Obviously, remittances increase revenues from external sources with potentially positive effects on the balance of payments, the standard of living of those who receive them, the local economic development. According to empirical studies, these remittances are used to the extent of 80% of the basic household consumption, between 5-10% are used for investments in human capital (education, health, nutrition). The difference covers costs of land acquisition, housing and so on, helps pay off a loan and very little money goes to productive activities. Because most of the money goes to consumption, the positive influences on the balance of payments can be cancelled by negative effects due to increased trade deficit determined by the purchase of the mostly imported goods.

Clearly, the main beneficiaries of remittances at the microeconomic level are the migrants’ families. At the macroeconomic level, there are mostly positive effects on domestic consumption, balance of payments, inflation, exchange rate, exports and imports.

However, the effects of migration in the long-term are difficult to quantify. They depend on how many go and who goes. In the first phase, migration causes a decrease in economic potential and income distribution. It can be said that the country of origin loses if the contribution of migrants was greater

than their marginal product [5]. In the long term, as mentioned earlier, there are studies which highlight both beneficial effects that are represented mainly by remittances and lower tensions on the labour market and the negative effects of reducing human capital by maintaining a low level of development, the lack of investments and dependence on remittances.

In the category of positive effects we can also include aspects of training the returning migrants, as well as the increasing level of education, as a premise for finding a job abroad. Nevertheless, it is clear that the impact of migration depends on the magnitude of the phenomenon: how many go and who goes. If migrants are highly qualified and educated than those who remain, the long-term effects are rather negative, while if those who leave have a lower skill level than those who remain, we can expect more positive effects.

A recent study conducted by Ambrosini in 2011 highlighted the fact that migrants, eventually, arrive in those countries of destination which best fit their professional qualifications. In terms of economic impact at the entry of migrants, research has shown that the experience of working abroad has as effect an increase in productivity of those returning which means a bonus of over 15% only for this experience [5]. It was also noted that, in general, migrants at entry have a much lower participation on the labour market, many of them working on their own as entrepreneurs [5].

The migration phenomenon also has implications for education. The prospect of getting a job abroad orients the educational choices of graduates. Depending on where they would like to work, they form their necessary skills to increase their chances of engaging in those labour markets. Therefore, we can speak of an economic rationality of migrants’ decisions. The opportunities identified in different labour markets, the policies in the field of human resources in the countries of origin and destination, the education policies may have a major role in the decision to migrate or return. In addition, these factors influence the length of migration. If there is the possibility of obtaining higher incomes in countries of destination or at home, migration flows change accordingly.

Conclusions

Migration policies represent an interesting topic for the political factors in a country, Romania being no exception to this. However, countries of origin do not have many tools to influence the decisions of migrants, they consistently depending on the efficiency and credibility of the efforts in the field of economic reforms which also include the labour market. At the same time, the reaction of the destination countries also occurs. They may restrict the migration flows in order to protect their citizens against the effects of unemployment. Moreover, other crucial social problems of migrants may cause adverse reactions of the host countries in terms of restricting the access to certain categories of migrants. But even if most studies emphasize the positive effects of migration, yet effectively, in the long term, they are difficult to quantify. In Romania, the situation becomes even more difficult from this point of view due to the absence of significant statistical data.

Under these conditions, direct and explicit encouragement of migration is a major political mistake. Encouraging your own citizens to leave in order to build a better life is equivalent to the economic recognition in your country. The Romanian authorities have sent many times, consciously or not, such messages, which were seized and subsequently sanctioned by the electorate.

Considering the finding of a job in another country as the only solution to obtain a decent living standard creates a disheartening and demoralizing effect on your citizens, which are then required to give a helping hand with the success of economic reform. This type of policy is nonsense with devastating effects in public consciousness.

Abstract

This paper aims analyzing the importance of education as a substantial determinant for an individual ability to obtain income and of economic growth. The first part of the article underlines the importance of investment in education argued by the fact that abilities and knowledge tend to increase productivity, generating in this way higher potential incomes. In the second part of the paper we performed a comparative analysis of thirty – three European Countries at every level of education i.e. tertiary, secondary and primary (lower). Our analyses shows that the tertiary aptitudes are the ones which matter the most in terms of growth in the case of Central and East European nations.

Key Words: development, education, institutions

J.E.L. Classification: A1, A20, A22

1. Introduction

Starting with 1966, authors such as Richard Nelson and Edmund Phelps, inspired by the ideatical context provided by Solow's lesson, have focused on a model in which the growth determinants are endogenous and economical growth is sustainable. In the core of this paradigm lies the authors article, *Investment in Humans, Technological Diffusion and Economic Growth*, where they argue that investments in education, in human capital, bring many benefits in the long run. Thus, the disparities which separate high income nations from poor countries, through education and knowledge perspective, are tricky problems that call for special attention.

The best way by which individuals may ensure a certain degree of well-being is by investing in their own abilities and values.

2. Literature review

The hypothesis from which the authors build their theoretical and empirical framework is formed on the assumption that the production activity requires some degree of adaptation to change together with a more general belief according to educated individuals are more capable to implement new techniques. Furthermore, educated individuals are much more inclined to innovate and, as the authors point out, “speeds the process of technological diffusion” (Nelson and Phelps, 1966: 70). Richard Nelson and Edmund Phelps tried to highlight the role played by education in the development of individual capacity to innovate and to adapt to new technologies, thus increasing their diffusion into economy. Empirically, in addition to the “index” of technology in practice, $A(t)$, Nelson and Phelps introduce a new variable, $T(t)$, named “theoretical level of technology”. The latter is defined as “the best-practice level of technology that would prevail if technological diffusion were completely instantaneous” (Nelson and Phelps, 1966: 71).

The technological level grows exogenously at an exponential rate \check{r} , thus:

$$T(t) = T_0 e^{\check{r}t} \text{ where,}$$

- T_0 is the initial level;

- \check{r} , is a positive exponential rate.

Nelson's and Edmund's analysis is based on a production function such as: $Y(t) = F[K(t), A(t) L(t)]$ where, $K(t)$ is the capital function, $A(t)$ an index of technology and

L(t) is labor. Their approach is directed towards *two models*:

The first one assumes the existence of a time gap between creation of a new technique and its implementation, being negatively correlated with the level of human capital

$$A(t) = T(t - d(h)), d'(h) < 0$$

By substituting the equation, we obtain:

$$A(t) = T_0 e^{r(t-d(h))}$$

where, A(t) is an increasing function of h and grows with a r̄ rate.

The second model, Nelson and Phelps highlights the fact that the technical progress depends on the human capital and on the difference between actual and theoretical technological levels. Thus, the model may be written as follows:

$$\frac{\dot{A}(t)}{A(t)} = \omega(H) \left(\frac{T(t) - A(t)}{A(t)} \right) \text{ where } \omega'(H) > 0 \text{ and } \omega(0) = 0;$$

“The rate of increase of the technology in practice is an increasing function of education attainment and proportional to the gap (T(t) – A(t))/ A(t)” (Nelson and Phelps, 1966: 73).

Nelson’s and Phelps’s approach related on the education topic is closely related to the technological process. Their regressions manage to bring on top new results and findings, from which we mention: *first*, from their analysis one can observe the significant positive impact of the secondary and tertiary educational levels that have over the productivity growth rate; *second*, the education marginal productivity is a increasing function of the rate of technological progress, thus the gains from investments in education are much higher as a countries’ economy is more technologically advanced; *third*, education should permit the poor technological countries to learn from the developed ones, increasing in this way their innovation productivity.

We are able to appreciate that both technological progress and education are considered to be fundamental *inputs* in the aggregate production function and important growth determinants that a developing country can use, in order to catch up with the high income economies. *By investing in themselves, people can expand their range of available*

options (...), a way that free people can improve their well-being (***) (OECD Observer No.261 Mai, 2007). For an individual perspective, there is an important motivation to invest in education argued by the fact that abilities and knowledge tend to increase productivity, generating in this way higher potential incomes.

In the same line, the studies made by Barro (1991) or Tanzi and Chu (1998) confirms the above assumptions. Hong Sang and Erick Thorbecke also suggest that “*both the size and efficiency of public education expenditures are important in improving socioeconomic performance*” (Hong Sang and Erick Thorbecke, 2001: 4). So the investment in public education represents the primary resource in the process of economical growth and development.

The educational package, as a measure of the quantity, availability and even quality of human resources is one of the possible ways to assess the impact of human capital in economic growth. Recent researches have raised the issue of finding alternative units of human capital measurement in economical analysis. The number (in percentage) of high school or university attendants, or even indicators of the educational level provides precise but limited information regarding the way in which a society can use educational package. A “decent” educational package might have a small impact over economical performances and regional disparities, if, human resources have not been used to its full capacity. Deficiencies in the framework of the educational system can be approached through attracting qualified workers from other parts of the countries or even from abroad (Andrés Rodríguez-Pose and Montserrat Vilalta-Bufí, 2008: 2). From this perspective, the indicators such as the adjustments between educational stock and labor demand, of the employment degree of the most qualified individual and of the migration level, are of much importance for the fact that they might very well be translated in the society’s capacity to transform human capital in economical growth.

Sab and Smith (2002) regard development in a broader sense, in which are included besides growth of income per capita, improvement in health and education as standalone objectives. Both health and

education are seen as important inputs in the aggregate production function and determinants of growth. According to their position, the fact that the human capital convergence have not clearly transformed into a convergence of the incomes at an international stage, reflects the existence of three main factors: *in the first place*, the vast majority of the developing countries still have a very young population, therefore a significantly gap between human capital accumulation and the increase in productivity and income will persist in the near future. *Second*, education may very well be a complementary input of other factors; Romer (Romer *apud* Sab and Smith, 2002: 543-573) suggests that rapid development results from the interaction between human capital and the availability of productive ideas. Developing countries will need to enlarge the technological transfer rates, which require an increase openness of their economies as well as an improved international assistance. *Third*, the political environment is, likewise, a significant determinant of incentives for productive use of educational capital.

3. Education Levels in European Countries

The graphs bellow show what the literature, shortly described above, tries to argue. Based on the statistical data published by Eurostat, we made several graphs in which we took the education attainment variable and we performed a comparative analysis of thirty-three European countries at every level of education i.e. tertiary, secondary and primary (lower).

In the line with the general view of the literature our analysis shows little or no surprises, at the tertiary level the countries with high scores are mainly developed or upper developing nations, and at the bottom of the list we low income developing countries. There also are some exceptions, in the case of Italy, but that may very well be some differences in demographic and regional income distribution within a country that can modify to a certain degree the overall results. Other than that, at the tertiary level, the picture resembles the main idea according to which as a country becomes more developed, the more investment in high trained and educated individuals it has and requires. If we take the case of, say, Denmark, Finland or United Kingdom, we clearly see that these countries have a high tertiary level of education attainment which traduces itself with

a proportionate investment in higher education and for this matter, a big demand of educated and trained people, which we know that tend to innovate more, thus they are more productive.

Figure 1. Tertiary education attainment*

Source: Authors calculation based on the data provided by Eurostat

* The data is calculated as average number of years of tertiary education received by people ages 25 and older

If we keep the examples and go further, we see that the levels of secondary education attainment, at all age groups, are at best average, which means that their economies are based more on high technological industries sectors than other activities, such as agriculture, which requires a comparatively lower infuse of innovation than industrial sectors. The big picture becomes, in this case, self evident if we take into account the lower level of education attainment, given the fact that, in average, twenty percent or less of the population who attained to school stops at the level of primary education.

Figure 2. Secondary education attainment*

Source: Authors calculation based on the data provided by Eurostat

*The data is calculated as average number of years of secondary education received by people ages 25 and older

In the case of low income economies, the story is the same, but spelled backwards. A good example is Romania, a developing country, member of the large EU 27 family, which has a performance mirror-like compared to the economies mentioned before. In this case, the highest values are seen in the lower education attainment graphs, at all age groups, especially in the age interval of 55-64. Another finding that spreads concern is the percent of population who attained only to lower education level. A near 50% of the individuals in the age interval between 25-34, which are today's and tomorrow's tax payers and "economical force", attended only to primary school, and this, indeed, is not an encouraging fact. If we move along and look at the secondary education attainment graphs, we see that the Romanian 'average Joe' is more interested in finding a job, without much qualification and without future prospects other than a satisfactory wage. These are the economy's work force and this fact speaks for itself of the amount of investment that Romanian government is willing to make in high technological industries. Because, as stated, that qualified and educated people tend to innovate more, a government who does not have the willingness or the ability to invest in such sectors is also not interested to invest in high specialized schools. This assumption is well enforced by the numbers shown in the tertiary education attainment graphs, where, in 2011, only an average of few percents above 10% of every age-group, finished a higher

education school, with a small difference in the case of 25-34 age-interval, where we can see an above 20% score.

Figure 3. Primary (lower) education attainment*

Source: Authors calculation based on the data provided by Eurostat

*The data is calculated as average number of years of primary education received by people ages 25 and older

However, one must not take the education-technology-development relation as a linear-causality, for reasons easy to anticipate. For instance, we all agree that investment in education affects the economical development of one nation through better human capital input, which in turn affects the technological progress, the amount of innovation, and the development of one or more economical sectors in the long run. But this seems to direct our attention from the 'demand' aspect of human capital seen as input in the production function and different particularities that one economy might have. For example, if the main driving force of one countries is, say, IT sector, this implies that the government and other institutions have to focus on investment in human capital in this specialization, on the very simple reason that the comparative advantage principle and cost-benefit analysis might point out that in this sector the growth opportunities are much bigger.

In other words, investment in education must not follow a pattern made by present developed countries without analyzing which economical sector has a bigger chance to

contribute to growth than other sectors. If we take into consideration this aspect, we may learn that a developing nation must not necessarily invest in tertiary education sectors if its economy is, say, based mainly on agriculture. In the long run, as long as the development process continues in a sustainable manner, the high productive industries will be formed and as a consequence of this, the investment in tertiary education will follow the demand for educated and innovative people. This might be a strong conclusion, but if we look closely on the first graphs we can argue that the case of Latvia and Lithuania, two EU countries and former members of the Soviet Union, follows this assumption.

The impact that growth has over the different education levels may seem to strongly vary conforming to the level of a countries level of development. In particular, while primary and secondary aptitudes may look to be related to growth in the case of low income developing countries situated at an intermediary level, the tertiary aptitudes are the ones which matter the most in terms of growth in the case of Central and East European nations. Even if the direction of the causality is still unclear (one might expect that because superior education has the highest cost, an increase in demand for it should come along with rising income), both the initial level and subsequent growth of tertiary education have been found to be closely connected with the income growth per capita in the analyzed countries (Gemmell *apud* Sianesi and Reenen, 2000: 9-28).

Figure 4. Tertiary education attainment and GDP level

Source: Authors calculation based on the data provided by Eurostat and OECD Reports

In the case of developed countries, economic growth is influenced by the technological advance, which in turn relies on human capital. Thus the importance of human capital is fundamental, primarily because of the existing disparities between nations. Most of the developing countries still have a young population and therefore, here the significant distances between human capital accumulation and rising productivity together with income, will persist for some time. Within these there is a wide range of factors that influence education, like: endowment of educational institutions, the level of professional training and abilities of the teaching staff, material and human resources etc. In this case, the costs for all the individuals that attend to other education level other than the mandatory one differs along the nations and are strongly influenced by political factors such as the duration of educational programs, the level of subsidies and other public financial support those willing to invest more in themselves.

4. Conclusions

No country has obtained sustained economic development without investment in education. Due to this observation, a large literature has dealt with analyzing the means by which education can and may affect development. From a descriptive perspective the paper emphasizes the impact that growth has over different levels of educations. The positive relation between growth and education tends to be more evident for the developed countries rather than for those lagging behind. Increasing the efficiency of the education system by investment in training of individuals, improving the service quality and social protection are just the primary steps that the lagging behind countries have to follow.

In developing countries education is considered a priority for poverty reduction. Different results obtained by the specialists in the field suggest the same thing: investment in education will improve social economic performance. In particular, while primary and secondary aptitudes may look to be related to growth in the case of low income developing countries situated at an intermediary level, the tertiary aptitudes are the ones which

matter the most in terms of growth in the case of Central and East European nations.

Abstract

Business decision-making environment must integrate as a whole the experience and beliefs of the techniques makers and decision support systems used. Currently, the business information environment is becoming more complex due to the increasing volume of information relevant for business area, the number of information resources and the number of technologies used for accessing and storing data.

Decision support systems should serve as the main tool for decision makers in order to keep up with the exponential growth in size, complexity and speed with which business should be conducted. A decision support system should be an integral component of the decision-making process that extends the ability to process information quickly and to tackle complex problems, time consuming, reducing the time spent in this process. Nevertheless, it will also improve the reliability of decision-making process, encouraging exploration and learning process, thus creating a strategic competitive advantage for the organization.

Keywords: risk, decision making processes, marginal distributions, marginal frequencies.

J.E.L. Classification: C01, C12, D80

1. Introduction

Transition to a market economy of countries with central-planned economies, was a complex process that has brought significant changes to the conditions for conducting economic activities. These markets were forced to adapt their sizes, structures and in some cases, the efficiency of economic activity in a market economy.

The existence of management cannot be thought without decision and, given the role played by it, some authors consider that the core of the management activity is represented by the decision making process. Consequently, the idea that assessing management starts from the analysis developed from the results of the organization as a result of the decisions taken, the decision representing the base of the management process, contributing to performance management and the appropriateness and effectiveness of the decisions thus contributing to increased efficiency of management process.

The increasing of complexity of structured relationships, stimulating the entire economic and social system, in addition to the development of science and technology has created significant changes in the approach of the theoretical and practical concepts of risk and uncertainty.

2. About risk and uncertainty

Economic, social, political and natural environment in which people live, work and develop, it is full of uncertainties. It is now commonly recognized that a system that works to get a future result, by definition operates, in a sphere of uncertainty, even if specific situations are characterized by varying degrees of risk, uncertainty or indeterminacy. Risk and uncertainty are not the subjects of choice; they are simply part of the human condition [1].

Uncertainties incite economic agents to make their own determinations on the base of economic principles, according to their hopes, that causes them to first consider the degree of probability of achieving goals and objectives. The plan provides a picture of the future, but whose future, because the planner creates many other prospective, for example: a desired future, a possible future and a future needed. Each of these types of measurements of the future has its own determinations or indeterminations. Strategic, political and economic plan, appear as effective tools to complete the operation mechanism and evolution of the global economic system with a mechanism partially consisting of conscious levers, or help integrate present future, the approximation of the three forms of the future, which would attract ideal form if they would overlap until identification, a process currently impossible to achieve, but, however, reducing uncertainty, strategy, policy and plan contain elements which determine the economic agents to act now in the name and spirit of the future requirements, forecasting tools that inciting searches at invocation, the inventions, modernization and rationalization.

The terms risk and uncertainty are often used to express the same aspect, but there is a clear difference between them [8]. Uncertainty is the fact of not knowing what will happen in the future, and the risk is considered as a characterization of the degree of uncertainty. The higher the uncertainty the more pronounced the risk and vice versa. Most human actions have a certain degree of uncertainty and risk, which is due, on the one hand, to those acting, and on the other hand, to environmental factors.

Uncertainty is, therefore, lack of certainty, which is uncertainty, doubt, hesitation. Uncertainty induces the opportunity to reach a certain danger, to have to face danger, trouble, to support a possible loss, for instance to have a risk. The risk is, in fact, to consciously expose yourself to a higher or lower risk. To continue with, the risk is the possibility of a loss as a result of the occurrence of unpredictable events and phenomena.

The notion of risk was and is still used mainly in insurance, but lately has found increasing application in many areas of human activity, each trying to get the best performance by managing it correctly.

Essential is the fact that with the development of the economic system, with its increasing in complexity, uncertainties multiplies and, therefore, become more vulnerable. Risk is part of the economic and social life, found in the form of commercial risk - the risk of maximizing products, competitive risk, price risk - social risk and production risk.

Following present studies on the subject, it has been emphasized that the concepts of risk and uncertainty is in the middle and at the base of companies' analysis and decisions. [9]

Triumph of statistical decision theory is precisely the possibility of measuring the degree of risk in terms of objective probabilities. Statistically processing the numerical results of measurements, statisticians can communicate a company manager the probability that the decision is wrong and is less than, 0.05. Taking into account all the factors involved, the manager may decide that the risk is acceptable. If the probability that the decision is wrong is too high, the manager may request additional tests, or take into account additional parameters. When we provide numerical results of some experiments, statistical decision theory allows us to measure the degree of risk associated with a decision of objective probabilities.

Taking as a basis a certain amount, a certain structure, and a way of presenting statistical information, decision management appears as a dynamic and rational process which require manager's ability to master complex mechanism of the whole management system of the company. In this

respect, computer subsystems, information - statistical and decisional can make a fundamental contribution.

