66.3%) and 33.7% men. This sample structure is considered as representative assuming that mainly women are responsible for their family shopping [2].

Regarding the age, 15.7% of the respondents belonged to an age group between 18 to 24 years, 21.6% from 25 to 34 years, 23.4% between 35 and 49 years, 20.2% between 50 and 64 years and respectively, 19.1% 65 years or more.

Regarding family structure 21.9% of the respondents come from families consisting of two adults, 26.8% from families consisting of two adults and one child, 38.7% of families consisting of two adults and two children, 4.4% of families consist of two adults and three or more children and 8.2% of respondents are in other situations. Regarding the education level of the respondents 10.3% are graduates of secondary level, 17.5% graduated professional level, high-school graduates 27.2%, 35.2% of university level and respectively 9.8% of postgraduate level.

What regards the socio-professional category of the respondents, most of them were employed in contract work (69.4%), 11.3% were retired, 11.3% were housewives, 3.2% were employed part-time while the remaining 5.8% were unemployed. In addition, the average income per family member ranged as follows: 14.4% below 500 lei, 18.1% between 501 to 700 lei, 33.1%

from 701 to 1000 lei, 18.8% between 1001 - 1500 RON and respectively, 15.6% over 1500lei.

Of the 385 respondents, 9.87% appreciated criterion „healthy food” as most important in food choice (Figure 1) and 32.99% considered this criterion as of great important in their consumption habits (Figure 2).

Figure 1. The opinion of the consumers regarding the criteria of food choices

Figure 2. The importance of healthy food in the consumption habits of the consumers

Regarding the potential user opinions on what can be ensured, namely, that the food can support a good health body, views are divided fairly balanced. Thus 26.49%, and respectively 23.64% of respondents, considered that the official statements of specialists in nutrition and medicine and respectively, of representatives of Ministry of Health, are necessary to ensure the support of health benefits of foods while 21.30%, and respectively, 20.52% of respondents considered that the health benefits of foods can be supported through information in the media and respectively, claim specified on the label.

Out of the total of 74.29% of the respondents considered as important to

authorize health claims on food by specialized bodies in the field, while 14.03% did not consider important this fact and 11.69% of the respondents did not acknowledge the need of authorization. Regarding the need for scientific evidence to support the health benefits of food 64.94% of the respondents considered that it is necessary, 9.87% of the respondents do not support this, 14.55% of the respondents believe that such evidence is not necessary, while 10.65% are not aware of the need for scientific support.

Most of the respondents (89.35%) considered as adequate the need of public communication of health benefits of foods, 6.79% of the respondents do not know and only 3.90% of the respondents considered that a public communication of the food benefits is not necessary.

Views on the elements that should be communicated to the public about foods with health benefits were diversified (Table 1).

Table 1. Elements on foods with health benefits to be communicated to the public

Element	Share in the total number of respondents (%)
Information about benefits on health	33.25
Information about food safety	27.27
Extending the possibility to elect a more balanced diet	15.06
Quality / price ratio	20.52
Other	3.90
Total	100

Regarding the respondents view on the central body activity and on the legislation adopted for food with health benefits, most respondents (69.61%) declared that they do not realize the extent to which that law provides support and promotion of functional food or adequate consumer protection, which shows a poor communication with them (Table 2).

Table 2. Elements provided by central bodies through the legislation adopted in foods with benefits field

Element	Share in the total number of respondents (%)
A proper support and promote of foods with health benefits	9.09
Adequate protection of consumers of any producers fraudulent claims	17.40
Not aware	69.61
I disagree with the law on foods with health benefits	3.90
Total	100

5. Conclusions

Today consumers want to know as much about the products they consume. They are becoming increasingly concerned about issues related to nutrition, health claims, food safety, food labeling, safety of food additives and ingredients used, and the effectiveness of inspection processes.

74.29% of the respondents considered important to authorize health claims for food by specialized bodies in the field. Thus, a hard task of research is needed to confirm the health benefits of each functional food or component of them. To transfer the potential benefits of functional foods on the health of the population, consumers must clearly understand this concept and have confidence in the scientific criteria used to support health claims. The scientific community continues to research the potential of functional food and their role in health insurance.

The availability of a clear framework for conducting scientific assessment of food is useful to all stakeholders. Consumers thus have to ensure that claims have been validated and that all claims are evaluated on the same criteria. Manufacturers and retailers who wish to seek such claims will know what evidence should be provided to substantiate them. Regulators thus have a clear understanding of the limits of validity

of any claims.

The research results present the importance of communicating the food health benefits to the public, the vast majority of the respondents (89.35%) considering it necessary. Given that consumers are increasingly interested in the relationship between nutrition and functional food and the market is experiencing a dramatic development, the question of how to communicate the benefits arising from consumption of these foods is becoming increasingly important.

The study presents the respondents' opinion on how to ensure the health benefits of foods, as follows: 20.52% by the present claims on the label or packaging of the product, 23.64% by official statements of representatives of the Ministry of Health, respectively, 26.49 % by official statements of specialists in nutrition and medicine.

The opportune and effective communication can help consumers worldwide obtain important information that has a positive impact on health and welfare.

Managerial elements in the educational system – characteristics and functions of the educational management. Types of managers

Drd. Lucica (Mitican) Cristea
„Alexandru Ioan Cuza” University, Iași, Romania

Abstract

The present paper focuses on the verification of the hypothesis according to which the organizational climate, the quality of all resources involved in the educational process and especially the quality of the management have a very important role in obtaining performance.

After the conceptual definitions which come as a necessity when describing the educational management, the characteristics and the functions of the educational management, as well as its types of managers, are to be subsequently presented.

In fact, the scientific paper constitutes a sequence from a more complex research. That is why the results of the enquiry are only partly presented in order to verify the hypothesis.

Key words: educational management, performance, organizational climate.

JEL classification: A2, M5, M11, M12

1. Educational management – characteristics and functions

There is no doubt that the social and economic transformations of the future society will lead to a change in managerial styles at all levels. Today's information revolution calls for new approaches to management science which appear to be even more necessary when we realise that such a science plays a vital part in educating society in general, and the work force required by the new economy in particular.

One of the main priorities of the education reform in Romania is concerned with the decentralisation process – the redistribution of responsibilities, decision-

making authority, public responsibility and resources from the central to the local level – and the creation of an organised educational system which should be administered and financed according to European regulations. This requires commitment, assuming responsibility, clear vision, strategic thinking, professional and managerial competencies i.e. a new managerial type. [3, p.10]

However, input from the preuniversity educational institutions in Romania leads to the conclusion that there are no managers to fit the profile at this level. Thus, it is not enough to create an appropriate legal framework and build a rhetoric to meet European standards. The existence of human resources able to carry out the decision-making function is of utmost importance in such a context.

Management, just like any other activity focusing on the individual, has an underlying set of rules and principles necessary for the administration of resources with a view to reach predetermined objectives. A certain manipulation psychology is inherent in the concept of management. Especially within the educational context, this type of psychology has a both a positive and a negative side. In this domain, the use of manipulation techniques is quite advisable to make sure that the educational objectives are met.

Educational management is enjoying more and more the attention of specialised literature nowadays and has been defined in various ways by the specialists in the field. Thus, it has been given different meanings, being construed as the theory and practice, the science and art of designing, organising, coordinating, and evaluating the elements of educational activity.

I. Jinga [4, p.26] maintains that educational management can be defined as the science and art of educating human resources and shaping personalities in accordance with specific purposes accepted by the individual and society.

S. Cristea [1] points out that educational management, as a psychological activity, is based on three characteristics:

- primary system leadership (overall approach to all educational elements and applications specific to leadership at various levels);
- piloting type leadership (turning to account the pedagogical resources of the education system through managerial functions such as: planning, organisation, coordination, and control);
- strategic leadership (innovative development of the system at various levels of organisation).

Educational management evinces a particular mentality, as well as a specific art of handling and putting into motion resources and organisational elements, which corresponds to the image of education as science and art.

Like other subsystems of any society, education is plagued by the scarcity of its resources [5, p. 298]. However, the crisis in the field is due not only to this insufficiency, but also to the poor management of resources, the lack of meaningful restructuring in keeping with current and future needs of the work force.

A significant amount of information in general managerial literature can be applied to educational management. Such is the case with elements concerning the interaction between small groups and between beneficiaries and the education personnel. [2, p. 14] To ensure that this information is efficient, especially within the education system, there is a need to develop a set of systematic and coherent strategies regarding reforms and adopt an action-oriented approach.

Alois Gherguț believes that the first step in this direction is the establishment of a set of clearly defined values which mirror the specific character of the profession. Moreover, he maintains that all the members within the organisation have to be involved in the decision-making process and a consensus on desired objectives should be reached starting at the lower management levels.

In his paper *New Management in Human Services* (1988), Leon Ginsberg sets out some efficiency principles [apud. 2, p. 15] pertaining to the practices in the educational system:

- orientation and inclination towards action – regardless of the level at which it takes place, management is the more efficient the more it is oriented towards actions established in accordance with

the new structures of society and the directions of its development;

- maintaining a close relationship with the beneficiaries – most of the times, the success in this field depends on the rapid identification of and adaptation to the needs of the community in which the institutions carry on their activity;
- ensuring the autonomy and initiative of the personnel – the personnel must be encouraged to experiment with ideas which are in keeping with the principles of the organisation;
- activity carried out by the existing personnel – this principle has been promoted ever since 1960 by D. McGregor under the name of “Theory Y” and it sets forth the idea that people like to be perceived as being important, useful and reliable with regard to putting new ideas into practice;
- adopting an approach intended for the achievement of realistic goals and the pursuit of stated values – an efficient organisation abides by its main goals and principles and tries to consolidate them;
- simple forms of organisation – the flexibility of these forms is particularly important; the more complicated the forms of organisation, the more difficult the management of activities;
- simultaneous initiative and coordination possibilities – this principle considers the productive correlation between coordination of and respect for the employees’ initiative;

These principles have been elaborated within an economic context, but they can be applicable to education institutions, the more so as the most important resource of this domain is the personnel of the organisations, and the end beneficiary is the entire society. In order to put these principles into practice in the preuniversity education institutions, some amendments can be made, such as:

- education cannot be brought to the level of any economic activity;
- education cannot be considered as ranking among “service providers”;

- education is an equation with more variables and its solutions must lead to results such as: “mature personalities”;
- educational activities require innate abilities on the part of the personnel; thus, the support for the autonomy and initiative of the personnel must be preceded by rigorous recruitment and selection of the human resources;

Educational management distances itself from general management in that it relates to educational goals, contents, activities focused on communicating information, behaviour of the people involved and the human resources engaged.

The educational management in itself assumes an interdisciplinary approach. There is an obvious relationship between educational management, sociology, political science and psychology [7, p. 29-33]. Thus:

- For an accurate planning of the school management activity, it is advisable that a management analysis should be done with sociological instruments. The concept of management, in sociological terms, is construed as the science of organising and handling social life through the agency of concepts such as system, structure, institution, change, leadership style, and reform.
- The political decision-making process provides educational management with an efficient action plan:
 - Identifying the problem;
 - Finding the optimal solution;
 - Putting the solution into practice on a social scale;
 - Assessing the results;
 - Operational assessment which determines new decisions to be made.
- At the psychological level, management reflects the internal mechanisms of human activity as a result of the motivation-goals ratio.

Just like general management, educational management fulfils specific functions. Regarding the definition, number and name of these functions there are several points of view.

Thus, some authors [7, p.33] point out that these functions are carried out in activities of planning, organisation, coordination, involvement, control, and evaluation. Other

authors [28, p.21] identify and depict the following functions: design and planning; organisation; human resources involvement/coordination and management; leadership; decision-making; control-evaluation-monitoring.

2.Types of managers

The managerial style is defined by the way in which management functions are carried out with the aim to reach organisational objectives.

The practice of a particular leadership style affects the organisational climate, the end results of human activity, as well as the individual and organisational performance.

The manager, through the leadership style adopted, not only builds and educates his/her team, but also sets the trend for the entire organisation. In the case of educational institutions, judging from the specific goals of this domain, one can rightfully assert that a particular managerial style adopted by managers goes beyond the bounds of the organisation. It spreads and encompasses the entire society.

Specialised literature [8, p.94-101], [6, p.43-47], distinguishes between the following types of managers according to the managerial style adopted (these types represent in fact a synthesis between the one-dimensional and tridimensional approaches to leadership styles):

- The leader – who is distinguished by his/her special innate talent, has a high decision-making capacity, is respected, enjoys authority and the admiration of the people around him/her;
- The creator – who is characterised by a balance between innate and acquired abilities, is meticulous, avoids taking risks and prefers stability to change;
- The destroyer – who advocates change and the abolition of outdated structures; he/she is the most indicated manager in crisis situations;
- The innovator – who has a penchant for innovation, meets the dynamic requirements of the techno-scientific progress;
- The autocrat – who is energetic, possesses a high decision-making capacity, but

constantly underestimates the work of his subordinates;

- The democrat – who is a supporter of participative management, acknowledging that the employees play an important part in building the managerial strategy;
- The delegator of tasks – who sets up the guidelines and provides general guidance, without restraining the liberty of action of his/her employees who assume a fair share of responsibility;
- The situational leader – who is highly flexible and adjusts his/her behaviour to the combination of factors which influence the current situation.

A different approach [6, p.46] focuses on five types of managers with the following characteristics:

- The participative manager – who is a reformer, innovator and creator; takes risks and understands the value of communication and active involvement; has clearly defined strategies;
- The populist manager – his/her priority is dealing with salary claims of his/her employees; is reluctant to deal with staff dismissals; lacks a clear management strategy;
- The authoritative manager – has extensive knowledge and experience, strong personality; is fair-minded and demanding; keen on boosting profits;
- The pacifying manager – adopts hand-to-mouth survival strategies; is good at conflict management and has the tendency to manipulate the employee unions;
- The incompetent manager – lacks initiative and a clear and workable strategy; easily corruptible.

Although the managerial styles have been analysed within the economic context, they are the same for educational organisations, describing educational managers with the same accuracy.

Worthy of notice is the fact that, in the preuniversity education institutions, the most frequently encountered type of manager is the “incompetent manager”. The data which come in support of this assertion are collected following a questionnaire-based survey with scales in measuring attitudes. The survey took place between May and October 2009 on a

random sample of high-school teachers in the central and south-eastern parts of Romania. The survey focuses on several objectives and working hypotheses and consists of 3 questionnaires.

The survey forms centred on the following criteria regarding the performance evaluation of didactic personnel in high-school education:

- The amount of time required for the documentation and elaboration of projects and didactic material;
- The qualification level, age and length of service in the education system of the didactic personnel and their influence on how they make use of their working time;
- Management and its impact on performance;
- The organisational climate and its impact on performance;
- The evaluation of the high-school didactic personnel;
- Material resources.

The main hypothesis of this survey was that the organisational climate, the quality of the resources committed to the educational process and, especially, management quality are of paramount importance in obtaining maximum performance.

Since it is not the purpose of this paper to focus on the entire survey, it will only show the results obtained from the interpretation of the scales corresponding to the questions pertaining to aspects of management and organisational climate in high-school education.

The tables no.1 and no.2 show the answers to questions related to the influence of management on the performance level of the educational institution.

Table no.1
The performance or lack of performance of educational institutions depend on its management

Yes	No
89	61

Table no.2
The influence of institution management on reaching performance

More than 50%	Less than 50%	Management plays no part in reaching performance
89	26	35

What can be inferred from this data is that, judging from the teachers' opinions, the management of the educational institution is responsible to a great extent for reaching performance.

Tables no.3 and no.4 show the data collected following the interpretation of the opinions expressed by the participants to this survey, which concern the influence of the organisational climate on reaching performance, as well as the extent of responsibility in this matter.

Table no.3
The influence of organisational climate on reaching performance

The organisational climate has a 100% influence	The organisational climate has a 50% influence	The organisational climate has an influence less than 50%	The organisational climate has no influence on performance
70	62	18	-

Table no.4
Responsibility for the organisational climate in high-school education

Responsibility for the organisational climate lies with the manager		Responsibility for the organisational climate lies with:			
Yes	No	The manager	The manager 50% and	The manager	The person

		100%	the personnel 50%	Less than 50%	sonnel 100%
141	9	27	106	-	17

It is easy to notice the fact that the impact of the organisational climate on performance is perceived by teachers as being rather high. However, responsibility for the organisational climate lies both with the manager and with the personnel of the institution.

To get a clear and objective picture of the influence of management and organisational climate on performance, it is vital to identify the managerial types adopted in these institutions.

Thus, the results of this survey match the managerial styles described in table no.5.

Table no. 5
Managerial styles adopted in Romanian high schools

Participative-reformist style	Populist style	Authoritative style	Pacifying style	Amateurish style
21	8	40	16	65

3. Conclusions

The 150 teachers who participated in the survey gave the following answers regarding the managerial style in their corresponding institutions:

- 14% identified a participative-reformist style;
- 5,33% identified a populist style;
- 26,66% authoritative style;
- 10,66% pacifying style;
- 43,33% amateurish style;

To draw a conclusion:

- All managerial styles are to be encountered in the Romanian high school education;
- The authoritative and amateurish styles are predominant;
- Responsibility for reaching performance lies mostly with the manager;

Responsibility for the organisational climate lies both with the manager and the personnel of the institution

HR Strategies, the Company's Step Ahead

Prof. PhD. Ion Criveanu
University of Craiova
ion_criveanu@yahoo.com
Ec. PhD. Loredana Iordache
loredanaiordache2006@yahoo.fr

Abstract

In the turbulent context in which Romanian companies operates in, the development of human resources strategies and policies, in close relation with overall objectives and strategies of the organization, becomes inevitable. In this respect, human resources strategy as part of the overall strategy of the company aims to raise awareness of the importance of human capital and to attract, develop and motivate it in order to ensure, at all times, an efficient implementation of modern service aimed at increasing customer satisfaction. The need to develop strategies and personnel policies becomes more current as reality shows that for many organizations, preoccupations to achieve strategies and resources are almost nonexistent. From here they appear a series of mismatch on the existence of overvaluation of staff, lack of labor for certain qualifications, with the most diverse consequences such as increased production costs as a result of unjustified increases in wages, or the inability to manufacture products due to a lack of unskilled labor.

Keywords: human resources strategy, personnel policies, strategic objectives

JEL classification: M12

The accent which Romanian companies put during the last period on human resources development had determined the changing of perception way to this organizations' component. For realizing their objectives, companies have to resist to some challenges which request capacity of ensuring and maintaining competition success through anticipating contextual evolutions.

In Romanian companies it is more and more spoken about human resources strategy. It was often used like an usually term, entering in the terminology of human resources domain without

being properly understand. We can't speak about human resources strategy without being available a strategy at organizational level. More than this, we can't create and implement a human resources strategy if we don't know mechanisms and components of human resources strategies.

Although there are a series of definitions given to human resources strategies, the scope of their conception and applying must be the same: more and more efficiently using of human resources for realizing company's objectives.

In this context, conception and implementation of human resources strategy do not have to be realized as an isolated event, without continuity, and it must be harmonized with strategic components of the company, with the demands imposed by specific business environment of the company, and also with internal demands of this.

Another aspect which must be taken into account in elaborating human resources strategies in consist by motivations, demands and compartments of actual employees, which are permanently changing. From this reason, human resources strategy must correlate these needs with company's objectives.

In the 60's, using the "strategy term" begun to be used in economy for define ones of the most important decisions of companies.

Starting with the 80's, all or almost all became strategic in economy, sociology and psychology, etc. Even it is about groups or individuals' compartment, or economic options, more authors started to think in strategic terms.

The "strategy" term received different meanings, lengthways time, depending on the domain in which it was used.

In human resources domain, in some authors' opinion, strategies express the fact that human or personal resources function is adopting a bigger perspective and a more dynamic vision through human resources, insuring their integration with the other organization's resources.

Another authors had lighted the fact that thinking in human resources strategic terms proves the superannuated anterior conceptions of enterprises which aren't preoccupied about concrete application of important decisions, just them considered strategic: an initial and planned version of strategy idea is criticized and renewed in participative management's perspective and strategic administration of human resources. It is spoken about realizing some links between decisions and their application, and so about different actors' associating at strategic level. This widens and partnership version of strategy is ruling today.

From another point of view it is considered that human resources strategy represents the ensemble of activities linked by planning, recruitment, integrating, perfecting, evaluating and motivating human resources.

From this widen approach could appear derivate human resources strategies, which make reference just to a part of these activities, like: personnel ensuring, employees' development, the reward, relationships with the employees.

Not taking into account the domains in which human resources strategies can be developed, these must be conceived for being in concordance with company's general objectives. At its turn, company's global strategy has to analyze the field of open possibilities of human resources strategy, and to fructify these possibilities.

The majority of authors consider that in any organization, indifferently of activity's nature, there are two types of objectives:

- strategic objectives on long term which regard a series of aspects contained by human resources strategies' definitions themselves.
- operational objectives, tactical and administrative which suppose activities regarding daily management of work groups.

Long term strategies have a series of objectives which regard aspects of human resources, like:

- satisfying human resources organization's necessarily for the next 5

years, as employees number and also as personnel categories

- maintaining wages and rewards at a sufficient high level for recruiting, keeping and motivating employees at all organization's levels
- realizing some harmonious relations between managers and the ones which are in their responsibility
- ensuring necessarily ways and endowments for maintaining and perfecting labor force's knowledge's and competence
- ensuring a properly communication system between management and other employees, and also between different organization's departments and functions
- ensuring necessarily mechanisms for permitting to the organization to stand up in face of human consequences of change.

Analyzing those objectives, we can remark a series of aspects referring to the fact that those are more qualitative and hard quantifying. Although, these objectives are knitting ones with the others, and attainment of ones offers the possibility of quantification through other viewpoints. In another words, we can measure the way in which personnel necessarily is satisfied, from the viewpoint of wages offered by the company.

More exactly, competitive wages, professional work frame ensure a low fluctuation and put into attention a high grade of employees' satisfaction. This leads to a stabile work frame, a good image of firm from external, which will determine the possibility of ensuring further human resources necessarily.

Practical, attainment of objectives linked to salaries and motivation strategy also leads to realizing objectives linked to human resources necessarily.

Global organization's strategy influents in a main way the strategies form human resources area. Not for a few times, it was established the impossibility of realizing some profitable projects for organization, because company's management was excessively focused on financial and technical aspects, not taking into account

human part. Unfortunately, there still is an important part of managers which still consider people like a machine which can be anyway and in any conditions used.

The experience had demonstrated that this thing was especially changed during the last years. Sometimes, people can put up to change, especially when the stress level which they are confronting is important. Sometimes, they aren't enough motivated for doing the necessarily effort to adapt at the new demands, or they do not understand which are new demands, being kept in the past and in old demands which they had realized.

Elaborating human resources strategy must be realized in concordance with company's objectives and it must offer human support for their attainment. There is a series of factors which must be taken into account in elaborating human resources strategy:

- analyzing existent human resources of the organization
- analyzing internal and external environment
- knowing general strategy of the company
- implementing personnel procedures and policies.

The influence of these factors leads to the conclusion that elaborating human resources strategy in an continue process of analysis and diagnosing, and during this process it must be permanently followed in which measure established objectives in human resources area correspond or they are actual to attainment general company's objectives.

Managers have an important role in strategy elaborating, and they have the responsibility of its creation, and also have the role to persuade employees to involve in these strategies' sustaining. The content of human resources strategies must reflect also the content of human resources management or theirs activities, and also the manifestation intensity of the others firm's functions linked by personnel.

The absence of organizational level of some coherent human resources strategies, makes impossible organizations' adapting at international frame's changes, human resources activities having to be understand in interdependence with all the other process spread at the level of one organization. Management of human resources, as strategic managerial process, is more difficult, comparing with

technical progress promotion or financial resources flow. Organizations which had teaches how to lead their people, applying a performing management of human resources, had passed a step in face of others, because ensuring maintaining human resources' quality are durable strategic processes.

Elaborating a human resources strategy involves elaborating some strategies on each activity on company's functions of human resources, in a smaller or bigger measure, depending of organization's life period. In an organization founded in the "born" period, it will be granting a bigger importance to the recruiting and selecting strategy, reporting with strategic planning of the personnel, for example, whom importance will be putted into evidence in the firm "growth".

Although in specialized literature there are a series of approaches referring to human resources strategies' elaborating, in practice had been often formulated the following strategies:

1. Strategic planning of personnel is difficult to be realized on long term in actual economic conditions, characterized through a high instability and a rapid change of market's conditions. Companies are preoccupied by solving moment problems, and they do not have necessarily capacity for a longer term planning of human resources. Although, we do not have to neglect the fact that company's objectives constitute the start point of any human resources prognosis. Although when we speak in practice about human resources prognosis we generally think to recruitment, especially in growing and maturity phases, we do not have to neglect the aspects linked to available resources' analysis. Making a personnel inventory on professions, preparing, performance it maybe is more advantageous to use personnel form your own company, than to recruit external personnel.
2. Elaborating recruiting, selecting and integrating human resources strategy is the most difficult attribute of managers, in actual conditions. A recruiting and selecting strategy

depends on a lot of many internal and external factors. First of all, knowing organization's objectives is very important. Next, are necessarily a series of researches of the following aspects: free posts can be occupied with existent personnel, or through recruitment; there are personnel's record well done, with the attributes of free posts; there is a certain evidence of passes, for recruitment necessarily determination; the free post's attributes can be redistributed.

All these analyses lead to elaborating recruitment strategy, which, as we had mentioned, depends on a series of external factors, like: company's image, demand and supply on labor force market, etc. Integration's purpose is the one of facilitating new employee accommodation with work's demands. The group demands aren't every time likewise the manager shows to the new employee. For this, there are many cases in which the new employee can't accommodate itself at work place.

3. Elaborating personnel motivation strategy. Specialized literature discussed a lot the problems about personnel motivation. In practice, these things are harder to be realized, because founding the most adequate strategy of motivating human resources supposes to know very well employees' necessities and demands, which must be corroborated with realizing organization's objectives. Unfortunately, there still is the mentality of a lot of managers that, if people are unsatisfied, they go and we can find others. Things had change a lot in the last 3 years. For that, together with the recruitment, managers have to find solutions for motivating and keeping prepared people. The practice shows us that employees maintaining is as difficult as their selection, but more expensive.

4. Strategies' elaborating regarding rewards system must take into account actual legislative frame-work, and also realizing a performing and motivating system, referring here not just at salary, but also at indirect rewards system, which, in the last years, is more and more important.

We can't say that we have exhausted the area of all human resources strategies. Each of these strategies can generate others, and all of them are strongly linked one with another. But, it is necessarily a new approach regarding the ensemble human resources function, referring to constructing some concrete policies and procedures for these strategies sustaining.

While human resources strategies express the ways of objectives attainment in a straighten future inhuman resources area, personnel policies have a smaller horizon, with a stronger measure of detailing and an operational character, their role being the one of sustaining human resources strategies in each of main areas of human resources management.

Establishing a concrete policy in human resources area must take into account personnel importance in a company, responsibility which devolves to the managers, strategic objectives of the organization. A correct formulated personnel policy is the essential element in performance obtaining.

For human resources area's policies attainments their objectives, they must fulfill a series of demands:

- to be clear formulated, redacted and written communicated to all the employees, for not letting place of interpretations
- to cover all activity domains of the human resources function, especially where the company had proposed strategies on this domain
- to be consequent and to obtain the whole personnel's adhesion
- to be transparent and to allure a bigger number of employees at it's conception and at it's transposing in practice, and so to act at all levels
- to be in concordance with general objectives and strategies of the company
- to stimulate at each employee the desire of continue improving of his own activity.

In various situations, there are implicitly personnel policies, as an attitude of managers to their subordinated, and as an organization's philosophy expressed through the way in which are approached personnel problems or through the manner in which they treat their employees:

Personnel's policies depend of organization's basal values and they are putting their stamp through organizational culture.

Although big majority of managers affirm that in their companies exist human resources policies, a careful analysis shows that a big part of them do not know to describe the nature and content of these policies. The reason is very simple: managers' aware human resources policies' importance, and they want their elaboration only when crises' moments appear into organizations.

For this, elaboration and implementation of human resources policies can't be realized without passing some steps:

- picking up and analyzing some information received from employees and also from managers regarding elaboration of some personnel policies very efficient
- the analysis of external organization factors, firstly referring here at legislative frame
- knowing general organization strategies and human resources strategies, regarding the elaboration of some individual human resources strategies on each area of human resources management
- knowing imparted and accepted organizational values and culture.

After elaborating and accepting human resources policy, this has to be communicated to all employees, an important role devolving to those persons who are putting it in practice.

Applying human resources policy also involves the supervising exerted by human resources managers, and also collaboration with the other departments' managers.

The efficiency of elaborating and implementation human resources policy can be verified through the following three ways:

- the way in which human resource policy facilities or not attainment proposed objectives
- the measure in which this is or isn't compatible with organizational values or culture of the company
- the measure in which actual legislation is respected

Analyzing the aspects linked to human resources policies, we consider that there aren't recipes in their elaboration and implementation. Each company has its own characteristics, and human resources managers devolve the obligation of founding the best methods for correlating company's objectives with the employees' desires and expectations.

More and more companies understand and try to obtain advantages, as a sequel of applying some coherent human resources policies. Awarding the necessity of human resources strategies and policies does not suppose just strictly specialists intervention in this area, but it also includes an awarding at global level and at each individual level.

Attributing the role of strategic partner in the business internationalizing actual context represents the recognizing of the human resources functions' role and importance, without organization's development weren't possible.

Developing Skills- a Priority for the Management of Human Resources

Radu Catalin Criveanu

Marius Mitrache

Magdalena Criveanu

University of Craiova

Abstract

The management system based on skills allows a relevant integration to manage and support the human resource in his career. Recent studies showed us that vocational skills training has become a priority in Management of human resources. The aim of these studies is to establish a correlation between the company's objective and the employees' skills. Human resources management, based on the organisation values will contribute to improving employment and rapid adaptation to market requirements. This work was supported by CNCISIS-UEFISCU, project number PNII-IDEI code 393/2008.

Key words: human resources, skills training.

JEL classification: O15;

Human resource management based on skills is a concept that was imposed rapidly in recent years not only in theory but in the practice of human resource management. And that is because the success in career depends more and more on the individual skills and on how we develop our personal skills required by a particular job.

It is known that human resources system has undergone a period in which the environment was fairly stable and less flexible. In current conditions it can no longer provide an effective management. That is why it should be adopted a slim framework for the management of human resources, which allows a relevant

integration to manage and support the human resource in his career. For this reason, it has to be realized a management system based on skills.

Lately it is put a strong emphasis on vocational skills training. Competencies are the most valuable good that an employee brings in an organization, together with knowledge and experience.

Beyond personality, skills bring added value and uniqueness of each employee. A jurisdiction may be a natural talent, a skill - that is learned or acquired over time through experience - or a combination of the two - the one that has jurisdiction for an employee is porting them, a thing which not a few times we forget. No matter what area of the human resources we speak about, specialists try to convince us of the importance and the need of the "skill based approach". The problem raised in this case is the following: Are we ready to establish a correlation between the company's objective and the employees' skills?

We take this overlapping of skills, talent, know-how with us whenever we change jobs. And exactly this combination is what makes us unique in a role, which makes the difference between success and failure even if there are two or more people with the same knowledge, in the same role.

Professional competence as a *core*¹ model for the management of human resources, stimulates the existence of several specific subsystems:

- professional. The differences noticed between the desired profile of competence and the assessment of the results and the individual potential induce the need for an individual professional development plan;
- and the selection of staff. Professional competence is the skills and qualities sought in the process of recruitment and selection;
- Analysis of skills associated with a profession determines a scale of remuneration, and the results of the evaluation of a person lie on one of the levels of the ladder of promotion. Individual assessment in terms of determining the potential applicable skills has as a result the promotion decision.

Taking in consideration the fact that it is expected that the European economy will create about 13 million jobs in the next 8 years², as most of them require superior professional skills, it will be a must for people to follow training throughout life to remain competitive.

Developing skills is a priority not only for employees but also for firms. The permanent job evolution in an organization creates the need for the knowledge of the employees' skills.

The approach focused on skills adds to the skills, knowledge, values, attitudes, personal and specific skills and reasons which contribute to achieving good results in achieving labor. Setting the profiles based on employee competencies with higher efficiency, it can be built the base on which it will be made a superior organization (in other words, superior performance will be the basis for improvement, training and effective recruitment of labor and providing for future needs of the market.)

To perform a skills-based management should be considered the following issues:

- The extent to which such an approach can be implemented
- Amendments to laws or policies where appropriate
- Knowledge and understanding of human resources based on competence

Beginning with the criteria applied in the recruitment and selection procedures, and ending with the last stage of career, passing through assessment, training, motivation, reward, the management of human resources based on powers may give performance to the policy of human resources of an organization by generating positive consequences both in the strategic plan (forecast staffing, organizational

culture, management style), and individuals plan (personal development, increased motivation).

It should be emphasized that the objective is not to create a normative model that finally all bodies should apply. In reality it is often recognized that in a process, this approach could raise more questions that do not provide answers. Dialogue and habit arising from its use will allow a better understanding of the measure to be set in the management of human resources, taking into account the outcome of consultations and practical experience.

Another approach based on competence focuses on the characteristics described as skills. These skills³ serve determining the staff and recruitment's needs, training, assessment, job mobility, pathways and professional recognition and remuneration.

For integrating a system based on skills it should be act in more ways:

1) Organization follows these steps: introduce a mechanism that allows the increasing of the link between human resources and strategic objectives of the organization, increase the ability to establish partnerships among organizations and other organizations, contribute to solving problems of equity and to raise barriers, which are often inherent, of an approach based on jobs and tasks; facilitates changes in human resource management by providing a good result both in the employees assessment among organization and in terms of gaps in the skills and requirements in terms of recruitment.

2) From the people point of view, it will enable a better understanding of the approach within their own functions, to self-evaluation and to establish a link between bonuses, recognition of work and remuneration.

3) In terms of human resource management, this system will provide a good result to develop criteria for the recruitment and selection, job descriptions, goals and objectives of employees, measuring performance, training needs based on gaps and plans for change.

How they make their individual contribution in a company is seen in the results. These results take the form of behaviors. Behaviors can be considered as a yield (effective or ineffective) or as an extent that an individual responds to the needs of the organization. The situation is reported to the applications. There is recruitment, selection, analysis of gaps, career planning and setting organizational profiles. Jobs are no longer basic elements of an organization. They were replaced by employees' competences (skills and abilities, knowledge necessary to achieve the strategic objectives of the firm). People will have to prove flexibility and be able to adapt to different situations.

The organization operates under a framework which includes vision, values and its mission defining, as well as its strategies and also the structure and support systems. Vision, mission and values define the nature of the organization. All these must be part of the organization. Skills and behaviors can play a major role in this situation. The main features of competencies that can be pursued in this type of management are: motivation, psychological reactions, self-image (attitude, value and image that a person has about himself/herself), knowledge, abilities.

Competencies are tangible, they can be measured and therefore changed. Competencies analysis involves the analysis of skills, habits and the main behaviors that a person must possess.

There are five essential elements that allow the definition of general competencies: strategic elements, professional and technical category, the specific of the company, the cultural values, human resources elements.

All employees should have an average competence in the above mentioned items. These elements serve to career planning, management efficiency, the training staff and activities. Characteristics which will determine the success of the organization will depend on the ability of leaders to formulate questions, to adopt a good perspective and to entrench people. To gather all these elements it must be an integrated system comprising enterprise's value, a vision, an enunciation of the mission, goals, objectives, an action plan and a back up system. Ability corresponds to the lowest observable measurable unit of work behavior. It varies with time. M. Cohen argues that in general the behavior is a

consequence. Ability is important because past yield is the best pledge of future yield, present yield devolve from past yield and more than effective behavior is effective and relevant.

The organization must create an integrated process of human resources by examining not only the skills and knowledge, but also the behavior that is required for the work to be done. Once the profile is established, it may be used the behaviors of the different purposes: the selection and recruitment, performance management, change planning and career promoting.

Planning change is a responsibility which develops upon the organization and the first step to define the skills, knowledge and ideal behaviors as well as the specific objectives of a job, and then to create a program to help candidates achieve its objectives. For this system to be successful, both the organization and the employee have to answer the following questions:

- What are the skills we need?
- What are the powers which they possess the employee?
- What is the spread between them?

The real process will begin with an assessment of employee skills and through an analysis of spreads between them and the required skills. Thus, in light of available resources, the employee will draw an action plan and its boss will help him/her with this task.

Training is essential in human resources policy, upon the manager rests the responsibility of two main objectives: the motivation and development skills⁴. In our opinions, one of the shortcomings in the training of Romanian firms is the chaotic manner in which they intend to achieve their training plans. In fact the success of this approach is influenced by several factors such as⁵ stimulating organizational culture, a participatory management that encourages employees and not least a motivated work force willing to learn and develop permanent.

We cannot talk about the development of collective and individual competences without employees' motivation and adherence.

Motivation is essential in the development of the competences.

We believe that in order to have an effective training program it is necessary to fulfill several conditions like:

- The courses should not only provide to the employees the training that the organization needs, but also awareness of their utility. General speaking, people perceive very well the utility of a course. Not few times, it happens that the decision going training courses to be taken by a person who doesn't have great connection with the work or has not done a proper job analysis. In these conditions, no matter how well organized is the course, people will not perceive its true value because they will not benefit from the information received. Therefore, we consider that, in order to have the desired success, the knowledge acquired during the course must be applied immediately in the workplace
- Choosing where to place courses and matching the training equipment to the training needs of students
- Instructors and lecturers should have adequate knowledge. Selecting trainers is very important to the success of the courses. This would require the establishment since the beginning of competencies that we want to achieve from the course and at the same time we must ensure that the chosen trainers can develop these skills.
- The evaluation system chosen for assessing the success or failure of the training courses.

Skill forming or development must be a continuous process that allows anticipation of the future needs of the organization and not to produce imbalances in activity.

Due to the focus/stress put on the skills, human resources management will become more flexible and will reduce costs and simplify bureaucracy. Also this type of management will contribute to improving employment and rapid adaptation to market requirements.

Management focused on skills supports people and, as it is based on the organization values, it is going to have a special contribution in creating a general picture of it.

Abstract

The automobile buyer's behaviour is a specific one and the knowledge and understanding of the motivations is important for the automobile manufacturers and distributors. Automobile buyers are the beneficiaries of complex high technology products, which have a long-term use. The paper is focused on understanding the mechanisms that underlie the buying process, the buyers' expectations and needs, as essential elements for producers and distributors. When these mechanisms are controlled, the company can create superior products in terms of technical quality and which comply with the pollution standards, and wanted by customers more than the ones of the existing competitors on the automobile market. The buying decision is a complex process which is the result of both the endogenous and exogenous factors to the purchaser. To meet his needs the Romanian car buyer chooses either to purchase a used car, most of the times an imported one, or to buy new brands, also mainly imported ones.

The underlying motivation of either option is twofold in the sense that it is rational and subjective, the proportion being different from person to person. In Romania, the automobile buyer's behaviour witnessed significant changes, the latest preferences being directed towards the used cars more than towards the new ones. The consumption behaviour is also different from one development region to another, the main factor of influence being the buyers' income level which is different from one region to another. The population with higher income has a higher tendency to purchase more expensive automobiles.

Key words: automobile buyer behavior, emotionality, rationality, motivations

JEL classification: R49;

1. Introduction

Companies in general, and particularly those in the automobile field, direct their activity towards meeting the consumption needs, towards what is required by the market. To achieve this objective it is required to know well the market mechanisms, the needs, the process of turning these needs into demand, the motivations underlying the buying behaviour.

The consumer behaviour knows a number of definitions both from the marketing perspective and from the psychological one, yet without having reached a unitary definition [6; 7].

Being a multidimensional concept, it is difficult to find a common denominator for a variety of approaches to consumer behaviour, especially given that many theoretical aspects have not yet found experimental verification or emotional validation as well as a general acceptance from the specialists [3].

Consumer behaviour is one of the key variables of the marketing environment that every company wants to understand and to influence to its own advantage. Consumer behaviour is a component of the people's economic behaviour, which, in their turn, represents a form of manifestation of the human behaviour in general [1].

In a broader sense, the consumer behaviour includes all the activities involved in the selection, purchase, and use and growing out of use of products and services.

Although the buyer's choice is considered free, there are certain factors that limit the

buyer's choice. A first limitation would be imposed by the influence of the groups, of the communities. Another limitation comes from the direction of the manufacturers who define and determine the nature and the quality of the goods to be consumed.

A final limitation in the buyer's freedom of choice comes from the belief that our purchases that we consider free choices are more or less subject to the social category to which we belong, respectively to which we wish to belong [5].

All the mechanisms that are based either on the subject's beliefs or on its external influences are the ones that finally determine the buying decision or a certain conduct of the buyer, and they must be fully understood by the producers of goods and services.

2. Consumer - characteristics and influence factors

One of the most important variables of the marketing environment on which the company has no control, but which it tries to influence it the desired direction, is the consumer. Consumer behaviour can only be explained by knowing the system of factors that act in close relationship and mutual interrelation, but the way in which they act and especially the role they have in the system are viewed differently and therefore in the specialized literature we meet different classifications of these factors [2].

In the analysis of consumer behaviour, the marketing departments must consider the following factors:

- - its dynamic character;
- - consumer behavior does not completely fit certain laws;
- - consumer behaviour determines interactions, being necessary to know what the consumers think (perception), feel (impression) and what they do (behaviour), as well as which are the factors that influence them (natural environment);
- - consumer behaviour determines exchanges between the participants in the buying - sale process;
- consumers are very different from one another;
- consumers act mainly emotionally and may act differently in different time moments;

- consumer behaviour can be influenced, he can learn and can change his attitudes and behaviour;

The multitude of behaviours that make up "consumer behaviour can only be captured through a systemic approach, because the act of buying is not a simple reaction between revenue and expenditure, but also requires other dimensions that determine the manifestation of certain attitudes [3].

The factors that determine the behaviour of consumers in their decision to buy a car do not only refer to the physical needs and do not solely depend on their buying power.

Most theories consider consumer behaviour as being a function determined by socio-cultural factors and by personal traits.

Among the socio-cultural factors with the greatest influence on consumer behaviour and respectively in developing the marketing strategy, one can distinguish: culture, class and social position, family and group behaviour (reference group).

Consumer behaviour is equally influenced by personal traits, the important ones being the age and the stage of the life cycle, the person's economic situation, occupation and education, motivation, perception, training, beliefs and attitudes, personality and self image.

Consumers change their preferences and behaviour according to age and stage of the life cycle. The economic situation also affects the person's behaviour, as consumer especially in terms of quality; the quality and the price are directly proportional characteristics.

Occupation and education are largely linked to income and social class, with a number of implications for the marketing activity because as the population's degree of education increases, it needs better quality products or services.

Motivation is that inner strength that mobilizes people in their aim to achieve certain objectives.

Motivations can be classified as it follows:

- a) primary, when determining the purchase of a product, from a certain category;
- b) secondary, in case they determine the purchase of a particular brand;
- c) rational, if they are induced by logical reasoning and assessment of the situation in which the consumer is;

- d) emotional - caused by the impression that the consumer has about the brand;
- e) conscious - because the buyer knows he needs a particular product;
- f) slow, if it operates at the buyer's subconscious level.

Once the motivation triggered, the way the consumer will act depends on how he perceives the information about the respective product.

Perception is the process through which a person selects, organizes and interprets the information to create an image on the natural environment.

Learning is at the basis of the perceptual mechanism and of the consumer's motivation to buy or not a particular product or service.

The beliefs and attitudes are factors which make the consumer's behaviour and reactions be better understood. Faith is the descriptive thought that a person has about something, and attitude is determined by the cognitive, affective and intentional component.

The self personality and image influence the perceptual and motivational mechanism of the consumer, thus his behaviour.

The effort to understand what is appreciated by a consumers database of global diversity in car interiors allows transforming the findings derived from the analysis of the consumers' behaviour into innovative and competitive products.

The analysis of the consumers' behaviour appreciates the major trends in society, population and technology they and are applied on the automobiles market.

The consumer establishes in every moment of his existence one or more consumption programmes. The consumption programme (or the consumption formula) represents the specification of some given quantities of different goods x, y, z, \dots, w which provides a consumer a certain utility (satisfaction).

The consumption programmes of each consumer are influenced by the social status and by the family situation, by the implications of the phenomenon of induction of the needs and orientation of the consumption through the media, advertising and publicity, imitation, fashion, etc. The consumption behaviour of each customer is individual and subjective [4; 8].

Due to the fundamentally different nature of the acts and processes that define the automobile buyer's behaviour, the way in which people behave in economic terms is not just a

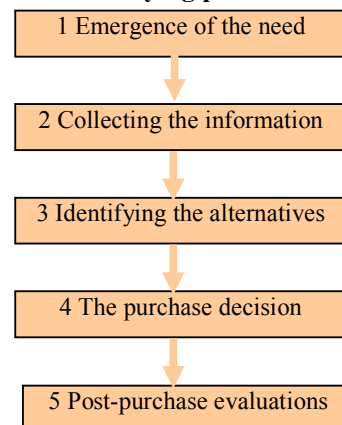

summation of mechanically repeated acts, but rather the result of the accumulation of a life experience and of an accumulation of influences from the group to which every person belongs.

3. The decisional buying process

According to the theory of consumer behaviour, the decisional buying process goes through several stages: the emergence of a need; finding information and identifying alternatives; mental evaluation of the alternatives; the outcome of the evaluation materialized through the purchase or non-purchase intention and the last stage, that of post-purchase evaluation.

Schematically, the decisional buying process is shown in Figure 1.1 and it involves the consecutive going through five conventional steps:

Figure 1.1 The stages of the decisional buying process

The person's final decision can take many forms, thus after the mental evaluation of the alternatives, the buyer may decide to purchase, to postpone the purchase, not to buy or to replace the previously selected car with another one, having higher technical and pollution characteristics and at an affordable price, as a result of a later offer.

4. Selecting the automobile brands in the buying process

On the automobile market the products are renewed at higher and higher speed.

The technical and performance features are becoming more varied and complex.

Buyers can be classified into two categories: car owners and those who are their first purchase. If the first category has a stock of information, mainly from the buyers' own experience, part of the knowledge acquired over time and therefore a new choice it is a decision based on a fairly substantial stock of knowledge for those who are buying for the first time, the decision is a more difficult process, the hesitation degree is higher than in the first case. Although the information about the wide variety of brands and models is available, the analysis of this information in order to adopt a buying decision is difficult. To buy one or another brand of car, the family, friends, distributors or the people who have that car brand are consulted. In the consciousness of many buyers or potential buyers there is a certain hierarchy of confidence in the car brands, but for most purchasers, the income constraints are an important element in choosing a car or a brand. The brand is an important attribute that the buyer takes into account when purchasing a car. The German brands inspire most confidence concerning the durability and the superior performance, being preferred by most buyers. Toyota is preferred due to the image of safe and highly performing brand, created in the buyers' consciousness.

5. Automobile buyers' behaviours

Automobiles are durable goods, which include high value-added, as a result of the high technology, from the most diverse areas.

The price of a car can range from several thousands euros to tens or hundreds of thousands of euros, which makes choosing a car be considered a very serious task. It would be natural that the selection was the result of a mainly rational analysis.

The generous offer of the car manufacturers, who continuously bring on the market new models with outstanding performance and with very varied prices somewhat give trouble to the buyers. This difficulty is explained on the one hand by the fact that the technical, technology and pollution performances are less known to the purchasers, because of the great abundance of products, making it difficult for the buyers to compare and to rationally evaluate the products. The result is that the choice is increasingly shifted towards the subjective, irrational side.

The automobile buyers from Romania have a behaviour that has suffered permanent changes, which made the task of the auto companies' marketing departments quite difficult. The preference for used cars is more and more obvious.

The motivation is a purely subjective one based on the conviction that they are cheaper and the prestigious brand provides a certain security and image within the reference group, especially in the young people's opinion. In Figure 1.2 the car buyers' preferences tendency is shown for 2006-2009 and for the first months of 2010.

Figure 1.2 The evolution of the car buyers' preferences

Data source: <http://www.drpciv.ro>

From the data presented one can see the tendency of preferences towards used cars in the first two months of 2010. Unfavourable trend begins with the adherence of Romania to the European Union when access to acquisition of imported cars has become very simple. The buyers' preferences are different from one geographical area to another. These preferences are the result of the influence of the group of factors specific to the development areas. The market of the development region Bucharest-Ilfov has a share of almost 50% of the national market.

As is shown in the table 1.1 on this market the buyers' preferences were directed in 2009 over 80% towards new cars as compared to the other markets where the buyers have oriented in the best case in a proportion of 38.3% towards purchasing new cars.

Table 1.1 the share on development regions of the car registrations

Development regions Year 2009	Buc - Ilfov	South-East	South	South-West	West	Centre	North-East	North-West	Romania
New vehicle registrations (%)	80,9	38,3	38,2	25,0	19,0	18,5	18,1	14,6	35,0

Data source: <http://www.drpciv.ro>

The development region with the lowest inclination towards purchasing new cars is North-west with 14.6%.

Figure 1.3 presents the evolution of new car registrations compared with the total number of car registration in the 8 development regions compared with the national average.

Figure 1.3 the evolution of new car registrations from the total of 2009

Data source: <http://www.drpciv.ro>

The analysis of the buyers' preferences regarding Dacia brand reveals a high affinity of the majority of the areas. As presented in Table no. 1.2 the highest preference for Dacia brand belongs the South development region with almost 46 local cars registered out of 100 new cars.

Table 1.2 Dacia cars registrations of all new cars registrations in 2009

Development region	South	West	North-West	North-East	South-West	Centre	South-East	Bucharest
Dacia out of the total of new cars registrations (%)	45,9	45,6	44,2	42,9	42,7	37,3	36,3	21,0

Data source: <http://www.drpciv.ro>

The Western region also has a high preference for Dacia brand although the influence of the Western brands is very strong. As shown in Figure 1.4 Dacia has the lowest demand on the market from Bucharest as compared to the other car brands.

Figure 1.4 the preferences of Dacia buyers on development regions

Data source: <http://www.drpciv.ro>

The Bucharest-Ilfov region prefers in a proportion of 21% the Dacia brand, being thus 10 percent below the national average.

6. The behaviour of used cars buyers

The buyers' tastes are very different; nevertheless, the German brands are by far the most preferred ones by Romanian buyers. As presented in Table no. 1.3 the most demanded brand is VOLKSWAGEN, followed at short distance by Opel.

On average, the brands of German origin dominate more than 70% of the used cars buyers' preferences.

Table 1.3 the top of the preferences of used cars buyers

No.	Brand	Preferences proportion
1	VOLKSWAGEN	28,20%
2	OPEL	22,90%
3	FORD	10,50%
4	BMW	6,80%
5	AUDI	6,60%
6	RENAULT	3,80%
7	MERCEDES-	3,20%
8	FIAT	2,90%
9	SKODA	2,20%
10	PEUGEOT	2,20%
11	SEAT	1,90%
12	SUZUKI	1,20%

Data source: <http://www.drpciv.ro>

There is an obvious preference for the German brands as an expression of the reputation and image that these brands have on the used cars buyers' consciousness. The explanation for this phenomenon is that of the price affordability for the used cars and

that of the reputation, of the confidence in the brand, the buyers having the sense of a special identity as compared to the owners of other brands, especially local ones.

7. The financial behavior of the automobiles' buyer

The automobiles' buyers have frequently resorted to crediting instruments in order to purchase automobile, their dependence being pretty high just like Pearson's correlation coefficient presented in the table 1.4.

Table 1.4 Pearson's correlation coefficient For vehicle registrations and banking credits

		Vehicle registrations	Banking credits
Vehicle registrations	Pearson Correlation	1	0,541(**)

** Correlation is significant at the 0.01 level (2-tailed).

The degree of acquiring banking debts has begun to decrease at the same time with the effects of the crisis, which determined a radical change of the acquisition behavior, the buyers being stricter when they decide to buy the used automobiles.

8. Conclusions

The decision of car buyers from Romania tends towards the subjective side of the choice criteria. Most of the buyers consider owing a car as more than a necessity. For them it is a way of expression, of reflecting on the social status, of superiority over other owners, usually of local brands. Young people in particular, prefer the German brands which inspire confidence and which in their view reflect the perfect choice, dynamism, speed and safety [9]. The design is an important criterion in choosing a car and it is considered, especially by the young buyers, a way of expression, a representation and personalization of their own image within the group, a fact which directs the choice of a car towards the subjective side. Because new cars are priced relatively high as compared with the used cars, the option usually is that of buying used cars belonging to prestigious brands. The effect of this choice is a very negative one since there is a decrease in the sales of new cars and implicitly the local ones with all the economic consequences involved, and on the

other hand pollution and the used cars maintenance and repair costs are high, effects which most often are not taken into consideration when buying a used car.

The unfavourable trend of preference for used cars in the first two months of 2010 could change together with the onset of the renewal programme of the car park in Romania. This programme is expected to cause major mutations in the low cost or middle cost car buyers' behaviour. The producing and selling cars companies might emphasize more the benefits. Although the effects of the financial crisis are fully felt by the vast majority of car buyers, the expensive, sports and luxury brands are increasingly being demanded. These preferences are the result of the financial wealth and of the social position of a class of buyers. Owning such a car is considered as being the expression of the owner's value and social status.

Organizational justice, key point in economic crisis management, a comparative study: can Romanian problems be solved by foreign solutions?

Cruceru Raluca

Academia de Studii Economice București

cruceruraluca@rdslink.ro

Abstract

A recent Romanian study shows that two out of three employees with higher education are affected by the measures recently taken by the companies they work as a result of recession. Eliminating bonuses, restructuring processes and even lower wages are relatively common phenomena encountered lately in organizations in Romania. Employees are affected indirectly by reductions and development budgets of the organizations they work for. Concern for the future is even greater. Thus, 3 of 4 employees with higher education are expected to cost reduction actions that affect them directly or indirectly. In an attempt to cut costs, rather expect top managers restructuring processes, while employees without managerial positions believe that the restructuring will take place near elimination of bonuses and wage loss. How can workplace justice can ease the pain? This article is attempting to give an answer to this complex question.

Key words: economic crisis management, organizational justice, romanian problems;

JEL classification: M54;F59;

1. Effects on labor market recession

The study was conducted by two counseling firms in March 2009, on a sample of 1158 employees with higher education until the age of 45 years. The sample is nationally representative for the population studied.

70% of employees with higher education attended the expenditure reduction measures in the firms they work for. Almost half (46.4%) of the same category is affected by

budget reductions of corporate development.

But more painful are the measures that have direct impact on employee income, and affects a significant number of employees. Thus, 30.5% of employees with higher education to admit that their company bonuses were eliminated, and a similar percentage (30.2%) of persons with higher education attended the restructuring processes in the organization. Nearly one in five employees with higher education have witnessed wages reductions in the company they work for and one in ten attended the reduction in working hours or downsizing.

Employees of small firms were less likely to costs reduction measures compared to employees in medium and large firms (52.5% from 69.8% average). This can happen just because small firms have a very complex cost structure. For example, reducing development budgets and eliminating bonuses are much less common in these firms, but lower wages is a percentage comparable to other companies. Employees of companies with over 250 employees (36.1%) are significantly exposed to strong restructuring process, while firms in Bucharest notice the largest percentage of employees exposed to the development budget reductions (54.9% from 46.4% average).

2. Concerns for the future

As budgets have already been established by companies for 2010, worries about budgets decreasing over the decline, does not significantly increase the budgets already established. Percentage of employees with higher education who believe that they will take place in the organization actions to reduce personnel costs is significantly higher than the employees already exposed to such actions. Thus, 39.2% think there will be

facing restructuring, 38.3% believe they will have their bonuses eliminated and 25.8% believe they will be deducted from their salary in the organization. (see Figure 1)

The predominant concern in small businesses is related to lower wages, while the biggest concern of those working in large firms is related to the restructuring plans.

There is also a major discrepancy between top management and employees with non-managerial perceptions regarding the future cost reduction activities in the organization: top management sees as more likely to reduce costs through restructuring, while non-management employees expect wage reductions and the elimination of bonuses.

3. Fields and companies analyzed:

- IT (Microsoft Siveco, Oracle, Adobe, Softwin, IBM, Google, Siemens, Hewlett Packard, Route 66, Nokia)
- Telecom (Vodafone, Cosmote, Orange, Zapp/Telemobil, Romtelecom, RDS/RCS, UPC/Astral, GTS Telecom, Media Sat)
- Professional/Media (Media Pro, Ringier, Intact, Realitatea, Catavencu, Deloitte & Touche, Price Waterhouse Cooper, Leo Burnett, McCann Erickson, Ogilvy, Ernst & Young, KPMG Romania, Accenture, Genpact)
- FMCG (Danone, Friesland, Cadbury/ Kandia, Excellent, Kraft Foods, Heineken, Ursus Breweries, InBev Romania/Interbrew, Pepsi, Coca-Cola, Nestle, Ferrero, McDonald's, Unilever, Procter & Gamble, Henkel, Oriflame, Avon, Sarantis/Elmplant, Beiersdorf/Nivea, Farmec Romania, Colgate-Palmolive)
- Financial/banking (Raiffeisen Bank, Millennium Bank, BRD, BCR, ING, CEC Bank, Banc Post/Eurobank EFG, Banca Romaneasca, Alpha Bank, Credit Europe Bank, Unicredit Tiriatic Bank, Banca Transilvania)
- Pharmaceutical (Sensiblu, Help Net, Dona Pharmacies, A&D Pharma, Romastru/Wyeth, Bayer Romania, Zentiva/Sicomed, Glaxo Smith Kline (GSK), Ozone Laboratories, Pfizer, Roche Romania, Sanofi Aventis)
- Distribution/Retail (Carrefour, Auchan, Billa, Mega Image, Kaufland, Selgros, Real, Cora, Plus, Metro)
- Construction/building materials (Holcim, Lafarge, Cement Carpat/Heidelberg, Dufa Deutek, Policolor, Kober, Lasselsberger,

Cesarom, Fabryo)
- Auto (Dacia, Renault, Romcar, Tiriatic Auto, Porsche Romania, Toyota, Automobile Bavaria, Iveco, Pro Truck, Mercedes)
- Other Industries (Petrom, Rompetrol, OMV, Lukoil, MOL, JTI, Philip Morris, British American Tobacco (BAT)) [1]

4. Possible foreign answers to complex situations: solving inner-team problems applying organizational justice principles

Managers facing the actual economic context, in full global crisis and pushed by a fast growing competition generated by the globalization process, whatever the domain they are in, have similar to mostly the same issues. Human resources are the most precious resource a company have, because it can bring profit or can bring the company down.

This is why the managers have to keep in mind that maintaining a general positive climate at work can make employees forget, in part, that they are subject to wage, working hours or personnel reductions and strategies to do so can be very useful in getting the best of what employees can give, without demoralize them.

Next there are shown two possible practical situations and some possible answers to the above mentioned issues, from a foreign managerial point of view, based on organisational justice theories [2]:

1. What are your aims in resolving workplace conflict?

- To make it go away?
- To keep it in-house?
- To keep costs down?
- To create an appropriate organizational culture?

All the above?

Justice theories and their principles:

- Procedural justice (steps taken to resolve)
- Distributive justice (fairness of outcome)
- Interactional justice (being treated with dignity and respect)

These are complicated by *internal dynamics of interests, rights and power*. *Interests*: the desires and concerns which motivate people to bargain or fight for what they want.

Rights: predetermined standards such as entitlements, rules and laws.

Power: the ability to coerce, convince, threaten and take action to obtain one's target.

5. Study case: the Z Company Dispute

What are the points of conflict escalation here?

What are the costs involved in this conflict?

At Z Company, which is a mine, workers store their boots in trays on shelves at the entrance to the bathhouse. Miners cannot report for work without their boots.

Joe finds his boots are missing. This is common for miners due to a combination of theft and pranks.

Joe reports the matter to the supervisor who tells Joe that he will not be allowed to sign on for duty.

Joe is very angry about losing a day's pay and quickly gains support from his fellow workers by calling a snap strike. The company loses a day's production.

What can be done in such situations?

Organizational processes assist conflict resolution and consist of:

- A workable grievance procedure which does not contain too many steps;
- Trained supervisors and managers who are skilled enough to deal with the dispute or refer it to HR;
- Employees willing and motivated to use the formal grievance procedure instead of resorting to other means of resolution;
- HR evaluation of the internal dispute resolution system measured by:

1. Transaction Costs

These are the euro amounts incurred through salaries, delays, tribunal/court expenses.

2. Satisfaction with Outcomes

A measure of how much the resolution fulfilled the interests that began the conflict

3. Effect on relationships

A measure of how well the resolution leaves the relationship intact

4. Recurrence

A measure of the chance of the dispute occurring again

5. Justice

A measure of how well the resolution satisfied the elements of justice

Procedural Justice

- Focuses on the fairness of the dispute system process

- This has resulted in set of rules often referred to as the 'rule of law':

1. Charge is relayed to the accused in writing with detail

2. Accused has an opportunity to defend him/her self

3. Decision maker is neutral

4. Decision maker provides reasons for decision

Distributive Justice

- Focuses on the fairness of the distribution of a scarce resource

- We judge the fairness of distributions according to:

- Equality (all get the same)

- Equity (more goes to the greatest contributor)

- Need (more goes to the needy)

Interactional Justice

- Focuses on the fairness of treatment within the dispute system

- People who have been treated with respect and dignity tend to accept the outcome of the dispute even if it is not to their advantage

The impact of justice on dispute outcomes:

- Procedural justice is a powerful predictor of acceptance of the outcome

- Importantly interactional justice together with procedural justice predict acceptance of the outcome regardless of the type whether the outcome is favorable or not.

- Disputants who receive procedural and interactional justice are more likely to blame themselves for a poor decision.

- Disputants denied procedural and interactional justice will not accept the outcome if it is unfavorable and will distrust their managers whether the outcome is good or bad.

6. Study case: John

Supervisor's report:

I am the Manager of the Survey Team. We conduct and analyze all the market and feasibility surveys for the organization. It's a small team and we certainly depend on the good will and hard work from our team members. Three months ago, I was offered the services of a surplus employee, John, who had worked for 28 years in the trades' area as a manager. He had good general

office skills, some research and certainly, marketing skills. I was keen to expand the team and was very happy to take on John.

Shortly after joining the team, John developed a very antagonistic attitude towards me as his manager. I don't know whether he has a problem with working with a woman. I have counseled him, but he remained sullen and refused to really talk. He has stirred up a lot of trouble in the team, and I think he's spread a great deal of discontent.

He is also unreliable and he is often away ill. He is simply not working out, and my advice from senior management is that I cannot dismiss him.

John's response

"After 28 years with the trades section my whole career was destroyed by an arbitrary decision by management to close it down and outsource it. I cannot believe after all I've done for this place and for all the work I've put in, that this is the thanks I get. So, they told me that I won't be let go - that they had other jobs for people like me who were surplus to requirements. You know what they've got me doing? Clerical work. I've been a manager for 15 years and now I'm a clerk. Oh, they pay me the same money, but it's not the money is it?

I am just so angry. When I go to work, I can hardly think for being so angry and upset that my section got the boot and other areas, like this stupid survey team can still keep operating. Look at their budget and the returns they bring in. What a joke!" [3]

Organizations from all over the world, including Romanian ones, who create a sense of organizational justice will obtain the human capital rewards in improved motivation, retention and fewer employment lawsuits. Unfortunately, companies who don't, may find themselves in the situation of not only losing a competitive possible advantage, but even getting themselves in the situation they have to close down.

According to an American study from 2008, companies find themselves in great difficulty not only in retaining employee, but also in recruiting them. Difficulties in retaining high quality staff are the biggest concern companies face through globalization, according to a study by the Economist Intelligence Unit on behalf of business advisory firm EquaTerra. North American executives were found to be 12% more likely than European ones to cite globalization as a challenge to retaining skilled

staff. Western European executives found their primary challenge was funding expansion into new markets. [4]

One of the possible solutions, for Romanian managers, if they are willing to apply it, lays in the complex employer-employee relationship and the degree of trust they give to each other. Interactional justice within an organization can make the *real* difference, even when people are downsized or salaries are reduced. People tend to get more tolerant with these problems when they are treated with dignity and respect and kind of "all alike".

The ones that want to survive in actual crisis and globalization context has to take whatever measure necessary for their business to "breathe".

7. Conclusion

- The provision of organizational justice – particularly procedural and interactional – will enhance acceptance of dispute outcomes and should underpin all decision making processes including performance appraisal, recruitment and promotion interviews;
- Grievance procedures provide a structured approach to ensuring workplace justice but:
 - Supervisors and managers need training (in process and interactional justice)
 - Employees need encouragement to use the internal processes
- Grievance procedures should be reviewed to ensure *Transaction Costs* are low; that there is *Satisfaction with Outcomes*; that there are no negative *effects on relationships*, that *Recurrence* has not occurred and that *Justice* was delivered [5,6].

Figure 1. Romanian case study-higher education sample

Changes made in the organization	%
Budget cuts were made (professional development, marketing, research, rewards, etc.)	44.7
Bonuses were eliminated	30.5
Restructuring took place	30.2
Low wages	19.1
A number of employees/all personal is working part-time	9.0
Some staff entered technical unemployment	8.6
None of the above	30.2

The Impact of Knowledge Management Systems Upon the University of Petroșani

Cucu Ioan

cucuiosan2002@yahoo.fr

Isac Claudia

isacclaudia@gmail.com

University of Petroșani

Abstract

Applying corporate Knowledge Management principles in universities has already proven to be one of the best ways to increase the administrative efficiency of the institutions as well as support researchers and faculty. However, implementing such a system has its barriers, mostly due to the poor understanding of the concept (and its long-term benefits) and due to the unstructured, closed sharing policies. The paper tries to provide some insight into how universities position themselves in relationship with knowledge management and knowledge sharing concepts.

Key words: knowledge management system, Efficiency, barriers, sharing policies;

JEL classification: I21;

1. Introduction

Considering the concept of *knowledge*, we find it is defined as the sum of what it is known, the body of truths, information and principles held by mankind. Knowledge is directly linked to intellectual abilities but also to observation, experience, study and investigation.

Knowledge Management is a more recent concept that implies that collection, storing and distributing information in a company in a structured, organization manner, leads to the increase of efficiency of its processes. The many success-stories in the area of Knowledge Management and the increased use of technologies in business processes and business

administration are a strong basis for the development of the *Knowledge Economy* concept, where capital and natural resources are no longer the main production factors, being superseded by Information (or Knowledge).

Facing the challenges of the businesses environment is hard to speak of, but in order to have a higher growth rate than similar companies, every wild card should be used. Knowledge Management can be just such a wild card, helping businesses on many levels. Personnel turnover, for instance, is one of the main issues every company has to face. Recruiting, selecting and training new employees, as well as disruptions in the normal business processes cause high undesired costs.

In order to deal with it, several actions can be taken: better employee motivation with specific human resources techniques, development of better company internal branding and corporate culture. Some voices even argue that this process is not entirely bad, as long as the best, most efficient employees don't leave the organization (the Applebees company in the USA is known to split its employees into three categories: very efficient - 20%, medium efficient - 60%, low efficiency and focuses its personnel retention efforts only on the first two categories) [9].

No matter how the issue is looked upon, turnover is a constant in every organization, thus new employees are constantly brought in. Their performances however, and their adaptation time is in direct link to the organization's integration and knowledge management policies.

2. Implementing Knowledge Management Concept within Higher Education Institutions

Knowledge Management researchers and practitioners - [6]; [8] - have agreed on the importance of Knowledge Management Systems in organizations: it is important for organizations to “know what they know”, to provide their employees with a constant growing base of information *anytime-anywhere*.

A study published by the *Knowledge Management Magazine* and IDC [4], revealed that the main reasons of adopting Knowledge Management within American organisations are the following:

- Retain expertise of personnel (51.9%);
- Increase customer satisfaction (43.1%);
- Improve profits, grow revenues (37.5%);
- Support e-business initiatives (24.7%);
- Shorten product development cycles (23.0%);
- Provide project workspace (11.7%).

The same study shows that the primary business uses or domains of Knowledge Management are to:

- Capture and share best practices (77.7%);
- **Provide training, corporate learning (62.4%);**
- Manage customer relationships (58.0%);
- Deliver competitive intelligence (55.7%);
- Provide project workspace (31.4%);
- Manage legal, intellectual property (31.4%);
- Enhance web publishing (29.9%);
- Enhance supply chain management (20.1%);
- Other (5.5%).

Later studies - [1];[4] - have shown that **the impact Knowledge Management Systems** have on the overall efficiency of a business **can be replicated to universities** even if there are some differences in the management style and the organization mission itself. However, researchers found there are important opportunities to implement Knowledge Management Systems to support every aspect of their activity: „Knowledge Management should not strike higher education institutions as a radically new idea; rather it is a new spin on their *raison d’être*” [3].

Another important finding is that the social dimension of Knowledge Management Systems – represented mainly by communication and

collaboration patterns and practices (or in the terms of KM – *knowledge sharing* patterns and practices) has a great importance in the success of implementing such a system, sometimes exceeding the importance of the other components such as hardware or software. In many cases, although collaboration – as a process where two or more people who share a common goal work together, share knowledge, exchange ideas and build a unitary result [7] is widely accepted as the most efficient method for creating value, some important barriers of knowledge sharing arise leading to the creation of *non-collaborative* environments.

3. Study regarding Knowledge Management and Knowledge Sharing within the University of Petroșani

The current situation regarding Knowledge Sharing was assessed based on a small survey conducted among the members of the Computer Science department at the “University of Petroșani”. The questionnaire based study was run on all the members of the department thus making its results reliable and representative.

The questionnaire comprised of several themes spread through 20 questions and shows, among other aspects, the degree in which respondents know the concept of Knowledge Management, how they see its importance for an organization and some variables that assess the knowledge sharing practices: the number of articles / books or other type of research offered to colleagues and the number of article / books or other type of research received from colleagues.