Decision making processes are based on using statistical data to develop mathematical models of economic phenomena and processes, which makes a further contribution of statistical inference as inductive research method that provides and validate mathematical criteria passage from particular to general. Inside the model presented, information circulates through exogenous or endogenous variables. Some may have a random variable and intervention model that allows this type of variable as an econometric model, as appropriate explanatory models aiming to study various functional relationships between variables that express a certain type of economic behavior. [11]

The economic model, reproducing in a symbolic way the economic theory of objective investigation, through the econometric model transformation, becomes an object of research and testing (verification) from which to obtain new information on the behavior phenomenon. In this way, econometric representations, unlike economic models, that explain economic phenomenon or process structure position of economic theory, always have a practical purpose, operational, they become instruments of control and routing, simulation and forecasting of economic phenomena. [12]

3. Case Study

Next, we present a case study testing the difference between two environments, one can use econometric methods form the basis of decision-making at the firm level.

SC Alpomob SRL, a company producing furniture, sourcing timber from two suppliers F_1 and F_2 . The company acquired in October 1900 m^3 of timber, as follows:

- ✓ 900 m^3 of timber from supplier F_1 ;
- ✓ 1000 m^3 of timber from supplier F_2 .

On the receipt of timber it has been ascertained the fact that 235 m^3 of timber do not correspond in terms of quality. Also, there has been established that trashes from both suppliers are distributed as follows:

- 100 m^3 of timber from supplier F_1 ;
- 135 m^3 of timber from supplier F_2 .

On the basis of the previous data, the office of SC Alpomob SRL decided to stop working with supplier F_1 , the reason being the poor quality of the materials provided.

The substantiation of the econometric decision adopted by the management company, we use the difference test between two environments.

First, we systematize the known information:

Table 1. Systematization of data

Suppliers (x_i)	Material Quality (y_j)		Total (N_i)
	Unsatisfactory	Satisfactory	
F_1	100	800	600
F_2	135	865	900
Total (N_j)	235	1665 (n_{ij})	1500 (N)

Source: Created by the author

$X = \{x_i\}, i = \overline{1, k}$ independent variable;

x_1 - supplier F_1 ;

x_2 - supplier F_2 ;

$Y = \{y_j\}, j = \overline{1, m}$ dependent variable;

y_1 - unsatisfactory materials in terms of quality;

y_2 - satisfactory materials in terms of quality;

n_{ij} - conditional frequencies of variable Y

After systematization of data there resulted a statistical two-dimensional series with two variables X and Y , resulting also two marginal distributions:

$$X : \begin{pmatrix} x_1 = 1 & x_2 = 0 \\ 900 & 1000 \end{pmatrix}$$

$$Y : \begin{pmatrix} y_1 = 1 & y_2 = 0 \\ 235 & 1665 \end{pmatrix}$$

Conditional distribution of Y variable depending on the suppliers is:

$$Y_{F_1} : \begin{pmatrix} y_1 = 1 & y_2 = 0 \\ 100 & 800 \end{pmatrix}$$

$$Y_{F_2} : \begin{pmatrix} y_1 = 1 & y_2 = 0 \\ 135 & 865 \end{pmatrix}$$

N_i - marginal frequencies of variable X;

N_j - marginal frequencies of variable Y;

The number of observations will be

$$N = \sum_i \sum_j n_{ij}$$

Observing the way of distribution of the frequencies n_{ij} following observations can be made:

i) there is a total independence between the two variables if:

$$n_{ij} = \frac{N_i}{k} = \text{constant}$$

$$n_{ij} = \frac{N_j}{m} = \text{constant}$$

ii) there is a strict dependence between the two variables if the conditional frequencies n_{ij} are distributed only on the main diagonal of the table, for the other elements of the table these frequencies are equal to zero;

iii) there is a statistical dependence if the conditional frequencies n_{ij} are distributed in a different way of the two cases mentioned above; in this case, statistical analysis will lead to one of the following conclusions:

- Acceptance of variant i);
- Acceptance of variant iii).

Analyzing the data from Table 1 we can observe that the distribution of conditional frequency n_{ij} fall into version iii).

Applying the difference test between two environments in order to analyze the decision taken by the office head of SC Alpomob SRL is made as follows:

Primarily, there will be determined the average percentage of inappropriate materials in terms of quality on each supplier:

$$f_{F_1} = \frac{n_{11}}{N_1} = \frac{100}{900} = 0,15$$

$$f_{F_2} = \frac{n_{21}}{N_2} = \frac{135}{1000} = 0,135$$

Then we will calculate the variances for each of the two suppliers:

$$\sigma_{F_1}^2 = f_{F_1}(1 - f_{F_1}) = 0,11 \cdot 0,89 = 0,0979$$

$$\sigma_{F_2}^2 = f_{F_2}(1 - f_{F_2}) = 0,135 \cdot 0,865 = 0,116775$$

We will note with α the materiality or the risk with which we choose the right decision and we will select $\alpha = 0,05$, value which is usually used in economy. For our example, the argument of the normal distribution, $t_\alpha = t_{0,05} = 1,96$.

We continue comparing the empirical value of the variable t_c with its theoretical value $t_{0,05}$.

In the case of dependent variables,

$$t_c = \frac{|\bar{x}_1 - \bar{x}_2|}{\sqrt{\frac{\sigma_{x_1}^2}{n_1 - 1} + \frac{\sigma_{x_2}^2}{n_2 - 1}}} \geq t_\alpha,$$

And in the case of independent variables,

$$t_c = \frac{|\bar{x}_1 - \bar{x}_2|}{\sqrt{\frac{\sigma_{x_1}^2}{n_1 - 1} + \frac{\sigma_{x_2}^2}{n_2 - 1}}} < t_\alpha.$$

In our study case,

$$\begin{aligned} t_c &= \frac{|f_{F_1} - f_{F_2}|}{\sqrt{\frac{\sigma_{F_1}^2}{N_1 - 1} + \frac{\sigma_{F_2}^2}{N_2 - 1}}} = \\ &= \frac{|0,11 - 0,135|}{\sqrt{\frac{0,0979}{899} + \frac{0,116775}{999}}} \cong 1,67 \end{aligned}$$

4. Conclusions

Therefore, $t_c = 1,67 < t_{0,05} = 1,96$ and we can state, with a probability of 95%, that between the quality of delivered materials by the two suppliers F_1 and F_2 there is no important difference.

We can assert that the decision taken by the company management SC Alpomob SRL to give up the collaboration with supplier F_1 due to poor quality of the timber supplied is not justified.

Abstract

"Kids today are customers, buyers, spenders, shoppers, consumers" [1]mainly because there isn't any field or market that didn't had direct or indirect contact with children. The role of children in the family and in society has changed. Nowadays they are more involved in the consumer market than their parents ever did. Furthermore, they have been given the freedom to not be subjected to their parents choices (clothing, food), because they are now parties with full rights in the family decision-market process, whereas children are consumers in the making [3].

Keywords: child, family, purchase decision, influence.

Classifications J.E.L: M30 ; R20

Introduction

Years ago, in the existing literature, children as an important part of the family purchase decision process with power of influence was not taken into consideration [12, 13, 25, 26]

A series of foreign studies have shown that research of children's influence in the purchase decision process as not being a priority for researchers.

The purpose of this study is to make a brief review of the studies that have had children's influence in the family purchase decision process as their subject.

1. Main factors which contributes to the implication of the child in the purchase decisions

In the beginning, researches were much more focused on examining the roles of spouse-husband dyad, which have been considered as the relevant decision making unit in a family [23]and the main deciders in the family setting. Consequently they have described in an erroneous way a family's consuming behaviour where the products are bought and consumed by both parents and children.

Because of its power to make expenditure, the family is seen as the most important decision, purchase and consumption unit in society [39]. Regarding consumer's behaviour, the mother and the father enables the individual to repeatedly get in touch, with products or product categories they use and to find information about them, since childhood.

Until recently, children have used mostly products that the mother or the father bought for them. Either they liked it or not, they had to use products designed for them(clothing, food) depending on the preferences of parents or what they thought it is good for them.

Further studies have shown that the understanding of purchase decision process in the family also depends on including children in the researches made. [4,14, 15, 25,39, 41]. Focusing researcher's attention on considering this group also(children) as main actor in purchase decision making is due to the fact that in recent years children's

influence upon purchase decision has increased.

Current changes in social and demographic structures are increasing children's influence on both their parent's decisions and their general involvement in family decision making. Among various reasons [41] that led to an increase in children's influence upon purchase decisions in the family we can mention the following elements: need of a higher income, increasing number of monoparental households, decreasing number of children per family, postponing the decision to conceive a child and increasing media exposure of the children.

Firstly, the need/desire to have a higher income per household member, has led to an increase in the number of families in which both parents work. Jenkins [22] or Geuens et al. [17] in the studies made stated that children's influence in decision making increases with those two incomes brought by the parents, because they do not have time for their children. Various studies [7, 19, 42] have shown that mothers who work can't say "no" to their children so easily in some cases or they tolerate inadequate behaviour as a result of the feeling of guilt that they do not spend enough time with their children. More often than not parents compensate the lack of time with money, thereby giving the child the possibility to make some choices in their place.

Secondly, in recent years the number of monoparental families (mother - head of household or father - head of household) has increased with the recording a large number of divorces or women who decided to have a child without getting married, thus leaving a greater influence of children in the purchase decisions. Albert Caruana and Rosella Vassallo[8], have shown in the study that the number of monoparental families has increased, and the children personally do the shopping, leading to a greater influence when it comes to making the purchase decision. Ahuja [1] said that children within monoparental families hold more power in the family's consumption decisions, because they feel constrained to replace the absent parent and to assist in decisions the single parent.

Thirdly the number of families that have a small number of children (one or maximum

two children) has increased. Shim et al. [34] and Geuens et al. [17] revealed that in families with fewer children, they acquire consumption ability earlier and they take part in the family's purchase decision process sooner than in the families composed of more members.

Fourthly, starting a family and of course conceiving a child is delayed until the workplace provides a satisfactory satisfaction for the individuals involved [17]

Last but not least, highly and repeatedly exposure of children to mass-media led to the socialization of children and thus to the influence exerted by them upon parent's purchase decisions. Television can influence children by asking for various products, making them aware of the necessity of those products (what is its usage) - 80% of advertising oriented towards children is made for the following product categories: toys, cereals, candy, fast-food and restaurants[24]. Spungin [36] quoted by Chavda et al. [19] claimed that, through the advertising designed for the small ones, companies encourage children to ask parents to provide them with various products or services. The increase in advertising for this segment, stimulates children to "harass" their parents for purchasing new releases, with the precise purpose of keeping up with the new trends.

Schor [33] states that parents find it extremely difficult to refuse their children due to the advertising and the existing campaigns [40]. The parents' process of giving in to their children is increasing significantly with the increasing in the age of the child. The parents' have an important role in the child's development as a consumer, because they are the first to take the child to the supermarket, they familiarizes him with this environment from a very early age - two months. From the age of 18 months, they can discern brands and by 24 months, they ask products by name [39]. Likewise, from the age of 7 to 8 years they can be considered consumers with full rights, who spend their own money, coming even from their parents or other sources (monthly allowance, money from relatives – grandparents etc).

2. The child in the family's purchase decision process

McNeal [28] identifies children development stages of behaviour as consumers as follows:

- they accompany their parents and observe;
- they accompany their parents and they request various products;
- they accompany their parents and in agreement they select products;
- they accompany their parents and they make independent shopping;
- they go to store alone and they make independent shopping.

Children learn about consumption by observing and imitating their parents' behaviour [35, 40]. So, the children shape themselves into consumers firstly under the influence of parents, as agents that introduce them in the commercial environment.

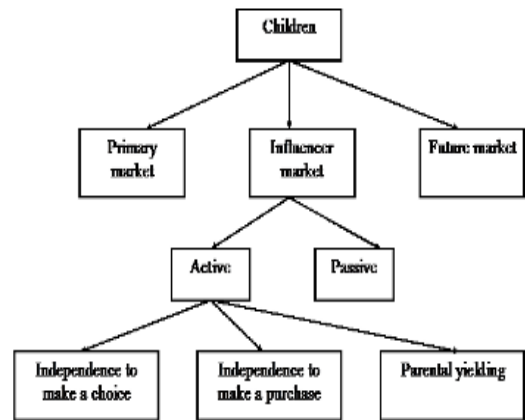

To acquire the desired products, the children resort to different strategies depending on the age. Obtaining things by toddlers (with ages between 3 and 11 years) is done with the simple gesture of asking, while teenagers use different strategies in order to influence their parents in the purchase decision making. Palan and Wilkes [31] observed that teenagers use strategies such as negotiation, persuasion or emotional strategies (e.g. pouting, flattery, negotiation, the state of guilt) instead of direct requests.

A series of studies [4,10,20,30] concluded that with the increase in age, the children exert a greater influence on their parents due to stronger cognitive abilities. At the same time one can say that the level of development plus the experience gained in time with the products make the older child hold more information about his role as a consumer.

Thus, children have become a very important consumer group in the marketplace, that influence the family's purchase decisions in many ways.

McNeal [28] states that the children are a primary market, an influencing market, and a future market (figure 1), very different from previous generations.

Figure 1 Children as Influencers

Source: Pavleen Kaur and Raghbir Singh [23]

Thus, for certain products, the children are primary users, i.e. the product is purchased by themselves or they made a selection of products(favorites) before it is bought by parents. For the category of products for the whole family, e.g. the brand of cereal they eat in the morning, the children can play the role of influencer in the purchase decision of parents. We can speak here about a direct influence of children, namely directly expressing, out loud, their preference for certain products. Other products are purchased by parents based on previous knowledge of children's preferences, for the daily consumption as well as for the whole family [23]. In the future they are the ones who will make the purchases, based on the knowledge accumulated about products, for the whole family, once adults – they are consumers with full rights.

Therefore, the children can have both a direct influence and a indirect one regarding the decisions in their families. A direct influence is exerted when the parents choose products and services based on the requests made by children - e.g. the restaurant where they are having supper, the type of dessert they will order. The indirect influence represents the choices made by parents at shopping (children not being physically present) based on the preferences they know that children have – e.g. favorite fruits.

The influence that children usually exert upon parents' purchases may vary not only according to the product categories used by the family but also by the stages of the

purchase decision process. Thus different individuals in the family may hold different roles in different stages of the purchase process.

Regarding the decision making process in the family setting, different authors have taken into account a different number of stages. The number of stages of the purchase decision process varies from nine stages [43] to two stages [32]. The first who used in the decision process three stages were Davis and Rigaux [11] or Belch et al. [5] i.e.: initiation, implementation of the choice and the final decision. Regarding the family, initiation is the process by which a member of the family proposes a suggestion or ideas. The second stage is represented by executing the choice of a certain type of product or service. The family members are searching and comparing different alternatives. The final stage is the purchase decision process. The influence and children's degree of influence in those three stages differs from one study to another.

Szybillo and Sosanie [37] in a study concerning choosing a restaurant, or choosing a family vacation, they reported that all the members of the family are involved in the stages of the decision process. In the mid '80, Belch et al [5] was of the opinion that the greatest influence of children is felt in the problem recognition stage and less in the final decision, when choosing how to spend free time or durable goods. Later, [21] ascertained that children's influence is greater in the final stages of the purchase decision process.

Based on the new existing changes in the lives of children (greater access to mass-media, free access to internet – information about markets), Belch et al [6] comes back with a new study claiming that older children are those who take purchasing decisions in families.

3. Conclusions

Actually it can be stated strongly that nowadays the children equally influence all stages of the decision process if the products in question are targeting them exclusively and have more influence over less expensive products and those for their own use [15]. Since the early '60 researchers became interested in the consumer's behavioral manifestations in children. As an important

entity in the market, the children are taken into account in researches conducted over time because of two reasons [29]. The children have a considerable monetary amount with which they satisfy their own needs and desires. Then, children's influence on purchase decisions in the family is ever-growing; the influence it is not limited only to products strictly related to children – candy, toys etc, but has been extended to the entire household products: mobile phones, computers etc. Children's different degree of influence on the purchase decision process varies and is due to the product category taken into account; decision-making stage – the child from the influencer to the decision maker in some cases; child characteristics – only child or with more siblings, family characteristics – traditional, monoparental.

The accelerated maturation of children, largely influenced by the little time parents spend with their children, by mass media which took the place of parents in some cases, as well as other factors - external and internal, led to a change of attitude in terms of their decision-making space relating to purchases made by parents and not only.

Future market – the children have their roots in childhood experiences as consumers with equal rights in the family in which they were raised.

4. Future works

Present paper is a preliminary study who support our next intended research about child in the family's purchase decision process on the Romanian market.

Abstract

Resource concept seems relatively banal, the economy using the general meaning: support element to meet the needs. Resources represent the inputs to the activity of any company and refer to: properties, employees, streams of information, knowledge, cultural values, organizational capabilities, etc. By their very nature, resources do not create value, they must be processed using existing technologies to design products and services in accordance with the mission of the organization.

Key words: business, services, resource, performance.

J.E.L. Clasification: D8, D83, L2, L21, L25

1. Introduction

The emphasized dynamism of external environment significantly influences the activity of services companies. Therefore, companies need a good understanding of market changes and features, and some strategies development and implementation according to the economic context.

Services companies set their market strategy according to the objectives they pursue, their available resources and the environment development in which they operate. Nowadays, successful companies tend to be those that innovate permanently, using the new technologies, the skills and the know-how of their employees. Performance in both commercial and services affairs supposes the existence of a solid theoretical

background which entrepreneurs can apply depending on their innovative capacity. Thus, innovation and vocational training become the most valuable assets for carrying out a successful business.

2. From tangibles to intangibles

Resource concept seems relatively banal, the economy using their general meaning: support element to meet the needs. According to Business English Dictionary Online [1], resource concept is explained as follows: economic or manufacturing factor required to perform a task; means of achieving a business and get the desired result; the three basic resources are: land, labor and capital; other resources are explained in terms of: energy, entrepreneurship, information, experience, management, time, etc.

Resources represent the input to the activity of any organization and refer to: property, employees, streams of information, knowledge, cultural values, organizational capabilities, etc., allowing the company to create value for its customers. *Resources are everything the organization owns to achieve its mission and strategy arising from this* (Băcanu, 2009, p. 67) [2].

In terms of management, there are two types of resources: tangible, also known as capital and intangible resources, considered a general category, relatively uniform.

By their very nature, resources do not create value. They must be processed using existing technologies to design products and services in accordance with the mission of the organization.

Tangible resources are those that we can see, touch, measure. They can be easily identified and evaluated. We can include here the physical and financial assets the organization uses to create value for its customers. For example: natural resources (infrastructure, locations, equipment, furniture, raw materials, books, etc.); human resources (people as integrators of physical properties); financial resources (the firm's cash accounts).

At the opposite pole, **intangible resources** cannot be seen, touched, and measured directly. They do not have a physical form, nor do they hold physical properties, their features and behavior are different. For example: human resources which include staff (people as integrators of other properties besides physical properties, namely: experience, talent, skill, intelligence, knowledge, creativity); computer resources (data, workflow information, tacit or explicit knowledge); the legal basis (licenses, copyrights, trademarks); the reputation of the company (company name, brands for various products and services) (Brătianu, 2006) [3].

According to specialists, all intangible resources of a company become more important than tangible resources. Intangible assets are strategic resources in getting competitive advantages, helping to create a solid reputation for the company and also possibly leading to its expansion. If we take the example of branding the products of a company, we can acknowledge that the brand is a complex symbol representing a multitude of ideas and attributes with emotional impact on consumers, which was created over time in the minds of the consumers by: brand name, packaging, advertising, public relations, promotion, etc. When the product has a strong brand name, it provides value over time, customers become very loyal, refusing to buy the competition's offer.

In the analysis of a various types of resources, a part of literature considers their classification as: **content-** financial, human, physical resources, etc.; **their functional way used in the organization-** production, marketing, human resources, etc.

Any authors support the existence of other organizational resources (Barney and Hesterly, 2006) [4]: the organization, cultural

value system, coordination and control system of the organization.

Ghe. Holt (2010) [5] presents four categories of intangibles resources: **market resources** (trademarks, market segments, assignment contracts, franchising, licensing, ordering supplies, distribution channels, etc. These resources create for the organization competitive pluses on the market, if they are efficiently used); **infrastructure resources** (technologies, methodologies technical processes specific to the organizations, which lead to its effective functioning. This type of resources shapes the culture of the organization, its financial structure, the databases management systems; these values determine the way in which employees work, communicate and establish relationships in the organization's compartments); **intellectual property resources** (patents, copyrights, software, trademarks, manufacturing secrets, know-how, etc.); **human resources** (professional skills of employees, their experience, intelligence, talent, ability to solve problems, etc.; these are crucial values of the organization, since they are difficult to identify, measure and cannot be reproduced).

An interesting category of resources is discussed in the literature by Scholes, Johnson și Wittington (2008) [6] and refers to: threshold resources and single resources.

Threshold resources are needed by the company to meet minimum requirements of economic survival.

Single resources are those that provide a competitive advantage and are very difficult to obtain by other competitors.

Literature pays special attention to intangibles resources, to which we return to detail the forms they materialize and to emphasize their significant impact on the both commercial and services affairs in terms of business performance.

Thus, the category of intangibles resources include: licenses, patents; copyrights; trademark, service mark; brand; reputation; knowledge or business related knowledge; the organizations' external relations.

The Oxford English Dictionary [7] provides us some explanations for these categories, as follows:

Patent, license: government authority who gives someone the right to exclude others from making, using or selling an invention.

Copyright: the exclusive right legally attributed for a fixed number of years to a person has published, printed, made a film or recorded literary, artistic, musical materials.

Trademark: symbol, word or words, legally registered by use as representing a company, a product or service.

The patent protects an invention, copyright concerns intellectual creation, idea or information, and brand refers to a name, word or symbol, all these being used to create distinctiveness of a product or service and to provide protection against competitors.

Brand: type of product manufactured by a particular company under a particular name. *Brand is a name, symbol, image or a combination thereof, serving to create distinct identity of a product, organization or institution* (Băcanu, 2009, p.73) [2].

Reputation: general beliefs and opinions held by someone about something or someone else; widespread belief that someone (something), has a certain characteristic. Reputation provides a signal of organization attractiveness, reflecting its past performance. It is difficult to quantify, but it appears as a resource with a global strategic potential, which lead to a sustainable competitive advantage (Petrik et al, 1999, p. 58-69) [8].

Knowledge: facts, information and skills acquired through experience or education; practical understanding of a subject.

Relationship: the way two or more persons (things) are connected; something's effect on the relevance of something else.

3. The resources importance in market positioning of the service company:

The literature outlines a first idea which refers to the fact that organizational performance was mainly due to its internal environment after 1980, but this approach is reflected by the year 1985 under the name: Resource Based View (RBV) in the works of an important authors: Wernerfelt (1984), Rumelt (1984) and Barney (1991).

The discussion about the relationship between resources and performance is justified by numerous studies, which are

based on two basic assumptions: *resource heterogeneity hypothesis* (Penrose, 1959) [9] that each company operates with a unique combination of facilities and resources; *resource immobility hypothesis* (Selznick, 1957) [10] originates in the works of David Ricardo and refers

to the fact that certain resources owned by a company are difficult or costly to imitate.

An approach to the relationship between competitive advantage and organizational resources was begun in the literature as the '90s with a series of papers: Dierickx și Cool (1989) [11], Conner (1991) [12], Peteraf (1993) [13], but representative is Barney's work from 1991, known as VRIO framework, used since 1991.

VRIO is an acronym translate by the attributes: value, rare, inimitable, organisation to be resources associated.

Resource is valuable if it allows the company to exploit the opportunities of the external environment and to remunerate his threats; resource is rare if it is owned by a small number of competing companies; resource is inimitable if the company can pay the costs difference to obtain and develop that resource; organisation's ability to sustain these valuable, rare, inimitable resources through its policies.

As a result of the resources evaluation, the service company may be in one of the following situations from its competitors:

- *competitive advantage:* when the distinctive resources are found in a relatively small number of competitors;
- *competitive parity:* when resources are found in the majority of competitors;
- *competitive disadvantage:* when the resources do not result in the same performance as those of competitors (Băcanu, 2009, p. 78-79) [2].

The intangible resources involved in the activity of the service company must be aggregate through a proper management to the company's strategies; their absence has implications in terms of market positioning, achieving competitive advantage, building a solid reputation and growth of the company.

4. Conclusions:

As a conclusion with implications for service businesses, we can say that the success of service companies is significantly influenced by its intellectual capital. This intellectual capital contains all knowledge involved in the service company development, which can be stored to a tangible medium: the talent and experience of employees, their commitment to the institution, educational and cultural level, the value of intellectual property rights, the organization's cultural values, customer's loyalty. *Companies should be aware that their most valuable assets consist of what is in the minds of people they employ* (Pistol, Ungureanu, 2012, p.491) [14].

Intangible resources have a pivotal role in building business, their contribution is reflected in market's corporate positioning and in achieving of competitive advantage; nowadays these elements are indispensable.

Recession of Economy and the New Aspects of Consumer Behaviour: the Case of Romania.

Anghelina Andrei,

¹"Vasile Goldis" Western University, Faculty of Economics, Arad, Romania
anghelinamm@yahoo.com

Abstract

In this paperwork the author intend to have a glimpse of the influence of recession on consumer's income and in the consumer behavior, especially in Romania. Also the author want to present the case study of Romania concerning the recession of economy and some new aspects of consumer behavior. There is a strong connexion between the income and consume and the time of recession show it in the best way. In this way we did some research on the market and by some analyses in a statistical editor we conclude that there is a strong determination in the consumer behavior by the income of the population especially in Romania, a country with a developing economy. The recession influenced the consumers in their biggest concern – their income. In the same time the recession changed some important trends in consume.

Key words: recession, consumer behaviour, income, dependency

J.E.L. Classification: D 10, D 12.

1. Introduction

The current financial crisis has hit hard many countries in Europe. Economies slowed as large corporations reduced production and fired personnel, and societies worldwide experienced prosperity downturns [1].

The Greek economy was one of the fastest growing in Europe during the 2000s.

The overall effect of Greek debt crisis was considerable high and its negative repercussions were felt especially by countries in South-Eastern Europe.

Romania and Bulgaria were the most affected countries in the region; that is why the author chose to describe the relationship between Greece and Romania given the

magnitude of the current economic crisis.

The way Romanians experience and perceive the effects of the crisis is strongly influenced by the line of business, the income level and age [2].

In this paper we will try to approach the level of income in Romania and the crisis impact on the consumer behavior.

2. Some aspects concerning income and consume

Income of a person "expresses livelihood available to it in the form of sums of money, goods and services obtained from the work, property or social consumption funds, and they may, in general, the desired goal without a restriction or obligation" [3].

Depending on their source, total household income consists of:

cash income, which includes:

-Salaries;

-Income from agriculture;

- Income from independent agricultural activities;

- Income from social benefits;

- Income from property.

b) the value of income in kind obtained by employees and beneficiaries of social benefits,

c) the value of consumption of agricultural products from own resources.

Money income of the population works on the market through demand for goods, conditioning, eventually achieving the supply of goods and market relations in general.

However, progress in the overall growth of gross domestic product, national income is a basic form of insurance and increase income of the population.

However, in Romania, the money income of the population is characterized generally by a rather low level, very low for some categories of households, a phenomenon with important implications on the level and

structure of consumption opportunities savings of the population.

3. Income and consume in Romania

In Romania, although the main source of income is the total money income, there is still high share of income in kind.

Total household income structure still stands by the large share of income in kind.

In the analysis based on household income level of education of household head, is that there is a direct relationship between the size of income and education level of people without income.

Thus, household incomes characterized by a higher level of education were 2.85 times higher than those of the household head have not completed more than primary school. Even compared to situations where the household head has completed secondary education, household incomes characterized by a higher education level were 83.9% higher.

In terms of total household income level, grouped by the number of the composition is observed that in the case of several members of households, average income per person remains lower than for households with fewer people. This can be explained by the fact that many live in households usually more dependents.

We can observe that in October 2011, the average gross nominal earnings were 2008 lei (RON), decreasing with 9 lei as against September. The average net nominal earnings were 1457 lei, decreasing as against the previous month with 7 lei (-0.5%). The highest values of the average net nominal earnings have been recorded in activities of IT technology services including activities of informatics services (3688 lei), while the lowest in hotels and restaurants (872 lei).

The real earnings index for October 2011 as against previous month, calculated as the ratio between the net nominal earnings index and the consumer prices index, was 98.9% (Fig. 1).

As compared to October 1990, the real earnings index was 117.7%, by 1.4 percentage points lower than the one recorded in September 2011 (Romanian National Institute of Statistics, Romania, Press Release 267 / 2011).

Fig. 1 - Paralel evolution of Consumer Price Index and Net Average Earnings Index in Romania during October 2009 – October 2011 (Source: National Institute of Statistics, Press Release no. 267 / December 2011 Average Earnings, Bucharest, Romania.)

The home consumption of consumer goods increased by 6% in local currency in the first six months of 2011 compared with the same period of the last year. This increase was influenced primarily by the high level of inflation. In volume, the market recorded a decline of nearly 2% while the phenomenon of down-trading (migration toward products in a lower price segment) is yet recorded.

Analyzing the main categories of products, we observe that the basic food segment was most affected by the rising prices, the amount spent on these categories being 15% higher, while the expenses with non-essential food increased 4%.

From the basic food products, oil values grew by 40%, while volume fell by nearly 2%. For ground and toast coffee - also considered essential items by consumers - the expenses remained relatively stable. However, consumption fell by 7% for a constant number of consumers.

Costs to home care and personal hygiene increase of 5% in the first half compared to the previous year. Among the non-basic products, households in Romania have paid slightly less for laundry detergent (-1% in value), while for shampoo costs rose by 12%, although consumption remained about the same.

After a period in which care products were affected by lower consumption, as a result of Romanians trying to adapt to difficult economic context, in the first half of the year categories like deodorants and toilet

soap registered modest growth of 4% each, while the number of households that bought at least once these products increased slightly.

Modern trade still gains ground at the expense of traditional drawing in the first six months of the year, entailing 47% of the total households in Romania for consumer products, up two percentage points over the same period last year. Boutiques and grocery stores, the main traditional trade formats, lost 4 percentage points in value, resulting in the first six months of this year only 37% of total expenditures on consumer products compared to 41% in the same period of 2010.

At the absolute expenditure level, hypermarkets and supermarkets have growth rates of almost 15% each, and discount stores by 14% during this period. The main engine of growth for modern trade formats is the higher number of buyers, a trend explained by the dynamic territorial expansion of large retail chains.

The study is based on information obtained by monitoring the household consumption of approximately 90 categories of consumer goods through the consumer panel of GfK Romania, on a sample of 2,200 households, nationally representative.

Euromonitor International has recently published an interesting study related to consumption expenditure and disposable income in Romania.

Romania is a relatively poor country, and increase revenue and consumption expenditure tend to be moderate.

However, the country has a large middle class expanding on marketing and sales that people should focus.

Although consumption expenditure fell considerably in 2009, is expected to increase sales significantly in the health and transport between 2009 and 2020.

In this interval it is expected to increase the available income per capita accordingly to expenditures (Fig. 2).

Major discrepancies are observed between consumption expenditures in the capital Bucharest plus some major cities and the countryside.

Fig. 2 – Incomes and expenditures in Romania per capita (Source: <http://www.euromonitor.com/>)

Market in Romania is constantly expanding. According to Euromonitor International, the annual income available in Romania was about 91.3 billion dollars in 2009. The state recorded the fourth highest disposable income of all Eastern European countries, positioning itself after Russia (U.S. \$ 743.6 billion), Poland (266.3 billion dollars) and the Czech Republic (103.2 billion U.S. dollars).

Romania was hit hard by economic crisis in 2008-2009: annual income available per capita decreased by 11.1% in real terms in 2009 compared to 2008, while consumption expenditure per capita fell by 12.7%.

Long-term evolution is constrained by the decreasing number of inhabitants and a rapidly aging population, plus the effects of slow economic growth.

Persons aged 30 and 34, mainly young self-employed enjoyed the highest average gross income in 2009. The capital, Bucharest and its surroundings experienced the strongest growth in consumer spending across the country in 2009.

There continue to be major social and economic differences between urban and rural areas, where most of Romanians live.

In 2009, the richest 30% of households were responsible for more than half of total consumption expenditure on clothing and footwear, transport, communications, entertainment and recreation, education, hotel and catering.

Another survey conducted by ING show that the Romanians save the lowest part of their income from the ten countries included in the survey.

“ING Consumer Resourcefulness” survey offers relevant information about the

consumers' behavior and attitude from ten countries from the entire world (the Netherlands, Belgium, Spain, Romania, Poland, the USA, Mexico, India, Korea and Japan) in relation with their personal finances and solutions used in every analysed country for their administration.

Out of the ten countries included in ING survey, Romanians save the lowest part of their monthly income – only 7% as compared to the global average of 12%.

By comparison, in Holland, Belgium and Mexic the consumers allocate savings 10% from their monthly income, in Spain – 11 % in Japan, 14% and in India and Korea over 20%.

In Romania, the highest monthly expenses are allocated to food (32% of the monthly income as compared to 26% at global level) and the products for the house maintenance (28% in Romania vs. 25% at global level).

Romanian consumers are more exposed to financial risks for short-term too since 42% of the Romanian households do not have an emergency fund.

However, according to GfK survey from august 2011, the technical consumer goods market has recovered from the fall that intervened right after the crisis started and *- *followed the trend set in the first quarter and continued its recovery in double digit figures. The market grew 12.4% in Q2 compared with the same period of 2010, while the growth for the first six months of the year is 11.6% [4].

The total market for technical consumer goods was EUR 306 million in the second quarter of 2011, and EUR 613 million for the six months ending in June. The IT sector was again the best performing market (+27.5%). Small Domestic Appliances (SDA) and Photo also had double digit growth rates, at 17.8% and 17.7% respectively. Telecommunication, Consumer electronics (CE) and Major Domestic Appliances (MDA) increased by single digit figures. The Office equipment (OE) market is the only one still in red but the decline slowed down in Q2 to only -3.6% (Fig. 3).

Fig. 3. – Sales trend of technical consumer goods in Romania (Source: GfK Retail and Technology, <http://www.gfk-ro.com>)

Also, according to GfK, the second quarter of the year witnessed the Small Domestic Appliance (SDA) market increase by 17.8%, EUR 4 million more than the same quarter last year.

Leaders, such as hot beverage makers and food preparation, left their mark on the Q2 2011 sales. Hair care appliances continued to struggle while traditional products such as irons and vacuum cleaners recorded double-digit growth.

The food processors category, which used to contribute to the decline of the sector, now changed its trend into an ascendant one and together with all food preparation markets has boosted sales within the sector.

Espresso machines sales are becoming stronger and had an important contribution to the overall positive evolution of the sector. Fully automatic, the most expensive category of espresso machines, had a remarkable performance and became the most important segment within espresso machines. Consumers are showing great interest in "fully automated devices" and in new innovative appliances, therefore, this market experienced a solid growth.

The first five SDA product groups out of eleven monitored by GfK TEMAX represent three quarters of the total sales of the sector.

This quarter showed that the purchase behaviour moved from personal care to traditional goods used for "in-home" activities of cleaning, ironing and preparing food or beverages.

Knowing the level of income and total consumption expenditure structure of the Romanian households, it requires as a fundamental requirement, identifying the link

that is established between these two variables. Thus, the relationship between income and consumption expenditures of the population can be highlighted using simple linear correlation coefficient.

Bravais-Pearson correlation ratio (or Pearson coefficient, or simply 'correlation coefficient', as it is called by those who use it frequently) is a method of measuring the intensity of linear association between two numeric variables

The correlation coefficient can range between -1 and 1, that satisfies the inequality:

$$-1 \leq r \leq 1 \quad (1)$$

Where r – Bravais-Pearson correlation ratio

Specifically, using our statistical data from the Romanian Statistical Yearbook, 2009 and 2010 editions, with correlation coefficient, we highlight the intensity of the relationship between the two variables considered (income and consumption expenditures). [5]

To do that we used a statistics editor called SPSS.[6]

The results of the modulation are shown in table 1.

Table 1. – Pearson Correlations – General

		VA R1	VA R2
VAR 1	Pearson Correlation	1,0 00	0,99 9
	N	10	10
VAR 2	Pearson Correlation	0,9 99	1,00 0
	N	10	10

Where VAR1 – total income,

VAR2 – consumption expenditure

As shown, $r = 0.999$, which indicates a very strong connection (relatively deterministic) between total revenue and total expenditure Romanian household consumption during the period 1999 to 2008. Thus, the size and structure of consumption expenditures of households are direct function of income level, which shows that currently the main focus is the consumption expenditure of households.

Calculating the correlation coefficient (r) for the two variables (total income and total consumption expenditure) for each type of household, we get the following results:

a) For households of employees - $r = 1,000$

Table 2. – Pearson Correlations – Employees

		VA R1	VA R2
VAR 1	Pearson Correlation	1,0 00	1,00 0
	N	10	10
VAR 2	Pearson Correlation	1,0 00	1,00 0
	N	10	10

b) For households of farmers - $r = 0.993$

Table 3. – Pearson Correlations – Farmers

		VA R1	VA R2
VAR 1	Pearson Correlation	1,0 00	0,99 3
	N	10	10
VAR 2	Pearson Correlation	0,9 93	1,00 0
	N	10	10

c) For households of unemployed - $r = 0.999$

Table 4. – Pearson Correlations – Unemployed

		VA R1	VA R2
VAR 1	Pearson Correlation	1,0 00	0,99 9
	N	10	10
VAR 2	Pearson Correlation	0,9 99	1,00 0
	N	10	10

d) For households of pensioners - $r = 0.999$

Table 5. – Pearson Correlations – Pensioners

		VA R1	VA R2
VAR 1	Pearson Correlation	1,0 00	0,99 9
	N	10	10
VAR 2	Pearson Correlation	0,9 99	1,00 0
	N	10	10

It becomes obvious that between the development and evolution of consumption expenditure and income, there is a very strong connexion. As the correlation coefficient calculated for these two variables recorded positive values very close to 1 ($r = 0.99$ for households of farmers, unemployed and retired) and even equal to 1 ($r = 1$ for households of employees), we can say that between total revenue and total expenditure Romanian household consumption, regardless of their type, there is a deterministic relationship, even fully functional.

4. Conclusions

The nowadays economic crisis is an unprecedented situation for the entire world if we consider its global dimension and the severeness of its outcomes. The negative economic evolutions of all national markets conducted to important changes in people's way of thinking, or behaving as well as in their system of values [7].

Romanians experience and perceive the effects of the crisis according to variables among which the income level is highly important. Romanian consumer behaviour has been analyzed accordingly.

The crisis has reduced the comfort and quality of life of middle to low and low income segments, and thus they adapt using strategies like reduce the purchased quantities of products, they buy what they need and only as much as they need, they choose cheaper products within each category, etc.

The consumption behavior has not changed significantly concerning middle to upper & upper income segments, the most affected areas being savings and holidays.

Opportunities for growing within the crisis context should be based on the fact that In the crisis context, price has certainly become more important. Utilities and food are the categories that are expected to grow the most.

However, in conclusion, the main focus of Romania's current household expenditure is consumption of goods and services, whose order of magnitude in the last decade, has covered about three quarters of total expenditure.

Influence Factors over Human Resources Management Practices within Romanian Companies

Anohi Ionut

„Ovidius” University of Constanta, Faculty of Economic Sciences

antohi_ionut@yahoo.co.uk

Dumitrescu Mihaela

Brăiloiu Liviu

Abstract

Human resources management within Romanian companies requires a complex process of renewal and development of specific practices.

A better understanding of this process will be possible as the influence factors are identified and analysed.

This paper aims to present the level of development for human resources management practice in Romanian organizations. The influence factors are presented both from an institutional and cultural perspective.

A clearer image on this issue could be achieved by conducting the analysis separate covering each perspective and could represent the subject of a future research.

Key words: human resources management practice, institutional factors, cultural factors, Romanian companies

JEL classification: M12

1. Introduction

Human resources management has constantly evolved, reaching the level of development that is well known and accepted in the specialized literature. There are still different debates upon certain issues concerning this domain. Such a debate that proves to be actually is the one regarding the human resources management practices and the elements that determine and explain their evolutions.

Considering the case of Romanian companies that are involved in a process of development of their human resources management practice such an approach proves to be useful. In this context a review

of the main theories is necessary and will be presented in the next section of this paper. These theories are presenting different models of human resources management.

2. Human resources management models

Specialized literature indicates that various human resources management practices based on the economical, political, social and cultural diversity of each country. Despite of these evidences two main categories of human resources management have been identified[4]:

- calculative practices – aiming the increase of human resources efficiency;
- collaborative practices – concerning a process of convergence between company’s objectives and the ones of its employees.

Starting from these two categories of practices, two models concerning human resources management have been indicated by the specialists:

- calculative human resources management model;
- collaborative human resources management model.

The calculative model – promotes those practices that aim to enables the accomplishment of the company’s activities in an efficient manner. The human resources are seen as any other economical resource that is assessed by the efficiency of use.

Therefore, this model proposes some practices such as: the individual performance assessment (for managers and different professional categories), the reward system tightly connected with the performance assessment, the estimation of the training programs efficiency etc.

Such a model is based upon a substantial

autonomy of management within the company that should be not restrained by specific legal norms or union pressure movements.

The collaborative model – that involves some practices that are focused more on the people. This way, the value of the employees for the company, ethic issues concerning the contractual relationship are pointed out. The employees are seen as an active partner within the organization, due with a high potential of creativity and innovation that should be properly used.

These practices are based on mission statement, the official report on the company’s strategy at all its levels, the existence of an employee’s communication policy.

It has to be noted that are differences that could occur in each country due to the specific legal framework regarding employment practices [3].

Another model, such the one proposed by Brewster, brings into discussion three level of analysis regarding the human resources management practices within European space[1]:

- international level – marked by international organization such as European union;
- national level – represented by culture, legal systems, economical system etc.;
- national framework of human resources management – consisting in labour market, industrial relations, educational system, trade unions etc.