The findings are as follows:

- On the first theme – **Knowledge Management concept awareness** - we found that only 50% of respondents know what KM implies. Looking further, at the level of understanding respondents claim to have, 50% of the respondents that know what Knowledge Management means (25% of all respondents) have a basic knowledge of the concept and 50% (or 25% of all respondents) have a medium knowledge of the concept. None of the respondents claimed have a good understanding of the concept through study and/or practical experience. Another related finding was the importance of the sub-group respondents were part of: Mathematics group

to and Informatics group. The findings show that the respondents from the Informatics group have more knowledge regarding Knowledge Management Systems than the Mathematics group: 71.4 % to 20% (the 50% average is achieved because the Informatics group is slightly larger than the Mathematics group). Interesting was also the fact that age does not seem to have an effect on Knowledge Management awareness, the answers being spread evenly among the three age intervals proposed: under 25 – 40, 41 – 55 and over 55;

- Considering *the importance of Knowledge Management Systems in the University*, the findings show a “positive feedback” with 25% of respondents choosing “useful” and 25% of respondents choosing “very useful”. 50% were missing answers, since those respondents do not know the concept of KM thus cannot have an opinion regarding its importance. Another interesting aspect is the tendency to give more weight to KM Systems as the personal knowledge of the concept increases (the Spearman and Pearson correlations show a direct connection even if it is only a medium connection);

- Furthermore, considering *the agreement to implement a Knowledge Management System in the university* and also the agreement to help in such an implementation, we found that no respondent is against it: 67% are positive towards it, while 33% can't answer / don't know. Moreover, 58% of respondents agree to help in an implementation project even though most of them (43%) only offer a couple of hours each week;

- Regarding *Knowledge Management barriers*, from the 50% that answered the question we found that 83% consider there will be difficulties for the implementation of KM Systems with the main one being the difficulty to change existing mindsets and systems (60% of the respondents who answered there could be problems). Other barriers were lack of time (20%) and poor communication (20%). The age of the respondents came into effect here, but in a awkward way: most of the respondents over 40 years old didn't answer the question (either because they don't know what KM is, either because there are not sure regarding problems

that may arise), while most of the respondents under 40 said there will be some barriers. That basically implies that the younger respondents believe that the current mindset will be the most difficult thing to overcome and that this is mostly due to their older colleagues. However, we would like to underline a limitation of our study in this aspect – the fact that 75% of respondents were in one age category. Further inquiry is necessary, including rearranging the age intervals;

- *Communication and overall collaboration and appreciation among colleagues* is another aspect we tried to asses. First, we asked the respondents to name three of their colleagues and their taught subject, with the professor-subject association being our main interest. Only 58% of the respondents could name all three and 16% named only two. Some (8.3%) could not make any correct professor – subject association and some made only one correct association. When analysing the mentioned professors we found that the most named professor was the newly appointed head of department and the second most named professor was the head of the International Relations department – which could imply that formal power is an important aspect of the respondents' mentality. When looking at this issue while considering the two groups we found that 90% of answers from the mathematics group named other professors in the mathematics group (and 10% from the informatics group) while 80% of answers from the informatics group named professors in the same group. This shows that group belonging is still highly important and more important for the mathematicians, mathematics being the older of the two groups. The other ways we tried to assess communication and collaboration was to ask the respondents to name five of their colleagues and their research interests and also five colleagues and their extracurricular activities. The findings show no profound communication practices: only 50% could name five professor – research association and most of respondents (58%) could not name at least one extracurricular activity of their colleagues;

- Regarding *Knowledge Sharing*, most respondents (90%) said they have received 0-5 books or articles from colleagues and all respondents admit to not having written any review for books / articles of colleagues. What we found to be intriguing is a contradiction between received books and articles and offered books and articles: 50% of respondents considered they did offer some of their work to colleagues (25% consider they offered 10-25% of their work and 25% consider they have offered over more than 50% of their work). While we cannot at this point be sure of all the reasons that led to this contradiction, we can imply a certain lack of structure: while some might have received papers from colleagues, they didn't find the time to read them, or even forgot about receiving them; on the other side some might have had the intent to offer some works to colleagues but didn't actually do so. Another aspect we take into account is the difference in scale: while the first question had a value based scale (0 to 5 articles, 5 to 10 and so on), the second had a percent based scale (0-10%) that could fit in some specific contexts. The percent based scale was chosen because of the need to determine not only the actual number of papers offered by respondents to their colleagues, but also (and more importantly) the degree of openness – what that number represents (10% of 5 papers is different than 10% of 50 papers). We are considering some change for the scale of these questions and even adding more questions or an in-depth interview to better evaluate the sharing policies;
- The last issue that we wanted to determine is *how respondents consider their colleagues' abilities as teachers and researchers as well as how they see themselves in relation to their colleagues*. The findings show a slight positive feedback: most of the respondents (54%) consider that the general level is “good” (on a scale consisting in below average, average, good, very good), while 36% consider the level as “average” and 10% as “under average”. Considering their relation to their colleagues, have more 30% consider themselves to be better than the average of their colleagues and 70% respondents who consider themselves better expectations thus they see the general

level lower. This finding could be another factor to take into account in relation to the non-collaborative environment: lack of knowledge is considered one of important barriers towards knowledge sharing (as shown by [2]).

4. Conclusion and Future Work

As paradigms on knowledge and knowledge creation shifted from the academic world towards corporations and other professional organisations [1] and with the impact of Globalization that led to “education being regarded as a commercial product, governed essentially by market forces” [5], universities in developing countries found themselves in a strong competition both on a national and on an international level.

Considering this tendency, conclusion of the study and observations made below, it is safe to say that the competition between organisations duplicated to a competition inside each organisation, where employees compete for acknowledgement, better positions and increased revenues. Personal interests still carry the most weight and when competitive advantages are based on personal knowledge – such as in the case of universities, *knowledge sharing* is less embraced.

Our future work aims to pursue two different aspects: the first aims to extend the study to partner universities, to establish the existence of knowledge sharing patterns (or lack thereof) in Romanian universities; the second will attempt to bypass the knowledge sharing barriers and implement a Knowledge Management System at the University of Petroşani.

Abstract

This article is about company's approach to innovation and how innovation could contribute to a useful strategy making. It is hard to open a business publication without finding optimistic articles on successful innovators. The message usually is, "innovators win" and it's reverberating in nearly every management suite. However, in companies that don't have a history of innovation, have made it primarily an R&D issue, or are struggling to make their innovation efforts pay off, executives need specific guidance on how to tailor a successful innovation strategy to their individual company situation.

Key words: innovation, useful strategy, R&D;

JEL classification: O30;

1. Beliefs about innovation

Some time ago, most executives viewed innovation as matter of coming up with new products or services, which was primarily the job of the company's R&D department. If pressed, they would have likely maintained that breakthrough innovations – innovations that significantly change customer expectations, the basis for competitive advantage, or industry economics – were either the result of dumb luck, or originated with a visionary leader like Steve Jobs, Richard Branson or Akio Morita [2].

But such views of innovation have become

obsolete. Drivers such as globalization, the blurring of industry boundaries, the explosion in the availability and accessibility of information, the increasing dispersion of knowledge, and the growing use of alliances and partnerships have dramatically shifted the landscape of innovation. As a result it is urgent that companies re-examine their assumptions about innovation and purge three common obsolete ideas [7]:

- Innovation is all about coming up with new products and services. New products and services are still vital to growth. But there are several other ways in which companies can innovate. Leaders need to ask themselves what new customers they might serve and what these customers need, how they might configure their value chain differently, and what alternative economic model they might use.
- Innovation is solely the job of the R&D department. Research and development are always important in innovation. But every group inside the company and beyond it – such as partners, customers and suppliers – need to be involved as well if you want to find opportunities to innovate that will produce competitive advantage.
- Breakthrough innovation occurs only through luck or a stroke of genius from a visionary leader. Luck is good and having an innovative genius leading your company is wonderful. But the majority of companies can't rely on either. So they

need to design and implement a systematic innovation process to maximize the chances that they will identify and take to market new profitable opportunities time and time again.

2. Design your innovation program

Once you are willing to challenge these three obsolete assumptions, you are ready to start designing your innovation program. A simple way to organize your thinking and actions about innovation involves challenging each outdated assumption by asking three key questions: What is the purpose of innovation? Who should be responsible for innovation? How do you innovate? The “what” of innovation: from product/service to business model [3].

3. The “who” of innovation

If members of a company’s R&D department aren’t the only people who should be involved in innovation, who else should be? The answer is two-fold: most functions, levels, business units, and geographies within the company have an important role to play; and outsiders to the company should get involved as well.

The *how* of innovation: from serendipity to systematic process. If it is systematic, it can’t possibly be creative! This is another obsolete idea, and one that successful innovators have overturned, as evidenced by the results of some surveys. It found that firms that had an established innovation process out-innovated firms that didn’t. An innovation process is critical to bring structure to a fundamentally unstructured activity without a process to bring order to the chaos this money is wasted.

The trick is not to let the process get in the way of the creativity of the participants – to use “disciplined imagination”. The simplest way to do this is to adopt an innovation process that allows for several successive phases of divergence and convergence. In each divergent phase, the emphasis is on exploration. In each convergent phase, the focus is on making choices and decisions [6].

In the first phase (discovery), the exploration (divergent) step aims at developing a wealth of new insights about the world and the company. The focus (convergent) step aims at selecting the ones that are the most compelling and the most likely to be of help in generating new

opportunities. In the second phase (opportunity generation), the objective of the divergent step is to generate lots of new ideas about what the company might do differently, while the convergent step focuses on selecting the most compelling ones. In the third phase (realization), the objective of the divergent step is to explore alternative business models for bringing to market the ideas that have been selected by running focused marketplace experiments. In the convergent step, a decision is made on the most appropriate business model for actually going to market and eventually scaling up the idea into a full-fledged business.

4. Initiative deadfalls

Companies that overcome obsolete attitudes and concepts about innovation and adopt the innovation architecture to organize their efforts will be well on their way to rejuvenating their innovation engine. Experience indicates, however, that there are a number of serious missteps that can trip up your program. While the obstacles executives encounter obviously varies from company to company, here are some of the most common ones we have seen, and ways to avoid them [4].

1. Overly relying on customers to find solutions. Meeting unsatisfied customer needs is the ultimate rule for successful innovation, but often customers have difficulty expressing what their needs are – let alone how to meet them. Often they can only convey a preference among current options. So observing customers in their own setting is essential for understanding their unsatisfied and unarticulated needs.

2. Generating ideas without new insights. People often equate idea generating with getting a group of people in a room in front of a set of blank flip charts. However, it’s incredibly difficult to generate useful new ideas without appropriate stimulus. So instead of asking “what new opportunities might we pursue?”, focus your team’s thinking on the ways in which you might identify and overturn your company’s obsolete assumptions, identify and serve unmet customer needs, recognize and take advantage of major external changes, leverage your core competences in new ways

– or better yet, do several of these things simultaneously.

3. Assuming that innovation is about making a few “big bets”. Many think innovation is inherently risky and always involves making big bets on unproven concepts. But most of the risks can be reduced by systematically testing the key questions about a new opportunity using focused experiments in the marketplace. This testing process provides initial answers to such questions as: Will target customers like the offering? Can we deliver on the value proposition? Can we construct a viable economic model that will make us money? And can we create sustainable competitive barriers?

4. Failing to give innovators time, training and tools. Some companies wrongly assume their employees can immediately become innovative when their bosses send out the marching orders. In the late 1990s, a leading industrial equipment manufacturer gave an internal team the mandate to come up with innovations that would help it maintain its leadership position during the next decade. When the expected results didn’t come in, the team was asked to diagnose why. They found that team members had been provided little training in innovation best practices, had been given few tools to facilitate their work, and were spending only 5-10 percent of their time on the effort. We told the executive team that unless they were prepared to do it right, they should kill the initiative. To its credit, the executive team accepted the feedback, devoted the necessary resources, and moved forward with a program that was ultimately very successful.

5. Confusing “involving many people” with “making it a free for all.” Involving many diverse groups from inside and outside of the company is key to generating interesting new ideas. But some companies make one or more of three mistakes. Some enjoy the diverging part of the process so much that they keep on creating lots of ideas – but then they forget to converge and select, and therefore never get anywhere. Others assume that any good idea is a good idea for them, when in effect some ideas might be better implemented by another company. Others let the people involved in the innovation process make all the decisions through a democratic vote – but executives should never abdicate their ultimate decision-making responsibility, even to promote wider involvement.

6. Letting a systematic innovation process become bureaucratic. There is enormous merit,

as described above, in adopting a disciplined innovation approach with a clear process, roles and responsibilities, due dates and the like. But sometimes, an overly eager project manager intent on making sure that everything gets done on schedule will let the calendar take precedence over the content and the quality of the outputs.

A consumer packaged goods company was working on developing a launch plan for a new concept that had passed the initial screen. As team members diligently followed the prescribed process, they discovered that the original customer research did not contain sufficient information to inform some intricate product design choices. Facing the prospects of missing the launch timetable that they had committed to, the team decided to launch the product without conducting additional research. As a result, the product was poorly received – a clear example of internal deadlines overcoming common sense.

7. Failing to insist on sufficient involvement from the executive group. When a large and diverse group engages in the innovation process, it’s tempting for top executives to postpone their involvement until they need to make decisions. If that happens, the innovation team needs to draw the executive team into the process, and to refuse to move forward if it doesn’t succeed. Otherwise, when the time arrives to start investing in the recommendations of the innovation team, the executives won’t understand the rationale for the investments and will either veto the recommendations or force the team to waste enormous amounts of time “replaying the movie” from the beginning.

5. Starting the initiative

That innovation is an unavoidable imperative is no longer in doubt. That innovation can be achieved by any company that sets its mind to it and implements a systematic innovation process has been demonstrated by the success of many firms – large and small, high tech and low tech, selling products or services, based in developed and developing countries. The key issue for executives is to figure out how to get an innovation effort with a high likelihood of success started in their

companies [5].

As a first step, use the innovation architecture to organize your innovation efforts. Determine who should be involved – erring on the side of broad engagement and remembering that in every company, imagination and creativity are randomly distributed; train the team you have assembled in the what (business model) and the how (systematic innovation process). Free up enough of their time so they can be effective, and warn them of the pitfalls they are likely to encounter.

Then, send them off on their discovery mission. Ask them to address new questions that typical planning or innovation processes don't address. In this phase these are: What are the outdated assumptions that we have (and that our competitors may well have as well) about our business that we might consider overturning? What are the unarticulated needs of our customers, and as importantly of our non-customers? What discontinuous changes are about to occur in the environment that we might be able to capitalize upon? What true core competencies does our company have that we might be able to leverage in different ways? And once they come back to you with answers to these questions, have them move to two by generating ideas that capitalize on the insights generated during the first phase [1].

As importantly, get and stay involved in the process as a coach, resource and sounding board – but not as a traditional reviewer or as a doubting one. Based on experience, you will be pleasantly surprised by the results.

Abstract

This article describes how top firms structure their intelligence teams, how the teams operate, and how they contribute to strategy making. Every business confronts some set of crucial business issues and strategic decisions, a unique combination of specific competitive changes that needs to be explored and specific choices that must be made. Each business issue or strategic decision must be supported by vital, forward-looking intelligence. For the corporate leaders and intelligence professionals, the challenge always is to understand the potential turbulence inherent in the relevant competitive or marketplace environment.

Key words: intelligence team, top firms, strategic decisions, marketplace environment;

JEL classification: M54; I29;

1. What intelligence teams do

An intelligence team is a group of individuals who work together to develop a deep understanding of a specific business issue with the intent of developing strategy-relevant insights, action possibilities, and recommendations. Based on our work across many organizations, intelligence teams designed to address core intelligence

challenges share a number of attributes. Team members are drawn from diverse functional departments or organizational units. They are typically headed by an intelligence professional whose dominant charge is to ensure that the team not only works efficiently and effectively but that it generates insights that add significant value to decision making. [7]

Intelligence teams almost always consist of both core and transient members. Core members assume responsibility for the team's process and outputs and typically include one or more intelligence professionals who manage the analysis process and ensure that the outputs support decision making. Transient members contribute specific knowledge or expertise at a particular point in the analysis and serve the role of connecting the team to key decision makers or external sources of information. Intelligence teams are charged with identifying and analyzing potential discontinuities in specific technologies, key transient members included external technology experts who were invited to participate in the middle stages of the team's work.

2. The focus of their work

Intelligence teams are not required for all facets of a firm's intelligence work. Firms create intelligence teams to address the "big" intelligence challenges. Executives and intelligence professionals thus must address an unavoidable question: What issues and decisions give rise to intelligence challenges that warrant the creation of an intelligence team? Answering this central question, we need guidelines that aim to weed out intelligence challenges that might seem to merit the team approach but actually do not.

Intelligence challenges that do warrant the team approach are simply too complex, ill-structured and substantial to be comprehensively and systematically addressed by just one or two individuals. Exploring likely developmental paths of alternative energy sources or possible strategic shifts by rivals in response to emerging technological discontinuities – two intelligence challenges being considered by a large industrial products firm – illustrate the need for a team dedicated to thinking broadly and digging deeply in domains that may be unfamiliar to the organization and characterized by multiple uncertainties. [3]

Here are some guidelines that aim to create broad-based teams with the requisite analysis capabilities:

Executive involvement. The executive "users" or "clients" the individuals who most need to learn from the intelligence and deploy its outputs in decision making must be, directly or indirectly, centrally involved in the intelligence team. Serving either as core or peripheral team members, they introduce key questions and challenges into the team's deliberations and learn first-hand the nature, extent and implications of the relevant uncertainties. Seasoned intelligence professionals leading a team can "manage" the well-known tendencies of executives to look for evidence to support their predetermined conclusions, to shorten the analysis process at the expense of considering multiple points of view, and to accept the first plausible "answers" to the intelligence challenge.

Breadth of data inputs. Never allow a team to be dominated by representatives of one functional unit or department. Individuals drawn from multiple areas contribute diverse data inputs: access to departmental data bases, secondary sources and prior analysis; data

obtained through their unique access to external sources; questions specific to their functional expertise; and enhanced ability to gather additional data inputs through interviews (e.g. customers and channels) and secondary data searches.

Diversity of perspectives. Insights are more likely when team members bring distinctly different perspectives to exploring an issue, identifying preliminary findings, specifying tentative assumptions or challenging emerging points of view. Thus, it is often necessary to choose one or more team members who are known for their willingness to challenge the conventional wisdom or who can develop and sustain constructive tension in the early stages of idea development and hypotheses generation.

Range of analytical skills. If appropriately structured, a team can deploy many analysis frameworks to make its way through the analytics of any intelligence challenge. The uncertainties that must be addressed in most marketplace issues, for example, rivals' changing strategies or technological shifts, require many different forms of skills and expertise.

Managing the team: shaping the team context. Intelligence team members –like any other type of team – may suffer the usual forms of distraction that can easily inhibit the emergence of a committed and smoothly functioning team. They report to other masters; they may not fully understand the potential organizational benefits of the intelligence project; they may feel that there is little benefit in the project for their own unit or department. Thus, rare is the intelligence team that comes together "naturally". In short, the context for an intelligence team must be shaped with great care if the team is to be something more than simply a set of individuals coming together to complete a task only because they have been asked to do so.

Here are three elements that when addressed as a group, establish a context for an intelligence team. [2]

Shape the strategy stakes. Make explicit that surmounting the intelligence challenge will contribute significantly to specific strategic and operational goals. Reconfiguring the strategy to avoid further loss of key accounts, or stated positively, to

build the “customer value proposition platform” made it clear that the stakes inherent in the intelligence work were of the utmost importance to the organization. Some organizations use a kick-off meeting as a forum for one or more senior executives to express how and why the intelligence project is central to strategy making.

Establish the intelligence charge. Often it is necessary to emphasize that all facets of the intelligence challenge are “on the table”; nothing is to be short-changed, downplayed or delayed. The executive team declared that no aspect of the firm’s prior strategy should escape analysis and any factor that influenced customers’ buying processes and predispositions should be investigated. The firm’s “sacred cows” and non-discussable issues, including its assumptions about how to do business in this key product segment and the reasons why customers traditionally bought from it, should be “put on the table”.

Create the executive platform. Intelligence teams become energized when there is an explicit expectation that the team will present its work to decision makers. Senior executives informed the intelligence team that it would present preliminary outputs to the monthly executive meeting, and the final outputs would be presented to all functional groups and to a specially designed session with the strategic planning group.

Managing the teams. Executives often lament that intelligence teams take too long to develop valuable outputs – outputs that feed directly into decision making. A common complaint is that the intelligence team becomes bogged down in its own processes. Upon investigation, what we usually find is that the team actually did not have an established analysis process and thus had no generally accepted team guidelines for collecting and transforming data into fast, insightful outputs.

Analysis intent. A succinct one- or two-sentence declaration of analysis intent focuses all members of the intelligence team on what needs to be accomplished.

However, as with all things in the case of intelligence teams, analysis intent may be a moving target. As team members dig deeper into the competitive context, learn more about the relative capabilities and competencies of their own organization, and become more comfortable with their collective analysis prowess, they may choose to extend and refine both the scope and

the intent of the analysis. [5]

Test leveragability of potential results. Analysis intent, by itself, does not indicate whether, and/or how, specific “findings” or “insights” can be leveraged by the organization. Although analysis intent always suggests likely or potential results (that is, findings and insights), rare is the intelligence team that will be able to anticipate all the results of its work.

Emphasize insights. Analysis intent and leveragability of potential results are both influenced sooner rather than later if from the outset the intelligence team emphasizes insights as the key analysis output rather than simply developing “data dumps”. Insight typically involves new understanding of a context or situation. Thus, attention to insights compels the team to address explanations of a context or situation rather than just describing or delineating it.

Intelligence team members can enhance both the quality and speed of the analysis process when they develop, communicate and test insights with each other once they have begun to collect and share data. Stated more emphatically, insight derivation should not be postponed until all or most data has been collected. [6]

Develop early inferences. Teams reach insights faster when they establish the following operating norm as a core feature of analysis process: draw inferences early in data gathering and test them with fellow team members. Once they conducted interviews with individual customers and with industry experts, team members developed specific inferences about what was causing customers to shift their specifications of the desired solution, why some competitors were responding faster than others to the changing needs, and why their own firm appeared oblivious to a shift in the internal dynamics within a number of customers.

Integrate alternative views. Central to the rationale and process of intelligence teams is the ability to generate and integrate alternative frames of reference or “views” into the analysis process. Alternative perspectives serve as the antidote to group think, the scourge of analysis in all organizations. Where group think prevails, the intelligence team loses its vitality; and it

is not likely to generate genuinely new insights.

Alternative views can be integrated into the team's work in multiple ways. Team members can adopt the perspective of customers, channels, suppliers, governmental agencies, current rivals, potential new entrants or even substitute product rivals. Sometimes these perspectives involve role playing – such as when the analysis intent is to anticipate and project rivals' likely strategic moves, or how a prospective new entrant might enter the market, or how our own firm might respond to rivals' incremental or radical strategy shifts.

Many intelligence teams formalize such role playing in war gaming, competitor profiling, scenarios, and even computer-based simulations. [1]

Because of the inherent uncertainty and ambiguity of the business issues and contexts they address, some intelligence teams find it necessary to identify distinctly different assumptions and then to test and refine those assumptions as a core element of its analysis process. Such alternative assumptions formalize the integration of alternative perspectives into the team's deliberations. One intelligence team analyzing the anticipated emergence of new products developed alternative assumptions around the source and speed of new product introductions. Some assumptions: products would emerge from traditional rivals or "new" rivals, they would appear in large or small volumes, and they would penetrate the market slowly or more rapidly. The alternative assumption sets allowed the team to identify distinctly different strategy implications and to present each set of strategy considerations to the management team for separate discussion. [4]

3. Intelligence team applications

Competitive strategy development. An intelligence team analyzes and projects a specific competitor's marketplace strategy, leading to the formulation of a strategy to compete with that competitor.

Strategic planning. An intelligence team identifies and assesses key assumptions with respect to the current and emerging competitive context. The intent is to ensure that the firm's strategic plan is tested against critical assumptions and that those assumptions are monitored to indicate as early as possible to need to adapt the plan to changing external

circumstances.

Major investment decisions. An intelligence team identifies alternative choices and likely competitor responses to investment plans associated with new plant construction or key technology programs new product introductions. The intelligence team serves as a competitor surrogate to "test" the roll-out plan's effectiveness.

Technology assessment and monitoring. Intelligence teams are used to assess the current state-of-technology – particularly the competitors' – in a given industry, projecting its likely future development and market introduction. The intelligence team continues to monitor the technology's progress, including competitors' R&D programs, so that you can decide whether your own technology program needs more resources or funding to ensure your R&D efforts are successful.

Supporting sales and marketing efforts. An intelligence team analyzes key marketplace trends in order to provide "tactical intelligence" and advice to sales teams as they prepare for client calls and to shape subsequent "offerings".

Major program/project bids. Intelligence teams play the role of competitors' in preparing and making large contract bids. Such efforts are used to shape and strategize such bids.

Win/loss assessments. An intelligence team prepares and executes win-loss analysis after the results of major contracts are announced. The intent is to better understand competitor bidding strategies and thus develop solutions more likely to win in the next contract process.

Competitive benchmarking. Intelligence teams are ideal for planning and conducting product and process benchmarking, especially when it involves current or potential competitors.

Merger and acquisition activities. Intelligence teams play a critical support role in merger and acquisition efforts. They help ensure the merger and acquisition Team is not blind-sided or out-manoeuvred by competing bids from either existing competitors or new firms intending on using the acquisition to enter the firm's markets. [8]

4. In sum

Intelligence teams help ensure that intelligence about external realities is not only insightful but relevant and useful to a range of critical business decisions and actions. They enable learning that takes individuals out of the comfort zone of their specific positions and functional units. Increasingly, they are viewed as ideal platforms for individuals up and down the organization to develop analysis skills and substantive expertise that will be helpful to them as they rise in the organizational hierarchy.

Future Exigencies Regarding the Necessity of Reorganization of the “CN CFR” National Society

Dăneci-Pătrău Daniel
Universitatea Spiru Haret
danusidenima2@yahoo.com

Abstract

The expansion of the societies' activity, internationally, suppose the development of the business complexity they produce and especially the expansion and the diversification of the instruments of the human resources management that they use to administrate cultural, economic, social, political and institutional variables which influence their activity in each country. All these evolutions determine the rethinking of the human resources strategic role at the organization level, people being considered the main competitive advantage they possess. A railway transportation system is seen, in most countries as an essential precondition for the overall economic development and for this especially, they allocate considerable amounts of resources for the construction and the improvement of the railway, but also to streamline and optimize the human resources system.

In this article, I presented the objectives and the principles of reorganization of the “CN CFR SA” National Society taking into account the SWOT analysis of the activity of the railway infrastructure and exigencies at present and in perspective regarding the human resources management in the railway transportation in Romania.

Key words: CFR Romania, railway activity, human resources role.

JEL classification: R49;

1. Introduction

Railway management has as purpose the maintenance and the improvement of the existent railway network, to allow its continuous use, through commercial exploitation of the traffic in an efficient and secure way. In addition, adequate management has to take in consideration the problems concerning the

productivity and the efficiency of the human resources use. The railway management can be seen as a process that tries to optimize the general performance of the management of the railway network over time [4]. The railway transportation effects are important; it is an essential component of the economic and social development process often absorbing a great proportion of national budgets. There is a strong correlation between the kilometers made and GDP. This fact helps the development through the trade facilitation, nationally and internationally too, improving population access to jobs, education, health care and other services.

The work relation is a characteristic element in all human resources management aspects. At its elementary level, the work relationship is given by a singular combination of convictions adopted by an individual and his employer regarding to what they expect one from another. The term ‘work relationship’ describes the relationship that existed between employers and employees at job. These relationships can be formal, as work agreements, procedure agreements or they can be informal, for example psychological agreement, which express certain presuppositions and expectations about what they have to offer and are willing to efficiently bring the managers and the employees [2]. Rousseau and Wade-Benzoni make distinctions between two types of agreements that define the work relationships namely: *transactional agreements*- they have conditions regarding the exchange between well defined parties expressed in financial terms; they have a limited duration and specified requirements about performance and *relational contracts* - are less precisely defined, in terms more abstract and refer to a negotiable quality of an organization member [3]. Performance requirements added to the continuous negotiable quality of organization member are incomplete or ambiguously formulated.

Work relationships can also be expressed in terms of psychological agreements, which after Guzzo and Noonan have both transactional traits and relational characteristics [1]. The concept of psychological agreement expresses the idea that, at its level or at the most basic level, the work relationship consists of a unique combination of beliefs that an individual and his employer have in connection to what each expects from each other.

The concept of work relationships is important for the staff specialist inside the railway transportation society because it governs most of what they have to know and to take in consideration the company the moment when the latter elaborate and apply human resources processes, politics and procedures. All these have to be considered in terms of contribution that they can or cannot engage in the development of a productive and satisfying work relationship between the parties involved.

2. The current situation of CFR SA National Society

The railway infrastructure management, public or private property of the state is assured in Romania by the Railway National Society, "CFR" SA. The society has the statute of a commercial society on shares and it develops businesses of a national public interest, with the purpose of carrying out the public railway transportation, having as main objective:

- The railway infrastructure management and making it available to rail carriers, according to law;
- The development and modernization of railway infrastructure in Romania in line with European standards to ensure compatibility and interoperability of European railway transportation;
- The leadership, organization, planning, coordination and control of exploitation, maintenance and repair activities of the railway infrastructure.

By achieving its objective, "CFR" ensures the carrying out of public railway transportation for passengers, merchandises and other goods, under transportation agreement with the purpose of satisfying the public, social and defense interest. The public railway transportation is organized and carried out on trade market principles. The "CFR" society manages the Romanian railway infrastructure, public property of the state and it

possesses the goods it endows and those acquired in its own name with any title.

The organizational structure of "CFR" society is established on several levels, namely: the society's management, synthesis central management, the regional level (8 regional branches: Bucharest, Craiova, Timisoara, Cluj, Brasov, Iasi, Galati and Constanta) and the basic subunits. Over the past years, once with the continuous reduction of state budget allocations for capital repair of public railway infrastructure elements in the agreed period of republican norms, as well as CFR service instructions in force, and the insufficiency of personal funds allocated for maintenance and current repairs of the public infrastructure elements, the technical parameters of the public railway infrastructure have suffered a continuous deterioration. As a traffic safety measure, the only measure, available for the "Lines" personnel, to ensure safety conditions during trains' traffic, restrictions of accidental speed have been placed on land, caused by the deterioration state of the component elements of the railway infrastructure.

According to legal provisions, the society's incomes have the following sources:

- tax incomes from the public railway infrastructure – TUI - tax paid by freight railway operators and passengers;
- incomes from rents and other charges for various services provided by railway operators or other traders, in addition TUI;
- other incomes from exploitation of goods and products;
- incomes from the state budget.

TUI is used only for covering the current functioning, maintenance and repair costs of the public railway infrastructure; the personal incomes from rents and other charges cover the functioning, maintenance, repair, modernization, development costs of the private infrastructure and incomes from the recovery of goods are used to cover maintenance costs of the railway infrastructure. The amounts allocated from the state budget are used only to cover the investments, repair, modernization, development costs of the public railway infrastructure and other investments needed for the projects of national importance which

ensure Romania's integration in the European transportation system.

Following the Government's imposition, there is an artificially maintained low level of TUI uncorrelated with the infrastructure costs, unlike other EU railway administrations where the infrastructure charge faithfully reflects the marginal costs or is partially completed from the state budget, through compensations awarded to the infrastructure manager to balancing income / cost. "CNCF CFR SA" Ministry of Transport submitted a draft legislative amendment to ensure compensation of TUI real cost to the budget. This initiative remained though unfinished, being rejected by the Government. The personnel number from the moment of setting up the society and until present has the following evolution:

Figure 1. The personnel number evolution at "CN CFR" during 1998- 2010

The personnel's number evolution from 47.427 employees in 1998 to 25.600 employees in 2010 was caused by the following:

a. In 1999, the Society's Business Agreement was approved through GD (Government Decision) no. 698/1999, where "Performance parameters" of the railway infrastructure were provided. It has created employment requirement in a number of personnel since early 2000 by adopting a new strategy in human resources policy, such as limiting hiring to a few specialists in poor areas and a minimum number of graduates of different forms of education as well as using the possibility of retirement as a result of fitting in Groups I and II of work. Given that labor productivity in 2000 should

increase by 2, 6%, of which 0.6% by reducing the number of personnel, it was necessary to create conditions for efficient use of personnel.

b. In 2001, difficulties were encountered regarding fitting in ICB (Income and Costs Budget), since the number of personnel could not be reduced because there were operating sectors that had a great shortage of personnel and that could not perform safely their activity. Therefore, as a reorganization measure, through GD 880 and 887/2001 it was established the setting up of 11 subsidiaries of the society, as companies, which were formed by conduct industrial sectors within the society. Setting up these subsidiaries and the natural losses led to reduction of society's personnel number by 2441 employees unlike 2000.

c. In 2002, the reorganization measures carried on the same personnel policy proposed even since the society's setting up and thus, hiring was limited to graduates of different forms of education, and for covering with qualified personnel the sectors related to traffic safety, personnel from inside the society was trained by qualification courses. Regarding fitting in ICB limits, the personnel number continued to drop and through GD 706/2002, other 7 subsidiaries were set up, amounting to a total of 4839 employees. Outsourcing personnel in newly set up subsidiaries from inside the society began in October 2002 and ended in December, the same year. In November 2002, following Government Decision 1199/2002 for the dissolution of Railway Management Services Society "SMF SA" a number of 1018 employees was taken over. However, at the end of 2002, the personnel number recorded a significant decrease, being with 3635 employees smaller than in 2001.

d. In early 2003 a number of 41,484 employees was recorded. As a result of the Restructuring and reorganization program of "CNCF CFR SA", from September 2003 the personnel number decreased by 5042 employees. During 2003, as a result of the privatization program, a total of 10 subsidiaries of "CNCF CFR SA" with status of joint stock companies, amounting to a total of 1154 employees have been privatized.

e. In 2004 the subsidiaries' privatization process continued by privatizing a total of 4 subsidiaries with status of joint stock companies, with a total of 631 employees. Following financial difficulties, in 2004 was applied a new Restructuring and reorganization program of "CNCF CFR SA", which had as result the dismissal of 1600 employees and the reorganizing of the society's structures. There was a series of activities outsourced by setting up a number of 4 subsidiaries with status of joint stock companies, amounting to a total of 4935 employees.

f. Between 2005-2008 the staff number remained relatively constant, by limiting the recruitment of personnel, including for the activities in which employment was poor.

g. From early 2009 until now, hiring within the society was stopped and reducing personnel by about 2800 employees was due to the retirement system and to the dismissal of 800 employees under the restructuring program of the railway system designed by the government.

Numerical distribution for the staff structure of "CNCF CFR - SA" is shown in the table 1.

Table 1. Numerical distribution personnel structure of CNCF "CFR"-SA

STRUCTURE	NUMBER OF EMPLOYEES
WORKERS- of which	20,769
Unqualified workers	45
Qualified workers of which:	20,769
-positioned on categories	1,733
-in operating activity	18,533
-other categories of qualified workers	461
SPECIALISED POSITIONS of which:	4,831
-executive positions	3,008
-management positions	1,823

From it, it can be understood that employees in specialized positions in the railway system

represent 20% of all employees, what makes difficult for them the re-employment in another domain, in the case of a possible dismissal from the railway, as it is currently provided. For qualified workers in operating activities, representing about 75% of all employees, this dismissal may affect them, but they can later find another job thanks to their training and experience.

3. The necessity of reorganizing the "CFR SA" society's business

Currently, the objective analysis of the activities performed by the society and through subsidiaries has led to the identification of some dysfunctions, as follows:

-From an organizational perspective it appears that there are too many sub-units, inadequately equipped and with personnel excessively dispersed, leading mainly to a reduced activity in terms of an employment shortage and of a technical equipment under average, although in the past 12 years there have been made investments in heavy track machines and small mechanization park and in safety installations and equipment of high performance and reliability traffic.

-In terms of costs there is an alarming increase of financial need, mainly generated by perpetual under-funding of the railway system which led to amplifying the phenomenon of the infrastructure degradation. Also, the decision to outsource such activities as organizational strategic subsidiaries proved to be inefficient, while the activity of these subsidiaries should have followed the logical tendency to attract third customers and to maximize profits from these activities while easing the financial effort of the society. Costs analysis in relation to the subsidiaries reveals that measures for outsourcing the activities have not achieved their purpose, the turnover of subsidiaries still being formed as a specified percentage from the agreements with the society.

Moreover, these subsidiaries have increasing costs, putting year after year significant pressure on society's budget. On the other hand, considering the loss of an important level on the transport market in favor of other transportation alternative, the

railway traffic has recorded a decreasing tendency which led inter alia to the appearance of some sectioning points without usefulness and without future perspectives on short and medium term.

In recent years, activity in Traffic sector was conducted with some gaps mainly related to the following issues:

- the necessary level of the personnel could not be provided, some positions related to traffic safety remaining vacant;
- defective personnel policy because of excessive centralization of this problem without taking into account the actual needs of each branch;
- the material base was provided to the necessary minimum and in most cases with large delays due to financial allocations failure to the required level;
- providing inadequate windows (especially on single lines) for work on line, with major implications in equipments productivities.

After analyzing the current business model, the parameters and the used resources, there were identified several shortcomings of existing processes for coordination and management of trains traffic. The main disadvantages of the current system consist of the large number of hierarchical levels in the traffic management decision-making chain (4 levels) and their large number of units (BCCTF, 8 RCR, 23RC with 85 RC wires, 992 stations). It is thus obvious the need of modernization and of efficiency of the railway traffic coordination and management process.

The SWOT analysis of the railway infrastructure and of the related activities is as follows:

Table 2. SWOT Analysis of the railway infrastructure activity

STRENGTH	WEAKNESS
-the existence of an extended railway network assures capacities for the intern requests as well for the extern railway transport for merchandise and passengers -the railway network includes pan-European corridors and magisterial lines -good territorial cover in all travel directions -37% from the network is electrified -27% from the network is a double line -the existence of a highly	-failure to provide in time or insufficient funds destined to repairs and investments to the public railway infrastructure -the existence of a lot of due assets to essential repairs (bridges, tunnels, lines, installations for traffic security etc.) which affects the system performances and the traffic security -the possibility for the traffic security to be affected by villains while an efficient legislation lacks -the lack of full coverage on maintenance and operating expenses for the railway

qualified staff ready to assure the right implementation of modernization steps (ETCS, computerization, high speed lines etc.) imposed by ensuring interoperability and intermodal transport -the existence of an information system with specific applications for the entire network -Romania's geostrategic position	infrastructure from TUI - lack of precise and efficient legal ways to recover debt from clients -the existence of historic debts -the lack of correlation between the railway network the road and the naval one -the lack of the state support in competition with the road branch - carrying out activities through subsidiaries, which leads to the rise of costs -the specificity of the maintenance of the railway infrastructure does not allow the use of a performance marker to reflect realistically the quality of the activity performed and the objective factors which influence it.
OPPORTUNITIES -the possibility to access extern funds, repayable or not repayable, for the maintenance, the development and the modernization of the railway infrastructure and of the railway patrimony -the EU politics to rehabilitate the railway transport -the EU politics to promote technologies that do not pollute -the EU policy support of intermodal transport -supersaturating of auto communication paths and the increase of the number of accidents	THREATS -the diminution of the economic agents' interest in the railway transport because of the growing number of private auto transport means -the existence of national programs for building highways -the climatic changes that affects through natural disasters the infrastructure condition -the states' integration from the former Yugoslav space in EU and the appearance of detours -the prices increase for raw material and fuel -the late approval for BVC and for values smaller than the fundamental ones which affects the good work or which can lead even to blockages

The reorganization objectives generally aim to generate/optimization issues of legislative framework on the financing of the railway system completed with internal organizational decisions and financial restoration to lead to the restoration of financial balance of the society through serious measures of financial discipline that mainly emphasize:

- To ensure adequate funding of the system, through TUI correlation with infrastructure costs and to ensure budget resources necessary to the recovery of repair works to public infrastructure;
- Increased income from ancillary activities;
- Reduce costs and streamline their activities through best use of exiting human resources and technical facilities, attracting private

capital for maintenance and operation of interoperable railway infrastructure
-Efficiency activities through structural reorganization of the company at different levels and subsidiaries;

All this requires other type of intervention from staff managers, namely an analysis of a socio-professional climate. In this category we included those procedures which are based on the collection and systematization of information to relevant staff on an issue, or all staff concerned, in order to achieve an objective description of a problematic situation and to identify ways to resolve or improve it.

The analysis of socio-professional climate can provide valuable information to the management unit in the form of suggestions or solutions to solve certain problems, possible levers to motivate employees' descriptions of possible future threats or opportunities for development and efficient society activities.

4. Conclusions

The difficult situation that the railway infrastructure in Romania finds itself in terms of technical status is especially due to the lack of providing adequate funding from state budget funds and to the impossibility to cover requirements of the society's own sources, due to the lack of income. As a result of insufficient funding from state budget for carrying out major repair works of the public railway infrastructure, the necessary volume of annual expenditure for maintenance (whose source is the coverage rate of infrastructure paid by railway operators) is increasing, being caused by the emphasized infrastructure degradation process and by the necessity of maintaining the minimal operating parameters and the trains' security.

Following the imposition by the government, there is artificially maintained at a low level of TUI uncorrelated with infrastructure costs, unlike other railway administrations of the EU, where the tax for using infrastructure either fully

reflects marginal costs or is partially filled from the state budget, through compensation awarded to balancing income/cost. "CNCF CFR SA" has submitted to the Ministry of Transport a project to amend legislation capable to ensure compensation of TUI real cost from the budget. This initiative remained though unfinished, being rejected by the Government. Though the number of society's employees was reduced in a period of 12 years in a percentage of 40%, this diminution was not compensated with financing to ensure the refurbishment and/ or upgrading work fluctuation and also a significant increase of productivity markers. Given that the limited value of salary fund established annually through approved ICB, it restricted staff hiring for the activities with employment shortage, the conduct of aggressive "specialists theft" policy by the private sector or by companies in the railway system is noticed, through attracting and taking over the "CNCF CFR SA", mainly on salary considerations.

Abstract

This study aims at identifying the effects of optimizing the process of professional training and at offering answers to two main questions that concern the business world: is the professional training a decisive factor in increasing the work productivity? Is it a crucial factor in reaching the strategic objectives of a company? In order to answer these questions as appropriate as possible, our study has the following specific objectives: testing the hypothesis “attending professional training programmes influences the decrease of staff fluctuation”; testing the hypothesis “attending professional training programmes contributes to the increase of the employee productivity” and, “investigating strategies of capitalization of the investments in professional training programmes within a Romanian organization”. Processing certain questionnaires led to some conclusions useful for supporting the managerial decisions regarding the carrying out of the professional training.

Key words: training, human resources, decisions

JEL classification: M53

1. Professional training, work productivity and staff fluctuation

While in the past century the production-based economy was the motor of social and financial growth, in the XXI century, the knowledge-based economy is obviously the main driving force. Under these circumstances, it is important to be aware of the need of investment in innovation, in knowledge and in creativity. The success company of the future is the one that attracts the best employees and that learns how to use their individual potential. Knowledge represents the driving force of the durable development. In a world confronted with fast changes, the elements that make the difference are **education, research, innovation and creativity**.

After the reforms imposed by the world economic situation, new workplaces will appear, requiring new competences. Another aspect is the management of the transition between the workplaces as well as between the professional training and the workplaces. In this regard, **flexicurity** will have to be developed at maximum. Flexicurity is the strategic policy in European Union, aiming at the flexibility of the labour force and the increase of the social security.¹(Wilthagen T., Tros F., The Concept of “Flexicurity: A new approach to regulating employment and labour markets” Pag.4.).

The challenge consists of finding the best modalities to enhance on the one hand the flexibility of the labour markets both from the point of view of work organization and of the

work relations, and on the other hand the safety offered by lifelong learning and an appropriate social protection.

In March 2000, The Lisbon European Council established a new strategic objective for the European Union: to become the most competitive and dynamic knowledge-based economy in the world. In order to attain this objective, the system of education and training should be reformed and adapted to the requests of the knowledge-based society and of the labour market. The European Council asked for the definition of a new framework of the basic skills necessary on the current labour market, a set of abilities that should be the base of the lifelong learning process. According to the Council, this set includes: computer skills, multiple language skills, social communication and entrepreneurship skills.

A significant aspect is the identification by the EU specialists of the need to pass from the “ability” term to “key competences” in defining the success elements in career. The “key competences” term refers to “a unique multifunctional and transferable combination of knowledge and abilities that allow an individual to get personal fulfillment, personal developments, social inclusion and make him easily employable. The basic competences should be developed until the end of the compulsory education cycle and should play the role of foundation in the individual lifelong learning process.”² (“Implementation of “Education and Training 2010” – Key competences for lifelong learning a European reference framework”, pag.6.).

The competences are the strengths of a person and allow him to achieve personal fulfillment through continuous development and a good integration in the society, as well as the maintaining of a high level of adaptation to the requests of the labour market. In comparison with abilities, which are strictly defined elements in concrete fields, competences are more flexible elements that can be transferred between different fields.³ (Implementation of “Education and Training 2010” – Key competences for lifelong learning a European reference framework”, pag.3.)

In order to support the investments in the human capital and to reach the established objectives, the European Union created also instruments of financing, the most important being the Sectoral Operational Programme for Human Resources Development (POSDRU), a structural fund that has as the main axis “Education and professional training for the support of economic growth and development of the knowledge-based society”.⁴ (Sectoral Operational Programme for Human Resources Development 2007-1013).

In order to confirm the priority of the professional training for the European institutions, there were a lot of investments both in the identification of the labour market current needs and in studies for finding some modalities of improving the practices in lifelong learning and professional training.

Such a programme financed by the European Union is “Education and Training 2010 work programme” that integrates all the European actions regarding education and training. It also includes references to the Bologna process that contains directives for the development of the high education at the European level. This programme will attain its objectives during 2010 and 2020. Its goals reach four important directions: implementing in the European countries the mobility concept of the competences and lifelong learning; improving the quality and efficiency of education and training; promoting equity, social cohesion and active manifestation of the citizenship; improving creativity, innovation, developing the entrepreneurial qualities at all levels of education and training.⁵ (Communication from the Commission to the European parliament, the Council, the European economic and social Committee and the Committee of the regions” Key competences for a changing world - Draft 2010 joint progress report of the Council and the Commission on the implementation of the “Education & Training 2010 work programme”, 25.11.2009).

An essential aspect in reaching these objectives is to sustain them through the legislative framework in the labour field of each European country. Romania harmonized its labour legislation regarding the legal framework

for developing the professional training within the commercial societies.

In the specialty literature, the concept of professional training is connected with several key concepts such as “work productivity” and “staff fluctuation”. **Productivity** is defined as “*production per unit of used inputs*”. The growth of productivity appears from the increase of efficiency in the use of the capital and of the labour force.”⁶ (Dictionar MacMillan de Economie Moderna, Ed. Codecs, pag. 317-318) In this case **labour productivity** is “*calculated either as the ratio production-work involved for attaining it, or as the ratio work expenses-obtained production.*”⁷ (Dictionar de economie, Ed. Economica, 1999, pag. 369).

The term of **staff fluctuation** designates “*changes of the number of workplaces - hirings and layoffs.*” Employment can end either from the employee’s initiative (resignation), or involuntarily, from the employer’s initiative (firings). Fluctuation can be defined as rate of the labour force fluctuation, by adding the layoffs and hirings, dividing the sum by 2 and giving the answer as a percentage out of the total employees number.”⁸ (Dictionar MacMillan de economie Moderna, Ed. Codecs, pag. 160).

The relation between these concepts was the topic of various scientific studies. Olaniyan⁹ (Olaniyan, D.A., Ojo, L.B., *Staff training and development: A vital tool for organisational effectiveness*, European Journal of Scientific Research, nr24 (3), (2008) pag. 326-331) states that the relation between productivity and training has become obvious. The personnel development through training is based on the assumption that organization can grow only through enriching the employees’ abilities. Training is a method of systematic development of the employees’ knowledge and competences, used for achieving the work tasks at a performant level. The new employees have different abilities that cannot be relevant for the specific of the organization and thus training appears necessary for the harmonization of the human resources with the objectives of the enterprise. Pollitt D.¹⁰ (Pollitt,D., *LTFS puts*

the sparkle back into training: Program cuts employee turnover and improves morale, Human Resource Management International Digest, Bradford (2008) Vol. 16, nr. 4, pag. 17-19) initiated a study about the effects of training within the Call Center Outsourcing firms. The conclusions of the study showed that the internal training that answers the needs of the enterprise leads to the decrease of the staff fluctuation, improves the staff state of mind and the services for the clients, increasing thus indirectly the efficiency and productivity. The condition is that the professional training programmes correspond entirely to the organization needs.

A data panel study coordinated by Danvilla del Valle¹¹ (Danvila del Valle,I., Castillo, M., Rodriguez-Duarte, A., *The effects of training on performance in service companies: A data panel study*, International Journal of Manpower, Bradford(2009). Vol. 30, nr. 4, pag. 393-407) aimed at identifying the impact of training investments on the economic performance. The study data were collected over a period of 9 years. The results confirmed that managers should see training as an investment, not as a cost. However, these results can be less obvious in small companies, without well defined professional training policies, and where generic trainings and specific ones are not correctly differentiated. A quantification of the relation between productivity and training was offered by Dearden¹² (Dearden,L., Reed,H., Van Reenen, J., *The Impact of Training on Productivity and Wages: Evidence from British Panel Data*, Oxford Bulletin of Economics and Statistics, Oxford (Aug 2006) Vol. 68, nr. 4, pag. 397) in the study carried out on the industry in Great Britain between 1983 and 1996, a longitudinal study that confirmed the increase of the investments in the professional specific tasks training with 1% leads to the growth with 0.6% of the added value per hour and to a wage rise with 0.3% per hour.

As regards the relation between staff fluctuation and training, the specialty studies offer us an answer. The study carried out by Munasinghe and O’Flaherty¹³, (Munasinghe,L., O’Flaherty,B., *Specific Training Sometimes Cuts Wages and*

Always Cuts Turnover, *Journal of Labor Economics*. Chicago (Apr 2005) Vol. 23, nr. 2, p. 213-233) investigated the relation between staff fluctuation, salary level and the specific training level. Staff fluctuation decreases as the time spent in the company is longer, but the salary level does not increase directly proportional with the time spent as an employee in the organization. The relation between the received training, salary and fluctuation is the following: as the salary level offered to an employee with trainings and abilities complying with the market requests is lower, the profit of the enterprise is higher, but the possibility that the employee could leave the organization enhances. That is why it is recommendable to update and harmonize the salary level with the productivity of the employee and his competences, taking into account that the salary level is a factor that influences the staff fluctuation.

Another data panel study¹⁴ (Conti, G., *Training, productivity and wages in Italy*, *Labor Economics*, volume 12, nr.4, (August 2005), Pages 557-576) investigated the relation between training, productivity and wages in Italy and covered all the sectors of the Italian economy between 1996 and 1999. The results showed that employee trainings led to a significant increase of productivity. On the other hand, the relation between the increase of the salary and the attendance of training programmes was not supported by evidence, this meaning that firms tend to benefit from the positive results obtained by the employees after developing new competences, but do not want to reward them immediately.

2. Study regarding the professional training process and its effects

As we mentioned above, the objectives of our study were the following:

The specific objective 1: testing the hypothesis “*attending professional training programmes influences the decrease of staff fluctuation*”;

The specific objective 2: testing the hypothesis “*attending professional training programmes contributes to the increase of the employee productivity*”;

The specific objective 3: “*investigating strategies of capitalization of the investments in professional training programmes*”.

In formulating these specific objectives, we started from the assumption that there is a correlation between the factors “staff fluctuation”, “productivity”, and “professional training”, as well as from the fact that there are multiple possibilities of capitalization of the investments in professional training programmes, each possibility having advantages and disadvantages. When an employee wants to leave a company takes into account more factors, including the possibilities of professional development; when an employee has performances means that he has active motivation and one of the motivators can be the need of professional development and of acquiring new skills. That is why an employee’s motivation and individual interests are decisive factors for fluctuation and productivity. Not in the least professional training is a complex process related to all the processes of human resources and management, but one of its vulnerabilities in general is quantification and capitalization of the investments. For this reason we chose to study this process especially under these specific aspects: staff fluctuation, productivity and capitalization. The process was analyzed taking into account the three main phases: training needs analysis, implementing and carrying out the process, training evaluation.

The study was carried out in January 2010 and the investigated sample was formed of 25 employees in IT field. The characteristics of the analyzed persons were the following: the age range varies between 19 and 30 years, with an average of 25 years; benefited from at least 1 professional training programme over the last 12 months; have results over average in attaining the individual objectives; have higher education (completed or in course); their work experience is between 0 and 5 years, with an average of 1.8 months.

These persons accepted to participate voluntarily to this study after they were presented briefly the objective of this research, the methods used, and were granted the anonymity.

To carry out this study we used combined research methods: the method of questionnaire-based survey, the observation

method and the method of data comparison for a certain period of reference time.

In the view of identifying the dynamic of the professional training process, the research aimed at pointing out the 3 main phases of the process, each of them with specific instruments:

- a) Phase 1: Training needs analysis
- b) Phase 2: Implementing and carrying out the professional training process
- c) Phase 3: Professional training evaluation

Following the objectives established for this study, the evaluation of the efficiency of the training programmes was done also by analyzing the data for a reference period: 2008 and 2009 in order to obtain the differences produced by the investments made in 2009, in the process of staff professional training.

In the following we will exemplify some of the study results:

a) the specific objective 1: testing the hypothesis “*attending professional training programmes influences the decrease of staff fluctuation*”

A significant negative correlation ($r = -0.80$, $p < 0.05$) and a real correlation of 64% between the 2 variables were obtained. This result means a strong correlation between variables: if the quality of the training increases, the staff fluctuation decreases and vice versa. (see Figure 1).

Figure 1 – Correlation between the staff fluctuation and the quality of the 2007-2009 training.

b) the specific objective 2: testing the hypothesis “*attending professional training*

programmes contributes to the increase of the employee productivity”

In order to investigate the correlation between the results obtained at the training and employee productivity, was tested the productivity expressed as a percentage per quarter and the average of the 2007-2009 training results (see Annex 1). Pearson correlation was used, leading to a significant positive correlation ($r = 0.71$, $p < 0.05$), and a real correlation of 50% between variables. This result means an average correlation between variables, demonstrating thus that when the training participant’s good results increase, his productivity rises too.

c) the specific objective 3: “*investigating strategies of capitalization of the investments in professional training programmes*”

Implementing a professional training programme raises some difficulties, one of them being the capitalization of the investments in training. Any manager wants results from his investment, but more than anything he aims at a quantification of these results. Creating a system of training “return-of-investment” can be difficult, but not impossible.

Here are some measures to carry out a capitalization of the investments in training:

- the provisions of the contract signed by each employee attending a training in the company.
- correlation of the productivity with the training results. If an employee does not reach the performance objectives, he will be “re-trained”. Anytime we notice a decrease of the activity indicators, the first measure is “re-training” followed by a period of monitoring and evaluation.
- another form of protecting the investment is preserving the confidentiality on the content, methods and all the information about the attended training.

The challenge to investigate the organization’s strategy of capitalization of the investment led to describing the strategies because there is no attempt to express in figures the training benefits. Until now it was not planned the “elaboration of a return-of-investment system for training, although there is a real interest for this aspect.

3. Conclusions

The current study approaches a topic becoming more and more important in the

present context. Ignorance can be extremely harmful. In Romania, the enterprises investments in training reach only about 11%, in comparison with other EU countries, such as Denmark (96%) and Sweden (91%). The attendance to professional training depends also on the size of the company, the big enterprises with over 250 employees, offer more training than the small ones (under 50 employees), and the companies in the finance and banking filed give the opportunity of the most professional trainings.¹⁵

While drawing up this study, we faced several problems. At the conceptual level we found out that there are few studies and statistics regarding the professional training in the south-east and central Europe, but there are European Union directives, programmes of financial and logistic support that favour the development. On the other side, the rich literature in this field began to enter the Romania market, too.

At the research level there were a few problems related to the efforts to persuade the students to read the whole questionnaire. Some of the subjects did not have patience to read attentively the question and to offer complete answers.

As a consequence of this study we consider that there are plenty of possibilities of development in the following directions: drawing up a training return-of-investment system at the company level and correlating the career management, the performance evaluation and the follow-up plan at the company level.

At national and European level we consider necessary the study of tendencies in the professional training field through scientific researches and modernization of the legislative framework regarding the occupational standards.

The Management of the Credit Institutions in the Context of the Elaboration and Implementation of the Banking Strategy

Dinculescu Elena Silvia
Mindreci Georgiana
Universitatea Constantin Brancoveanu Pitesti
nataliadinculescu@yahoo.com

Abstract

The success of a credit institution is mainly due to tenacity and to a large dose of creativity which may manifest itself both at the level of superior management and among the performers in the activity of solving the problems encountered and in the process of formulating the overall strategy. According to the international standards in order to be considered truly modern banks, the Romanian banking institutions are required to submit a strategic program, and therefore within the major commercial banks there were set up departments of strategy that deal with the elaboration and implementation of strategic programs.

Key words: credit institutions, banking strategy, international standards;

JEL classification: F33;E59;

The strategies of the credit institutions have always taken into account the nature and the major changes occurring in the global banking sector. During the post-war period, the credit institutions have benefited from a comfortable silence, due mainly to the economic policy concerns with the restoration, development and consolidation of the industry. If initially the activity of the banking institutions was conducted in terms of industrial risk, starting with 1970, when the first major monetary disturbances took place there were recorded important changes in the policy and in the vision of big banking institutions. First of all, there are modifications in the concept of banking company. Due to the revolution in the technical progress in the financial field, new banking products and services have appeared, currently

no banking institution no longer offers a single product or service, but provides a comprehensive range of activities. The progress has led to facilities such as: transmission of data in real time between units worldwide, comprehensive computerization, use of satellites, all of these leading banks to adopt development strategies that increasingly take into consideration the global costs.

In the context of an increasingly fierce competition on the banking market, the risk has increased and new uncertainties have emerged. At present one can not cope with the pressure of the competition without an adaptation to the technical progress. This evolution may lead to the restructuring of the staff, causing serious difficulties in the process of managing the human resources. For this, the strategy of each banking institution should aim to change the mentality and behaviours of the employees in a timeframe as short as possible.

In contemporary times, the banking strategy included a broad area and recorded an increased complexity, adaptation represents a continuous struggle and involves considering the transformation of the population's attitudes concerning the banking activity in general.

The banking strategy consists in ordering some objective values, of some banking policy elements, which require a constant concern for their application in various fields of credit institutions' activity.

The concept of banking strategy is characterized by defining all the components with a view to:

- the position occupied by the banking organization within the system;
- the activity of promoting the banking products and services;
- the relationships between the bank and the customers, partners and public institutions;
- strategic alternatives for penetrating the marketing, the development and the counter-balancing of the competition;
- strengthening the four pillars that stay at the basis of any banking structure: human resources, territorial units network, investments in infrastructure and in the information system.

At the level of the credit institutions, their top management presents as fundamental attribute the elaboration of the strategies and policies in order to achieve the set objectives. [1] The policy is subordinated to the development strategy of the banking organization, a strategy that covers all the aspects of the banking activity referring to: sizing and setting up the organizational and personnel structure; the banking institution's relationship with the customers having in view the likely development of the economic, social, financial internal and external environment; designing the banking products and services.

The essential objective when adopting a strategy, the national banking institutions, is to maximize the profit level, in an environment characterized by risk and uncertainty, in terms of caution and supervision regulated by the National Bank of Romania.

The process of implementing the strategies in a banking organization involves adoption some decisions that can be implemented using the tools and instruments that are found in the strategic plans, directed primarily towards: customer segments, human resources, financial resources and offer of banking products and services [2].

It can be argued that the banking management and strategy involve each other. The action of implementing a strategic program in a bank actually represents the concrete

manifestation of banking management since the strategic plan materializes by putting into practice the major decisions concerning the key areas of the banking activity.

The strategic management process follows a very simple pattern and involves three stages [3]:

The strategic analysis involves taking into consideration the set objectives, the analysis of the current situation in which the bank is found, the resources it has and not least the constraints it is subject to;

The strategic choice is to identify the options, their assessment and the choice of the preferred one;

The strategic implementation is materialized by planning the mode of action, its application, monitoring the achievement and comparing the obtained results with the initially set objectives.

The goals aimed in a banking strategy may be of economic, financial, social or political nature, they extend as time span between 3 and 5 years and take into consideration the following components [4]:

- the place on the market;
- superior management from the level of the central office or of the branches in the territory,
- indicators of efficiency and profitability,
- banking policies,
- products and banking services,
- the structure of the banking organization,
- international relations.

Carrying out the strategic management process in organizations requires the existence of both some specialized departments, which will deal with the analysis of the environment evolution and with providing prospective information to the banking decision-makers, and some departments involved in the achievement of the banking policies. These prospects play a decisive role in determining the "axes" of the banking strategy in setting the general objectives, in determining the economic and financial hypotheses of the

strategic planning process on medium or long term.

Not always a well thought process can also mean a perfect strategy. M. Porter presented the fundamental errors often committed in the strategic planning:

- restructuring as strategy - restructuring in itself is not a strategy, many banking organizations have opted for restructuring in order to successfully implement a strategy;
- attracting competition and not fighting it - this may often reduce the number of competitors, eliminating the surplus costs on the market and the increase of the owned market share, but as in the case of restructuring, it should be seen as an aspect of the strategy and not an overall strategy;
- setting up alliances – must be seen as a stage of strategy implementation. Making an alliance with another stronger and more dynamic banking company could soon make the former look weaker than to bring it long term benefits;
- imitation and not innovation – the competitive advantage is achieved just by differentiation;
- diversification for the sake of growth – it is acknowledged that, on long term, diversification in new areas only to increase the turnover makes the organization become vulnerable.

The implementation of the strategy is the latest stage in the strategic planning process and it consists of communicating the purpose and its implications in an efficient and concrete manner to the banking staff. This implies that all managers and bank employees from all the levels of the organization to know and to understand both the overall strategy, but especially how they will contribute to its successful realization.

In the case of each banking department the performance (orientation) indicators are established, which may be unique for each organization separately and they show what is necessary for the future – the market segments in which the bank is competing, the operational objectives, the individual development skills, and depending on what is found in practice, the results (gap) indicators are formulated, which tend to be generic (profitability, market share, the degree of customer retention, employees'

satisfaction) and reflect the actual situation of the banking organization. They can be grouped in a matrix to reflect on how to achieve the set objectives in four key areas [5]:

- financial: return on investment and the added economic value;
- customer area: satisfaction, maintaining the market share and the value in the account;
- operational: quality, reaction time, costs for introducing a new product;
- the human resources: employees' satisfaction, their skills and information availability.

If after the evaluation of the actual results it is shown that they were deficient in relation to the established performance indicators, it results that either the strategy has not been properly determined or its implementation manner was not adequate. If the managers and staff within the banking organization are informed on the strategic process, they can provide accurate and timely feedback in the case of situations in which problems occur or certain opportunities may be missed.

The balanced system of indicators is a tool meant to contribute to the synergy of the strategic management, and it appeared as a consequence of the need to find a method to evaluate the results of a credit institution which is not primarily based on the accounting indicators.

The goal of a balanced system of indicators of a banking organization's activity is to help its management in identifying the essential success factors that will lead to achieving the set goals. These factors depend largely on both the culture and style of the organization and on the strategy that it tries to accomplish.

This balanced system of indicators is a method that has managed to gain wide recognition and continues to be adopted by banking organizations worldwide.

Optimization Strategy to Capitalize on the Romanian Tourism Potential

PhD Lecturer Dindire Laura
PhD Reader Dugan Silvia
“Constantin Brancoveanu” University of Pitesti
lauradindire@yahoo.com

Abstract

An important direction of the improvement of promotional activities achieved both by the decisional governmental and non-governmental organisms within the tourist services sector and by the tourism firms, both on an intern and international level, is the promotional strategy. Consisting in the mastership of obtaining the best results, through organizing, coordination, prediction, communication and control activities, the promotional management means knowing and understanding the intern and international promotional strategies typology, in a way that we could choose the best option. By the comparative presentation of the main international strategies regarding the promotion of tourism, such as the standardized and the adapted promotion, we aimed the development of knowledge and abilities regarding the adaptation of the tourism promotion process to different cultural and national backgrounds.

Key words: capitalize, romanian tourism potential, promotional strategy.

JEL classification: R19;

1. Introduction

Strategic development of tourism country is imperative, especially in the current context of global economic crisis, to overcome the obstacles generated by the lack of liquidity, by strong growth in unemployment, by the current instability on the international market. Tourism could be an opportunity to relaunch the Romanian economy and the escalating negative effects and consequences of the crisis, because does not require large capital investments such as other fields such as industry. Course to achieve such boosting economic targets on tourist activity, it must be integrated within a coherent macroeconomic policies, should have

competent human resources, strategies well grounded and adapted to domestic and international tourism market .

2. Context of European tourism

Worldwide noted, in 2009, a decrease in consumer demand of tourism products, registering significant decreases in the number of visitors. According to Eurostat, in the first six months, compared with the same period on previous year, in European countries, the decline was 7.4%, topping Romania is among countries most affected, with a decrease of 18%, outpaced only by Latvia, Lithuania and Cyprus [1]. Falls off, so, the next idea: poor recovery of the tourism potential of a country which has many tourist attractions, but, because of inadequate infrastructure, often of a non-specialized personnel and training summary, of a faulty promotion and a unfavorable internationally country image, failed to assert a high-value sector, that of tourist services. European Commission, through the policies applied, gives a clear support of European tourism, this contribute to the major EU objectives such as sustainable development, economic growth, employment and economic cohesion - social. Even the contribution to the Lisbon goal of creating more and better jobs, is evident, because in the European tourist industry are employed about 8 million people, representing 4% of total employment and a rate of over 4% of EU GDP, and if taken into account and related fields, resulting an occupancy percentage of the workforce of about 12%, which generates indirectly, 11% of EU GDP [2].

3. Support tourism performance by using the most appropriate policy strategies and promotional techniques”

We can customize the promotion of tourism as the interdependent whole of all methods, procedures and promotional media, used both at the microeconomic level (travel agent) and macroeconomic (at governmental, or NGO profile, the civil society) that have a synergistic effect: to make known the tourist potential of a geographical area or a country or region, in order to improve tourism activity. In tourism, promotion is intended to make known areas, regions or countries, to boost and diversify of tourism activity, to improve the image of domestically and internationally tourism products and services, with major and profound implications for managers of country image.

The strategic vision of promoting tourism is of high importance in the current economic context. Irrational use, on empirical bases, without a systemic structure of the diverse promotional techniques, researches have proved that they cannot lead to performances in the economic agent's activity anymore. However, the majority of books, especially Romanian, focus on the promotional techniques presentation, without highlighting their interdependence and their synergetic effect used in order to draft the strategy. In the foreign profile literature, strategy has a proved role, but rather in advertising creation specific tourist activity, in the public relations process, in marketing study and choosing different media for promotion of tourist activity, which are very important, but not enough to conceive the tourist promotional strategy.

The predicting activity for establishing the tourist promotion strategy must start from investigating the consumers' perception on the company, on the tourism products or services offered. The importance of management activities on the scientific basis of the development of a strategy is presented by specialist Jack Trout, as "the use of appropriate strategies is how to survive in a world of fierce competition and to resist the so-called tyranny of choice " [3]. Strategies should be high on the priority list of every facility manager [4].

Both at the microeconomic level, the travel agency, but also at government level, tourism

promotion should be made based on the strategy. As appreciated Altstie and Grow [5] even in small companies, setting strategy should be one of the responsibilities of the person designated to promote your business, along with: research, establishing contacts with clients, identify the advertising agency that will carry out production, public relations process.

So, travel agencies and organizations and specialized institutions in the tourism sector have to graft promotion on attending the following process: setting clear as to promote and to budget, the decision on the choice of environments that can adapt best tourism product and budget, designing promotional messages so as to based on the brand and attracting attention, testing promotional messages, and finally, after it was believed that the message works or promotional campaign, following its implementation [6]. But not necessarily, a large budget allocated to ensure effective promotion is a good measure; developing and implementing strategy remains an important element of success in this environment [7].

The strategy is based on positioning the tourism product or service and the differentiation from competitors. They are an important element in building tourism promotion strategy on which company's efforts need to focus.

The strategic approach of promoting business is also regarded as a strategic triangle and includes: the segmentation of the target audience, the foundation of the functional, emotional benefits supplied by the brand, which provide the valuable in the market segment (brand value proposition) and the axis of the persuasion instruments that will be used to reach for promotional goals [8]. To develop a tourism promotion strategy, therefore, one should clearly set the objectives. These may be: to provide information to stimulate the demand, to differentiate the tourism product, to emphasize the value of the tourism product and to increase the sales using a promotional mix to ensure the achievement of all the promotion objectives [9]. The variety of means through which travel agencies can promote their products make it difficult to

choose optimally the promotion strategy. A variety of means of promotion: television, press, promotions based on the product itself provides various promotion strategies for each company [10]. Glazer and Kennedy feel that success derives from the diversification of the promotional message and its transposition in as many environments as possible so as to achieve a greater range of consumers [11]. Belch noted the need to use all the promotion instruments by companies, based on the strategy so as to convey a unified message to consumers [12]. The main promotional techniques, that can be used successfully in tourism, in the opinion of various authors and practitioners are: advertising, sales promotion, sales force, public relations [13], or advertising, public relations, participation in exhibitions and tags [14] or advertising, sales promotion, public relations, sponsorships, exhibitions. In the specialized literature there has appeared the hypothesis according to which the promotion effect in an environment, for example TV, depends on the level that the company has in another environment, for example, in the newspapers (media interaction effects), this interaction can be positive or negative [15]. The advertising strategy also has an important place in the researchers' and practitioners' study in the field [16], [17], [18]. The full structural integration of all the techniques, promotional methods and means in the promotion strategy requires channeling the investigative approach in this direction as well.

The main techniques in tourism promotion policy, which can be used to promote Romanian tourism are: **tourist information**, held in the permanent or occasional information centers within exhibition salons, telephone and through printed information (brochures, proposals, catalogs etc.), **tourism advertising** done in newspapers, on television, radio, Internet, etc., **public relations** in tourism [19] (consisting of organization of events in tourism: promotional days or weeks, gastronomic events, commercial days or weeks, managing relations with the media, country image building etc.), **participation in national and especially international tourism fairs and exhibitions, sponsorship**. Also can be used **promotion incentives**, which take effect in the short term and whose activities are materialized in discounts and rates, promotional offers, sales group. They involve offering packages that include transportation, meals, accommodation,

other tours and visits to places of entertainment, organization of competitions, games, raffles. These techniques should be integrated into well-grounded promotional systems to achieve a successful tourist promotion. Independent utilization in isolated actions without taking into account the complex of similarities and differences existing in international tourism, does not produce the desired results.