Such a model proves actual and the influences presented should not be ignored considering the European membership of our country.

This brief review of these models points out various factors that could exercise different types of influence over the human resources management practice within a specific country.

3. The development of human resources management practices within Romanian companies

The status of human resources management practices within companies located in our country was subject of different studies and surveys. The results of

the most significant are presented and analysed below in order to point out a clear image over this particular field. In the same time, the elements that are exercising influence over the domain are to be identified.

Several studies have indicated that within Romanian companies were functioning and still are traditional personnel departments fulfilling administrative tasks.

According to the results of these studies one major difficulty pointed out by human resources managers is the bureaucracy occurring in the relationship with authorities. Such a situation could easily represent an obstacle for a development process regarding the specific practices.

The decision process regarding human resources field in the company is usually the responsibility of general manager. This proves a restrained authority of human resources manager. Therefore, decisions meant to improve the specific practice are not taken by the specialised people, which could affect their efficiency [6].

Other studies have identified the same situation as the one presented above, but have underlined an improvement of human resources management strategic role within the companies.

Another improvement refers to the fact that the human resources managers became on a larger scale members of company’s board.

Payroll issues are the responsibility of general manager and chief accountant. The lack of implication on behalf of human resources department could create a gap between the level of performance and payment.

In order to achieve a greater efficiency at the company’s level, human resources management involvement in compensation matters should be increased.

The development of human resources management practices, specialized training should be considered as a priority. The results indicate that are still a reduced number of human resources managers that are viewing this situation as a priority. The area identified to be covered by training are[5]:

- conflict management – 34%,
- personnel motivation – 28%,
- interpersonal communication – 25%.

The level of development for human resources management practice and achieving greater efficiency are strictly determined by the level of competence among the human resources specialists.

Another solution for improvement at the level of human resources management practice within local companies is represented by the outsourcing process. Although, the human resources management professionals are aware of it, there is still a reduced usage. Whenever it is used, such a solution regards especially the recruitment and selection activities or the training process.

One issue that has to be considered when we take into discussion the matter of human resources management practices within Romanian companies concerns the cultural influence of our society upon this domain.

There is a study that has established the main cultural dimensions of our society based on Hofstede methodology. Starting from these results some predictions were made regarding the human resources management practices within Romanian organizations. [2]

Human resources planning should be based on a thorough analysis of positions and should avoid frequent changes within organizational structure of the company.

When the recruitment and selection process is considered it should be noted that the Romanian employees are more concerned with the job security than with promotion opportunities or job nature.

Moreover, Romanian managers tend to appreciate more loyalty than the level of performance when recruitment and selection are involved.

Considering the cultural influence the performance evaluation proves to be no easy task. Using clear objectives and a tight correlation between the level of performance and the level of payment could generate anxiety among employees.

It is recommended a system that will not generate competition or adversity between company's employees.

The reward system should consider the fact the Romanian employee proves a greater appreciation towards the level of salary, job security and working conditions.

A bigger fixed salary is considered very attractive. The system should consider also

the annual bonuses and benefits packages (health care, child care etc.).

Training and development practices should be based on the assumption that the employees are expecting the company to offer them training and protection.

The training programs are in their majority very complex and theoretical oriented. We can note that the situations when the employee is preoccupied with the development of his skills level are rare.

One major problem of these training programs remains the lack of feedback between managers and employees; in order to assess on a real base their efficiency.

4. Conclusions

The development of human resources management practices within Romanian companies represents a complex process.

A better understating of this process requires an analysis of elements that are influencing upon it. This approach implies the use of different points of view such as the institutional one, the cultural perspective and also the rational perspective.

Specialists have argued over the right approach when the matter of human resources management practices is discussed. As a result different models of human resources management have been proposed. Each model underlines various factors of influence over this domain and indicates several categories of practices that can be used.

In our country case we can assume that a complete approach on the subject could be realised starting from the model Brewster proposed.

It is clear, that as a member of European Union, our country will suffer the influence of legal framework regarding human resources field.

In the same time, we should consider the institutional influence existing at our country level. We are talking about institutions and legal regulations (such as Labour Code) that have an important role in human resources management practice within Romanian companies.

Another valuable perspective is the one based on cultural specificity of our society. Cultural dimensions exercise a great deal of influence over the human resources

management practices.

In this context some practices are suitable for our companies, while others are to be rejected by employees or managers. We remind that the Romanian employees are more concerned with the job security than with promotion opportunities or job nature.

Romanian managers tend to appreciate more loyalty than the level of performance when recruitment and selection are involved.

Considering the above mentioned elements we appreciate that a better understating of this issue could be realised based on a thorough analysis from institutional perspective or cultural one.

The Improvement of Human Resources Management through the Development of Best Practices

Anohi Ionut

„Ovidius” University of Constanta, Faculty of Economic Sciences

antohi_ionut@yahoo.co.uk

Bujduveanu Aurica
Ștefănică Virginia

Abstract

Human resources management practice has been subject of numerous studies. Specialists have brought into discussion the concept of human resources management best practice.

The issues related with this concept have generated intense debates among specialists.

This paper aims to present the theoretical background of the concept and the influence that could exercise upon the level of development for human resources management practice.

A clearer image on this issue could be achieved by discussing the model offered by the multinational companies in the development and diffusion of best practices related with human resources management domain. A through analysis of this issue could represent the subject of a future research.

Key words: human resources management practice, best practices , multinational companies

Jel classification: M12

1. Introduction

Human resources management evolution has brought into attention a new concept related with specific practice, the best practice. It generated intense debate among specialists.

It proves to be actually, especially in a larger context regarding the human resources management practices and the elements that determine and explain their evolutions.

Specialised studies have analysed the role of multinational companies in the process of

promoting best practices related with human resources management field.

2. The best practices in human resources management

Human resources management has evolved constantly towards its present level of development. Such a process has involved the concept of **best practices**. According to this the models offered by the top companies in the world can be use in any other company with necessary adjustments to their particular context. We can discuss the degree to what these practices are fitting to an individual (company) case.

There are various definitions of this concept in the specialized literature. One clear and suggestive definition presents the best practices such as specific methods, approaches on human resources management practices that positively affect organization's level of performance, due to the improvement of employee's level of satisfaction, customer's satisfaction and the development of the key areas of the business. [3].

The best practices allow an optimal usage of human potential of a company in order to improve its performances. It can be used in various areas such as: reward, personnel motivation, recruitment and selection, human resources planning [www.hrvillage.com].

For example, in case of reward system, salaries and other benefits that a company is offering should be covered by its budget. In the same time those elements should be incentive in order to attract and maintain valuable human resources for the company.

Another example refers to the legal regulation usage. In such case the experience of other companies proves to b very useful, considering the importance of this issue.

The necessity of this concept in practice can be justified by the following aspects [4]:

- they offer a framework for human resources specialist despite the specific area of activity;
- could be identified those practices that are leading to the best results within a company;
- strategies concerning human resources can be developed establishing a correlation with cultural values, the goals and objectives of the organization.

Related to this concept has evolved and it is used widely another one – **benchmarking**. It could be defined as process that involves a continuous comparison of similar areas of different organizations in order to establish those best practices meant to improve the company’s level of performance.

Such a process supposes a measurement of company’s performances, identification of best practices on a regular basis, an analysis of top companies experience and adjustment of these practices to the specific context of each enterprise.

Throughout the benchmarking process could be identified and spread out the best practices emerged from the most efficient companies. This could represent a solution for the improvement of human resources management practice.

The benchmarking process implies a continuous analysis of ones company practice, comparing with the model offered by top companies in particular field of action. Therefore, several stages have to be covered [5]:

- problems identification – evaluation of company’s own practices regarding a functional area;
- identification of top companies in their domain – which companies are the best;
- documenting – implies the study of reports or visits in order to establish exactly what are the practice of these companies;
- best practice implementing – considering the specific context of the enterprise;
- results evaluation – establish to what degree such practices have been integrated and the effects that are

generating.

The use of such a system could bring major improvement to a company’s level of performance in any functional area and especially in human resources management field.

3. The development of human resources management best practice throughout the multinational companies’ experience

There are many studies that have analyzed the issues regarding the human resources management practices within multinational companies towards and their subsidiaries placed in different countries around the globe.

In most of the cases, the major fact that has been considered was the degree of centralism regarding the human resources management practiced within the multinational companies.

The parent company plays different roles in the process of establishing the policies and the specific practices

Considering the case of the American companies, presented in most of the specialized studies, it was pointed out that these organizations manifest a high degree of centralism in this field. Thus, the parent company set out a general framework that has to be respected by all the subsidiaries. This framework could be, in some situation, adjusted to the local conditions. The procedures regarding the human resources field are in the majority standard.

For example, the surveys regarding employee’s opinion are compulsory for the most companies.

The issue of the degree of centralism within the management of the American multinational companies reveals some particularities concerning the control that the parent company manifests towards its subsidiaries [1]:

- the control process shows a higher flexibility of the American companies to the changes within the context in which they operate. Comparative to this situation the the german system is more institutionalized and relatively rigid;
- there is a trend of developing centralized policies regarding human resources field;

- in the same time the management of the subsidiaries tries to exercise its own influence taking into account their knowledge and the experience related to the local background. Therefore, the local managers need to act very diplomatic in relation with the parent company.

There is also necessary to determine the content of the practices proposed as a model and the way they will be operating in the new context (in the original form or an adjusted one).

Considering these issues a comparison between the American model and the British proves to be useful. The analysis identifies many similarities due to the fact that the two systems are standard ones.

The usage of practices and knowledge from the parent company to its subsidiaries is a complex process that aims different domains such as: reward and performance, workforce diversity issues, the management of the managerial carrier etc.

The integration level of the activities within the international context has a great deal of influence over the formal character of these processes. Even the most standardized practices and procedures are adjusted to the local real conditions.

Therefore, a study regarding these issues related to American companies and their subsidiaries in Great Britain has revealed the following matters[1]:

- the human resources management practiced within the American companies is different from the one of the other organizations. The trend is to use a centralized approach toward this domain. This could be explained by the fact that the American organization have always had a stable managerial system, that has represented an important condition for their competitiveness;
- in the same time there is a certain open attitude toward changes and innovations (opposite to the German system, for example). However, there are a lot of constraints regarding their adoption due to the existence of some models;
- there are differences between the companies form these countries due to the lack of any institutional constraint

in the American business environment and also to the strategical option that is primary set to the company's level. Such differences show up at the sector level, too;

- the practices tend to be modified in contact with the host country legislative background, resulting combined forms that are reflecting both the origin background characteristics (American context) and the ones of the host country's background (British context);
- subsidiaries management could have an important position in establishing the policies and practices regarding human resources, if it proves able to compel the parent company regulation combined with the specific objectives of the subsidiaries (business case).

Another approach of best practice issues reveals the **convergence/divergence** problem in human resources management practice within organizations in different countries.

The convergence issue implies that the best practice can be applied in any organization, despite the country. In this context, the economies of different countries will evolve toward similar structures – the concept of **competitive isomorphism** (the companies will assimilate the same best practices within similar economical background).

Another approach that has imposed itself is the one that assumes the national differences, based on national culture and its representative elements. The companies and theirs practices cannot be separated from the particularities of the cultural environment 2].

4. Conclusions

The development of human resources management practices represents a complex process. It raised different debates among specialists.

Such a debate was the one regarding the concept of best practice in human resources management field.

This approach implies the use of different points of view such as the rational perspective and the cultural perspective.

Specialists have argued over the right approach when the matter of human resources management best practices is

discussed.

Such practices emerged from top companies' experience covers various areas of human resources management field.

These practices could generate major improvements at company's level of performance.

The development of best practices involves a continuous process, known as benchmarking. It offers models of practice developed by the top companies.

Another discussion regarding the best practice matter has been centred on the way a company should adopt such practice. It was pointed out that adjustments are needed accordingly with the specific context of each company.

Moreover, there are specialists that are arguing that the diffusion process of best practice could be blocked by the cultural background of each country.

Specialised studies have pointed out that the multinational companies are to be considered important model for the development and diffusion of best practice in human resources management field.

The Bank's Success through Optimisation Promotion Strategies

Balaceanu Valeria Arina

Ecological University of Bucharest, Faculty of Economics, Romania

arina.balaceanu@gmail.com

Abstract:

Banking success is conditional on compliance with certain requirements of communication from the institution, the consumer must send financial confidence - which leads to a relationship of authority to the target segment; to be attractive – identification mark is very important; and not in the least credible: messages must match the entire value system of banking institution. We believe that success in banking will be influenced by redesigning and diversification of services and products that will lead not only to obtain customer satisfaction, but also to attract them by using carefully designed marketing strategies and applied in practice.

Keywords: marketing; marketing strategies; efficiency; banks

J.E.L. Classification: M1; M3

Introduction:

In globalised conditions, designing their institutions policies and strategies, through which outlines the objectives and directions of development in the future, but also the ways of achieving them, to ensure permanence in the market and overall development. Because of the multiple changes that occur in the marketing environment of the institutions, they exhibit a particular behavior, a certain attitude, which completes in shaping the strategic directions and of the ways of achieving that are reflected in the contents of the marketing policy of the institution. *We believe that marketing strategies that lead to success are those that emphasize market opportunities and competitive advantages in their stand based marketing control results highlights: risks, favorable situations, strengths and weaknesses of the institution, marking the*

defining periods in the institution. Such strategies emphasize what follows in essence the period, followed directions, targeted objectives, marketing mix strategies outlined can all be put into practice if they answer the following questions:

- *What are the needs and desires of consumers?*
- *What new services and products will be launched on the market?*
- *What market segments to be targeted?*
- *What are the weaknesses of the competition and their use in favour of the institution? Study of the competitive environment and the key issues;*
- *What are the objectives of the institution?*
- *What is the mix of marketing strategies to most effectively attain the objectives? (product strategy – defining the product; price strategies – establish attractive prices to customers; distribution strategies-choosing the most cost-effective distribution channels; promotion strategy – which will be transmitted message clients).*
- *What are the campaign results?*

The answers to all these questions materialized in the main forms that you dress up marketing strategies that mirror all functions of marketing.

We believe that in order to successfully promote products and services, banking institutions must communicate clear and honest information to clients about existing offer, so customers can take a decision regarding the purchase process. Some banks in Romania have chosen to promote their image, products and services with the help of celebrities from the world of music, sports etc. The strategy consists in the fact that public figures have a great effect on consumers. (example: BRD-Groupe Société Générale is associated with big names in the sport: Gheorghe Hagi, Nadia Comaneci, Ilie Nastase; Millennium Bank chose the

Holograf promoting mortgage loans and refinancing etc.).

Banks performance are visible when you know customers tender, purchase, and have confidence in that institution and thus in their offer. Figures and a display picture have no value unless they are part of an integrated marketing communication, supported by an appropriate budget. Creating a powerful images, positioning in the minds of consumers, the differentiation of the competitors, customizing products and services according to customers, all this implies a great effort on the part of all employees of the Bank.

Bank offer on the market differentiation is manifested by the quality and reliability offered by the institution, which leads to satisfying customer needs. Building a strong brand is the essence in winning the notoriety of a Bank and a large number of consumers. Banks are today in a position to seek various ways to enhance efficiency, replacing some tools with new ones, modern to offer them better economic benefits. Each tool used and cost characteristics. Therefore, marketers must be familiar with these features when choosing promotional tools. In the continuous development of the banking market, will be promoted new banking products and services, the aim being one – maximizing profit, which will foster the emergence of new banking operations that will inevitably lead to the development of operating systems. Communication with current customers or potential customers is taking shape through the transmission of information about the Bank's activity, the offer of services and products, but also receiving instruction in which they are received and appreciated by potential customers. Thus, the Bank is an open system to its environment, external source of messages aimed at strengthening the image and reputation of the services and products on the market that unfolds. Achieving such an objective implies the selection of information to be aired because the use of inefficient assets can lead to unpleasant situations with negative effects on the image of the institution.

The highlight - success is conditional on compliance with requirements communication from source: thus, it must be strong - which leads to a relationship of

authority to the target segment, attractive - brand identification is very important, and not least Credit: messages must match the entire value system of the bank. We believe that the success of the banks will be influenced by redesigning and diversifying services and products so as to converge not only to obtain customer satisfaction, but also to attract them using well thought out marketing strategies.

The mix of marketing strategies - As a member of the European Union, Romania is trying to keep up with Europe, not only in the services offered to customers, but also to marketing strategies and promotion related to the banking system. In the banking sphere, marketing came later than in the field of industrial products and consumer. The environment in which enable banking institutions affect their decisions affect their services and products as well as how they are promoted on the market. Marketing services and banking products tries to take into account both their market, but also the impact that regulations and competition may have on the activity of the institution.

Market study highlights the advantages of the Bank's competitive market, as well as developing marketing strategies, based on these advantages. Bank marketing strategies are developed taking into account the following factors environment. (Odobescu E., Marketing bancar, Editura Sigma, Bucuresti, 1999):

- *regulatory factor*-includes the legal framework for economic activity in general, and to the banking business, in particular, as well as BNR regulations;

- *political factor* refers to the macroeconomic policies and strategies adopted and implemented;

- *economic factor*-refers to the State of the economy, inflation, interest rates, changes in consumers purchasing power, customer requirements relating to banking products/services;

- *the social-demographic changes, cultural and lifestyle changes, changes of attitude and perception of consumers;*

- *technological factor* is usually associated with new information technologies;

- *the "competitive environment" refers to the analysis of activities, performance and competition reactions.*

Environmental factors are factors related to purchasing behavior of customers.

Placing on the market of a new service/bank product involves a marketing strategy which should fix at least the segment of the market concerned and the position you want to be obtained within it.

Marketing strategies in banking is based on the quality of services and products, the value and importance of consumers and stimulate the creativity of staff.

Devising such strategies involve finding answers to the following three questions. (Berry, L.L., 1995):

- *What attributes\characteristics of the service\product are considered to be most important for the segment\target segments?*
- *Which of these attributes of services\products are weaker competition?*
- *What is the present and future capacity of the company?*

The answers to these questions find their resolution by performing a thorough analysis of the needs of banking services and products of the current or potential consumers, who are not satisfied by the competition and which could be provided by the institution through a marketing strategy well made point.

Any coherent marketing strategy and complete presumes the following stages:

- *Market analysis;*
- *Consumer Analysis;*
- *Competition analysis;*
- *The choice of the most appropriate distribution channels;*
- *Development of marketing mix;*
- *Evaluation and control strategy.*
- *Banking strategies targeting objectives: positioning on the market of the institution; appropriate banking policies aimed at streamlining the activities and operations of the Bank; central and local management that gives safety, stability, efficiency in carrying out the activities; indicators of efficiency and profitability (is carried out permanently comparisons with the evolution of competing banks); the structure of the Bank (territorial network, staff, information and technology investments in buildings and upgrades); Bank resources; placements; the range of services and*

products; relations with other international financial bodies.

Under the conditions of a strong competitive environment, development of marketing strategies leading to increased efficiency, diversifying the range of banking services and products, and choosing the best distribution channels.

Product strategy - the first component of the marketing mix, and the most important is the underlying strategy and market is dependent on and linked to the strategy of price, distribution and promotion. Has all options in the institution relating to dimensions, structure and dynamics of the range of services\products. In shaping the product strategy and the evolution of institutions have in mind: internal factors: we refer to the expectations of shareholders and management, objectives and utility firm leadership, resources available, the potential human, material and financial institution, technologies; external factors: Dynamics and market structure, level and characteristics of competition, consumers demand expectations; the market positioning of the institution and the overall profile of it. Product strategies are developed over long periods of time and reflects the main directions of action, the institution's attitude toward those kinds of services\products offered on the market in order to achieve certain objectives. Once adopted, the product strategy is very much influenced by market segment used. Depending on the goals of the institution, it can through product strategy to address the overall market (what is called the undifferentiated strategy), i.e. to try to meet the needs of diversified categories of consumers. After choosing the target institutions segment, product strategy, you need to keep in mind:

- *size range of services\products offered on the market;*
- *strengthening the position of the product and within the current consumer segments;*
- *increase in consumer penetration of a particular product;*
- *quality of services\products;*
- *enhancing the spread on the market by attracting new customer segments;*
- *the degree of selling of the services\products*

- *permanent monitoring of the competition;*
- *differentiation of similar or closely related products of other manufacturers or distributors;*
- *best positioning within the range and increase the market share of the product.*

Product strategy influences much success and the image of the institutions, for which reason particular attention should be given to all the stages completed in shaping this strategy. Brand and positioning are major elements in the strategy of product, influencing the "lifetime" of the services\products launched on the market. These two elements are closely related, i.e. a strong mark without a positioning on the market, properly designed, can lead to success.

The conclusion that emerges from those shown is that product strategy is followed by the successful when: the institution he outlines a clear idea of the conception of a new product based on the needs and desires of consumers; stripes carefully; Choose the target categories of consumers; determines the desired marketing positioning on the market.

The next component of the marketing mix is the **price Strategy** – important factor of global marketing mix. Each institution (organization) sets the single price of services\products. Fixing of competitive prices for services\products banking institutions require the elaboration of a policy for price, that translates into pricing for all services\banking products and their modification in line with the market situation. (the price of services and financial products is represented by: interest, fees, premiums, different rates etc). In practice, price strategy is defined in connection with the product strategy and the quality of the offer. Thus, according to Ph. Kotler may identify more variants (Kotler, Ph, 2001):

- *maintaining price and perceived quality – the consequences are smaller market shares, and lower profitability, but helps to maintain loyal clients. In the long term this approach is not recommended due to the spectacular evolution of the market and competition;*
- *the rising price and perceived quality – beneficial over the long term; lower market share and profitability unchanged;*

- *the drastic reduction in price and maintaining quality perceived – is not recommended over the long term; However results in discouraging competition in price and increase sales volume;*

- *drastic reduction of price and decrease the perceived quality – the consequences are a smaller market share, keeping the profit margin, reducing the long-term profitability.*

The price is conditioned and consumer reaction to the level and form of the price. For efficiency, price strategy of banking institution must be appropriate consumer profile. Factors influencing the formation of prices of services\banking products are:

- **External factors**, here we mean: the price charged by banks competing for a service\product similar or identical; economic climate: economic growth, recession etc.; customer feedback: acceptance or rejection, satisfaction or dissatisfaction from consumers;

- **Internal Factors** are: financial factors: banks are considering covering expenses and getting profit; marketing mix: the influence of other elements of the marketing mix on the fixing prices; the institution's objectives: increase profit or acquiring a top positions (i.e., able to fix some lower prices to attract new customers) or defending the service\product to counteract the actions of competitors.

From these there are several possible strategies for pricing for banking services and products. Regardless of the strategy chosen by the Bank, the pricing policy must have as a starting point the client's ability to pay up to a certain level for the services\products you receive. New services\products launched on the market faced mostly with problems in attracting new customers. To avoid this unpleasant effect for the Bank, launching on the market of services\products with promotional pricing may be used as a method of stimulating test. The Bank must be perceived as a successful, offering safety and confidence in consumers using the services\banking products. Many of the reviews have in mind the price level of services/banking products before using them; that's why price policy constitutes a very important tool available to the institution.

In our opinion, the success of the price policy is conditioned by:

- *defining the strategy of the price that must be correlated with the other components of the marketing mix and to convey all the same message;*

- *the prices charged (should be accepted by your target customers);*

- *attention to constructing messages conveyed through price;*

- *flexibility and customising prices according to consumers.*

The Conclusion is that the price strategy is based on the definition of value as an expression of what awaits the current or potential customers of the Bank's products. Correct and complete formulation of the strategies of price is the result of the merge of all factors arising from the objectives and policy banking institution.

Distribution strategy - distribution is to determine ways in which consumers accessing banking services and products. Advanced technology and business development banks have led to rethinking the distribution systems used by banking institutions. Today, more and more banks put the emphasis on improving the relationship between the client and the Bank by introducing advanced technologies allowing access to bank services 24 hours a day, and the desire to reduce the time of serving the customer. To meet the increasingly complex customers, banks have established a joint venture distribution strategy. The responsibility of the personnel in charge of marketing, in a bank doesn't stop when they have been identified those services and products which meet the needs of consumers. Following the identification of the most effective channels of distribution of the Bank's bid to be accessible, where you want and at the right time. Establishment of distribution strategies in the context of globalization must take into account the characteristics of each segment of consumers. Distribution channels to deliver services and products to customers and communicate with the market. In the conditions of competition on the market, choosing the most effective distribution channels still raises issues banking institutions. The success of a quality management is found in the combination of distribution channels to ensure that costs generated by service or product development (promotion, delivery etc) and getting profit.

The income that you get Bank are generated by number of customers, market share, number of uses of the product or service person and marginal income on each product.

Distribution channels management has turned into a main task for the banking institution due to further globalization. Technology development has led to fundamental changes in the system of distribution of services and banking products through the creation of new distribution channels. Fierce competition for customers, the use of new distribution channels are essential for banks because they want to increase the quality of services rendered, increase market share, reduce costs, and last but not least maximizing profit.

Today banks are faced with numerous challenges in the globalized economy of the 21st century, mainly strong competition and the danger of diminishing market share, what requires: *trying to abandon reagent management style and adopt a proactive style that anticipates the changes and is innovative; desire and concern for the development of new services and products; positive attitude for seminars involving market studies; building of comprehensive databases and updated with current customers and potential customers; financial efforts to use new technologies.*

Promotion Strategy involves choosing an effective communication channel for sending and receiving messages between consumers and the banking institution. We mean not only the physical channel through which to communicate, but also how effective implementation in practice.

Promotional activity sets it apart from the following, on the basis of which criteria will be formulated the following specific strategic:

- *Depending on the objectives of global promotional activity, there are: the global strategy to promote the image of the institution; exclusive promotion of the product; image enlargement strategy of the institution.*

- *Depending on how you progress over time, we have: promotional activity and permanent strategy strategy promotional activity flashing.*

- *Depending on the role of promotional activity, distinguish: offensive strategies; defensive strategies.*

- Depending on the location of market structures, we have: concentrated strategy; differential strategy.

- Depending on promotional activity based: promotion strategy developed with forte's own or through specialized institutions.

Developing communication techniques lead to shaping a new model of communication which, out now in full affirmation is based on an increase and even acceleration: *interactive procedures, especially through the expansion of the Internet; to the individualization of practices, including in the case of forms of work organisation more socialized.*

Communication made between the Bank and its current or potential customers takes a variety of forms, many of them extremely original. Under stiff competition, effective communication has an essential role in the marketing strategy of the institution. To inform and advise clients in future options are essential aspects for the Bank, because it contributes to add value to products and services. By communicating with customers create arguments to persuade consumers to purchase products and not on the institution of the competition. Strategy to promote modern banks involve the use of media and consumer incentives so that the banking institution, product/service cause favorable changes in mentality and their consumption habits, also important is the establishment of a communication actual employees, shareholders, competitors. Strategies presented take into account the profile of consumers, their needs and wishes, but also the reactions of the competition. The use of consumer segmentation models lead to offering products and services to banking and to ensure that the needs of the consumers, not only by achieving the goals they have set them, but also by providing a psychological comfort when I use financial products and services. Strategic marketing decisions, to generate success on the market must be focused on the development, maintenance and communication of competitive advantage.

We believe that successful strategies are those with which market opportunities are determined, based on the results of the marketing control which put out the following elements: the risks, the favorable

situations, the strengths and weaknesses of the organization. Through their implementation in practice has to create a well defined system of links between the organization and external environment, so as to ensure placing them in a better position in dealing with the other competitors.

Conclusion

Getting performances in the financial-banking sector is conditioned by knowledge and understanding consumer behavior in the context of the competitive environment, technological, economic, political, demographic and socio-cultural. Marketing planning purpose consists in identifying and creating a competitive advantage. Marketing goals must be in accordance with the overall objectives of the Organization, which are defined for each product and for each target market. Thus, the objectives of marketing concerns only MARKET and PRODUCTS. Thus, at the functional level, marketing goals will keep track of what products are to be sold and in which markets. In the new economy, built and developed on the basis of information technologies and communications, in establishing marketing strategies the starting point must be the consumer and its needs. Through Bank marketing strategies, marketers follow so choosing the best combinations between the various distribution channels, but the share of each in the whole distribution system. This choice depends on several factors, among which: the market; financial culture; the financial possibilities of the reviews; the financial possibilities of the Bank; the benefits that can be obtained from the use of a particular distribution channel.

Abstract

Are of recent date the multiple attempts of reformation and modernization of the public administration. An important objective of the process of reformation oversees the implementation of the decentralization measures to make the public administration in general more efficient. The current article brings to the attention of the readers the pros but also the cons that the application of the principle of decentralization may bring.

As a basic rule in the organizing function of the local administrative system, the decentralization presents a series of advantages that we've highlighted in the content of our study.

However the decentralized administrative model brings with it a series limitations that must not be ignored.

Based on this study, we strongly think that implementing the decentralization measures can not be considered an good option or a less good option, but essential is the way in which this process is translated in the practical field, to limit the risks raise the winnings that such a administrative model offers.

Keywords: local public administration management, decentralization, local community, public authorities

J.E.L. Classification: H83

1. Introduction

In the current reforming context that aims the entire society, the public administration reform and modernization is put with more and more acuity in an attempt to optimize it

on the whole. From this direction, we believe that the decentralization of local public administration constitutes a reality of the present and future society, with important implications for economic and social plan. Decentralization is a long and continuous process which requires the creation of a stable and coherent framework for supplying and financing the local public services [4, p. 3]. Applied judiciously, it can contribute to a significant improvement of the efficiency concerning the resource allocation and of the public service quality provided to the local community. For this, however, local authorities must be able to take the new responsibilities and to meet them from the managerial, institutional, as well as the financial point of view.

The correct application of the decentralization principle in local public administration management ensures the growth of the administrative capacity at the local level, the improvement of local service delivery and the citizens' more active participation at the life of the communities they belong.

An important element in achieving democracy on the local level, decentralization is seen as a solution to improve the quality of public services delivered to local communities and that a centralized system couldn't provide.

Decentralization offers different advantages, as a model of administrative management, capable to bring many challenges and new trends, ensuring the approaching of the decision right from the center to local human communities. Decentralization represents a system of administrative organization which enables

human communities or public services to manage themselves, under state control, which confers legal personality, allows the establishment of their authority and endows them with necessary resources.

2. Conceptual determinations on decentralization – the basic principle in the organization and functioning of local public administration

The principles underlying the organization and functioning of public administration in administrative-territorial units are formulated specifically by the constitutional provisions as well as by the provisions of the Law regarding local public administration. Among these principles decentralization is part of them, as a fundamental rule without which the efficient functioning of local public administration wouldn't be possible.

The legislative background is filled in with the decentralization framework-Law no. 195/2006 which prescribes through art. 2 letter l) that decentralization is the transfer of administrative and financial powers from the central public administration level to local public administration level or to private sector.

By interpretation, we note that decentralization involves the transmission of tasks and skills from the center to the authorities of the territorial-administrative units, while passing on the local level the financial resources necessary to the accomplishment of these transferred skills. If the conferred responsibilities aren't accompanied by resources appropriate to their exercise, we can't speak of a real decentralization. In other words, the financial component is essential in implementing the decentralization process, the local authorities are the most entitled to decide on the allocation of local funds, as they know more closely the needs of the community whose interests they serve.

The transfer of responsibility refers to planning, decision making, (finance, taxation), legal responsibilities (issuance of regulations, legal decisions) and the management of public services for which the transfer [7, p. 33] is being made.

The relevant literature in this area [8, p. 3] recognizes three types of decentralization:

- political, providing local community and its representatives more power in decision making;

- administrative, concerning the redistribution of authority, responsibility and resources between different levels of governance, adequate capacity and institutional power are the conditions for the efficiency of the decentralized system.

- financial, involving responsibility for revenue growth, access to transfers and decision making on current spending and investment.

In the practice plan, the implementation of the decentralization principle is about to lead to a greater concern for the needs of the local public environment, while ensuring a match between the administrative decisions of local authorities and the requirements of the members of the community in whose name they are acting.

In the system of administrative decentralization, measures and decisions can be made more quickly by local authorities, as they no longer have to wait for approval from the center, and material and financial resources can be used more efficiently in response to priority needs, that local authorities know better than those from the center [1, p. 10].

On the whole, the implementation of the decentralization principle will provide the premises for a better functioning of local administration that, in this way, they will respond and correspond, through their entire activity, to the requirements of the local community members.

3. Advantages and risks of implementing the decentralization principle in local public administration

Seen through the benefits that it provides, decentralization takes the form of a powerful, autonomous and participative model of local administration, that has broad and real powers for local self administration and for supporting the process of local development.

We can say that the process of decentralization facilitates and stimulates local development. Decentralization provides the appropriate climate for local interests to settle on better terms, according to local conditions and in line with their real needs.

Local authorities have to be more efficient in allocating resources, to provide local community better and more appropriate information and to better understand better the local needs, to be more receptive to them than the central authorities.

The central authorities don't know the specificity of local problems as well and especially that these problems differ from one area to another and may be only partially reflected in the measures taken by central authorities. No one knows more closely and in detail the needs of the locality than local authority itself and also, no one could find and identify the most appropriate means for satisfying them. In this way, the local interests [3, pp. 10-11] can be satisfied in much better conditions. Decentralization facilitates the adaptation of the solutions for local problems to local conditions. Since each community is empowered to manage its own affairs, they will be able to adapt their programs or solutions to local problems that reflect the special or preferential conditions of those localities.

At the same time, at local level it can be realized a more strictly evidence of money, this thing representing a potential for generating local income. As funding the responsibilities is very important, financial decentralization was and is a major component of the decentralization process [4, p. 4].

Fiscal decentralization will reduce the current practice of extracting resources from the periphery and to concentrate them to the center. Thus more resources will be retained at local level and will help to stimulate the local economy and to support the local development initiatives. Only if a transfer of resources takes place, decentralization can produce economic and social benefits.

Another advantage is that decentralization determines a greater participation of the population in government, bringing government closer to people and thus it allows the citizens to be better informed, facilitating the accomplishment of a closer relationship between those governing and those governed [6, p. 343].

In a decentralized system it will be easier for communities to pursue their development objectives and to get support from local government through their participation as a real partner in the local administration

process. The residents' participation, through election, to the designation of local authorities emphasizes their spirit of responsibility and initiative, motivating them to find their own solutions for solving local problems. Thus, the elections constitute the criterion of decentralization which is based on the free exercise of citizens' rights and freedoms at local level [2, p. 183].

Decentralization can ensure judicious administration of localities, using nothing else but the strict, necessary number of officials for satisfying the local interests, while in the centralized regime the number of civil servants is much greater, and their working time is consumed for the preparation of the materials required by central authority and for the implementation of the orders they receive from this one, in the regime of administrative decentralization, civil servants remove, to a greater extent, the bureaucratic phenomena in local activity [3, pp. 10-11]. Citizens can influence the decisions regarding public services through mechanisms which make them capable to indicate the type, level, quality and quantity of services they want and the cost they are willing to offer for such services. Local public services can be managed more efficiently by local authorities, in a regime where they do not have the obligation to comply with orders and instructions from the center [6, p. 343]. Thus, another advantage of decentralization is to increase efficiency in establishing the nature of public services needed by community members.

Decentralization leads to a better division of labor in public affairs administration. Creating strong local governments, with the ability to effectively manage local businesses enables central government to focus on high level duties. Decentralization generates a sense of local freedom, the interest in the benefit of the locality, fact which determines a special development of human communities in the administrative-territorial units.

The listed benefits presents decentralization at a maximum potential, which unfortunately is very rarely encountered in practice. With all these mentioned advantages, it should be remarked the fact that decentralization has certain limits that reduce its efficiency.

From the perspective of the risks entailed, decentralization can't be considered a universal option. Reducing the force of the central power, the decentralized administration model gives priority to these local interests over the national interests [3, p. 11].

Decentralization creates the potential for the existence of a conflict between local and national interests, but this thing may serve to identify local problems and to take them into consideration. But if they are not treated properly, they could become a destabilizing factor.

The interregional inequalities may increase and thus the level of poverty is increasing in some localities, because regions are endowed differently in what concerns the natural resources, the level of economic activities, etc., in some areas there will be more revenues than in others and this will allow their citizens better services than those offered in poorer areas.

The transfer of tasks to local authority isn't often doubled by a fiscal decentralization also, and the local management systems often have insufficient resources, unlike the central governments which continue to retain much of local funds. For a local government to accomplish effectively the decentralized tasks it should have an appropriate level of revenues locally collected or transferred from central government, as well as the authority to decide on spending.

Corruption is a phenomenon frequently met in the local elite, people elected in local positions by allocating resources in order to benefit themselves and their relatives. Abuses in terms of decentralization are aimed at the overbid of local peculiarities, which may extend to endangering national unity.

According to the opinion of the Professor Tarangul, quoted by M. Preda, the choice of decentralized authorities introduces, in local administration, the party politics that engulfs and vitiates everything. The lack of competence and responsibility, the demagoguery, the servility are some of the biggest drawbacks of this mode of recruitment of the decentralized authorities [6, p. 344]. However there is the danger of monopolization of resources by local elites. There is the risk that local elites to use the local resources in their interest. Local

authorities may adopt solutions influenced by the policy of some pressure groups, whose interests are in contradiction with the national ones.

A decentralization in the true sense of the word requires a strong support from the part of the central governmental institutions. This would mean the development of the legislation in order to provide the local governmental units the ability to act autonomously and independently, and also the ensuring of the revenues necessary to an adequate management of local services [5, p. 17].

We don't have to ignore the problems surrounding decentralization, their solving entailing much more responsibility from the part of local authorities and the communities they represent, as well as from the part of central management which will have to find a solution for that money raised locally is allocated at local level, too. At the same time, in the decentralization regime, local authority may find a solution and operatively satisfy the local requirements, unlike the centralized regime, where central authority is acting from the distance, delaying the problem solving.

4. Conclusions

With the support of the above mentioned, we can conclude that decentralization constitutes a solution of improving public administration with important implications in the economic and social plan. A correct transposition of it in the practice plan is likely to contribute to a significant improvement of the quality of the services available to the community, as a whole, and to each of its members individually.

We believe that the success of the decentralization process depends on the capacity of local authorities to assume the new transferred responsibilities and to cope with them from the managerial, institutional and financial point of view. In addition, the existence of a strong center concerning the reconfiguration of the relationships between the central and the local level of administration depends on the success of the decentralization.

As we presented in the content of this work, the benefits of decentralization are not few in number, but this model of

administrative management will always have a series of possible risks. If the measures aren't adapted to local conditions they may prove inefficient, and the community members won't feel any improvement.

We have the right at this point to emphasize the fact that decentralization isn't a universal solution, but it has its limits, reason for which the authorities at the center and those at the local level should make considerable efforts in order to reduce or even to eliminate them with the aim to improve the administrative work and to satisfy at the highest rates the community needs.

Services Economy in the Context of Globalization

Boiță Marius
“Vasile Goldis” Western University of Arad
Faculty of Economics
b_marius19@yahoo.ro

Abstract

Development of services in the current context of globalization, through efficient allocation of resources, will provide a higher volume of services with increasingly less resources.

Free movement of services requires a general abolition of restrictions, non-discrimination on grounds of nationality or residence and their liberalization by all countries.

Keywords: services, economy, globalization, circulation, regionalization

J.E.L Classification.: L80, L90

1. Introduction

Free movement of services requires a general abolition of restrictions, non-discrimination on grounds of nationality or residence and their liberalization by all countries. The share of traded services across borders, in the last decades, was reduced in the whole trade and regional harmonization was seen by most economists as extremely difficult because of the national peculiarities of regulatory and supervisory regimes.

2. Globalization

Similar to major historical transformations that open new paths to the future globalization is accompanied by disturbing changes in all forms of existence of human society.

Two major features accompany debates everywhere on globalization: on the one hand, their vast load of anxiety and dilemmas about the fate of countries and their national sovereignty, especially of the smaller and economically weak ones and on the other hand, is the assessments paradox - some only

laudatory, others only negative - that make globalization when a panacea when a general danger.

There are at least four reasons justifying the historical importance of globalization (Belli, N., 2001) [1]:

First globalization causes a real assault on the nation-state. This attack starts from the assumption that the national sovereignty and state borders are concepts outdated by history and, as such, must be removed.

Second, globalization requires the creation of a new economic and political world order. Coming on the wave of the information revolution and reflecting the new global power relations, globalization involves restructuring the entire system of relations between the countries of the world, according to new historical conditions.

Third, globalization commits in its course, all countries, regardless of size, scale and profile of their economic and political development: it is therefore a universal problem.

Fourthly, globalization, envisioning a new historical reality brings into the socio-economic and of the historical experience field a new value system.

Different from the one created by industrial development of human society, this new system of values calls into question not only the concept of nation-state, national sovereignty and national borders, but also many other concepts that made the era in the economic theory.

It is obvious that the new realities created by globalization through joining national markets into common or sole markets without national borders, cannot be explained by the old notional instruments of knowledge of the economic theory and policy. It requires restructuring of these instruments through reconsideration of concepts and notions, or also creating new one, therefore asking for a

new social economic thinking of the development.

In contrast, globalization is global, i.e. a situation in which markets transcend national boundaries. Trying to conceptualize the global economy, the authors conclude that it involves two approaches: one radical and the other more nuanced, namely:

The radical definition of globalization takes into account a global economy "in which the markets transcend national borders in such a way that individual nation-states lose much of their economic and even cultural significance". It is clear that this vision is of a radical nature: it assumes that the most important economic decisions are now taken not by sovereign governments or by their agents, but by transnational corporations, monetary speculators, those who operate on the non-governmental markets of the finance capital.