One of world class advertisers, **David Ogilvy**, proposed 14 specific ways to reinvigorate demand for tourist services. The most important include:

- highlight differences, the elements of exclusivity; people travel to get rich with new experiences, to see what they can not find in their country;
- if you saw a product at a good price, place this statement since the header;
- use specific facts, avoid generalities whereas only conduct client determines to buy without seeing;
- present product as a first, very high quality;
- not hide the best arguments of the sale, place them in the header, otherwise the ad will go unnoticed among all other ads;
- intelligently choose pictures that are twice as important, more meaningful than the text;
- always predict in advance which documents will notice a positive impact on demand;
- in advertising for the little-known countries is very important to provide the wealth of information [20].

Another decision the company must focus its efforts on is when the promotion strategy is being built, is the choice between using the **adapted promotion or the standardized one**. Management leaders such as **Theodore Levitt** from Harvard and **Kenichi Ohmae** from Mc Kinsey have brought arguments in favor of some products and global marketing efforts. They notice that tastes and styles are becoming more homogeneous throughout the world, a key argument in the use of standardized promotion being the fact that one can make savings on a large scale regarding promotion [21]. On the other hand, the use of adapted local promotion is based on considerations such as: the existence of traditions, consumption habits and local symbols.

Standardized tourist promotion requires that planning, execution and implementation in tourism promotional campaigns to achieve in a global context, the text is being translated without intervening creative elements. In this respect, it committed a promotion agency which has the central responsibility to conduct tourism promotion.

Promoting tourism adapted is to achieve tailored strategy and promotional messages according to specific local tourist market. The company appeals to promote agencies services in each country, so that promotional campaigns to be tailored to the needs and culture of each area. Most often, in this situation, organizational control it is decentralized.

In fact, few companies use one of these two strategies in pure form, but they must be sufficiently flexible to be able to adapt promotional methods, techniques and instruments to the linguistic differences, cultural, social and economic, depending the country who want to enter. The following example of international standardization error used to promote Romanian tourism is significant in this regard. It derives from cultural barriers, the incompatibility of promotional messages to local culture, of language differences. It is Romania's tourist promotion slogan, "The land of choice", which has negative connotations for the American public. It seems that in the U.S., free translation of the expression is "country where abortion can be", which bring great disadvantages Romania, causing confusion among the American public. A more appropriate approach would be, according to the American diplomat, Glenn Carey, "the land of many choices, which means the country with many opportunities: Black Sea, Carpathian Mountains, Danube Delta, Transylvania, Bucharest, medieval monasteries in Moldova etc. as for Americans, the word "choice" can have connotations which disadvantages such slogan [22].

So, it must choose the most appropriate international tourism promotional strategies.

MOBILE MARKETING - TRENDS ON THE ROMANIAN ADVERTISING MARKET

Dinu Cristina,
dinu.cristina@gmail.com
Iatagan Mariana,
iatagan.mariana@yahoo.com
Natalia Manea
nataliamanea@yahoo.com

Spiru Haret University, Faculty of Marketing and International Business

Abstract

In these times of economic crisis, the advertising market goes through a difficult period, as companies reduce marketing budgets drastically trying to reduce their costs. For some companies, mobile phone can be a very effective communication channel because mobile ads are much cheaper than classic advertising, offers many advantages as a means to promote and may become an "ally" of those companies that support sustainable development and social responsibility.

The article presents a SWOT analysis of the mobile marketing medium and it proposes ways to develop wide-scale mobile marketing, given that, at the present, promoting this environment is viewed with skepticism both by companies and consumers at the same time.

Key words: mobile marketing, advertising, communication channel

JEL classification: M37

1. Introduction

According to the Mobile Marketing Association, "Mobile marketing is a set of practices that enables organizations to communicate and engage with their audience in an interactive and relevant manner through any mobile device or network."¹ Mobile Marketing uses mobile phone as the communication channel with the target audience.

Nowadays, mobile phones are used for much more than just making and receiving

calls. Besides voice services, mobile users send Short Message Service (SMS) and message picture, use Multimedia Messaging Service (MMS), Bluetooth and the Mobile Web. These are four most prominent mobile marketing tactics. Because these media channels carry both content and advertising mobile phone offers advertisers many attractive possibilities. The playing field is wide open.

Applying strategic thinking and creativity when employing mobile marketing tools and tactics can provide endless opportunities for innovation. According to US surveys mobile marketing will become increasingly effective in years to come.²

Figure 1. Future mobile marketing evolution³

² (http://www.kodak.com/US/images/en/corp/aboutKodak/onlineToday/Mobile_Media_12-11aSP.pdf)

³idem

Figure 2. US Mobile Advertising Spending⁴

Figure 4. Consumer Behavior Online⁶

Figure 3. Interactive marketing spend⁵

According to Forrester Research, one-third of Europeans surveyed have use their mobile phone to play a game, one-third have sent MMS/picture messages, nearly two-thirds have taken pictures, and 80 percent have sent an SMS/text message. The graph above shows the number of European mobile internet users in 2014 is projected to be triple what it was in 2008. In addition, 3G-enabled mobile phone usage is projected to grow from 46 percent to 81 percent in the US and from 34 percent to 70 percent in Western Europe from 2009 to 2014, making even more advanced features and tactics possible.

Figure 5.
European mobile Internet users⁷

Launched in 2007 in Romania, mobile advertising remains at an early stage. Now, in conditions of crisis, marketers have noted this environment being that constrained to find a cheaper way to target potential customers and more efficient.

How a marketer can send an ad to young people aged 19-25 years who go to the movies on Sunday night in the Vitan area ? .. or how can he send an ad to employees of a business centers at noon ? At that time, the targets we are talking about can not access TV or radio, or press, not even the Internet. Surely, they have a phone... and they are ready to pay attention to it. In the next period may gradually become an important component of the communication strategy for many Romanian companies.

Considering that the advertising market becomes more crowded and the consumer is bombarded with advertising messages on all channels, the Unlock Research company's study wanted to see what is the Romanian consumer attitude towards mobile advertising, as a new communication channel. The sample was composed of 150 persons, mobile users, women and men, aged between 19 and 45 years who normally reside in Bucharest, with a high income and education. According to this study, the main

⁷Unloc Research, "Overall potential of mobile marketing concept- Quantitative research -When numbers tell a story" ,October 2008 available at www.slideshare.net/confirm/MjQ1NTk1MTU7ZGludS4=/1271863-f45407bf89ac6d2203c49fa8393900f3c17f98ca-slideshow

advantage that offers mobile advertising is to inform.⁸

Figure 6. Benefits of mobile ads⁹

2. Strengths

Mobil marketing offers many benefits :

- mobile phone is an always-on devices and create a personal communication channel. One mobile phone typically has one unique user. The relationship we have with our mobile phone is more intimate. The phone is an accessory that we do not borrow anyone as it can happen with your PC and the customer has the feeling that the ad it addresses only to him/her. So, the communication is direct, highly personalized, bidirectional, fast and efficient in terms of cost
- mobile is valuable as a stand-alone medium for advertising, but it's also well suited for a vital role in fully integrated cross-media campaign plans, including TV, print, radio, outdoor, cinema, etc.
- this is a fresh, innovative way to reach your customers and give them access to your brand at any time, wherever they are.
- practice has shown that an SMS campaign combined with the mobile Internet, can generate click-rates are up to

⁸ idem

⁹ idem

20-25% higher and purchase rates over 10%, unlike simple online campaigns.

- marketers recommend that a company should turn to mobile marketing when this wants to increase sales, because it may be the most effective form of direct marketing, if it is properly implemented. And who does not wants to increase sales in these times.

- besides helping to increase sales, mobile marketing achieve other objectives related to brand reputation, creating a database of customers or potential customers, the onset of viral mechanisms - SMS is easily passed on when the offers is tempting. Besides, the text messagin include many advantages : it is reliable, it is quick and easy, it is cheap, it is discreet and confidential, etc.¹⁰

3. Weaknesses

Because the phone is seen as a very personal communication channel, users feel inconvenienced, resent the advertisements would not be interested. Even those who want to receive messages will be resent if they receive more than 5 messages per day, as shown and Unlock Research study.

- 27% of the respondents who want to receive mobile ads consider that the optimal number of messages received on mobile is between 2-3 messages per day, 25% believe a message/day is optimal, only 5% of respondents considered that 5 messages per day would be the optimal number

- the company that act in this sector have to respect a compilation of accepted industry practices. The Mobile Marketing Association's (MMA) Consumer Best Practices (CBP) committee strives to implement policies that encourage the growth of the off-net industry but the primary focus is on consumer protection and privacy.¹¹

4. Opportunities

- Despite sometimes limited creative space, ads are usually easy to develop

- Once displayed, messaging ads can engage users directly in various ways, such as interactive message reply/forward, click-to-Mobile Web and click to call.

- Mobile marketing has the ability to measure channel usage, unique ad exposure and obtain detailed campaign results analysis. Campaign results can be easily measured. Marketers may have access to real-time response information and may modify the campaign according to the results, long before a campaign terminates.

- Unlike sending an email, sending an SMS is not a free operation, and this means that spam is more difficult to invade the mobile space.

- In Europe, mobile penetration rate registred is between 80-120%, depending on each country. SMS is 100% compatible with mobile terminals that are sold today, WAP site with 70% of them, and MMS's with 50% of the terminal. In other words, SMS marketing campaigns can reach everybody and even a mobile Internet campaign can reach about half of the population, i.e. just like any email marketing campaign, the Internet price¹².

- As major companies such as Apple and Google invest in technology development introducing whole new mobile devices and buying up ad firms specializing in the small screen, this area has great possibilities for development (ex. Google opened up their AdWords platform for advertisers wanting to target the iPad).¹³

5. Threats

- Mobile phones have all the attributes for successful communication campaigns, but continue to encounter problems that lead including a greater reluctance of users

¹⁰ Alex Michael, Ben Salter, "Mobile Marketing : achieving competitive advantage through wireless technology", Elsevier Ltd., 2006, pg. 19

¹¹ "U.S. Consumer Best Practices Guidelines for Cross-Carrier Mobile Content Programs, April, 22, 2010, version 5.0 available at <http://www.mmaglobal.com/bestpractices.pdf>

¹² Roxana ONEA, "Avantajele marketingului și ale publicității mobile: spam redus, personalizare mare", 2007-03-20, , available at http://www.comunic.ro/article.php/Avantajele_marketului_%C5%9Fi_ale_publicit%C4%83%C5%A3ii_mobile_spam_redux_personalizare_mare/2860/

¹³ <http://www.mobilemarketingwatch.com/google-quick-to-adapt-adwords-to-the-ipad-6100/#more-6100>

towards mobile advertising. In Romania, the users' perception of mobile marketing messages depends largely on how wrong the advertisers choose their target audience for such campaigns. This is a big problem considering the weight of which is occupied by each element of the promotion in a direct marketing program, as was shown by Stone and Jacobs: 15% text, 40% the list of those who agree to receive mobile messages, 30% the offer and 15% how the offer is made.¹⁴

- Unlike other forms of marketing, mobile marketing has a special characteristic : it requires the express consent of the consumer to receive future communications. Strong consumer privacy standards are essential to the success of mobile marketing by protecting mobile users from unwanted communications on their mobile devices. For one thing, some marketers remain worried about trying it, for fear of annoying consumers by intruding on their personal space.

- As revealed research conducted by the firm Unlock Research, one of the main limitations of this channel of promotion is a low adoption of MMS in Romania's - is one of the few services that have not been successful domestically, as opposed to growth of SMS traffic to mobile Web. More than 50% of those surveyed use modern technology (internet or bluetooth). SMS is the most common mobile data service.

¹⁵Unloc Research, "Overall potential of mobile marketing concept- Quantitative research -When numbers tell a story", October 2008 available at www.slideshare.net/confirm/MjQ1NTk1MTU7ZGludS4=/1271863-

- Besides technical limitations, in Romania there are still a few companies that have their own databases, limiting their lack of exploitation possibilities of mobile marketing services

- Attention that the users give to mobile ads. The study results of the Unlock Research company reveals that 29% of the respondents asserted that disagree with the idea of mobile advertising and only 13% are really agree with it. Only 8% of young respondents and 15% of adults agreed to receive ads on mobile.

Figure 8. Agree/Disagree with mobile ads¹⁶

- Not involving mobile operators in supporting and developing the field. Vodafone was the first mobile operator in the world which launched services in just 135 days of license approval (1997) and in Romania is and Romania is the most active proponent of mobile marketing, organizing conferences and having many projects with direct marketing Romanian companies. Operator which launched the first 3G mobile portal in Romania (June 2005).¹⁷

6. Conclusions

Mobile marketing is so new and evolving so fast, we're still learning. In conclusion, we make several recommendations that would lead to the development of mobile marketing field in Romania :

¹⁶ idem

¹⁷ <https://www.vodafone.ro/despre-vodafone/descriere-si-istoric/detalii-despre-istoricul-companiei/index.htm>

- Mobile Marketers should target and limit mobile messages to that which users have requested.

- Mobile messages should provide value to the user. Value may be delivered in multiple ways, including : product and service enhancements, reminders, sweepstakes, contests, requested information, entertainment, or discounts. According to Unlock Research study, the response when subjects were asked "what would you change for the better perception regarding mobile ads?", 98% of the people who did not wish to receive mobile ads said they are motivated by service unlimited send / receive MMS, service unlimited send / receive SMS (84%), 71% want to receive a material reward for every advertisement received and 67% said they would encourage free Internet access on mobile.

- Mobile Marketers must take every steps is necessary to ensure that user information they collect for the purpose of delivering targeted advertising is handled responsibly, and in compliance with applicable law.

- Mobile Marketers must implement reasonable technical, administrative and physical procedures to protect user information collected in connection with mobile marketing programs from unauthorized use, alteration, disclosure, distribution or access.

- Mobile firms and advertising agencies should be more involved in promoting this channel of communication and to inform users on the benefits they can bring. This actions should benefit of the ARMAD's (Romanian of Direct Marketing Association support

- Companies should engage in creating and managing databases of customers and potential customers

e-mail: liliana_maruntelu@yahoo.com

Abstract

Information transmission and exchange between interlocutors and cultures seem to be real communication problem. Indeed, with the present internationalization context, any enterprise is forced to master the fundamental concepts of intercultural communication. Moreover, throughout their communication process, managers use a multitude of language manners that are necessary in order to transmit and receive correct information, at a verbal, non-verbal or para-verbal level, while each communication form is strongly influenced by factors of cultural nature.

Keywords: intercultural, cultural dimension, collective programming, cultural models, intercultural communication.

JEL classification:: M12, F24, J24.

1. Introduction

Communication appears to be an administrative strategy at the level of enterprises, groups and individuals. Cultural influences become a stake with a great additional value. This excerpt tries to shape some of the influences of intercultural communication by answering basic questions related to the subject, such as: "How is the notion defined?", "Is perception an extra obstacle?", "How did teams around the world adapt to intercultural communication?". In this competitive international environment, one of

the faster ways to remain competitive is to look for strategic collaborations. One of the factors that characterize contemporary enterprises is probably the need to have under control the growing feeling of incertitude. Moreover, it seem that the communication style within enterprises has changed as the new forms of cooperation modified their working style (internal and external) thus making collaboration more powerful.

2. Factors that increased the importance of intercultural communication

The beginning of the twenty-first century brings new challenges in all scientific fields, as well as in communication. The political and social events that shattered the world left a print especially on people and the way they communicate. People are becoming more open, willing to get to know other people, to communicate and relate to them. Intercultural communication is at its climax of consciousness and mediatisation.

Perhaps the most important factor that led to the extension of intercultural communication is people migrations. *Migrations* represent an essential point in the emergence and development of intercultural management. Migrations represent the movement of a great number of people belonging to a certain ethno-cultural origin, different than the one specific to the place they establish or transit. The last century brought new form of migrations, most of the movements having been imposed on

individuals by professional or university development, the research development within a multinational team, by professional migrations in order to find a work place as well as systematic tourism. In this manner, intercultural areas, where people use hybrid languages and form new “traditions”, were created.

Another factor consists of the *competition* between great corporations, also encountered in IMM's, lead to the pursuit of proper solutions in order to keep their place on the market and to conquer new markets and new collaborators. One of the solutions involved getting to know the cultural element from the local area where branches of the company were situated, taking into account that the client would be easier to influence once his/her customs, traditions, behaviours etc. were taken into account while his/her employee, the local manager is better motivated to act for the company.[7]

The extension of business forced companies to use specialist from other countries, which led to a process called –free circulation of specialists. This decision turned out to bring challenges especially for the human resources departments in companies, as the new comers belonged to different cultural areas and sometimes failed to adapt to the new conditions and also in reaching the company's goals. Therefore, the relationship between employers and employees belonging to different cultures became an issue of great importance in contemporary management. [10].The spectacular evolution of informational and communication technique and technology favoured this exchange of specialists at an international level and lead to the continuous need of knowledge, of discovering new opportunities, evolving, succeeding. In this his manner, intercultural training and shaping of managers started playing a very important role in a firm's activity.

The problem of communication and the implication of identity in the intercultural field are meant to lead to a deep analysis of the relationships between communication, society

and politics in the context of the changes generated by the technological and informational revolution. It is considered to be extremely important the fact that cultural roots remain an essential point for the individual and society, especially because the cultures' connection owed to telecommunications, businesses, tourism, immigrants' circulation, endanger the coexistence between nations.

3. The impact of enterprise evolution on intercultural communication

Within everyday language, the notion of *culture* is used with a broader meaning in order to describe a number of different concepts as well as a pattern of thinking, acting and expressing feelings. Culture thus refers to the specific way of spiritual existence and social behaviour of a group a community or society. The definition of culture gains more and more attention in the social and human sciences, but also in fields like international management, marketing, advertising, tourism, etc.

As far as the field of business is concerned, the culture of the firm enters a conflict with other entities cultures (clients, competitions) so that the management activity takes place in an environment characterised by *cultural diversity*. When the firm's business take place at a global scale, the importance of culture for management conception and practice distinguishes itself on more than one level: global, when regional cultural differences are taken into account (Western/Eastern society); international, when differences between national cultures are considered (e.g. American management/ Japanese management); corporation, when the connection between firms' culture is analysed .

Business is one of the fields in which intercultural communication is frequently considered. The relationship between employers and employees belonging to different cultures became an issue of great importance in contemporary management. The study of cultural differences in management starts from defining the notion of culture and

the establishment of connections between national and enterprise culture.[3]

Intercultural and comparative studies are also becoming more and more important to the global business environment. Contact and communication with other cultures are dominant features of modern life. *Intercultural communication* comprehends the inseparability of culture and communication concepts, referring not only to the understanding of a new group, but also to the acceptance tolerance of differences. [1]

As far as Romania is concerned, communication and the problem of identity within the intercultural plan imply the existence of interest for the Romania popular customs. Traditions are considered to be picturesque folklore manifestations, including as well the relation created between people and nature, the surrounding environment. Customs present social life and its significant aspects. Therefore, custom as a cultural communication act establishes a connection that involves change of information, possessions, and services its partners.

Communication is one of the most frequently discussed issues also in the workplace. Every day we interact with others in an attempt to communicate; lack of communication may create misses of the target, anger or frustration, mistakes, and more.

4. Identifying mechanisms of intercultural misunderstandings

The coexistence of cultures became an issue of citizens' equality in the majority of democratic countries where this phenomenon was present. The most powerful manifestations of culture, whether through the number of those who possess it, or the political and economical power of these people, tend to dominate, to monopolise, and finally to annihilate all other cultures found in the same space.

Communication barriers have a special role in the process of internal communication, their analysis having a great importance for the

international management strategy. Communication could be affected in the international environment by barriers such as: *failing to understand the communicated language*; *cultural impact* (the inability to understand or accept people that have different values, standards, lifestyles), *ethnocentrism* (meaning the belief that one's culture is superior to all other cultures), *lack of openness*, due to a formal and rigid attitude that affect free exchange of opinions. [2]

An essential aspect in the intercultural exchanges is *language*, the common code that makes communication possible. The key element of the language policies in Europe is the *national language*. The majority of the European states made the uniqueness of the national language an expression of the national and political unity, therefore including language in the very principle of the national state. Obviously, minorities and immigrants are those who have to learn the mother tongue of their adoptive country, needed especially in the work field, leaving the pleasure of exercising their own language among members of their previous community.

Stereotypes represent another limitation and perturbation causing factor to the intercultural communication. For instance, throughout movie- history, African-Americans were portrayed as being unintelligent, lazy, or violence-prone. As a result of viewing these stereotyped pictures of African-Americans, prejudice against African-Americans has been encouraged. Without any doubt this perception of African-Americans also represented a disadvantage as far as finding a work place is concerned. [2] Stereotypes concerning Romania also travel outside our boundaries. Unfortunately, due to the acts of violence that come against low in any country, some members of the Gypsy community that emigrated from our country laid a negative perception of all Romanian population. Understanding the nature of prejudice, stereotypes, and discrimination is the first step in combating these practices.

Ethnocentrism also represents an intercultural misunderstanding, having as

purpose the conservation of culture and civilization, not only by overestimating one's own culture but also through more aggressive means such as of extension, domination or constraint. Alongside ethnocentrism, *perception* of cultural difference is another factor that makes people aware of diversity, whether it relates to language, customs or style. The business field is again probably the wake up call in this process of diversity perception.

5. Ways of improving intercultural communication

In order to achieve intercultural competence that would finally lead to a successful dialog between cultures specialist are drawing attention towards elements and languages of intercultural communication. Intercultural competence, an imperative basic feature that individuals must possess today requires the following aspects: *changing of human behaviour* by accepting cultural influences, the perception of different cultural patterns other than one's own, selectively *adopting* standards from other cultures, *engaging* in positive relationships with people belonging to other cultural spheres, with cultural legacy and cease all intercultural conflicts.[6] Therefore, *intercultural communication competence* represents the capacity to negotiate cultural significations, to manifest efficient communication behaviours, to express positive attitudes and solve communication problems between cultures in diverse contexts.[5]

The cultural and intercultural context of communication can induce different stages of understanding and reciprocal acceptance or confusion, denial, rejection, conflict. Taking into account the meaning of communication only through *verbal and written language*, is quite restrictive and can create contradictory interpretations in the case of relationship between different cultures, which is why people must gradually learn to master signals of *non-verbal communication* as well.[2]

Intercultural training could be followed by a successfully recruitment of highly appreciated

specialist belonging to other cultures if simple rules are taken into account throughout the interviews held by human resources departments. Anyone recruiting people will have one identical aim - to hire the best. It is crucial for the recruiters to gain some intercultural insight into interviews.[4] The key to any successful intercultural interview is to overcome assumptions about people. Assumptions can relate to many things but in the context of the interview they are really about: assuming how someone should respond to a question, behave or act. Communication styles differ too, from culture to culture. In an intercultural interview one needs to bear in mind that people give information in different ways. Explicit communicators put all the meaning into their words. On the other hand implicit communicators use other subtle ways of getting their message across such as body language, tone, eye contact and inference. Some of the questions that can be encountered in intercultural interviews are: "*How does your life here compare to the life you had in your country*", "*Have you had any challenges after you came here?*", "*How did you pick up your cross-cultural skills?*" or "*Could you give me any advice about learning from experience?*".

With the present internationalization context, any enterprise is forced to master the fundamental concepts of intercultural communication. Moreover, throughout their communication process, managers use a multitude of language manners that are necessary in order to transmit and receive correct information, at a verbal, non-verbal or para-verbal level. Working in a global team and dealing with business partners or customers across cultures, raises challenges and demands new attitudes and skills. Without the right approach, cultural differences greatly reduce the effectiveness in the early stages of a relationship. But active management of the internationalization process and a conscious effort to acquire new skills will release fresh sources of competitive advantage.

6. Conclusion

People around the world have been confronted with intercultural problems long before the issue was defined, thought about or taken into consideration. Present issues such as globalization, as well as human interdependence and culture development taking place throughout the world forces people not only to take into account intercultural problems but also to find viable solutions

The image of cultural world has become more complex due to the process of social development and transformation (linguistic and demographic changes, mobility, relationships with other people). The concept of multicultural society in Europe's context, becoming everyday more unified, are some of many issues, but also opportunities. The historically built European societies, where national symbols and ethnic attributes lay at the basis of their identity, are forced to accept cultural pluralism.

As far as multi-international enterprises, the issue of communication within the firm becomes even more complex as it is influenced by many factors, such as: the national culture of the original country of the firm, the national cultures of the host countries of branches and their organisational culture. Due to the activity that branches have been carrying in diverse cultural environments and to the communication relationships that have been established, internal communication gradually becomes intercultural.

Abstract

This work was supported by CNCSIS – UEFISCSU, project number 224 PNII – IDEI code ID 793/2007).

Within the context in which nowadays the health services suffer changes that have never been met before concerning in significant reforms in progress, having a new approach in providing the services, the hospital has to face up with major challenges within an obsolete and difficultly undertaken system. The external pressure but also the internal one obliges the hospital to make structural changes, efficiency changes and changes made in their service and quality, in the care safety, in the technology used and in the degree of the patient's satisfaction. The asymmetry of the information, the rigidness of the offer, the rigid price politics, the resources penury make all these changes to seem impossible and incompatible with the exigency of the quality and of the performance. Starting from a constructive research (literature review), the paper proposes the realization of a SWOT analysis within a surgery section, which aims at emphasizing the main difficulties with which the sanitary management services confront when increasing the efficiency and the quality of the medical act as a premise of the improvement of the population's general state of health.

Key words: SWOT analysis, surgery system, sanitary amangement strategy;

JEL classification: I11;M11;

1. Literature review: the concept and the analysis of the SWOT analysis

SWOT analysis is a strategic planning method used to evaluate the Strengths, Weaknesses, Opportunities, and Threats involved in a project or in a business venture [7]. It involves specifying the objective of the business venture or project and identifying the internal and external factors that are favorable and unfavorable to achieving that objective. The technique is credited to *Albert Humphrey*, who led a convention at Stanford University in the 1960s and 1970s using data from *Fortune 500* companies.

A SWOT analysis must first start with defining a desired end state or objective. A SWOT analysis may be incorporated into the strategic planning model. Strategic Planning, including SWOT and *SCAN analysis*, has been the subject of much research.

Strengths: *attributes of the person or company that are helpful to achieving the objective(s).*

Weaknesses: *attributes of the person or company that are harmful to achieving the objective(s).*

Opportunities: *external conditions that are helpful to achieving the objective(s).*

Threats: *external conditions which could do damage to the objective(s).*

Identification of SWOTs are essential because subsequent steps in the process of planning for

achievement of the selected objective may be derived from the SWOTs.

First, the decision makers have to determine whether the objective is attainable, given the SWOTs. If the objective is NOT attainable a different objective must be selected and the process repeated.

Practically, the SWOT analysis **starts with the realization of an inventory of the internal qualities and weaknesses** afferent to an organization. Then the **external opportunities and the menaces** which can affect the organization are identified, basing on the market and the environment. There are though other options, meaning that some authors suggest the accentuation of the external opportunities and menaces before qualities and defects.

In each of the four zones the factors that seem more relevant are taken into evidence. The main purpose of the SWOT analysis is to identify and associate each factor, negative or positive to one of the four categories, fact that allows us to see the business with an objective eye. The SWOT analysis will be a very useful instrument in the development and the confirmation of the marketing strategy.

Strong points

Strong points concern the positive internal aspects of the business and add value and offer an advantage in the case of a competition, being an opportunity for the management to revise the value of the business. As a consequence, they describe the positive, tangible and intangible internal attributes of an organization which controls them: What are we doing well? What resources do we have? What advantages do we have in front of the competition?

For example, strong points can include the positive attributes of the humans involved in the business, including their acquaintances, their past, education, references, contacts, reputation and capacity which come inside the business together with them. Strong points also include the tangible goods as the available capital, equipment, credit, stable clients, existent channels of distribution, materials with author rights, patents, information and processing systems, and other value goods from the organization's business [2].

Weak points

Weak points concern the negative internal aspects of the business which diminish from the offered value or place the organization on a concurrent disadvantage. As a consequence, these represent factors which are controlled by the organization and which delays it to obtain or to maintain a competitive quality: *Which zones should be improved to compete with the strongest competitor?*

For example, weak points could include the lack of experience, limited resources, and the lack of access to technology or capacity, inferior service offer or a weak location of the business [3].

Opportunities

The opportunities evaluate the external attractive factors that represent the reason of the existence and of the prosperity of a business: *What opportunities are there in the market sector of the organization or around it from which we can hope to benefit?* Therefore, these opportunities reflect the potential that can be realized by implementing the marketing strategies. Identifying the opportunities which will be internal to the organization and which are controlled by it will be classified as strong points.

For example, the opportunities can be the result of the market increase, of changing the life style, of solving the problems associated to a current situation, of the positive perception over the business of the organization or of the capacity to offer a higher value[4].

Menaces

Menaces include factors outside the control of the organization which could jeopardize the marketing strategy and even the business. These are external factors on which the organization has no control, but it can anticipate them if it elaborates an emergency plan.

A menace is represented by the challenge created by an unfavorable trend which could determine the diminishing of profits.

For example, the current or potential concurrence, the increase of the prices by the

providers, the governmental settlements, the negative effects of the media, the changes in the behavior of the consumers who determine the diminishing of the sales and the introduction of a technology much more advanced that leads to the moral usage of the products, services or equipments [5].

2.SWOT analysis – application for the surgery section

The analysis will allow us to use in the advantage of the entire section the talents, the abilities and the opportunities supporting this way its development within the hospital. By understanding the weak points of the section, we could solve and eliminate the risks easier. In addition, regarding us and our competitors through this analysis, we will be able to create a strategy which will allow us to distinguish ourselves on the market of the hospital medical services in our area.

The proposed strategy has as main objective the creation of a professional surgery section, performing from all the points of view, safe and trustful for all the patients, no matter the age, sex, the social environment from which they originate. We propose to analyze this by:

1. Obtaining good financial results by optimizing the expenses for the maximum satisfaction of the patients, taking into consideration the financial constraints connected to the price systems; obtaining increasing profitability by introducing with success some new operatory techniques, medical machines of the last generation with the help of whom the patients will receive new services.

2. Offering some high quality services from a medical, hotel and administrative point of view; the insurance of the patients' rights to information, security, confidentiality, trust; the maximization of the patient's degree of maximization.

3. The insurance of solving rapidly the patients' requests (work schedule, waiting time between the processes, the planning of the operator block resources) with better results than in the similar sections from other hospitals and the creation of a working environment which encourages the team spirit and the opened communication.

4. The continuous perfecting of the medical and auxiliary staff and the obtaining of a competitive advantage basing on the competences and knowledge.

For the effective realization of the SWOT analysis we started from the formulation of the following questions, whose answers have included the points of view of the collective and of the patients [1].

Strong points:

1. What advantages has the surgery section?
2. What surgical interventions do we perform better than in other similar hospital sections?
3. What are the unique resources that we have?
4. What are the diminished prices that we have?
5. Marketing?
6. Innovative aspects?
7. Qualification, certification?
8. Procedures, IT, communication?
9. What do our patients identify as being our strong points?

Weak points:

1. What could we improve?
2. What should we avoid?
3. What do other patients regard as weaknesses?

Opportunities:

1. Which of the opportunities can we identify?
 2. Which are the important tendencies?
- The opportunities could come from elements as:
1. Technological modifications
 2. Legislative changes
 3. Modifications of the patterns or of the social habits, of the lifestyle, of the population profiles
 4. Local, regional events

Menaces – risks:

1. What obstacles expect us that menace our surgery section?
2. What do our competitors do?

3. Do the specifications of the profession or services modify?

4. What problems of financing do we have?

5. Which of the weaknesses could affect seriously the surgery section?

The other steps are to be found below which represents the SWOT analysis for the surgery section:

Strong points:

1. In the section, there are performed sufficient surgical interventions both regarding the typology and their number.

2. The improvement of the satisfaction level of the patient regarding the offered medical services (The rate of mortality within hospitals in sections; The proportion of deceased patients 24 h after their hospitalisation per section; The proportion of the deceased patients 48 h after their surgical intervention per section; The rate of nosocomial infections per section; The rate of the re-hospitalized patients (without a previous planning) for 30 days from their discharge; The index of concordance between the diagnosis given at the hospitalisation and that given at the discharge; The percent of the hospitalized patients and transferred in other hospitals.)

3. Higher degree of trust of the patient regarding the surgical services that we offer (The number of the patients' complaints; Loyalty degree of the patients (coming back for check-up)).

4. Competitive advantage, based upon knowledge, abilities and aptitudes of the medical and auxiliary staff.

5. Solving in time all the processes to which the patient is subdued (hospitalization, investigations, surgical intervention, treatment, discharge).

6. The respecting of the budgets (Budgetary execution to the approved expenses budget; The percentage of personal incomes of the section of all incomes of the hospital).

7. The efficient usage of the resources (The structure of expenses on each type of intervention depending on the income sources).

8. Optimizing the expenses for maximum satisfaction of the patients (The percentage of the expenses on medication of the section of the

entire sum of expenses of the hospital; The percentage of capital expenses of the entire sum of expenses of the hospital; The percentage of personnel expenses of the section of the entire sum of expenses of the hospital).

Weak points:

1. Poor computerized medical equipment.

2. High hospitalization costs in the case of surgical interventions.

3. The lack of an integrated informatics program to interconnect all the sections.

4. The lack of hotel optimum conditions.

5. The existence of some equipments morally and physically used.

6. The lack of a modern functional circuit of the sick people, of the aliments, of the wastes and visitors.

7. The migration of the medical staff.

Opportunities:

1. The definition of some precise standards for each task realised by the employees of the medical and executor –operational branch; The learning of those standards by the employees and the checking of the degree of their awareness concerning the expected results; The elaboration of the following mechanisms of standardization: the guide regarding the surgical operator protocol; the protocol for the prevention of the infections caused by operatory plague; specific guide for the circuit of laundry in the hospital; The protocol for effectuating the daily cleanliness in the hospital, for the cleanliness in rooms, in other locations; The elaboration of the protocol for the attributions of the sanitary stuff in the prevention and control of the nosocomial infections; the protocol used to prepare the surgical instruments for sterilisation; the collection and weighing protocol of offal; The elaboration of the protocol of the aseptic technique in the operator block.

2. A new approach of the relation with the patients in surgical services; The realization of a procedure capable of solving the complaints and its permanent execution; The development and the implementation of an improvement plan of the patient's confidence; Benchmarking regarding the patients loyalty.

3. The creation of the department Public relations which contains: large public (patients, community), volunteer groups, mass-media: groups of journalists who present the realisations(difficult operations, innovations), permanent actualisation of the web page; The strategy of counteraction of negative publicity (complications and deceases presented in an exaggerated manner in the press, unsatisfactory work conditions and attempts to gain profit in illegal ways.

4. Introducing the total system of Preventive Maintenance; The supplementary equipment of the salons with alarm systems for each bed for emergency cases.

5. The improvement of the awareness of the medical and auxiliary staff concerning the safety problems through training and communication; The intensity of controls regarding safety; The introduction of security supplementary personnel especially in the night; The stimulation of the patients' involvement regarding public safety through communication (offering brochures).

6. A construction of the operatory program regarding the time; A construction of the daily operator program; Time management in the operator block.

7. Identifying the causes of the failed surgical interventions depending on the type of intervention, sex and age groups; The elimination of the causes, respectively of outdated procedures, outdated instruments, of the consumable materials and inappropriate medicine, the avoidance of human mistakes by permanent clarification of the stuff.

8. Introducing a privatization system of paid hotel services.

9. The analysis of the processes of acquisition of the consumable materials and of medication and also its best execution; The realization of a department of Clinic engineering to ensure the continuity of the logistic system having a technical nature of medical activity and to optimize the cost of activities; Adopting the maintenance of the medical technical systems (preventive, systematic preventive, conditioned).

10. The usage of operatory techniques less expensive.

11. The externalization of catering activity; The introduction of the budgets for types of surgical intervention .

Menaces – Risks:

1. The precarious financing due to the period of crisis.

2. The lack of staff due to the phenomenon of aging and the emigration of labor.

3. Legislative instability.

4. The competition of the private hospitals.

5. Low standard of living due to the high rate of unemployment. Diminished possibilities of using the co-payment services.

6. The increase of the costs of the medical costs

7. The diminishing of contact if no optimal accommodation conditions are created.

8. The staff politics sometimes dictated by the tutelary forums.

9. The social pressure through the lack of personal possibilities of house treatment or care of the patients.

10. The prolonged sub-financing of the performed services and the lack of investment funds to continue the consolidation-modernization works till present, affects not only the capacity of adaptation to the European norms, but also the current development itself of the medical act (its quality).

3. Conclusions

1. The theme remains open for reflection and controversy in the **public business world**, excepting the medical sector in which the notion of marketing is easier to notice and assimilate.

2. To optimize the functionality and the performances of such a public institution – expressed under the name of “gain” – gain for all those who made supply and demand, providers (doctors), patients, administration and budget, we consider that the **SWOT ANALYSIS**, although not compulsory, is necessary because it views the practice from an objective manner as “a systematic, critical analysis of the quality of the medical act”, or as “an attempt to improve the quality of the medical act.”

3. **The SWOT analysis** in the hospital environment uses scientific methods to establish explicit criteria for the good practice, it measures the performance, it selects the cases, it compares the results and evaluates the actions of

improvement, this being realized at several levels:

The care structures – the organization of the activities, the equipments and the competences of the medical staff are analyzed.

The care procedures – the degree of correctness is analyzed in the application of the medical protocols

The care results - the degree of cure and bettering of an affection as well as the absence of complications

The orientation of the sick person in the demand for care – the accessibility to a certain type of service is appreciated.

Abstract

This work was supported by CNCIS – UEFISCSU, project number 224 PNII – IDEI code ID 793/2007).

As the services have distinctive features which differentiate them of the manufactured products, the services marketing is different of the product marketing. Due to the fact that initially they were designated to the marketing goods, the traditional “4P” of the marketing combination (**product, price, placement and promotion**) have proved to be inappropriate for the services marketing and more for the medical marketing, not addressing to the distinctive characteristics of the services and not taking into consideration the importance of the human element. **STAP** – **service, tariff, access, promotion** – is a pretty new term which is due to the fact that the medical institutions have been through the latest organizations of performing the services that applied the modern marketing in their activity. Starting from a constructive research, the paper proposes to realize a research destined to the adaptation of the STAP concept within the medical system.

Key words :product ,price; placement, promotion,service,tariff,access,promotion,medical system;

JEL classification: I19; M31;

1. The basic characteristics of marketing: the concept of the “4P”

In the specialty literature, the traditional “4P” of the marketing combination are defined this way [7]:

1. The product is represented by *a good or a service which satisfies the necessities of the client.*

The product politics represents an ensemble of techniques and strategies that aims at the dimensions, structure and the evolution of the services scale that constitutes the object of the activity of the organization and which includes a multitude of activities:

The innovation – it refers to the creation of an appropriate climate in all the compartments of the unity for: research and the diversification of the services scale.

The modeling of the service – it consists in its conceiving and report at a certain qualitative standard.

The legal insurance of the performed services.

2. The price represents the value received in the exchange of the product

The price politics is an ensemble of strategies, tactics and techniques that allow the organization to model the prices depending on the demand, conjuncture and the market dynamics.

3. The promotion is defined as *a modality of communication between the buyer and the seller.*

The promotion politics represents an ensemble of actions meant to facilitate the

communication of the enterprise with its exponents in the external environment, totalizing a series of activities meant to attract a large number of consumers towards the offered products, releasing the action of buying on one hand, and on the other hand, meant to contribute to the increase of the economic efficiency.

4. The placement is the process of distribution of the product by the consumer.

By the **politics of placement** or distribution we understand the effectuation in the basis of a well determined plan, of a pluralism of specific actions which develop within the interval between the closing of a performing process of the service and its entrance in the possession of the final consumer.

2. The marketing of medical assistance and the STAP concept

In what concerns the politics of the “4P” this takes the form of the STAP concept - Service, Tariff, Access, Promotion within the marketing of the medical system [7].

1. The service. A first aspect which must be taken into consideration is represented by the **characteristics of the medical services**:

(a) The intangibility – it aims at the immaterial aspect of services, consisting of the fact that these cannot be seen, tasted, felt or smelt before being bought.

(b) The inseparability – it refers to the characteristic of the medical service that cannot be separated of the performer, being realized only through direct connection doctor-patient.

(c) The invariability – it refers to the fact that a medical service cannot be repeated more than once identically, being determined by the pathology of the patient, by the medical staff that administrates the treatment and by the material and medical support which stood at the basis of the treatment.

(d) The perishableness – it refers to the fact that the medical services cannot be stocked to be ulterior reused.

A second aspect is represented by the fact that one of the demands of formulating the marketing strategy is represented by the identification of the necessities and the patients’ desires, **the necessities** being defined as “*a psychological feeling originated from a need*”,

and **the desires** as a “*need appeared from the patient’s personality*”. Within the current context, the concept “desire” becomes an element more and more important. The simplest example would be the **interaction patient-medical assistance, as a phenomenon having two sides: the need – the health problem – and the desire – characteristic to entertainment, comfort and to the level of communication**. The priority of the services offered by the medical system comes from the identification of the needs and desires.

Mainly, for the patient’s satisfaction, **the relation doctor-patient presupposes at the same time [7]:**

(a) A medical dimension – referring only to the medical act itself. The patients’ satisfaction means cognitive evaluation and emotional reaction to the elements of the structure (human, material and financial resources and the hospital environment), of the process (technical aspects), as well as to the results of the provided medical services. Further on, the researches in the domain demonstrate that the satisfaction interacts with the perception of the technical aptitudes, the intelligence and the qualification of the medical staff. Though, the patients appreciate mainly the interpersonal communication aptitudes of the medical staff.

(b) a dimension of communication – which must aim at the information of the patient both in what concerns the diagnosis, the treatment, the recuperation and the consequences on the quality of his life which, not of few times, can be shocking. The patients must be asked what are their expectations concerning the doctor. A frequently studied aspect of medical care is the extension and the accuracy of the communication doctor-patient. The patient’s satisfaction is strongly dependent on the clarity of the offered information, and this could be an important sign of the quality of the doctor-patient communication.

(c) An affective dimension – which must exist during the hospitalization and which must aim at the care of the medical staff not only concerning the medical actions, but also the recognition of the new “statute”, that of patient, which passes quickly from the healthy man to the sick man. Taking into consideration the fact that in general a surgical intervention is

perceived as being complicated, the affective dimension is necessary in order to maintain the patient's equilibrium (example interdisciplinary teams surgeon – psychiatrist – psychologist).

First of all, the patients' needs need to be identified so that the medical staff foresees them, using adequately the medical techniques and procedures.

One of the most important directions and current moments that are connected to the medical assistance is the patient's placement in the center of care and attention. This is why the opinion of the patients can be considered a key in the evaluation of good or insufficient activities in the context of the marketing strategy. The quality of the sanitary services refers equally to the increase of the client's/user's satisfaction, to the professional audit and to the improvement of the efficiency or the reduction of the costs, being approached differently by each category of doers involved in the sanitary systems: the government, the patients, the professionals and the management of the sanitary organizations.

Due to the fact that nowadays in the sanitary systems a high importance is given to the idea of reaction to the response of the client/user of medical services and to the idea of offering to him what he desires, the methods and techniques of study of the patient's satisfaction are used at a larger and larger scale within the sanitary organizations.

2. The tariff represents the equivalent of the price in the general marketing and is defined as *the value attributed to the product or the procured system*.

Transposed in the hospital universe, **the tariff of the sanitary service** can be defined as *an ensemble of methods of fastening and constructing the prices which are to be paid by the patients in the exchange of different services that we will receive*.

Thus, **the tariff** generally consists in *fastening the price of the consultations and of the medical acts on one hand and in fastening the prices concerning the hotel services on the other hand*.

The consultations represent the services provided to the patients to diagnose and prescribe medical services. **The price of the consultations** should be fixed depending on the *level of competence of the doctor and on the*

price of the foreseen recovery. We ascertain that the difficulties connected to the determination of a structure of these prices justify the fastening of the price of these consultations.

The price of the medical and paramedical consultations represents the price of the medical act itself performed by the doctor on the patient during his hospitalization. These prices **should be determined depending on the nature of the medical acts: laboratory, radiology, stomatology, surgery, etc.**, depending on a general nomenclature of these acts. To each service or medical act a so called **key letter** corresponds to which a value is associated. These key letters correspond in fact to the medical acts mentioned previously: A=laboratory, B=radiology, C= stomatology, D=surgery...etc. Further on, the price of a service is obtained by multiplying the coefficient of the key letter corresponding to the service with its relative value.

3. The access represents the equivalent of placement, and the current tendency regarding the medical assistance is the diversification of the places of performing the service – home medical assistance, mobile unities (medical control, diagnosis, etc.) – or the increase of the reserve of the service at the “classical” place – the increase of the number of the hours of consultation, the work during the days of rest etc.

For the exemplification of the access we present the a public proposal of politics which aims at ***the improvement and the development of the quality of the lives of the dialyzed patients' lives by creating facilities for the transportation, treatment and psychological consulting of the patients coming from the disfavored rural environment***.

Purpose: **The creation of equal opportunities for the dialyzed patients in the rural environment regarding the access to the medical services and to the social assistance equivalent with those existent in the urban environment.**

General objective: The improvement of the access of the dialyzed patients coming from the rural environment to the medical services and to social assistance and the making environment to the medical services and to social assistance and

the making responsible the authorities in this regard.

Specific objectives:

1. The structuring and the organization of a network of transportation of the dialyzed patients until the end of the year 2013 in all the counties of the country.

2. The increase of the specialty medical staff's number who look after the sick in the peritoneal dialysis program at their homes in the rural environment.

3. The modernization of the dialysis center by involving the private capital, within the private public sector in this domain. The usage of modern, performing machines which offer medical and technical safety, superior conditions of monitoring, adequate diet and superior conditions of socializing.

4. The organization of services of social assistance for their patients and families.

5. The development of the social function of these patients with the help of the psychiatrist or of the social educator.

6. The implementation of the program **Holiday dialysis** through which the patients in Romania can spend the holiday at the seaside, at the mountains or abroad, benefitting of booking of the dialysis sessions in the nearest personal or partner center.

Direct beneficiaries: the dialyzed patients in the rural environment.

Indirect beneficiaries and categories affected by the implementation of the politics: The families of the dialyzed patients; The sanitary and social assistance corps in the counties' hospitals; The firms of transportation and maintenance of the means of transportation.

The variants of solving which were proposed are rendered below:

Variant 1: The creation of a network of transportation in the rural environment to take the dialyzed patients from their homes and to ensure their transportation to the counties' hospitals.

Impact 1

Social: The development of an adequate specialized system of transportation to respond the best possible and in due time the needs of the dialyzed sick.

Economic: It promotes a financing system that goes from Ambulance to the private sector.

Risks: Exceeding the costs initially anticipated.

Variant 2: The creation of a network of specialized social assistants who go and look after the sick in the program of peritoneal dialysis at their home in the rural environment.

Impact 2

Social: It allows the care of the dialyzed patients in their familial environment; It eliminates the discrimination in what concerns the different way of treatment of the patients in the rural and urban environment; It determines the increase of the number of the social assistants.

Economic: It presupposes exceeding the limits of the budgets of the County Hospitals to sustain the network of social assistants.

Risks: The over sizing of the social assistants' network does not insure their performing.

Variant 3: The creation of some zone dialysis centers.

Impact 3

Social: It allows maintaining the dialyzed patients in their social environment.

Economic: The diminishing of the costs when talking about treatment, exception making the transportation, the hospitalization, etc.

Risks: It determines the increase of the investment costs.

The recommended variant of solving: Variant 1 is the variant recommended for the implementation.

Motivation: a network of transportation will be created in the disfavored rural environment which will transport the dialyzed patients from their homes to the county hospital and back, network which will insure equal rights and non-discriminating for the dialyzed patients in the rural environment. The acquisition and the administration of the ambulances will be realized by the winner of the auction's organizer.

Direct beneficiaries: the dialyzed patients in the rural environment.

Indirect beneficiaries: The families of the dialyzed patients; The sanitary and social assistance corps in the counties' hospitals; The firms of transportation and maintenance of the means of transportation.

Social: The development of a specialized adequate system of transportation endowed with performing devices for the dialyzed patients; The development of a system which responds in due time to the needs of the dialyzed patients; The development of a system which responds in due time to the needs of the dialyzed patients; Easy access to the medical services of dialysis; The insurance of some equal rights non-discriminating for the dialyzed patients in the rural environment.

Economic: It promotes a financing system which goes from the Ambulance to the private sector; The management of the hospitals will register a significant diminishing of the transportation expenses for the dialysis, appointing this way in the limit discounted by the County House of Health Insurance for the non-medical transportation; Capacity of efficient administration of the bought ambulances; The respecting of the program schedule of functioning of the dialysis centre and the avoidance of this one due to delays.

Risks: Exceeding the costs initially anticipated; Delays in the development of the activities due to some unpredicted events (unfavorable meteorological conditions); The reticence of the families regarding the safety of transportation (road accidents).

Performance indicators: The increase of the number of the dialyzed patients coming from the rural environment who benefit from these transportation services; The number of the dialyzed patients entered for the first time in the program; The diminishing of the number of dialyzed patients who renounced to the program due to abandon or death; The degree of occupation of the jobs approved for the medical staff who will function on the ambulance; The degree of satisfaction of the dialyzed patients basing on the evaluation questionnaire, approved by the order of the president of CNAS (NHHI-National House of Health Insurance – 1 questionnaire/semester).

4. The promotion consists in informing the patients on the type of services, the purpose and their quality, the place and time of performing the services as well as the medical tariff. As in the case of the general marketing, the purpose of the promotion does not consist only in offering the information, but also in the creation of a

reputation and images (the creation of an atmosphere similar to the “brand name” in the general marketing)

Example: the main objective of publicity will consist in announcing the patients about the spectrum of the services offered by the surgery section and the obtained successes (new surgery techniques, difficult interventions which saved the patients’ lives, etc.)

3. Conclusions

1. The medical marketing based on the concept SPAP has as **purpose the increase of the quality of the offered services to increase the patients’ satisfaction** and in the final **the improvement of the health condition of the population.**

2. The main objective of the medical marketing based on the STAP concept is the **offering of qualitative health services**, insuring progress regarding the offered treatments, of the medical used equipments and of the medical staff trained and oriented towards the patient

3. The purpose of the medical marketing based on the concept SPAP is to make the medical service more **accessible to all the patients no matter the age, sex or social environment they come from.**

4. The purpose of the medical marketing based on the concept SPAP is to **adapt the medical service to the patients’ expectations and to present it to them** taking into account **the asymmetric information of the patients** due to the social environments they come from.

The Organizational Framework of Modern Companies – Present and Forthcoming Tendencies

Dura Codruța

codrutadura@yahoo.com

Cucu Ioan

cucuioan2002@yahoo.fr

University of Petroșani

Abstract

The need to reorganize the classic structure of contemporary companies is generated by the occurrence and manifestation of cross-correlated trends and phenomena such as: markets globalization; accelerate internalization of economies; profound technical and technological changes, the informational “explosion”, the diversification of demand together with the “personalization” of commodities and so on. Thus, the emergence of innovative approaches regarding strategies and organization is very appropriate knowing that contemporary business organizations will have to achieve multiple goals (i.e. economic, social, moral, technological and ecologic objectives) and that technologies hard to imagine nowadays can become familiar in the future.

The strategies of the third millennium in correlation with the immediate structural development call into requisition the original concept of development as a series of waves of change, revealed by Alvin Toffler in his well-known book “The Third Wave”. Starting from this metaphor, the paper makes a survey of some relevant theoretical approaches regarding the unprecedented transformations that will occur within organizational structures of future companies in the near future.

Key words: modern companies, organizational framework, tendencies;

JEL classification: M19;

1. Introduction

Dynamic and unpredictable, the contemporary strategic environment has changed

a lot during the last decades, so that continuous changes and the complex characteristic are now the background against which companies develop. This situation is the result of the often cross-correlated new phenomena and tendencies, which are considered challenges even by companies that are 3-millennium old. Here are some of the following phenomena and tendencies: the tendency of market globalization; the globalization and internationalization of economies which leads to an interconnected economy in a world “without frontiers”; important technical and technological changes; information blast; the intensification of international competition, as well as the shifting of emphasis from price to quality and technical level; the diversification of demand, doubled by the “personalization of consumption”; the limited character of resources and exigencies regarding environment protection and ensuring the ecologic equilibrium; the cost and high mobility of capitals, etc. The changes mentioned above, together with other tendencies, are not only trouble makers, but they also have the ability to open new doors for companies and managers who prove to be creative and flexible in conceiving strategies [7].

Under the circumstances, the improvement of global strategies becomes a necessity, especially for international companies; in this context, this process represents a refinement of present and future strategies, subject to the necessity to diminish the uncertainty and to capitalize the changes; this process has the role to indicate the evolution trajectory towards multiple accomplishments of contemporary businesses (this does not imply only the traditional economic dimension, but also the social one, the moral, technological or the ecological ones). The emergence of innovative approaches regarding strategies and organization

is more plausible knowing that technologies hard to imagine nowadays can become familiar in the future, and the demographic structure of labor power is already experiencing spectacular changes [4].

Global communications, information networks, laptops and other technological innovations allow people from different corners of the Earth to interact. It is highly probable that in the future, a mere access code to the computer network of an international company would be the only clue to its status. Allowing for these realities, management specialists unanimously admit that organizational structures of the future companies will have very different configurations compared to the present ones [2].

2. Various Approaches Regarding Organisational Structures and their Relationship with Managerial Strategies

Efforts to conceive the innovative organizational structures have as reference point *the classic frame of reports between corporation strategies and organization structures*. The American specialist Alfred D. Chandler was the first to analyze this in his book "Strategies and Structures" [1]. Based upon the study of the structural development of 70 great American companies (among which we must mention the names of some notorious international companies like General Motors, Du Pont, Sears or Standard Oil), Chandler postulated the unique sense of the relation between strategy and structure: "*structure follows strategy*", that is to say that strategy changes are the ones that shape the organizational structure. The experience of the studied companies demonstrates that their structure followed, in the long run, the coordinates imposed by the development strategy that was chosen. This process has the following steps: originating a new strategy; the occurrence of administrative problems; economic revitalization of the company. During the same period, there were also authors who disagreed with the idea of determining the structural configuration only through the chosen strategy; they gave examples of situations in which the relation between strategy and structure was quite the opposite [3].

In 1980s, the two approaches reached an agreement: the researches performed determined a mutual influence between the strategy of a

company and its structural organization; they were both integrated in the company's managerial system. However, there are several axioms which were validated by the management of the big companies, for example the quick forming of the most appropriate "*structure*" based on the chosen strategy has substantial competitive advantages; some strategies had been allotted specific structural "*recipes*" (for example, market differentiation is associated with divisional organization structures) [3].

The strategies of the third millennium in correlation with the immediate structural development call into requisition the original concept of *development as a series of waves of change*, revealed by Alvin Toffler in his well-known book "*The Third Wave*" [6].

In his book, Toffler describes three types of societies, based on the concept of 'waves' - each wave pushes the older societies and cultures aside.

- *The First Wave* is the society after *agrarian revolution* which replaced the first hunter-gatherer cultures thus ensuring the material and spiritual conditions for the development towards a superior level.
- *The Second Wave* is associated with the *industrialization* phenomenon and it still covers an extended area on the Earth. The main components and values of the Second Wave originate from materialism and the supremacy of the individual power; from this also originate competition, self-conservation, consumption, security as a characteristic of financial wealth, etc. A series of problems were brought about by these values: pollution, crime, mass and ecosystem destruction, consumption of natural resources, unbalance between incomes and living standards, etc. This phase of development is synthesized by the following saying: "*we are separated so we must compete*".
- *The Third Wave* is the post-industrial society and is still in competition with ideas from the previous wave. The components of the Third Wave are: preoccupation for equilibrium, cooperation and mutual support. The "*breakdown*" of the Second Wave value system is reflected by the attention paid to

some preoccupations like reducing ecological risks, supplying services for others, creating possibilities for development and professional satisfactions, in the detriment of certain “conventional variables” like severe competition or money. The slogan for the Third Wave is “*we are connected so we must cooperate*”.

The metaphor of the “waves” of change was later extended because of the emergence of a *Fourth Wave*; its central axis represents the integration of every life dimensions and responsibilities into a unique system with a common identity. The values of the Fourth Wave are synthesised in the saying: “we are all in one and we choose to create together”. These values are: self-confidence, interconnection, global thinking, cooperation as the only way to create a promising future for the entire Planet [5].

3. Classic Organisational Framework Versus Innovatory Structures

From the contemporary strategic management point of view, the connection to the changes imposed by the Third and the Fourth Wave implies the improvement of the relations between strategies and structure due to flexibility, dynamism and adaptability. At first, managers had to work to improve and renew the organisational elements characteristic for companies that still function according to the Second Wave. The organisational structure characteristic for the Second Wave is *the classic industrial bureaucracy*, formed as a pyramidal system, at the top of which stands a management that controls a chain of permanent and functional departments, often inflexible and incapable of immediate reaction to changes. The values of the Second Wave are “*borrowed*” from the army and they are the following: *survival, auto conservation, eliminating competition, victory* and so on. The development strategies for companies from the Second Wave are conceived for a relatively short period of time of 5 – 10 years. This classic form of business organisation led to separation, destructive conflicts, rigidity and inefficiency.

A better and improved alternative for the traditional hierarchical structure is *the matrix organisation* which is based on the principle that generates synergies between permanent

functional departments and work teams. This is not necessarily a very efficient structure: it divides the decisional process because of the double subordination of employees; reduced credentials; managers play a double role, they are not very flexible and this brings about important competitive disadvantages. Just like the traditional hierarchical structure, the matrix structure is based on a central management. In fact, regardless of the organisation structure – bureaucratic or matrix structure –, the role of the manager within Second Wave companies is the traditional one, that is to say that he has the role of supervisor and judge according to his knowledge and status, ignoring the fact that the company should be “teaching school” for employees from all levels.

Nowadays, the shifting from the matrix structure to the *business unit* organisation is considered a major development, despite the fact that the latter is also associated with the Second Wave. Autonomous groups of businesses, which form the basis for this organisational structure, have several advantages: autonomy, loyalty, a common unique objective – identifying and satisfying the needs of the market – and flexibility. Companies with a matrix structure reject this decentralised form of organisation because the transition towards this structure implies the “demolition” of pyramidal structures and especially sacrificing the managerial powers. Moreover, the strategy of dividing plans into autonomous groups of businesses, implemented by IBM in the year 1991, is interpreted as an identifier of flexibility and prompt reaction towards this organisation structure.

Putting the Third Wave in perspective, the team work was planned; *team work* is based on cooperation, trust, integrity and equal rights of team members. Managers, elected by team members, are both trainers and “servants” of the team and they represent the interface between that team and other work groups. The advantages of team work are: autonomy, flexibility, democratic character of the decisional process and the ability to solve the problem of diversity through an immediate reaction to market changes. Companies that implement such organisation structures have a tendency to become flat because multiple hierarchical levels are eliminated and the decisional process is handed over to team members. According to this approach, administrative levels, which are very

few, focus on supervising activities and ensuring longer periods of time for “*strategic coordinates*” that must be implemented and improved. Although great efforts have been taken by big avant-garde companies – Hughes Aircraft, X.E.L. Communications, Weyerhaeuser, etc. - in order to assimilate this organisational structure, small and medium size companies from America have the tendency to “*revolutionize*” their own administrative systems which lead to the Third Wave.

The Fourth Wave company will be structured according to a *communitarian organisational model*, which from a spiritual point of view is based on the changes registered in people’s conscience. This organisational structure will be a democratic and a participative one, subject to its objective to serve clients and the community. Future strategies, associated with an extended period of time (which includes generations or better yet, centuries), will be unanimously determined using either predominant intuitive processes and techniques or logic and rational methods familiar to classic management. Because of the total absence of hierarchy within this organisation structure, decisions, principles and the system of values will be agreed upon by community members [5].

Most big and medium size companies which function in Europe and in the United States are faced with the so-called “*implosion*” phenomenon; this phenomenon represents the gradual clearance of patrimonies, the reduction of the production capacity, of technologies, of research work, of market development programmes and of the number of employees, in favour of achieving the maximum income during a short period of time [5]. The strategic solution in order to avoid the risk of implosion is a severe change in the business philosophy of companies; this means shifting the attention of companies from production to *servicing clients, employees and the community*.

The message of these changes is obvious as far as organisational structures are concerned, develop and attend to others. The strategy of the company in the third millennium will gather together a set of characteristics which are different from the present ones: it will be subject to the new type of “*servicing*” organisation, generating moral effects; it will transform the company into a “*welfare community*” as the stakeholders’ interests come to an agreement; it

meaning that companies will have to completely revise their organisation structures. Thus, *the adaptable company*, oriented towards global serving of clients, is considered a permanent “*frame*” which links a set of temporary module units, associated with team values. According to Toffler, “*modules*” can be formed up either of external independent organisations or of internal semi-autonomous agents; they can be re-organised or even cleared, according to needs, since they go “*with the wind of change*”[8].

The Fourth Wave will be based on the objectives of contemporary economic activities. The new system of post-economic values will force companies to take interest not only in economic performances, but also in social achievements and in splitting responsibilities so as to ensure the welfare of local, national and global communities. The globalisation concept is extended due to the integration of some problems which go beyond national borders – ecologic destructions, environment pollution, gaps between regional life standards, international terrorism. For the sake of global serving strategies, international companies will direct, for example, their resource availabilities and infrastructure towards re-positioning some spare physical installations in several areas or towards identifying infrastructures and maintenance processes which developing countries will find easy to implement. In such a context, “*clients*” will identify themselves with an entire country or region. The idea, subject to “*global servicing*”, is that the production capacity should cover the material needs of the inhabitants of the Planet; a system of values, which equally distributes production, is also necessary.

At this point of development, the adaptable company does not have a single economic objective; it becomes a “*multi-objective*” organisation which is perfectly integrated in the social, moral and physical-ecologic environment, “*a means*” through which humans

will bring forth local action plans considering the new economic concept of globalisation; it will have flexible, democratic organisation systems to guide it though the implementation process; it will integrate and achieve complex objective; it will promote research activities in the advanced technological field etc. [9].

4. Conclusion

Most of present companies, still blocked in the Second Wave of changes, have a centralized and hierarchic structure which focuses on material values like profit, efficiency and development. The variety of activities performed by these companies is reduced to economic and technological processes, while the “*globalization*” concept is limited to the perception of economic investments in foreign countries.

The transition from the Second to the Third Wave implies, according to Toffler, the setting up of adaptable companies; therefore, managers will have to “decentralize” companies, that is to say that they will have to divide them into smaller and various businesses, which are capable to meet the variety of consumers’ requests. Thus, it is considered that if the company with the most efficient production outrivalled competition in the past, nowadays the company which promptly decentralizes itself in order to satisfy each client, is on top of the wave of change.

The Fourth Wave will be based on new values that will urge the managers of future companies to be concerned not only in economic outcomes, but also in social achievements and in splitting responsibilities as to ensure the welfare of local, national and global communities. Thereby, at the

beginning of the third millennium, the adaptable company will have to develop new flexible organisational systems in order to bring together the above mentioned characteristics of serving organisations.

Abstract

The most significant changes in the practice of marketing during the last decade in the shift in emphasis from a transaction orientation to the customer relationship management (CRM).

Customer relationship management is a strategy of organization to identifying the main desire of the customer and the behaviour commercial business, the beneficial use of information acquired in order to improve relations with these factors, with the objective of increasing customer satisfaction requirements.

Key words: customer relationship management, customer behavior, customer satisfaction;

JEL classification: D12;M31;

1. Introduction

The approach by the client has always been a base principle of the marketing. Kotler says that “the marketing people and the customers must work together in order to find out how the client can be satisfied better”.

The acronym of CRM entered recently in specialist’s language.

Most specialist’s use CRM to refer to customer relationship management. Other use CRM to mean customer relationship marketing.

Another group, in the belief that not all customers want a relationship with supplier, omit the word relationship, preferring the term customer management.

In the 1990’s companies began to improve the CRM, with the premise of forever changing the way business small and large interacted with their customer bases.

At the end of 1990’s, CRM ended up high on a agenda of many a top manager, thanks to the marketing efforts of software companies, as well as other factors. Their IT system enable companies to interact with large groups of customers on an individual basis and at a relatively low cost. As a result, companies may accumulate individual customer knowledge which they may use in offering customized solutions and in developing long-lasting, mutually profitable relationship. On the one hand, these solutions improve the operational excellence of organization’s front offices, and on the other, they offer the potential to develop a long-lasting relationship with customer. To date, companies experiences with CRM are somewhat disappointing, and this may be for a variety of reasons. Too many CRM initiatives are still dominated by technology and the strategic and organizational aspects of CRM tend to fall by the wayside insufficient attention is focused on the interpretation of the marketing strategy: who are the right customers and what do they want; how each organization dialogue with them ?

On the other hand, too much energy is invested in the creation of the communication infrastructure and the orchestration of the dialogue with the aid of IT.

In the years between 2000 and 2004, CRM was a constant topic of corporate discussion.

Today, CRM is still utilized most frequently by companies that rely heavily on two distinct features: customer service or technology. The three sectors of business that rely most heavily on CRM, and use it to great advantage and financial services, a variety of high tech corporations and the telecommunication industry.

2. Definition and elements of CRM

The concept was defined as a software product, a data collect method, a sales strategy or a data analyze. CRM totalize this definition and many others depending on each user necessity.

Ed Peclen, in his book “Customer Relationship” says that “CRM is a business strategy and therefore more than a functional strategy alone. It affects the organization as a whole: marketing, IT, service, logistics, finance, production and development. HR, management.

Another definition – CRM – is an information industry term form methodologies, software, and usually internet capabilities that help an enterprise manage customer relationship in a way.

Paul Greenberg, in his book “CRM at the Speed of Light: Essential Customer Strategies for 21st Century”, says that “CRM is a philosophy and a business strategy, supported by a system and a technology, designed to improve human interactions in a business environment.”

3. Elements of CRM

The realization of a CRM strategy depends on a number of components or competencies. Perhaps the most obvious competency is related by the ability to create the infrastructure, which makes it possible for customer and supplier to recognize one another and to be able to interact in “real – time”.

The four cornerstones of CRM must be mentioned first are:

- a. Customer knowledge
- b. Relationship strategy
- c. Communication
- d. The individual value position

a. Customer knowledge

Knowledge of the individual customer is essential in order, ultimately, to develop a long –

term relationship and to supply customization. Customers, but also prospects, must be identifiable; it has to be possible to determinate who someone is. At the some time, the customer’s profile must also be known. What has the customer purchased, how does he or she prefer to communicate and how may he or she characterized further? Without this type of knowledge, it would be unthinkable to attempt to build a long – term relationship with the customer.

Companies must develop the competency or capability to develop this type of individual customer knowledge for a large number of customers. Databases will have to be filled with correct and current data which will be transformed by analyses into individual customer information. Individual customer data will have to be supplemented by outcomes of anonymous market research so that a more complete image of the customer may be created.

b. Relationship strategy

The individual customer information must be used to develop a long – lasting customer – supplier relationship. In the other words, a marketing or other type of strategy must be implemented which truly differs from a strategy which merely focuses on the simulation of transactions and thus requires other competencies. Companies that concentrate on the stimulation of sales became proficient in the art of “seduction”. They have a certain means of communication, a short – term horizon and a limited interest in the customer. They measurer their success by their sales and the number of completed transactions. Market share represents a very important criterion for success.

On the other hand, organizations with a relationship strategy in place have a long – term horizon, “tell” and “listen” more than they “sell”, and have a broader and deeper interest in the right customers.

c. Communication

In the communication between customer and supplier, the relationship strategy will have to prove itself to a great extend.

4. Implementation of CRM

The Financial Times report identifies the major components for the successful implementation of CRM as:

- a front office that integrates sales, marketing and service functions, across media (call center, people, stores, internet);
- a data warehouse to store customer information and appropriate analytic tools with which to analyze the data and learn about customer behavior;
- business rules developed from the data analysis to ensure the front office benefits from the firm's learning about its customers;
- measures of performance that enable customer relationship to continually improve;
- integration into firm's operational and support (or back office) systems, ensuring that the front office is promises are delivered.

5. Banks and the CRM

Banks seem more and more interested to introduce CRM, which allow them to guide their activity according to the customer's request. A person can be a possible or a real customer, may come in contact which the bank through a multitude of methods, such as:

- Bank's advertising;
- Press announcements;
- Information requested by phone;
- Information requested in writing;
- Asking at the front office;
- Accessing the bank's

In consequences, the banks have obligation to select the personnel and train it to have the appropriate behavior; best advertising for the bank is the favorable impression its personnel gives to the possible and real customers. Bank-customer relationship is a continuous process that has as main subject satisfying the customer's demands in order to maximize the bank's profit. Priorities of the customer relationship management in the banks area are:

- the necessity to bring in new customers;
- the growth of the deposits' quantum and the member of opened accounts for credit;
- the growth of the member of eligible clients for the proposed loan policy;

- the growth of the money circulation through the customer's accounts;
- the diversifying of takings and paying and the growth of incomes from commissions;
- higher degree of loyalty.

The bank must design a database with information on every single customer that needs to be upgraded periodically in order to acknowledge and evaluate the clients from economical and financial point of view.

The bank – customer relationship has for main target to bring additional value to both partners on the basis of following principles:

- the mutual relationship must bring growth of both partners;
- the bank must focus on assisting a reasonable number of clients, the loyal ones before others. This attitude brings a “premium” for the bank;
- value means transparency and continuity in satisfying the basic banking necessities for the client;
- the customer should compensate the bank by swinging of cooperation opportunities;
- the customer expects cooperation from a healthy, strong bank system that should offer a large category of banking services.

Communication During Human Resources Recruitment, Selection and Integration Processes in Organizations

Florea Nicoleta Valentina
Valahia University of Targoviste
floreanicol@yahoo.com

Abstract

Organizational communication is becoming more and more important in attracting, maintaining and motivating human resources, gaining strategic role and function. The different functions of communications are explained through the transformations that have marked the modern organizations in an environment in continuous change. In this article is presented the efficiency of communication which allows the organization to make known its mission and its objectives in obtaining success. The strategic advantage of an organization is recognized as being obtained through people- these are becoming the key resource to obtain competitive advantage. To make known its vacancies the organizations must create the advertising so, to attract a sufficient number of competent candidates, not-discriminating, giving real and relevant information according to the principles of organizational ethics.