Nuanced definition of globalization suggests that while the markets growingly become global and therefore threatening national sovereignty, it is still possible for the states, through recognizing their growing interdependence, to work collectively to solve economic problems.

Another problem that still bears controversies is the clarification of the two concepts, namely globalization and mondialization. Some authors consider that the two words are synonymous, but from different backgrounds, so the concept of globalization has a francophone linguistic origin, while the concept of mondialization has an Anglophone linguistic origin. Economic globalization means closely connecting the national and regional economies in order to achieve a world economy governed by rules established by international and bilateral- or multilateral agreements between companies, countries or regions.

Globalization complexity results from its adjacent reasons of political, economic and socio-cultural nature. Usually globalization is associated with its implications.

It is not seen as an irreversible process, but rather in its dynamic perspective.

One of the most commonly used definitions of the concept of globalization is the following one: "Globalization is the process by which geographic distance becomes a less and less important factor in the establishment and development of cross-

border economic, political and socio-cultural relations. Global networks of relationships and dependencies acquire a growing potential to become international and global. "(Bari, I., 2001)[2].

Importance of transnational corporations is a key element of the globalization of the world economy. However, views on the importance of globalization of corporate work for national and international economic affairs differ greatly. According to some analysts companies believe that today multinational corporations have freed themselves from the national economy and became a powerful and independent force, decisive both for international economic affairs, as well as for the political ones. Other analysts reject this claim and believe that transnational corporations remain a part of the national economy.

The role of multinationals increased significantly with the integration and organization of the global economy. However, it is important to appreciate that most economic activities are still mostly based on nationality. Often, the idea that multinationals are intended to govern the global economy may prove to be incorrect. Global politics and economy are based and must continue to be based on a safe social and political foundation and there is no guarantee that these foundations will survive for years to come.

The size of multinationals, their power on the market and tracking their global strategies have raised concerns for many groups of countries of not to be subjugated and exploited by the globalization of production and services of multinational companies. These concerns are not without foundation, because transnational companies are indeed a concentration of economic power and frequently political one.

Transnational corporations are a pioneer in the process of globalization which, in fact, is the expansion of free market capitalism.

3. Global economic integration

The relationships existing between the global economic system and national economic entities reveals one of the trends of the global economy: global economic integration. It is observed thus a complex process based on an increased international

economic interdependence due to the complexity of the distribution channels of consumer goods, investment, goods, and commercial services. In other words, the prosperity of a country is closely linked to global development, because of the existing relations between trade policies of various partners.

4. Globalization of the services market

Intensification of the harmonization and mutual recognition process led to the progress of the free movement of services. It is obvious that in the services area, which became majority in Gross Domestic Product (GDP) of developed countries over the past three decades, however it had a slower progress on the line of cross-border free movement compared to the free movement of goods, though it was positively influenced by it. Integration of the services market depended quite strongly on several factors, including the free movement of goods, free movement of some productions factors such as capitals and labor, and harmonization of policies, extremely difficult to accomplish, especially on the main components of the labor force. Because the service sector has expanded and diversified continuously, both the commercial one and the one of the social/public, in this process having an increasing role the storage, processing and transmission of information, and their share in the GDP and international trade has increased appreciably, the issue of liberalization and integration of national markets services was more insistent stressed. To what it concerns the globalization of the circulation of services, some conclusions are formed from the experience of the European Union (EU), which highlights both the necessity and advantages offered and also the difficulties encountered in its implementation.

4.1. Financial Services

Financial and banking services, of insurance and investment raises the question of their proper establishment and operation regime, but the creation of a single market involves harmonization and centralization in some financial areas, which has implications in terms of economic, fiscal and monetary

policy. In our view a wide unique global financial assumes: the single market in financial services, free movement of money and financial capital, a common currency, tax and accounting harmonization. Financial services have developed on a regional scale as cross-border movement of capital has grown, in the postwar period, which is a dominant feature of globalization of the world economy. Free movement of goods, whether goods or services, can't be fully achieved without free movement of financial capital, which is undoubtedly one of the factors that determine comparative and competitive advantages of products.

In what it concerns the transnationalization, the financial-banking sector has lagged behind the industrial one because, at an international level, the free movement of goods was easier than the free movement of services, the first being strongly promoted by the international trading system. If in the industrial sector, where mega-mergers mirrored some deepening of specialization in production at the expense of too severe diversification that caused difficulties in the line of production and research, in the banking sector strategic alliances and cooperation agreements were a good way to get to new markets or to provide cross-border services. In what it concerns the insurance area, here the liberalization has progressed steadily, reaching full size in the reinsurance area. A single insurance market requires a unique authorization and financial supervision of insurance companies by the Member State of origin. This licensing system allows insurance companies to operate in any country under the regulations on establishment or under the freedom to provide services, but complying with the conditions governing the insurance business in that country.

4.2. Transport services

Applying a common global policy to road, rail, river, sea and air transport requires a program for the creation of a free market in transport services through their progressive liberalization and the elimination of competition distortions. The major problem in the integrating sphere of transport is the modernize and compatibility of the transport infrastructure that assumes: improving

transport by corridors, reducing transport costs in the transit countries, integration of peripheral regions in community networks, special links between major cities (A. Cociuban, 2003) [3].

4.3. Telecommunications services

In the telecommunications area, the infrastructure was increasingly open to competition in the 90's. Information technology revolution has created the conditions for the construction of the information society and of a huge information market dominated by electronic commerce.

4.4. Audiovisual services

In the audiovisual services area, the focus is on their free movement and promoting their production. The public broadcasting service must be organized. An example at the European level would be the MEDIA programs where the European industry of film and television programs is supported, because in the General Agreement on Trade in Services (GATS) has been expressed the strong position to conserve European cultural and linguistic diversity and to exercise full freedom of action in the audiovisual sector.

4.5. Advertising services

In the advertising area, in recent years has been seen an obvious trend towards standardization of advertising campaigns to promote products and services, as well as targeting a particular activity or service.

The proliferation of television programs has encouraged advertising activity, but it was also a handicap for the development of the pan-European advertising type, due to excessive fragmentation of mass-media.

With the popularization of the internet network, online advertising is growing like never before.

4.6. Public utilities

In the public utilities area liberalization was expanded particularly in the early '90s, especially in the gas and electricity market liberalization. In this area we believe that is necessary a greater price transparency and

facilitating transit through distribution networks, as well as gradual abolition of the monopoly over the production and distribution of gas and electricity.

5. Conclusions

Development of services in the current context of globalization, through efficient allocation of resources, will provide a higher volume of services with increasingly less resources. By developing and implementing effective strategies, global and mondial development of services will evolve and will experience significant growth.

Globalization of services is a step that will not have barriers and restrictions for the pursuit of the activity of all countries of the world, regardless of their location worldwide.

A Theoretical Approach on Entrepreneurship in Knowledge-based Society

Boldureanu Daniel

University of Medicine and Pharmacy „Grigore T. Popa” , Iasi

boldureanu@yahoo.com

Boldureanu Gabriela

University „Petre Andrei” from Iasi

gabrivaleanu@yahoo.com

Abstract

Entrepreneurship is a process that requires innovative and flexible educated personalities with a vision oriented towards quality, individual responsibility, rewards, and realistic system of alliances with a turbulent environment.

The phrase knowledge-based society call in question the aims and content of higher education, which graduates gain the knowledge, skills and competencies that help you face new challenges related to research, innovation and exploitation of knowledge, especially in the context of the European Union by the Lisbon Declaration (2000) and Barcelona (2002) aims to become the most competitive area with economy based on knowledge.

Keywords: entrepreneur, entrepreneurial education, knowledge-based society

J.E.L. Classification: L26

1. Introduction

In the present period we can speak of a new economy in which the fundamental change is the transition from economy to economy, entrepreneurial management. In this context, entrepreneurship is a fundamental component of the knowledge-based society because the potential value of new research ideas and results of knowledge can best be harnessed by SMEs (Andretsch, 2002).

Great thinkers of the classical R. Cantillon, J.B. Say thought is the main figure of the entrepreneur economics and economist J. Schumpeter (1883) stated: "there is an understanding in the entrepreneurship that we do in connection with a particular type of

behavior and cognition, including: organizing initiatives and reorganization of socio-economic mechanisms, acceptance of risk and failure."

In the literature, there is no consensus regarding the definition of entrepreneur, this varying depending on the theoretical approach. So its historical evolution (Marian, 2007) a contractor is:

- Beaudou (1797): the person who bears the risk, which plans, organizes, supervises and controls business;
- Jean-Baptiste Say (1803): profits entrepreneurs separated from capital gains;
- Joseph Schumpeter (1934): the entrepreneur is an innovator and develops new technology;
- David McClelland (1961): the seller assumes risk, is energetic and moderate;
- Peter Drucker (1964): contractor maximizes opportunities;
- Alberts Shapero (1975): take the lead contractor, organizes socio-economic mechanisms and accepts the risks of failure;
- Karl Vesper (1980): contractor saw different economists, psychologists, businessmen and politicians;
- Gifford Pinchot (1983): the manager is an entrepreneur in an organization has already received;
- Robert Hisrich (1985): entrepreneurship is a process of creating something different, adapted to the change.

We can conclude (Boldureanu, 2012) that the developer so any person who initiates and carries out a set of activities involving risk and innovation with the aim of obtaining material and personal gratification.

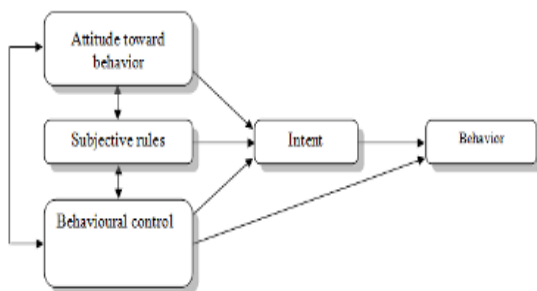

2. Models of entrepreneurial of intent

The main model in use today is the development of two basic models (Pintea 2007). The first is the one built by Ajzen (1991) and that is a general model of human behaviour prediction through specific intentions toward those behaviors. The second Shapero's belongs to and has been produced specifically for entrepreneurial intentions prediction, being in good measure similar to the first.

a) Model of planned behavior (Ajzen)

Ajzen's theory has inspired numerous researches on entrepreneurial behaviour. Planned behavior theory identifies three factors that precede the intent to perform a specific behavior: attitude toward the behavior, subjective norms (including social norms and pressures) and perceived behavioural control, as shown in figure below:

Figure 1 Ajzen's model

Although Ajzen has not designed the model to explain entrepreneurial intentions, a series of subsequent studies have applied this model in research of entrepreneurship, in particular for predicting behavior showed through entrepreneurial intentions.

b). Perceived feasibility model (Shapero)

Unlike Ajzen's model, the model developed by Albert Shapero is one entrepreneurial intentions explicitly dedicated to prediction. He is in many ways similar to the one launched by Ajzen, but presents several specific elements and.

Thus, Shapero's model is a model of adjustment to the issue of entrepreneurship but Ajzen a refining it. In this idea are worthy to note the two variables in the model

introduced by Shapero: precipitator and natural event available to action (Pintea, 2007).

Thus, for entrepreneurial intentions Shapero (1982) are determined by three factors: perceived desirability and feasibility of certain behaviour, as well as its propensity to act on the basis of the opportunities.

Figure 2 Shapero's model

The models presented here have in common the following elements:

1. a previous entrepreneurial event sequence
2. include elements of social learning theory, mainly variations of the concept of auto-efficacy,
3. contain the cognitive dimension (ways in which information, interpretation) as the central element of the model, so go on size rather than on attitudinal traits of personality.

Accordingly, the decision to start a business is a rationalized or planned behavior and intent to this conduct is a good predictor of behaviour showed itself (Ajzen, 1991; Krueger et al., 2000). For example, Krueger (2000) believes that entrepreneurship is a planned international behavior, arguing that starting a business always involves a project, even if the moment of actual new business (Organization) is relatively unplanned, and may appear on an unexpected opportunity.

3. Towards an entrepreneurial education

A number of researchers and experts in the field of entrepreneurship (Fayolle, 2003; Watson, 1998; Timmons, 1999) through numerous studies have shown that the creation of new businesses is a key element in the process of development and economic revitalization. The newly created firms generate jobs and contribute to the development and implementation of innovations with a positive impact on economic growth in general.

In terms of the factors giving rise to the phenomenon of entrepreneurship, research or define in detail globality in a number of aspects: while Timmons (1994) insist on psychological factors which justify the first appeals of entrepreneurial motivation, Shapero (1982), analyzes the contextual factors of the primordial that the new deal should benefit, Fayolle (2003) insist on economic factors, technological, financial and secret, Watson (1998) outlines the major role that education and a study on final results but all reveal that besides the major interest of the person to develop a more relevant knowledge is required in the field of innovation and entrepreneurial education.

In the knowledge-based society, it reconfigures the objectives and content of higher education graduates, the way you gain knowledge, skills and competencies that help you face new challenges related to research, innovation and exploitation of knowledge, especially in the context of the European Union by the Lisbon Declaration (2000) and Barcelona (2002) aims to become the most competitive area with economy based on knowledge.

About the leading role of education entrepreneurial University attention a number of specialized research, work (Veciana, 2005; Sany Lee, 2005; Franke, 2004) stating that the development of SMEs, which requires specialized knowledge and technical frameworks in the field of business, cannot be made without a solid business education to students and graduates.

From statistical files of the European Commission (European Innovation Scoreboard, 2009) has shown that the European companies there is a reduced capacity for innovative ability of main competitors to customers in the United State and Asia. For this reason it is necessary to analyse how students perceive the phenomenon as potential entrepreneurs, innovative, trying to pinpoint where they accuse of entrepreneurial education gaps and offers educational or training programmes, stimulate new ideas that lead to the creation of enterprises.

In this respect, a number of research carried out in Europe (Sánchez-Escobedo, 2011; Pagliacci, 2006) were focused on highlighting the effects of education on the theme of modernizing and entrepreneurial

skills of young people by higher education, trying to carry out a regular evaluation of the differentiation between the educational process or courses taught and practical effects of specific programs on entrepreneurial education inclination by the students.

4. Conclusions

In the knowledge-based society is reconfigures the objectives and content of higher education graduates, the way you gain knowledge, skills and competencies that help you face new challenges related to research, innovation and exploitation of knowledge, especially in the context of the European Union by the Lisbon Declaration (2000) and Barcelona (2002) aims to become the most competitive area with economy based on knowledge.

Thus, the main challenge to the institutions of higher education is to develop entrepreneurial capacity, because young people by creating new businesses are given vocational integration opportunities for students and graduates, representing a major challenge at the professional level, and the development of young people and the creation of new enterprises.

Analysis of Private Health Units through Management Functions

Boldureanu Daniel

University of Medicine and Pharmacy „Grigore T. Popa” , Iasi

boldureanu@yahoo.com

Boldureanu Gabriela

University „Petre Andrei” from Iasi

gabrivaleanu@yahoo.com

Abstract

Along with the health system reform it has been developed the private health institutions. The article explores the private health institutions through management functions.

The case study was conducted at the “Arcadia” Hospital in Iasi, the largest private medical institution in the Northeast region.

In the paper are analyzed the management functions: planning, organization, coordinating, control and evaluation at the “Arcadia” Hospital, focusing on the Swot analysis.

Keywords: management functions, health units, swot analysis.

J.E.L. Classification: M1, I12.

1. Introduction

In an organization's performance is done through functions of management: planning, organization, coordination, training, monitoring and evaluation [1]. The common characteristics of management functions are [2]:

- specific activities only managers;
- shall be exercised in all organizations, regardless of their size and profile;
- different functions as a form of expression and content;
- functions have a different weight in the organization;
- the functions differ from one compartment to another.

2. The case study presentation

The case study was conducted in the

private hospital "Arcadia" Hospital Iasi in September-October 2012 and was aimed at evaluating management functions within the institution, as well as the development of solutions and recommendations in order to improve and optimise the management activity.

The private hospital "Arcadia" Hospital is a medical centre complex, offering integrated health services-consultation, investigation, diagnosis, treatment in over 35 medical and surgical specialities [3]. The main activity of the company is "hospital service activities" according to CAEN classification.

3. The planning function at "Arcadia Hospital"

The **missions** promoted by “Arcadia Hospital” are as follows:

- Innovation: meeting the needs of patients;
- Quality: fulfilling the promise of bringing private medical apparatus market of the highest quality;
- Safety: ensuring the high level of standards for patients;
- Respect for people, the community;
- Open: to dialogue and to hearing the needs of patients.

The **values** promoted by the “Arcadia Hospital” are as follows:

- Performance: both technical and vocational training;
- Tie: the same attention and care to each patient;
- Privacy: keeping strictly to medical information and data that they provide the patient at the time of the call to hospital services;
- Bioethics: the medical staff shall comply with the code of professional ethics;

- Commitment: to craft and science, as well as to the patients;
- Integrity: in any situation, even outside working hours, the medical staff has the responsibility to maintain personal integrity to conduct as their image is not affected, and especially to affect the image of the hospital at which they work.

The institution itself through staff and politics adopted complies with the core values of bioethics and organizational cultures, values which allow patients to obtain public/service, secure unconditional and none of the risk factors (e.g., disclosure of a diagnosis, of the identity or Catatonic data individually and confidentially).

Otherwise the values/rules lay down by the Arcadia Hospital, medical staff comply with the moral code of conduct, which does not allow yellow and the image of the institution, in the spirit of protecting hospital and guarantee the best services offered by an honest and personal integrity.

None of the doctors did not suffer any serious misconduct or are not charged in any part of the process of corruption or malpractice.

4. The organization function at "Arcadia Hospital"

A. Marketing Department

The Marketing department deals with strategic planning that aims at promoting the hospital and the services it offers, market research, setting prices for products/services they offer. It handles the communication between the departments and the institution, internal communication between employees and external.

B. Human Resources Department

The Human Resources department is in close liaison with the marketing staff is selected in accordance with the strategy proposed by the director of marketing.

C. Medical Department

Medical department includes staffs that deal with the performance of the main function of the hospital, the medical emergencies, receiving treatment of patients, setting schedules and other medical needs. It includes: teachers, doctors, practitioners,

doctors, nurses are the primary crews for emergency service.

D. Financial Accounting Department

Financial accounting department shall develop and implement economic policies in line with the objectives of the organization, manages the accounting documents, report the results of the financial institution.

E. Administrative and Technical Department

Administrative and technical department deals with the functioning of hospital equipment, updating the site, the creation of programs or databases, the coordination, organization and operation of the department. It includes: computer scientists, site administrator, engineers, administrators and apparatus responsible.

5. The coordinating function at "Arcadia Hospital"

The current structure of the “Arcadia” Hospital includes:

- a multidisciplinary hospital (Arcadia Hospital);
- a polyclinic (Arcadia Polyclinic);
- an investigation unit (Arcadia medical imaging Centre);
- a mobile medical services
- an interventional cardiology (Cardiovascular Arcadia).

The “Arcadia” Hospital in numbers means:

- a total capacity of 220 beds;
- 4 operating rooms-one with additional facilities for Paediatric Surgery;
- 4 intensive care units (General, Coronaries, Neonatology, Paediatrics);
- 1 laboratory and interventional cardiology;
- 2 rooms of natural childbirth;
- more than 80 reserve standard and VIP.

Currently Arcadia Hospital has been ranked by the Ministry of health, depending on the facilities and medical services they offer patients in level 4, that is, the level of competence in which are included the units serving the administrative-territorial unit and is limited to diseases with low degree of complexity.

The hospital has six majors' clinics: Maternity and Neonatology, Paediatrics Surgery, General Surgery, Gynaecology, Gynaecological Surgery/Orthopaedics and Traumatology, Cardiology and Interventional. Holding facilities the performance data for the convenience of patients and visitors.

The “Arcadia” Hospital was certified according to the quality standard SR EN ISO 9001: 2008 by consulting firm and international certification TUV Austria.

The SR standard E NISO 9001: 2008 is an international standard governing the organization and management of the activities of a company, applicable to companies that provide services and medical services which are carried out in accordance with the customer requirements and regulatory requirements (laws, national and international standards).

The “Arcadia” Hospital was certified for:

- services of general and specialized medical assistance (this certification is valid until the date of 12.05.2013);
- for the management system applicable to the work of the hospital established in accordance with the EN ISO 9001: 2008 (this certification is valid until 12.05.2013).

6. The control and evaluation function at "Arcadia Hospital"

The control and evaluation of the sanitary unit studied was conducted through Swot Analysis [4].

Strengths:

- the largest private medical investment Romania during the crisis (12.5 million euros, with more than 250 employees);
- the first private multidisciplinary hospital in the Northeast region;
- gathered specialists from national and international scale, a very well bred and very well prepared;
- have technical features and performance equipment;
- special conditions for the comfort of patients and companions: a full service personalized medical care, hospital-based, full-service food for patient care products and accessories and personal

hygiene for the patient, medical accommodations in standard or VIP;

- offers patients effective prevention, early diagnosis and treatment, health education and information continues;
- contract with the National Health Insurance House ensures that cost-cutting procedures, but also the ability to attract patients from all over the country, the population served from a large territorial area
- availability management team and the entire staff for the change;
- pleasant, warm, highly trained staff, with emphasis on both the physical wellbeing, and the good psychic
- potential major Community (can become an emblem for the city, for the region).