Keywords: communication, recruitment, selection, integration

JEL classification: M51

1. Communication in recruitment processes

In any domain it is sustained the idea that people are “the most precious thing “of an organization. Human resources recruitment is an essential and a difficult activity and has an important influence over the whole activity. Knowing the personal necessary allows carrying on of recruitment process in good conditions and with more chances of success.[9] If the recruitment process is made efficiently, than the selection process is much more easier to make.

On employment advertise bases is staying the personnel specifications and job description. [3,4] The formulation of recruitment advertising must not only inform about the main features of the vacancy, but to attract the potential candidates. To attract the best candidates and to achieve its objectives, the organization launches the recruitment advertising, in the country or abroad, depending on finding the best prepared candidates.

The content of a recruitment advertising must: present the organization name and profile (its main activity) with brief references, because is a form of indirect advertising and the organization may become known; the organization with a good reputation will attract valuable candidates[12]; provide enough details regarding the main features of the job. It won't be detailed the job responsibilities, but expressing the main directions of the job will help the potential candidates to identify if they are matching with their interests; summarize the basic attributes that should have the job holder; make necessary references to any desired attributes of the candidates to make them understand if they are incompatible with the job; set out the main conditions for employment and the desired advantages for the organization; establish to whom must be sent the papers required for a vacancy, the way to contact the organization (now is used more and more, besides phone and fax, the mail address, as affordable and fast application method, advantageous for the employer and for the candidate, too; respect the legal regulations(on the bases of ethics principles, equitation, equal opportunities and nondiscrimination[14]).

In the end the advertise must contain information about where, how and until the candidate can apply for the vacancy. The advertise details must be short but comprehensive. The advertise form vary,

depending on the importance of the organization and the discrimination must be avoided.[7]

The composition of these advertising is also an important factor which contribute to the efficiency of recruitment.[12] So, the human resources specialist must have the right technology and the art to communicate efficiently. The biggest danger for the organization is to show an eronated image about itself and not keep its promises made in the recruitment process - Gunther Everart, recruitment manager.

Advertising - is the most efficient method of attracting the candidates. The question is where should appear the advertising, and if the recruitment must be made by the organization or by recruitment agencies.[1]

The publication of a recruitment advertising may be a costly activity.[8] When is made an advertising, the organization must take into account certain factors: -the number and the place where are the potential candidates; -the cost of advertising- to be effective the advertising must attract a sufficient number of prepared candidates; -the frequency- the frequency that an organization wants to publish its advertising is important in choosing the publication; -themes and range of movement of the publication- an economic publication will be read by those who search working in this domain, and a general interest publications will attract more candidates and less prepared. The moment of appereance of the advertising is very important, especially if the chosen method are specialized newspapers and publications.

Publicity - is a vital element of recruitment process and is the most clear method of attracting the candidates.[11] When is used this method, it must take into consideration three criteria: the cost, the speed and the probability to find the best candidates.

The main instruments of employment advertising are: local newspapers; national newspapers; technical/professional periodicals; centers of professional integration; other agencies; posters at the factory entrance[4]. Organizations from United Kingdom to strength its market position in terms of advertising for employment, publish in the daily national certain categories of posts in a certain day of the week [4]. For example, The Times and The Daily Telegraph publishes advertising for managerial positions in each Thursday. The Guardian

publishes vacancies in education only Tuesday, and from public sector only on Wednesdays. This system comes to help the organization which is looking for employees, and the employees who seek a new job, because both know exactly when is the "market day" for the followed type of the job. Specialized magazines usually appear once a month and address for a specific group of interests. Due to their predictable nature and their access to specific groups of potential employers, magazines represent an important tool in recruitment advertising. Another important advice is that section where the advertising appears must be on the odd page because they are generally read more often than from even page. The efficiency of an employment advertising can be appreciated about : -the number of information asked by the candidates ; -the number of applications ; -the degree of compatibility between the employees and their conditions.

When an organization make an advertising, it risks in a certain manner its own reputation and its public image. That is why some organizations make important efforts to establish a quality standard for all its employment advertising.

The success of advertising is highlighted by four steps(AIDA) :

- Attention- because on the work market there are other competitors who look for good candidates, the advertising must capture the attention of target audience.

- Interest- the advertising must be made to keep awake the candidate interest[8] and to read all the content, to communicate interesting and attractive information about the job, the organization, employment conditions or the requested qualifications. It must be created the interest over the job, but it doesn't be unduly praised nor be overstated.[1]

- Desire- the advertise must arouse the reader's desire to take the opportunity offered.

- Action- the message must be written in a certain manner so to attract the look and to encourage to read it till the end, and to receive a sufficient number of applications.[1]

A recruitment advertising should begin with an irresistible title and contain information about organization, the job and personnel qualifications (courses, experience), the wage and the location. The title is very important. The most simple and obviously approach is the describing of the job with bold letters. To attract

attention, is recommended to specify the wage and the benefits. It is proven that the wage and the car are the most important in attracting the candidates, that is why must be specifically mentioned.[1]

2. Verbal and nonverbal communication during the selection process

From the moment that the organization managed the recruitment activities so that to attract a sufficient number of suitable candidates from the external labor market, the selection must identify those competent and suitable candidates for the tasks in job descriptions [3]. The selection represents a biunivoc process: not only the organization make an evaluation of the candidates but also the candidates evaluate the organization. For organization, the selection represents an operation of "marketing and sales", as the recruitment.

During the interview it is established a relationship between vacancy requirements and competencies of each candidate. Almost in all cases of selection, takes place the interview and in some cases it represents the only used technique, but not the most irrelevant technique in terms of interviewer subjectivity. It is used for any hierarchical level, for promotion of staff, transfer within the organization and employment outside the organization.[10] Applicants should prepare very elaborate and sell their talent, skills and competencies to be chosen from all the competitors. But also the recruiting team should be well trained in "the art of questioning" the candidates and to read their reactions. Performance of selection process is given by the degree of specialization of the interviewing team. The team should be better prepared to lead successfully the selection process: it must study carefully all the relevant documents (job descriptions, personnel specifications, applications, recommendations) and it must be aware of his subjectivity. Necessary competencies to lead a interview in order to obtain performance is: adequate preparation, not discriminating, listen carefully, not interrupte, take notes, to have the capacity for analysis and synthesis, for empathy, the ability to ask open questions, the ability to analyze a candidate's image, provide relevant information without boring the candidate, to transmit a good image of the organization, maintain a relationship of

communication with candidates, manage permanently the discussion with tact and diplomacy.[10]

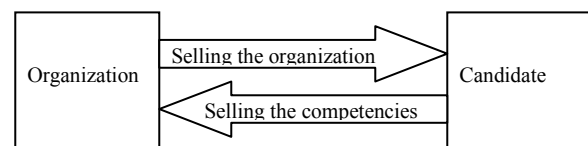

"The ability to find the right question is more than half of the fight to prepare the response"
Thomas J. Watson.

In the end of the interview, should immediately make the evaluation in a candidate assessment sheet[4]. To be effective, the interview must be used to identify those qualities of the candidate that can be analyzed best through methods such as dress code, language, motivation and nonverbal behavior. The interview should be structured in stages, in order to allow the interviewer to make a complete picture of the candidate, to facilitate sorting. The interview should take place in a relaxing atmosphere, in which the candidate should not feel pressured, stressed or in inferiority.

Communication in the interview is to inform the candidates about the organization, vacancy and its demands, being an instrument of public relations of the organization and give the candidates the opportunity to provide more detailed information on their professional past and their future aspirations.[10]

Interview selection is a form of communication with specific characteristics resulting from its specific purpose. The message needs to pass from transmitter (interviewed) to receiver (interviewer) and must convince by using the techniques of argumentation and persuasion.[11]

Fig. 1. Biunivoc character of communication in interviewing time

If the organization wants to transmit information effectively, it must first analyze the situation of communication. The adaptation of the message must be continuous, because every time are observed and analyzed the candidates reactions: non-verbal language, changes of physiognomy, gestures, words, inflexible of the voice, which is representing clues about a candidate. Simple and concise phrases, carefully chosen with a clear language, without becoming

precious are considered essential in choosing candidates and sorting information.

It is important, in the interviewing time to analyze the human behavior, because it is considered the truth behind the words.[5] Knowing the body language make possible using language of our own body, and the interpretation of the behavior collaborators, having so the opportunity to react efficiently in these relationships.[9]

If the resume and letter of intent was elaborated without stress, the interview involves a spontaneous speech, with elements of improvisation and changes of scenario, developed in conditions of maximum stress.

The interview will be structured so that to cover all the important aspects related to candidate:

A. the plan in seven points[Alec Rodger, 1998]:

1. physical aspects - has this person physical constitution necessary for the job?
2. knowledge - he has the experience, the academic and the professional qualifications necessary for the job?
3. IQ level- how intelligent is this person and how he can use this quality?
4. specially skills- what skills he has which can be used ?
5. interests- what is his motivation for the new job?
6. disposal- what kind of personality has he and what are the implications for the new job?
7. circumstances- what effects has the events over his careers and how can these influence its work performance?

B. The plan in five points [John M. Fraser, 1998]:

1. the impact over the others- what kind of reactions he generates and what kind of behavior has he?
2. the qualifications and the experience- has he the necessary knowledge and skills for the job?
3. natural skills- how rapidly can he think and what are the implications for the job?
4. motivation- what kind of work is better for the candidate and how much effort is he disposed to make?
5. emotional adaptability- how rapidly can he adapt of a new situation and what are the implication ?

Usually during the interview has an impact the first and the last impression. The first

impression depends on the way the candidate is dressing, the way he is smiling and looking, the speech fluency, the verbal and nonverbal language. The psychological mechanism is that the first impression will act like a filter, and will let passing only the information which sustain the first impression. That is why is good to take advantage of the primary impression and the last impression, beginning and ending the interview in force.[11]

An appreciated quality to a candidate is the speech fluency. The studies show that this quality is making the candidate more intelligent and having especially interpersonal skills. The interview ends by informing applicants with the decision taken, but also candidate informs the employer[13] and [6].

"If you are rejected from a job that you know you can do it, put it on account of a inexperienced interviewer, not to an error of yours" Phil Boyle, CEO Ramsey Hall Limited.

If after the interview organization decided not to hire the candidate, it is better to transmit immediately or after a reasonable period, by letter or by e-mail that he was rejected, but will be retained in the organization database.

3. The communication during integration process of new employees

Socio-professional integrating represents the assimilation of a person in the professional environment, adapting to the demands of work and the behavior of group in which is working, accommodation and the adequacy of his personality to the group.[11]

Integration is when the new employee become familiar with the organizational internal regulations, working time, breaks and social activities. Successful organizations will make sure these processes are treated as important and allocate them sufficient resources.[8]

The main reason is that new employees who browse an effective programme of professional adaptation increase their chances of reaching a good performance on the job, faster than those whose accommodation was not done properly. They are less likely to leave the organization in an early stage compared with those who have not done an adaptation program. These phenomenon are called "crisis of adaptation" and signify

phases of dissatisfaction relative to the post, the organization or both.[8]

A nice receiving doubles the chances of maintaining the new employee into organization for a long time.[7] A special attention should be paid to those who have just graduated school and have never been employed, those who return to work after a long period of time, people with disabilities, minorities and those promoted or transferred. [8]

Professional integration is familiarity with the new place and conditions of employment, accommodation of new employee with the group work, creating an atmosphere of safety, privacy and belonging, so that the new employee and to acquire confidence in their ability to perform job duties.[10]

Integration means not only the aid granted to the employee but also a longer observation after employment, thereby identifying the attitudes, interests and aspirations, progress, responses to different stimulus, satisfaction in work, the team spirit and participation in achieving the organization objectives. Forcing the rhythm of professional integration can lead to growth of staff fluctuation, with negative effects on organization. The period of integration of a new employee is required because he can not work effectively without a knowledge of the organization and complexity of tasks make impossible their fulfilling without an initiation in advance. Some organizations do not take into account these arguments and require the employee to work from day one. For the employee appear a stressful situation, on professional and in the relationships plan.[11]

To prepare a programme of professional integration should be taken into account motivation, requirements and behavior of potential employees, who is in continuing change. Responsibility of professional integration will be divided between the manager (chief hierarchically superior) and the Department of Human Resources.

Direct boss has the duty to make his general training and should also reserve some time from his work for staying with the new employee in his first day of work. He will adopt a friendly, optimistic and relaxed attitude. [11] Among the integration methods we can include professional visits within the organization led by hierarchically chief, providing information necessary for the proper fulfillment of tasks,

maintaining a permanent dialogue between employee and boss, providing "a welcome map", which contains information about the organizational structure of the institution, the daily work programme, formalities of evaluations, internal regulations, data on safety and accident prevention.[16]

A person who knows what to expect is more probable to remain on the organization, in spite of some unfavorable aspects, but anticipated. Integration can be considered finished when the new employee has reached maximum capacity to perform the job tasks. The rhythm of integration varies from a few months to a year, depending on the employee's personality and temperament, the experience, the complexity of work and efficiency of the integration. The efficiency of this process can be evaluated by tracking feedback map integration (which is done by filling in unsigned questionnaires for new employees, periodic interviews, group discussion with new employees, etc.) and by a large number of processes and methods that differ from one organization to another (new employee manual, for guidance counseling, training, video training, working under the tutelage-mentoring, coaching).[10]

Integration may be direct (for executive functions) and indirect (for management positions), through the organization discovery and entrust of some missions.[11]

Even if there is a coherent strategy for integration into an organization, it can reorganize, depending on the situation, in order to face successfully the challenges of the moment.[12] Because of the organizational integration importance and complexity it is necessary to create specific programmes of integration, who can ensure the problem solving of both sides.[17]

4. Concluzions

«The word is the messenger of human thought» (T. Vianu).

Business communication is a fundamental feature of organizations existency. All the managerial functions, including the human resources management are sustained by the communication, like a process of understanding between people, transferring the information.

This optics is used in many organizations and in personnel recruitment domain it borrows

many of the elements specific to advertising. Knowing to behave right and knowing to communicate appropriate and efficiently is representing, next to professionalism, factors of professional success[11]. Attracting «the right people at the right time and the right place»[15] is made through an effective advertise to obtain results and to achieve its objectives.

The communication into the interview time has the role to inform the candidate about the organization, the vacancy and its demands, being a tool of organization public relations and give the candidate the opportunity to present information about its professional past and its perspectives. In the opinion of many experts in the field, nonverbal communication is stronger than words, because reveals how things really are, and the emotional part of our communication.

The research shows that interlocutors are impressed by the words used at a rate of 8%, by the intonation at a rate of 23%, and by body language at a rate of 69%. «Our body has something to say when communicate, and sometime only our body is communicating».[2]

Respecting the legal regulations, based on the principles of ethics, equity, equal opportunities, and nondiscrimination make the organizations communicate efficiently and attract a sufficient number of competent candidates who can obtain competitive advantage and to achieve the organization objectives.

Role of Public Relations in the Information Society

Forfolea Mariana

Free International University from Moldova

marianaforfolea@yahoo.com

Abstract

Systematic effort to create and maintain goodwill of an organization's various publics (customers, employees, investors, suppliers, etc.), usually through publicity and other non-paid forms of communication. These efforts may also include support of arts, charitable causes, education, sporting events, etc. Public relations are the opposite of advertising. In advertising, you pay to have your message placed in a newspaper, TV or radio spot. In public relations, the article that features your company is not paid for. The reporter, whether broadcast or print, writes about or films your company as a result of information he or she received and researched. Publicity is more effective than advertising, for several reasons. First, publicity is far more cost-effective than advertising. Even if it is not free, your only expenses are generally phone calls and mailings to the media. Second, publicity has greater longevity than advertising. An article about your business will be remembered far longer than an ad. Publicity also reaches a far wider audience than advertising generally does. Sometimes, your story might even be picked up by the national media, spreading the word about your business all over the country. Finally, and most important, publicity has greater credibility with the public than does advertising. Readers feel that if an objective third party—a magazine, newspaper or radio reporter—is featuring your company, you must be doing something worthwhile.

Keywords: broad-based public affairs, planning, budgeting.

JEL classification: H83

1. Introduction

Public relations is now a profession with a scientific body of knowledge. In addition, public relations become a managerial

function rather than a communication technique. Problems and challenges that public relations will face in the future are manifold. We agree with the fact that public relations now have a scientific body of knowledge and that quickly becomes a managerial than technical communicational function. The authors say that the strongest trend in public relations is a strategic move towards a managerial role. Ironically, the key problems and challenges are closely intertwined forces limiting the role of public relations and development management body of knowledge of the discipline. The first problem that public relations have to face the confusion caused by what is actually means strategic public relations. The idea that public relations should be strategic rather than tactical is very popular today in professional circles. [2] However, Swiss scientists, led by Francesco Lurati University of Lugano, noted that most practitioners public relations define public relations as strategic communication supports rather implement organizational objectives. Using Lurati's words: "From this perspective, strategic corporate communication is considered when pursuing objectives that are simply the corporate line. Term strategy does not change the nature of the tasks performed by tactical communication ... communicative function has no contribution to defining the strategy corporate.

We believe that this misunderstanding of the concept of strategic public relations is most prevalent among practitioners who are guided by what we call the interpretive theory of public relations. Believe that there are two major theories contrasting public relations, both in practice and in academia. These perspectives can be called symbolic

paradigm, interpretive, and strategic management paradigm or behaviorist..

2. Literature Review

Scholars and practitioners following the symbolic paradigm generally assume that public relations tend to influence how the public perceives the organization. These perceptions are theorized in cognitive concepts such as image, reputation, brand and identity impressions. Practitioners following the interpretive paradigm emphasize advertising (publicity), relations with media and media effects. Communication tactics, which they maintain this theory, creates an impression in the minds of publics that allow the organization to be separated from its environment, using theories of Cees van Riel, Danish specialist in communication. Separation involves creating an "artificial screen" positive message to mask the true organizational behavior, which allows the organization to establish a behavior. Unlike the symbolic, behavioral paradigm, strategic management, focusing on participation by public relations directors in making strategic decisions to help manage organizational behavior. According to the scholar Van Riel, the public relations function of a connection than separation. Intended for building relationships with stakeholders rather than a set of activities aimed at separating transmitting messages to their organization. The strategic approach, public relations directors are involved in managerial decisions. Their role is to identify potential consequences that decision might have on stakeholder consequences that create audiences. They communicate before making decisions and with audiences, because they may have reasons for decisions and to take account of their interests. PR people build relationships with these audiences to improve the quality of managerial decisions and to reduce risks and costs of these decisions. Interpretive paradigm is the belief that strategic rather than tactical appears in discussions on public relations evaluation. For example, research firms have tried to establish the idea that favorable media placements are closely linked to business objectives, such as sales, profits or consumer preferences. Others have tried to demonstrate that money spent on publicity have a higher investment return than money spent on advertising. In contrast, strategic management

approach necessary measurements are deceptively simple. Should measure the nature and quality of relationships between organizations and publics and should monitor the value of public relations. It is necessary to evaluate public relations strategies and tactics to determine which are most effective in building these relationships. This difference in thinking on the strategic role of public relations and the controversy is the link between public relations and marketing and management. Communication has always been a part of public relations specialist and practitioners are obviously more of a marketing budget. However, such research, including Strategic Public Relations Center at the University of Southern California shows that it is unlikely that public relations executives to play a strategic role and be understood and appreciated by other executives when relations limited public support to a management role. In general, when public relations are limited to marketing support, do so by emphasizing a role separately messaging. Research shows also that public relations should not avoid collaboration with marketing. Rather, public relations seem to play the most important strategic role when marketing public relations component is part of a greater strategic role (integrated communication) public relations rather than be subsumed Marketing (Integrated Marketing Communication) .

3. Methodology Research

I therefore consider that there are three key challenges that public relations profession has to face: 1) change the way in which practitioners, their colleagues and customers perceive the public relations management from an interpretative role, insulator, a role strategic management, 2) conducting a survey to identify theories and tools to perform a strategic role management, and 3) educating both practicing and future managers on the strategic role of public relations and management tools of its application.

Socio-political role of the public relations profession. Currently, most companies / organizations have too high expectations from public relations professionals. Most

people seem to perceive public relations as having a symbolic function, interpretive and that their aim is to prevent them understand how they may affect corporate actions, governments and other organizations. The general public assumes that public relations is immoral and unethical nature. We believe that companies should expect to provide public relations publics a voice in decisions affecting them. We believe that companies should expect profesioniștii public relations advisers to the ethics of taking decisions, both consultation on the consequences that their decisions may have on others and on moral obligation to communicate with those affected by those decisions.

Public relations are to develop relationships, and society is a network of relationships. As individuals, have fewer conflicts in life if we develop good relationships with spouses, children, neighbors, colleagues, bosses, teachers, friends and even our enemies. The same is true for organizations that interact with each other and with audiences in society. In general, both individuals and organizations develop better relationships (characterized by trust, control exercised by both parties, commitment and satisfaction) that, if they communicate and interact with each other, using certain strategies. Communication should be characterized by openness, authenticity and transparency - what we call symmetric communication. Should also behave in a responsible manner and in a way to serve both the interests of others and their own. Thus, the strategic role of public relations management is a socio-political role. Public Relations develops relationships with audiences and organizations in society, interacting in the political system to determine decisions in a collective manner, serving to meet the interests of as many elements of a democratic system.

If the dialogue - or debate - is the rule of the game in a democracy - where transparency is the elixir of the information society. Courage comes from a sound knowledge of the power of belief and acceptance of our role by others. Most professionals today lack at least one, if not more of the conditions needed to develop the courage to be what we call "an activist in-house [6]. As an activist in-house, a public relations professional would support transparency and authenticity in communication. He or she would appeal the decisions of socially irresponsible and unethical behavior. And when he or she would think that management is mistaken, suggests that

publics welfare. Although many have the courage to play that role should go martyrs of the cause rather than champions of public relations profession, if not enhance their knowledge, faith in their beliefs and if they do not accept others to him. PR professionals should develop more knowledge on social responsibility, ethics, strategic management and symmetrical communication. You must really believe in these values of the profession of public relations, to develop confidence in their beliefs, joining the public relations firm. Equally important is to convince the others - both managers and organizations in the population itself - that it is their role.

Journalists, academics and many critics dispute the value and values of public relations. We believe that most journalists dispute the value and values of public relations as all practitioners are guided by the symbolic paradigm, interpretive public relations. As I explained in an earlier response, we believe that many practitioners follow and believe in this interpretative approach. When practitioners follow this approach indeed, journalists and scholars disputing critics are right values and behavior of public relations people. Meanwhile, journalists and academics same critics refuse to recognize that there is a type of practitioner seeking behavioral paradigm, strategic management. Their criticism is focused on the most unethical and efficiency of practitioners, thus overshadowing the company valuable role played by the best practitioners. Thus, we believe that their critical attitude of many practitioners reflect actual behavior which in turn is based on a lack of understanding of excellence in public relations.

This behavior of practitioners and how the profession can be exchanged is understood. We demonstrated that the interpretative approach to public relations was established in the minds of most practitioners of public relations. PR community must work to be restored as a strategic management function. Establishing long lasting. One can only gradually changing our course. And we think we can do this by changing the behavior of many public relations practitioners by changing how public relations are described in textbooks and university curricula and

society gradually showing that this is a responsible and valuable profession, by providing a number of increasingly great examples of responsible practices.

4. Conclusions

If we see public relations as a management function that uses communication to cultivate relationships with audiences who have a say in the conduct of the organization. Today's public relations help in management decisions socially responsible. Edward Bernays demonstrate that: "Public relations is the practice of social responsibility." We agree with him. We believe that the ideal public relations organizations to be more socially responsible. Identify and realize the negative consequences of their decisions and behavior management on publics. "Negative" are clearly the result of decisions and irresponsible behavior. Profesioniștii PR can identify negative consequences only listening and communicating with audiences before deciding to identify explaining the possible consequences and nature management consequences publics. Scenarios can be developed on the consequences of which affect how the public and affected public can organize to address these consequences through litigation, legislation, adverse publicity, etc..., Actions that have negative consequences for the organization. These scenarios can be used to help management make decisions knowingly. Profesioniștii public relations can then arrange symmetrical communication programs to assist management and the public to negotiate reciprocal behavior, so as to minimize mutual behavioral consequences. I really think that modern public relations can be public "activist in-house which helps the management to adopt socially responsible decisions. However, to do so, practitioners must develop knowledge, confidence and belief in their acceptance by the other things described.

We underline, that practitioners who are addressing the symbolic, interpretive programs often perceive very different way. Instead of seeing CSR as something related decisions and behavior daily management, they see corporate social responsibility as philanthropy or business image with very little to do with strategy and organizational behavior. In this approach, CSR activities are only used to create positive messages in hopes of protecting the organization from accusations and criticism of irresponsible or unethical behavior. Such image making activities should not equated with corporate social responsibility. There is nothing wrong in doing charity, but charity should be made for strategic stakeholderii that are valuable as employees, communities, consumers and government and not only because it provides positive publicity.

Methods of penetration in foreign markets

Lector Univ. Drd. Franca Stancu
Universitatea "Tibiscus" din Timișoara
francadumitru@yahoo.com

Abstract

The decision on how a firm penetrates a foreign market segment is one of the most important decisions that can be made by the management of the company. Once the penetration method was chosen, its implementation will have significant implications on the firm that makes the decision, as well as on the market segment that it wishes to enter.

A firm's program of penetrating a foreign market is mostly determined by the method chosen in penetrating that market.

The company should consider all possible options, positions, the possibilities of losing control over how the product is presented to the final consumer and all the risks involved in penetrating foreign markets. Once he was chosen the method of penetration, management must provide strategies, objectives and time in which they should be achieved.

Key words: foreign markets; penetration method; management;

JEL classification: F23; M19;

Generic strategy

For a company involved in operations on the international market, there are the following general strategic options [1]:

A. Maintaining a national basis (in a country) to produce goods and export them using the distribution channels of the controlled foreign company or the foreign ones controlled downstream. In this way, the company expands its international market.

B. Multiple markets strategy is also an extension of the market. In this case, the company focuses on two aspects.

The other aspect is to draw specific strategies for each market so that they match the needs of

the buyers and the competitive conditions in each market that the company operates on.

C. Global Strategy. The starting point is the global vision of the market, without taking into account national and regional differences. Global Strategy does not mean the same approach for each company. Various global markets have different needs and the company's competitive position and its internal resources influence, in turn, the global strategy.

D. Low cost strategy

Low cost strategy is based on scale and experience. Therefore, companies using such a strategy resort to sets of coordinated strategies, especially in manufacturing and marketing, focusing on scale economies and rapid accumulation of experience or both.

Experience may be obtained using one of the following strategic alternatives:

- Gaining market share in one market;
- Gaining market share in several markets;
- Combining the first two alternatives;
- Introducing new technology or components by appealing to the benefit of experience.

The chosen alternative depends on company's resources, the competitive situation of the market or markets and firm's desire to lead the competition.

E. Differentiated strategy.

The company chooses marketing variables based on the markets or market groups. The changes in products are made to suit the market and to differentiate from competitors. Differentiation may be unique in terms of physical characteristics or quality, a particular type of service or network of intermediaries.

F. Focused strategy

In this case, the efforts are focused on satisfying a segment of the international market, or a reduced number of markets. Focused strategy is a special case of differentiated strategy. The concept of a market niche means occupying a part of the market that competitors, especially new ones, do not have access on.

International focus is most useful when it is costly or difficult for competitors that seek satisfaction in multiple markets / market segments to satisfy the specialized needs of niche markets, while other rivals don't try to specialize on the same target market segment, when a company doesn't have the necessary resources and when the sector in which the firm is active has many areas, allowing the interested companies to select an attractive segment to measure forces and capabilities.

Global generic strategy

The strategies [2] adopted by companies targeting global opportunities are essentially four types: dynamic high technology strategy, low or stable technology strategy, advanced management skills strategy and strategies streamlining production and marketing activities for the international market.

A) Dynamic strategy in high technology

In certain sectors, companies can become market leaders by developing different skills in technological innovation. This places them in a strong negotiating position with local governments.

B) Low or stable technology strategy

Although some firms are in sectors with low and stable technological innovation, they become market leaders by developing distinct skills in other competitive areas such as brand identity or know-how of the production.

Nevertheless, because their technology is widely held, they are not in a strong position for negotiating with local governments as described above. The main advantages that companies should have in order to adopt and use this strategy are the reputation, know-how in the production, economies of scale and the capacity to deliver standardized products and globally interchangeable components.

C) Advanced skills management strategy

Companies can become market leaders also by developing different skills in management such as marketing and coordination.

D) Strategy to rationalize production and marketing

Companies can become market leaders in their sectors and export to other markets to increase global markets. They can also streamline marketing activities so that they have a competitive advantage over competitors. A

firm that adopts such a strategy must meet four requirements of commercial importance, namely:

- The product should have a relatively high ratio between the value and volume or weight to compensate the transportation costs from the place they are produced to the market where they are consumed;

- Parts of the production process have to be intensive in labour force and separated from the rest of the production process for placing these activities that require more work in markets with low costs of the labour force;

- Control over the production process is essential to ensure coordination and maintenance of various production units and to maintain the quality standards required by the finished product and the destination market.

Company must [2] exert a close coordination of its international marketing organizations and logistics with access to one or more national or great trans-national markets. For example, controlling the distribution channels and the influence on price are often obtained by known brands.

Strategies for market presence

Depending [3] on the companies objectives in terms of market presence, it may use several strategies that are influenced on the one hand by the competitive ability of the company and, secondly by the market situation and developments.

The main strategies that can be used by a firm which intends to report its competitive dynamic between capacity and market development are:

Development strategy

The company seeks market expansion in order to have greater market share. To this end, it expands the product range, distribution network and promotional activities.

Consolidation strategy

It complements the previous one. Such a strategy is followed when the company has grown to a point that is sufficient to his purpose. Therefore, if doesn't develop anymore, a company must strengthen its market position and does so by using the entire arsenal of marketing activities and tools.

Maintenance strategy

When firms [1] use this strategy they no longer have competitive advantages or the

competitive power required for the possession of a strong market position.

Restriction strategy

This strategy is necessary when the company can not meet the market's requirements and loses customers and its market share is diminishing.

Competitive strategies

That firms operating in international markets face two major problems in terms of competition: competitive behaviour and response to actions by competitors.

Given the way the company behaves a market can distinguish the following:

The role of advertising, trade and industrial exhibitions in entering foreign markets

Starting from the complexity of the policy components of the promotion and the marketing objectives pursued, this activity must meet certain requirements:

- Providing information to the buyer about new products, their utility and to re-sellers to be able to offer information to their potential customers,
- Stimulate demand by accelerating awareness of needs, the cultivation of desires and aspirations;
- Product differentiation. With how a brand is more individualized compared to others from the same category, the bidder can count on a higher success, but, actually the buyer makes a difference.;
- Even relative loyal customers should be currently and regularly advised about the

benefits of products not to change their preferences, especially in conditions of competition by novelty

- Combat bad information, especially by rumours spread that can harm the companies and the product's image;
- Smoothing demand situation especially in low season for certain products;

Dedicated marketers consider that the advertising message performs its functions if they respect the C.I.D.D. principle. Meaning:

C = calling attention

I = inciting interest in product

D = desire challenge

D = to determine product purchase.

It has a number of advantages, especially when it is promoted to media centres, when the

- Influence of opinion leaders, people in positions of responsibility, the decision-making even at government level;

- Influencing public attitudes, especially through public interest campaigns against habits as alcoholism, smoking behaviour on public roads, etc.

A) Advertising

The term is of Latin origin "publico - publicare" - to address the public, to notify the public.

The forms of advertising are based on a number of factors and it diversifies in line with the increasing competition between operators.

A. advertising product that essentially aims to stimulate consumer demand by doing the following:

- Informative advertising on the occurrence and presence to the market of a new product
- Conditioning advertising when the presentation focuses on conditions, conditions that facilitate the identification of products in the overall mass of the offer that the company is in competition with;
- Comparative advertising in which the presentation is sometimes subtle used compared to competing products- usually a repudiated and forbidden practice
- Resuscitation publicity, the desired strengthening effect of previous advertising activities;

B. Brand advertising (brand publicity), with the emphasis on brand image highlighting the product being offered.

C. Institution advertising which aims to establish a positive attitude, even an attachment towards the business or the enterprise.

To influence an immediate purchase and an early use of a product is used:

B) Publicity

Time is of Latin origin and it makes sense "clamare" - calling, urging the purchase.

product may be known nationally. But the costs are very high and very difficult to customize.

C) Techniques and means of advertising

It has a very wide range taking into account the developments in sociology, psychology and especially in the media, rightly called the industry. The major Medias used to support the transmission of the message are: print, radio, television, billboards and outdoor posters, promotional prints.

- Print media

Is the main means of transmission of advertising messages with a number of advantages that start with a good efficiency as far as territorial distribution, time of publication, access to a various category of socio-professional readers, circulation, sale price of the space, print quality, etc.

D) Sales Promotion

As noted, by sales promotion means using media and techniques to stimulate, enhance and increase the sales of goods and services that form the business offer at a certain time.

The most frequently used promotional schemes prove to be:

- Promotional price reduction with an undeniable effect and it is used in different situations such as: elimination of purchase reluctance, for some consumers for whom price is considered too high;
- Reduction in stocks of slow or difficultly sold products;
- Maintain sales levels of efficiency especially in reflux periods of demand;
- Stock lots of the products that will be replaced;
- Counter competitive actions and use the opportunities offered by certain cyclical market situations.

E) Public Relations (Public Relations)

It was recently established as a separate activity and it involves the cultivation of consistent and systematic direct contacts with different audiences, with influential people, with the media, with representatives of the public and opinion leaders, that may be treated as lobby actions.

Conclusions

Depending on the companies objectives in terms of market presence, it may use several strategies that are influenced on the one hand by the competitive ability of the company and, secondly by the market situation and developments.

The Improvement of the Company's Management Using Econometric Techniques

Cornelia Gaber
Universitatea Petrol-Gaze, Ploiești
dinugaber@yahoo.com

Abstract

During the managerial process of making decisions, it is necessary to have information about the future events, and this kind of information can be obtained by using different prediction techniques. This study presents the use of the Box-Jenkins predicting technique, used to prognosis the make of a product and to underline the impact the method has on the decision making process.

Key words: managerial decision, prediction, development

JEL classification: M19, C5

1. Introduction

The productive activity that takes place at a certain level involves creating a base (production capacity, labour resources, and technology) for reaching the same level, at least during the future period of time. Therefore, part of the economic processes depends on the previous performances, and the idle behaviour is emphasized using the autocorrelation. The particularities of the economic behaviour and the quantification and prognosis possibilities for the lag and auto-adoptive models have allowed the American econometric experts George E.P.Box and K.G.M.Jenkins to create the stochastic prognosis models.

The planning and control are key managerial elements considering that for making a decision the time variable changes from a few years to a few days or even hours. The information about the future events can be obtained using the prediction techniques, whereas the presented plans depend on the future expectations [2],[3].

2. The Box-Jenkins method

The purpose of this study is to present the use of the Box-Jenkins prediction technique [1],[6],[8] in order to forecast the make of a close necessary product.

The analysis and prognosis of the chronological series using the Box-Jenkins modelling methods is specific for the stationing series (a result of a stochastic stationary process) having some constant elements, that repeat themselves during the process, that offer a solid base to the prognosis and that make performance possible if they are kept as a model [5],[7].

The data series used for the actual make of the Box-Jenkins modelling consists of the created quantities of the "P" strictly necessary product, during a 3 year period of time. The records are monthly reported and they are presented in Table1

Table 1. Statistical data

Time	Production (kg)	Time	Production (kg)
1	2499	19	4162
2	2304	20	4425
3	2570	21	4443
4	2468	22	4143
5	2590	23	3686
6	2451	24	3692
7	2138	25	2792
8	2608	26	2050
9	2804	27	2534
10	3087	28	2952
11	3123	29	3462
12	3028	30	3532
13	2989	31	3766
14	2799	32	3315
15	2275	33	2920
16	2543	34	2799
17	3084	35	3084
18	3640	36	3692

The shape of the graphic that is presented in figure 1 indicates the non constant characteristic of the data series

Fig.1. Production in terms of time

The auto-correlation function, that represents the key element for the entire prognosis stochastic modelling process can be estimated using the auto-correlation coefficient [4]:

$$r_k = \frac{\sum_{t=1}^{n-k} (y_t - \bar{y})(y_{t+k} - \bar{y})}{\sum_{t=1}^n (y_t - \bar{y})^2}$$

where r_k represents the estimator for the auto-correlation coefficient

k – the lag.

Following the calculations these certain values are obtained $r_1 = 0.822153$, $r_2 = 0.512862$, $r_3 = 0.201263$, $r_4 = -0.06326$, and the values for the auto-calculation function are $c_1 = 0.822153$, $c_2 = -0.5131$, $c_3 = -0.07789$, $c_4 = -0.13037$.

The r_k coefficients follow a normal allocation. The average value is 0 and the value for the variance is $\sigma_{r(k)}^2 = \frac{1}{n}$ meaning

$\sigma_{r(k)}^2 = \frac{1}{36}$. For a probability of 0.9545 one must determine the limits of the reliable interval which are $\pm 2\sigma_{r(k)} = \pm 0.33$ and it can be noticed that r_1, r_2 are not part of the interval which means that the series is non-stationary. Therefore, it is necessary to differentiate the original series in order to reach stability. The values for the differentiated series are presented in the following table (table 2).

The auto-correlation coefficients obtained for the new values of y_t and presented in table 2 are $r_1' = 0.347$, $r_2' = 0.049$, $r_3' = -0.156$, and the result of the statistical testing of these coefficients is: $t_1 = 1.9936$, $t_2 = 0.25116$, $t_3 = -0.80463$. The fast decrease of these coefficients to values close to 0 attests the state of stationary series. The partial auto-correlation coefficients are the resulted values of the Tule - Walker equation system [9].

Table 2. The values of the differenced series

Time	Value	Time	Value

10	283	28	418
11	36	29	510
12	-95	30	70
13	-39	31	234
14	-190	32	-451
15	-524	33	-395
16	268	34	-121
17	541	35	285
18	556	36	608

$$c_1' + 0.347 c_2' + 0.049 c_3' = 0.347$$

$$0.347 c_1' + c_2' + 0.347 c_3' = 0.049$$

$$0.049 c_1' + 0.347 c_2' + c_3' = -0.156$$

By solving the prior system, the following values are obtained: $c_1' = 0.347$, $c_2' = -0.082$, $c_3' = -0.167$ and the result of their statistic testing is: $t_1' = 1.9936$, $t_2' = -0.4686$, $t_3' = -0.9619$. A sudden decrease can be noticed after the increase of the lag, where the increase is equal to 1.

An ARIMA model [6] can be suggested for the analysed series following the previous analysis. The equation is

$$y_t - a_1 \cdot y_{t-1} = u_t - b_1 \cdot u_{t-1}.$$

The auto-covariance must be determined for the initial estimation of the parameters for this model. This is presented in table 3.

The value for the residual variance and the value of the a_1 and b_1 parameters that have been obtained following an iterative process are: 119224, $a_1 = 0.1403$, $b_1 = -0.2367$ and the initial model is:

$$y_t - 0.1403 \cdot y_{t-1} = u_t + 0.2367 \cdot u_{t-1}.$$

Table 3. Auto-covariance

136511	-44953
47375	-15289
6648	4594
-21340	19686
-48955	4278
-52450	42233

Using the criteria of minimizing the residuary squares one can determine the final estimations for the a_1 and b_1 parameters, not forgetting to mention that by using the initial estimations for a_1 and b_1 , the sum of the residuary squares has the following value: 114503.

The final values chosen for a_1 and b_1 in order to reduce the value of the residuary square sum are $a_1 = 0.0029$ and $b_1 = -0.648$. The reduced value for a_1 is the consequence of the fact that the partial auto-correlation function has a crown and after that it is cancelled. The same thing can be said about the auto-correlation function, which indicates the existence of a weak correlation between the values of the series. The final equation of the model is:

$$y_t - 0.0029 \cdot y_{t-1} = u_t + 0.648 \cdot u_{t-1},$$

and the obtained residues, for this particular case, are presented in table 4.

The sum of the residues square is 55.24 in this case. Validating the model presumes the calculation of the auto-correlation and partial auto-correlation functions for the residues. The results are presented in table 5, along with the values of the corresponding t test. It must be taken into account the fact that $|t| < 1.25$ for the 1, 2, 3 values of the delay and $|t| < 1.25$ for the other values.

Table 4. The residues of the analysed periods

-	0.17	-2.72
0.196	-0.45	0.47
1.383	-1.00	3.67
-1.104	2.38	-0.19
0.67	0.82	0.27
-0.78	0.05	-1.32
-0.52	-0.10	0.49
2.35	-0.78	-2.06
-0.82	-0.74	1.35
0.26	-0.95	-0.45
-0.74	-0.47	0.80
-0.39	1.38	1.39

Table 5 Auto-correlation functions for the residues

fac-rez	t-val	facp-rez	t-val
-0.21	-1.18	-0.21	-1.18
-0.10	-0.57	-0.15	-0.88
0.04	0.24	-0.01	-0.08
-0.19	-0.87	-0.18	-1.04
-0.07	-0.36	-0.16	-0.89
-0.19	-1.03	-0.33	-1.91

It can be clearly seen that the „fac-rez” and „facp-rez” values are mainly insignificant from the statistical point of view.

The test that Ljung and Box have developed takes into account the calculated value,

$$Q = n \cdot (n + 2) \cdot \sum_{k=1}^m \frac{1}{n - k} \cdot \hat{r}_k^2 = 10.53$$

which is lower than the critical value of Q for 9 degrees of freedom and a significance level of 0.25 that is 11.4.

Taking everything into account, the ARIMA model (1, 1, 1) is proper for the analysed series. The quantity of the strictly necessary product obtained using the ARIMA model is of 2957 kg.

3. Conclusions

A concern of high importance is represented by the prediction of the economic phenomenon, as a consequence, the managerial decision takes considers the reach and exceed of the previous results during the period of time that follows.

Assuming that the manager uses the prediction methods for planning the short time activity of the company, the method can be of great support for the managerial decisions. The results that are obtained by using the Box-Jenkins technique, along with the results that are obtained by using other predicting techniques lead to the building of a complex method of making decisions, and it is an important managerial instrument that can be used for the proper development of a company's activity.

The company's management can benefit from the information provided by the prognosis models for making the activity more efficient.

The Romanian Market of Ecological Products

Gangone Andreea-Daniela

Chirila Camelia-Andreea

„Constantin Brancoveanu” University - Pitesti

andreeagangone@yahoo.com

cameliachirila2004@yahoo.com

Abstract

The preoccupation to preserve the integrity of the natural environment for the benefit of the future and present generations, generated by the creation of an ecological awareness for more and more people, represents the foundation of the ecological products market.

In Romania, this market is still at an early stage, its development being stopped by a series of factors such as: the legislative ambiguities, the lack of ecological education with the Romanian consumers, the lack of subsidies for the ecological agriculture, the reduced number of ecological processors, the lack of an adequate commercial infra-structure, a reduced level of living.

Resolving these issues cannot be made on a short term and fundamentally involves the increase of the living standard and the ecological education of the Romanian consumers.

Key words: ecological products, consumers, market

JEL classification: Q57

1. Introduction

The decrease of the quality of the natural environment and the perspectives of its accelerated degradation, on one hand, and the considerable diminution of the natural resources on Terra, on the other hand, up to the point in which the specialists may approximate when a part of these resources will be completely finished, constitutes the support of the **ecological movement**, which appeared and developed as a reaction to the negative impact of the human activities upon the natural environment.

The ecologists are worried about the damages produced to the ecosystem by the surface mining, the forest cutting, the fall of acid rains, the reduction of the ozone layer,

the inadequate storage of the toxic waste and garbage, the reduction of the recreation zones

in the open air as well as the multiplication of the health problems caused by the poor quality of the air, the water pollution and the chemical treatment of food products [1] etc.

These issues are not recent, but they intensified along the XXth century, in the period of the so-called “wild capitalism”. Thus, Jean Jacques Cousteau stated, in 1996, that, in this century, the environment has been more affected than in all the other altogether and has considered that in this situation it has been determined by the free market system and the explosive increase of the population.

The market system, considered Cousteau, harms the planet since everything has its price but nothing has a value. Since the long term does not have a price on the market today, the fate of the future generations does not get in the economic equation.

The factors previously mentioned started a „revolution” in classifying the consumers’ values, as they have become aware of the importance of approaching the issue regarding the completion of their own needs and desires from an ecological perspective, respectively in a manner that treats the environment with respect. In other words, the consumers have acquired **ecological awareness** and have started to exercise a series of pressures upon the economic organizations so that they could assume a series of ecological responsibilities.

In the last decades, the **environment protection** became “a major social task of the humankind”, in order to secure the quality of life for the future generations [2]. This attitude reflects the preoccupation of the economic organizations to keep into account, when establishing their medium or long term objectives, the obligatory necessity to protect the natural environment by promoting a sustainable development.

According to the World Business Council for Sustainable Development, the **sustainable development** “wants to satisfy the needs and the aspirations of the present without compromising the chances to satisfy those of the future. Without any suggestion to stop the economic development, this concept admits that the problems of poverty and underdevelopment cannot be solved in the absence of a new era of economic increase, within which the developed countries could play a major role and get the intended results” [3].

In this vision, the sustainable development thought as the reconciliation between the economy and the environment, reconciliation which involves a sustainable support of the human progress, not only in few places of the world and for a couple of years, but for the whole planet and for a long future [4].

According to this approach, the major purpose of any economic activity is no longer the maximization of profits, of consumption or customers’ satisfaction but **the maximization of the life quality**.

2. The concept of ecological product

Such a general objective can be reached only by reconsidering the importance of the organizational purposes, in the sense of placing the sustainable development in the avant-garde of the results expected by the organizations.

Consequently, the companies are forced to find new methods to produce the non-polluting goods and some non-recyclable or biodegradable wrapping, new methods to control pollution more efficiently and at lower energy consumption [5].

The results of the ecological production process are the ecological products. Regarding this aspect, we must underline some terminological and content details.

From a terminological point of view, the European Union considers as being synonymous the notions of *ecological product*, *biological product* and *organic product*, each member state choosing to use legally one of this notions. In our country, we use the notion of ecological **product** [6].

We can also observe the Romanism consumers’ confusion in what regards the usage of the notions of ecological product (biological or organic) and the notions of natural or naturist product, confusion which is created, on one hand, from the lack of consumers’ poor ecological information, on one hand, and the

economic agents’ abusive behavior, who resort to all kinds of unreal presentations and promotions wishing to increase their sales.

From the point of view of the contents of the notion of ecological product, the situation is not simpler, because of the relativity of the concept. The relative character of the notion of ecological product is determined by the fact that, in reality, there are no pure ecological products, but only products which affect to a smaller extent, the integrity of the natural environment.

Thus, the **ecological product** can be defined as *that product which fulfills the same functions like the similar conventional product and brings less prejudice to the environment along its life cycle*.

In other words, an ecological product implies a combination of three attributes: it satisfies the consumers at least as good as the traditional product, it does not affect the company’s economic efficiency (it generates profit) and it affects the natural environment in a smaller measure.

The compatibility with the ecosystems is not a purpose; it is realized to satisfy the consumers’ needs in order to obtain the profits. The issue that needs to be solved is that of finding the means to offer the benefits to the consumers and maximize the profits without affecting the environment.

More than that, it is important to say that the notion of ecological product regards not only the product, but also its fabrication process. From this perspective, the ecological attributes of the product can be distributed in two main categories:

- a) *attributes specific to the product* – life duration, recycling facilities, quantity of materials used to obtain it etc.);
- b) *attributes specific to the fabrication process* – water and energy consumption, generating wastage etc.).

Also, the standards according to which they evaluate the ecological quality of products differ from one nation to another and from a period to another, which provides a dynamic character to the concept of ecological product.

Finally, the ecological products are evaluated differently from the categories of participants at the market operations. Thus, regarding from the *producers’ and the dealers’ perspective*, a **product can be considered ecological** if it corresponds to the green legislation. On the other hand, *the*

consumers can appreciate a product as being ecological if it fulfills their exigencies and their expectations regarding the environment and the health, which can sometimes surpass the regulations and the producers' availability regarding the environmental features of the products [7].

3. The offer of ecological products

Forming an ecological conscience to consumers generated the need for various products which could bring less prejudice to the natural environment, but at the same time could satisfy the consumers' expectations.

Observing the change in the consumers' attitude, a series of producers and distributors were preoccupied with creating and bringing on the market various products which satisfy their needs.

In this context, **the market of ecological products** was created, first in the industrialized countries, and later in the less developed countries.

Presently, we may observe the apparition of more and more specialized and well-defined market segments, (especially the agricultural and food sectors, washing powder, cosmetics, toiletry, car sector etc.), made up of consumers who have already developed an ecological conscience, being disposed to pay a higher price when purchasing various ecological products.

The world market of ecological products has had an average development rate of around 3% per year. Thus, the market value has increased from 13 billion dollars, in 1998, to 46 billion dollars, in 2008.

In what its *dimension* is regarded, the Romanian market of ecological products has increased, in 2009, up to the value of 20 million Euros, which represents around 1% of the total retail market value.

This percentage is still low, both in comparison with the rate in the European Union, of 5-6% on the retail market, and with the objective of 5%, which Romania intends to reach in 2013.

Figure 1. The sales evolution of the ecological products in Romania (in millions of Euros)

Source: Realized by the authors on the basis of the data obtained from www.madr.ro

The ecological agriculture is an important supplier of ecological products on the Romanian market, an aspect proved by the fact that the entire ecological cultivation land has continuously been extended in the last five years, reaching approximately 100,000 hectares (in 2005) to an average of 400,000 ha (in 2010), which represents around 1% of the agricultural existing land.

If we take into account that, in the European Union, around 3.7% of the agricultural land is cultivated organically, we observe that it is a low percentage, but the development rate of the land cultivated ecologically is high, the Ministry of Agriculture and Rural Development intends to extend it up to 750,000 hectares, by 2013 [8].

Figure 2. The evolution of the entire land cultivated ecologically in Romania (in hectares)

Source: Realized by the authors on the basis of the data obtained from www.madr.ro

Another relevant aspect regards the fact that most eco-products traded on the Romanian market are imported, as, in our country; there is a major discrepancy between the number and the capacity of the producers of ecological products, on the

other hand. More than that, the ecological agriculture generates more products than the small number of Romanian producers may process.

Figure 3. The chronological correlation between the number of producers and the number of processors registered with the ecological agriculture

Source: Realized by the authors on the basis of the data obtained from www.madr.ro

Out of this reason, around 90% of the raw ecological products obtained by the local producers are exported (in 2008, the Romanian exports of ecological products were of 130,000 tones, respectively 100 million Euros), returning into the country as finished products and four times more expensive.

We can thus explain why the prices of the ecological products are 20-40% higher than the price of the traditional products.

Figure 4. The structure of the Romanian exports of ecological products in 2008

Source: Vaschi Maria, *Bio, eco or organic, free to retail!* in *Piața*, no. 54/2009, pp. 24-28.

In Romania, around 60% of the ecological products are sold in specialized shops, where the consumers have the possibility to study them, read their labels or even taste or test them.

These shops are situated mainly in big cities and the capital city: Pukka Food (Bucharest), Biocoop (Sibiu), Naturalia (Bucharest and Voluntari), Leacul (București), Bio Market

(Timișoara), Natura Food (București), Coșul Verde (Cluj), Ki-Life (București), Bio-Bazar (Tg. Mureș) etc. [9]

The eco products are also traded in the large chain-stores. Thus, the main chain-stores have introduced the ecological products and have set special selling departments for them: Carrefour, Cora, Gima, La Fourmi, Kaufland and Mega Image, but products of the same category we may find in almost all the other important distribution channels.

4. The demand of ecological products

The green consumer (or the ecological consumer) is that consumer who has in his purchasing attitude a real preoccupation for the environment protection, looking for and purchasing goods with a low impact upon the environment.

The real ecological consumers do not want only a substitute made from recycled materials or healthy for environment. They want to breath fresh air, drink pure water, eat healthy products, and make sure that the future generations could do the same [10].

An ecological consumer can also judge a brand product in conformity with its ecological qualities. For these consumers, the ecological attribute is a valuable attribute of the product. Recognizing and accepting this attribute may be concretized into:

- higher prices paid for the ecological products;
- the refusal of some polluting products;
- choosing the ecological products instead of the conventional ones when the two categories will be similar (from the point of view of their price, offered facilities etc.).

As we can't talk anymore about pure ecological products, we can't either say that there are consumers with complete ecological attitudes. In fact, the reality is far from that.

In Romania, most consumers do not understand or they understand less than they should the impact on the environment and they are satisfied if they succeed in making some simple, symbolic changes in their consumption or personal attitude. Out of this reason, the cases of ecological attitudes are superficial most of the times.

A study made in 2005, with the support of the Ministry of Agriculture and Rural Development, tried to make the profile of the

Romanian consumer using ecological products: persons aged between 26 and 39 years, getting mainly a high or medium-level education (in other words, mature, active persons, in a social ascension).

The Romanian consumers appreciate most the food-related ecological products, respectively: dairy, eggs, fruits, vegetables and meat-based products, but also cosmetics with biologically controlled ingredients friendly detergents, or organic liquid food supplies.

The main reasons for not buying the ecological products in Romania are:

- the ecological products are expensive as the production costs are higher, while the profit is lower. In the future, at the same time with increasing the volume of eco-products, but also the number of local producers, we expect to have lower prices;
- there is a small number of ecological shops and they are situated only in the large cities, an aspect which limits the access of many Romanian consumers to quality ecological products;
- the diversity of the ecological products is still reduced;
- the wrong labeling of the ecological products on the shelf (in supermarkets or hypermarkets) and the lack of delimitating them from the rest of the products;
- the Romanian consumers who are still in a period of accumulation (of material goods and properties), manifest a low preoccupation for protecting the natural environment, a reason for not choosing the ecological products. Regarding this aspect, we may also observe the Romanian consumers' tendency to consume ecological products only after they obtain a certain life standard;
- the Romanian consumers do not pay the necessary time to study the offer carefully;
- the Romanian consumers cannot make a comparison with respect to the price of some similar ecological products;
- the Romanian consumers cannot ask for further details or look for information about the producers or the products;
- there is a conception that the producers are interested to sell their products by inducing the consumer into error when labeling the product as being "ecological", and lying

about their real impact upon the environment and their health;

- the Romanian consumers' confusion between the notion of natural/naturist product and ecological product;
- the producers' selection can only be made on the basis of the usual criteria, as well as the producer's brand, the bio certifications and the obtained quality standards;
- the ecological products can be less safe and less efficient.

5. Conclusions

Presently, the ecological purchasing and consumption attitude becomes more and more spread, sometimes being and integrating part of the life style of those people who are aware of the environment issues. The rapid development rate in the green consumption also places the environment in the situation to become a competitiveness problem for an increasing number of activity sectors [11].

In our country, these tendencies are, for the moment, at an early stage, but it is to expect that they will become more and more pregnant while the Romanian consumers will get an ecological conscience and will solicit more and more products that bring no prejudice to the natural environment.

Some of the methods that could contribute to the increase of the ecological products consumption in our country we can mention:

- ✓ it is believed that one of the major problems of the present society is the lack of information regarding the environment. Thus, it is necessary to develop, in this sense, a series of information campaigns for the consumers, with the participation of some non-profit organizations (ecologist and consumer protection) and non-governmental as they present a higher credibility compared to the private operators;
- ✓ effectuating some information campaigns for the producers, to train them and promote the concept of ecological product, made by state and private organizations;
- ✓ offering European financial support to the information and promotion programs proposed by the professional associations in the field.

- ✓ establishing some strict restrictions regarding the usage of fertilizers and pesticides, growth stimulators and regulators, hormones, antibiotics, animals intensive growth systems;
- ✓ the strict interdiction to use organisms genetically modified (OMG) and their derivatives;
- ✓ making some ecological products with taste, texture and authentic and attractive qualities;
- ✓ producing more hygienic food, proper to the human body metabolism;
- ✓ trading some ecological products only the registered traders;
- ✓ developing some "models of pair-customers" or some "models of family-customers";
- ✓ using the fidelity cards with the help of which the customers accumulate loyalty points when buying ecological products traded in specialized networks or shops;
- ✓ influencing the customers' purchase decision when revealing the impact of various products upon the environment or certain additives upon the health;
- ✓ promoting the concept of ecological agriculture in order to make the consumers aware of the advantages of the consumption of ecological products;
- ✓ intensifying the customer-directed actions regarding the importance of certified ecological products for our health;
- ✓ intensifying the information actions regarding the environmental projects and accessing European funds;
- ✓ allocating subsidies for the ecological agriculture, as this is a key-sector in the National Export Strategy for 2010-2014.

Finally, we need to clarify the impact of the economic crisis upon the Romanian market of ecological products. Obviously, the crisis has affected this sector of the Romanian market, but we consider that, in spite of the recession, there will continue to be some clients loyal of the

ecological products, who will permanently look for diversity, quality and natural taste. Besides, the Romanian consumers of ecological products are less sensitive to the price, at least while they consider that they pay a fair price for a quality product, and they are loyal to the brands which best respond to their needs.

The Logistic Centre, Expression of the Distribution Globalization

Gheorghe Dan

“Ovidius” University of Constantza

secretariat@traian-sa.com

Abstract

"Within the current market expansion and globalisation of the product distribution, which becomes an essential element of the economic and social International Systems, their specific economic activities and the modern trend have made possible the building of different trade channels.

Based on this theory the logistics centers - Strategic Investment Projects, enables the implementation of the most advanced technologies within merchandise logistics and distribution, achieving economical efficiency through costs benefits and in the same time competition advantage, followed up by all the marketing channel actors."

Key words: independent logistic centre, globalization, modern solutions for lay-out and building, logistic activities, connectivity, competitive advantage.

JEL classification: L81;

1. Introduction

The present paper focuses on emphasizing the keen interest in the development of the logistic channel's constituent. Due to the globalization of the distribution activities in general, and of the logistic ones, in particular, this theme appears as a novelty which covers the trends in the restructuring of logistic channels, and all the processes and activities related to this important sector.

The theme under discussion is concerned with the practitioners' (marketers') research into the logistic channels locations, their sizes, the accompanying technological novelties, whereas the specialized literature investigates only the description of certain logistic activities.

The aim of the paper is to look into the emerging conditions, the position of the logistic

centre in the context of globalization, and, above all, its contribution to the creation of a horizontal integration, with respect to processes and activities, which would be able to come up to the economic restructuring under the impulse of IT and communications.

2. The assumptions that have entailed the logistic centre

The free movement of the goods and capital at global level has generated basic changes of the marketing and logistic channels, and the assertion of structures that allows them the access to emergent markets on national or global level.

The global brands (alimentary and non-alimentary goods) are found sometimes at great distance from the demand manifestation place, and in order for the producers to promote these goods on the respective markets, they will resort either to intermediaries of the marketing channels that have the necessary logistics to realize the distribution, either to independent logistic structures that assure the physical distribution support of the own goods to the final consumers.

The producers of the consecrated goods and of the goods that have rising demands, specially the ones that imply new technologies, will be concerned to develop the product markets abroad, and in this way they will appeal to consecrated distribution channels or to determine the apparition of new structures, respectively of the logistic centre in order to make possible the conquest of new market areas.

Another assumption that has imposed the appearance of the logistic centers is the expansion of super and hypermarkets chains, that have build logistic centers in order to expand on new market areas and to furnish the goods fund necessary to the own built stores chain.

The free movement of the capital has permitted to the strategic investors, besides the members of the distribution or logistic channels, to develop logistic

centers, capable to cover broad areas, geographical areas that exceed the borders of a country.

The producers (the exporters), the importers (the distributors), inclusively other members of the marketing channels interested in logistic services (logistic activities) of the independent logistics centers, are imposed as a necessity for the development of these modern structures.

If in the first phase these logistic centers have appeared in the developed countries, as a consequence of the economical evolution, these centers have followed the natural path of globalization, towards the emergent zonal centers, where they became consecrated structures. Here, the investors enjoy the competition of the territorial administrations, where the emplacement will be realized, because the logistic centre leads to a development of the infrastructure and transport networks in the respective area. Likewise, it is a generator of new jobs, creating the assumptions of the economical development of the respective area where these structures are emplaced.

The emplacement of the logistic centre will mean in the firstly the accessibility to the transport routes, especially in the interference areas of different transport types: on water, on roads, on rail or on air.

Taking into account the actual distribution expansion conditions and the globalization process of this activity, that becomes a major component of the socio-economic international system, the specific activities of this sector, the modern trends that occur here, made possible the birth of distinct commerce structures among this field. This way, the logistics centers, strategic investment projects that brings the modern technologies in goods distribution and logistics, assuring the needed costs cuts, and also competitors advantages desired by the marketers.

3. The logistic centre - the considered activities

As it results from the factors analysis that has generated the development of the logistics centers, we will meet groups, in function of the investors:

- logistics centers attached to a global brand producer or a distribution chain,
- independent logistic centers, developed and exploited by a strategic investor.

In both cases, the features of the logistic centre are the ones that exceed the amplitude of the classic storage areas (reaching dimensions of 100.000

square meters), assuring a diverse paddle of activities - here all the activities can be found, the basic ones as the supportive ones realized in the frame of a classic logistic channel.

The difference between the two types of logistic centers is that on the attached one, the property of the goods belongs to the owner of the centre, whereas at the independent logistic centre the realized logistic activities are demanded by the goods owner or by his proctor.

The design and the realization of the logistic centers will take into consideration the nature of the goods that will make the purpose of the logistic centre, thus to assure the maintaining or the improvement of their value. They will dispose the technological rigging to allow the transport, storage, manipulation, the stock management, encasement, batching, systemic transmission of the information, in order to increase the economic effectiveness and efficiency.

The modern constructive solutions, the building materials, the current building technologies enable the realization of the most modern logistic centers, that administrates the whole palette of solicited activities of the marketing channels members for different goods.

The independent logistic centre can assure to its clients the whole palette of logistic activities such as:

I. Basic activities:

1. - specific activities for the expedition houses, respectively the engagement on the whole displacement route of the goods transport capacity, storage, manipulation, assurance and other necessary activities.

2. -goods transport activities when it has its own park for the goods transportation from the production place to the distribution place, or from the distribution place to the destination place demanded by the producer or the owner of the goods, respectively the importer. This transport activity can be realized with rented transport capacities such as: on water, on roads, on răii and other transportation means.

3. - storage activities - these can be realized for the clients in seif name, or by renting storage areas to the producers or goods owners. Because the logistic centre disposes of big storage areas, these permit to the exporters (producers), importers, the storage of big batches of

goods with implications on obtaining an optimal cost/price ratio on the product unit.

The storage technologies found in the logistic centers will attract the current projects performances that assure the acceleration of interchanges, fluxes, continuity, and an accelerated rhythm of the goods party movements. At the same time these technologies assure the merceological conformation of the storage norms (frigorific chains), compatibility norms, assuring the circulation goods fluxes, of the entries, of the outgoes, etc.

4. - stock management activities when these activities are requested by the producers or the goods owners, assuring at the same time services for dispatching batches communicated by them, tended to the destination points in the envisaged areas on the market.

II. *Support activities:*

1. - logistic centers can assure, as a consequence of the existent rigging and by the technical possibilities available, the continuation of the production chain by technological operations of ageing the products, encasement and prepacking, and for some categories of goods, remedies in the guarantee and post-guarantee period.

2. - goods manipulation will achieve modern technologies features, that will use advanced technologies (sincrolift, R.D.I. systems), ticketing, that will be based on information adaptation and accounting data technologies.

3. - information management and communication towards the clients of the logistic centre, by the large use of informational technologies referring to realized logistic activities.

4. The advantages of the independent logistic centre

A first advantage offered to the members of the marketing channel (producers-exporters, distributors - interagents, services tenders) refer to total elimination of the investment effort in developing the storage, transport, technological support capacities and other investments necessary to realize the distribution: (selling) of the goods, industrial products, etc.

The possibility to unreel big volumes (batches), comparing to the classical logistic channel, the

amplitude of the goods groups unwounded by the intercession of the logistic centre, is conceived to satisfy the exactingnesses of the different marketing channels clients, different groups of alimentary or non-alimentary goods, of large or current consume, etc.

The most modern standards of technical riggings assured by the independent logistic centers, makes possible the getting over of the whole physical tack of the goods till the manifestation place of the consumer's demand (figure no. 1 annexed).

The assurance of the realization of the whole palette of activities that accompanies the goods logistic channel, standards that satisfy the demands of a modern physical distribution, transability, flexibility in adopting adequate solutions, the duration reduction of the transfers realized in the logistic centers, adaptability, increased productivity, will bring valuable economies.

Today the logistics centers use IT systems, where the data and order steps are being automatically processed (picking, goods reception, in-out documents, stock management, income report and management, loadings planning, delivery routes optimizing by performance software use). These systems have as basis connectivity communication systems.

Recently, the IT systems based on connectivity with the help of EDI system (electronic data interchange) will be used in the relationships of the logistic center with the clients that use the EDI system (suppliers, exporters, importers, business companies, clients, etc), systems that allows also in transit stock management. The development of EDI system allows also trough broad connectivity, issuing of reception notes, delivery notes or invoices.

The same connectivity solution will be used for Management systems of stocks, orders, sales, purchasing and also for on-line customer orders, by the sales agents, and also to gather information regarding the financial status of the customers.

The implementation of the IT system based on connectivity allows the reduction of the amount of time necessary for making the information available for the management team in order to prepare the budgets for products, sales predictions, in order to be able to respond in real time to the customers needs.

This IT system based on communication connectivity software allows the disappearance

of paper support, manual data processing, avoids human errors, allowing the development of a data base (reports, detailed analysis) flexible and complex, which is so necessary in order to support the management decisional process.

The economies brought as a consequence of the conditions offered by the independent logistic center, comparing to the classical logistic channel, with more participants, has as aim to bring an efficient answer to the final consumer (C.R.M.) by reducing the goods value distributed by the members of the marketing channel.

5. Conclusions

The logistic centre provides, first of all, a symbiotic integration of the logistic processes, activities and the marketing channel, which correspond to the current requirements of the global goods distribution.

The logistic centre responds to the departments in charge of the managing, planning, integration, control and evaluation of the logistic processes and activities in order to guarantee full capacities demanded by the current goods distribution networks.

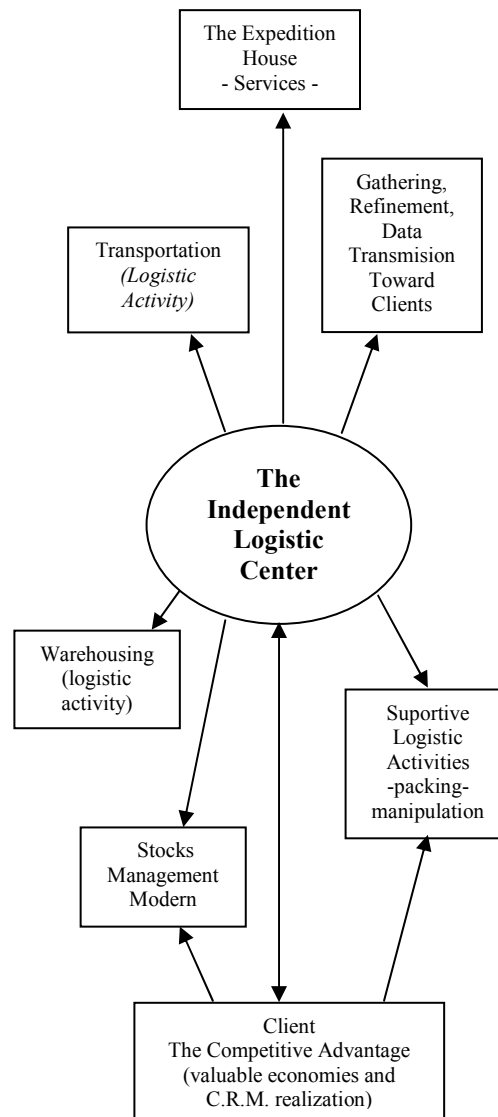

Through the implementation of the data processing and communication technologies, logistic centres become essential parts of companies' geographical concentrations which, if associated, can generate competitive advantage.

Logistic centres meet the implementing conditions of the informational system based on connectivity from the production place to the consumption place, which ensures a rapid flow of information necessary to decisions on sending out orders, thorough analyses of data for a qualitative management, able to bring enhanced value and generate a positive reaction from the customer or end-user.

Changes within Distribution System for Goods

Dan Gheorghe

“Ovidius” University of Constantza
secretariat@traian-sa.com

Abstract

Researches into the field of goods logistics and distribution have constantly held the attention of specialists, practitioners, marketers, as well as of the scientific and professional investigations. Although the basic notions regarding this field of goods exchange are conceptualized and theoretical, because of the technological innovations, the changes in consumer behaviour and the movements generated by the economic context, the premises of checking, matching concepts, redefining processes and activities which characterize the field analyzed in the current study are created.

Besides the presented aspect, this theme also provides a careful documentation of these changes which account for a new theoretical approach of the actual contents of goods logistics and distribution.

Key words: distribution systems, global brands, chains of international hyper and supermarkets, merchandising, self-checkout system.

JEL classification: L81

1. Introduction

The paper seeks to reflect the changes in the distribution system under the influence of the economic structural fluctuations, towards the access to the functional market economy, the European political and economic structures, but also as a result of the process of globalization of this economic activity.

From the perspective of this approach, one can forecast the future development of the goods logistic and distribution systems, the power changes in marketing channels, as well as the

new technologies used in this activity. Through its endeavour, the paper examines the current prevailing changes which serve as a base for training the future specialists, marketers and students in the educational and practical process. The paper intends to offer an updating of the concepts existent in the goods distribution theory, given the growth and technology of the specific processes and activities which do not waive the meaning of well-known terms.

2. Significant changes in marketing channels

The required steps made in order to enter and integrate within economical structures, where the most important principle is the free market economy, will generate the deployment and application of all the instruments, processes and most of all the functional principals of this developed economy.

The integration will be made within a certain period of time, in which will be valued all the opportunities, the favorable economical activity, in parallel with the development of the existing mechanism, reorganization and acceptance of those economical structures and activities that will allow the fulfillment of the functionality of the economical processes on the free market.

Based on this statement also the distribution of goods will know significant changes, that will be overtaken as results of the presented data and of the economical changes.