Weaknesses:

- services of general and specialized medical assistance (this certification is valid until the date of 12.05.2013);
- the lack of a means of transport directly to the hospital;
- unfavourable geographical location, which limits the access by car in the Hospital just one Street, which bypasses the hospital;
- relatively high costs: accommodation, administrative, maintenance, surgery of the hospital, etc.;
- insufficient funds offered by the House Health Insurance House (HIH);
- lack of Emergency Unit (EU);
- inpatient are usually flat on Friday, the weekend is working only if they are patients with outstanding issues, with a serious situation, come in, or complications;
- the period from the opening of the hospital makes people not yet familiar with the existence of the hospital or have reservations about the competence of the staff;
- small number of beds for internment requires the establishment of a schedule before coming to the Hospital (except for emergencies).

Opportunities

- expansion of the hospital: currently is working on the establishment of the two Clinics at Arcadia, which is a part of

- Arcadia Imaging Clinic Medical Centre
- has an ambulance in which patients can call at any time;
- the existence of stem sure system through which it can conserve the stem cells;
- the location of advertising panels, promotions, sampling, both within the city of Iasi (Iulius Mall, Palas Mall), and other surrounding counties (Neamt, Suceava, Botosani, Vaslui), which can attract patients from different areas of the country;
- installation of traffic signs throughout the city to facilitate the access to the “Arcadia” Hospital;
- the development of a human resources policy, based on attracting both young staff with higher education, as well as more experienced staff, allowing a selection based on competency.

Threats:

- the establishment of private hospitals and the like;
- competition with other private hospitals and clinics;
- the possibility of losing/to reduce the contract with HIH Iasi;
- reduce customer by maintaining high prices and offers and to bring potential customers to share their own experience through;
- lack of mutual promotion win contracts end win (for service) or services that may benefit patients (e.g., to order a taxi, patients must turn to the reception without a phone made available direct);
- getting a lower level within the classification of hospitals approved by the Ministry of health, which will have the effect of lowering the funds received from CNAS. Therefore, the patient will have to pay more for investigation;
- trust in a new drive on the market (which still does not know too much information) compared to State hospitals which have already recognized with the passage of time;
- information insufficient patients linked to still offer medical services;
- the economic crisis and job cuts in the last period, the unfavourable economic situation negatively influences the addressability hospital.

7. Conclusions

Analysis of the hospital management Arcadia highlights an industry which is growing, requiring the hospital to focus on strengthening its market position through the development of strategic objectives, such as: opening of new specializations that will significantly broaden its sphere of attendance; increasing labour productivity; continuation of the contract with national

House of health insurance that will ensure lower costs and procedures will increase the population to be served; completion of the work to the highest standards which will make “Arcadia” Hospital to gain fame in a relatively short time.

Although it is the first on the market, and the patients are not ordinary with his name, as well as with the private hospital, private hospital can earn through: professionalism, modern equipment, speed of the investigation, the quality of the medical act and by the attention given to patients by all staff.

New Types of Romanian Energetic Small and Medium Enterprises Under Crisis

Boteanu Carmen-Mihaela
Valahia University from Tirgoviste
carmenboteanu@yahoo.com

Abstract

Century-network, emerging company, virtual enterprise is key words in the recent debates on SMEs. In this context, this paper wants to present some relevant aspects regarding the Romanian energetic SMEs forming networks which can improve the efficiency and effectiveness absolutely necessary to win the globalization battle.

Keywords: fair value, convergence, market
J.E.L. classification: H12, J54

1. Introduction

In the field of energetic SMEs, specific to the end of the second millennium and the beginning of the third millennium, is the shaping of a new type of energetic SME focused on knowledge. Its main features are: the predominance of intangible assets, the incorporation of activities involving a high density of knowledge, using a strong specialized workforce, intensive development of research and development of highly innovative products and services, using cutting edge technology, offering products and services likely to be exported, the short life of products and services [9].

Business network or networking consists of a set of firms legally independent, which develop between multiple, complex and permanent human, informational, commercial, technical, and financial, etc. relationships, which enable them to achieve and commercialize jointly market products and services on a superior price / quality ratio, based on more efficient capitalization of knowledge and resources available to component organizations.

Connected through a complex and dynamic system of formal and informal relationships, the members of the network

appear as a single entity during their performance. Each component of the network focuses on those segments of the value chain to promote its maximum contribution to it. The network is based on cost-effectiveness, without constraints on size, geographical location or technology used by its members.

Acting without a common legal framework, directives or instructions, the network members assume roles successively in order to achieve network's goals. Each member, with specific objectives and different end therefore, contribute to its expertise and resources at the time and manner agreed within the network. Organizational culture and individual reciprocity, trust and loyalty between members are absolutely necessary conditions for the survival of the network.

Contour of network is often difficult to determine, its structure and functioning having their developments. Areas that comprise the network continuously transform both the form and the area, while being able to expand by attracting new members (which can add value through their skills), or compress when these skills are useless. Also, some areas can swallow the others, when such adjustments are imperative.

2. New types of Romanian energetic SMEs in the current economical context

Successful companies increasingly manifest themselves as true open systems, whose position in the market depends not only on their internal resources, but also their relations with configuration and external entities with complementary skills. External network of the company is basically an extension of the internal borders between the two types of networks becoming increasingly difficult to identify.

External networks of companies, based mainly on cooperation, may develop

spontaneously with operators working in the same territory, usually in close proximity and belonging to industry, or suppliers, specialized service providers, distributors etc. to rationalize the various phases of production and distribution of goods. Integration into external networks such synergistic effects materialized in generating competitive advantages for its members.

Competition is increasingly manifesting, not in terms of quantity and quality of resources owned or higher powers, but in the plan of the ability to quickly and efficiently find partners who have complementary skills and resources. Increasing consumption of specialized services (marketing, applied research, specialized sales, financial services associated with management services etc.) constitute an added value difficult to copy [6].

The basis is the principle stakeholder networking, networking incorporating all or part of stakeholders considerable specialized or focused on specific products and / or services, and operations on the same market and / or in the same area. Characteristic network knowledge economy is the incorporation of innovative companies.

Without claiming a comprehensive approach, in Table 1 it is provided a summary of the main forms of networking, indicating some of its most dominant features.

Table 1. The main forms of entrepreneurial networking

No. crt.	Forms	Predominant size	
		Formal	Informal
1.	Relations with co-owners at the same firm entrepreneurs		x
2.	Relations with customers	x	x
3.	Relations with suppliers	x	x
4.	Relations with the bank	x	x
5.	Relations with their business managers		x
6.	Relations with employees own company	x	x
7.	Family relations		x
8.	Relations with local government	x	
9.	Relations with competitors		x
10.	Relationships with consulting firms	x	x
11.	Relationships with training companies	x	x
12.	Relations with SMEs and other business organizations		x
13.	Relations with chambers of commerce		x
14.	Social relationships with the local community		x

Examining the items listed in the table we see the complexity of most forms of

networking, for the purposes of combining strong formal elements with the informal. Specific relationship is informal networking them on human contact, which has a major role in their implementation. It is noted that informal elements tend to be more intense than the formal.

Network-like structure can take many forms. Strategic alliances, for example, are an association between two or more companies to obtain a more collective performance by coordinating the resources and means necessary.

Strategic alliance can be a goal of reducing transaction costs, strengthening the strategic position of firms on their markets, or the transfer of know-how trading among allies [1]. Partnership is another viable form of association for energetic SMEs, which includes interest, by exploiting common resources and skills complementary results. Network members' contributions can take, if necessary, form: material contributions (commercial, land, capital, etc.) and / or intangible (expertise in a field - managerial, commercial, organizational, etc., Licenses, etc.).

Among the many advantages of networking small and medium obtained that have emerged recently noted: enhancing access to markets and resources, providing superior full product, including the service required, reducing unit costs of production, reduction of the manufacturing and marketing and risk reduction for each participating company.

According to literature [2] a cluster is a network of companies using all forms of sharing knowledge. So, the very decisive factor in defining clusters is knowledge, while considered as key resources and product group of companies involved.

Cluster is a mechanism which intercorelates companies at high level components, causing them to act as an integrated, cumulating to a higher plane the advantages of diversity and addition of the network, and the intense interpenetration of the activities involved, largely similar with the larger organization. Proper functioning of the cluster depends on a key element around which decisions and actions of its components. This key can be a company or brand name of a product. The whole process of knowledge generation and treatment is

modeled and exploited in this light.

With regard to cluster development, notes that this type of organization is in the forefront of trends and academic schools of thought, current efforts to Alfred Marshall and growing. Before 1990 few researchers applied mathematical modeling for the formal economic geography issues. Models show that the formation of geographical clusters for energetic SMEs occurs when income growth is very large scale, companies have the ability to set prices, transport costs are low, customers and suppliers are geographically mobile.

Clusters offer energetic SMEs stable relations between producers and users vertical chain between producers and suppliers or distributors, which reduces the flow of information costs, risk of introducing new products or services and time to transfer knowledge from research institutions to companies that can turn into marketable products. Also, horizontal relations of cooperation between energetic SMEs in the same sector creates “collective efficiency” [8] form of reduced transaction costs, more direct access to the market and increasing innovative capacity in the exchange of knowledge between firms. Additionally, due to agglomeration of firms and institutions in the same location, clusters provide so-called “positive externalities” [5] easier access to employment, infrastructure, and services.

In recent years [12] there has been a strong tendency to proliferation of clusters, because of the many advantages presented in Figure 1.

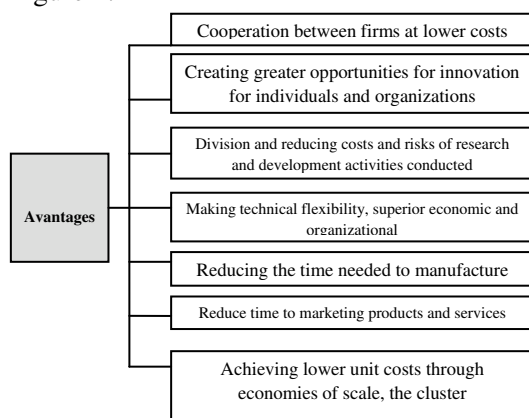

Figure 1. The main advantages of cluster firms

Today, however, the existence of clusters began to be felt in traditional sectors,

accelerating technological progress and give energetic SMEs the opportunity to become part of the innovation process [13].

In Romania, according to economic cluster analysis is not mature, and those that have been identified are at best protoclusters or emerging clusters, which present only a low level of cooperation between firms and between public and private sectors. Another feature is the distinction between natural and public clusters. In the series of interventions unproductive sector, the Romanian state has tried to promote agglomeration of firms through public policy. These policies have given rise to public clusters, by law; have the status of industrial, scientific, technological and a limited degree of success.

However, only 3% of small and medium enterprises are 21% of innovative SMEs share of cooperating with foreign companies is less than 3% for small firms, 4,6% for medium and 16% for large firms.

Although it appeared from the ninth decade of last century-network company is not manifested only sporadically, especially in the U.S. Company-network shows the following [7]: setting up a small company whose main activities are manufacturing and marketing a product, which runs only through other firms, incorporation into the company of a small number of people - usually three to ten - which, except for one to two officials, former managers and professionals are all reputed in the field or fields of activity involved in the manufacture and marketing of the product; possession, as the main resource of the founders, of all knowledge management, legal, commercial, financial and related essential technical product or group of products that are the object of activity, business activities mainly based on intellectual capital represented by the knowledge, relationships, reputation managers and professionals established company, other forms of capital with a role of adjacent, complementary, development of company-network to a rigorous project finance, manufacturing and marketing, which is expected to be achieved through the participation of several companies that perform necessary activities based on very detailed and rigorous controls; conclusion by the company-network long-term contracts with companies that compete with parts of product, services marketing, sales,

distribution, etc. to conduct business, business-networking components work focus on coordination, supervision and reward participants in the project, without interfering in the actual conduct of the activities of production, human resources, marketing, etc., maintaining control of the business by protecting thorough knowledge of key up vector value. Only they possess and manage their entire company-network managers, network focusing on business-management firm, recovery and renewal of knowledge concerning its objectives.

Company-network, which has the configuration shown in Figure 4, will proliferate greatly in the future, as more and more very good managers and professionals will want to capitalize knowledge independently, on their own, become entrepreneurs and managers, creating -and a greater freedom of decision and action in the generation, use and management of their knowledge, in terms of obtaining higher incomes.

Structural-organizational group focused on innovation - so generating and using new knowledge, emerging company has crystallized in the U.S. in the past decade, the peak areas of science and technology such as biotechnology, microprocessors, etc. synthetic chemistry [1]. Emerging companies are characterized by their focus on generating new knowledge, with a marked originality and the use of them commercially on complex design and implementation of innovative mechanisms and management, technical and human resources.

Mention of specific elements of their large share of research and development, rapid changes in size and dynamics of their appeal to particular forms and management which in turn has a strong dynamic.

The management of stage technology and emerging companies, particularly in the marketing stage is essential to their technical and economic position in an environment with a strong dynamism [4]. At the beginning, the management company is able to innovate effectively in that niche related technology, and development firm subsequently survival depends on access to the entire chain of complementary assets required for marketing the new technology. Positioning the company involves the adoption of four key decisions as shown in

Figure 2.

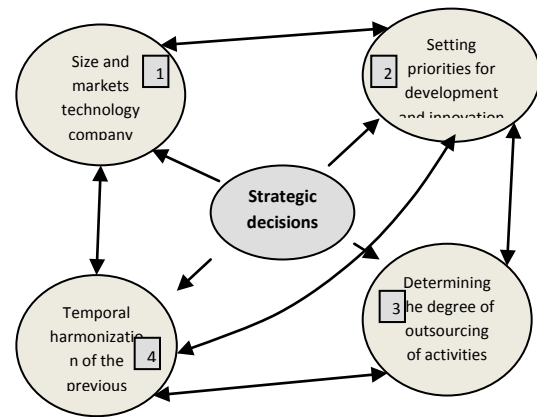

Figure 2. Technical and strategic positioning decisions of the firms emerging

Given accelerating the transition to knowledge-based economy, there will be a multiplication of both emerging companies and a substantial shortening of the duration of the three stages that are specific. Emerging companies, although it will be very numerous, representing a low share of total firms will have a major impact on technical developments, economic, commercial branches of art.

Electronic commerce has become an indispensable way of doing business. The most important benefits offered by e-business activities are related to reducing costs and increasing volume and speed. The European Union has focused on building a functional basis for the digital economy. The new Member States would be beneficial to existing catch “the evolution of the e-business is not just the technology, [...] but also refers to structural changes in the economy, both within companies and the relationships between companies.” [10].

The literature [3] is unanimous in defining the virtual enterprise. A virtual enterprise can be described as an opportunistic temporary alliance of several companies separate, existing ad-hoc meetings are pooling skills, competencies and resources to better respond to business opportunities and whose cooperation is based on use computer networks. A virtual enterprise is intended to be an organizational form that gives the best by a combination of synergistic core competencies of individual partners to create a maximum degree of customer satisfaction for a specific project. Several manufacturing companies in the network appear to

customers as a single entity.

Energetic SMEs will have to find ways to meet organizational global opportunities without suffering the effects due to limited resources available. Virtual enterprise is a form of cooperation in the network can be seen as a suitable alternative to overcome these deficiencies. If energetic SMEs want to be more than marginal players in the economy of the future would have to cooperate in specific forms of production networks. Major strategic benefits leading energetic SMEs to cooperate are sharing the costs, infrastructure, and research responsibilities. Along with the aggregation of complementary skills and greater flexibility during the design grow [3].

Virtual enterprise efficiency depends not only on coordination and control. Confidence has increased significance because they act as a substitute for two critical factors often absent in virtual enterprise, which are traditional hierarchical control associated organizations, rarely found in networks of independent companies and necessary legal framework for regulating the formation, operation and dissolution of the organization, which is much less developed for virtual enterprise as long contractual negotiations would reduce or cancel the positive effect of virtual enterprise with rapid response [4].

The most important features of virtual enterprises are the virtual enterprise value is created. The purpose of virtual enterprise is to create value by changing opportunities in its environment, the virtual enterprise is a temporary cooperation objectives. To capture a new opportunity quickly, cooperation between distributed sites is required. This cooperation is structured for a limited period of time, with a limited purpose, and with a minimum coordination, virtual enterprise restructuring facilitates learning. Virtual organization is restructured from within, in order to capture the value of short-term opportunity.

For some specialists [2], virtual enterprise is an approach for achieving high efficiency in inter-organizational supply chains. Supply Chain Management (SCM) and Efficient Consumer Response (ECR) are seen as early examples of virtual methodologies and toolkits. From this perspective, the focus for development of energetic SMEs is to improve the virtual inter-organizational

cooperation, coordination and control. Integration of information flow (e.g., Electronic Data Interchange) and material flow creates transparency in the value chain and virtual doubling in the company's efforts. However, for others, virtual enterprises are possible means of self-organization. It is the objective of virtual energetic SMEs to improve the overall efficiency of inter-company processes for a particular purpose and sharing rewards.

Weight application specific instruments virtual organizations is small when we consider all Romanian energetic SMEs (we consider the actual implementation), although it is evident that large software manufacturers (Microsoft, Oracle) tend to offer products that address the main share of energetic SMEs. On the one hand, we see concern “government”, who preach support the implementation of national and European programs, on the other hand, we cannot but note that this field cannot oppose the use of new technologies. Risks that the organization is required to take are not neglected: very large initial investment, uncertainties related to software adaptability, increased staff responsibilities and significant hidden costs, especially those related to training employees. At the level of funds between 2007 and 2013, Romanian energetic SMEs can access structural funds to support projects in ICT. According to the bulletin of European integration, EU-RO Newsletter, the value of these funds amounted to 336 million Euros. Strategy to use these funds would be beneficial to include, “inter alia”, operations such as connecting to the Internet SMEs, building “telecenters” in deprived areas, support electronic business applications, the introduction of electronic bidding and increasing security of electronic transactions. If applications are a key to access integrated inter-organizational networks, European funds are the answer to financial problems. Thus, the offer may be covered by the application. On the supply side, the software market Romanian energetic SMEs is covered so well-known companies (Microsoft, SAP, Oracle, Scala), and offers 100% Romanian (CRIsoft, TRANSART, Bit Software, Total Soft Wizrom, ASIS, EXMAN etc.). Analysts believe [2] that this market is still developing, because our country is in the stage it is only the beginning - resource

planning software SMEs.

Given the intended use of the Internet / Intranet in Romanian energetic SMEs, statistical data [11] reveal that in 75,43% of companies' aims to communicate with suppliers or customers, in 62,88% of companies aimed at obtaining information about business, in 44,04% of the organizations aims to facilitate communication within them, and in 38,49% of business units or electronic payment transactions are carried out. If we consider the newly created virtual companies, this rate of 39,64% is SMEs.

Conclusions

Grouping firms by region, energetic SMEs in the Central region has the highest share of services in virtual enterprises and energetic SMEs in the West have the rule of virtual economic unit in which the activity is electronic commerce.

For some energetic small and medium enterprises, electronic commerce means any financial transaction using computer technology. Due to this diversity of market conditions that include a large number of service providers and is in constant change, it is a necessity to make available to small and medium enterprises, a “source” where to find adequate support for the application e-commerce solutions in their own activity.

There is the conclusion that, although support policies are particularly important in the evolution of clusters, the establishment of successful all over the world, took place following the initiative of companies, not governments. The imposition by a government program of construction of a cluster is counterproductive and proved to be so in most cases. Instead, support the development of a cluster initiated by private actors, through legislative and administrative framework enabling or contributing to the improvement of physical infrastructure such location is a welcome action by governments. Policies and institutional infrastructure to support cluster development are important, but fundamental role in creating clusters of entrepreneurial firms it has to manage to see the benefits of cooperation and exploit them properly. Identify opportunities can then be followed by a sustained process of adaptation of management, organizational structure and

relationship with customers and partners.

In conclusion, Romanian energetic SMEs will result in obtaining performance virtual competitive domestic and international markets, as the nature and foundations of their manufactured products, knowledge, information and communication means used meet the fast development.

Abstract

This paper is the result of a survey concerning the perception of the Romanian students about the educational alternatives offered by the dynamics of the electronics media. Using the qualitative research methods, the author investigates the impact of the new technologies already being in service inside the Romanian universities. The research is part of a series of studies about the e-learning in the university education in Romania. The development of the discussion tool and the interview guide in this case is the result of a systemic approach, which allows obtaining of coherent results at educational system level by corroborating of the two component units. The obtained results have the same parameters as the similar researches made at European level: an educational system systemically underdeveloped, of which access to the existent technology is hampered by the lack of funds and undeveloped infrastructure and lack of vision.