In the present the population structure with good material resources do not exceed 5%, which can afford a consumption related to the medium level or to the elite class of the developed economies [1]. Will still persist on a larger population segments, a higher weight of the primary consumption and for it's buying ,they will use the little shops, simple, traditional

merchandise structures without using the modern merchandise structures (hypermarkets), where the risk of higher spending is already known.

Tendency of material goods, which are making the distribution object. In parallel with the maintaining of a higher trend of the spending on primarily goods and with the current requests will be remarked the expansion tendency of global brand buying [2]. On the global level there are 43 brands registering with seals greater than 1 mld. \$ (GILLETTE, DURACELL, PANTENE, NIVEA, COLGATE, KODAK, TIDE, etc.) including also the food brands, produced by 23 global Producers. All these products are present within the local distribution.

All the 43 brands are registering sales on the global level of 125 mld. USD, and three quarters of the total amount is related to 8 producers, from which 7 are located in Europe.

Based on consumer modernization and on digital technology boom, which has brought on the market many new products that compete on the same price level, will determine from the distributor side a higher attention on the merchandise processes, that will have as a result the selling growth.

From the consumer modernization tendencies will remain forward the higher innovation grad of the products that will include the material, primary goods and also those which requires modern technologies.

These tendencies are reflecting the restructuring of the consumer demand on some population segments with a specific edge, most of all on the younger, socio-professional segment with a higher educational level.

Free competition on the internal markets, between different distribution systems and channels, countries with developed free markets having characteristics as: price competition, the development of own distribution channels with higher merchandise capacity (Hypermarket) based on a fast and developed technology have conduct to internal market satiation and the premises of expansion on the international and global markets.

Based on the growing trend of the markets within East Europe, sustained also by the demographic factors and the Integration in the European Union will generate the expansion of

the globalization of the distribution system in Romania, where all the multinational and international corporations will take part.

In our country we will assist on the concentration of the existing, conventional distribution structures and of their related marketing channels, from point of view of their capacities, localization, and using the financial deposits or credits, in order to be able to compete with the strong competition, which was caused by the release and development of the international supermarkets. These will generate, through the launched distribution systems, major changes within the distribution processes and on the selling goods.

Great projects within this domain have been registered through opening of commercial shops (en gross), utilizing, most of all warehouses, belong to other companies, who have been developed them, through internal resources.

As a great impact tendency in our days as for the future is the incoming of international hypermarkets: METRO, SELGROS, BILLA, KAUFLAND, MALL, CARREFOUR, GIMA, MEGA IMAGE, PROFI, XXL etc. The reason are the internal resources, which are impossible to be bound and developed in order to be able to fulfill such commercial structures that are conducting to distribution channels on internal level.

The incoming of international distributors was generated from the lack of opportunities and development on the internal market, registering a high level of concentration, maturity and restrictive legislation and from the higher operational costs. On the other side, in our country, these structures have been found a less developed distribution, economical liberalization and privatization, permissive economical legislation, low operational costs and a tendency of a higher consumption increase.

The mode of entering in our market was though organic development, meaning building of Hypermarkets: CARREFOUR, SELGROS, METRO or though stocks buying from commercial structures as supermarkets: MEGA IMGE, XXL.

Every company Hyper or Supermarkets have had different strategy of entering on the Romanian market, concentrating on building and opening of Hypermarkets near the big cities, or within province.

The incoming of Super- and Hypermarkets within the distribution system have been brought many changes for the distribution concepts. The first characteristic is the bigger and various number of products “ everything under the same roof“.

Beside this variety of products is seen also the various prices of them, which could cover the requests of different level of consumers, under the condition of retaining the same level of quality/price.

It have been developed new methods of merchandising for the traditional products (electronics, house hold appliances) and also for the selling campaigns has been implementing the improved merchandising for the innovating products (computers, office products and music articles).

Through the shops system implemented by all the Hypermarkets there are brought on the market a larger products and services category:

- Financial and banking services offered by the bank subsidiaries, located within the Hypermarket area, sustained from the partnerships between financial institutions and Hypermarkets and using the Smart card operations, which will change the ATM function, from the cash supplier to the one of helping the client to proceed, directly all his payments to the supplier (Hypermarket), based on the POS system. The implementation of the POS system, containing cards with chip microprocessors will allow a larger data base and faster and safety transactions.
- Another characteristic of the acquisition system is that internal suppliers are obligated to accept the distribution system developed by the Hypermarkets, with other discounts and delivery terms, in order to be able to build longer partnerships with this, helping them, forward to be more competitive on their market segment.
- The total distribution transformation though implementation of a centralized procurement department of the Hypermarket/ Supermarket on the national level. This procurements center will modify the traditional distribution channels, through his impact on the based and additional distributions activities and their management,

assuring the competition advantage from the other distribution channels of goods.

- The implementation of the self-checkout system [3], POS, used by the buyer to scan all the brought products, that will reduce the waiting time on the cash registers, and also avoiding the unsatisfied clients. The innovation of technology has create some dispositive with small dimensions, that allow the self-checkout system, through it's utilization, directly from the client, scanning all the chosen products and after receiving from the Shopper Personal, the payment receipt and finalizing the transaction on an U-Scan, where the smart-card can be shown.
- The implementation of the advanced construction technologies is conducting to the building of eco shops on the internet [4], where the lightening system is natural and the system of photo sensors measures the level of the natural lighting, which come and adjusts the artificial lightening and has as a result the minimum consumption of the electrical charges. The Use of the passive ventilation, generated by the shop building is cutting out the air conditional, with higher energy consumption and the energy generated by the wind turbine and by the sun panel is used for lightening. In the same time it is using a recycling chain of the through fall and residual water, which are used forward for green field irrigations.

All these news are using a benefit atmosphere offering to all clients a comfort sensation.

Another tendency of the distribution system is teleshopping.

Teleshopping as a word definition is the direct presentation activity of the sales products through telephone or television. It contains two aspects: first- product publicity with direct response on the telephone and the second one – distribution channel until at the client house.

Franchise system is a new tendency within the distribution system development, where the one who takes the franchise receive from the bigger companies (entities who sell the franchise) the right to operate under the same commercial marks and are using the same merchandise processes on an agreed period of time. The franchiser will receive from the supplier marketing and publicity materials. Based on this

it have arise shops as BODY SHOP, MC DONALD’S, PIZZA HUT, etc.

3. Hyper and Supermarkets on the Romanian market.

On the background of the recession period, on the global level characteristic through stock exchange decrease, the lower interest rates, higher unemployment rates, for the first time, after 1982, the World Bank is announcing that the bigger economies USA, Japan and European Union are going, in the same time, under recession. The same recession has affected dramatically the consumption.

While the economical forecast are pessimistic the demographic data is optimistic because until 2010 the number of the consumers will grow at 700 million people. The most important concern is the grow of the old segment of population, which will spend more on medicines and on all the related health services [5].

Despite on the negative economical situation, the global traders have been respond immediately on all the consumer changes through new shop types, a diversified product range and a diversity of services offered to the consumers, from interest offers to internet services.

The consumers are expecting to order a product by telephone or by internet with the possibility to return it if this is not compliant with them expectations.

In the last period of time we can encounter, in many times ,the incompetency of the small traders to honor the market requests, thing that will bring to higher bankruptcy rates and in the mean time the larges distribution channels are developing through new shops openings helping the globalization process.

Also the technology innovations, that the most important companies have been implemented successfully have generated cheaper globalization efforts , a higher efficiency and the entire distribution channel with all it’s new merchandising processes more efficient.

After all these, it have been remarked the Discounters (shops) especially in this economical situation, where are assured to the

consumers, prices, generated by the economical grow.

In our country the development rate of the Super- and Hypermarkets was higher, based on, in some cities it have been registered a 20 m area / resident. In the present this rhythm is slower, but it will be forecasted for the year 2009 a market share of 35,7% from the total sales volumes (28 mild. EUR).

For an example in 2009 in Romania there are registered the following distribution channels [6]:

“Table 1. Network super and hypermarkets as total sales area “

Loc.	Distribution channel	Total area (qm.)	Variation area in comparison with 2008 %
1.	Kaufland-Hypermarket	220.653	12,57
2.	Selgros-Cash&Carry	170.000	4,71
3.	Carrefour-Hypermarket	162.500	4,31
4.	Real-Hypermarket	138.494	21.32
5.	Metro-Cash& Carry	162.976	0,00
6.	Plus-Discount	78.020	29,92
7.	Penny and XXL-Discount	63.050	33,31
8.	Auchan-Hypermarket	63.000	16,67
9.	Billa - Supermarket	47.800	14,15
10.	Cora-Hypermarket	39.000	0,00
11.	Profi – Discount	24.301	47,94
12.	Mega Image-Supermarket	25.628	24,40
13.	Interex-Supermarket	25.965	14,64
14.	MiniMAX-Discount	20.000	41,34
15.	Carrefour-Supermarket	17.042	37,14
16.	Unicarm-Supermarket	16.700	0,00
17.	Trident – Supermarket	17.100	-5,85
18.	PIC - Hypermarket	42.500	-70,59
19.	Fidelio-Supermarket	16.600	-25,90
20.	G’Market - Supermarket	10.962	0,00
21.	Trei G-Supermarket	8.570	0,00

22.	Spar-Supermarket	20.758	-59,13
23.	Primavara-Supermarket	8.650	-19,65
24.	Annabella - Supermarket	6.550	-1,50
25.	Ethos - Supermarket	11.940	-49,33

“Table 2. The market shares of the largest 25 retailers based on their turn over in 2008”

Loc.	Channel	Turn over 2008 (mil.EUR)	Market share 2008 %
1.	Metro	6.014	7,66
2.	Carrefour	3.800	4,84
3.	Selgros	3.162	4,03
4.	Kaufland	2.865	3,65
5.	Real	2.643	3,37
6.	Cora	1.469	1,87
7.	Penny	1.257	1,60
8.	Billa	1.192	1,57
9.	Auchan	1.025	1,31
10.	Plus	1.021	1,30
11.	Mega Image	486	0,62
12.	Profi	441	0,56
13.	Pic	412	0,53
14.	Carrefour-Expres/market	385	0,49
15.	Interex	353	0,45
16.	Trident	202	0,26
17.	G'market	193	0,25
18.	Primavara	179	0,23
19.	Spar	166	0,21
20.	Minimax	159	0,20
21.	Oncos	149	0,19
22.	Angst	144	0,18
23.	Ethos	123	0,16
24.	Fidelio	93	0,12
25.	Trei G	76	0,10
	Total Top 25	28.009	35,70
	Total Romania	78.469	100

The strategies of the modern retailers, based on their marketing techniques have been benefit on a higher notoriety level. The satisfaction level of the buyers was determined by their experience and also by the influence of their family, friends etc.

The opinion of the Holian Riccardo Petrella is that the power will be own of an alliance between retailers on a global level and governments of some cities will support, economically those retailers that are within [7].

As an negative aspect that I would like to highlight is the global standardization of the commercial centers, entities, that will be excluded by the biggest retailers and will bring to a homogeny image, in which no

characteristic of the local culture and historical tradition of this entity will be present.

4. Conclusions

Firstly, the paper emphasizes the basic changes in goods logistic and distribution systems, the impact of hyper and supermarkets chains that will be of great importance within the marketing and logistic channels.

Secondly, the impact of high technologies on serving the customers, along with these modern distribution chains, have triggered essential changes in customers' buying behaviour, even in those with an income below average.

In addition, the recorded changes have created a modern management concept of the logistic chain, especially the one attached to these hyper and supermarkets chains, which envisage an overall cost able to bring a positive reaction from the consumer.

However, one should not neglect that, in the course of the distribution activity development through international chains, these create a standardized image of these activities and eliminate the traditional historic urbanism of commercial centres.

Establishing the Connection Between Wage and Economic Activity of the Organization

Greco Gheorghe
A.S.E. Bucharest
elianro@yahoo.com

Manolescu Aurel
A.S.E. Bucharest
aurel_manolescu@yahoo.com

Abstract

The targets of the company or institution must be in accordance with the restrictions imposed to the employees (economic, technological, institutional type). The wage system must be designed and chosen with both parties collaboration – employers and employees (their representatives).

Key words: wage system, performance wages, individual performance wage system, employee, collective performance wage system

JEL classification: M19

1. Introduction

Any wage system must be adaptable to the concrete context in order to recruit necessary personnel, to encourage great efforts, to generate loyalty, desire of changing and innovation. The targets of the company or institution must be in accordance with the restrictions imposed to the employees (economic, technological, institutional type).

The wage system must be designed and chosen with both parties collaboration – employers and employees (their representatives). The same condition is imposed to the reexamination of a wage system. In order to have the best system it is essential to create a simple and transparent implementation, combining both parties' interests in an equitable spirit.

2. Recommendations for the implementation of the time-based wage system

Time-based wage system must be applied when we deal with a small, non repetitive manufacture that doesn't justify a study time. This study could be long and based on a disproportionate wage to the desired result. Therefore it could be imprecise and with many errors. If a fragile system based on results is implemented, there will be a risk of affecting the employee and company's interests.

However it is useless to make an approximate assessment of the execution time regarding similar manufactures or using the assistance of a professional executant. Thereby the personnel performance can be controlled ensuring a fixed hourly wage.

We recommend combining this time-based wage system with an hourly special bonus according to a series of criteria.

We also suggest the use of the method known as "individual monetary contribution", which gives excellent results regarding this type of works that use timework.

3. Recommendations for the implementation of the performance wage system (in agreement)

The expression "performance wages" refers to the wage systems where at least a fraction of the employee's income differs directly depending on the performance changes, measured according to some preset rules.

Depending on each individual's features, the wage systems can have different targets. These purposes must be strictly formulated according to the performance's aspects which are considered the most important ones for the organization efficiency. For example the systems designed to bring manufacture to a high level can make more difficult the promotion of a behavior favorable to innovation and collaboration or can modify a healthy policy of professional relationships.

The performance measurements used in performance wage systems must be also global because employees are often more preoccupied by the measured and remunerated aspects of performance. In a parallel way the measured performance must be directly controlled by the employee himself.

3.1. Recommendations for the implementation of the individual performance wage systems

As we already know the advantages of individual performance wage systems are the following: increasing productivity, reducing global cost of the manufacture and raising the employees' salary; reducing surveillance budgets; a higher level of freedom for the employees regarding the work system and the earning opportunities; the possibility of a more precise assessment of unitary costs for labor force manufacture.

Nevertheless experience shows us that these advantages can be partially or totally cancelled by some problems such as:

- Increasing health affecting and security risk as a consequence of accelerated work rhythm or instigation to back away from the preset work methods
- Difficulty in preserving quality regulations and avoiding an uncontrolled wage increase beyond the negotiated decisions of wages adjustment;
- Management costs of the organization can become high in regard to the expected manufacture improvement;
- Manufacture processes complexity;
- Negative effects upon motivation and conflicts as a consequence of unpredictable oscillations of income, differentiated income or effort provided by different employees and competition categories;

- Manufacture restriction by employees that are afraid of their income increase, which might entail an increase of manufacture rules or a decrease of basic salaries raising rates;
- Persistence of employees to work methods changes, their transfer to new jobs or temporary redistribution in case of an income decrease;

It is be recommended for individual performance wage systems to be simple so that the employee can simply verify his income, and capable to lead to a significant income increase and based on an equitable hourly rate structure and precise rules which entail major bonuses for fatigue, personal needs and other known factors of good practices for work measurement.

The most used wage systems are called "**proportional**" because beyond the guaranteed time-based wage rate, the income differs directly in relation to manufacture. Giving the fact that employees do not experience any difficulty in understanding these systems, because they represent a strong performance stimulant and employees consider them equitable and easily accept them, they can think first of all, of adopting these systems. There will be no examination of other wage methods only if special circumstances require their implementation. Especially, the so-called "**fixed**" or "**regressive**" systems where income will increase less than manufacture are not generally recommended only if starting performances are considered quite weak, if there are frequent work interruptions, if it is difficult to establish and preserve specific manufacture rules or if too high performance achievement can be harmful.

Generally, employees' performance must be measured and remunerated after a very short period of time, in order to set up a direct connection between effort and income. However, if work entails very long cycles, where it is difficult to measure or there are frequent strikes, it must be used a longer period of time for performance measurement **in order to reduce income oscillations.**

We suggest that employees should benefit from protection against unpredictable income oscillations with the help of a **time-based wage guarantee**. As far as possible this guarantee for time-based rates must operate

for a reasonable period of time to ensure that the bonuses achieved for a certain period are not lost as a consequence of a later decrease of the manufacture level.

Likewise we recommend that the variable part of the income be quite important in order to encourage employees to a better performance, but not as important as the moment when its variation is generated by independent causes. When all the conditions for the successful individual performance wage system implementation are not fulfilled, the variable fragmentation of wage system must be reduced in order to ensure that individual performance wage system continues to be accepted and to avoid its erosion.

It would be useful to previously set up an average sum of the bonus because a system is designed to produce, serve as an indicator of the way in which the system operates. It would be recommended that the guarantee for wage in case of work interruptions caused by causes independent of employees will, be the time-based wage system.

To ensure that rules will not enforce only because wages are too big, rules rectifications must not be operated with the exception when both parties have agreed upon these changes of content regarding work places or manufacture methods, or correction of computer materials' errors, or when there is an agreement from the employees and their representatives.

The rules for work studies development must be previously established and if possible, in agreement. Dissimulated studies should be forbidden and employees and their representatives should be informed before the development of these studies. Employees must have the opportunity of contesting new rules thanks to an appeal mechanism whose target should be to facilitate a fast settlement of disputes.

In case of appeal, there must be provided all relevant information according to the way in which the rules have been set up and if necessary to reexamine previous studies. Employees' representatives' participation in the process of setting up the rules must be preceded by a method of collective conventions. Such participation can be: collaboration for work studies development; a meeting regarding the persons responsible for time keeping, or negotiations on introducing new rules or

participation of reexamination organizations which are announced by appeals.

Adequate measurements must be previously set up between management and employees, in favor of the employees that can lose their job as a consequence of the system implementation. These measurements can be applied only if there is a specific agreement in this matter which includes as a priority jobs transfers – if they exist or are being justified by the economic situation of the company – or severance pay (layoff). The application methods must be carefully explained to all affected employees. It can be elaborated a document, usually distributed to the employees and their representatives, which presents the system principles, applicable employees, wages guarantees and other guarantees, as well as all the facts that refer to the system implementation.

Unitary wage system shall be used only in the case of wide manufactories, very stabilized, that entail only a minimum risk in their development.

A measured study or using standards is feasible only in the above hipotesis. It allows a precise method of establishing the manufacture processes and the correspondant execution time.

This type of wage will meet the expectations in repetitive manufactories with a relatively short cycle (a few hour centimes). The operation methods must be precisely designed at the beginning of the series and the personnel must be perfectly informed through a special record. Therefore, before the beginning of the series, the personnel must be advised regarding any modification of the manufacture process that will need a new time study. So, any improvement of the operations cycle can be translated into a significant time profit, which will have as effect the increase of real and paid activity.

The employee's work will also increase through the "habit effect" if the series is quite important. This revision clause is actually hard to apply. As a consequence of daily improvements, in a rough manner, a simple comparison on a long period of time allows the measurement of achieved results without any real rectifications of the manufacture conditions. This phenomenon,

well known by the method offices, is called “aging times”.

If determining time is not possible in a precise manner for the manufacture in development, there must be implemented a slow wage system Towne – Halsey.

This system’s target is to be less brutal than unitary wage system, when executant’s activity goes below 1. In case of errors in manufacture time determination the executants will be remunerated at a higher rate than the one that he would have received in unitary wage system.

So, this system allows partially reducing time errors without a great impact on the employee. However, it entails an application difficulty when the executant’s activity goes beyond 1, either as a consequence of error by excess in manufacture time determination, or consequence of the employee’s habit. In these conditions the hourly wage is inferior to unitary wage (with equal activity) and the employees want unitary wages.

This type of wage system is used when execution time can not be determined with a high precision of almost $\pm 5\%$ (10% absolute value). It is currently applied in remuneration of boarding works where the guarantee for the lifted material strongly differs from one piece to the other and the allocated time can only be an average, determined on a quite important series.

The Rowan salary will be the best when the execution time runs the risk of differing in great proportions because of the unpredictable risks (especially maintenance works). The curve shape shows that the maximum hourly income reaches two times the basic salary s_0 when the activity is “infinite”. Financial consequences of an error are limited for the company. This aspect of the Rowan system allowed mean interpretations in its implementation. It was frequently said that “Time determination has no importance because the system forgives errors”. Allocated time has revealed the greatest fantasy which has contributed to discreditation of this wage system in some companies, which gives good results if it is correctly implemented.

However, time assessment must be quite large in order to ensure no injury of the employee.

When manufacture is organized in a perfectly rational manner, without any risk (assembly or band convention) there could be used a Gantt salary that will ensure a great regularity in manufacture. Therefore, when the rule is

followed the employee has no longer interest in increasing his manufacture rhythm and sets up a stable balanced pattern.

In certain “band” manufactories, where the rhythm is independent of the executants, it can be reused an hourly wage system because it is possible to control the manufacture at any moment, which will be placed in a preset system.

In all cases the responsible personnel must have all information regarding implementation and assessment methods, in a very complete manner. It will have to understand the mechanisms and the philosophy of the adopted wage system.

The supervisors (organization personnel) will be entitled to settle problems and to give explanatory answers from the personnel or their representatives.

All wage problems will be managed with great honesty and further information will never be refused.

Annual meetings will be necessary in order to inform responsible personnel regarding the context and rectifications of the interpretation errors that might have happened.

3.2. Collective performance wage systems (or workteam systems)

The major advantage of collective performance wage system in comparison with the individual performance wage system is that it remunerates **collaboration behavior between team members**.

These systems must encourage employees to reduce dead times and abusive absences, to help their colleagues to eliminate narrow places and late work, to supervise more carefully manufacture quality, which will pass to other team members, to adapt when there are manufacture changes, to have more flexible teams that can accept work methods rectifications or allocation changes. Collective remuneration can also improve work organization being less sensitive to imply health or security risks. It can easier be avoided erosion processes of the system, as well as salaries deviation and income disputes are reduced so that incomes become more stable and uniform for group members, and rules become easier to control. Administrative costs decrease because

establishing rules is easier, accounting is more simple, surveillance cost decreases because there are less quality control points and wage system management requires less time.

Finally, team members will facilitate information and training of the new members in their team.

The main problem of collective performance wage system is that the less strong support between individual salary and performance runs the risk of involving a relaxation of the effort compared with individual system. Conflicts can appear in a group if the members with the best performance start thinking that not all team members are entirely providing their efforts.

Collective remuneration applies to cases when work places are interdependent, either because they represent a series of operations in their band work, or an additional effect is necessary in order to ensure a good performance. This remuneration is indicated also in the case of groups that have a great influence on their members and promote equal opportunities in earnings.

The stronger teams are through **social affinity, qualification level, work closeness and interest community**, the more favorable position they will have regarding collective wage system. Collective performance wage system should also be used when wage measurement for individual manufacture is not possible at a high precision; when it is important to include in the system work aspects that are capable of being measured only at group level; when because of frequent rectifications in manufacture or work processes it is encouraged a flexible and adapted behavior, there must be seen a change to group manufacture methods or when an individual system runs the risk of causing numerous disputes which break the work rhythm.

Although the most part of the design, introduction and administration aspects are common to individual performance wage systems and collective performance wage systems, there are also **some specific problems**:

- if things are equal (*ceteris paribus*) it is better to maintain the size of group as small as possible so that the relation between effort and results be the most direct one.
- groups must be relatively homogeneous in terms of performance and with a strong connection between the job nature and human relationships ;

- group must be stable in an equal manner because new members will normally have in time an inferior performance compared to the experienced members (if necessary adequate dispositions must be applied to new members, young or old employees in order to reduce at minimum the effects on group's income);
- whatever the chosen method is for bonuses' distribution, the group members' incomes must be elaborated according to their aspects regarding individual contribution to collective results.

3.3. Department or company performance wage system

Relying on performance measurement in its wide meaning, these systems are designed to form a better connection between objective principles of the company and employees' expectations, as well as a more efficient collaboration between different employees' categories or functional units of the company. In fact we refer to promoting behaviors that entail innovation, adaptation skills and collaboration spirit in order to use, in a more efficient manner, the company's resources. Employees are encouraged to suggest rectifications that generate economies, collaboration team for a better knowledge distribution, to help each other if there is necessary and to easily accept flexibility in tasks' distribution, as well as technological and organizational changes. Employees must prove themselves less tolerant regarding planification lacks, cash increase, dead times, manufacture delays and low quality work. Consolidating collective behavior and more frequent opportunities to participate in company's businesses are changing the state of mind and improving work satisfaction. Other practical advantages are: access to global performance measurement, a faster start-up, an administration cost less higher and a relatively easy control.

The main problem is that there can be emphasized only a **distant relationship** between the employee's effort and the bonus. Furthermore, performance measurement is difficult to understand and also very often a

subject of great variation because they are independent of the employees and management's will.

Company or department systems should give the best results in the following cases:

- when the accountant unit is small enough so that the management and employees defend the contract, defining an adequate performance measurement not become too complex and employees can observe that there is a certain connection between achieved progress and the received bonus;
- when each individual is convinced that the company's success is related to a continuous adaptation, workteam and collaboration spirit and the possibility of increasing productivity and reducing costs will not fastly reduce in time;
- when performance measurement can be simply defined, easily and frequently assessed, in a strong dependence with the employees effort;
- when manufacture nature and methods are quite stable so that there isn't necessary to frequently negotiate performance rules;
- when management is capable of ensuring efficient communications, receptive to employees new ideas and available to allocate necessary time to the system implementation;
- when employees have a real technical competence and are willing to participate in decisions, and are long-term attached to the company;
- when there is a great confidence in the company and when labor unions are supporting the systems and don't think that they are threatening their right of defending the members' interests by collective negotiation.

Systems of this type best operates when they are accompanied by a participation programme which promotes:

- translation of practical suggestions that have an agreement of methods or manufacture processes' rectifications.
- both ways communication at all levels regarding operation difficulties and general trends of the economy;
- direct participation of employees in implementation procedures of wage systems in order that they can be sure that performance bonuses are equitably established.

4. Conclusion

All in all, even having complete knowledge of the issue there is difficult to choose the wage system.

That system which was satisfactory in a company will not be suitable for another one because implementation conditions and circumstances are never the same.

Abstract

The interdependence between wage system and employees implication-participation in work generated and it continues to permanently generate a preoccupation of managers of all improvement levels of wage methods, wages set up and differentiation criteria. To elaborate or project an adequate wage system it is necessary to take into account: the market for which the company works, technology and manufacture factors that is using, labor market context and socio-cultural environment.

Key words: wage system, ergonomy, performance, employee, wage level

JEL classification: M19

1. Introduction

Wage systems implemented in organizations as well as the efficient use of their human resources are delicate aspects always under the attention of everyone (both employers and employees). If we are to see what is happening nowadays in the budgetary system, where they are trying the elaboration and implementation of a unique wage system, we shall observe that things are not quite easy to resolve. This debated aspect creates tension between employees from different fields of the budgetary system, which manifests through frequent protests of the labor unions, unbalancing more the state budget. In private organizations problems are the same: results not quite good of the organization determine small salaries which have as consequence the lack of motivation, increase of personnel oscillation, work collective conflicts. The interdependence between wage system and employees implication-participation in work generated and it continues to permanently

generate a preoccupation of managers of all improvement levels of wage methods, wages set up and differentiation criteria.

In organizations' life ergonomy has a central place having an important role in their improvement process. This fact determined specialists [1] to say that in the current context it is necessary to integrate ergonomy in the business strategy.

Organizational reality imposes the development of a convergence between manufacture criteria, efficacy, security and health [2].

Under their technical aspect (with their own mechanisms) remunerations often don't give the desired results if the personnel's reactions are not taken into account. So it is necessary to have in mind the man's adaptation at work, a suitable work for the man as well as adjusting the man to the company where he works and of course to the team members where he is working.

2. Man's adaptation at his work

In the human values system appeared a series of changes which show their interest and preoccupations for the life quality, in general, and their professional life, in particular. In this context it was important to create new strategies regarding jobs design, especially to improve individual and organizational performance. A major issue in the design of jobs becomes the quality of work conditions.

Adjusting the man to his work, giving the job that is suitable for him – this is the problem. Discontent appears not because of work monotony, but because of the employee's failure to adapt, who has the feeling and reaction of a deported man.

Because the employee of mass manufacture is working only in one stage he must find satisfaction in that particular stage. The organizational error was making the man to wear the efforts of accelerating work rhythms of unadapted employees, instead of noticing this failure to adapt.

3. Suitable work for the man

The work division in simple elements is the most productive, but the separation of these elements between different employees is not compatible with the human psychology and physiology.

This specialization of repetitive movements is not the most satisfactory solution for the problem of rational and human usage of man's work.

Work is well divided in several basic operations, but each employee must carry out more than only one. For the surprise of technicians this led to a manufacture increase. Furthermore, teams can work harmoniously without a tense, nervous atmosphere as it is usually on bands.

Taylor and Gantt have taught us to divide work in operations, then operations in basic movements. But we must understand to regroup these movements in operations that satisfy not only the basic movements' technique but also the man's ability and his psychological and physiological needs to fulfill coordinate operations.

4. Adjusting the man to the company and to other team members where he is working

Employees indicate "good fellowship" or "good relationships with other work colleagues" as cause of their work satisfaction.

The error does not refer only to manage the technical problem of man in manufacture, like the one of a machine or instrument, but to the incapacity of understanding the profound nature of mass manufacture where "human efforts integrate".

Analisis and work division in manufacture rates are not wrong, they are even indispensable to mass manufacture, but this must not be made with "the price of human or company social desintegration".

The employee has a desire of integration but without an effort from the outside, he can not identify himself with work, product and company. The company's management must resolve this integration.

A wage system is not successful if it doesn't meet a number of the personnel's moral and material needs.

It has frequently been said that abandoning the performance wage system brings a significant decrease of the execution performance.

High qualified personnel have been and it will always be conviced that performance remuneration will not reduce work performance.

Tendency for time-based work is determined by higher security of the work place and salary that are not subject to circumstantial oscillations of different types of performance wage system. From this point of view also the great labor unions have supported a higher security of employment, salary, social measures in case of accidents and decays, better retirement conditions, etc.

Bosses have seen performance not only as a manufacture profit but also as a series of disadvantages which they have not yet mentioned:

- fixed times in elaborating wages are often fake;
- instantenous control shows that medium performance is weak and not as it is believed to be
- high stocks between operations because the number of positions is big and with no balance between them;
- high percent of wastes and even rubbish
- unbalances between workshops and stocks
- performance bonuses for employees in agreement are a disadvantage and are affecting the most qualified, creative, innovative employees who support the development and repairs of the machines, because they are time-based remunerated.
- it makes difficult (impossible) to move the employees between workshops and work places ;

The abstract of solutions entails the following fields:

- better work organization and liberating supervisors of administrative tasks;
- decrease of waste dimensions;
- selection of best employees;
- multipurpose training of the employees;
- intelligent control of the employees' activity;
- promoting new operational models;
- equitable remuneration.

Summarizing, solutions are linked to psychological and technical aspects, building homogenous workteams with professional skill and responsibilities, informed upon the company's status and with knowledge regarding several workshops of the company; teams will eliminate redundant personnel without replacing the vacant positions; forming a hierarchy of team employees.

Work standardization must not be the only criterion for personnel remuneration. Work has and must use different parameters such as: manufacture quality, multipurposes, collaboration, formulating technical or organizational suggestions etc.

Before changing any wage system there must be carried out a complete study regarding general operating conditions of the company. A problem can not be well resolved without knowing and simultaneously dealing with the other ones. The implemented wage systems must integrate in a harmonious assembly and must translate (reflect) the profound reality of manufacture processes.

Romanian societies are generally facing a series of problems regarding the inefficient use of human resources and unsatisfactory ways of employees' motivation (encouragement). The major part of personnel is unsatisfied with their salary, while the organizations where they work are facing serious problems related to productivity and performance. It is practically a vicious circle from which one can escape only by thinking again the way in which positions are elaborated and remunerated nowadays and it is necessary a wise correlation between advanced expenses and achieved effects. The fact that managers maintain smaller salaries than the market level only deprives the company of good employees and of additional profit that they could bring. Furthermore, sometimes the lack of productivity and employees' level lead to an increase of employees number, meaning the

situation where instead of a good employee there are two weaker.

A good wage system should operate according to some conditions:

- to be well structured so that each position of the organizational chart correspond to a wage level suited to the work market level for that specific qualification and fitted in the budget; the structure avoids the trap of discrimination and negotiation.
- to be stimulating, i.e. informed and understood as based on a correct assessment system and objectively and predictably related to performance.
- to have enough resources so that it can hire the best specialists and any rectification must be analyzed according to the budget.
- to include protection mechanisms for the company and individual and suited to the economic environment and legislation.
- to be implemented in accordance with the policy of other benefits at managers initiative responding to employees requests. Some managers prefer giving bonuses instead of permanently increase the income, considering that this way people are more motivated and fitting in the monthly budget is easier to achieve.

Salary is seen as a right meanwhile bonus depending on the performance. Generally they are right, but particularly they must be aware of the following:

- employees tend to judge the bonus as a right and they start to have higher expectations;
- salary confidentiality is respected but for the bonus rarely;
- employees hardly support payment conditioned by the boss's gentleness who gives bonuses, by additional hours or independent criteria (such as season sales which leaves them with no money for holidays) and see the system as a useful trick only for the company in order to avoid taxes (which is no longer so true)
- bonus conditioning makes the employees become more and more aware of the extrinsic motivation rather than the intrinsic one.

5. Conclusion

There are managers and bosses that prefer all salaries with a fixed part and a variable one according to the company's performances. Company's achievements generally depend more on work organization and management rather than each employee. Therefore, the system can operate for management but not for employees. Any wage system which is hard to communicate, influence or check by the employees is not motivating.

We can say that there is no good wage system, this can be good or bad according to the way in which it is used. Actually, a good remuneration entails a good organization.

Abstract

The paper carries out a short literature review on public sector and public marketing terms. The findings of the paper's study shows that the Romanian public sector should give more importance to marketing activities, as 87% of the respondents sustained when asked about their necessity. Within a public institution, the marketing specialists should cooperate with research & development, sales and financial departments. The study results reaffirm the importance of the 4 P of the marketing mix when making an offer, and place them on the top positions.

Key words: public marketing, public administration, survey

JEL classification: H80, M 31

1. Introduction

The paper presents approaches considering the public sector, aspects on public marketing, the marketing necessity in Romanian public sector, the importance of cooperation between marketing specialists and other departments inside a Romanian public institution, the marketing components when making an offer and conclusions. A short literature review and a structured evaluation of current knowledge on public marketing are carried out. The paper includes an analysis that seeks to highlight the necessity, the collaboration and the mix of the public marketing obtained through a survey

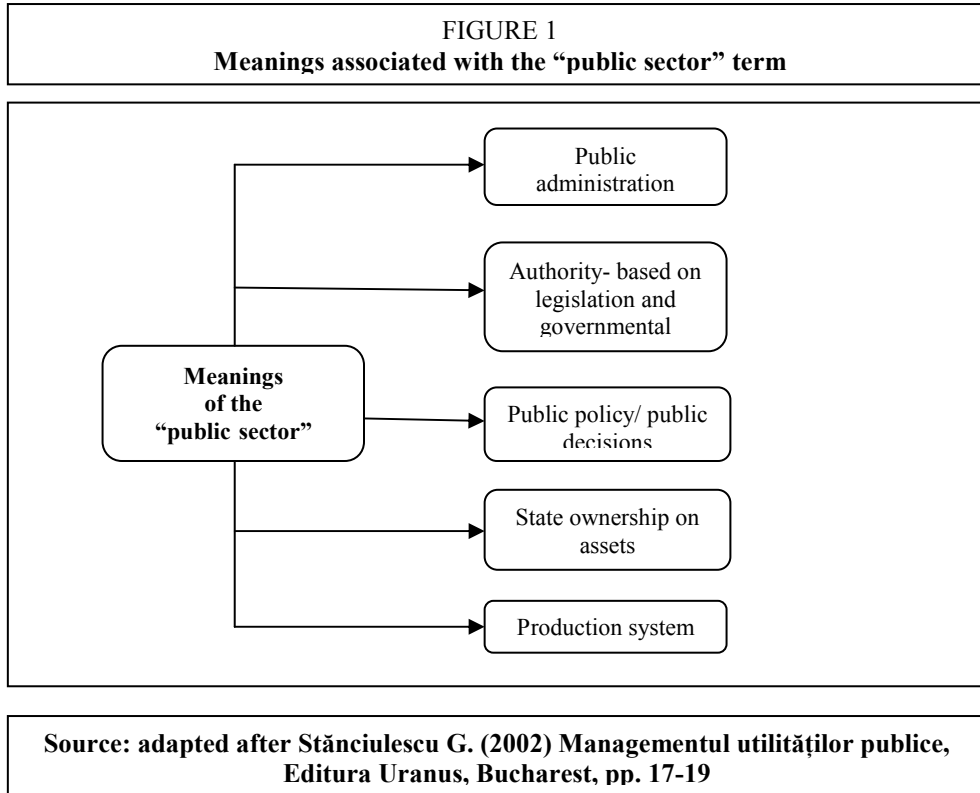

(processing 384 questionnaires) applied to employees from Romanian central and local public administration.

2. Approaches of public sector

The public sector is the allocation system managed by the state, which influences the economy in general, through regulations, controlling of revenue by collecting and redistributing it. The purpose of the public sector is to ensure fairness and social equity for all the citizens at different levels (local, national, European).

There are numerous ways of explaining the term of "public sector" and also different perspectives on it. (figure 1) The public sector should be seen beyond the financial approach, which implies budget expenditure and revenues in relationship with the private sector, by detailing the functional mechanisms and its outcomes, according to the established purposes.

The most used meaning of the "public sector" is public administration, which is associated with governmental activities, through which the budget funds are allocated for consumption, investment and income transfers. As authority, the public sector includes the characteristics of public administration, being more than the budgetary allocation and is focused on legislation and governmental power. This posture of authority generates actions on the business community, by regulations and operations affecting market relations.

The third meaning associated with the “public sector” term implies the criteria of public policy making, which consists of relevant fields according with the national strategy. Taking the example of Romania, policies are presented in the Governance Programme (2009-2012) and are referring to fiscal-budgetary policy, justice and anticorruption policies, education, health, labor market, social insurance, family and child protection, teenagers and sport, business environment, SMEs, competition and consumer’s protection, transport infrastructure, scientific research, development and innovation, informational society, agriculture and rural development, regional development, public infrastructure of local interest and tourism policies, energy and mineral resources, environmental protection, public administration reform, public order and citizen safety, foreign policy, culture and national heritage, national defense, European affaires and policies on ethnic relations. As ownership of assets, the public sector has the right to control the activity of all the budgetary organizations from the public administration and even decide on the obtained results, including selling towards private sector.

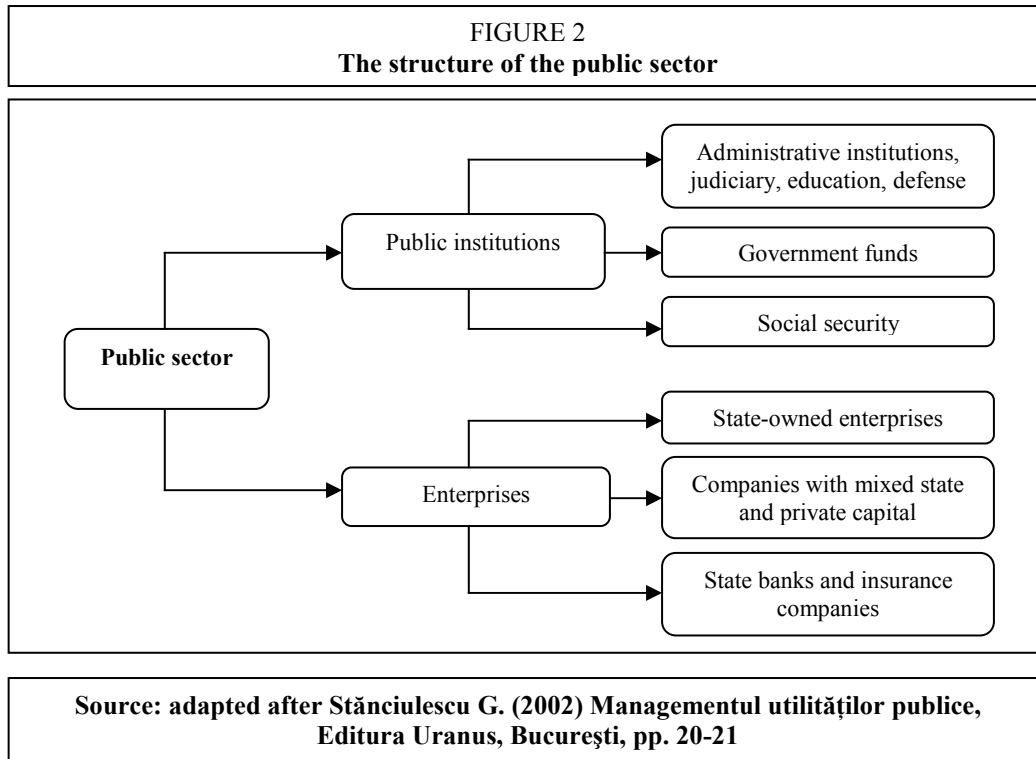

The last meaning refers to the public sector as a production system, considering the size of demand and supply of public goods and services established by specific mechanisms of budgetary sector and the ways of action on building the individual and public interest. (Stănciulescu, 2002)

When talking about the structure of the public sector there are identified two types of state organizations, such as institutions and enterprises. (figure 2)

Public institutions include ministries, agencies, and offices, organizations that are financed by the state or local budgets. For example, Romania has fifteen ministries, at the national level, and prefecture for each county.

The second category includes enterprises that are state ownership and obtains income by selling their production on the market and in addition, benefit of subsidies from the state budget, when the expenditure is higher than the income.

The decisions that are taken at the governmental level are of impact for both public and private sector, because of the means and instruments used by the public sector, such as regulations, taxes, subsidies, price controls.

Depending on the government objectives, these elements stimulate or inhibit the activity of business community. Furthermore, positive attitude towards citizens and increase of their satisfaction could be obtained by marketing activities of the public sector.

3. Aspects on public marketing

The contemporary marketing is situated in the sphere of methods for managing resources and can be mobilized by economic agents or by macroeconomic bodies in order to obtain an increase of profit, number of clients, image improving, keeping the clients of an enterprise, institution, public or private administration or government body. [6].

Nowadays, contemporary marketing, in general, adopted a holistic orientation which implies the engagement of an institution, in particular, in more diverse relations and represents a sum up of relational marketing, interior omnipresent marketing, socially responsible marketing and integrated marketing. [4]

Public marketing represents a modern concept considering the orientation of public organizations, with an overall of planned,

scheduled and developed activities, by using specific methods and techniques with the purpose of satisfying the contributors needs or/ and of promoting expected behaviors, inside the collectivities which represent the target market. [2] Being part of the marketing concept, public marketing has different approaches, such as economic perspective, business perspective, client perspective and social perspective.

In comparison with the purpose of private sector marketing, that consists of obtaining customer value and satisfaction, the public sector targets citizen value and satisfaction. [5]

Public marketing has some final objectives, which consist of:

- „- understanding the aims of public organizations, the way to measure them and how the marketing can contribute to them.

- understanding the public marketing policies under the political, economic, legal, social and technological circumstances of the public organizations.

- the analysis of the possibilities of organizational behavior directed towards the established objectives.

- the design of public marketing policies and strategies for the public organization.”

[1]

As mentioned before, the public sector generates changes in the private sector, by using different instruments, but more and more partnerships appear and the private component is emerged in most of the public services, underlining the importance of the public marketing. Although, marketing is a daily activity in a wide variety of countries its use is rarely encouraged or even considered as normal.[3]

4. Necessity, collaboration and marketing mix

4.1. Research method

The survey was made on a group of 384 subjects. The questionnaire was focused on marketing, in general and more specific on the necessity of marketing in public sector, collaboration with other departments and citizens, marketing mix, the need of specialists in public marketing, marketers' characteristics, the changes needed in public sector in order to obtain better public services. This paper presents the results about: (1) the necessity of marketing activities in public sector, (2) private-public collaboration by knowing the citizens needs, (3) the marketing mix components' importance.

Among the respondents, persons that have their age between 20 and 40 years accounted for 60% and on the second place with a 33% are placed persons that have between 40-60 years old. Regarding the highest educational qualifications obtained, 49% had university degrees and approximately 26% had postgraduate studies.

4.2. Data analyses, results and discussion

(1) Starting with the question that reveals *the necessity of marketing activities* in was analyzed the question „Do you think that the public sector and the public interest services should carry out and develop marketing activities?“, where the respondents had to answer with yes or not, from the total of 384 questionnaires, 329 registered a positive answer, 50 respondents negated the need for marketing activities and 5 questionnaires were eliminated at this question, because they did not marked a choice. From the total of 379 valid questionnaires, on one hand, 87% persons sustain the development of

marketing activities in public sector and on the other hand, there are a small percentage of 13% persons that do not encourage the presence of marketing activities within the public sector. (figure 3)

FIGURE 3
The percentage of respondents that are for or against marketing activities in the public sector (percentage)

In the following (figure 4) there are presented the percentages of respondents that agree or disagree with the necessity of marketing activities in public sector, structured into three categories by their level of education (middle educational level, university studies and postgraduate studies). The highest percentage of the respondents that disagree with the development of marketing activities in public sector is registered at the category of persons with a middle educational level, 22,54%, compared with approximately 11% for each category of respondents that have university studies or postgraduate studies. As a suggestion, the marketing benefits should be known by all the employees, especially when concerning a public institution, where the citizens should be the main central point.

(2) The following question makes *the connection between marketing activities and future collaboration with citizens* and it is formulated like this: “Do you think that the knowing of citizens' needs and expectations could improve the relationship between public and private sector?”. The necessity to know the citizens needs and expectation, registered a very high percentage (97%) of positive answers towards the identification of contributors' needs and expectations.

FIGURE 4
The percentage of respondents that agree or disagree with the marketing activities in public sector, divided by their level of education

Employees of Romanian public institutions are aware of the fact that the needs and expectations of the citizens should be on a very important place, because when the citizens' opinions are taken into consideration it generates satisfaction among them, thus meeting the main purpose of the public sector.

(3) Regarding the question about *the marketing elements that should be taken into consideration by the marketing specialists when making an offer*, the asked subjects had to hierarchy components, such as product, price, distribution and promotion (the 4 P of marketing mix), human resources, process (ecological technologies and others) and the organization good-will. (table 1)

From the hierarchy of marketing mix components, it can be seen that the respondents put on the first places the fundamental elements of the marketing mix. On the first place, with a majority of 199 options, is placed the product, followed by the price, which occupies the second place with a number of 141 options. The distribution and promotion register the most frequently options for the third place, but the promotion has a higher number of registers than the distribution, so that the latter occupies the fourth place. Respondents put little accent on good will and process so they place them on the following places. The human resources component has the most numerous options in order to be placed on the last position. The

TABLE 1
The hierarchy of marketing components when specialists have to make an offer

Making the offer	Position	Product	Price	Distribution	Promotion	Human resources	Process	Good-will
	1	199	35	4	73	10	28	38
	2	52	141	22	61	24	34	28
	3	46	58	66	79	28	30	36
	4	28	49	50	59	45	44	42
	5	7	27	58	31	68	47	38
	6	8	16	61	29	36	49	53
	7	7	17	34	10	72	51	52

Source: from the applied questionnaires with 384 respondents

respondents are focused on the main components of the marketing mix by putting them on the top and place the other three elements on the last positions.

5. Conclusions

A limitation of this study is that presents part of the survey and it was focus mainly on public administration from central and local levels. Cultural, national and institutional diversity would be relevant factors [7]. Applying this questionnaire and mainly the specific questions that are detailed in the paper, in other European would be very much strengthen this study's findings or even make comparisons. In addition further improvements of the questionnaire will bring into attention the interdependence between the public and the private sector, through marketing activities.

5.1. Implications and future research

Summing up, marketing should become a base building block of the Romanian public sector and this fact is sustained by the majority positive answers of the respondents (87%), when asked about its necessity. All most everybody (97%) agree that the improvement of the public administration services is related with citizens' needs and expectation. Knowing them could be better provided. The survey results reaffirm the importance of the marketing mix elements. Unfortunately the classic 4 P (product, price, distribution and promotion) was highlighted in the answers; less importance was given to personnel even if all agreed that it is very important for building a good relationship.

For a future research it has to be considered to find out if this result was obtain due to the analogy with the private sector marketing, less knowledge of public marketing, commodity in answer or is the real quotation the subjects are given to the marketing elements.

Other issue to be taken into consideration is the relationship between public and private sector (business community and citizens) in order to find out the current situation of the marketing importance/impact and what improvements can be made for further cooperation.

Abstract

Currently, brand marks and trademarks and service trademarks are used extensively in all countries - whether developing or industrialized, with a market or planned economy – and they play an important economic role in trade marketing.

Trademarks serve both the interests of those providing goods and services on the market - such as industrialists, manufacturers, distributors, retailers and wholesalers - as well as the interests of consumers, public authorities and the economy, in general.

Key words: trademark, brand, legal framework, emblem

JEL classification: M31, K11

1. Trademark vs. Brand

The English word "brand"¹ is often used as a synonym for the word "trademark" and it reflects this use: the "brand" represented the marking of cattle with hot iron, made by farmers [1]. Therefore, the English word "brand" that comes from the Norwegian word

"brand", which means to burn (also called "marking" cattle), appeared together with the first private enterprises at the end of the eighteenth century. In the given example, the

trademark is the sign or trace printed from the reddened iron on the skin surface of cattle, but the brand was a "family coat of arms" and today, it is a "company coat of arms" whose value and significance is assessed by customers and, as seen, this value can increase (by reputation, quality, loyalty), stagnate or be lost.

As Professor Vlad Dinu Sasu considers, "the struggle between brands does not take place in advertisements or in the pages of publications, but within the human mind and psyche."²

In Romanian language dictionary, the word brand [Brend] is equivalent to the trademark of a factory or product³.

In our opinion, a trademark may be considered a brand in an area where it has become a successful trademark, with a substantial economic value, after a sufficient market experience and if it entered among the so-called "consumer brands".

In our case, the word "brand" has another meaning than the word "trademark" - even in English there are used different words ("trademark" and "brand"). Thus, the trademark - registered or not - is the unique sign which distinguishes the products of a trader from those products of other traders.

On the other hand, the brand represents all physical and emotional links created between

¹ In Romania, the word brand was originally translated as "trademark." Therefore, today's "registered trademark" is identical with the "brand" - branding. While a trademark is a name without a representation in mind of the consumer, the brand is an active presence in the consumer's spirit, beyond the physical "interaction" between his/her retina and the object. The brand often plays the role of a status object. Its values are also the owner's values and, by extension, of the aspirant to him. Brands with good designed values, viewed brands, have, beyond any connection with the product it presents, a legitimating role for the buyer. It is already known phrase "Charles Revlon did not sell lipsticks to women. He is selling hope". In other words, have the brand had the following promise: "the aspiration to beauty is, by Revlon, a tangible reality." pr-pub.blogspot.com/2006_10_01

² Vlad Dinu Sasu. *Diferențe și similitudini între marcă și brand.*

<http://docs.google.com/viewer?a=v&q=cache:SHhfzDckssJ:steconomice.uoradea.ro/anale/volume/2004/64.pdf+brand+marc%C4%83&hl=ro&gl=ro&sig=AHIEtbRZfbpdzTdZ9Crrw--ZWTNB2zOjVQ>

³ DEX, Ed. ARC&GUNIVAS, Chișinău, 2007, p. 245.

a well-known product and the existing/potential customers, the public. In technical language, the brand is an intangible asset that some accounting systems admit even in the balance sheet⁴ and the banking system - after a survey of the economic market value - can accept a particular brand in lending transactions, in the form of mortgage.

If anyone can own a trademark, very few trademarks have become (or will become) brands, creating value for their owners. Lately, in the Romanian advertising industry, it is almost fashionable for many so-called experts to talk easily about logos or names, referring to them as brands.

In conclusion, "brand" is a word that covers a distinct reality and for which there is no equivalent in Romanian; therefore, the use of the two concepts of "trademark" and "brand" (for the time being in industry language) comes as a natural solution for this situation.

2. Trademark vs. emblem or logo

More often, in everyday speech or in the media, businessmen use expressions with similar meanings between trademark and emblem or logo, when speaking about the originality of a product or a service. From a legal perspective, the term "emblem"⁵ is omnipresent in both

public and private activities, mainly in commercial activities⁶; as regards the word "logo", it is not found in any normative act. For this reason, it is wrong to say in legal terms that a trading company is the property of a protected logo.

The legislation on industrial property, namely Article 3 A) of Law no. 84/15.04.1998 on trademarks and geographical indications, provides that the trademark is a sign capable of graphic representation, serving to distinguish goods or services of a natural or legal person from those of others; distinguishing signs may constitute trademarks, such as: words, including personal names⁷, drawings, letters, numerals, figurative elements, three-dimensional shapes and, especially, the form

⁴http://www.brandient.com/ro/noutati_si_opinii/interviuri_si_articole/brand_sau_marca.html

⁵ The word emblem, without relating it to the word trademark, is found in many laws, such as: 1) the Order of the Ministry of Culture no. 408 of 06.02.1992, the provisions of art. 3, set for the books and brochures published by Romanian publishers, bibliographic and identification data, which will be drawn up on the special pages, in the following way: the emblem, the name of publisher, place and year of occurrence of the edition, 2) By means of the Establishment Act of the "Romanian Post" SA National Company, of 03.07.1998, published in the Official Gazette, Part I no. 250 of 06.07.1998, the emblem of the "Romanian Post" National Company - SA, registered at the State Office for Inventions and Trademarks under number 22.799 of April 22, 1993, 3) the Statute of the Chamber of Auditors of Romania, of 14/09/1999, Published in the Official Gazette, Part I no. 463 of 24.09.1999, "the Audit Chamber will have its own stamp and emblem, which are registered at the State Office for Inventions and Trademarks" [Art. 2, paragraph (2)], 3) Emergency Ordinance no. 34/2000, on ecological agricultural products, from 17/04/2000, published in Official Gazette, Part I no. 172 of 21.04.2000, tickets will include a specific emblem for the inspected ecological products, registered at the State Office for Inventions and Trademarks, issued and affixed under the certification system, indicating that the product complies with the rules of ecological production [Article . 6 (2)].

⁶ Emergency Ordinance no. 161 of 13/10/2000 amending and supplementing Law no. 18/1996 on the guard of premises, goods and property values, published in the Official Gazette, Part I no. 557 of 09.11.2000, [Article 22 (4)], The equipment of the security personnel will be engraved only with the name and the emblem of the company, approved on the occasion of its authorization.

⁷ According to art. 2 of Directive 2008/95/EC, amending Directive 89/104/EEC on the rapprochement of the laws on trademarks, "Trademark may consist of any signs capable of being represented graphically, particularly words, including personal names, designs, letters, numerals, the shape of the product or of its packaging, provided that such signs are capable of distinguishing goods or services of one company from those of other companies." (SN) The same provision appears in Law. 84/1998 on trademarks and geographical indications, art. 3 point a. In these circumstances, in the database of trademarks there can be found, as registered trademarks, names such as: Raluca, Laura, Anna, Peter, Eloïse, Teddy, Miriam, etc., recorded for different classes of goods or services. If the case of the name Elodia, there is recorded in the national database a number of 3 applications. The first application, number M 2007 10868 was filed by SC Simplus Invest S.R.L. and it was rejected. The second application, numbered M 2008 08417 was filed by Mr. Cristian Constantin Cioaca and it was removed for failure to pay examination fees. A third application, the number M 2010 00542 was filed by SC Petrans S.R.L. and it is pending in the examination procedure. In the case of the name Nicolae Ceausescu, in the national trademark database there are several trademark registrations, including Ceausescu trademark, numbered 087503, the only one in force at this time and it is held by Mr. Valentine and Mr. Oprean Ioan Mircea. Ceausescu trademark is registered in all classes of goods and services included in the Nice Classification. <http://bd.osim.ro/marci/index.jsp>.

of the product or its packaging, or color combinations, and any combination of these signs. The right to the trademark, according to article 4, is acquired and protected through its registration at the State Office for Inventions and Trademarks.

The same confusion can be made in the case of the brand. A brand can not be subject to legal protection, whereas the list of goods and services can not be registered; protection can be given only to the name and/or figurative element that come with certain products or services.

3. The Law on the use of logo

Case T 289/01, Der Grüne Punkt - Duales System Deutschland GmbH v Commission of European Communities⁸.

The system for the collection and recovery of packaging marketed in Germany and bearing the logo Der Grüne Punkt – Exempting Decision... Court Decision (First Chamber) of 24 May 2007. Summary of the decision. Competition - Agreements - Prohibition - Exoneration - Commitment proposed in administrative proceedings (Art. 81 EC)

4. Decision. Legal framework

B. The collective system of Der Grüne Punkt - Duales System Deutschland GmbH, logo usage agreement and service agreement.

Since 1991, Der Grüne Punkt - Duales System Deutschland GmbH (hereinafter "plaintiff" or "DSD") is the only company that operates a collective system throughout Germany (hereinafter "DSD system"). To this end, DSD was approved by the competent authorities of all provinces in 1993.

In order to use the DSD system, manufacturers and distributors have to sign an agreement with DSD, in order to give them the right to use the Der Grüne Punkt logo, which corresponds to the collective trademark Der Grüne Punkt, whose owner is DSD. Instead, these producers and distributors shall pay a fee to DSD. The logo usage agreement is subject to Commission Decision 2001/463/EC of 20 April 2001 relating to an implementation proceeding under Article 82 [EC] (Case COMP D3/34493 - DSD) (OJ L 166, p. 1). This decision is the

object of the action for annulment brought by the plaintiff in Case T 151/01, DSD/Commission.

In the DSD system, the plaintiff does not collect and recover the packaging waste which bears the Der Grüne Punkt logo, but it subcontracts the collection service to a collecting company. The relationships between DSD and these companies are governed by an agreement, amended several times, whose object is to create and operate a system for packaging collecting and sorting (hereinafter "the Service agreement"). Once sorted, these materials are transported to a recycling center, in order to be recovered.

Law. c) On the alleged harm to the function of Der Grüne Punkt trademark. Arguments of the parties.

Originally, the Commission notes that some critics of the plaintiff do not cover the service agreement, subject to the contested decision, but the agreement for the use of the logo, which is the subject of Decision 2001/463 and which should not, therefore, be examined in this case.

The Commission states that the plaintiff seems to want to claim an exclusive right to use the collecting facilities, because it authorizes their owner to apply on their facilities the Der Grüne Punkt logo, which can not be accepted. Indeed, this would mean that a collecting company which applies the Der Grüne Punkt logo on the truck collecting the packages could use this truck only in the DSD system and not for other waste transports. Not only that the service agreement does not contain a provision supporting this reasoning, but the answers given by collecting companies to the demands of information sent by the Commission would show, in particular, that these companies use their vehicles for other orders.

The plaintiff could not, therefore, claim this exclusive right. Furthermore, the Commission states that, when it throws a package bearing the Der Grüne Punkt logo in a collecting facility belonging to the DSD system, the consumer is not misled, because the question of the common use is incident on consumer conduct. In addition, the final beneficiary of the return and recovery service proposed by the DSD system is not

⁸<http://eur-lex.europa.eu/LexUriServ/LexUriServ.do?uri=CELEX:62001A0289:RO:HTML>

the consumer but the packaging manufacturer or distributor. There is, therefore, no evidence that the alleged misleading claimed by the plaintiff brings prejudices to the Der Grüne Punkt trademark.

Findings of the Court: First, the service agreement does not prevent the contractual partner of the DSD collecting company to provide its collecting facilities to a system in competition with the DSD. Indeed, under the Service Agreement, it is stated only that "[i]n its actions to promote the system, the collecting company will highlight, appropriately and consistently, the Der Grüne Punkt logo conferred by DSD, for example by printing it on correspondence paper, advertising material and collecting bins, as well as by highlighting it on the vehicles and equipment used in the operation of the system" [Article 2 (5) first paragraph, fourth sentence] and that the "use of the Der Grüne Punkt logo is free for the collecting company" [Article 2 (5), third paragraph, first sentence]. The fact that DSD authorizes the collecting company to apply, for free, the Der Grüne Punkt trademark on its collecting facilities is not sufficient for DSD to claim the exclusive use of those facilities. On the contrary, under the service agreement, it is stipulated that the application of this logo serves no other purpose than to indicate, "in promotional purposes," that the facility in question is part of the DSD system.

On the other hand, given the importance of the application of the Der Grüne Punkt logo on the packages - one of the possibilities in section 4 (2), the second sentence of Annex I to Article 6 of the Ordinance to enable consumers to identify the participation of the package to a collective system (see Section 6) - the Court ordered in Decision DSD / Commission, T 151/01, paragraph 133, that, since the achievement of the recovery rates provided in the Ordinance and the division of the quantities of packaging between the systems is made

on the basis of the masses of these materials and not according to the packaging as such, whether or not they bear the Der Grüne Punkt logo, the latter does not have the role and the importance claimed by the plaintiff.

Thirdly, it must be borne in mind that the file shows that not all the collecting facilities used by the DSD system bear the Der Grüne Punkt logo. It is therefore legitimate to think that, when depositing the package in the collecting facilities, consumers do not associate these installations with the Der Grüne Punkt trademark, but with the packaging type (sales packaging) and especially with the type of the material which is made of (lightweight materials, paper/cardboard, glass etc.), which must be deposited in different types of collecting facilities.

Finally, it should be noted that neither the first obligation nor any technical constraint of the shared use of the collecting facilities do not require to the DSD competitors to be authorized by it to use the Der Grüne Punkt trademark. It is thus conceivable that common collecting facilities to have no logo or indication or, conversely, that each system to be equipped with a means of identification. Therefore, it is not arguable that the first obligation requires DSD to grant to its competitors a compulsory license for the free use of the Der Grüne Punkt trademark

Lile Ramona

Universitatea „Aurel Vlaicu” Arad

ramonalile@yahoo.com

Abstract

The work contains some achievements of higher education in Romania and perspectives of its development in the contemporary society, called the knowledge and teaching society. Efforts by state authorities and university communities in developing the Romanian Higher Education are aiming to its integration in the European Higher Education Area and to redefine and keep active its role through the development of the society. Universities should also shape their educational offer and potential of scientific research to meet the needs of this changing society.

Keywords: education system, higher education, quality, university scientific research.

JEL classification: I29

Contemporary society bases its strategy of sustainable development through more and more replacement of material values with knowledge values in the context of all its manifestations, global or digital.

Sustainable society focus on developing human capital, which must acquire knowledge of highly specialized requirements of the corresponding new society from the beginning of the third millennium, called the knowledge and learning society.

In his work *The Management of the future*, Peter F. Drucker notices: in the highly specialized knowledge society, a large number of individuals, perhaps most, benefit from something more important than the financial security: social status or *”social wealth”*.¹ In the

specialized knowledge society personal failure also represents social failure”.¹

In contemporary society, called the knowledge and teaching society, the role of education becomes more and more significant.

In his *”Education on the border of millenniums”* G. Vaideanu emphasizes that man is the product of the school, of the educational system of each country and the development of the society is strongly influenced by the quality of education: Education precedes and makes development possible with the condition of being adapted to the national needs and demands of the future, therefore, be relevant and modern.²

In terms of a scientific, technologic, economic and very dynamic environment, universities in the entire world have to redefine themselves in order to keep their active role in society.

Without giving up the traditional values, in the new society, universities around the world have to shape their educational offer and the potential of scientific research on the needs and expectations of local and regional community.

They must ensure the return of graduates to university in completing their studies and even to change skills and professional knowledge acquired during initial training, using modern means of open learning distance education.

To respond to the new demands of the contemporary society, the educational systems in all countries have important tasks such as:³

- permanent renewal and in an accelerated rhythm of content and structures, as well as decentralization of responsibilities

¹ Drucker, P.F., *”The Management of the future”*, Publisher ASAB, Bucharest, 2004, page 251

² Vaideanu, G., *Politics*, Bucharest, 1988, page 19.

³ Hanganu, S., *”Management and Higher Education in Romania”* Publisher Aurel Vlaicu Arad University, 2008, page 39

- diversification of education to adapt more easily to the requirements of economy, science and modern technology. There have to be created training courses and new interdisciplinary programs.

- harmonization of the education content and profile with the increased requirements of the society and labor market

- establish a balance between general and professional (speciality) training, in terms of trends converged to professionalize the higher education and to develop disciplines of general and theory education into technical education, for the formation of polyvalent personalities, able to adapt more easily to changes taking place in the contemporary society

- students to develop skills needed for a high level specialist by constant changing of programs of study, content of teaching methods, as well as periods of practical training and professional experience, which will be included in the program/curricula

- scientific and theoretical preparation basis to be solid, with a range of options, specializations

- complementary training for research through students participation in research

To solve these tasks, universities should establish strong links with science and research, to find new ways of transmitting knowledge to improve the educational offer for upgrading the educational performance.

In order to train and develop the professional skills and competencies of the students, to develop the spirit of initiative and creation, university managers must promote scientific techniques of evaluation and self-assessment. They must take into account views of the international bodies based on research in scientific fields.

University management should also aim to quality and efficient management acts. In this way, academic managers determine the strategy for achieving the targets and motivates university community members to obtain high performance.

Romanian higher education should play an important role in the new society. Romanian universities should be open to the environment that surrounds them, to develop an active partnership between universities and industry and public services, through strategic development policy of the university, by changing the policy of their funding

(diversification and increasing the financial contribution of beneficiaries).

Under the new policy, higher education not only must adapt to the requirements of the market, but should also constitute its own domestic and external market.

Domestic market is achieved by means of recruitment of students, by the quality of services offered, the degrees conferred and by developing relationships with cultural economic organizations, etc.

External market is achieved by the cooperation within European programs, participation in European networks of university teaching and research, accepting certain foreign university subsidiaries or opening university branches abroad, etc.

In the context of developing relations between the university and the social, cultural and economic environment, university strategic management should consider the following:⁴

- institutional internal assessment to determine the mission and the immediate and future objectives

- elaboration of institutional immediate and perspective policy, to identify resources necessary to fulfill the aimed objectives

- establish a flexible organizational structure of the university to enable notification of new opportunities, finding new solutions, encouraging the innovative spirit of the academic staff, diversification of services for the external environment

- adoption of a new financial management, to boost scientific performance and academic excellence.

For the correlation of education in Romania with European systems of education, starting with the 2005/2006 academic year, universities issue free of charge to each graduate a diploma supplement whose content is in accordance with European norms, including in a language of wider circulation.

Curricular reform in Romanian universities aims to increase the insertion capacity of higher education graduates in the labor market.

Boosting scientific research in universities contribute to fully achieving the mission of higher education.

⁴ Hanganu, S., "Management and Higher Education in Romania" Publisher Aurel Vlaicu Arad University, 2008, page 28

Boosting university research is made through the establishment of schools of advanced studies, which involve team research activities, with the improvement of individual young students who are studying under a master or PHD degree program, under the leadership of scientific coordinators of international fame.

The Ministry of Education and Research recommends universities to create centers of technology transfer and innovation, to ensure the interface between universities and local communities, in the field of scientific and technological research.

All these exchanges are influenced by specific historical conditions of each country.

After decades of isolation of the Romanian higher education from the outside, boosting international exchanges, access to international scientific publications after 1990, constituted a major concern of the Romanian universities.

Universities valuing the new legal and institutional framework involves promoting international collaboration through joint university training, organizing PhDs in co-tutoring, the participation of the Romanians at scientific research programs at European or global level.

Today, as in the Bologna Process, Higher Education in Romania is clearly included in the battle for making it compatible with the structures and performances accepted in the European Higher Education Area.

In order to do this, beyond the necessary technical and organizational measures, the quality of acts and educational processes are absolutely necessary.

Romanian higher education is in a period of reform.

Quantitative accumulation has been achieved by increasing the number of students and the licence degree cycle, but in the future, emphasis should be on quality.

Efforts in Romania to increase quality in higher education have been materialized in:

- a new structure through the reorganization of higher education studies in three cycles: cycle I – license, cycle II – master, cycle III – PhD
- building the national quality management system - began in 2005 with the adoption of GEO no. 75/2005, approved by Law no. 87/2006 on quality education and by establishing ARACIS, whose activity field is the quality management in higher education nationwide.

ARACIS began to function effectively in 2006, by attending and piloting standards and methodologies afferent for external evaluation of universities. In order to develop international cooperation and participation of the Romanian universities, the Ministry of Education and Research has funded a research program of quality education in Romania, called CALISRO, to implement effective mechanisms for quality assurance, based on detailed studies and discussions with academic representatives.

- recognition of qualifications obtained in higher education through the National Center for recognition of diplomas affiliated to ENIC / NATIS.

- introduction of a system of transferable ECTS type credits, by Law no. 288/2004.

- with regard to the mobility of the students, teachers and researchers, authorities were created to facilitate mobility, such as National Agency Socrates and Leonardo da Vinci. The National Office for Scholarships Abroad was also created.

To improve the mobility of students, the Ministry of Education and Research and Socrates National Agency initiated the "PHARE and users support" project and in order to support the exchange of experience at educators level, in 2004 The Socrates National Agency initiated a PHARE program. All these measures have been taken in order to make the university curricula compatible.

- steps were taken in the evolution of continuing education. Education Law no. 84/1995 regulates adult education and continuing education, ideas, reinforced by the Government Ordinance no. 129/2000, which regulates the distance education as a mean of achieving education for adults.

- to contribute to the development of European dimensions of higher education integrated studies were extended through mutual agreements between universities and Government, study programs have been developed in foreign languages, the Jean Monet program was initiated, involving 9 universities which have developed training modules on the European Constitution

- in order to promote the activity of European higher education, seminars, conferences, meetings and debates to promote European trends in higher education have been made. Thus, in 2003, was held in Cluj-Napoca an EUA

meeting, organized by the University "Babes Bolyai", supported by the National Agency Socrates.

For the future, the Romanian Government, through the Ministry of Education and Research, has developed strategies related to the Bologna Process, aiming at:

- increasing the quality in higher education in Romania
- linking national qualification framework with the labor market, compatible with the European Qualification Framework
- monitoring the placement of graduates in the labor market
- participation in programs and activities for internationalization of higher education in Romania

The position of Romania about the European Community Acquis provides full adaptation of legislation and regulations in the field of education, which shows that the future of higher education in Romania can not be other than as part of a European Area of Higher Education, participating actively in its construction.

The main objective of the development strategy of higher education for the period 2001-2010 is to improve structural Higher Education.

In order to achieve this strategic goal a number of operational objectives have been established, such as:⁵

- Optimizing national network of institutions of higher education, aiming to balance the structure of higher education centers. This can be achieved through:
 - ranking of universities based on performance
 - correlation of the universities' distribution by region, in relation to their population and resources
 - optimizing the structure of State higher education
 - promoting private quality higher education institutions
- Strengthening university autonomy in parallel with the increasing synergy and coherence of the whole higher education system. To achieve this objective, actions are necessary to decentralize the education activities, increasing accountability in university management

decisions, creating new relationships between universities and ministries, increase flexibility and demanding quality from the universities.

- Improving the performance of students and teaching staff. To do this, increasing the demand is necessary in promoting the teaching staff, reorganization of teaching, improving the selection and motivation of students to obtain performance, reviving the university level research.
- Improving university infrastructure through attracting new financial resources, others than the allocated budgetary resources, attracting private investors, developing the entrepreneurial dimension of the universities.
- Better correlation of higher education with the labor market, by connecting the academic specializations with the nomenclature of occupations by monitoring the insertion of the graduates in the labor market
- Reorganizing the teaching process by the implementation of modular systems, course packages, establishment of experience exchange at national level and inter-school cooperation, etc..
- Stimulating the integration of the Romanian Higher Education in the European one and the international cooperation through reform measures, in accordance with the evolution of European higher education and supporting academic exchanges.

In the scientific research and technological development, our country recorded very serious gaps to the European Union, both in terms of personnel, as well as those related to infrastructure for research and technological development.

To reduce these disparities, the Romanian Government launched the National **Strategy for Research, Development and Innovation (RDI)** for 2007-2013, approved by the Government Decision nr.217/2007.

The strategy reinforces the support of the planning and the implementation of RDI policies promoted by the National Agency for Scientific Research (ANCS) in the post-accession period.

The main instrument for the implementation of the Strategy is the **National Plan for Research, Development and Innovation**, developed in consultation with a large part of the scientific community and a large number of structures and personalities in the economic environment.

⁵ Source: Romania's National Report for 2004-2005, Bologna Process, <http://www.almamater.md>

In 2006 the *Impact Program* was launched, which aims to identify and develop RDI projects supported by structural funds, in major areas such as:

- research partnership between universities, research institutes and development companies,
- investment in the RDI infrastructure
- SME's access to the RDI activities

Regarding the development of the scientific and technical international cooperation, the Ministry of Education, Research and Innovation by ANCS, offers its financial support from the research budget, to the following forms of international cooperation:

- participation in European and international research programs, such as Euratom, Eureka, the NATO Scientific Program, Scientific and Technical Cooperation Program - COST etc..
- connecting the national programs to European projects, i.e. ERA Net, ERA Net+.
- bi and multilateral scientific and technical cooperation, including at regional level, based on intergovernmental agreements.

- scientific and technical cooperation in international bodies such as CERN (within 4 experiments: ALICE, ATLAS, DIRAC, LHC) ICGB – Trieste International Center for Genetics Engineering and Biotechnology, Initiative BSEC-Black Sea Economic Cooperation, etc..

In the future, Romania has to solve the quality and capacity development of the RDI in order to help at the technology and gap reduction to the countries of the European Union.

In order to make the system of higher education in Romania compatible with the one from the EU, it needs to develop a competitive educational system of training, able to develop skills, creativity, initiative, originality and respect for values.

European market requires a high standard of mobility, flexibility and work reconversion.

From a qualitative point of view, Romanian universities are still performing poorly. No university in Romania have entered the Shanghai top, containing the most advanced 500 universities worldwide. The Estimations of the Ad-Astra Association of the Romanian researchers show that the best universities in Romania should increase their score by the least twice, to enter the top.

Romanian higher education has yet to solve very serious problems related to:

- under-funding
- low quality of education
- incomplete university autonomy
- staff salaries, to eliminate overlapping the hours
- training and educating the population about the role of the continuous studying
- increasing the connection between universities and business community
- developing practical skills, specialized, entrepreneurial, among the ones of general culture
- creating a system of educational network, with many centers of excellence.

Of course the results will be visible on long term and they require a radical change of the Romanian people's mentality in favor of permanent learning, throughout life.

Winners And Losers In The Context Of Global Economic Crisis

Humă Elena
Scoala Doctorală , ASE Bucuresti

Abstract

When contemplating a merger, acquisition or portfolio purchase, strategic objectives should be defined in advance along with your tolerance for risk. This process can be used to pre-screen transaction candidates, assemble a project team and establish the scope of work. Ongoing communication among the project team is essential to identify high risk elements that could jeopardize the viability of the transaction. If the transaction is not a good financial, geographic and cultural fit for your organization call it a day and move on to the next transaction candidate.

The global financial crisis was clearly stamped "Made in USA," but the outlook for growth in emerging economies is being rapidly scaled back, proving that globalization is for real. We are all in this together. What started as a US housing market problem has morphed into a worldwide economic slowdown and could be turning into something worse? The crisis is still in the early stages in many developing nations.

Key words: crisis, trade, recession, risk

JEL classification: E39

1. The European Economic Crises

Central and Eastern Europe was arguably the region hit hardest by the global downturn. It's still suffering, but hopeful signs are clearly emerging.

It wasn't meant to be like this. According to the original script, Central and Eastern Europe (CEE) was to have celebrated the 20-year anniversary of the fall of communism this year with unalloyed enthusiasm. The countries would look back on how they built competitive, successful free market economies and attained NATO and EU status—with Slovenia and Slovakia also benefiting from the Euro zone membership^[1]—and consider how they were increasingly making their mark on the world stage. Former Polish premier Jerzy Buzek's becoming president of the European Parliament would be the latest proof.

In short, 2009 was supposed to be all about how CEE was becoming increasingly indistinct from the Western Europe it has long sought to catch up with.

In most countries of the former communist world, free market concerns like recession, increased bankruptcies and growing unemployment are the new reality. Relatively fragile political systems have struggled, with new governments emerging from the economic rubble in Latvia, Hungary and Bulgaria, to name just three. Croatia's respected premier Ivo Sanader stepped down midway through his term in early July without explanation, overwhelmed by Croatia's worsening economic crisis and faltering progress in its EU application.

Meanwhile, each latest report the International Monetary Fund releases grows more pessimistic. After forecasting in April that GDP this year would contract 3.3% across CEE (with growth recovering to an anemic 0.8% next year), its latest report sees growth plunging by 5% (albeit with 1% growth in 2010), with the Baltic's, Ukraine and Hungary all faring much worse than average. Only Poland has any reasonable chance of growth this year.

The region's problems are, in part, a reflection of its success in opening up to the world, much of which is now also deep in recession. Its once-closed economies are now among the worlds most open, with Hungary, the Baltic States, the Czech Republic and Slovakia all having trade-to-GDP ratios of over 80%. Poland, the largest and most self-sufficient economy, has the lowest ratio at around 40%. By comparison, India's trade-to-GDP ratio is just 10%, Brazil's 15% and China's 35%. Trade openness was accompanied by high dependence on foreign capital flows, which before the global downturn kept the region's economies moving forward. Financial institutions from countries such as Austria, Germany, Sweden and Greece own most of the banks and were happily lending—usually in euros—to local businesses and consumers.

This, like much of the trade flow, all came to a sudden, shuddering halt in the fall of 2008 and has yet to resume, despite the efforts of the IMF, EU and other multilateral bodies to keep funds flowing. At the same time, local currencies have plunged, increasing private and public debt levels to worrying new highs. The IMF has warned that CEE could experience problems in rolling over the \$413 billion in external debt due to mature over 2009; especially given that many countries also need to finance large current account deficits as well. In April the IMF suggested the financing gap could reach \$123 billion, with a further gap of \$63 billion opening up next year.

With governments struggling to contain growing deficits and keep their economies afloat, most bets about joining the euro within the foreseeable future are off. Poland, which had hoped for 2012, has now admitted that looks unrealistic, given the fiscal situation, the downturn and currency instability. The earliest possible date is now 2013, with 2014 more likely. The Czech Republic's traditional ambivalence has deepened amid concerns the euro could act as a straitjacket on growth, while Hungary's enormous external debts and other problems suggest 2015 at the very earliest. Nobody wants to estimate entry dates for the Baltics or the Balkan states, despite the former having already fixed their currencies against the euro.

2. Winners and losers

Among the winners, Poland stands out, with a stable banking system, generally low levels of debt, a cohesive, effective government and some prospect of growth—though not much—in the “annus horribilis” that was 2009. The Czech Republic and Slovakia, though they have suffered economic contraction reflecting a heavy dependence on auto manufacturing, also deserve an honorable mention: Policymaking has been consistent, and banks are well capitalized. Although unemployment has risen in Slovakia to around 15% (on the back of a 11.2% contraction in GDP between January and April), membership of the euro has meant there is no currency risk, which is one reason why VW chose it over the Czech Republic for its new \$435 million plant to build the company's new family car.

Among those suffering worst, all three Baltic States, but particularly Latvia, deserve special mention. Major real estate bubbles

have burst, while the massive expansion in credit that gave these economies unsustainable growth rates up to 2008 has completely dried up. At the same time, unprecedented wage increases have made the economies uncompetitive. Meanwhile, exchange rates pegged against the euro have robbed policymakers of a vital tool, even while they fought to prevent further deteriorations in confidence and increases in foreign debt. The IMF believes Latvia's GDP could contract by 18% this year, leading the multilaterals representative in Riga to comment, “Latvia is in for an incredibly tough year.”

Hungary, for so many years the darling of foreign investors in CEE, has also fallen hard. Its problems include sluggish growth, huge external and fiscal deficits and private sector foreign-currency over-gearing compounded by political near-paralysis and a continuing failure to get a handle on such problems as a large, costly and inefficient public sector and an unreformed, bloated pension system. ING Barings reckons GDP will shrink by around 6.5%.

Romania and Bulgaria continue to be blighted by corruption, lack of transparency and huge, inefficient public sectors as confirmed by the EU's latest progress report, published in late July. Bulgaria's situation has been made more parlous by the collapse of the real estate and construction boom, which at its peak accounted for almost one-third of GDP growth. GDP contraction, however, may not be as bad as elsewhere: The new government in Sofia projects a 2.5% contraction for 2009 against the 6% decline for Romania predicted by its economy ministry.

Further east, things look even grimmer. Moldova, as ever, is struggling for its very viability as a nation in the wake of continuing GDP declines and political crisis. Ukraine, defined by one analyst as “an economic disaster zone which has done almost nothing to help itself in the current crisis,” expects GDP to contract by up to 20% on the back of major falls in demand for steel, its single biggest export.

3. Moody's Report concerning Romania's situation^[2]

Romania's convergence to the EU average will spread over a long time, probably around 40 years, given that a more normal long-term growth rate for the country is most likely of 3-4% per year, according to a Moody's report

published this April. "The combination of a reasonable business environment, EU membership, and improving physical and social infrastructure – bolstered by EU funds – should sustain superior investment rates over time, allowing a gradual rise in real income towards the EU average. Nevertheless, this trend will take considerable time, probably around forty years," Moody's report reads. Moody's assesses Romania's long-term economic strength to be high, mainly because Romania is significantly poorer than most other EU countries. Moody's expects Romania's recovery path to be gradual. Economic growth is unlikely to reach pre-crisis rates for sustained periods, especially if European economic growth remains muted. A more normal long-term growth rate for the country is probably 3-4% per annum, bearing in mind that there are still several obstacles to rapid growth in Romania, particularly a heavy structural reform agenda and lackluster infrastructure. At this pace, however, income will take a relatively long time to converge to the EU average," according to the report. Romania's economy boomed between 2001 and 2008, averaging 6.2% real growth per year even as the population declined. The rating agency estimates the Romanian economy would contract by 8.9% this year, but will post a 1.2% growth in 2010. Moody's analysts added that signs that growth was becoming unsustainable became more pronounced in 2006 and 2007, as asset prices soared, the current account deficit jumped and domestic credit growth accelerated.

A surge in external borrowing and government spending leading up to the elections in autumn 2008 also increased the country's vulnerability to the deteriorating global economic environment, the report reads. Moody's

considers that Romania's return to growth may come more quickly than for other countries in the region, such as Bulgaria or the Baltics, because the Romanian private sector is less leveraged, and because of the flexible exchange rate which is easing the adjustment in the trade balance.

On the other hand, the recession, coming after an extended, credit-fuelled boom, could be more protracted than expected and cause serious economic dislocation. Output will need to re-orientate towards traceable goods and services, which means that corporate insolvencies and unemployment are likely to continue to rise for some time," according to the agency. Moody's is the only major rating agency that still has Romania on a stable, investment-friendly recommendation; after Fitch and Standard & Poor's placed Romania's rating in "junk" category last fall. In the second quarter, the economy fell 8.7% on the year, and 1.1% compared with the first quarter, according to the National Statistics Institute. Romania agreed in March with the IMF a EUR12.95 billion two-year stand-by loan, as part of a EUR19.95 billion financial rescue packages that also includes funds from the European Commission and other international institutions.

1929, 1973, 2008: Brand-related Attitudes

PhD student Ichim Cosmin

Al. I. Cuza University, Iași, Romania

ichim_cosmin@yahoo.com

Abstract

History should prevent us from repeating the mistakes of the past and learn from those who made it through with glory. This article focuses on the analysis and interpretation of the branding and promotion events that occurred during the so called, Great Depression (1929-1933) and the 1973-1974 Crisis, projected on the decision of the marketing and management specialists of our times. The economic manifestations, such as: the unemployment rate, the decrease of the purchasing power, the crediting related difficulties, etc., specific to all periods of recession, revolve around the consumer and the way he modifies his consumer behavior. This paper tries to find an answer to the following question: given the decisions made by the managers in the 30s and 70s, what brand attitudes are recommended for this period?

The answers to the question above are the object of the conclusions of this article. The recommendations provided herein invite us to meditate upon the crises from the previous century and to take a critical look at various marketing related attitudes, such as the disregard for rebranding or brand creation and the diminution of the promotion budgets.

Keywords: brand, crises, products, consumers.

JEL classification: M 39

1. Introduction

In 1970, in his book entitled *Future Shock*, Alvin Toffler, in disagreement with the specialists of those times, who believed that science and technology were the main causes of the future product standardization, predicted that, with the passing of time, people would suffer because of a paralyzing excess of options,

and not because a lack of products that one could choose from [14]. There are too many products, too many societies and too much *marketing noise* [15]. *Consumer Digest* magazine conducted a study which showed that a common family covers between 80 and 85% of its needs with the help of 150 products [16]. 150 brands – this is the new economy.

The brand has gained a crucial place in the history of marketing, for it has enabled us to make a distinction between various products and contributed to the creation of attitudes such as consumer trust and loyalty. Larry Light, a professional in the field of advertising, was interviewed by one of the editors of *The Journal of Advertising Research* about his predictions in relation to the development of marketing over the next three decades. Light's analysis proved to be very revealing: *The marketing battle will be a battle of brands, a competition for brand dominance. Businesses and investors will recognize brands as the company's most valuable assets* [4].

This paper presents the brand in two different hypostases (the 1929 and 1973 crises) and identifies a series of brand attitudes that may help marketers who see the brand as an efficient weapon for communicating with the consumer and adjusting to their new *consumption habits*.

I will position the brand in the two time periods discussed herein. This positioning will be strictly correlated with managerial behavior, for which purpose I will resort to case studies. Finally, I will try to give shape to a series of recommendations for the current crisis, which have as a starting point the analyzed cases.

2. The brands of 1929

The period 1922-1928 represented, for the American and European economies, a period of confidence and contentment with the outstanding results obtained, especially in industry. Economic development was accompanied by prosperity, salaries became bigger and bigger and unemployment almost disappeared. The crediting system facilitated the development of demand and, implicitly, of production. In his desire to increase productivity, imperatively necessary for augmenting demand, in his work entitled *Principles of Scientific Management*, 1911, [11] Frederick W. Taylor stimulated the trend of scientific management, which advocated for production on assembly lines, with the strict timing of each operation. However, Taylorism enhanced fatigue and led to a decrease in the workers' technical creativity. The "robotizing" Taylorism was the source of the non-rationalization of consumer decisions.

Our consumer was more and more eager to consume, and, because of the normalization, and standardization principles applied to products and services, he would become loyal to the products he liked. Most marketing specialists argue that it is during this period that the packing and the brand start to act as information and pressure instruments on the buyer. They start to promote real or imaginary features of a given product or manufacturer [10]. The exodus of the population to the city, in search for better paid jobs, accelerated urbanization; electrical appliances and the radio become part of the life of ordinary people. Mass-media infiltrates in society via the radio, newspapers, the cinema and even television, leading to the diversification of the communication channels and thus laying the foundations for many of the marketing principles and practices.

In contradiction with all the above mentioned aspects, on October 29, 1929 (the so-called black Thursday) people witnessed the shock of the fall of the share prices at the New York Stock Exchange. The Wall Street Crash was followed by a wave of bankruptcies, account withdrawals and insolvencies. The purchasing power suddenly dropped, companies significantly reduced their activity, and some of them even closed for good. The unemployment rate reached unimaginable values; where the employers kept their employees, they had to reduce their salaries. The product abundance faced a lack of

buyers. The poverty caused by the lack of employment and by the diminution of the salaries led to large scale social movements: strikes and demonstrations of the unemployed, hunger marches, actions of the veterans, farmers, etc. [1].

I will proceed to the analysis of some brand related events, in strict correlation with the economic and social context presented above.

Rebranding. In 1930, Pepsi underwent a rebranding process and invested significant amounts for the promotion of the new image [5], also supported by a new shape of the bottle. Coke Cola, its main competitor, invested primarily in repackaging and brought the six-pack on the market. Even if sales dropped, neither of these companies reduced promotion costs.

Reconstruction of the architecture of the brand portfolio. Ivory, the 99.44/100% pure floating soap and the first successful brand of Procter Gamble, resists the pressure of reducing promotion expenses and even manages to sponsor some of the first radio soap operas, The O'Neills. Procter Gamble launches, also in this period, the Camay soup, unfortunately in the shadow of the Ivory brand. The company envisages, for the first time in its history, the creation of a brand management team, in charge of a marketing program and of its coordination with sales and production. This was a crucial event in the history of branding [4].

Birth of a brand. In 1931, two years after he had lost his job with Steyr, because of the crisis, Ferdinand Porsche set up his own company, in Stuttgart. This would actually be the beginning of Porsche [6]. The first project dealt with the design of an average class car, but they subsequently returned to the idea of a popular car. Later, Ferdinand would manufacture a high speed vehicle that equaled the *Silver Arrows* during an age when German cars dominated Grand Prix races. A while later, Ferdinand faced new challenges: his car was supposed to carry two adults and three children at a speed of 100 km/h, to consume little fuel, not to have problems during the winter season and not to cost more than 990 Reich mark – a little more expensive than a motorcycle.

Innovation through creativity. Walt Disney stated: *I hope we never lose sight of*

one thing – it was all started by a mouse [8]. Mickey Mouse is the name of the first cartoon to have managed to synchronize sounds and image. When the crisis was the primary concern of the entire population, and all the politicians were preoccupied with their anti-crisis programs, Disney launched their first color animated cartoons. Nowadays this is one of the most powerful media and entertainment company in the world.

Non-interruption of the scheduled launches. In 1932, Chrysler launched the Plymouth model and sent a message that was considered, at that time, unorthodoxly honest. The message incorporated an image of Walter P. Chrysler, supporting his leg on the new Plymouth model, and the slogan: *Look at all Three!* [17]. Chrysler seemed to encourage the public to compare the new model with those of his competitors, Ford and General Motors, before making a decision. This kind of honesty led to record sales for the new model. Chevrolet also scheduled the launch of new models: Chevrolet AC (1929), AE Independence and ½ Ton Pickup (1930). In his turn, Ford did not stay behind and launched, during the depression, Ford Model A (1929), Ford V-8 Model 18 (1932) and 20 other models.

1929. The end of the second wave of company mergers and purchases. After Ford had managed to become a vertically integrated company, being, via the purchase of companies, its own producers of tires and car bodies, General Motors embraced the same type of attitude [12]; Colgate and Palmolive-Peet also decided to merge and to create the Colgate-Palmolive-Peet Company brand.

3. The brands of 1973

The Second World War, like the first one, gave birth to two highly significant periods in the economic history. First, there was the epoch of mass production from the 20s up to the Great Depression and then the period of the consumption society, from the 60s until the 1973 crisis.

In the beginning of the 60s, the Western World saw itself in a light of welfare and abundance. This period of time is characterized by the fact that most of the families earned more than the equivalent value of their psychological and biological costs. Also, just like in the 20s, the market offer increases, putting the companies in the position of studying the preferences, the

wishes, the attitudes, the aspirations of the consumer. The return of the mass production, a sort of upgraded Taylorism and Fordism, is the start of a conflict with the limited character of the natural resources and with the possible degradation of the ecological environment.

The 70s were perhaps the worst decade for the economic performance of most industrialized countries since the Great Depression [7]. Although there was no severe economic depression, as witnessed in the 30s, economic growth rates were considerably lower than during the previous decades. As a result, the 70s adversely distinguished itself from the prosperous period between 1945 and 1973.

From an economic perspective, the 1970s were marked by the energy crisis which peaked in 1973. On the 16th of October 1973, The Organization of the Petroleum Exporting Countries (OPEC) announced a decision to raise the posted price of oil by 70%, to \$5.11 a barrel [18], a decision that had as background the end of Bretton Woods agreement and the war between Egypt, Syria and Israel (Yom Kippur War). In the 694 days between 11 January 1973 and 6 December 1974, the New York Stock Exchange's Dow Jones Industrial Average benchmark lost over 45% of its value, making it the seventh-worst bear market in the history of the index.

Again, I will proceed by analyzing some brand related events, in strict correlation with the economic and social context presented above.

Rebranding. In 1971 the Pepsi logo was slightly modified to a more rounded version which was used until 1991 [5]. This is the second time Pepsi uses rebranding to adapt to a new social and economical environment.

Reconstruction of the architecture of the brand portfolio. 1974 is a turning point for the successful Volkswagen brand: Beetle [6]. The increase in the design costs and a weaker dollar resulted in a bigger price (from 1893 dollars in 1970 to 3000 dollars in 1973) which was very not healthy for an economic alternative car. The magic of the brand also lost interest in the consumers' mind [4]. VW tried to transfer the Beetle capital to a new model called Rabbit, which distinguished itself through its simplicity and practical

nature (the symbol of the brand was a cute running rabbit). 1974 is also the year of the birth of a myth called Golf [6].

Birth of a brand. In 1974, the term Duracell was formally introduced as a brand. It all began when breakthrough advertising was trying to develop the message that Duracell alkaline batteries lasted much longer than ordinary and inexpensive zinc carbon batteries. A small pink, fluffy bunny was created, who, powered by Duracell batteries, was able to outlast all others in an array of colorful challenges [3]. The Duracell Bunny made his debut appearance in the US 35 years ago, in a commercial that included a group of drum-banging pink bunnies. The winner was the Duracell Drumming Bunny, the message was loud and clear - powered by the long-lasting Duracell battery, he's unstoppable.

Innovation. On September 25, 1928, Paul V. Galvin and his brother, Joseph, incorporated Motorola's founding company, Galvin Manufacturing Corporation, in Chicago, Illinois, USA. Having a large portfolio in the industry of communications, in 1973, Motorola demonstrated a prototype design for the DynaTAC portable radiotelephone, using cellular radio technology. In 1974, Motorola sold its television business to the Japan-based parent company, Panasonic, to concentrate on cellular radio technology [2].

Non-interruption of the scheduled launches. It was nothing scheduled in the motor industry. As in Western Europe, U.S. automakers were significantly impacted by the 1973 oil embargo and energy crisis. By 1971, the standard engine in a Chevrolet Caprice was a 400-cubic inch (6.5 liter) V8 with a big consumption figure. European and Japanese automakers began to export more compact cars into the US to meet the new demand. This forced the Big Three (General Motors, Ford, and Chrysler) to introduce smaller and fuel-efficient models for domestic sales [7]. The Chrysler Omni or Horizon, Ford Fiesta, Ford Fairmont, and the Chevrolet Chevette all had four-cylinder engines and room for at least four passengers by the late 70s. In the current crisis we find great interest in alternative power source motors such as: electric, hydrogen or solar ones.

The end of the third wave of company mergers and purchases. On the heels of post-World War II prosperity, a prolonged merger wave ensued. During this period, which is sometimes called the *conglomerate merger wave*, numerous

established US companies embraced the diversified conglomerate paradigm. In addition, entirely new conglomerates were built from the ground, such as International Telephone & Telegraph (ITT), Ling – Temco - Voight (LTV), and Litton Industries. Diversification became widely accepted because management skills were assumed to be easily transferable among industries [12]. Brands begin to represent enormously valuable pieces of legal property that can influence consumer behavior, be bought and sold, and provide the security of sustained future revenues to their owner [9]. The merger wave gradually ended in the early 70s as the Dow Jones Industrial Average fell by more than a third (e.g. the largest conglomerates fell 86%, and computer and technology stocks fell 77%) and a worldwide energy crisis began. This led to tight money for merger activity and a devaluation of the US dollar [12].

The greatest merger, in time of the 73-74, is the one between Peugeot and Citroën (the birth of PSA).

4. Recommendations for the current crisis

The social and economic context specific to the period of the Great Depression and the 1973 crisis has many common aspects with the reactions to the current crises. Bankruptcies, account withdrawals, insolvencies and the decrease of the purchasing power characterize all analyzed periods. However, it is worth stressing the fact that our consumers did not reduce their expenses to zero; many of them started to thoroughly analyze what a brand really has to offer. They started to seek those products that bring more value to the earned money. The brands that succeeded in doing this, during the Great Depression and the one that took place in the 70s, gained loyalty, affection and long term trust.

The events which took place in the period 1929-1933 and 1973-1974 in association to the presented successful recipes represented the basis for the recommendations below.

Do not put an end to investments in advertising. The most intelligent decision made by the companies during the two periods was to invest in the promotion of

their own brand. We must not lose sight of the fact that, by resorting to a new brand, we strive to gain loyalty, affection and trust. If we reduce the marketing budgets, the consumers will feel abandoned and will reorient towards the products of the competition. If all the players in your field give up promotion, it is wise for you to be the only one that does not take such senseless measures. Thus, you will gain the long term loyalty of your customers.

Resort to advertising agencies or to specialists in the field. As the new consumer seeks to transform all purchases into a good deal, it is crucial for your sale process to achieve an efficient transformation of your message into perceived value. A flawed sale process will lead to wasted resources. Promotion campaigns, together with price decisions and promotion channels must be conceived in such a manner as to obtain the best possible results.

Rebranding. As we are dealing with a new type of consumer, with new consumer habits, we could try to adjust to this new reality by means of a new brand. It is absolutely necessary to question our consumer on the way he perceives our brand at present. Many of the current rebranding strategies focus on simplicity and clarity (e.g. the rebranding of Pepsi).

Reconstruction of the product portfolio. **Say no to price discounts**, focus on a new brand, and, implicitly, on a new product, depending on the positioning of the product in relation to its price. The *luxury industry* (or the industry of premium brands) has numerous rebranding opportunities; this is a strategic course, with beneficial effects as concerns the profit of a business, recommended for lowering a premium brand to an *upper-medium* or medium price level. It is worth mentioning that it is not advisable to return to high prices for the same brand. Consumers will focus on the *average price segment* and, consequently, this is where the battle between the producers will occur. The *low segment* does not have rebranding potential, since the consumers and the services in this segment are primarily motivated by the price and not by a potential emotional connection. **A new brand**, if it relies on innovation and on a potential need. We must keep in mind that recession comes with threats, as well as with opportunities. Ferdinand Porsche started his own business in 1929, when he became unemployed.

Cobranding (combination of the name of two or several brands), in case of takeovers or

strategic alliances – this is the only solution for the brands subjected to mergers or acquisitions. Even if the Great Depression and the ‘73-‘74 one represented the end of the second and the third wave in the history of mergers and acquisitions, the current crises showed us that some companies resorted to such strategies (see the cases of Caroli and Campofrio, which would become Caroli Foods Group, the taking over of Rompetrol by the Kazakhs and their desire to change the name of the fuel stations into *Litro, powered by Rompetrol*, the possible takeover of Zapp by Cosmote for the mobile Internet services owned by Zapp, the takeover of Volvo by Geely). Their decisions could not be more uninspired. The companies that resort to this type of strategies lose sight of the fact that this crisis will not last forever. For example, I wonder how Caroli and Campofrio will act when they see that the economic situation is back on the right track and they wish to be independent again. Acquisitions are

Figure. 1. Brand recommendations, suitable for times of recession

recommended during this period, as they strengthen powerful companies and offer a chance to those that have not come with any solutions to the current crises. Anyhow, it is advisable to use cobranding in order to explain your customers what happened with their favorite brand and to aggressively promote the new identity.

Our recommendations are primarily oriented towards those managers who, so far, have not seen the brand as an efficient weapon for communicating with the consumer. I hope that this article will stir the interest of managers and determine them to thoroughly analyze this phenomenon.

5. Conclusions

The lessons learned by those who experienced the Great Depression and the '73-'74 crisis have already been successfully applied in the current economic and social environment. Nevertheless, this research has been limited by the historical positioning of marketing. We started from the premises that history repeats itself and that marketing is, after all, an ahistorical field [13]. Our recommendations are, however, purely subjective and strictly correlated to historical facts. They invite us to meditate upon the recessions from the past century and to take a critical look at attitudes such as the disregard for rebranding or brand creation and the diminution of the promotion budgets. We must keep in mind that recession comes with threats, as well as with opportunities.

Abstract

The pressure on businesses to incorporate the principles of sustainable development into policies and activities is mounting. Project management methodologies are not excluded from this pressure. The current project management frameworks do not effectively address the three goals of sustainable development, i.e., social equity, economic efficiency and environmental performance. A prerequisite for aligning these frameworks with the principles of sustainable development is a clear understanding of the various life cycles involved in a project and the interactions between these life cycles. The way forward to achieve true Sustainable Project Life Cycle Management in the manufacturing is subsequently outlined.

Keywords: project management, product life cycle, processes, information.

JEL classification: M19

1. Introduction

In today's challenging global market, enterprises must innovate to survive. Business innovation must occur in all dimensions - product, process, and organization - to improve competitiveness and business performance. To differentiate themselves, enterprises must capture, manage, and leverage their intellectual assets. This can best be accomplished through proper application of a Product Lifecycle Management (PLM) approach that addresses the needs of the extended enterprise. PLM is a strategic business approach that helps enterprises achieve its business goals of

reducing costs, improving quality, and shortening time to market, while innovating its products, services, and business operations.

CIMdata Inc. defines PLM as: A strategic business approach that applies a consistent set of business solutions in support of the collaborative creation, management, dissemination, and use of product definition information across the extended enterprise from concept to end of life-integrating people, processes, business systems, and information.

2. The Evolution of PLM

PLM has evolved in much more than terminology. There has been a continuous evolution of what PLM represents, as illustrated in the figure below. Fifteen years ago, custom implementations focused on precise applications wrapped around primarily engineering design data. In the late 1980's, the major emphasis was on how to manage engineering drawings, with limited solutions primarily sold to managers in engineering departments.

Figure 1. The evolution of PLM.

Precisely what product-related lifecycles are companies seeking to manage with today's PLM solutions?

CIMdata defines the overall product lifecycle as comprised of three major, interacting lifecycles:

- Product Definition
- Production Definition
- Operational Support

Figure 2. Major Enterprise lifecycles

Supply chain management was often used by procurement to support the production function. Once the product was in the field, CRM systems helped manage the customer relationship. As described in the previous sections, today's businesses require enterprise solutions

3. PLM definition

CIM data defines PLM as:

- A strategic business approach that applies a consistent set of business solutions that support the collaborative creation, management, dissemination, and use of product definition information
- Supporting the extended enterprise (customers, design and supply partners, etc.)
- Spanning from concept to end of life of a product or plant
- Integrating people, processes, business systems, and information

It is important to note that PLM is not a definition of piece, or pieces, of technology. It is a definition of business approach to solving the problem of managing the complete set of

product definition information-creating that information, managing it through its life and disseminating and using it throughout the lifecycle of the product. PLM is not just a technology, but is a approach in which processes are as important, or more important than data. It is critical to note that PLM is a concerned with "how a business works" as with "why is being created."

Three core or fundamental concepts of PLM are:

1. Universal, secure, managed access and use of product definition information;
2. Maintaining the integrity of that product definition and related information throughout the life of the product or plant;
3. Managing and maintaining business processes used to create, manage, disseminate, share and use the information.

Supply chain management was often used by procurement to support the production function. Once the product was in the field, CRM systems helped manage the customer relationship. As described in the previous sections, today's businesses require enterprise solutions that can integrate all of this disparate information to optimize product development, production, and deployment. CRM data must be used to embody today's customer requirements into the next product generation. To save money, SCM systems must be active from the beginning of the product definition lifecycle, saving procurement time and money while supporting the product development process. Business partners, suppliers, and customers must all have visibility into this information to optimize their decision processes to benefit the enterprise. PLM is becoming the overall view port or portal into such product definition information and processes, providing collaboration and integration functions to synthesize information residing in CRM, SCM, ERP, and other business systems to enable new, complex business solutions.

Relationships Among Enterprise Solutions

Figure 3. Relation among enterprise solution

4. Benefits of PLM—Improving Business Performance

PLM solutions bring benefits to an enterprise's product or service performance in terms of lower costs, higher plant uptimes, quicker delivery, and higher quality. PLM solutions help an organization address customers' needs more effectively, overcoming the competition as a result. Product and service quality as perceived by the customer is of paramount importance in today's business climate. In this important area, PLM solutions help enterprises provide faster response to customer queries; more efficiently design personalized products, leverage previous designs and components, and reduce the number and severity of errors and product changes, to name just a few. Additionally, PLM solutions improve an individual's performance by managing not only product definition information, but by guiding and facilitating their tasks through well-defined business processes and work-flows. PLM solutions have a very positive effect on process efficiency and effectiveness by supporting and encouraging work in a more structured manner and providing the right information, at the right time, to the right people.

5. Project Life Cycle Management

The nature of project management has changed since the 1960s.

Companies in the new millennium are managing projects on a far more informal basis with less paper work by relying on techniques such as "checklists for end of phase reviews". Critical to these informal project management approaches are an appropriate methodology and an understanding of the life cycle phases [6].

Benchmarking studies supports these concepts by concluding that companies, which are successful in project management, all use a company-specific, simple and well defined project management framework that defines a staged approach for all projects under all circumstances. The framework specifies major activities and deliverables for each project phase as well as guideline questions for the phase end reviews or gates. These specifications of deliverables and activities establish a level of management control.

6. Sustainable Project Life Cycle Management

It is thus the asset life cycle resulting from the project, and the subsequent product life cycle resulting from the asset, that have economic, social and environmental consequences, which are in turn associated with an implemented project. Aligning project management (and appraisal) methodologies with the principles of sustainable development therefore requires that the sustainability consequences of these asset and product life cycles must be considered during the project life cycle.

A comprehensive sustainability evaluation framework is therefore required to assess projects during the early life cycle phases in terms of sustainability consequences of the future implemented assets and products. Fig. 4 shows such a framework that has been developed, specifically for sustainability performance evaluations, which can be used business processes. Indicators for each criterion are needed and must then be utilized in the project appraisal process.

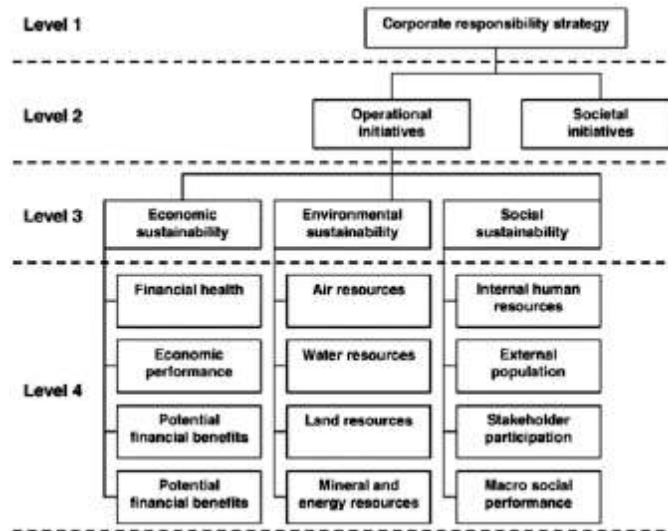

Figure 4. Framework to assess the sustainability of operational activities.

7. Conclusion

More work is required to develop a Sustainable Project Life Cycle Management methodology:

- Indicators for the social sustainability criteria must be refined and are in a process of development. The methodology that will be followed relies on expert panels to determine which social sub-criteria should be dealt with in a corporate governance framework for projects and which in a project itself;
- Furthermore, calculated indicators for project specific criteria are constraint by the type of information that is available (pertaining to the asset and product life cycles) in each project life cycle phase, as well as the available data in the society in which a project is deployed. Case studies of the different asset life cycle phases are being undertaken to establish the suitability of the calculated indicators for.
- The social and environmental indicators must be incorporated into real time project appraisals and decision-making processes to assess the relevance of introducing the indicators into project management methodologies.

The global sustainability trend is forcing companies to internalize social and environmental externalities. The aim of the

proposed future work is to ensure that project management methodologies facilitate this internalization.

The Quality of Romanian Touristic Services and Products

Assist. Ph. D. Candidate Ioniță Roxana
Assist. Ph. D. Candidate Pîndiche Elena

„Dimitrie Cantemir” Christian University-Faculty of Tourism and Commercial
Management-Constanta, Romania

Abstract

The image of a superior quality of a certain touristic service or product represents a major advantage on the market, given that tourists perceive the existence of high risk in connection with the acquisition of touristic travels. Therefore, the increase in the quality of the touristic services provided is the key element in the attraction of a greater number of both Romanian and foreign tourists.

Keywords: services, products, quality, customers, tourism.

JEL classification: M39

Tourism as a phenomenon has a powerful impact upon a country's socio-economic life. Its role may be viewed through the perspective of the large number of natural persons consuming, but also providing, touristic products and services.

Due to its complex content, tourism may be perceived as a stimulator of a country's development because it ensures the economic growth of the other connected branches: industry, agriculture, transportation, constructions etc.

The contribution of tourism to the economic growth can also be emphasized through the perspective of the touristic supply which affects the manifestation and effective realization of demand, which can be considered real and concrete only provided that it has a corresponding supply. Thus, the development of the touristic supply represents the premise for a suitable evolution of the demand, for its modernization, and more importantly for the increase in the quality of touristic services.

Environmental changes impose modifications in the supply of enterprises involved in tourism, which are effected firstly in the improvement of the existing products and services. The improvement focuses on the quality, which means offering customers what they want, respecting the standards and specifications that they want, with a predictable and acceptable degree of conformity and uniformity, within a price range that responds to their needs. In the field of tourism, the assessment of the quality of the services provided to tourists is based upon the customer's perception in comparison with the service delivered [3].

Customers react to a great variety of indices in order to assess the quality of services. Indices are those attributes or characteristics of services based on which customers form their own perceptions, and they can be placed in two categories [4]:

- Intrinsic: those attributes which are part of the service structure and which cannot be changed without changing the service;
- Extrinsic: those attributes, such as price or label, which are connected to the service, but are not indissoluble.

The image of a superior quality of a certain touristic product represents a great advantage on the market, given that tourists perceive the existence of high risk in connection with the acquisition of touristic travels. It has been a fact that for the last few years, more and more Romanians choose to spend their holidays abroad, which brings up a question regarding the quality/price ratio of national touristic products and services. The low quality of the services remains the main problem with which Romania's tourism industry is confronted [2].

One of the strategies which can be adopted to increase the quality in the field of tourist services is the one based on National Program for the enforcement of the Q label, which aims at the enforcement of criteria allowing the total assessment of quality, and of all the factors which can ensure a high degree of customer satisfaction, respectively.

The quality of touristic products depends upon the value and attractiveness of touristic assets, upon the technical performance of the touristic infrastructure, and upon the skills of the staff involved in service delivery. Moreover, it must be emphasized that the subjective customer factor has a strong influence on the assessment of a touristic product's quality level. Therefore, the customer's level of satisfaction following the consumption of the touristic product depends upon the degree of accordance between the actual components of the touristic offer throughout their stay and the image that they had envisioned previously [1].

At the moment, there is a noticeable increase in tourists' exigency regarding the quality of touristic arrangements. Thus, the image or the reputation of a certain touristic product's superior quality represents a major advantage, attracting a host of tourist flows and leading to the development of tourist loyalty. In this context, it must be mentioned that, following the discreditation of a certain touristic product, the restoration of its image requires special long-term marketing efforts, because distasteful experiences create strong impressions which are difficult to change [2].

Generally, the quality level of touristic products can be analyzed from a range of perspectives [2]:

- Regarding natural elements (the beauty and authenticity of landscapes, air and water purity levels, the climate, the flora and the fauna, the hydrographic network, etc)
- Regarding technical elements (the accessibleness of touristic sites, the safety and comfort level of touristic means of transport, the state and the degree of wear and tear of accommodation establishments, noise levels, the visitor carrying and outturn capacity of accommodation equipment, transportation, food, entertainment, city and buildings architecture, etc.)
- Regarding organization (the structure and the execution of the circuit and touristic programs, the number, structure, politeness

and availability of the staff, resort opening and closing periods, the degree of agglomeration of touristic destinations, the time range of service delivery, etc)

When appreciating the quality of touristic products, the consumer considers their price in relation to classification category of the means of transport, the accommodation unit or the food.

If we consider the particulars of the touristic product (consisting mainly of touristic services), its quality depends greatly on the professional skills of the service delivery personnel (their politeness, availability, punctuality, efficiency) [2].

Aspects related to professional ethics (correctness, reliability, honesty) are perceived by the consumer as inseparable from the quality of a product. At the same time, the tourist's perception regarding the quality of the service delivered will depend on the providers' level of involvement. In this context, the assurance of an income level in accordance with professional qualifications and work conditions will have a positive influence on staff perpetuation and, implicitly, on the quality of the service delivered [2].

As far as the quality of Romanian touristic services is concerned, it must be noted that Romania holds an essential advantage in relation to other countries due to its rich and varied touristic potential, being able to provide all the requested touristic forms: visits to the seaside, mountain resorts, balneo-climatic resort, winter sports, hunting, fishing, cultural and religious tourist circuits, agritourism and rural tourism, etc.

Nevertheless, the Romanian touristic potential we are so proud of (mountains, beaches, sun, climate, folklore, history, culture, etc.) is not harnessed enough to represent a real and powerful touristic attraction.

Unfortunately, a study conducted by Horwath, the British consulting company, reveals the fact that Romania is represented in front of foreign tourists by "*an obsolete touristic product, an inadequate recreation and leisure offer, equipment whose physical state reflects the lack of care and investment.*"[2]

The fact is that more and more Romanians choose to spend their holidays

abroad, which brings up a question regarding the quality/price ratio of Romanian touristic products and services. If we analyze the competing foreign offer, another decisive reason can be distinguished: the overwhelming majority of the products provided by countries which represent our direct competitors (Hungary, Greece, Turkey, Bulgaria) provides a much better price/quality ratio, while the safety conditions are at least equal to those in Romania. For example, as a touristic destination, Bulgaria has gained during the last few years a rather large share of the tourists traditionally attracted by Romania, who used to visit the Romanian Black Sea region quite frequently. Between 2006 and 2008, tourism industry represented over 5% of Bulgaria's GDP (Gross Domestic Product), while Romania remained under the level of 4%. Another example is that of Hungary, which exploits its natural resources much more efficiently than we do. Although lacking any mountain resorts, seaside or delta, the Hungarians earn around \$3.5 billion annually from over nine million tourists, while Romania touristic income, despite all the attractions mentioned above, does not exceed a billion dollars.

One of the decisive factors influencing the quality of the services provided is the state of the material resources specific of tourism. In Romania, the material resources are generally old, the infrastructure has degraded and is often obsolete, the equipment is mostly insufficient and outlived, which implicitly leads to inadequate quality. Thus, the quality of touristic delivery is way under the standards to which Western tourists are accustomed. The classification criteria of accommodation establishments have been adapted to the present situation: although the tariffs correspond to a three-star unit, the comfort provided is specific of a foreign two-star unit. Therefore, Romania has become an expensive touristic destination, given that the services are inadequate, and the material resources old-fashioned.

The low standards of public foodservice further contributes to the negative image of Romanian touristic products, in terms of general aspect, atmosphere, quality and variety of the dishes, staff behavior and honesty, inadequate music, as well as the lack of entertainment provided for the tourists.

Due to the lack of infrastructure necessary to accommodate a very large number of visitors

at the required standards of quality, Romania is presented to the world as a niche touristic destination (our country has an inadequate and badly managed roads and highway network which cannot provide optimum conditions for the connection between Otopeni international airport and the mountain or seaside resorts.)

Another problem of tourism in Romania is the mentality of the employees in tourism industry, which is difficult to change, thus leading to the misunderstanding of the psychology and needs of foreign tourists. The staff from Romanian hotels have not yet understood that smiling does not cost a thing; on the contrary, politeness ensures comfort during a holiday, which in most cases occurs only once a year.

Moreover, it is absolutely necessary to ensure a diversified supply of souvenir products. More consideration should be given to maps, leaflets, postcards and handicraft.

All the facts mentioned above prove that, at the moment, Romanian tourism is only sustained by natural resources and historical sites, with only a minor contribution from infrastructure. The quality of touristic services does not attract foreign tourists, on the contrary, it drives away Romanians as well, since they have discovered that, for the same amount of money, they can be provided services of superior quality in other countries such as Greece, Turkey or Bulgaria.

Many statistics prove the fact that, at the moment, Romanian tourism is in a state of decline, and one of the causes of the decrease in touristic demand is the product policy of tourism agencies, which have not taken into account the evolution of the domestic and international market, and consequently have failed to adapt touristic offers to the ever-increasing exigency of both Romanian and foreign tourists [2].

An effective way of invigorating and reviving Romanian tourism consists of the proposal and support of an ample process meant to create some attractive touristic products which would succeed not only in attracting a large number of foreign tourists, but also in determining them to return to our country.

Employees' Motivation, Essential Premise of Performance Ensuring

Ec. PhD. Loredana Iordache
University of Craiova
loredanaordache2006@yahoo.fr
Prof. PhD. Ion Criveanu
ion_criveanu@yahoo.com

Abstract

Preoccupation for what employees want should be one of the main concerns of the companies. That is because between motivation and performance is a reciprocity condition relationship. Practical experience shows that active or talent individuals who aren't appreciated according to their influence on the company tend to leave it. And this appreciation and motivation doesn't have to be represented just by money. Sometimes, a good organizational climate can sustain a long term motivation even if the financial stimulants are fewer. Still, the motivational system must be chosen depending on people you work and reasoning/motivating factors have to be different from a person to another.

Keywords: motivation, performance, climate, employees.

JEL classification: M12

Preoccupation for what employees want, referring to what motivates and offers them satisfaction isn't just a caprice permitted by international company, but their success key. One company's image on market is in a large measure designed by employees' satisfaction. For this, we believe that each manager must understand that the measure in which employee's motivation and satisfaction grow up, this will be seen in company's benefit and in its further possibilities of development.

Although it has an important role in performance obtaining, the most managers grant little importance to this aspect, forgetting or unknowing that the measure in which employee's motivation and satisfaction grow up, company's benefit will grow up too.

In company's management, real sense of employees' actions and behavior can't be discovered without knowing the generator

reasons. Conflicts, sabotages, defensive compartments are just a few of manifesting forms of personnel's dissatisfaction. Intense fluctuation, permanent dismissal is the consequence of performance's flaw, and motivation, implicitly.

Specialized literature treats in great deal motivation problem, and for this reason, many times the theories are contradictory. With all off this, from conceptual point of view, there is a unity, great majority of definitions completing each other.

So, P. Golu had defined motivation as being: "subjective model of objective determination, determination which is psychically reproduced, gained in time, transformed and transferred through knowledge in individual internal acquisition."

From managerial conception's point of view on which it is basing, we can see two major motivation's acceptations¹:

- motivation in the restrictive sense, based on a classical company's and management vision, which refers only to the employees or company's personnel. This means the correlation of necessities, aspirations, and personnel's interest with realizing objectives and exercitation of charges, competences and responsibilities' attributed into organization.

- motivation in the extended sense, based on a modern vision through organization and management.

Its essential characteristic is constituted by focusing on stakeholders, on those persons, personnel's categories and organisms which have major interests in company's progress and performances.

¹ Nicolescu O., Verboncu I. "Management"- Ed. Economica, 1999, pag 471

Through this definition, we can say that motivation represents decisions and actions ensemble which determines company's stakeholders to contribute directly and indirectly at functions and superior performances realizing, basing on correlating their interests in approaching and realizing company's and subsystems' objectives.

Analyzing those two definitions, we can praise two important aspects:

- internal company's conditions, which have the main role in motivation can't be observed and isolated when we are analyzing a comportment. Reasons as security or value's recognition can't be seen. What we can observe are just resulted comportments of these internal needs

Because of this, a lot of aspects regarding motivation involve some models' building and using some specific terms which describe unobserved processes.

- one motivation's result in the action. With another words, people are responding to their internal needs through activities which they consider satisfaction's generating.

In practice, the phenomenon of human resources training gravitates around motivational force. This is the factor which determines performance's realization.

In labor context, motivation can be regard as being availability's extent of employees to involve in their labor and to make sustained efforts in some professional's objectives attainment, individual or organizational defined.

So, motivation can be more considered as being the result of interdependence between individual and the organizational context in which he is doing his activity, than a result of individual motivations' dominances.

About performance, it is obviously the fact that between motivation and performance is a reciprocity condition relationship. When there is an overlapping between individual expectations and organizational demands, there is the chance of obtaining professional performances, and in the other case, performance being more difficult to be obtained or maintained².

Motivating people means to cash reward their contribution to company's progress, initiative, effort and successful, and also to develop for

themselves the utility given by subjective dimension of work.

Many Romanian companies do not understand that equal repartition of incomes has a motivational effect. Cash rewording's difference depending on efficiency, qualification and successful is an efficient way of motivating. Practical experience shows that active or talent individuals who weren't different appreciated had left the company. Other tried and even succeeded to obtain in existing system a form of power's exercitation through machination and domination.

We consider it is necessarily for each firm to create a salary system and motivated material advantages, without diverting from competitiveness and managerial equality's rules.

Together with material motivation, important role revenues to motivation basing on not cash reward. Many studies show that many categories of individuals can be motivated in their actions on other ways than material ones.

In the paper named "The form and content of industrial democracy", published at London in 1969, Emery and Thorsrud shows seven psychological needs which determine the individual to work: the need of hiring his physical resistance in a labor less monotone, the need of knowing through work, the need of knowing work's nature and the way of realizing it, the need of taking decisions and to have initiative, the need of acknowledgement in organization's frame, the need of putting his activity in company's activity and linking his life to the organization's one, the need of ensuring the future.

It is true that identifying main reasons can be a difficult process many times, because there is the risk that managers take into account their own motivations when they appreciate the ones of their collaborators. With other words, knowing real reasons of employees, do not have to be an intuitive process, and it must has to base on a whole motivational tools. It is very easy to have wrong ideas referring to what makes people to work or not. If the diagnostic in wrong, the measures destined to correct existent situation could be improperly. For this, knowing employees' reasons, and also the

² www.winmark.ro –Employees' motivation ans satisfaction

actions made by managers for determining them to use their whole physic and intellectual reserves, for established performance level's attainment, could represent optical chance which certain lead at workers motivating.

For motivation, and implicitly performance's realization, we consider that Romanian companies should take into account the following aspects:

- potency own trust of the employees, with the scope to motivate them for hiring in complex activities
- work valuating through creating opportunities, for satisfaction obtaining and unsatisfactory avoiding or through making a climate of appreciating well done work
- ensuring constructive competition and ensuring a simulative salary system.

A lot of managers consider that according a good salary is a sufficient factor for growing employees' motivation. In reality, motivate factors are different from a personnel's category to another. The attention which must organizations accord to motivating and retaining is bigger in the conditions in which Romania is confronting with an important crisis on labor-force market. It is very important for the employers to find the best solutions for employees' motivation. Generally, people leave organizations when they consider that aren't motivate by actual work-place. In fact, motivating an employee must be followed with attention from the selecting phase. Big majority of recruiters especially try to find motivated employees. A new motivated employee could bring a positive change in the company.

There are some factors, like low salary level, unpropitious work conditions, inequality of employees' salaries, different treatments for organization's personnel, organizational climate, and all of them lead to employees' un-motivation. I personally consider that treating motivation and employees' level of satisfaction must be seen in two ways:

a) un-motivational factors, which affect the entire personnel, referring here at communication flaw at company's level, for example, or at organizational culture and climate.

b) un-motivational factors on personnel's categories, understanding here that some factors, as low salaries' level is an un-motivational factor for a personnel's category,

while for another category, appreciation's flaw is an un-motivational factor.

Practically, a demand once satisfied, the employee will desire more and he will reconsider his motivation. Usually, what had motivated the employee in the past does not motivate him now.

Salary's growth, an attractive package of benefits, job's attractiveness, responsibility, job's autonomy and authority, successes acknowledgement, professional development are psychology factors which bring extra motivation to the employees. This is a very important way of motivation, especially for low or medium hierarchy's level employees. The idea that money motivates people, and people work only for money isn't always true. For a short period, money can motivate, but on long term, employees form an uninteresting job, which a tensed work-climate will prefer an improving of personnel's conditions to a salary's growth. A salary's growth will never been a motivational factor if it will grow in the same proportion to all employees, for example, including here even the ones with lower results.

On the contrary, if an employee is expecting, basing on his results, to have a higher salary growth, and it will be under his expectations, he will feel unmotivated. For such employees' categories, especially for management personnel, salary's growth stops to be the main preoccupation, and an attractive benefits package will take the role of stimulating labor's effort.

The job itself can offer the most and important rewards. An attractive job is one which offers you satisfaction, which makes you to permanently wish to perform at your job. When employees are well instructed, they want to have performances at their jobs and they are motivated.

Promoting, hierarchy ascending, is a main motivational factor and a way of appreciating. Employees' possibility of professional development, through participating at different trainings, through their involving in different projects or through their participation at different decisions' taking, is an important motivational factor.

Obtaining some good results motivate people, but realized performance's

acknowledgement and its adequate reward are real motivational factors. On the contrary, a job's successful which wasn't recognized can demotivate.

We consider that realizing a concordance between job and employee is a very good way of motivation. If right employee is on right job, he will be very motivated to fulfill his demands. Extending job's attributions can be a way of employee's motivation. We believe that it is very important to know the job very well, from recruiting phase, to know what kind of personnel to hire.

An important role in employees' motivation is the attitude to the employees. Although in theory, big majority of specialists consider that management style should be chosen depending on what motivates the employees, we consider that things are exactly against, in practice. In most cases, a manager will chose in his team a person able to adapt to his management style. A manager with an authoritarian management style will never accept to hire a person who has high ambitions and who contradicts him in any dialogue, and, if he will have such a person, he will never be able to motivate him.

Motivational system must be chosen depending on people you work with. A thing which represents for ones a motivational factor, for others does not represent anything. Founding best solutions for motivating people means their performances' appreciation.

As a firm, you can't have performances if you do not motivate people. A performing motivational system means little personnel fluctuation and the firm's image on the market. It is essential that each company creates its own motivational system, taking into account its personnel's categories and its preoccupation to satisfy its employees.

In case in which salary is correlated with performance, this becomes a motivational factor. But if salary increases in the same measure for all employees, we can't consider it a motivational factor.

One of proposal linked to employees' motivation refers to the principle of "compartmental reinforcement", concept introduced by B.F. Skinner and continued in what we call today the new-skinnerian model. The idea of this concept is that if we want to module employees' comportment in a certain direction, we can introduce in daily practice and to use systematic rewards, for encouraging such

a behavior. At the beginning of this process, motivational system must be constantly realized, and after that it can be realized just occasionally, for maintaining this behavior.

Unlike the motivation of salaries' growth and benefits, behavior's reinforcement motivation can be less expensive and it depends in a great measure of creativity and external opening which is detained by decision's factors through motivational phenomenon, but, surprising, their impact can be considerable.

Some specialists have identified a series of techniques regarding behavior strengthening³:

- social increase: verbal comments to congratulate the employee, facial expressions and gestures (a smile, an encouragement, gratefulness)

- graphic increase (a badge, a flip chart having the name of the employee of the month on)

- activities strengthening (more free time)

As you can see, the purpose of these motivating methods is to recognize the employees' desert and to supply feedback for the accomplished performance.

We consider that we should insist on this motivating ways because these aspects could be used as they are, can be improved or combined, according to every activity. Most of the managers consider that a raise or some financial benefits express the content that they have towards employee's work. Studies have demonstrated that although the man is satisfied by these benefits for the moment, he feels frustrated by the lack of feedback. They end up thinking that these financial benefits are just a payment for the given effort, but not increase motivation and satisfaction for the work that the have done

A different aspect that managers neglect instead of develop is that they should focus more on teamwork motivation. To build a team is a very difficult thing, but it is even more difficult to know how to motivate their teamwork. In order to motivate a team you have to make each person to feel like a part of the group. You also must have a set of values and directions that they all accept and

³ Charles, C.M. Building Classroom discipline, Longman, London 1990 pg 26

a performance rewarding system that they all know and approve

Managers have to encourage the people that they are working with into becoming a team and constantly sustain them as a team to gain proficiency, by stimulating every member to work at his maximum potential. Motivation must also come from every employee and generate competition. This way the key elements of professional motivating, personal a professional developing, own value recognition, will come natural.

A manager cannot ask his employees to motivate themselves, but can create a climate that motivates them. Both organizational culture and climate influence the employees' performance. In order to have a positive impact on it, the organizational culture is to be spreader and accepted in the entire firm. Managers should still identify the cultural elements and tensed situations inside the company and turn them into attitudes, values and behaviors that favor objectives' fulfillment. Identifying the firms' organizational culture has an important role in the human resources activities.

Observing problems like personnel fluctuation, work attendance, work relations indicate problems that were connected to a weak motivation.

In certain periods, financial or moral stimulants can be a motivation for the employees but we consider that a good organizational climate can sustain a long term motivation even if the financial stimulants are fewer.

Finding the best methods to stimulate the employees shows up in the firms' success. We often wonder why some companies are wanted by candidates, and why others cannot find the right people although they offer good salaries. The organizational climate, the preoccupations with the professional employees' development, job's attractiveness, are some of the things that plead for the wanted firms, disfavoring the other firms, that even if they offer good payment, they do not have the same motivations.

Abstract

Within the Leonardo da Vinci Program, phase II(EAC/11/04)-2006- the first priority pilot project “Development of new measures and tools that describe, promote and compare standards and qualifications at a European, national and divisional level”, there has been developed the New Hospitality Project (European Works without Borders). The project has run between October 2006 and October 2008 and has gathered partners from various countries. The accomplishment of research activities has contributed to the identification of methodologies and instruments of description, comparison and promotion of qualifications and competences within the hospitality industry, supporting transparency, recognition and transferability for developing employment opportunities and increasing sector’s competitiveness in the European related area. Desk research aimed towards the study and the analysis of demand and supply in the hospitality domain, the employees’ position in the hotel sector and the utilized competences and abilities certification systems.). Desk research was completed by the development of a report made by each partner while the project coordinator has collected contributions of all partners and compared the results. Field research is based on desk research due to the fact that during this stage the common elements that appear (as well as the characteristics of hospitality structures and professional qualifications), are main indicators for both the construction of the sample and for the utilized tools content. The entire research done within the New Hospitality project has created an important database of information concerning minimum criteria for competency necessary in the hospitality industry.

Keywords: Leonardo da Vinci Program, The New Hospitality Project, research, market.

JEL classification: M31

1.Introduction

Within the Leonardo da Vinci Program, phase II(EAC/11/04)-2006- the first priority pilot project “Development of new measures and tools that describe, promote and compare standards and qualifications at a European, national and divisional level”, there has been developed the New Hospitality Project (European Works without Borders). The project has run between October 2006 and October 2008 and has gathered partners from various countries: **Bulgaria** with the National Chamber of Commerce and Industry (BCCI) and the National Tourism Research Institute; **Italy** with the Italian Centre of Advanced Studies of the Tourism Studies and Tourism Promotion (CST) - project coordinator and Federalberghi, Work Italian Union (UIL)–TuCS; **Malta** with the Tourism Studies Institute and Malta Union of Teachers (MUT); **Romania** with the Chamber of Commerce, Industry, Shipping and Agriculture, Constanta (CCINA), “Ovidius” University of Constanta, the Faculty of Economic Sciences and the Cross-border Association for Training and Vocational Mobility, Bucharest (AS.FOR.M); **Slovenia** with the Centre of the Republic of Slovenia for Vocational Education and Training (CPI) and the Workers Syndicate within the Hospitality and Tourism Industry, Slovenia (GIT).

The increasing labour force mobility in EU, as well as the technical and organisational structural mutations within the labour sector

have altered the qualifications profiles required by workers in this sector, emphasizing the increasing need of harmonizing the professional qualifications on the European labour market.

2. Projects' objectives

The New Hospitality Project's main objective has been represented by the analysis and the implementation of a European system of qualifications and standards within the hospitality sector for a borderless transparency and recognition. The following specific objectives have been established: (1) elaboration of a methodological toolkit for analysis and description of professions within the hospitality industry; (2) defining comparable and divisional competences and their examination according to the activity and training sector; (3) promoting transparency of competences by means of creating a concrete mechanism for competences' description and qualification within the integrated system of the EUROPASS tools. Within this context, the New Hospitality Project has meant the implementation of several activities during the two years of development: (1) a stage of defining methodological and research instrumentation; (2) a stage of economic and contextual analysis of the hospitality sector in the partnership countries, during which besides outlining the framework of reference in terms of demand and supply and operational business indicators within this sector, there have been identified both the related competences and the systems that are able to certify these skills; (3) a stage of divisional research within the hospitality industry, by which, with the help of questionnaires distributed to both employers and employees, it managed to create a repertoire of competences that correspond to the new communitarian directives regarding qualifications' transparency.

The accomplishment of research activities has contributed to the identification of methodologies and instruments of description, comparison and promotion of qualifications and competences within the hospitality industry, supporting transparency, recognition and transferability for developing employment opportunities and increasing sector's competitiveness in the European related area.

3. Research organization in the New Hospitality Project

The New Hospitality Research has been characterized by three dimensions. The first one, having a cognitive character, tends to analyze the phenomena and the problems in different partnership countries by means of special chosen indicators and parameters for examining different aspects. As a consequence, the second dimension has to offer an interpretation of the examined phenomena, in order to attract the attention from the sector's environment to a broader context, which includes the economic aspect. The third one, the comparative analysis should allow the identification of both common and divergent factors within different European contexts of the hospitality industry in order to reach a homogenous referential frame which is necessary for the realization of the competences' cross-border repertoire.

The research has developed under a quantitative and qualitative aspect. The economic analysis of the hospitality sector and of the competences certification system (specific to the sector) within the partnership countries has been accomplished thanks to a set of indicators chosen in a way to be: (1) significant for the evaluation's purpose; (2) relevant for the examined reality; (3) easy to be measured in different geographical contexts, by means of a data series that can be compared in time; (4) easy to understand even by an uninformed public; (5) synthetically and capable to offer a considerable amount of information in a numerical value.

4. Desk research within the New-Hospitality Project

Desk research aimed towards the study and the analysis of demand and supply in the hospitality domain, the employees' position in the hotel sector and the utilized competences and abilities certification systems. The structure of the desk research has been the following:

- *In-depth examination of the rules in force in the Partnership nations, regarding the regulation of authorization and classification of hotel structures.* The main characteristics of the public tourism organizations (from the following countries

participating in the partnership: Italy, Bulgaria, Malta, Romania and Slovenia) have been defined, in order to offer a subsequent better comprehension of the functional mechanisms in force for the hotel system, namely, their classification and the related criteria, the regulations for obtaining authorization to open and run such structures and the price regulation regime.

- *Survey of the rules in force in the partnership nations, pertaining to labour contracts in the hospitality industry.* For a more profound and complete comprehension of the context in which the various professional figures of the hotel industry operate, a comparative analysis has been made of the various labour contract typologies existing in the countries of the partnership by delineating the essential outlines of the different juridical reference institutions.
- *Economic, cognitive, interpretive and comparative analyses of the hotel industry in the partnership countries.* An economic analysis of the hotel system in its peculiar productive characteristics was made on a level of the individual countries.
- *Analysis of change trends in the hotel sector of the partnership nations.* In the awareness that consistent change trends are in act, it was necessary to delineate an overview of the trends that will have greatest repercussions on the professional figures in the hotel industry, in the form of new professional competences and knowledge.
- *Analysis and comparison of professional profiles and relational competences in the national hotel sector.* In this context, cartography of the competences existing in the hotel industry has been created, facilitating the identification of the standard professional profiles, where different qualifications emitted by certification national systems have been placed.
- *Analysis and comparison of the existing certification systems in the partnership nations.* The aim of this specific research activity has been to define the position of the competences and certification system within the professional training and education domain in regard to the hospitality industry in the partner countries. We can also mention that this research has been a

qualitative one in which there had to be presented the strong/weak points and the evolution lines of systems presented in each partner country.

Each country partaking in the project has developed, depending on the geographical area activities, the following activities: (1) economic analysis in the hotel industry (the national legislation analysis in tourism, the economic and structural analysis in the hotel sector, the analysis of operational professional profiles and related competences in this sector); (2) analysis of certification system (an overview upon the competences certification's related laws, focusing upon the competence of the professional indicators in the hotel industry).

As a consequence, the desk research has been directed towards the study of two structures: a cognitive (analysis of territorial reality within a sector, using common indicators and parameters) and an interpretative one (analysis of the hotel sector from the touristical area of every participating country). Desk research was completed by the development of a report made by each partner while the project coordinator has collected contributions of all partners and compared the results.

Desk research allowed us to identify the specific characteristics of the hotel sector in the geographical zones of the partnership countries, affecting directly or indirectly both the existing developing professions and their competences.

5. Direct research in the New-Hospitality Project

Field research is based on desk research due to the fact that during this stage the common elements that appear (as well as the characteristics of hospitality structures and professional qualifications), are main indicators for both the construction of the sample and for the utilized tools content.

The field research aims towards two objectives: (1) to test and validate the cartography of competences (being made during the desk research process); (2) to indirectly offer the training feedback to the examined participants by creating a comparison between the ideal and what is actually real, between what is perceived and what is really wanted, between what exists and what should be obtained.

The labour methods utilized in field research involves:

- a determination of the examined sample regarding the industry and the direct interlocutors (entrepreneurs/managers and workers) who have been asked to explain the expectations they have from various positions;
- the elaboration of questionnaires which are based on the competences models that resulted in the desk research;
- the validation of questionnaires using the Delphi method;
- the administration of questionnaires to the entrepreneurs/managers and workers who should accomplish an evaluation and a self-evaluation of the requested/possessed competences, and who should also express their opinion regarding the importance a set of necessary technical and specialty competences has.

The instrument for validation and integration of the competence model elaborated during the desk research phase has been represented by two types of competence model assessment questionnaires with identical content, but which have different question formulations for the 2 samples of entrepreneurs/managers on the one hand, and workers within the hospitality sector on the other hand.

The questionnaire has offered a cross profile of the heterogeneous assessments (comparison with the competences model) and self-assessment (comparison with personal human resources for entrepreneurs/managers; workers' self-comparison in exercising the professional role) on the subject's analysis and self-analysis at a level of competence.

From a formal point of view, the questionnaire has been made of grids for each examined profile and will contain lists of competencies by means of each the investigated person should indicate as according to his/her opinion the presence/absence of certain competences and assess the general importance of the selected competences model.

The New Hospitality field research has been structured in 4 sections:

- first section – Methodology and research tools (there have been established: the aim of the research, the researched sample, research questionnaires and data collection methods);

- second section - Collection and analysis of field research results;
- third section - Results comparison;
- fourth section – Repertoire of competences.

At a trans-national level, the hotel sample which comprises 167 units is represented with priority by structures situated in both the seaside localities (47.3%) and in the cities (21%). The most representative part of the sample is made out of 4 star hotels (41.3%), followed by 3 star hotels (38.9%) and 2 star hotels (10.8%); the higher and lower categories have reached 7.2% (5 star and more than 5 star hotel) and respectively 1.2% (1 star hotel).

Out of the total number of one hundred and eighty workers chosen to participate in this research, 47.2% work in 4 star hotels and 33.3% work in 3 star hotels, while 15% operate in high class hotels (5 stars) and 4.4% in 2 star hotels. 41% of the interviewed workers activate in hotels within the cities, 31.7% in seaside structures and 12.8% in spas. 46.1% of the interviewed workers activate in small and medium accommodation structures, while 44.4% work in hotels of big dimensions (over 151 rooms). In this sample the participants are 56.7% females and 42.8% males.

6. Results of research carried out during the New Hospitality Project

The results obtained through the New Hospitality Project research are:

- the research kit stands for an efficient tool in harmonizing the profit criteria of desk and field research among partners;
- the New Hospitality desk research which contains the study and the analysis of demand and supply within the hospitality sector, as well as of the utilized skills and abilities certification systems;
- the field research which includes the results of the conducted research based on questionnaires for employers and employees within all national contexts of the partner countries;
- database for the New Hospitality criteria of competence which comprise information about the minimal criteria of competence in regard to the hospitality sector.

- New Hospitality Europass – it has been elaborated the software and the related instruction manual that will guide workers in this sector in drawing up a European Curriculum Vitae (concerning the individual skills/abilities section) in order to ensure eligibility of the contained information.

7. Conclusions

The New Hospitality research has highlighted the similarities and the differences regarding the tourism workers' technical-professional competences in the partnership nations; it has accomplished their harmonization and it has reached the conclusion that those who work in the tourism field should possess a neutral image of the whole system, namely a distribution of competences and their means of working together. It is essential to establish and promote measures that assure an initial and/or continuous

professional development of personnel within tourism, in order to respond to the modifications and the tendencies of the European labor market.

The obtained results have determined the members of the project to start new research programs with the view of harmonizing qualifications and competences within the food industry and within other activities in tourism.

Is the Behaviour of Tourism Services Consumers Different According to Gender?

Quantitative Research in the Centre Development Region

Assist PhD Erika KULCSÁR

Faculty of Economic and Business Administrations Cluj Napoca, Romania
elerhetetlen@yahoo.com

Abstract

As shown by the relevant literature the consumer behaviour of women differs from that of men. Women go shopping not necessary from need, but for the feeling of delight, the shopping is not in rush, they go shopping in the company of friends, spending hours in shops selecting very carefully; in terms of consumer behaviour of men, it is opposite to the feminine one. This paper includes a series of bivariate analysis conducted in order to find an answer to the question which is actually the title of this paper.

Key words: consumer behaviour, assumptions, Mann-Whitney test, Kolmogorov-Smirnov test.

JEL classification: M31

1. Introduction

Consumer behaviour is defined as his/her acts, attitudes and decisions on the use of his/her income for purchases of goods, services and savings. [4]

The theory of consumer behaviour has become, in the last half century, especially after the emergence of the modern marketing concept, a distinct and important field of marketing, able to give many competent answers as in this case. [2] Studying consumer behaviour is unthinkable without marketing research. It is also true that by univariate analysis important information can be obtained but it is a first level of analysis of marketing data.

The bivariate analysis can be considered as a second level of deepening the investigation of primary marketing data. The

analysis considers the research of the link between two variables that can be measured with the same scale or each with different scales and the analysis of differences that may exist between two groups or populations in terms of a given variable. [3] For carrying out the statistical tests I have covered the following stages: first I formulated the H_0 and H_1 hypotheses, I chose the level of significance, the next step was to establish the theoretical distribution used for testing hypotheses, the calculation was made by using the SPSS program.

At first I worked on the data obtained through a quantitative marketing research. The questionnaires were distributed to hotels in Braşov, Predeal, Poiana-Braşov, Sfântu Gheorghe, Covasna, Miercurea-Ciuc, Gheorgheni, Tuşnad, Târgu-Mureş, Sighişoara, Sibiu, Alba – Iulia and other localities that have linked this route.

I distributed over 2,000 questionnaires.

The quantitative research was conducted between 15.05.2009-17.10.2009.

This marketing research included a number of 410 questionnaires.

Next I will present the results attained based on the information obtained through questionnaires.

2. Parametric tests comparing differences between two groups of people

Testing differences between means

For the test I started from the assumption that there is no difference between male and female regarding the mean of assessments on the possibilities available for spending leisure time.

Thus, the statistical assumptions are:

$$H_0 : \mu_1 = \mu_2$$

$$H_1 : \mu_1 \neq \mu_2$$

For the group of 180 female of the total of 410 subjects who provided an answer to this question the mean of 3.66 points was obtained, with a deviation of 1.095. At the level of the group of male the mean is 3.68 points with a deviation of 1.057. The difference between these means is 0.02 (Table no. 1)

„Table 1 Descriptive Statistics at the level of the two groups”

Gender	N	Mean	Std. Dev.*	Std. Error Mean
Male	230	3.68	1.057	.070
Female	180	3.66	1.095	.082

* Deviation

First I read the results of the Levene test. $F_{\text{calc}}=1.582$ value (Table no. 2.) was compared to the theoretical value of $F_{0,05;1;408} = 3.84$. It can be seen that the critical ratio is less than the theoretical value, therefore we can not accept the existence of differences between variances of the two groups. The same decision was taken also based on the level of significance that can accept H_1 . It is 0.209, being higher than 0.05, so the null hypothesis is accepted. Since the variances of the two groups can be equal, I analyzed the results of the first data row of Table no. 2, due to the assumption of the hypothesis of equal variances of the two groups. $t_{\text{calc}} = 0.253$ is lower than the theoretical value $t_{0,05;408}=1.96$, so therefore H_0 is accepted.

„Table 2 Testing the difference between the means of the two groups”

Levene's Test		t-test for Equality of Means			
F	Sig.	t	df	Sig.*	Mean Diff.
1.582	.209	.253	408	.800	.027
		.252	378	.801	.027

* 2-tailed

The same decision was made also based on the level of significance, which is found on column Sig. (2-tailed). Since this level has the value of 0.800, so higher than 0.05, the H_0 hypothesis is accepted, namely that the two means are not different at the level of total population. The signs of the ends of the confidence interval are different which means that the interval includes the 0 value, thus the null hypothesis is accepted.

Testing differences among percentages

Starting from the percentages obtained at the level of the two independent samples we can test whether there are differences between the two population groups under certain conditions of probability. [1]

Statistical assumptions are made as follows:

$$H_0 : \pi_1 = \pi_2$$

$$H_1 : \pi_1 \neq \pi_2$$

I shall try to test the existence of a difference in the total population regarding the percentage of those who traveled alone to accommodate in the Center Development Region among female as compared with the percentage for male.

At the level of the sample, the mean of the two groups for the dichotomic variable analyzed are 0.44 for male, and 0.42 for female. These values converted to percentages means that 44% of male have traveled individually, while among female 42% have traveled alone. The standard deviation in the first group is 0.498 and in the second group 0.494 (Table no. 3)

Table 3 Percentages and descriptive statistics in the two groups”

Gender	N	Mean	Std. Deviation	Std. Error Mean
Male	230	.44	.486	.033
Female	180	.42	.494	.037

From Table no. 4 it can be seen that for the test "Levene's", the minimum level of significance that can accept alternative hypothesis is 0.275. Since this is higher than 0.05 we can not guarantee a 95% probability that the variances of the two groups are different. $t_{calc} = 0.543 < t_{0,05;408} = 1.96$, which means that the null hypothesis is accepted. The same decision can be taken also based on the minimum level of significance that can accept H_1 . Since this is higher than 0.05 (Sig.-2tailed = 0.588), the null hypothesis is accepted. Analyzing the discrepancy between the two percentages it is noted that it is 2.7%. At the level of the total population, the confidence interval for this difference is between [-0.070; 0.124], containing the zero value which means that the two percentages can be equal.

„Table 4 Testing the difference between the percentages in the two groups”

Levene's Test		t-test for Equality of Means			
F	Sig	t	df	Sig.*	Mean Diff.
1.194	.275	.543	408	.588	.027
		.543	386	.587	.027

* 2-tailed

Kolmogorv-Smirnov Test

Kolmogorov Smirnov Test is a nonparametric test used to test differences between two independent samples. [6] Based on Kolmogorov-Smirnov, I shall test if the views on the statement “The room is furnished aesthetically” are different depending on the gender of the respondents. H_0 = Maximum difference between the two

cumulative frequency is zero H_1 = Maximum difference between the two cumulative frequencies is different from zero

„Table 5 Distribution of percentages according to the two groups”

	Gender		Total
	M*	W**	
total disagreement	4	0	4
disagreement	26	6	32
neither agreement nor disagreement	30	36	66
agreement	74	84	158
total agreement	90	52	142
Total	224	178	402

*Man

** Woman

The sizes of the two groups of respondents to this question at the level of the sample were 178 women and 224 men. (Table no.5)

„Table 6 The values calculated for the Kolmogorov-Smirnov test”

		The room is furnished aesthetically
Most Extreme Differences	Absolute	.110
	Positive	.100
	Negative	-.110
Kolmogorov-Smirnov Z		1.092
Asymp. Sig. (2-tailed)		.184

a Grouping Variable: Gender

$D_{calc} = 0.110 < D_{\alpha} = 0.195$ so H_0 is accepted, i.e. between the two groups there is no difference. By analyzing the minimum level of significance for which we can accept $H_1 = 0.184$, we can draw the same conclusion, that the null hypothesis is accepted. (Table no.6)

Mann-Whitney Test

The *Mann-Whitney test*, also known as *Wilcoxon-Mann-Whitney* or *rank-sum test*, is used like the previous test to assess whether two independent samples were drawn from the same population, or from populations with the same distribution, for the variable being tested, which is assumed to be at least ordinal. [5]

As a first step I established the two hypotheses, meaning that H_0 indicates that there is no difference between the two groups in terms of the analyzed variable, and H_1 expresses that there is a difference between those groups in the analyzed population.

In this part of the essay I will test the existence of a significant difference between the two gender categories with to the importance of the services quality in choosing hotel.

Following the application of the test I obtained the table containing the size of each group in the sample, the rank sum and average ranks.

„Table 7 The sum of the ranks for each group”

Gender	N	Mean Rank	Sum of Ranks
man	230	204.42	47017.00
woman	180	206.88	37238.00
Total	410		

The sub-samples are of large dimensions, both being more than 30 people. (Table no.7)

„Table 8 Values corresponding to the U test”

	Services quality
Mann-Whitney U	20452.000
Wilcoxon W	47017.000
Z	-.220
Asymp. Sig. (2-tailed)	.826

a Grouping Variable: Gender

The decision can be taken based on the values calculated $Z_U = -0.220$, which is compared to the value in table of the level of significance $\alpha = 0.05$. It can be noted that $Z_U = -0.220 > Z_{\alpha/2} = -1.96$, therefore null hypothesis is accepted. The decision may be taken based on the level of significance. It has the value 0.826, higher than 0.05, which determines us to accept the null hypothesis. (Table no. 8)

3. Conclusion

Following the bivariate analysis we can not guarantee with a 95% probability that:

- the means related to the appreciations of the possibilities of leisure in the Centre Development Region during the stay at the level of the two different groups are different at the level if total population,
- between the percentages of people who have travelled alone at the level of the two groups there is a difference in the total population,
- between the two groups there are differences in terms of opinion regarding the arrangement of the rooms,
- between men and women there is a difference in terms of the importance given to the quality of services as the criteria underlying the choice of a hotel.

As a final conclusion I can state that there are no differences between the behaviour of the tourist services consumer by gender, at least in terms of the variables analyzed.

The evaluation of job satisfaction – study conducted in the organisations from Bucharest

Viorel Lefter

The Bucharest Academy of Economic Studies

vlefter@ase.ro

Ramona Ştefania Puia

The Bucharest Academy of Economic Studies

Ramonapuia@gmail.com

Abstract

The increasing of employee job motivation represents for the human resources departments a strategic objective to enhance performance and achieve the fundamental objectives of the organization. But we can not substantiate methods to improve employee motivation without knowing the reasons for their dissatisfaction. In this paper we intend to do a quick review of the most popular models for assessing the degree of job satisfaction used in Europe and to present some preliminary results of a study evaluating the job satisfaction of employees in organizations in Romania led, currently in Bucharest organizations.

Key words: motivation, job satisfaction, human resources.

JEL classification: M50, M12

Introduction

In order to achieve political and strategic directions to improve motivation and job satisfaction of employees in Romania, is absolutely necessary to evaluate the decisive factors influencing satisfaction, motivation and work performance of employees in different countries of Europe, more developed in terms of management practices. We can not keep in mind that a generally valid recipe at European level can only be a utopia, especially given the existing mosaic of cultures and particularities of each country, its historical background and level of development. We can only to draw some conclusions based

on different surveys conducted in several European countries and to build a new approach of the employee job motivation in Romania. In this paper we tried to point out some of the methods used in Europe to assess employee job satisfaction and to highlight some of the main factors influencing the motivation of employees.

The European Motivation Index

In Europe, there is intense concern regarding the employees' level of satisfaction and whether they are motivated to provide the quality of work in accordance with the standards set by the organizations. One of the most significant indicators calculated at an European level is The European Motivation Index, an initiative of Efectory organization, one of the largest organization concerned with research related to the workforce in Europe. The European Motivation Index provides valuable information regarding the satisfaction, the motivation and the commitment of the employees throughout Europe, but also other critical variables in human resources management.

The European Motivation Index makes an average of the scores obtained in various European countries and takes into account the direct dependence of these values of the factors that may influence the human resources such as management style, development opportunities offered by each organization, the degree of internal communication, etc.

The human resources variables (HR variables) incorporated by this indicator are based on reliable conclusions obtained

through the analysis of different theoretical models. The variables also took into account the trustworthy opinions of the best known specialists in human resources.

Traditionally, human resource management aims the welfare of employees by monitoring and increasing job satisfaction. Satisfaction is actually the key factor in creating a pleasant working atmosphere and increased productivity. Every organization wants to increase performance, and this is directly dependent of the work conducted by employees.

The first variable considered in the indicator of motivation is the commitment of European employees. Commitment enables the organization to grow up and be competitive on the market. It is a key variable in determining employee performance. Commitment implies the strong relationship between the employees and the organization. This link motivates the employee and determines their employment outcomes. Commitment can take three forms:

Affective commitment – an employee remains in the organisation because he wants this, because he identifies himself with the organization;

Normative commitment – an employee stays in the organisation because he feels compelled to continue working;

Long-term commitment - an employee remains in the organization since his departure personal costs are too high: for example, where age no longer allows him to find another job.

Of course, ideal would be for any other company to have employees who are bound through an affective commitment to the organisation, bringing added value and being determined and proactive when working and contributing decisively to the high quality of products and services.

Another variable considered by The European Motivation Index is the involving of the employees in their work. This can be defined as the degree to which the employees of an organisation express their passion for work. Passionate employees accumulate a larger amount of information in a much shorter time and express their creativity. They could be characterised as the ambassadors of the organisation, as the

involvement determines them to focus on the company's objectives and achieve the expected results expressed by the management of the organization. Involvement often causes customer satisfaction, reduced turnover rate and efficient services.

The third variable considered is employee satisfaction, the satisfaction that one feels from the experiences of the workplace. Satisfaction enables employees to work in a more enjoyable, stimulating and facilitating performance work process. This variable is one of the most frequently measured in Europe. The organizations are aware of the fact that dissatisfaction determines only disregard, absenteeism and bigger turnover rate in the company. Satisfaction degree may vary depending on the size envisaged. For example, an employee may be content with his work and less satisfied with the opportunities he has in terms of financial rewards or career perspectives.

The most important variable took into account is, of course, the motivation of the employees. It is hard to define motivation, as it is rather a process that determines the employees to act, to make effort in order to obtain high results at work. The main motivating factors at the level of an organization are:

- A good financial reward;
- Attractive fringe benefits;
- The attractiveness of the job;
- Authority, responsibility and job autonomy;
- Results recognitions;
- Intellectual and professional development;
- Professional career opportunities.

In 2007 and 2008, the European Motivation Index study [1] was conducted in eight European countries by calculating and averaging the results obtained in each country. On a scale of 1-10, the motivation index is around 6 in 2007 being higher in Germany, Holland, Belgium and Sweden. We note the emergence of differences within the four dimensions considered in 2008, primarily an increase in employee job satisfaction and motivation across Europe, but a decrease in their commitment to the company and maintaining a degree of

involvement. In 2008, the European motivation index decreased from 6.67 to 6.65. But we can not appreciate the importance of this decrease, whereas the study did not provide information on the number of the organizations, number of employees interviewed or the types of questions used.

The studies conducted by Effactory revealed that the Germans are the most work involved employees in Europe. Moreover, along with Belgians, the Germans are the most satisfied employees in the countries surveyed, giving an average score of 7.1. In contrast, employees in Britain recorded a lower level of satisfaction; the average score in the first months of 2009 was 6.1, identical to that found in France, perhaps because the two countries are both affected by the global economic crisis.

The European Employee Index

The European Employee Index was developed by some human resources specialists in the northern European countries (Sweden, Denmark, and Norway). The research and the developing of the model were based on annual questionnaires conducted in more than 20 countries which offered the best international benchmark. Accordingly to this model, the employees' motivation, their job satisfaction and sense of loyalty are the result of a large number of factors directly related to the employees' perception of job and work environment. In the European Employee Index, these factors were gathered into seven dimensions, levers that the company and the individual manager can pull in order to improve motivation, as we can see in figure 1.

Reputation is the employees' perception of the general knowledge of the organisation and how this is perceived externally, both as a workplace, as a player in society and in relation to the products that the organisation delivers.

Senior management is the perception of the general direction of the organisation and the people in charge.

Immediate superior is the quality of the management and support offered by formal immediate superiors as perceived by the

individual employee in the daily work and which is reflected in an assessment of the qualifications of these superiors.

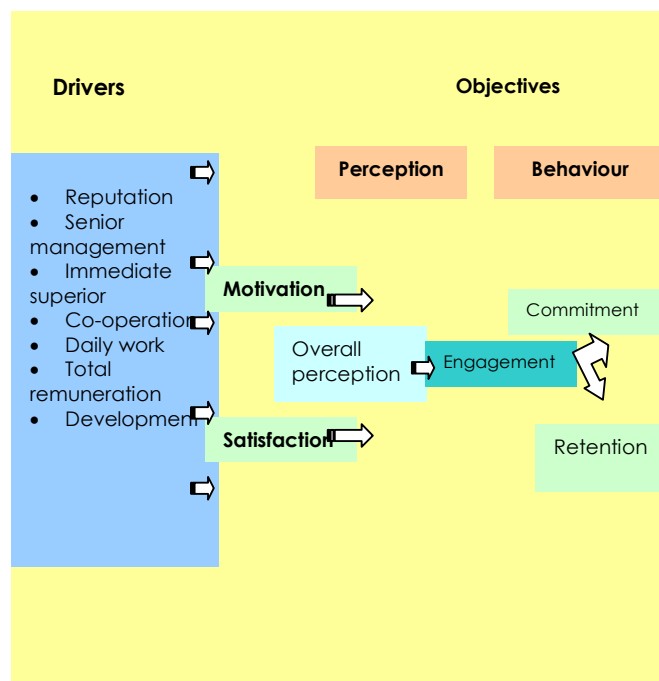

Cooperation is the quality of the interaction between people in the organisation – in relation to the performance of a specific task, the general sense of community and atmosphere as well as the social interaction with colleagues both in and outside the workplace.

Daily work is the employees' general perception of the specific content of their daily activities in the workplace and the working conditions related to the performance of these activities.

Total remuneration is the employees' perception of all the elements involved in the compensation that they receive for performing their job.

Development is the employees' perception of the individual acquisition of competences (both professional and personal) which takes place in connection with the employment in the company. Competences can be acquired in connection with formal education, courses, on-the-job training, everyday challenges and feedback from managers.

Figure 1. The European Employee Index Model [2]

The last study conducted in 2008 shows no change in the top two countries that have the highest motivation and satisfaction: Denmark and India, two very different countries. For every country, a different driver was found to be the most important, definitely influenced by the cultural features. For instance, senior management is especially important for employees in Ireland, the United States and Japan. Immediate superior is important in United Kingdom and Japan, while co-operation means a lot for the employees in Netherlands. In the Czech Republic and Russia remuneration plays the most important role. The study also brings into light the fact that, no matter the country, the development of human resources and the daily activity are very important factors for increasing employees' satisfaction.

Study regarding job satisfaction evaluation conducted in the organisations from Bucharest

The study conducted to evaluate job satisfaction inside Bucharest organisation was conducted in different companies from Bucharest on a sample of 99 employees, the organizations belonging to different domains of activity.

The questionnaire is conducted on an electronic platform www.surveymonkey.com allowing real time processing of responses from people participating and statistically processing of all information. Survey console is an electronic platform used by large U.S. companies and universities around the world like Microsoft, World Bank, Napster, Alcon, White & Case, UBS Investment Bank, U.S. Bank, etc.

The questionnaire can be accessed by any other person at the web address <http://evaluareasatisfactieiengajatilor.surveymonkey.com> and it is very easy to fill.

The questions used were the standard type: Multiple Choice - allowing the choice of one or more responses from a number of

variants, the Open-ended text - open questions allowing the respondent's opinions, Matrix Boards - questions matrix type, offering relevance to provided answers, testing both the appearance of a phenomenon and the phenomenon level.

Most of the respondents were aged between 21 and 30 (50.00%) and between 31 and 40 years (28.26%). Most respondents were female (76.09%). 71.43% of the men and 82.86% of the women who responded to the questionnaire have executive workplaces, the rest having managerial positions. Overall, 80.22% of respondents occupied executive positions and 19.78% had management positions. As it regards the level of education, most of the respondents have higher education, only 12 of those surveyed having a bachelor degree. More than 90% of the respondents have worked more than 6 months, so they have work experience.

The surveyed employees belong to very different fields of activity. Regarding the type of organization, interviewees fall into: 41.76% work in public institutions, 52.75% work in private organisations and 5.49% in non-profit organizations. 49.45% of the respondents are working in large organizations, with more than 250 employees, the rest of them working in SMEs.

In the research conducted to assess the degree of job satisfaction of employees, we established eight categories of factors that may influence the job satisfaction:

- Cooperation within the organisation and the department;
- Communication and the flux of information;
- Direct management and the relationship with the immediate superior;
- The daily work and the work conditions;
- Professional development;
- Reputation and organisational culture;
- Remuneration;
- Work/life balance;

As regarding cooperation within the organization and department, 31.18% of the employees fully agreed with the statement "In the department where I work, people are cooperating very well" and 47.31% agreed

with. The high percentage (over 78%) of the employees satisfied with how they communicate and collaborate in the department is also the same when it comes to collaboration with other departments, 52.22% of respondents stating that collaboration with the other departments within the organization is without major problems.

Furthermore, we observed that only 31.03% of the respondents were in total agreement with the fact that both at the level of the organization and the department, the communication is working out smoothly. Also, the interpretation of the questionnaire responses suggests that age does not influence the way they collaborate within the department, although often we tend to believe that older people are more rigid.

The study revealed that, as it concerns the communication of the fundamental objectives of the organization, the respondents said that often they are made aware of the organization and department goals and strategies. We conclude, however, that often changes taking place in the organization are not sent on time because at the statement "All the changes taking place in the department I belong are communicated in time", 26.67% of the respondents were undecided, 17.78% disagreed with and 4.44% were in a total disagreement with the statement.

With regard to direct management and the relationship with the immediate superior, 9.78% of the respondents believe that they are directly involved in every decision affecting their work. 48.91% felt that they have a word to say regarding their work, 13.04% said that they are rarely involved in business decisions and only 1.09% responded that they are never involved in taking decisions. Regarding the way the superior fulfils its duties, half of the respondents indicated that most of the times, the immediate superior meets its duties in time.

A very acute and important problem for the Romanian employees, with multiple social implications, is workload. The study revealed that 16.30% of the employees surveyed considered that the workload of their job is very high, 45.65% considered it high and no one considered it very small.

On the other hand, the Romanian employees are largely satisfied with the work they are performing, the content of their work fulfilling their self-respect needs. 66.30% of the respondents believe that most of the times, the work they are performing makes them happy.

Differentiated by gender, men are in a higher proportion satisfied each time (18.18%) and most of the times (63.64%) by their work content against women (5.8% - each time, 66.67% - most of the times, 21.74% - sometimes, 5.8% - very few times). Another significant result is that young people between 21 and 30 years responded in a large percentage that are only sometimes (28.89%) or very few times (2.22%) satisfied with their work.

In Romania, the employer brand concept arose with the advent of multinational companies who came with the managerial know-how gained over many years of experience in other capitalist countries. From the perspective of the reputation and the values promoted by the organization, the study highlights that often the values of the organisation do not correspond to the employees' values, 48.91% of the respondents indicating that only sometimes there is a correlation between the value systems. However, when they were asked about the sense of loyalty for the organization they work in, 17.78% expressed their opened loyalty, 40% of the employees would recommend the organization to other friends and more than 30% considered that their organization is loyal to them.

Although a large percentage of the surveyed employees declare they do not feel exploited inside the organization where they work, many of the respondents would leave the organization if they would find another job or are undecided: "Had I found another job, I would leave the organization tomorrow". The responses were: Strongly Agree 15.73%, Agree 8.99%, Undecided 37.08%, Disagree 21.35%, Totally disagree 16.85%.

The employees participating at this study were asked to rank, in an ascending order of importance, the main factors that motivate them at work. Not surprisingly at all, we found that the income is still the number

one in the hierarchy. 33.33% of the employees placed on the first place the income. 24.44% of the questioned employees ranked on the first place the work environment and the team, 18.89% considered the most important the intellectual development, 17.78% the professional opportunities and only 5.56% placed on the first place the working conditions. We also noted that the second option of the respondents after the income is, in most of the cases, the career development.

Conclusions

The study conducted revealed a not at all surprising fact: that there are many factors that determine the employees dissatisfaction in Romania, factors related to the degree of collaboration and communication with the management of the organization, the rewards system used, the working conditions, the extended program and the stress at work, the organization values and the extent to which it offers the opportunity develop a professional career.

However, it is surprising to see that, in comparison with the results of the studies conducted previous years ago in European organisations, the respondents' satisfaction increased. Perhaps because the organisations are now more aware of the fact that human resources are the most important resource of the modern organisation.

Leadership in Opposition to Facilitating Change for the Romanian Organizations

LILE Ramona
HANGANU Silvia
"Aurel Vlaicu" University Arad
ramonalile@yahoo.com

Abstract

One of the most important roles of the Organizational Change expert is based upon his or her expertise in the *process* of change itself. The Organizational Change expert must be able to coach and educate senior managers in how the process of change takes place in Romanian organizations. Change is a process that follows a relatively predictable pattern. Unfortunately, many managers have never been educated about the change process. It should come as no surprise that leading change without knowledge of the change process itself typically leads to failure of the change effort.

This lack of senior management understanding of the change process itself creates one of the most important roles for the Organizational Change's expert — Change Process Advisor/Educator. The Organizational Change expert should be prepared to advise/educate senior managers on how to effectively lead change.

Management change is not the regulation of the Organizational Change expert. Management change is the responsibility of the company's senior management. The Organizational Change expert should serve senior managers as an advisor/educator and coach.[2]

Keywords : leadership, change process, crisis, strategy.

JEL classification: L19

Principal Steps in Management-Leadership Change

In this article we will not get involved in the debatable over how many realism steps there are in the change management process. A lot of experts disagree many with strong arguments.

For our purpose of advising/educating managers on how to effectively lead change, lets follow [10] model of eight steps:

1. Establish a sense of urgency.
2. Must be create a Guiding for change
3. Develop a good Strategy for the Management Change, specific for every organization
4. Communicate the Change Strategic Plan to all organizational members
5. The big power Employees for Completely - Based Action
6. Create Short-Term for Wins organization
7. Consolidate gains and produce more change.
8. Important the Change Organizational Culture

1. Establish a Sense of Urgency

A lot of managers agree with [10] that the first step in a change effort is to establish a sense of necessity. Managers are very busy people. To get the attention and commitment of the organizational managers, the change leader must convince these busy managers of the importance, the urgency, for the change.

The manager, with the guidance of the Organizational Change expert, should consider ways to counteract what [10] calls "sources of complacency":

1. the absence of a major and visible crisis

2. too many visible resources
3. low overall performance standards
4. organizational structures with narrow functional goals
5. measurement of the wrong performance indexes
6. lack of feedback from external sources
7. a "kill-the-messenger-of-bad-news" culture
8. denial of problems
9. too much "happy talk" from senior management

2. Must be create a Guiding for change

The manager in the Romanian organization must be create a strong coalition of organizational leaders to guide the change effort.

The issue here is not executive knowledge. We have met some extremely knowledgeable executives in organizations. The issue here is "buy-in." Without buy-in from key players, the change effort will be fail.

The big experts in this domain, [10] suggests four principal key member characteristics for effective coalitions:

1. position power the coalition needs key players, including board members and line managers
2. expertise and diversity the coalition needs the expertise and diversity necessary to make informed, intelligent decisions
3. credibility the coalition must have the credibility, based on the members' reputations, to be taken seriously
4. leadership the coalition must have proven leaders [p. 57]

[10] also suggests qualities to avoid; people to keep off the team. He recommends avoiding big egos and "snakes."

These team leaders must pass along essential information to organizational members. Team leaders must immediately confront rumors and provide inspiration for their teams. These leaders must "know how to encourage people to transcend short-term parochial interests" [10, p.65].

3. Develop a good Strategy for the Management Change, specific for every organization

Every organization must be already have a clear strategy and a good vision for future. When leading a specific change effort, it is important to develop a strategy for that management change, in the Romanian organization.

The change management in every organization should actively break participation from all of the coalition members. This participation provides valuable input into the decision-making process, and it gives the coalition members a sense of ownership in the strategically plan [2].

[10] believes the following six characteristics should be present in an effective vision:

1. imaginable
2. desirable
3. feasible
4. focused
5. flexible
6. communicable

An imaginable and desirable vision paints a picture of a very appealing future. [10] correctly states the vision must "appeal to most of the people who have a stake in the enterprise: employees, customers, stockholders, suppliers, community" [10, p.73]. Obviously, you cannot please all the people, all the time. But the strategic development process should, at least, consider the long-term interests of all stakeholders. If groups of stakeholders believe they are we forced to make unreasonable sacrifices, resistance to change maybe insurmountable.

4. Communicate the Change Strategic Plan to all organizational members

A group strategic and well-crafted development plan is of small value if it sits on a shelf gathering insufficiently. The value of the strategically plan is the guidance they provide in goal setting and decision making. To provide guidance they must be communicated throughout the organization.[2]

The expert in this domain [10] warns managers about "under communicating" and I sending "inconsistent messages." The general managers must think beyond communicating to only their immediate subordinates. A strategically plan must be developed to communicate the vision to all the members in the organization. Now in Romanian organization

must be exist the survive plans because is crisis period.

[10] offers the following seven suggestions for communicating the strategy:

1. simplicity
2. metaphor, analogy, and example
3. multiple forums
4. repetition
5. leadership by example
6. explanation of seeming inconsistencies
7. give-and-take

A lot of forums and repetition are essentials for successful communication of the strategy. The strategy must be communicated through training sessions, meetings, press releases, the company's intranet, etc.

Finally, give and take is necessary to maintain an open, interactive organizational culture. General managers should actively solicit feedback and make modifications as necessary.

5. The big power Employees for Completely -Based Action

The powering employees for the Romanian organizations are based on the leadership principle called unique and simply theory. The theory (perhaps, more accurately) leadership style begins with establishing a objective with the employee. Then, the leader's remaining responsibility is to help clear the path so that the employee can accomplish the objective. Empowering the employee is dramatically different from the management style of micromanaging and controlling.

In this new management style, managers serve as facilitators. Managers work to acquire the resources their employees need to reach their objectives. These resources could include the important things: time, money, personnel, or training.

[10] states, "new behavior, skills, and attitudes will be needed when major changes are initiated" [p.108]. Satisfying these needs may require considerable training.

Employee empowerment may also require changes in management. The command-and-control management style must go. If these old-style managers cannot be retrained, they must be dismissed. [10] correctly states, [if] "others see that these people are not being confronted ...they become discouraged" [p.114].

6. Create Short-Term for Wins organization

In general business leaders, especially in the Romania, ignore the short-term results. While it is important to have long-term plans for success, no change agent should ignore the importance of providing some short-term wins.

Usually, anytime a change expert is leading change there are resisting forces and driving forces. It is important to keep the driving forces committed to the cause. All general managers are under pressure to present short-term wins. Therefore, the coalition managers must have something to show. Short-term wins build the credibility of the plan for change.

[10, pp.121-122] lists three characteristics for good short-term wins:

1. Its visible
2. Its unambiguous
3. it's clearly related to the change effort

Short-term wins, with these three characteristics, should be woven into the timetable for the change effort. [10] recommends "six months" for small companies, and "eighteen months" for big organizations.

Short-term wins let organizational members know that the sacrifices are worth it. These win also "turn neutrals into supporters" [10, p.123]. It is important to build and maintain momentum for the change effort.

[10] offers the following general rule: "the more cynics and resisters, the more important are short-term wins" [p.123]. Kotter goes on to say, "Short-term pressure can be a useful way to keep up the urgency rate" [p.127].

7. Consolidate Gains and Produce More Change

In this part, after create and consolidate some short-term wins, general managers must continue to perseverance monitor the progress of the change effort. Remember, the resisting pieces are "waiting for an opportunity to make a comeback. Whenever you let up before the job is done, critical momentum can be lost and regression may follow." [10, p.133].

This is a good time to revisit Kurt Lewin's Forcefield Analysis. Re-evaluate the current scenario. What or who are the resisting pieces now? What or who are the current driving

pieces? Current circumstances may call for a new plan to build support. Perhaps it's time to expand the guiding coalition.

[10] believes, "the credibility afforded by the short-term I wins [can be used to] push forward faster, tackling even more or bigger I projects" [p. 140].

During large transformation efforts, multiple changes may be taking place at the same time. It may be necessary to sequence these changes to maximize the use of resources (time, energy, and money). The guiding coalition members should contribute and "buy-in" to this sequencing or scheduling of events. [2]

This part requires general management's best efforts to not only maintain but also to build momentum for the organizational change.

8. Important the Change Organizational Culture

[10] eighth step is the same thing Kurt Lewin called "refreezing" in his Three-Step Model of Change. Once positive change happens, management must work to make it part of the organizational culture.

The new organizational culture must be reinforced by the policies for recruiting, selecting, promoting, compensating, evaluating, and training.

9. Conclusion - Managing the Transition

Organizational change plans in the Romania are rarely accomplished in one quick step. Implementation usually requires general managers who can lead the organization through a transition and crises period.

[1] discuss three major activities and structures to lead the transition: activity planning, commitment planning, and change-management structures.

Activity planning "involves making a road map for change, citing specific activities and events that must occur if the transition is to be successful" [5]. Activity planning should receive participation from all key stakeholders. Achievable, incremental objectives should be identified on the "road map."

While it is important that activity planning be well thought out, the plan must be adaptable enough to react to the feedback received during the transition. A successful transition will

include both proactive and reactive decisions. Activity planning should provide the general direction for efforts during the transition period.[2]

Commitment planning involves "identifying key people and groups whose commitment is needed for change to occur" [5]. Commitment planning should be done early. Commitment is essential from those who can wield influence and control resources.

Change-management structures for the transition period can help provide needed direction and security for this frequently turbulent time. Members of major constituencies should play major roles during the transition.

Human Resource Management Improvement in the Romanian Trade Enterprises in the Context of the Demands Induced by Globalisation and the EU Integration

Lector dr. Luț Dina Maria

Universitatea Creștină „Dimitrie Cantemir”, Facultatea de Management Turistic și Comercial Timișoara

E-mail: dinalut@yahoo.com

Abstract

The Romanian trade enterprises are at the end of a long and difficult period of transition towards market economy, while also facing the competitive pressures induced by globalization and the EU integration. The present paper thus suggests a possible solution to the challenges that the Romanian trade enterprises must face, bringing arguments to show that one of the answers to the complexity of the environment is to develop the human resources and to adapt the management of these resources to the demands of the environment, with the purpose of increasing competitiveness. The suggestions regarding the human resources management improvement in the Romanian trade enterprises are based on the conclusions of the research performed among the 41 companies in the Timiș county, dealing mostly in trade sector.

Keywords: trade, market, human resources, demands.

JEL classification: M12

1. Introduction

The Romanian trade enterprises, over 90% of them micro-enterprises and small companies, are at the end of a long and difficult period of transition towards market economy; this gives them the advantage of a higher flexibility and adaptability to the changes in the environment, but this advantage given by their small size is not enough to maintain their viability in the context of the influences and demands coming from the environment.

The external environment in which Romanian trade enterprises work, has a distinct characteristic: in addition to the

factors currently generating changes at world level, the companies in our country are also confronted with the action of some specific factors, whose intense manifestation was caused by the major political and economic transformations that took place after 1989 (the authority void following 1990, the changes in the field of ownership, the multiple changes in the operation and structure of the economy, etc.).

The Romanian trade enterprises are also facing the competitive pressures induced by globalization [1], [4], and the EU integration.

Romania's integration in the EU firstly leads to the increase of competition both on the domestic market and on the external one, with companies forced to cope with the Western technologies, product supply, and price-quality ratio offered by similar companies in Western Europe. At the same time, during the past years, we have seen, as a form of globalisation, an afflux of large-scale distribution, mainly sustained through direct foreign investment, making visible in Romania the same major phenomena that mark commerce at world level: concentration, development of integrated distribution systems, the use of new information and communication technologies. [2]

In the context of the competitive pressures specific to trade, the challenges faced by Romanian trade companies (most of which are small or middle-sized) are numerous and refer specifically to: the reduction of costs so as to attain a level of performance comparable to that in the EU countries, at a time when the adoption of the community acquis in certain fields related to commerce (food safety, compliance with the technical regulations for products that are potentially hazardous for the consumers' health,

regulations regarding product certification and standardisation, etc.) also involves additional costs; practising some competitive prices, but which should provide sufficient profitability as to allow the sustaining of the investments imposed by the technological upgrades and the rise in the consumers' expectations.

Under these conditions, companies that wish to obtain performance must be interested in the implementation of some modern organisation methods, in the use of integrated management systems that can support them and their employees in their attempt to adapt to the new requirements.

The experience and results recorded by world famous companies show that these challenges can be successfully approached by focusing priorities towards the *development of human resources*. We believe that the development of human resources through a management focused on effectiveness, efficiency, and performance is a factor that can generate competitiveness for the Romanian trade companies as well, in a competitive environment induced by the processes of globalisation and regional integration.

Based on these considerations, aiming mainly to improve the *human resource management in Romanian trade companies in the context of the environmental requirements in order to increase competitiveness by developing human resources*, I performed a research among the 41 companies in the Timiș county dealing mostly in trade sector.[2]

2. Research methodology

The research aimed to show the way in which human resource issues are approached (taking into account their role and importance within an organisation), as well as the degree to which the human resource management system contributes to the increase of the performance of these companies, as well as their adaptation to the demands of the contemporary competitive environment.

When approaching the aspects mentioned above, the research comprised two distinct channels: on the one hand, the managers' perception and their attitude towards the elements studied (with the help of information resulted from the application of Questionnaire 1), and, on the other hand, the employees' perception and attitude towards the same

elements (with the help of the information resulted from the application of Questionnaire 2). This approach allowed me to perform a parallel analysis regarding the more or less different or compatible position of the two categories of respondents.

In order to have a better understanding of the problems of human resources management in enterprises with main activity of commerce, we have used as a **research method - the survey (inquiry)**, and as an **instrument - the questionnaire**.

The sample method chosen for the inquiry by survey that we have conducted is simple aleatory. In our case, the first operation for the sampling was to established the population interviewed. This is formed, on the one hand, by managers (human resources managers, where there are such job titles or by top managers and managing owners) in enterprises dealing mostly in trade sector, and on the other hand, by employees in these enterprises. In this respect, sampling units were enterprises dealing mostly in trade sector, from Timis county, having as stratification criterion the size of enterprises, depending on the number of employees (micro-enterprises: 0-9 employees, small enterprises: 10-49 employees, middle-sized enterprises: 50-249 employees, large enterprises: over 250 employees).

Starting from the data base of trade enterprises in Timis county (which can be found in CCIAT Timiș), we identified a total for each category based on size. Afterwards, we established the proportion of surveys that were to be applied on each category of enterprise. Based on the list obtained and the estimated number we established a sampling step for each layer, a step which was eventually applied. Finally, a number of 41 enterprises *accepted to be included in the research* all having as main activity commerce and all carrying out activities in Timis county.

The surveys were conceived separately for the 2 target groups that were studied in the field of commerce: managers and their employees. From this point of view, the hands-on approach of the problems of human resources takes into consideration the main dimensions of organizational structure: the managerial dimension and the executive dimension. Our researches catch the

multitude of relations and variables that are established between the two dimensions in the process of human resources management. From this perspective, the methodology of research, both in projecting instruments and in collecting and analyzing data has seen important adaptations.

Given the large difference between the sampling volume and the quality of respondents in the two target groups (managers and employees), the complexity and the used indicators were different. If, in the case of *managers the survey was direct, in the case of employees, the surveys were self-managed*. The fact that the questionnaires were directly applied to managers, presupposed a face-to-face communication relationship, stimulating the verbal behavior of respondents. For employees, the self/management of questionnaires facilitated the increase in sampling volume, but it also implied the risk of obtaining refusals to answer and obtaining non-answers.

Our research aims to follow concrete aspects which represent *specific objectives of research* and which have been captured by applying the two questionnaires.

Questionnaire I, applied to managers, includes 31 questions and facts and it targets subjects from the field of human resources. Thus, the following aspects related to human resources are studied:

- The existence, inside the surveyed firms of a **strategy of human resources** and of some employees or collaborators specialized in HRM (questions 1-5).
- As a concrete strategy of human resources in policies and activities related to human resources, the questions were aimed at:
 - the characteristics of a **recruitment policy and selection of personnel** (questions 6-10);
 - the existence or inexistence of an **integration policy in the firm of new employees** and the actors who put into practice this policy (question 11);
 - characteristics of **the training policy of employees** (questions 12-14);
 - characteristics of **the assessment policy of professional performances and development of employees** for the surveyed firms (questions 15-20);
 - characteristics of **motivation and rewarding policy of employees** by: assessing the peculiarities of the rewarding system of employees (questions 21-23); assessing the

satisfaction of employees by looking at managers appreciation (question 24); highlighting motivational factors used by managers to motivate employees (question 25).

- Self-evaluation **of performance as a whole and of the relationship between the results of the firm, human resources management and employee satisfaction** (questions 26, 27, 29).

- Assessing **managers views on the importance of human resources** and highlighting the most frequent problems from the field of HRM that managers are facing in the surveyed firms (questions 28, 30).

- General characteristics of surveyed firms (questions 31).

Questionnaire II, applied to employees in the trade enterprises surveyed, has a total of 14 questions distributed equally from each of the studied themes:

- **Motivational factors taken into consideration for employees** in order to carry out an efficient activity and to obtain good results (questions 1, 2, 4).
- The problem of evaluating **motivation and employee satisfaction** as well as determining factors (questions 9, 10, 11, 12, 13);
- The problem of assessing **individual performance, management and company performance** as a whole, as well as the relation between them, by looking at employees' appreciation of: their own results (question 3), quality of management (questions 5, 6, 7, 8).
- Socio- demographic characteristics of respondents (question 14).

The time awarded for surveys was estimated to 25 minutes for respondent managers, and 15 minutes for respondent employees.

Finally we obtained answers from 41 managers (human resources managers, and in their absence, we discussed with representatives of the firms: *managing owners*, executive managers, associates, administrators) and 193 employees all belonging to the executive area. In order to processing data we used SPSS version 13.0 (Statistical Package for Social Sciences) and EXCEL software for Windows. Apart from outlining the image of the human resources

problematic in surveyed trade enterprises, the research has underlined, with the help of correlation analysis [3], the existence of statistical relations among some variables that define the rapport between motivation - performance - satisfaction or the influence of quality management on performance of a company as a whole etc.

3. Suggestions regarding the human resource management improvement in the Romanian trade enterprises in the context of the demands induced by globalization and the EU integration

Following the analysis and the results obtained, we can conclude that there is a general state of disorientation and confusion, a type of behaviour meant to generate substantial short-term material gain, and this can be seen both at the level of the managers and at that of the employees. This behaviour is largely sustained by the objective social, economic, and technical conditions in which the respondents operate. We are witnessing, at the same, a vacillating behaviour going either towards self-leadership, self-motivation, self-control, or towards guidance, control, or even constraint and extrinsic motivation. The explanations of this behavioural model can be found in the cultural and behavioural model that characterised the previous period, and at the same time in the inability of the managers (or the managing owners, who prevail in the small and medium-sized trade companies) to capitalise on and develop the human resources they have at their disposal, either due to the lack of information, of professional or material skills and abilities, or simply due to disregard.

On top of all this comes the dissolution of the general system of values without the complete consolidation of a new system of values that should be a reference point for the manifestation of a new behavioural model.

The dire need is therefore felt for a *new system of values at the macro-economic and macro-social level*, and for the **creation of a new inter-human relations culture** at the micro-economic level, and the interiorisation of this culture by all the members of the work groups, which should lead to the shaping of a new mentality, a new attitude towards work, substantiated in the practical manifestation of a

genuine competitive behaviour.

An essential part in this respect is played by the promotion of an effective managerial style that presupposes the sharing of some humanist values recognised and accepted by all the members of the company, which will lead to the increase in employee satisfaction and at the same time the rise of their loyalty towards the company. Under these circumstances, those managers with a managerial philosophy based on well defined values will totally change the approach to human resources: they will treat employees not only as a costly resource or a mere means to obtain profit and do business, they will interpret human relations not only from the point of view of their concrete manifestation in financial contracts, and they will conceive the workplaces so as to stimulate employees to reach performance.

We believe that such a human relations culture should focus on values and principles such as: dignity, correctness, and consistency in thoughts and actions, mutual respect, trust in the others and in oneself, the involvement in self-improvement and professional and personal development, the promotion of a differentiated, personalised appraisal, the promotion of flexibility and adaptability in thoughts and actions, the encouragement of initiative and creativity, and last, but not least, involvement in the work performed. The challenge for the owners, managers, and at the same time for the employees in trade companies is to find the most appropriate ways and means to transpose these values and principles into practice.

Our research performed among a series of companies operating in the field of trade in the county of Timiș reveals that most of these managers are not fully aware of the role played by human resources in determining the competitiveness of a company and the fact that the effectiveness of the human resources management influences the company's performance. This reality is confirmed by the fact that most of the activities in the human resource field are delegated to non-specialists, and the organisation and carrying out of these activities are unsatisfactory. It is true that a large part of the commerce companies are small companies that do not justify the

setting up of a human resource department, but there can be other ways or solutions to manage human resources, so as to capitalise on the experience and training of some specialists in the field.

We therefore believe that at this point, one of the most important requirements for the development of human resources refers *mainly* to the **professional training of human resources**, in order to acquire the knowledge and qualifications corresponding to the new technological, informational, and communicational developments taking place in the world at this time, in all fields, and which are also felt in the Romanian trade. The emergence of new occupations or the enrichment of the profile of some occupations specific to trade lead to the increase in the demand for skilled staff, as well as to the increase in the level of professional training of the workers in this field, making **continuous learning and training** absolutely vital. These conditions are essential in order to maintain (or reach) competitiveness in trade companies, in the actual context of globalisation and EU integration, and address the *managing owner* (concentrating several functions and therefore one of the central elements in the development of human resources in these companies), as well as the *sales staff* (ensuring the direct contact with the consumer and influencing the image and the – favourable or unfavourable – attitude of the buyers towards the company). Therefore, investment in professional training and proper involvement of the human resources in trade is actually a preoccupation aiming to improve the quality of the trade act.

Secondly, I believe that we need to **reconsider the strategy for motivating the trade staff**, in the sense of increasing the weight of the subjective dimension of labour, so that, in addition to paying substantial and fair salaries as a reward for the contribution to the company performance, participation should also be stimulated through non-financial means.

As the results of our research show, motivation is too often associated (both by the managers and the employees) with a high salary, and too little with non-financial rewards. *It is time for the employers in the Romanian trade companies (as well as those in other fields) to understand that there are other means, besides financial motivation, that can be used to*

motivate employees and keep them in the company.

Non-financial motivation is a viable and, at the same time, a complementary alternative to stimulate employees and make them more faithful, more efficient, and better performing. Moreover, for small-sized trade enterprises, whose economic and financial power is rather small, this type of motivation becomes a necessity in the attempt to generate employee loyalty and decrease staff turnover, to increase individual performance and, finally, the competitiveness of the company. There are multiple instruments for non-financial motivation, including: the presence of a set of clear rules and well-defined and realistic individual objectives, the highlighting and rewarding of special merits, the creation and maintaining of a friendly attitude among the employees, based on cooperation and mutual respect, consultation and involvement of the employees in the setting of individual goals and of the means of rewarding results, as well as in the solving of some problems connected with the current activity, the leaders' interest in the employees' professional and personal development, the existence of a transparent system of rewards and promotion, etc.

The financial means of motivation, of an extrinsic nature, are efficient especially when one aims at increasing productivity in a short time, but also for a short time. The decrease or removal of these motivational means almost automatically leads to the decrease of productivity. For this reason, obtaining high and lasting performance is done, in the context of the increase in work complexity and degree of professionalism, by creating a motivational complex based primarily on intrinsic motivation, and only secondly on the extrinsic one. This aim involves mentality and attitude changes on the managers' part, as well as on that of the employees: on the one hand, *managers or company owners need to have a long-term broad vision of the company evolution and a clearly shaped managing strategy, in which human resources should be given a central place and role;* on the other hand, *employees need to adopt the set of norms and values specific to the culture of the company for*

which they work.

Although the general reward system has an overall influence on the behaviour and performance of employees within a company, one must take into account the **individual motivation** as well, considering the unique character of the human being, each person's different wishes, aspirations, and objectives. A very important role in this respect is played by the *system of appraising and measuring the employees' professional performance*, which needs to be rigorously conceived, transparent, and most of all to allow the differentiated highlighting of individual performance and merits, rather than one standard evaluation for all employees.

The problem connected with the non-individualised motivational system is not characteristic only for trade. The human resource management in Romanian companies is still largely influenced by the old approach, deeply rooted in people's conscience, but employers are not the only ones promoting such a system; the law sometimes enforces standard evaluations for all employees, without taking into account the personality factor. Employees can only be efficiently motivated by knowing their needs (or rather need hierarchy) and allowing them to satisfy these needs.

To this end, the owners or managers of trade companies can resort to different motivational theories, adapted to each employee's situational context and motivational structure.

4. Conclusions

For the Romanian trade enterprises the impossibility to make long-term investments in the development of human resources actually means an impossibility to adopt the new forms of organisation, which are more modern and more efficient and could help maintain competitiveness.

In such a situation, I believe that it would be a viable solution for trade companies (but also for small companies in other fields), in their confrontation with large-scale distribution, to *integrate or participate in various forms of cooperation between companies*. For Romanian trade companies, building company networks would be an opportunity to develop human resource management and also to learn by relating to others in a cooperative environment.

Public trade policies also play an important role in this respect, as they should promote and support the development of human resources within small and medium-sized enterprises, as a main means to increase their competitiveness.

Abstract

The global economy and its current characteristics are strongly influenced by the development of multinational companies, players increasingly important in the national economy of any country, regardless of its location on the globe. Moreover, human resources management began to be recognized as a determinant factor of success or failure of international affairs [1]. The theoretical or empirical approaches regarding the links between human resources management and overall business strategy in an international context is intensively explored by the specialists in the field. This article aims to analyze some of the influences of the expatriation practices in multinational companies on human resource management: the main reasons for using expatriates and their countries of origin, selection practices, training practices and the success rate of expatriation.

Keywords: human resources, strategy, potential, employees.

JEL classification: M54

1. Introduction

The internationalization of corporate activity, becoming more frequent in recent years highlights new topics for discussion and research on the strategies and management practices. Both theoreticians and management practitioners began to raise questions about the best methods to operate at an international level and if inside multinationals the practices should be converging or diverging [2].

A number of studies suggest that technological development, global communications systems and the cooperation between organizations will remove the barriers caused by different values and traditions of national cultures, resulting in similar managerial practices and therefore convergence inside multinationals. Contrary, the arguments supporting the divergence suggests that at the level of the sub-units of multinational companies, cultural differences significantly influence the management process. Perhaps there can not be established a clear verdict about the necessity of divergence or convergence of the managerial practices in international companies as it is an extremely complex issue, influenced by a multitude of variables. However, most studies conducted so far argue that expatriation practices used by multinationals have a decisive role in the convergence or the divergence of managerial practices in general.

2. The impact of using expatriate employees on human resource practices in multinationals companies.

But what are the expatriates or „expats” in a language commonly used in multinational companies? Expatriates are employees with international experience who know very well the organisational culture of the company, catalysing local talents and enhancing their development potential. Often, when the know-how transfer from the local to expatriate management is complete, local managers are assigned leverage decisions.

As regards human resource management, since 1982, Tung [3] achieved a first comparative study about expatriates conducted in 80 American companies, 29 European companies and 35 Japanese companies on the following topics:

- Employment policy – the reason of using expatriate employees;
- Selection methods;
- Selection criteria;
- Training;
- The success and failure rate of expatriation and the motivation.

More recently, three studies were conducted to compare management practices on expatriation (Peterson, Sargent, Napier & Shula-Shim, 1996, Peterson, Napier & Shula-Shim, 2000 and Tungli & Peiperl, 2009). All of these studies are focusing the multinational companies from Germany, Japan, United Kingdom and USA as they host the majority of top multinational companies, classified according to their turnover (The Global 1000, 2000). The study conducted in 2009 by Peiperl and Tungli [4] in 136 companies (35 from Germany, 20 from Japan, 34 from the United Kingdom and 47 from USA) analyses four aspects of the expatriation: why use expats and their countries of origin, selection practices, training and the success rate of expatriation. Surprisingly, the 2009 survey results are very similar to the results obtained by Tung in his study, with over 25 years ago.

The study revealed a variety of responses regarding the main reasons why multinational companies are using expatriate employees. For example, in Germany, the main reason is „to develop international management skills”, in Japan and in the United Kingdom it was „to set up a new operation” and in the United States it was „to fill a skill gap”. In Table 1 are presented the reasons why the multinational companies from Germany, UK, Japan and USA are using expatriate managers and their importance given to a 6-point Likert scale. If we were to try to emphasize an indicator of convergence, the study emphasised that all analysed companies have placed "to set up a new operation" and "to train and orient local staff" among the main 5 reasons for the use of expats.

Table 1. Reasons for filling managerial positions with expatriates.

	Germany	UK	Japan	SUA	Total
To set up a new operation	4.70	5.13	5.21	5.25	5.07
To fill a skill gap	4.18	4.83	4.68	5.33	4.82
To develop international management skills	4.91	4.77	4.11	4.53	4.63
To train and orient local staff	4.41	4.57	4.32	4.61	4.50
To control the operation	4.00	4.07	4.61	4.53	4.29
To ensure the same company standards worldwide	4.48	4.00	3.56	4.43	4.22
To coordinate with headquarters	4.12	3.80	4.68	4.16	4.14
To provide career development opportunities	4.03	4.53	3.41	4.23	4.14
To establish and maintain corporate culture	4.09	3.83	3.74	4.14	3.99
To learn about local business practices	4.30	3.90	4.11	3.60	3.94
To maintain the image of the operation as "foreign"	3.15	1.90	2.72	1.91	2.35
To find jobs for surplus managers	1.88	1.60	1.72	1.68	1.72

(source: Tungli & Peiperl, 2009)

The study conducted by Tungli and Peiperl (2009) but also the studies done by Peterson (2000) and Tung (1982) revealed that the most of expatriates are parent-country nationals. But, as we can see in Table 2, in Britain and American multinational companies the expatriates originate from countries other than the mother country, the highest percentage being in the UK (37.45%). By contrast, the multinational companies from Japan use in 98.76% of the cases, Japanese expatriates managers. In Germany we also found a poor use of expatriate managers coming from another country than the country of origin (11.86%).

Table 2. The origin of expatriates.

	Germany	UK	Japan	SUA	Total
Parent – country nationals	79.42%	55.90%	98.76%	67.41%	71.72%
Third – country nationals	11.86%	37.45%	0.47%	23.11%	20.92%
Expats in the headquarters	8.72%	6.65%	0.77%	9.48%	7.36%

(source: Tungli & Peiperl, 2009)

According to Tung's study, in the early '80s, only 3% of U.S. multinationals, 5% and 14% of Japanese multinationals in Europe measured the technical competence of candidates in any way. Networking skills were assessed in 5% of cases in the U.S. and 21% in Western European multinationals. None of the Japanese company interviewed reported such assessment for expatriates. The 2009 study highlights the use of various methods in the selection of candidates, structured interviews being used regularly and seldom references and self-nomination. Japanese multinationals use these two last methods more often and in a lesser degree the structured interviews. The rarest methods used for selecting expatriates are psychological and cognitive tests. Only in Britain sometimes are used these last

methods when selecting employees for foreign assignments.

Using expat employees requires training before departure. The most used types of training for expatriates are language courses, intercultural communication courses: country specific cross-cultural training and general cross-cultural training. (Table 3). In recent years specialists found that an increased number of expatriates originate from developing countries. Therefore human resources professionals and trainers need to adjust their training programs both in terms of content and in terms of group that is addressed. For example, often for expat employees is provided English language training, although they will not be detached in countries with English as an official language. The main reason is that English language became an "official" language of communication in most multinational companies.

Table 3. Predeparture training provided for expatriates.

	Germany	UK	Japania	SUA	Total
Foreign language training	4.60	3.79	5.05	4.26	4.35
Country specific cross cultural training	3.37	3.27	4.25	4.27	3.78
General cross cultural training	2.49	2.97	4.85	4.13	3.50

(source: Tungli & Peiperl, 2009)

Besides formal and specific pre-departure training, more general pre-departure preparation might involve informal conversation and exchanges of helpful tips and advice through gatherings and other encouraged interactions between pre-departing employees and their families and any other available inpatriates. In the pre-departure preparation, a mentor or coach from the home workplace could be assigned to keep in regular contact during the assignment, helping the expatriate navigate

through the inevitable adjustment and ongoing challenges. The extensiveness of the training time, experiential exercises and supportive learning materials should depend on the degree of the learning and adjustment required with the inpatriate assignment.

There are also situations where the efforts of selection, training and motivating of the employees detached in various countries are useless, expatriates returning home earlier than it was planned. The reasons brought into light are diverse: operational problems, poor performance on the job, inability to adapt to local circumstances, family problems.

Tabelul 4. Failure rates.

	Germania	UK	Japonia	SUA
Less than 10%	90.60%	93.40%	94.40 %	86.30 %
More than 10%but less than 20%	0.00%	3.30%	0.00%	2.30%
Equal to or more than 20%	9.40%	3.30%	5.60%	11.40 %

(source: Tungli & Peiperl, 2009)

Analyzing the enormous costs involved in using expatriates (30% of expats in Russia, 27% of expats in Hong Kong, 26% of expats in Japan, 25% of expats in Switzerland and India earn more than \$ 250 000 per year [5]) we may wonder why their numbers increase from one year to another. Besides the fact that they know very well the management and the company policies, expatriate employees are more involved in the business than non expatriates, but much harder to keep.

A study conducted by Kenexa Research Institute indicate that more than half of expatriate managers are seriously thinking to leave the organization as they tend to see the relationship with their employer as a short time project. However, when it comes to job involvement, expatriates are more focused on current tasks, 53% of them being fully committed to their job.

Career Management in the Psychiatric Hospital Socola Iasi

Alexandra Marinescu,
Student A.S.E. Bucuresti
Gabriela Marinescu
Professor Ph.D. UMF Gr.T.Popa, Iasi

Abstract

Career can also be studied as a mix between the individual and organizational elements. The job perception and the attitude of the individual depend on the compatibility between what is desirable (skills, needs, preferences) and what the job offers (motivation, constraints, opportunities, in short, rights and obligations).

Career orientation is a relatively stable pattern of talents, values, attitudes and occupational activities.

Career has been analyzed as a dynamic process with double dimension:

- External: the objective sequence of positions that the individual crosses during his active life
- Internal: the interpretation that the individual gives the individual experiences of its objectives in terms of subjectivity.

Key words: career, motivation, organizational context

JEL classification: J59

1. Introduction

This study is an analysis of organizational context inside which takes place the career evolution in an organization from the health system. The organizational climate reflects the way in which employees are motivated to grow professionally through relatively stable patterns of talents, values, attitudes and occupational activities.

The individual progress is measured multidimensional according to the shifting within an organization or occupation: horizontal shifting (skills and abilities

development), hierarchical shifting (to the top-level of the hierarchy), shifting towards obtaining influence and power. The concepts and models regarding career are found in endless combinations, each unique mix giving again the unity measure in diversity.

The created organizational context has to allow identifying the technical skills and the preferences of employees regarding the career and determining the organizational structures that fit with the guidelines identified. Following these issues regarding career may be useful in establishing job descriptions, growing stages, in order to find a good or reasonable relation between the organization's needs and possibilities and preferences of each individual starting from the moment of hiring (enrollment).

Career influences several aspects of a person's life, its evolution rising questions like:

- How much money he will win?
- What clothes he will wear?
- What benefits will result from this job?
- What organization / company he will work for?
- What people he will get in touch with?
- What kind of work he will do?
- Where he will work?
- How long he will work?
- What responsibilities he will have?
- What things he will learn?
- What skills are necessary?
- What personal interests will find expression in this work?

2. Material and method

The case study was conducted at the Psychiatry Hospital Socola Iasi and the following methods and tools were used in order to collect and process the information:

1. Questionnaire on organizational climate and human resources in terms of career satisfaction
2. Direct observation,
3. Polls Interpretation
4. Centralization of results;
5. Graphical representation
6. Descriptive analysis.

The investigation regarding the organizational climate and career development was made at the Psychiatric Hospital Socola on 2 groups which consist of 80 people. The questionnaire regarding career development was applied to a sample of 74 respondents of which:

Table 1 Structure of respondents by job nature

	Types of jobs	Number of items	%
1	Assistant Psychologist	2	2,7
2	Primary care nurse	26	35,13
3	Stretcher	24	32,43
4	Bearers	8	10,81
5	Resident doctor	4	5,41
6	Medical recorder	1	1,35
7	Orderly	9	12,17

Table 2 Structure of respondents by age:

Table 3 Structure of respondents by length of service:

	Length of service	Number of items	%
1	Less than two years	8	10,81
2	Between 2-5 years	20	27,03
3	Between 5-10 years	44	59,46
4	Over 10 years	2	2,7

Table 4 Structure of respondents after studies

	Study	Number	%
1	a post-	16	21,62

	secondary school		
2	post-secondary studies	32	43,24
3	University Graduate	24	32,43
4	Postgraduated	2	2,7

Tabelul 5 Structure of respondents after salaries:

	Salary	Number	%
1	500-1000 RON	10	13,51
2	1000-1500 RON	40	54,06
3	1500-2000 RON	16	21,62
4	Peste 2000 RON	8	10,81

We examined the following specific aspects of career management, namely:

1. the safety of a long-term job,
2. career development opportunities within the organization
3. the promotion system within the organization according to their performance,
4. regular training system;
5. regular job redesign based on skills and knowledge of employees,
6. the degree of autonomy and responsibility given in fulfillment of its responsibilities;

	Age	Number of items	%
1	20-25 years	4	5,41
2	25-30 years	26	35,14
3	30-35 years	6	8,11
4	35-40 years	12	16,22
5	40-45 years	16	21,62
6	45-50 years	6	8,11

7. improvement of professional expertise and managerial skill development.

3. Case Study

Actual implementation of the study was conducted during September 2009 - March 2010. In order to made this study we have

asked for the agreement of the head of the institution.

Difficulties encountered during the investigation:

- lack of time from respondents;
- a part of the respondents didn't answer to all the questions;
- difficult or inappropriate questions

Following the application, processing and analysis of questionnaire responses were established key elements influencing career management: organizational climate, value system, value hierarchy, human resources satisfaction to the conditions offered by hospital. Data was also analyzed from the concepts point of view: communication, performance evaluation, motivation, rewards, organizational culture.

4. Results

1. After long-term job security criterion we found that 97.29% of the respondents pay a lot of attention to this criteria, but 40.54% have no confidence in job security, especially within the crisis, when budgeting are threatened by large layoffs.

2. After the criteria of career development opportunities within the organization we found out that 62.16% of respondents are satisfied with the career

development opportunities within the organization, and 94.59% of them are very interested in career perspective

3. After the criteria of promotion system within the organization according to their performance, we found that 59.45% of employees are unhappy with the promotion within the hospital, while 91.89% considered this very important to them.

4. Following the criteria of lifelong learning, 59.45% of respondents are not satisfied with regular training system, and 91.89% consider that training system should be improved in the future

5. After the criteria of specialized skills, 91.89% consider this very important, but 64.86% are dissatisfied with the regular job redesign based on specialized knowledge and skills.

6. Following the criteria of autonomy and individual responsibility, 48.64% of respondents are not satisfied with responsibility and freedom granted in accomplishing his own responsibilities, although 89.18% considered this very important to them.

7. After the criteria of supporting the individual in career development, 56.75% of employees are not satisfied with the types of personal career incentives applied in the hospital.

5. Conclusions

The career development, the resonant organizational climate, the continuous learning, performances, innovation, creativity, efficiency have lower percentage values. We believe that this is due to the fact that the authoritative style of leadership predominates in the hospital. Employees are concerned about accomplishing the tasks and respecting the organizational measures. Can be observed that many respondents appreciate that the job climate is a pleasant one, or at least acceptable.

The study and statistics show that such sectors of activity are attractive to people who have as career anchor the safety, stability and prestige. In many public sector health organizations we can meet traditionalists'

individuals, conformists who adopt the values and standards of the organization in which they work. Their main goal is to maintain balance and peace of the professional and family life. The image of these people is described by expressions as "trusted assistant" for superiors, because of their desire to do what is requested. The main reason of obedient behavior is the exercise of the chosen profession, the authoritarian style of managers, the bureaucratic climate, but also the desire of a having a secure job, to get a decent income and to ensure a financially comfortable retirement perspective .

An individual's career and its problems move their center towards lifelong learning, vocational and multicultural, specific and interpersonal skills. Professional individuals, intuitive "players", multiple intelligences are concerned about reaching contextual performances and developing discernment.

Choosing and developing the career are managerial strategies directed outwards, strategies that resonantly integrate individual goals into the group or organization's goals.

In a resonant organization managers and employees must communicate for the good of the individual and the organization. For example, the career employees develop and pursue its plan proactively and not reactive, and support and not obstruct or managers neglect the development of staff. Career is a cumulative process that, as employees accumulate experience in a post at a certain hierarchical level they develop their skills entitle them to occupy important positions in hierarchical levels or above. In general, a certain level positions tend to be steps toward the next higher stations, complex phenomenon that we refer to pyramids and hierarchical organizational structures.

Considerations on Monitoring and Evaluation of Public Funded Projects as Part of Their Implementation

Desiree M.A. MARINESCU
Academy of Economic Studies, Romania
desiree_marinescu@yahoo.com

Abstract

An increasing interest in public funded projects is emphasised during the last period.

Monitoring and evaluation represent two of the main activities included in the project cycle. Understanding the concepts and the reason of performing them with due diligence contribute to a successful implementation of public projects as well as provide useful information for improved future public interventions.

The management performance of public projects is assessed through specific indicators defined along the 5 criteria set out by the OECD – relevance, efficiency, effectiveness, impact, sustainability.

Key words: public funded projects, evaluation, monitoring

JEL classification: H43

1. Introduction

European Union provides financial assistance through various programmes to support national development efforts. The growing interest for public funded projects and the amount of allocated funds outlined a new principle important for the use of public financial resources: *accountability*.

Responsibility for public money requires particular attention to assessing Government actions. Therefore, evaluation, and monitoring, is not only a process that assess the results in relation to a defined set of criteria and specific performance indicators, but also a process that analyses the performance of existing actions and provides recommendations for improving future interventions.

The present article presents the concepts of evaluation and monitoring to better understand their role in project implementation.

2. Evaluation and monitoring concepts

In 1992, the European Commission adopted a set of tools for developing and managing a project, based on logical framework analysis method, called Project Cycle Management (PCM). Moreover, this method has been widely used by many other financing organisations, including some EU Member States, and encouraged by the Development Assistance Committee of the Organization for Economic Cooperation and Development (OECD).

The six phases of the project cycle are detailed below.

Programming is the first phase of the PCM, consisting in setting up the framework, the general guidelines and principles for cooperation, agreement of sectoral and thematic focus. It outlines the broad ideas for projects and programmes.

Identification is carried out under the established framework by analyzing problems, needs and interests of possible stakeholders. Ideas for projects and other actions are identified and screened. Pre-feasibility studies that help to identify, select and compare specific options are conducted. The outcome is a decision on whether or not the options developed should be studied in more detail.

Appraisal analyses all the important aspects of the project idea, given the overall objectives and priorities, the key quality indicators and the views of main stakeholders. Relevance and feasibility issues are key issues in this phase and detailed plans for implementation of activities are prepared. The outcome is a decision to take the project forward, or not.

In the **financing** phase a decision is taken by the relevant parties about whether or not to

fund the project.

Implementation refers to the material and human resources allocated to implement the project, employed to achieve the project scope. Activities implemented under the project typically involve procurement of contracts for studies, technical assistance, goods and works. Evolution of project activities is monitored and, if necessary, adjustments are proposed when changes in the initial conditions occur. At the end of implementation, a decision whether to close or extend the project should be made.

Evaluation is an estimative, systematic and objective as possible activity of the project design and implementation results. The scope is to assess consistency by comparing project results with proposed objectives, by determining the relevance, efficiency, effectiveness, impact and sustainability of the project.

The assessment must provide reliable and useful information, allowing the incorporation of lessons and best practices. It leads to a decision to continue, change or stop a project, and its conclusions are taken into account when planning and implementing similar projects.

Practical Guide of the European Commission (PRAG), prepared by DG Budget defines the main purposes for conducting

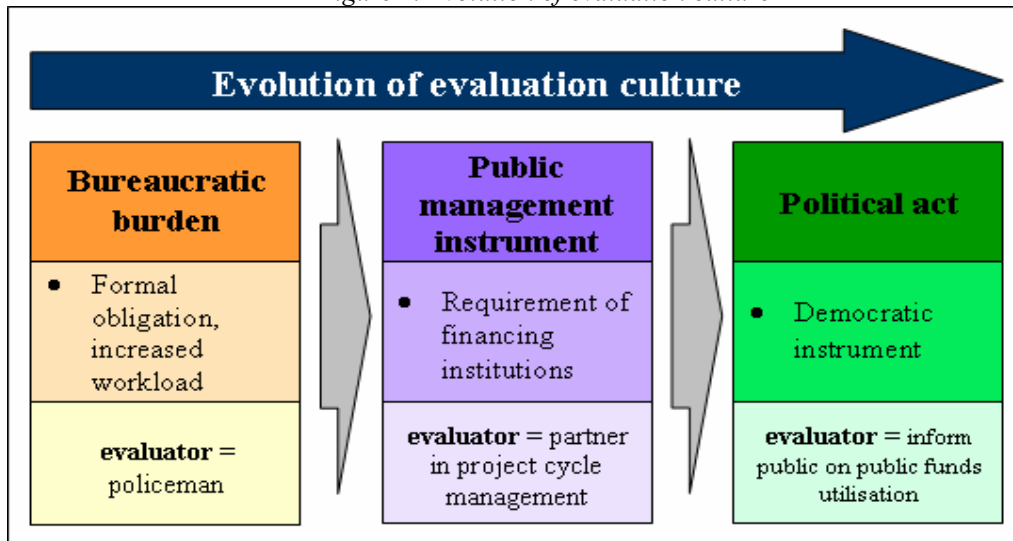

evaluations, as follows:

- to contribute to assistance development, including information for determining policy priorities;
- to help the efficient allocation of resources;
- to improve quality of implemented actions;
- to report on achievements and results of interventions.

Evaluation is considered to the process that allows independent analysis of the benefits of a public funded intervention, by reporting to specific, such as the impact of funded projects, their efficiency and effectiveness, continued relevance to the beneficiaries needs as identified the programming phase.

The evaluation should provide objective analysis and present analysis the assessed project. Independent evaluation is the assessment made by entities outside the activity under evaluation. These entities are outside the control or influence of those responsible for the development or implementation of actions.

Figure 1. Evolution of evaluation culture

In addition to evaluation, another important activity is monitoring. Monitoring represents a

task which can not be missed. Thus, an effective checking on the operation of management and control system, including

monitoring system is made.

The need for monitoring of project implementation is determined by:

- ensuring sound financial management;
- fraud and irregularities prevention;
- ensuring that project meet schedule and objectives are achieved;
- possibility of early intervention when problems come up.

Financial corrections may arise from the identification of deficiencies in management and control system, and because of changes in environment.

An operational monitoring system envisages the following:

- a monitoring plan;
- a risk assessment;
- an effective and clearly determined operational structure;
- sufficient resources for monitoring;
- monitoring actors know their roles and fulfil them accordingly;
- monitoring tools are mobilised according the schedule;
- visibility monitoring is conducted;
- monitoring conditions are achieved;
- effective resolution of discrepancies.

Monitoring is conducted at several levels through specific instruments. Monitoring is taking into consideration as well horizontal priorities, which refer to cross-sector issues, impact on society as a whole:

- equality regardless of gender, religion etc.;
- environmental impact;
- relevance to minority and vulnerable groups.

Monitoring activities are carried out continuously and as planned during the project implementation, and if adjustments are needed the required measures are taken, including decisions on rescheduling activities.

3. The evaluation cycle

Evaluation can be conducted during the implementation of the project (interim evaluation), at the end (final evaluation) or

after the implementation (ex post evaluation), either to support a better targeting of the project or to draw useful lessons for future programmes. Evaluation should lead to a decision to continue, revise or stop a programme, and the conclusions and recommendations should be taken into account in designing and implementation of future programmes.

Ex-ante evaluation

The main purpose of the ex-ante evaluation is to gather information and to make analyses to support in defining objectives, to ensure that these objectives can be met; the instruments used are effective in terms of cost and possible subsequent evaluations relevant. European Commission stresses out that a quality ex-ante evaluation is required for the following main reasons:

- allow a proper assessment of the level of proposed financing and resources to understand if it is consistent with the results and expected impact;
- ensure the premises of an ex-post viable evaluation, and hence the justification for the results and impact, which is largely dependent upon the quality of intervention preparation at the beginning stage

Interim evaluation

Such types of evaluations aim to verify the investment programme progress and to propose possible changes during implementation, until it is finalised.

Many times confusions are made on terminology. The following table presents a comparison table between the assessment (particularly referring to interim evaluation), monitoring and audit concept.

Table 1. Comparison between assessment-monitoring-audit concepts

Question	Evaluation/ Assessment	Monitoring	Audit
What?	Mainly, analyses on efficiency, effectiveness, impact, relevance, viability of policies	Mainly analyses on efficiency and effectiveness as a systemic management activity	Standard checks of financial operations and declaration on legal and contractual compliance. Additionally, it is made the Performance Audit, referring to efficiency and management issues
How?	In-depth analyses	Quick and continue analyses, applied immediately for improvement of following actions	Checking on financial reports
Who?	External evaluators specialised on specific subjects	Internal and external evaluators	Professional external auditors
When?	Once or twice, during implementation, to re-orient the programme if needed; essential is the ex-post evaluation which provides lessons for future actions	At regular intervals, few times per year	During or at the end of implementation

The ex-post evaluation of a project is conducted after the completion of the project, focusing more on the impact.

General purposes of ex-post evaluation are as following:

- offering the best opportunities to learn useful lessons for the beneficiary of the evaluated project for future similar situations;
- maximizing the diversity of issues and areas covered by the assessment process.

The methodology used is based on four major sources of information: monitoring reports, interim evaluation reports, views collected from the authorities responsible for implementation and in-depth investigation (case studies).

4. Evaluation criteria of public funded projects

The most applied criteria in evaluation of public funded projects are the *DAC 5 Criteria*. These are developed by the Organisation for

Economic Cooperation and Development (OECD). The five criteria are as following:

1. *Relevance*: examines the extent to which stated objectives are appropriate to the addressed issues and the project feasibility in relation to the environment where it is implemented;
2. *Efficiency*: evaluates the link between resources involved in project, activities performed and obtained results if the cost is reasonable, in other words *value-for-money*;
3. *Effectiveness*: concerns the degree to which the project achieves its objectives through the envisaged activities and provision of foreseen outcomes;
4. *Impact*: follows the impact of short, medium and long term, how the project affects the environment, the political and social aspects, changes in behaviour etc.;
5. *Sustainability*: refers to long-term positive benefits that the project can bring, taking into account its connection with other projects.

These criteria are not limitative. Additional

criteria include: coherence, economy, utility, consistency, distributional effects, acceptability etc.

These criteria are not necessarily considered in all phases of the project cycle. The relation between the evaluation criteria and the temporal scope of the evaluation is defined according to their main applicability:

- the relevance criterion is assessed during ex-ante evaluations;
- the efficiency and effectiveness criteria are assessed during interim evaluations;
- the impact and sustainability criteria are assessed during the ex-post evaluations.

5. Conclusions

Monitoring and evaluation as part of project cycle have a significant importance in assessing project implementation and contribute to defining future actions. Each of them has a specific role. However, confusions in terminology are often seen. The DAC criteria applied through specific indicators provide common grounds for assessment. Understanding better both activities contribute to successful public interventions.

New Management. Empowerment and Ethics

Gabriela Marinescu

Profesor univ.dr. U.M.F. Gr.T.Popa Iași
E-mail: marinescu.gabriela@ymail.com

Alexandra Marinescu

Studentă, A.S.E. București
E-mail: alexandra_m@yahoo.co.uk

Abstract

This paper is just an attempt to more penetrate the complex phenomenon of management in organizations. The theory and the experience of many organisations show that the empowerment is a dynamic system of values, useful to distribute the authority, resources, responsibilities, benefits and opportunities between the members of a group. The empowerment help managers to make decisions more efficiently, to motivate their teams and to satisfy better their employees, clients, partners and the community. By the other part, ethics, in the philosophical acceptance of the concept, it takes part in this system of values, enriches and supports its dynamics.

Keywords: empowerment, bioethics, heart management, values.

JEL classification: M19

1.Introduction

The organizations and their management, in the largest acceptance of the syntagma, go through a difficult process of transformation and adaptation to the changes of general paradigms like globalization, consumerism, IT equipment and even global warming, phenomena that influence directly the relationships, the institutional relations, legitimacy, responsibility.

How can empowerment and ethics positively influence the manifestation of these phenomena? The management is compatible with social and then economic efficiency as far as the reforms in Romanian system includes deregulations and decentralization. On the other hand, responsibility must be stimulated not only for those inside the system but at the

level of each individual that must take care daily of their state. We notice it problems gravitate around the concept of responsibility, an essential term both for empowerment and ethics.

2. Theoretical and Empirical Study

“Empowerment” represents according to some authors¹, “offering responsibilities to the staff of an organization simultaneously with creating opportunities for their assumption. Power and authority from organization are distributed officially by clear establishing of responsibilities concomitantly with the assurance of the means of fulfillment of the understood, motivated and assumed tasks.

Ethics, according to the moral philosophy² and by the principle of justice, becomes the regulator of the system of values, especially in the situations where resources are insufficient for the needs and responsibilities superior to rewards.

The system of values of an organization is first made of human values, specialists, professionals trained to fulfill the mission of the whole to whom they belong and are devoted.

The right division of power, authority and responsibility among the members of the group supposes managerial changes, first in communication, the most frequent source of conflicts, failures but also successes. Two or more people agree to certain objectives and to attain them they come into contact, collaborate, inform, execute, answer,

[1] Olaru, M., Isaic-Maniu, Al., Lefter, V., Pop, Al. N., Popescu, S., Drăgulănescu, N., Raucea C., Tehnici și instrumente utilizate în managementul calității, Ed.Economică, București, 2000, p.133

[2] Harris, J., Bioethics, The history of bioethics, Readings in Philosophy, Oxford, 2001, p.1

contradict each other and enjoy. Empowerment, as a balance of resources and responsibilities, may be a real means of progress if the members of the group are motivated and act ethically and reasonably despite the differences³ among them. To come to a consensus, the members of the organization and first of all managers must possess the ability to lead and communicate convincingly. The reasonably-emotionally intelligent managers use as “compass” of public ethics integrity, responsibility, empathy. This leads, slowly but surely, to the increase of trust in those who lead, the increase of self respect and respect of others, the diminution of stress or a better management of it.

The transformation of the managerial communication in a real progress factor is accelerated or retarded by the work atmosphere “established” in the institution, by the natural principles of correctness and justice, ethics and empowerment.

Empowerment may be idealized like a balance in relative equilibrium, a barometer of responsibilities in terms of motivation, possibilities and resources. Ethics, as integrity and justice of a professional exceeds the written codes and becomes the organization binder, the unwritten law that may interpret a written law, if the values it subscribes to, require that. Empowerment accentuates the duality of management more precisely, the simple and clear organization on one hand, the delegation of authority and power, on the other hand (delegation that is made in favor of those people seeking to maximize the ratio positive effects – negative effects /costs).

Empowerment and ethics allow the construction of a strong and famous identity by implementation of an individualized, flexible, high quality and stimulating management. This type of management circumscribes to the triad, «responsible - ethic – practical» in the management of a real and modern organization.

Management: “Responsible -Ethic -Practical”
(R.E.P.)

A triad of power and organizational culture, “Responsible – Ethic - Practical” becomes condition and cause of a modern and new managerial system since:

- Responsibility supposes the clear definition of organization’s mission and

objectives depending on the real and relatively secure financial, human, material and IT resources. Responsibility refers to the obligations of the organization members and to their assuming possibilities by establishing some behavior rules accepted and used by both managers and their subordinates. Authority decentralizes responsibly and in a motivated manner because obligations and rights are explicit and managerial relations pursue objectives both for the individual and the unit.

Once created, the new culture, relying on authentic values, becomes the cause of some performances that will be, at their turn, a reason for future ones imposed by the permanent changes of micro, macro and world environment.

Managerial responsibility, on the other hand, represents the obligation to fulfill the activities attributed to the position. Thus:

- It is an assumed obligation, a reason for which it can never be delegated;
- It is a formal and informal engagement to exercise the management functions afferent to a job and a hierarchic level, giving value to the supposed and acknowledged competences;
- It is a willing agreement, a contract on the basis of which the manager assumes clearly defined rights and obligations;
- It means the formal description of the activities attributed to a manager that can be found in the job description;
- It is an organization strategy from the following points of view:
 - Responsibility of top managers;
 - Distribution of tasks for other positions;
 - Responsible actions: individual and group actions

Responsibility also represents a unique set of changing subassemblies of individual, collective, moral, professional, social, natural, formal, partial or total responsibility.

Professional responsibility covers the space of legal practices of a profession in the and supposes the exercise of managerial attributions with specific competences and under the empire of law and reasonable-emotional discernment. It supposes the mediation of group interest conflicts, the pre-eminence of the general or public and collective interest to the detriment of the personal fraudulent one.

[3] Popescu, A., Diferențe de gen în managementul performanței, Centrul Parteneriat pentru Egalitate, 2006

The moral responsibility naturally adheres to the professional responsibility, both of them forming a whole circumscribed to the values, beliefs, and customs of a community or group. "To do" or "not to do" become both moral and professional. The compass of the institutional ethics is made of integrity, responsibility, empathy.

- Ethic becomes an extremely complex concept as manifestation and effects, special and different from any other field. The central concepts with which the institutional ethics operates are duty and usefulness. What do these mean in the health field? Judge's duty and responsibility before the client are not influenced by his/her motivation, too?

A set of moral rules resulted from the abidance by the most elementary notions of ethics must contain:

1. Abidance by the engagements made. We all want to have the certitude that the promises made by others are kept because not abiding by this elementary norm, the social interaction built with effort tends to stop and relationships will deteriorate. Any moral theory is useless if it does not abide by the promises made or conditions change.

2. Non-violence. Indirect threat of physical integrity by psychic pressure, worry, lack of motivation leads to the appearance of some complexes with negative implications in the work environment; truth will be hidden and life will be distorted. With rights and obligations correctly highlighted in codes of ethics and bided by equidistantly we may built a communication way by which conflicts may be prevented.

3. Mutual help. Morality and bioethical code regulate the human behavior in the health institution. "Management and other organizational processes must be capable to assure the maximum probability that, in all interactions and relations within the organization, each member, in the light of past, values, wishes and their expectations, should consider experience as being supportive and that this will develop and maintain for them the feeling of value and importance of their own person"⁴.

4. Respect for the other may start from the expression "each human being is superior to me". Ethics asks for compassion, empathy as

reciprocal manifestations of an intelligence manifested by our fellow creatures.

5. Respect for property and the equidistant law in a state of rule. People want to use the right of property over goods and if they consider that their own body is a property this represents a corollary of the respect for person.

3. Conclusions

The modern organization relies on people with very diverse needs, wishes, feelings, and emotions. The motivation of each individual for the work they do is the result of a complex system of intrinsic and extrinsic factors, subjective and objective, that combined give an average of everyone's behavior in society. Each employee is a multiple and controversial personality who wants to be known and acknowledged, appreciated, motivated for what they do. In practice they notice that the subjects involved in different activities adopt more easily an ethical attitude if they are motivated (financially, professionally, spiritually). Work in some field suppose more than in any other domain, intellectual, practical, emotional implication transposed in managerial communicational interactivity. Conscious that they belong to the organization and that they mean a lot to it, motivated corresponding to solicitations, activity and competences, individuals get involved emotionally and ethically and come into strong interaction with third parties becoming more flexible, more optimistic and especially more correct, more credible and more productive. Their achievements are acknowledged, appreciated because the information exchange – ideas, rules, solutions, warnings - occurs at a correct rate of priorities of everyone towards partner or group. Credibility, the core of the image, correctness and quality result from the practicing of emotional, ethical, motivating management liberated from political-bureaucratic, collective or individualist aberrations.

Management comes holistic and oriented towards the creation of value, measured in satisfaction of all people involved: managers-patients-employees-community. The results of implication of ethics, its effects in the terms of political economy are not totally quantifiable in the measure units corresponding to the lucrative enterprises.

- Practically the value system proposed by empowerment in management means first a

[4] Likert, R., The Human Organization: its management and value, Administrative Science Quarterly, vol.12, nr.3, dec.1967, p.503-506

serious reconsideration of criteria and indicators used for financing and evaluating different activities, in the multitude and complexity of its facets. It practically means the increase of authority and competence of the organizations' managers hindered by restrictions in using their own funds, by ministerial decisions, and conservative conceptions. The informational asymmetry specific to some organizations is a strong argument for managerial-decisional decentralization absolutely necessary at all levels so as to become more practical, ethical and motivated.

As a corollary of the ideas expressed above, we sustain that empowerment and ethics support a management of competences, the only one developing a strategy of desirable and possible things based on hierarchy and also orientation, mobility, flexibility, and heterogeneity.

Abstract

This paper examines the fundamental assumptions that competency based frameworks are based upon in relation to leadership development. It examines the impetus for this structure becoming the existing theoretical base for developing leaders and tracks the historical path to this phenomenon. Research suggests that a competency-based framework may not be the most appropriate tool in leadership development across many organisations, despite the existence of these tools in those organisations, and reasons for this are offered. Varying approaches to developing effective leaders are considered and it is suggested that leading is complex as it requires both competencies and qualities in order for a person to be an effective leader. It is argued that behaviourally-based competencies only cater to a specific part of the equation when they relate to leadership development.

Key words: leadership, behavior, competency, development;

JEL classification: M12/F23/ J24;

1. Introduction

A great deal of attention has been given to leadership development, and it has emerged as a profitable industry in its own right over the last decade. This paper questions the effectiveness of a competency framework for developing leaders in a work-related environment and considers the reasons why it may not be appropriate as the prevailing theoretical base for developing leaders. Further, although competencies may be suitable for some types of skill development, the competency framework system from whence it

derived is not easily migrated to cater to the complexities of leadership and its development. Developing leaders is a complex issue and a competency-based matrix may be fundamentally too narrow to prepare someone in such complexities. [4] For the purposes of this paper, 'leadership' is defined as being distinctly different from 'management'. Day (2001) suggests that a management role refers to processes and activities that need a person to manage them, whereas a leadership role is more about a person leading in scenarios whereby there are no prescribed situations or outcomes. He suggests that the leader must work in unforeseen circumstances and, in order to do this effectively, the person must have considerable skills, attributes and knowledge. The role of the leader is about engaging others to work within a context that has no predetermined outcome, and therefore both Hollenbeck, McCall and Silzer (2006) and Day (2001) caution that due to the complexity of leadership and the outcomes that are sought, we must not confuse a leader with a person who 'manages' a set and given task.

2. A competency-based framework reviewed

Hodge (2007) reminds us that competencies incorporate 'skills, knowledge and behaviours'. However, literature on management and leadership has extolled for some time that leadership competencies and qualities are two distinct but critical elements of effective leadership and that, in a development sense, both these aspects need to be taken into consideration (Donovan & Jackson 1991). There are numerous sources regarding competency systems and frameworks that address the

political and economic drivers underpinning the introduction of such systems (e.g. Hawke 2000, Hodge 2007).

It has been suggested that competency-based systems have led to a shift in the way training is conducted and that they have led to a more corporate based training focus; however, it is argued that the critical paths that led us to the competencies of today has had both a political and social impetus that stems from the USA over two decades ago. Gonczi (2000) questions the effectiveness of such a framework, and examines what has occurred in other countries in his attempt to evaluate it. He examines the complexities of adult education and suggests that there are many factors that determine if a worker is competent which are outside the somewhat prescriptive nature of a competency system. [10]

3. The limitation of developing leaders via a competency-based approach

Competency-based leadership development has clearly emerged as a dominant framework, with research in the USA showing that over 85% of companies in that country utilised a competency framework for leadership development.[7] However, it has also been suggested in other studies in the USA that having a competency-based framework for leadership development has had limited impact on growing effective leaders [4]. In this research, it was discovered that other approaches to leadership development may be shown to be more effective, and the research outlined what they considered were the critical aspects to leadership development ahead of leadership competencies.

It could be argued that leadership is greater than the mix of skills, knowledge and behaviours which competencies were first defined as, and that the essential missing ingredient is 'qualities' [1] for which, we would argue, a competency-based approach is not entirely able to cater. Writers on management development often separate these two aspects of leadership, and we believe this is due to the fact that leadership is a far more complex set of abilities that extend beyond the technical competence to 'manage' something.

Necessary leadership traits such as integrity and intellectual capability are very difficult to develop and locate within a competency matrix.

Sixty two managers from a large financial institution were interviewed about their own progression to leadership appointment and the way they make appointments themselves. All the leaders interviewed spoke about qualities rather than competencies as the decision points for these leaders when making senior leadership appointment [3]. A convenience sampling approach was utilised for this study, and interviews were conducted in 2006 and 2007 across Victoria and New South Wales as part of a pilot study on leadership succession. All twelve spoke at length about what they looked for when appointing a senior leader.

Each interviewee was given a copy of the questions in advance and was offered full anonymity. Questions included:

- What factors did they look for in a person when appointing them to a leadership role?
- How did they assess such factors?
- How did they utilise and value the services of Human Resources in these processes?

One managing director talked about Maslow's Hierarchy of Need as the basis he uses when talking about good leaders and also when recruiting and evaluating if a person would make a suitable leader for his organisation. He spoke at length about how he would evaluate if a person was nearing a state of 'self-actualization' or if they were less secure as a personality and were more focused on survival or self-gratification. The questions that this managing director would ask people in an interview were structured so that he felt he could gain insight into a person's positioning in regard to his interpretation of Maslow's Hierarchy of Need. Another interviewee talked about trust and intelligence being the key characteristics he used when he evaluated leadership potential.

These characteristics for effective leadership from the perspective of the interviewees do not appear readily compatible with a competency-based approach to leadership. It is also notable that in this pilot study, although all senior leaders felt that Human Resources systems had a role to play in an organisation, they did not feel that the leadership development and assessment processes commonly adopted by their Human Resources departments provided valid tools or methods when it related to leadership. One reason for this may be that there are perceived inadequacies which constrain the opportunity to engage with the less tangible, non-technical

components of leadership; the result being that ostensibly these leaders made up their own system and criteria. This research is not exhaustive, however, and needs to be further developed to understand more fully the requisite role of Human Resources in leadership preparation. From this study, for senior leaders outside of Human Resources, competencies are not taken seriously when considering leadership effectiveness, particularly in the context of identification of leadership potential and as criteria for leadership development. In this context, it is interesting to note that a recent study in the USA found that, although 85% of companies had a competency-based framework for leadership development, less than half of these companies actually used this framework for senior leadership appointment [7].

4. Other factors to consider when developing leaders

The need for skills to be gained on the job, Lombardo (2000) claims, is critical. It is about mastering a job, not just being competent at it. A number of writers (Cornford 1997, Gonzci 2000) are concerned that there exists too narrow a definition of 'competent', provided by a competency system which emphasises minimal standards of skill acquisition rather than the mastery required by the truly effective leader. Learning to engage people, design a strategy, share that strategy with others and motivate people, are not such straightforward skills for a leader to master easily; there is timing and wisdom gained, which enables this to be achieved and developed [3].

The Corporate Leadership Council (2003) suggests two major factors for successful leadership development, based on leaders in the business acting as role models, and senior executive commitment to leadership development as a distinguishing factor. The Council (2003) suggests that, if these two factors are not present in a corporation, there is far less probability that effective leaders will emerge in that business, despite the presence of competency systems. Although one could conclude that having leadership competencies in place can assist leadership development, effective role modeling and rewarding desired management behaviours that matter are more beneficial. This leads to the question of what

other elements may be needed in order to assess and design leadership education. McCall (1998) suggests that self-awareness and feedback are important elements in leadership development and that, during the evaluation and development of leaders, it is critical to gain data from numerous people about how the particular leader is able to lead. This reduces the likelihood of the assessor or educator being manipulated into believing a person is more advanced in leadership skills than they actually are [9]

It has been suggested that learning new behaviours is harder for people than learning a new job or technical knowledge (Goleman 2002). Goleman suggests that a person may be high on ability to learn a new job but very low on ability to learn new or more effective behaviours. This clearly differentiates between a competency based approach to leadership development which sees behaviour as related in a simple linear fashion to skill and knowledge, and other approaches to leadership development which conceive of behaviour as mediated by personality in addition to the other components characteristic of the competency-based approach. Lombardo (1998) suggests that some leaders are able to perform in a superior way and that these abilities are superior in first time conditions. We know that this success is also indicative of a person's cognitive ability, which, it has been suggested, is an ability a person is born with [6].

This consideration of competencies and qualities prompts the often asked question: 'Are leaders born or made?' According to Goleman (2002), leadership is learnable; Lombardo (1998) would agree with this, as would McClelland (1985) to a degree. Donovan and Jackson (1991) argue that certain aspects of leadership can be taught, but that it is not from a blank starting point. There must be a propensity for leading, and qualities in which to embed enhanced skill, for example, more effective ways of communicating and planning. The view that there needs to be an aptitude for learning and a personality make-up that is conducive to effective and ethical leadership is also supported by research conducted by Hare (2003) and Morse (2004) which suggests that over 25% of chief executives and leaders in the USA have qualities that lack integrity. Hare's view is that leaders who are charismatic may also be insincere and manipulative, and that often the people with whom they are dealing are

not aware of being manipulated. He states that other qualities such as insensitivity, blaming, impatience, unfocused and parasitic behaviours are all important deficiencies to identify when looking for and assessing a potential leader. These attributes may go unnoticed in a narrow competency assessment and a person may be deemed as competent when in fact they would be a poor leader due to the lack of certain desirable qualities. Hare is referring to traits and qualities that are more complex than basic skills, knowledge and behaviour. When examining a company's 'development offering', the Corporate Leadership Council (2003) suggested that educational frameworks rather than psychological diagnostics are the fundamental key to developing leaders. The Council suggested that there does appear to be merit in a competency framework but, if used to the exclusion of all other approaches, such a system may leave a company short on effective leaders. That is, competencies may be a part of the equation for leadership development although certainly not the whole picture.

5. A key educational challenge – are leaders born or made?

If a key factor in leadership effectiveness is the culmination of more than just skills, then the other 'qualities' that make effective leaders need to be identified in order to understand if these qualities can be developed or not. One interesting perspective comes from an examination of leadership motives. McClelland (1985) has argued that the motives for leaders are not linked to values, and that these cannot be changed. His research suggests that people are either born with their motive (a doubtful proposition) or that it is developed and cemented at a very early age. He suggests that these motives are critical to leadership capability and success, however because they are established at an early age, they are generally thought to be highly resistant to change.

The three prime motivators outlined in his research are the achievement motive, the influence motive and the affiliate motive (McClelland 1985), and each is manifested in a different type of leader. McClelland's research showed that two-thirds of all effective leaders have the influence or high achievement 'driver'; however his research does show that an

individual's motive must be consistent with the motive of the organisation in order for that person to be a successful leader.

As pointed out earlier in this paper, a person is born with, or develops early, certain key characteristics, such as cognitive ability, motivators and traits. If these are critical in effective leaders, then as adult educators we must ask: can we develop such characteristics if they do not exist or, alternatively, assist in their enhancement once identified as being present in the person we are wishing to develop. If so, where does a competency framework fit in? Other research in Australia from Richards (2008) also suggests that competencies were not used in leadership appointments in a large Australian institution, despite there being in place a sophisticated competency based framework for leadership development. The phenomenon that this research uncovered for the organization was the importance of mentors, at the time of a leadership position becoming available, these being more essential to leadership success and sustainability for a leadership post than formal development. Crucially, personality characteristics or qualities, and the fact that these were congruent with the existing leadership's perceived qualities, were valued more highly by mentors than more narrowly assessed competencies. Research in other parts of the world also support such findings [4, 10, 1].

6. Conclusion – a multi-tiered approach to leadership development?

Leadership development cannot simply be concerned with meeting a standard as prescribed by a competency-based system. Adult educators need to focus on developing leaders' skills and abilities to work within a particular organisation effectively, with that person having the qualities appropriate to that organisation and strategy [1,9]. The 'influencing leader' who is able to engage people may come in many guises and the opportunity exists for human resource practitioners and education professionals alike to consider each individual on merit. Adult educators play a key role in showing how educational interventions can help an individual become a better leader, however they are limited by the characteristics of the individual with whom they are dealing and the environment within which that individual operates.

We do not know what the leader of the future looks like nor what the organisation of the future looks like (Florida 2002). The workplace is changing rapidly and so is our society – politically, socially and economically. These factors all mean that leadership is becoming more important than ever. However, they also suggest that the elusiveness of the effective leader appears to be more prevalent, although we would suggest that increasingly, people are looking for ‘ethical’ leadership by people with the requisite qualities to provide this type of leadership rather than a set of narrowly prescriptive skills and practices coming off a poor character / personality / qualities base. Adult educators need not to stay safe behind a matrix of competency standards and frameworks in the pursuit of a systemized approach to their profession; rather, they should question at each turn the outputs of their work, and how best they can adapt a theoretical base to suit the needs of individuals and organisations.

If organisations want to develop people to be more effective leaders, they not only need a competency-based framework which includes a rigorous educational framework, but also must consider the type of person with whom they are dealing, and design specific interventions that are relevant for that individual in the context of their field of leadership practice.

Developing an individual’s traits and abilities may not be entirely possible, and it appears it will not come as a by-product of leadership competencies. I believe we need, with the consent of the individual, an understanding of whole personalities and must design programs appropriate from that knowledge base.

We need to understand what motivates an individual and with this knowledge, combined with their skill set, design a robust educational curriculum for that individual. The goal should be to ensure that individuals coming out of an education process actually meet the outcomes that are required for a particular role, which is what every adult educator seeks.

Leadership development is complex, as is the role of being a leader. In this paper, only certain approaches have been addressed, rather than a comprehensive examination of all methods of leadership development. More research is needed on leadership development on a more empirical basis so that we can understand the suite of tools that may be used in order to

address this most critical issue of leadership development.

This new approach may well include a number of theoretical bases coming together – psychological, educational, sociological and anthropological – as a suite of interventions that, when put together will provide a higher quality of development initiatives for leaders. This may include competencies, but only as a component of a more comprehensive approach. Only with a multi-tiered approach, which is methodologically consistent, will there be any really sustainable leadership development that can bear the scrutiny of robust research in this field.

Abstract

As companies rely on people to cope with the current world economic crisis and with competition, in general, academics and practitioners specialists continue the research to find the answer to the classic question „*what drives us?*”. The latest discoveries regarding the implications of financial incentives on creative performance are surprising. Several findings show that rewards are often ineffective and, in some cases, they have a harmful impact on the overall performance.

The classical management instruments are outdated and companies need to engender a new vision that takes into account scientific research findings regarding intrinsic motivation. Creativity is limited by the use of financial motivation techniques. The negative effect of financial incentives on creative performance is not something to ignore.

Our aim is to emphasize the need for an improved research methodology that can enlighten the relationship between financial incentives, creativity and performance.

While there is no clear answer on the effect of intrinsic motivation on performance, many companies are building a new management conception based on autonomy, mastery and purpose, the three elements of a new operating system according to Daniel Pink’s view. [5]

Keywords: motivation, creativity, companies, performance.

JEL classification: M12

1. Introduction

People’s perception about work is distorted. Ideally, work should be a purpose in life and not means. But rarely this is the case. Therefore, academics and practitioners specialists try to find an answer to the dilemma: what drives people? Finding the answer to this question is even more important as companies rely on people to cope with the current world economic crisis and with competition, in general.

It is a well known fact that employees may constitute a competitive advantage, so that identifying the ideal solution for motivating them is the main concern for managers who want to improve employee performance. Over time, many motivation techniques have been applied, but the question „*what motivates us?*” remains current.

Therefore, what motivates people? Certainly the first idea associated with motivation is financial reward. Yet, what if this association is improper? Or incomplete? What if there is a possibility that what really motivates us does not cost anything? Or, on the contrary, what if the financial incentives have, in fact, the opposite effect - to degrade the performance? This seems hard to believe and without evidence we would be tempted to believe this is nonsense. But there are findings of repeated studies that show how creativity and innovation are stifled by high rewards.

2. Research findings

Daniel H. Pink¹, a career consultant which has been concerned with the scientific study of intrinsic and extrinsic motivation, brings this research to attention in his latest book *Drive: The Surprising Truth about What Motivates Us*. He emphasises the huge gap between the latest discoveries and what happens in companies relative to the implications of financial incentives on performance. [4] Daniel Pink states that even though financial incentives are sometimes successful, in most cases they don't work and often have an opposite effect, reducing performance.

In this respect, we consider necessary to present a series of arguments which underpin the study of Daniel Pink. [6]

A. The first argument is related to a research involving the „candle problem“. This problem was invented in 1945 by Karl Dunker with the purpose of studying the *functional fixedness*, which he defines as a mental block against using an object in a new way for solving a problem.

For this problem, participants are placed in a room where on a table they find a candle, a box of thumbtacks and a matchbox. Their task is to fix the candle alight on the wall in a way that prevents wax to fall on the table. The study shows that, at first, participants try to fix the candle with thumbtacks directly on the wall. Then they try to melt the bottom of the candle and so sticking it on the wall. None of these solutions is viable. The solution is to not consider the thumbtacks box as a container, but as a support or as a platform for the candle. Participants must set the box on the wall and then use it as a candle holder. Subjects have difficulties to solve this problem because they fail to see other functionalities of the box, other than a thumbtacks container.

To study the link between creativity, motivation and reward, Sam Glucksberg, a psychology professor from Princeton University,

USA, has proposed this problem to a number of subjects which he divided into two categories. He told one of the groups to solve the problem in order to determine an average time required to find the solution. For the subjects of the second group Sam Glucksberg establishes two levels of financial reward, so that whoever solves the problem faster will receive \$ 20 and the first 20 percent will get \$ 5.

The findings were surprising: those who were promised a financial incentive needed on average 3 and half minutes longer than the others. So, the financially motivated group had lower performance than the group which was not promised anything.

To deepen the study, Sam Glucksberg changed the problem data. Like the first time, he divided the participants into two groups and kept financial incentives for one of the groups. But he simplified the problem by emptying the thumbtacks box, leaving the box empty. Surprisingly, under these conditions, the financial motivated group had better performance, obtaining a better time.[5]

B. The study of Sam Glucksberg is not unique, it has been replicated repeatedly. Renowned economist, Dan Ariely, together with his colleagues from Carnegie Melon and the University of Chicago and with MIT students, conducted a research as well. He built a set of games requiring invention, creativity, motor skills and concentration power and gave those games to the students. The researcher set three levels of incentives: low, medium, and high and then he informed the students that if they have a high level of performance they will obtain a high reward.

The study finds are summarized below:

- If the games involved primarily motor skills, the higher the financial incentive the higher the level of performance.
- If the games implied even primitive cognitive skills, as the reward was greater it lead to a lower level of performance. Those who were promised the highest reward had the lowest performance.

C. Another enlightening study was conducted in 2009 by business analysts from the London School of Economics. They studied 51 financial rewards for performance plans within companies. Their conclusion

¹ Daniel H. Pink is a former White House speechwriter and the author of the bestseller *Free Agent Nation*, a contributing editor at *Wired* magazine, he has written on work, business, and politics for *The New York Times*, *Harvard Business Review*, *Slate*, *Salon*, *Fast Company*, and other publications.

was that *financial incentives may have a negative impact on overall performance.* [6]

The general conclusion that emerges from these studies is that even though financial incentives can motivate people to make more effort, they don't stimulate creativity. Still, financial incentives are effective for simple tasks, with clear rules that do not involve innovation. For tasks that require creative solutions, financial incentives narrow thinking and distract attention from the solution of the problem towards the reward. People can't focus on finding the best solution; instead their attention is focused on the aim of obtaining the reward.

D. There are, however, studies that cast doubt on these results. Robert Eisenhower and Linda Shanock draw attention to some behavioural studies that underline the fact that when subjects are asked explicitly to find creative solutions, the financial motivated group has a better performance.

Thus, when individuals know they will be rewarded for creativity, the creativity will increase, these individuals obtaining better results than those who receive no reward. A possible explanation is that individuals will seek creative and unusual solutions with more involvement. Individuals perceive the task as requiring creativity and thus soar in seeking new solutions. To achieve the desired results, people should be informed that creativity will be rewarded; otherwise they will seek common solutions.

If creativity is currently rewarded, individual behaviour will be oriented towards finding creative solutions every time. But research shows that managers mostly reward conventional performance and not creativity, so that employees believe that this type of performance is required. [3]

Despite the fact that the promise of financial rewards can motivate individuals to engage in the laborious process of searching for information, when employees have to generate creative solutions or to solve a problem, they will get better results if they are intrinsically motivated rather than being concerned about getting a reward.

3. A new management philosophy

Although there is no clear answer yet on the effect of financial incentives on creativity and on the implications of intrinsic motivation on performance, many companies are building a new conception based on autonomy, mastery and purpose, the three elements of a new operating system according to Daniel Pink's view. [6] Some of the new work process approaches are presented bellow.

A. ROWE

One radical example is the Result Only Work Environment (ROWE). This new system was founded in 2003 by Cali Ressler and Jody Thompson, two American advisers. *The Result Only Work Environment (ROWE) is a new management philosophy based on the premise that giving employees complete control over their time is the best way to increase productivity in the workplace.* [2]

This working system is practiced today in about 20 companies in North America, and the results of its implementation are: increased productivity, increased commitment at work, increased job satisfaction and reduced staff turnover. ROWE implies unlimited paid vacation time, no schedules, no mandatory meetings, and no judgments from co-workers and bosses about how employees spend their days. [4]

The inventors of the system, Cali Ressler and Jody Thompson, believe there are several techniques that can ensure successful implementation of ROWE: [7]

1. *Make meetings optional.*

Employees should have complete control over their time, they are the ones who have to make the decision whether to participate at meetings or not.

2. *Stop judging how people spend their time.*

3. *Reward employees based on results, not on how much time they put in at the office.*

4. *Don't prescribe what work-life balance looks like for your employees.*

Employees know best what they need and managers must respect the decisions they make.

5. *Don't handpick who gets to be flexible*

and who doesn't.

To be efficient, this result- based program must be applied to everyone.

6. Stop managing by walking around.

The best way to check the work progress of employees is by email. Meetings and telephones disrupt and divert attention.

7. Quit using fake crises as a management tool.

Time pressure decreases the quality of work results and frustrates employees.

8. Stop relying on human resources to do the "people" part of your job — get clear about performance goals, communicate often, and hold people accountable.

The two inventors emphasize the importance of communication. Managers should pay attention to the needs of employees and focus on how to help them succeed.

9. Trust your people like you trust yourself.

Managers should trust their employees. If employees feel under surveillance, this work system will not have the results expected.

B. 20 percent rule

Another version of how intrinsic motivation (autonomy, mastery, purpose) can be used to improve workplace performance is the *20 percent Rule* adopted by Google company. Employees have the possibility to use 20 percent of their work time for personal projects, having complete autonomy over that time, their team and the techniques used. Products created in this time period represent approximately 50 percent of all the products made in one year (such as Gmail, Google News etc.). [6]

C. Other examples

Like Google, Atlassian, an Australian company has implemented the same work system based on autonomy. After implementation, the company reported an increase of workplace performance.

Another example of the effect of financial incentives on performance in opposition with that of intrinsic motivation comes from the comparison between two encyclopedias: on one hand, Encarta, Microsoft's encyclopedia published by highly financial motivated professionals, and on the other hand, Wikipedia. The Wikipedia project has been successful, although no one has received any money to work

on it, while Encarta has been withdrawn.

Microsoft Encarta is a digital multimedia encyclopaedia created in 1993 and discontinued in 2009. In 2008 the complete English version consisted of more than 62,000 articles, photos, illustrations, timelines, maps and atlas, and others.

Wikipedia is an online, free encyclopaedia which has grown rapidly into one of the largest reference web sites. Created in 2001, Wikipedia consist now of more than 15,000,000 articles in more than 270 languages. The English version has more than 3,250,000 articles.

4. Conclusion

Financial incentives are the most popular tools used for motivating employees. Yet, if employees must generate creative solutions they will get better results if they are intrinsically motivated. Still, decades of research did not succeed to produce general agreement concerning the effects of reward on creativity [3].

Today's society is oriented towards innovation. The classical management instruments are outdated and companies need to engender a new view that takes into account scientific research findings regarding intrinsic motivation. Creativity is limited by the use of financial motivation techniques. The negative effect of financial incentives on creative performance is not something to ignore.

In order to fully understand the implications of intrinsic motivation on performance and creativity, specialists must develop an improved research methodology. Our belief is that a much complex approach of the relationship between creativity and motivation is required. It is necessary to take into account other variables, such as: time, information, past experiences.

The Evolution of the Romanian Leasing Market Related to the Current Global Crisis

Mărăcine Mihaela Simona

"Constantin Brancoveanu" University, Pitești

Faculty of Management Marketing in Economic Affairs

mihaela.maracine@yahoo.com

Abstract

In the same context in which the Romanian economy becomes increasingly close to the developed economies and aims to achieve the intended objective of mature market, leasing, as financial transaction makes its own way by adapting to the shocks of the changes. The current financial crisis had a strong impact on the Romanian leasing market, reflecting the temporary decline of an emerging economy, with still fragile mechanisms.

Keywords: leasing, leasing market, financial crisis, leasing companies.

1. Introduction

Leasing has appeared and developed once with the amendment of the nomenclature and the increase of the value of machinery and equipment making up the object of international trade. The rapid obsolescence, the high volume of investments that certain equipment require, such as computing, transportation, apparatus and measurement instruments, in terms of ongoing processes of modernization, led to the emergence of the leasing companies. [1]

The leasing market witnessed in 2009 the largest drop in history: -74% to 776.65 million euros because of the economic crisis. Although the views are optimistically directed to 2010, in the sense of stagnation, a return to the level of 2008 will not be possible in a time shorter than 3-4 years, according to the estimates of the

Association of Financial Companies from Romania (ALB).

The leasing companies still calculate their losses since 2008, and the last weeks of 2009 have served only to maintain the negative evolution of this market. The currency fluctuations, the economic instability and the increase of the unemployment rate are the main causes, according to the analysts, of widening the imbalance in this segment of business. [2]

The areas of accelerated decline were exactly those which reported significant increases every year: the auto industry, constructions and real estate. Globally, it is expected to have a decrease of about 76% of the auto leasing, of 77% of the leasing for equipment and of approximately 40% of the real estate leasing. Under these conditions, all the leasing companies had modest performance in terms of the volume of new contracts, others have chosen only to preserve their existing portfolio of contracts; others have achieved a balance between the three major product segments by reducing the volume on the car segment.

But all were forced to cope with the degradation of the payment behaviour of their customers, with the increase of the reserves, and, not least, with the "resettlement" of the legislation on the pollution tax and forced execution or enforcement. In the last 12 months, the intensification of the resale activity meant for the leasing companies to allocate significant human and material resources, the most affected being the specialized companies subsidiary of the banks or independent ones.

The advantage held by the captive companies was represented by their access to the existing

know-how and infrastructure within the groups to which they belong, such as warehouses, the existence of specialized servicing sites or even of some sales entities/forces specialized in selling second-hand cars.

The ALB data shows that the market share of the independent leasing companies fell to 13% from 18% in first half of 2009 compared to same period in 2008, in favour of the IFN captive companies (24%) and of the banking ones (63%), detailed the president of ALB [5].

”Figure 1. Romanian Leasing Market Structure by Type of Lessor 2007 – 2009”

Source: Association of Financial Companies – ALB Romania

In 2008, the largest loss reported by a leasing company amounted to 50 million euros. The same company has passed last year through 20-million frauds. The large losses caused the company to stop the funding activity and to focus solely on the resale of the recovered goods. [3]

Even if for other companies the losses were slightly lower, most of the players reduced, in the first half of 2009, the financing on the car segment, even by 60%. The measure was prompted by the sharp decline in sales of cars, both for import and for domestic production. Specifically, in the first nine months of 2009, the sales were reduced by 52% as compared to the

same period of 2008, according to the data announced in October by the Association of Car Producers and Importers (APIA). [6]

Concerning the structure of the leasing market in the first six months of 2009, vehicles had a share of 63%, as compared to 70% in the same period of 2008, and the share of equipment financing fell to 20% from 22% in favour of funding the real estates, which have gained share at 17% from 7% in the first six months of 2009.

”Figure 2. Romanian Leasing Market Structure by Asset Type 2007 – 2009”

Source: Association of Financial Companies – ALB Romania

2. Losses for the leasing companies

Because they granted funding with 10 to 15% advance, in some cases even 0%, the leasing companies find it very difficult now to cover the loss caused by the customers who cannot pay the lease rates, by reselling the repossessed goods. These goods are now sold with an average loss of 30-40%, as estimated by the director of a leasing company. Which is the cause? It is the limited expertise that these companies have in the recovery for cars, commercial vehicles and recovered industrial equipment. The lack of such an expertise is eventually justified, since the object of activity of these companies is the financing of assets and not their trade, the dealers or suppliers being good at the latter activity.

A leasing company representative believes that companies could have recovered more of the value of the repossessed goods if there had been professional operators for the resale services, who could deal with everything that means the preparation and best use of those goods. So far the solution is that of not repeating the mistake, namely that the leasing companies will establish a higher advanced money and less specialized assets, which they may make the most of more easily, as most players in the market claim.

On the other hand, companies expect in 2010 to deal with fewer cases of late payment of the leasing rate. The National Bank of Romania (BNR) has approved, some time ago, the access of the leasing and consumer-finance companies to the Central Banking Risks (CRB). Thus, firms will be able to check on the applicants for funding if they had arrears in the past and they can report on the bad payers. Compared with the Credit Bureau, where the population's loans are reported, at CRB only the loans higher than 20,000 lei are recorded.

3. Solutions for the crisis

- Even since last year, the large companies have began to develop various services auxiliary to the classic leasing product, designed to provide added value to the customers. At the same time, they have restructured the internal activity, so that the applicants can obtain financing with less bureaucracy. The classical procedure is to analyze the file by the risk department and the transmission of the decision to the salesperson. Currently, the answer can be given on the spot by the sales agent after a scoring analysis. If one accepts the funding, the agreement can be downloaded from the internal program and signed on the spot, and the client can go home by car. [4]
- Another made facility available to customers by several major leasing companies is the ability to access financial information online. The customers can check the contract, they can follow the issued invoices and the progress of the payments, including those relating to car insurance. Customers can also send messages through an application

directly from their account related to various problems, these being further directed to persons authorized to handle the problem. This way, there is a time saving. The customer is no longer moved from one department to another since, from the very beginning, he is contacted by a qualified person to help him in his specific problem.

- The leasing companies should be very mindful of the costs during the crisis and not to invest now in areas with low potential for development next year. [7]
- On the other hand, companies have turned to sale&lease-back products since the product provides immediate liquidity and at the same time the costs and risks lower for companies, these being taken from the operational leasing company. The sale&lease-back option is one of the winning solutions towards which a growing number of companies in Romania will turn in the next period because of the liquidity problem they are facing.
- The financial crisis could eliminate the opportunistic companies and those that have financing problems. The major players have turned to implementing some scoring models to reduce the response time in the analysis of the applications for funding and now offer to customers the possibility to monitor the lease contract online.

4. The operational leasing market has growth potential

What will happen on the domestic leasing market this year exclusively depends on the economic context. Some experts believe that the operational leasing market will remain at the level of 2009. Others do not exclude a slight increase, up to 10%, provided that the economic situation does not worsen. Nevertheless, the market analysts talk about the very high potential in the next three years, of the Romanian operational leasing market, but also of the similar markets abroad. It is assumed that in the next three years, 63% of the European companies will use the operational leasing solutions.

In Romania, the operational leasing market was estimated, in the summer of 2009, to 20,000 units. Operational leasing is an outsourcing solution through which the client-company transfers all the tasks related to the fleet car management to the leasing companies.

The crisis is an opportunity for the large operational leasing companies. The impact of the financial crisis will be felt on the operational leasing market by the increase of the costs with the liquidity, especially since the main players on the Romanian market are subsidiaries of the major European and international companies.

Despite the low visibility in Romania, operational leasing is gaining ground on the local market precisely thanks to the large companies that are familiar with the benefits of outsourcing the fleets' management services. With an estimated value of 800 million euros, the local market of operational leasing has a share of less than 10% of the total auto leasing market, according to Arval company, but the increase of the costs related to the maintenance and administration of the fleet, to the fuel prices, to the taxes related to the carbon dioxide emissions will turn more and more the attention of companies towards the operational leasing. The market growth potential for the next years is estimated at over 30%.

At present, few local companies are moving towards outsourcing the financing services of vehicle use, of maintenance and administration of the auto fleet. Thus, the degree of penetration of the operational leasing on the market of the vehicles used by companies is low, of approximately 4%.

5. Conclusion

2010 is predicted to be as difficult as 2009, noting that the leasing companies have learned something from the new rules of economy, in terms of the global crisis.

The optimists can hope for a stable or slight market growth, based mainly on the timid attempt to solve some very old problems of the Romanian economy, with direct reference to the infrastructure, environment and even agriculture problems. And in these optimistic circumstances, the level of the leasing market in 2010 will be below the level recorded in 2005.

Strategies of Merges and Acquisitions on the Telecommunications Market

Gheorghe Meghișan

Abstract

The acquisitions are generally associated to merges. In reality, the two operations are distinct from an economic point of view.

When Vodafone adventured for the first time overseas, its expansion methods were the acquisitions. Through these, Vodafone was a minority investor, the rest being divided between the other companies such as: the financial investors or other telecommunications companies. Such approach towards the international expansion was dominated by a desire to minimize the risk, investing in many countries. Throughout its fusion with AirTouch, Vodafone extended in new countries (not only the USA, because AirTouch owned several subsidiary companies abroad) and consolidated its position as shareholder in some international acquisitions.

Keywords: strategy, market, acquisition, re-branding.

JEL classification: L1

1. Introduction

A survey made on 100 multinational headmasters from North America, South America, Europe and Asia shows that more than 70% of these opted for acquisitions, because of their quality to lead to profitable growth objectives within the shortest period of time [1]. Thus, the acquisitions represent a substantial part of the total of 43.436 operations of merges and

acquisitions announced for 2007 and susceptible to correspond to some transactions valued 45.000 billion dollars. [2]

2. Merges and acquisitions – a Phenomenon of Actuality

„The action of merging represents the union of at least two preexisted societies throughout the absorption of one by the other or the creation of a new society that “absorbs” its creators” [3]. The absorbed society is dissolved and its patrimony is transferred to the absorbent society. It is created thus, what is called the dissolution without liquidation.

Contrary to fusions, „acquisitions are more advantageous, because they correspond to a taken of control of the new entity without no ambiguity.” [4] If the target is quoted on the stock market, the taken over can be made throughout a public offer of buying or exchanging.

Besides the alliance, an advantage of the merges and acquisitions is their reactivity and the rapidity in the new markets’ development and services’ providing, if we take into consideration the problems that may result from the different interests between the partners and the complex decision processes of alliances. Within this optics, the merges and acquisitions became a veritable strategies competing with that of alliances.

Besides these advantages, the merges and acquisitions strategies can lead to the growth of the operators’ market power. In fact, the

buyer of an enterprise assures the control [5; 6]. This signifies that the absorbing operator can react more independent and, thus, more rapidly, than if it had conceived an alliance or a co-enterprise for the same purpose.

Regarding the inconvenient of the strategy of merges and acquisitions within the telecommunications field, they can be resumed to: the risk of integration of the absorbed operators is made not as well as it was expected, the risk of voting power decreases regarding the issue of new stakes to finance the acquisitions (this is the case of the WorldCom operators that made various acquisitions), the financial risk to a more important debt reported to the intrinsic capital, but also the limits to fund collecting [7; 8].

In terms of structure and strategy of the mobile communications sector, there are evident two primary influences. The first one, is represented by the impact of fusions and acquisitions and the second one concerns the privatization impact.

3. The Growth through Acquisitions – the Case of Vodafone Telecommunications Company

Before the taking over of the AirTouch from USA, Vodafone was an important company listed on the stock market of UK. Unusual, no other telecommunications operator didn't achieve an important stake in this company. Vodafone began as a subsidiary of Racal in 1984, with a similar license dating from 1982 and, at that time, it was the only competitor from this sector for Telecommunications (BT).

The parent company (Racal) knew all about technology, but it didn't know how to sell its products. Once Vodafone generated success on the mobile telephony market, a public offer became feasible and wanted as a way to generate liquidities for Racal. An internal public offer of 20% of the capital took place at the end of the years 1980 and freed Vodafone from the restrictions imposed by the parent company. The enterprise, renamed Vodafone Group, freed itself from Racal in September 1991.

The first digital mobile operator of the UK market, with a license dating from 1991, Vodafone became and remained leader on the market, eventhough it had to confront competition from the part of other three digital networks – Cellnet (60% owned by BT and with

a license from July 1994), Orange (with a license from April 1994) and One-2-One (with a license from September 1993). BT acquired the minority stake of Cellnet and Securicor in October 1999. The majority shareholder of Orange was Hutchison Whampoa, with headquarter in Hong Kong. One-2-One was owned by Mediaone from USA and Cable & Wireless from U.K. It was sold in March 1999 and bought by Deutsche Telekom.

Vodafone was the company with the most thought of internationalization from the four operators present on the UK market. At the end of 1998, it showed interest in Europe, some of the companies being fully acquisitioned, other being partially bought so as to obtain licenses. In other parts of the world, it had stakes in, for instance, Australia, Fiji, Malta and South Africa. However, it was not present on two markets outside Europe: USA and Japan.

Taking into consideration its international strategy, Vodafone could take advantage of its unusual situation. Its critical point was that Vodafone would also expand itself so as to gain a coherent network worldwide and gain economies of scale or it could wait to be taken over by other American or European operators. Not surprisingly, it preferred the first option and was capable to fulfill this, because of the rapid growth of its stakes on the market

4. Re-branding

The users of mobile telephony services in developed markets would change the brands without no concern that the new service is more different than the current one. It is still unclear if the mobile telecommunications market can develop a powerful loyalty towards the brand, but the providers prefer to believe in this possibility. This is the reason why, on the 28th of July 2000, the company announced that Vodafone AirTouch would become Vodafone Group and would be treated, whenever possible, as simply, Vodafone.

A disadvantage of Vodafone towards Orange is the fact that the latter already had a set of brand values and an image that helped it to register a rapid growth regarding the users' number. It is not surprisingly the fact

that France Télécom was moving faster to make Orange become its universal mobile telecommunications brand. As a comparison, we could say that the Vodafone brand lacks a personality. Collecting various brands on different markets, Vodafone needed a powerful global brand image.

The wish was that the Vodafone brand becomes universal, but the initial step was the mix with an existing brand – for instance, D2 brand of the ex-Mannesmann in Germany would become D2 Vodafone; in Italy it took the name of Omnitel Vodafone and in Portugal of Vodafone Telecel. A similar re-branding took place in Greece, Holland, Spain and Sweden, with the exception of Belgium and France, because Vodafone didn't own the majority package of stakes within the relevant operator. Vodafone remained under its own name in Malta and Hungary, but it could not take a re-branding politics in Poland and Romania, for the same reason.

Table 1. Vodafone Group's operations in Western Europe, 30th June 2003

Country	Operator	Holding (%)	Subscribers (thousands) ¹	Prepaid (%)
Austria	A ²	-	-	-
Belgium	Proximus	25,0	1 047	-
Denmark	A	-	-	-
France	SFR	43,9	6 012	-
Germany	Vodafone	100,0	23 261	53
Greece	Vodafone	74,8	2 724	71
Ireland	Vodafone	100,0	1 765	71
Italy	Vodafone	76,8	15 044	92
Holland	Vodafone	99,8	3 312	58
Portugal	Vodafone	100,0	3 129	73
Spain	Vodafone	100,0	9 184	57
Sweden	Vodafone	99,1	1 331	30
Swiss	Mobile Com	25,0	895	-
U.K.	Vodafone	100,0	13 313	59

Source: Compilation from Vodafone Annual Report and Account for 2002 and 2003 and www.vodafone.com [9; 10]

¹The subscribers represent the Vodafone's proportion, based upon the percentage within the holding, on the total percentage of network's subscribers.

²A – Vodafone signed a partnership accord with Mobilkom Austria in Austria; TDC Mobile in Denmark; Radiolinja in Finland and Og fjaraskipti in Island, where the Vodafone's roaming services are marked by the associated names. The company has also agreements with Swisscom to cover Liechtenstein. These agreements cover the cooperation regarding the roaming services and also, the development, marketing and management of the associated products.

5. Vodafone worldwide

Vodafone owns stakes also outside Western Europe, two of them are the most important, judging after the corresponding subscribers' number.

First of them is Verizon Wireless from USA. In April 2001, Vodafone paid 973 million dollars cash for 34,5% of stakes from the second operator from Mexico, Grupo Isuacell in which Verizon Communications already owned 37,5% from stakes.

The second one is in Japan. At the beginning of December 2000, Japan Telecom, one of the most important rivals of the MTT Company, was partially owned by AT&T and BT throughout a holding, in which, the former owned 10% of the stakes. In exchange, Japan Telecom owned 54% from the J-Phone Communications' stakes (JPC), a holding that, with 9 million subscribers was the main rival of NTT DoCoMo Company – both received free licenses from the Government, and a third license was allocated to KDDI Company. Vodafone owned 20% from BT Company's shares. In exchange, J-Phone Communications was controlling the three companies: J-Phone East (JPE), J-Phone West (JPW) and J-Phone Tokai (JPT). Japan Telecom was operating also the J-Sky service, which was providing Internet access for 4 million subscribers. This complicated situation led to the thought that BT and Vodafone would fight for what it was supposed to mean JPC, a real treasure. In December, Vodafone bought 15% form Japan Telecom's shares from two of its railway companies for the amount of 2,2 billion dollars cash. However, in December, as a response to a planed take over of 16% from the AT&T Wireless' stakes from DoCoMo, AT&T offered to sell the stake in Japan Telecom. In February 2001, Vodafone offered to buy the stake for the amount of 1.35 billion dollars cash. As a result, Vodafone had also direct and indirect stakes of 39% in JPC Company. In May 2001, BT agreed to sell the stakes owned in Japan Telecom for 5.3 billion dollars. Vodafone owned 45% direct stakes in Japan Telecom, 45% direct stakes in J-Phone and minority packages in the three subsidiary companies of J-Phone. It had also inherited from BT the

possibility to buy another 5% from the stakes of J-Phone's subsidiaries.

Vodafone arranged that the J-Phone's subsidiaries merge under the name of J-Phone Co in November. As a result, Vodafone ended up with 39,67% from J-Phone's stakes, while Japan Telecom owned 45,1%, but the stake owned by Vodafone in Japan Telecom meant the fact that its economic interests in J-Phone were about to 60%. In October, they reached 69,7%, when Vodafone bought from East Japan Railway Co 8% from the stakes of Japan Telecom in cash, as part of a tender offer to buy a total of 21,7% for 2,6 billion dollars and thus it gained the control upon Japan Telecom with 66,7% from the stakes.

The acquisition of a key company in China, the greatest growing market from the world, it wouldn't so simple, but the situation was made easier by IPO, part of China Mobile (Hong Kong). In October 2000, Vodafone signed an agreement to buy 2,18% from China Mobile's stakes (HK) for 2,5 billion dollars cash. In May 2002, it acquired up to 3,27% by subscription of new stakes worth 750 million dollars. [11]

At 24th August 2001, Vodafone completely stand off from the South Korea market, probably the most advanced market regarding the mobile telecommunications development, selling 11,68% of its stakes in Shinsegi Telecom to SK Telecom for an estimated amount of 150 billion dollars.

6. Conclusion

The case study raises a number of points helping us to understand how the value of Vodafone Company decreased. The Vodafone's strategy of extension throughout acquisition is a result of the time circumstances. During its mandate as CEO, Chris Gent saw how the Vodafone market raised, and if he spent almost 200 billion dollars, few were cash. The investment in Vodafone was seen as a better business than the investment in companies that Vodafone owned.

Vodafone's strategy had some deficiencies from some points of view. For instance, mobile telephony penetration can not exponentially rise, even though the saturation is not achieved till there are not achieved greater levels of penetration as it was thought that it happened several years ago; the achievement of new networks would not lead to an unending growth

of the Vodafone's turnover. It is obvious that Vodafone was not aware of this strange characteristic of mobile telephony, and this led to the 3G movement and the acknowledgement that the mobile data will continue there, where the mobile voice can not reach. The recent technological problems that stumbled the introduction of GPRS and 3G technology don't have much to do with operators or the equipment providers.

Surprisingly, Vodafone continues to trust its projects, having a business model that remained unchanged over the time. Due to the rise of the demand for voice services or SMS, Vodafone can be right to continue, no matter what the analysts' opinion would be.

The critics show a rise of the competition, with the tendency of the decreasing of the average income per user and a rise of the acquiring costs for the subscribers and the regulation will stand against the excessive roaming costs and fixed-mobile calls.

Vodafone rose especially throughout two acquisitions – that of the AirTouch in USA and Mannesmann in Germany.

The ability of Vodafone to coordinate these international businesses in its favor was restricted by the presence of other shareholders. Its international businesses were signed in the favor of all the shareholders and not only in favor of Vodafone Company. If all the shareholders' interests were the same, this would have facilitated the effective business management, but taking into consideration the fact that some shareholders tried to impose different strategic imperatives - it is the case, for instance of SFR France, having a local company, while the others were foreign – that's why, there were inevitably agreements and disagreements.

At the same time with the acquisitions, Vodafone started a rebranding politics for its international businesses. The rebranding politics represents a clear demonstration of the control that Vodafone was capable to exercise upon its different international businesses. Vodafone was capable to exercise such a control because it was a powerful shareholder in general, owning the majority stakes.

Project Management Techniques

Mihalache Anita

Universitatea George Barițiu, Brașov
anita.mihalache@gmail.com

Sălăgean Liana

Universitatea George Barițiu, Brașov
lianaugb@yahoo.com

Abstract

Project management is a technique that can aid in the planning, scheduling, and monitoring of complex projects characterized by numerous, non repetitive jobs called activities. Examples of projects that would use project management include:

- developing a mass rapid – transit system for a metropolitan area;
- organizing the relocation of a corporate headquarters;
- planning the production of a concert, film, or play;
- developing and marketing a new automobile;
- constructing a high – rise office building.

Without thoughtful planning, projects like these are likely to be loaded with unanticipated, missed deadlines, poorly allocated resources, and a guaranteed budget. In short, any significantly complex project will almost assuredly cost more and take longer to complete than would have been the case had project management been used.

Key words: project management, techniques, methods, planning, control, evaluation

JEL classification: M10, O22

1. Introduction

Analysts using project management can discover critical information essential to effective project planning and control. In particular, they can determine, in advance:

1. The individual activities constituting the project;

2. The interrelationship among these activities with respect to their chronological sequencing; that is, which activities must be arranged in series (one after the other) and which can be run in parallel (simultaneously);

3. Educated estimates of the time and monies required for the normal completion of each activity;

4. The time needed to complete the entire project;

5. The activities that are the most likely to extend the project completion date (critical – path activities);

6. The earliest dates that the different activities can be started and finished without changing the project completion date;

7. The latest dates that the different activities can be started and finished without changing the project completion date;

8. The amount of time that individual activities can be delayed without causing the project to be delayed.

The importance of project management to business is wonderfully illustrated by the Microsoft Corporation begins their ad for the microcomputer software package.

Producing a brochure. Introducing a new product. Moving your entire company across town. Every project has a start date, a completion date, and a date beyond which you absolutely, positively, cannot go. The drop dead date. Blow that date and you've got positively, absolutely no excuses.

Microsoft Project tells you which activities are essential to keeping your schedule. And which you can let slide. Give it your best to worst “what – if” scenarios. It tells you what must be accomplished. By whom. By when. At what cost.

2. Traditional Project Management Methods: P.E.R.T. and C.P.M.

The most commonly used methods in project management are the program evaluation and review technique (P.E.R.T.) and the critical – path method (C.P.M.). Although developed independently during the 1950s, these two methods are essentially only two distinctions usually made. The first difference is the way activity durations are estimated. In C.P.M., only a single time value is used. For P.E.R.T., a three – valued distribution is used to generate a weighted average time. Therefore, C.P.M. can be viewed as a deterministic method, whereas P.E.R.T. is a stochastic model. The second distinction is that, whereas PERT focuses exclusively on the planning and management of time, C.P.M. extends its focus to include time – cost tradeoffs. Therefore, the ultimate decision regarding which of these two methods to employ will rest largely on two criteria:

1. The complexity of the project and the variability of project activity durations;
2. The budget for the project.

Nevertheless, for our purposes, we will not discriminate between two methods. Both will be explored later in considerable detail.

3. Project Management Structure and Limitations

There are two basic rules that we must follow in laying out a project network:

1. Each activity is represented by a single arrow or arc.
2. No two activities can begin and end on the same two event nodes.

Rule 1 is essential in order to provide a unique identity for each activity. The need for rule 2 is a little more subtle and for this reason will be discussed in detail later, when concept of the dummy activity variable is examined. Let it be sufficient to say for now that, without rule 2, spurious constraining relationships would be in would make the analysis of the network impossible.

Before begin to plan any project, information regarding the basic elements of a network must be generated and organized. In particular, you will have to, at the bare minimum:

1. Identify each activity (task or job) necessary to complete the project identification number;
2. Estimate how long it will take to complete each activity;

3. Identify the predecessor activities for each subsequent activity in the project;

There are also several limiting features of P.E.R.T. – C.P.M. models. These include[1]:

1. All activities must be completed before the project can be completed: that is, no task can be partially finished or overlooked;
2. All activities must be completed in chronological order; that is, no later event can occur before all prior events have been completed;
3. No activities can be repeated; that is, no looping can occur;
4. For stochastic activities (P.E.R.T.), the distribution is limited to the beta – type;
5. The project must end with one and only one terminal event;
6. The critical path consists of the activities, from beginning to end event, with the longest cumulative time duration. (In the case of P.E.R.T., the duration is the mean time lapse).

4. The Critical Path Method (C.P.M.)

So far, we have been spending most of our time on understanding the language and schematic representation of a complex project schedule through the use of a network. We know how to identify the individual activities constituting a project, to make estimates of how long each will take, to establish the dependent or independent relationship between each (serial or parallel configuration), and to diagram it chronologically. But this understanding does not provide us with information that any manager obviously must know, such as how much time the total project will take. Since completion can occur only after each individual activity is completed, the total time for the project will be equal to the most time – consuming path through the network. This route is called the critical path. To determine this essential piece of information we will have to calculate five key time criteria [2]:

1. Earliest start time for the i^{th} activity, ES_i ;
2. Earliest finish time for the i^{th} activity, EF_i ;

3. Latest start time for the i^{th} activity, LS_i ;
4. Latest finish time for the i^{th} activity, LF_i ;
5. Slack time for the i^{th} activity, S_i .

The earliest start and finish times are, literally, the earliest time that any activity can begin or end, respectively, taking into consideration the time constraints established by precedent activities in the network. The latest start and finish times reflect the latest that an activity can begin or end, respectively, without extending the total time needed to complete the entire project. The slack time reflects the amount of time that any activity can be delayed without extending the project completion time; we find it by measuring the difference between the early and late start ($LS_i - ES_i$) or the early finishing and late finishing times ($LF_i - EF_i$) of the activity of interest. If an activity has zero slack, it cannot be delayed without the entire project being delayed. This means that the path through the project of activities that have zero slack time will be the longest path, and these activities are, therefore, the critical – path elements.

5. Project Cost – Time Tradeoffs: Cost Crashing

Sometimes, even painstakingly careful project planning will not ensure completing the project on time or staying within budget limits. When this occurs, managers have a choice: (1) do nothing and incur any contractual late penalties that may result from an overdue project, or (2) bring in more resources to shorten the critical – path activities (and the corresponding total project duration) so that the due date is met. The selection of a specific strategy depends on the magnitude of the late costs and the non economic costs resulting from client ill – will when there is a project deadline overrun versus the added costs involved in bringing in extra resources needed to keep the project on time. The method used to make this delicate assessment is called cost crashing. It is usually possible to decrease the time needed to complete an activity by concentrating greater resources on that activity. This frequently means allocating more skilled people (or the same people, working overtime), additional equipment, or more money, or some combination of these [3].

A step – by – step process illustrating the application of the cost – crashing technique follows.

Step 1. Construct a summary table consisting of the following column headings: (1) activity; (2) expected activity completion times for (a) normal and (b) crash conditions; (3) activity costs for (a) normal and (b) crash conditions; (4) change in activity cost (usually an increase); (5) change in activity completion time (usually a decrease); and incremental cost per unit time.

Step 2. Identify only the critical – path activities that can be “crashed” (non critical activities can be ignored, because crashing activities with slack will not decrease the earliest completion time for the project).

Step 3. For those activities identified in step 2, construct a summary table identical in format to the one designed in step 1.

Step 4. From the table developed in step 3, select the activity with the smallest incremental cost – per – unit – time quotient (column 6). Use the crash – time value for this activity to replace the normal value used in the original network, and recalculate the new critical path for the project. If, however, this time increment is greater than one unit, it is often circumspect to crash by single – time – unit increments to avoid making larger than necessary time reductions. You will soon see how multiple – time – unit reductions can sometimes shift the critical path midstream, and cause superfluous expenditures on activities no longer critical. If there are two or more activities with the same incremental cost per unit time, make separate critical – path calculations for each, and select the activity that results in the lowest project completion time.

Step 5. From step 4, calculate the sum of time along all network paths. The path with the longest total time is the new critical path (there may be no change from the original network).

Step 6. Repeat steps 2 through 5 until all critical activities are crashed. Display the relationship between project costs and completion time for this network.

6. Stochastic Project Management: Project Evaluation and Review Technique (P.E.R.T.)

When we can make time estimates with a high level of confidence – such as with projects that are repetitive and with which we have considerable experience – a single time value may be sufficient. But what happens if the project does not have these characteristics? What does manager do when faced with a complex, non repetitive project for which there is no previous experience? Our time estimates, in this setting, would be guesses, and the use of a single time value possibly would be naïve. It is precisely in these more ambiguous situations that P.E.R.T. is most useful.

The P.E.R.T. approach uses three time estimates to gauge the probability of completion of each of “n” activities along a specific path: (1) most optimistic, a; (2) most pessimistic, b; (3) most likely, m. These three time estimates from a continuous, bounded, and usually skewed probability distribution called the beta distribution.[4].

Figure 1 – The Beta Distribution

This distribution, although not mathematically proven to be the most suitable for P.E.R.T., has been represented the expected completion time for the i^{th} activity and is given by the following relationship:

$$t_i = \frac{a_i + 4m_i + b_i}{6}$$

The mean duration along the entire critical path, t^* , is equal to the sum of the individual expected completion times for the activities constituting the critical path:

$$t^* = \sum_{i=1}^n \left(\frac{a_i + 4m_i + b_i}{6} \right) = t_1 + t_2 + \dots + t_n = \left(\frac{a_1 + 4m_1 + b_1}{6} \right) + \left(\frac{a_2 + 4m_2 + b_2}{6} \right) + \dots + \left(\frac{a_n + 4m_n + b_n}{6} \right)$$

where:

n – number of critical path activities.

The beta distribution standard deviation for the i^{th} activity S_i , is:

$$S_i = \sqrt{\left(\frac{b_i - a_i}{6} \right)^2}$$

The standard deviation for the expected project completion time s^* , is approximated by:

$$s^* = \sqrt{\sum_{i=1}^n \left(\frac{b_i - a_i}{6} \right)^2} = \sqrt{\left(\frac{b_1 - a_1}{6} \right)^2 + \left(\frac{b_2 - a_2}{6} \right)^2 + \dots + \left(\frac{b_n - a_n}{6} \right)^2}$$

Once the critical path is determined, it is possible to determine the probability of completing the expected critical path within a given duration of time by using the standard normal distribution. This makes it possible to determine the probability of completing the project, along any path of interest, within a given period by using the mean and standard deviation along that path and the properties of the standard normal distribution [5]. It is important to keep in mind, however, that, in actuality, the set of activities that eventually forms the realized critical path may be different from this statistical estimate.

7. Conclusions