Keywords: *e-learning, educational marketing, qualitative research, Romanian education, consumer behaviour*

J.E.L. classification: M31

Introduction

For a long time is not a novelty that our students and even our children are multitasking and multimedia connected. This is not new that our brain can do simultaneously many things (e.g. driving and listening radio, eating and talking or watching TV). Several symposia, conferences and public debates are organized on this subject, trying to identify negative influences of such human brain

overload. As a result, debates are open yet and the conclusions are far away.

Unlike most adults who are more recently exposed to current technologies, like Facebook, text and digital gaming, young people have been raised in an age of media saturation and convenient access to digital technologies. Net Generations have distinctive ways of thinking, communicating, and learning [10]. According to an North American study, "80 percent of teens (...) log on to their online networking pages to virtually hang out in the same way that previous generations would congregate with friends at a coffee shop or burger joint" [11].

The psychiatrists (e.g. Hallowell) call multitasking a "mythical activity in which people believe they can perform two or more tasks simultaneously." [9] and the psychologists (e.g. prof. Poldrack) "We have to be aware that there is a cost to the way that our society is changing, that humans are not built to work this way. We're really built to focus. And when we sort of force ourselves to multitask, we're driving ourselves to perhaps be less efficient in the long run even though it sometimes feels like we're being more efficient." [12]

Despite specialists opinions, educators from everywhere and at any level must contend with the fact that multitasking is a way of life for many of today's students. [9].

1.1 Romanian e-learning environment

Due to the economic and political conditions, the Romanian e-learning environment hasn't changed in a significant way since last year (2011) when could be so described as: lack on personal contact between teacher and students, poor e-content capacity when teacher works alone, lack of technical support, lack of confidence in the outcome of e-educational process, need for change

in students' and teacher's minds, long duration and hard process of building e-content, lack of experience in e-education, modest offer of e-contents and relatively small market for e-educational content due to Romanian language. [3]

1.2 Subject review

The subject “Perception of e-learning among university students isn't new for the educational market in Romania. Several quantitative studies [2,4,5,7] were conducted among various sample, the single domain of study addressed, local area and without qualitative research performed. The results have been various too, as follow:

- according Indreica and Cazan the preference for distance learning is largely because of the flexibility of use for time and location and work commitment and most students are not satisfied with teaching and learning by distance offered by the university, their reason being diverse, such as the individual competence to use computer, and the technical support for students [4];

- according Cocorada, Pavalache and Scutaru the results of their study cannot be generalized because of the reduced and conventional sample, but for sure the successful use of online learning requires teachers to be sensitive to the various impacts on the students and their learning[7];

- according Berteau, the results revealed that there is a connection between technical abilities and students' attitude towards e-learning. Attitude is also influenced by the time dedicated to computer use, indicator of PC experience. There were found differences of attitude in the case of hired students compared with the unemployed ones. [2]. The main limit of this study is theoretical approach, students haven't use e-learning;

- according Cirnu and Nedelko the Social Network in general, and Networked learning systems in particular hold great potential for school improvement and for turning them into learning organizations [5].

Our present work addresses the gaps of this research and presents an effective investigation about the Romanian electronic learning environment.

2. Qualitative study – perception of e-learning of among university students

The e-learning world is all about connecting people with one another, around subjects of mutual interest, about transferring information and about

creating a future personal and professional network. Media technological tools, if used appropriately, are powerful devices that can enhance learning. Relationships between faculty and students are more personal and they jointly construct knowledge through cooperative learning activities.[8]

2.1 Methodology of the study

We used the qualitative research tools. The study consist in 12 focus-group interviews with university students half groups from the 1st cycle, half from the 2nd cycle; mixed gender proportion 50%-50%; each group consisting of 8-12 persons, aged 20-30 years. Location Bucharest (3) - 1 for 1st cycle and 2 for 2nd cycle and 6 main university towns: Constanta (1) – 2nd cycle; Iasi (2) – 1st cycle and 2nd cycle; Cluj (2) - 1st cycle and 2nd cycle, Timisoara (2) -1st cycle and 2nd cycle, Craiova (1) - 1st cycle, Brasov (1) -1st cycle. The students have various specializations like: medicine, mathematics, physics, history, economics, biology, chemistry, law, constructions, telecommunications, communications, foreign languages, geography, computer science, sports, various engineering departments.

The interviews were conducted in their university locations during academic visits or in our marketing labs, face to face or on-line, at various hours, depending of their programs, in April-May-June 2011. Each group interview has lasted between 60- 90 minutes.

2.2 Background and marketing objectives

The research is part of a series of studies about the e-learning in the university education in Romania and is, in this sense, an addition to the qualitative research about the perception of the teachers regarding the e-learning methodologies, published in 2011 [3].

The pressure exerted by the European Union, European educational market and Romanian educational market over the academic institutions increases their interest and action in order to organize, develop and improve e-learning.

The development of the discussion tool and the interview guide in this case is the result of a systemic approach, which allows obtaining of coherent results at educational system level by corroborating of the two component units.

Student perceptions of e-learning can be studied across a wide variety of domain thereby making more general results. Perception of e-learning

results from occupational satisfaction, affective reactions, useful reactions and perceived training transfer.

As e-learning tools we set our discussions on this table (table 1):

EDUCATIONAL TECHNOLOGY USED IN THE MARKETING ON THE INTERNET COURSE	
Chat room	An Internet Relay Chat (IRC) system for weekly real-time chat sessions with the instructor and students
Electronic discussion group	Using Majordomo's listserv, this was a closed, unmoderated online forum for instructor-to-class and class-to-class email communication
FAQ page	The "frequently asked questions" page that contained a wide variety of questions (and answers) about all course elements
Instructor home page	The page containing links to all course syllabi, research interests, professor contact information suggested books and pertinent resource links
Internet project	Students have a choice of one of nine projects that required a written analysis on an Internet marketing topic. This project required students to search the Internet for sources and present their findings online in .html format
Lab-only classes	Class periods when students were taught technological topics in a "hands on" computer lab setting (e.g. browsing, searching, creating, publishing Web pages)
Online homework assignments	Twenty homework problems, about some aspect of marketing on the Internet, were assigned. All assignments required Internet research. A one- to two-pages typed paper was required for each homework assignment.
Online lecture outlines	A Web page with PowerPoint lecture outlines and hypertext links to sites shown during class meetings
Online readings	Hypertext links to readings about each course topics
Online syllabus	This page included the course description, policies, grading scale, course requirements, method of

Online students directory page	evaluation, course schedule and links to other course components. A directory of students name, e-mail addresses and home page addresses for student-created home pages
Online students grade page	Students grades listed by a four-digit code
Technology lectures	Traditional lectures classes that entailed discussion of technology-related topics
Web site project	This project required students to develop several Web pages (e.g. home page, resume page, hotlinks page, etc) and then publish them to their web site.

Table 1, Educational technology used in Internet course [6]

According to this figure, the e-learning tools offer is wide, rich and comprehensive. Unfortunately, Romania has not developed and applied a specific strategy in order to improve or facilitate access to this tools.

2.3 Research objectives

Similar to the teachers study, present study plans to identify:

- forms of e-learning known and used
- perceived place of e-learning in teaching activities
- perceived role of e-learning in Romania
- students' opinions about e-learning
- degree of interest about e-learning
- degree of acceptance of e-learning
- importance of e-learning for university students
- importance of e-learning for students in terms of their interactions with university teachers
- suggestions about e-learning in order to help educational process
- influence of e-learning for educational process over relationship teacher-student

Objectives decide interview topics. They shape the questions to ask and guide final analysis and reports, pointing to the right direction.

2.4 Main findings

The students' opinions about e-learning are almost homogeneous, they are "pro". The e-

education can be altered and even improved by incorporating greater autonomy in learning and e-learning offer very good tools here: “we need a teacher, a good one, we respect a teacher's work, but some activities we can do alone”, “is totally stupid to write the course during the classes, we have books, we PC's, laptops, tablets, iPhones and we have (God) Internet”. Student asks for a responsibility increasingly greater choice, sorting and evaluating information.

All students feel comfortable with basic computer-based technology activities, such as using email, typing, accessing the Web, sending, receiving, and downloading documents and with more advanced activities, including downloading multimedia materials, listening to audio or viewing video on the computer. “it is something normal (common), we do this since high-school”. And also, all students are well informed about e-learning tools and processes, even they don't know exactly educational process as “e -learning”. Unlike their teachers students do not confuse the mere use of technical equipments during classes with e-learning.

What is greatly appreciated at e-learning is the variety of communication: e-mail, forum, news groups, e-agenda, audio and video conferences. The main ideas are teams for solving problems, and underlying collaborative projects is that the joint effort of many actors leads to a better outcome than any actor could achieve individually.

Teachers [3] have claimed the lack of personal contact that demotivate learners and increases the dropout rate. Students from first and second stage have separate opinions.

Students from the 1st stage agree the e-learning process, but most of them (the younger ones, new high-school graduate) need more human attention, in terms of personal contact, in order to: reduce stress of the major change, high-school vs. university; maintain degree of socialization and receive quick and direct feedback from the teachers. “It's ok to have e-courses and e -labs, but we need personal contact with classmates and teachers”, “we are humans, first of all”.

Students at the 2nd stage (master) consider that they have enough face-to-face contact during the previous educational stages and now the system could be more relaxed. According their opinions, the first educational stages were important because “we have learned to acquire and use information; prepare for work and lifelong learning; solve problems; make informed decisions; develop and test hypotheses; systems thinking; critical, creative, and analytical thinking”. According to them,

depending of educational field, master – as 2nd stage is more useful an exclusive e-learning process because different objectives and many positive findings. At this level they need to learn how to: transfer learning to new situations, create quality products and performances; review products and performances; contribute and adapt to the scientific and technological changes and “this does not require permanent personal presence of a teacher”

Other positive aspects identified by this study of e-learning for Romanian students were: reduces commuting time and costs “I don't waste time and money to go to school”, allow study at desirable place and time, allow many interest areas in the same time; allow network communication and in this way gives communication a different perspective. E-learning is seen as a source of comfort.

Everybody is aware about complex IT tasks and professional effort for teachers and need for new technology acquisitions for universities. E-learning becomes a means of pressure to reshape higher education. “We need well IT trained teachers and good equipments”, “we need free Internet access and each classroom well equipped”

Differences between young and old, as well as between IT or non-IT skilled teachers have been also noticed. Simultaneously they recognize that is no connection between IT skills – tutorial skills and professional skills. “It is almost sure that an older professor prefers older methods, dislikes IT tools and is afraid by the e-world”, “younger teacher (I mean here assistants) are high IT-skilled, but have less professional experience/ knowledge”.

Technical support was another related subject. Students notified the poor IT infrastructure of the universities and in general the poor high speed Internet connections. “E-learning is a useful and interesting concept, but we can't reach e-materials without having the right technical support”, “just imagine a video-tutorial, or a video-conference at 2Mbps or downloading 1G tutorials at this rate...”.

The E-learning can provide students major satisfactions due to amount and variety of learning materials. That is no guarantee for the quality of the learning materials, depending on teacher professional knowledge, his experience and IT skills. “Indeed we can have a lot of e-materials, but may be a lot of poor quality if good teachers haven't IT skills or some IT help”

The self motivation is the main trigger in achieving success into e-educational environment. Laziness may appear because of convenience: “when you only stay at home and download

materials, harder part is to open all this materials and do your homework”.

The main accusations launched by the Romanian students (also by the Romanian university teachers) related to the e-learning are: it can create an artificial education market (both aiming to obtain profits) and can stimulate false educational needs [3].

3. Conclusions

The Romanian students want to be able to access e-information and will assume the freedom to interpret it from their personal point of view. Some of them are actively engaged in the online communities where educational tools are discussed (Facebook, Twitter, community sites & forums), and are committed to staying up to date with the new technologies and rapidly evolving tools, the rest of them are strongly interested in such possibilities to obtain educational information like the above.

The E-learning tools offer the possibility to use interactive classes and this enables a good transfer of information. The E-tools offer real time scenarios and games which lead to better knowledge acquisitions.

The E-learning can produce in Romania great results by decreasing the costs and improving the performance.

Analyzing both research reports, teacher and students, we reach a single conclusion: the Romanian students are ready, the Romanian teacher aren't ready and also the Romanian social and economic environment isn't yet permissive to “e-learning”.

4. Limitations and future research

The main limitations of the study consist in the general limitations of the qualitative studies. The qualitative research is a highly subjective research discipline, designed to look beyond the percentages to gain an understanding of the customer's perceptions, attitudes, feelings, impressions and viewpoints.

The research is part of a series of studies about the e-learning in the university education in Romania and is, in this sense, an addition to the qualitative research about the perception of the

teachers regarding the e-learning methodologies, published in 2011. The results of the future quantitative researches about both collectivities: teachers and students using the e-learning in Romania are to be published in the near future.

The Concept of Customer Relationship Management A Critical Review of Literature

Cabău Liviu-Gabriel

Facultatea de Economie și de Administrare a afacerilor - Universitatea de Vest Timișoara
liviu.cabau@feaa.uvt.ro

Abstract

This article is considered to be a landmark in both academic and business area, regarding the Customer Relationship Management (CRM).

Based on previous research found in the literature, the paper aims to clarify the concept of CRM. Critical research results are reflected in the formulated responses on the following aspects of CRM: CRM context, CRM definition, CRM importance and objectives, CRM failure and CRM research.

Finally, the article presents the main findings and some conclusions related to the current research.

Key words: CRM, CRM Strategy, CRM Processes, CRM Software.

J.E.L. Classification: M15, M31.

1. Introduction

Interests towards the concept of Customer Relationship Management (CRM) has manifested itself since the 1990's - years that marked the transition from transactional marketing to relationship marketing, therefore in 2004 CRM became a top priority for Directors of Information Technology. Therefore, focusing on the creation of a large number of short-term transactions began to be gradually replaced by the philosophy promoting medium and long term relationships with all types of people and organizations who have a direct or indirect interest in the firm's activity.

Customer Relationship Management, a concept enshrined in literature and in business as CRM is based on the creation and development of personalized relationships with customers to increase their profitability. Being in front of a variety of products comparable in quality and price, sometimes

difficult to differentiate, customers tend to appreciate more product related services (both before the act of sale, and later) and quality of the relationship with the manufacturer or seller.

However, managers of firms are considering the following aspects: (1) the costs of bringing up a new customer are five times higher than the costs of preserving a customer; (2) an unhappy customer will tell his negative experience to a number of 7-10 people while a satisfied customer will recommend it to a number of 3-4 business acquaintances. This difference is fundamental. Hence the results of other studies: an increase in customer retention by 5% can make additional profits by up to 125%, depending on firm profile (PIMS study), (3) also found that 1 USD invested in advertising will bring long-term 5 USD, while 1 USD invested in strategies for Customer Relationship Management, particularly in customer loyalty, in the long term will bring 60 USD (CRM CREATIVE GOOD study).

Therefore, personalized relationships with customers are some of the most important assets of firms and creating a system to manage these relationships embodied individual determines competitive advantage in increasing customer loyalty and retention. Adoption strategy of CRM represented the third great revolution in business organization, the invention factory in 1718 and the introduction of assembly lines in factories in production in 1913 [39].

2. CRM definition

Given the scale and importance of Customer Relationship Management, as diverse opinions and often limited, the lack of a clear definition has had a negative impact on the successful implementation of CRM in firms [19], although progress in

research comes just after addressing a phenomenon from multiple perspectives [22]. The large number of definitions of CRM [39], [32], [40], [6], [13], [25], [8] have led Zablah [58] to group the definitions in the literature into five categories according to the elements that prevail in each formulation: process, strategy, philosophy, capability or technological tool. Later, Payne and Frow [29] have reviewed these definitions and have reclassified them in three categories, depending on issues of tactical nature, technological or strategic.

On one hand, the definitions formulated in the literature considering the following coordinates assume major CRM:

- Strategic nature. Relationship Management with Customers represents a business strategy, not limited to only one of the firms, to be precise the area of marketing. Relationship Management with Customers is relevant and profitable for firms that are contributing to their objectives as well as to generate value for the customer and the firm;
- The role of solutions in Information Technology. CRM provides increased opportunities for using data and information to both understand customers and to better implement relationship marketing strategies. This requires an integration of human resources, operations, marketing processes and capabilities / Information Technology, which is enhanced by integration of information, technology and applications [28]. So, Information Technology helps develop and implement strategies capable of meeting the firm's objectives in relations with customers and developing their loyalty. Also, Relationship Management solutions help firms to measure customers performance in the implementation of strategies and programs in the field of Customer Relationship Management;
- The purpose of CRM. CRM and Information Technology unite the potential of Relationship Marketing strategies to create profitable long term relationships. Develop and implement strategies to develop customer loyalty and develop a profile of preferred supplier for applying business strategy

CRM major aim is to create value for both partners in the relationship, supplier and customer. To be recognized and adopted by the customer, the value should be meaningful and relevant perspective.

On the other hand, these definitions can be classified into three different but complementary elements according to their precedence: the philosophy of CRM [39], [32], [40], Information Technology in CRM [6], [13], [8] and CRM strategy [39], [25].

However, holistic approach to CRM as Payne [28] is the recommended one: "CRM is a strategic approach interoperable aimed at creating higher value among shareholders by developing appropriate relationships with customers reference and with other segments of customers. He unites the potential of Information Technology and Relational Marketing strategies to create profitable relationships long term".

Therefore, CRM involves radical change of business and development strategies in relation to traditional firms. If old target marketing concept was selling, new marketing concept has as its objective the development of relationships in which the sale represents just the first step. The stage where customers are considered as number or total value of transactions, firms should focus on establishing and maintaining long-term relationships with each customer relevant, relationships that will ensure business expansion terms based on Information Technology.

3. CRM importance and objectives

CRM has a high importance for firms. Compared to previous decades, today customers are "moving targets". Markets do not have a relatively, stable structure, being extremely dynamic, with segments and niches whose profile evolves. In this context, CRM strategy aimed at attracting and retaining profitable customers through the development of long term relationships and fostering customer loyalty. Advances in Information Technology are the basis of the most appropriate strategies to develop relationships with each customer in the portfolio firms, they can enjoy unique and personalized experience. With solutions, all data are integrated for each customer

between various departments of the firm and have been collected through various channels of communication with the customer during the interaction - the staff "front-office" and Web-based applications [3]. This yields a unique customer view, highly valuable for firm [9].

A key element in any business is to define the objectives. The objective of CRM found in the literature are: (1) increasing the customer retention rate [35], [39], [5]; (2) increasing the customer lifetime value [39], [35], [40]; (3) increasing the share of existing customer base [5]; (4) providing customized products [39], [40], [5]; (5) increasing the value for both business and customers [39], [16]; (6) improving aspects of an operational nature and providing value to the firm [1], [5]; (7) improving and expanding customer relationships as a result of new business opportunities [8]; (8) transforming customer information into knowledge for firm [39]; (9) choosing the most valuable customers [7]; (10) maximizing customer satisfaction by providing higher quality services [39], [8]; (11) developing more profitable relationships with customers [39], [6]; (12) deepening the relationship between products / services and customers [5]; (13) reducing the cost of sales [39].

4. CRM failure

Although between 2000 and 2005 firms have invested around 220 billion dollars in solutions for CRM [28] though most of them have not experienced a significant return on investment [39], [34] implementation failure rate ranging from 60% to 80% [20]. In fact, we may say that is one of the greatest paradoxes at this level of high investment in CRM.

On one side, cases that have limited the success promised by the solutions for CRM were recorded at a customer level [19]. They may react negatively to use a strategy CRM by a firm. For example, Palmatier et al. [26] show that there are some customers who do not require or unwilling to maintain a deep and long-term relationship with a firm relationship to their costs being greater than their perceived benefits. There are authors [14], [10] indicate that different studies can lead CRM and undermine a relationship, not only to strengthen it.

On the other side, there were some causes of failure identified at firm level [19], which are the most: (1) poor project management [2], [20]; (2) technical and organizational barriers [31], [38], [14]; (3) underestimation of the complexity of the CRM [31], [39]; (4) adoption paradigm "focus on the product" rather than "customer focus" [24]; (5) lack of an appropriate organizational culture [4]; (6) focusing on Information Technology instead of firm's strategic objectives - "Software Strategy Before" [18]; (7) lack of support from managers [20]; (8) misunderstanding of the concept of customer lifetime value [20], [37]; (9) lack of employee motivation [39], [5].

So what firms need to understand is that the most important change is by no means the technical one. True change must lie in a change of employee behavior, that ultimately use the technology to meet the strategic objectives of the firm.

5. CRM research

The concept of CRM is the subject of several previous studies. Ngai [25] in the critical review of literature identifies five main streams towards the concept of CRM, namely: (1) CRM (concept and issues this study, management, planning and strategy, performance, personnel); (2) marketing (channel management issues, consumer behavior, customer loyalty, customer retention, customer value, privacy, product, segmentation, targeting and positioning; trust); (3) Sales (accounting issues, cross sales and purchases, sales force, sales management); (4) services and customer support (call center issues, customer satisfaction, the service, quality management, self-service , aspects of social / non-profit); (5) Information Technology (data issues, Information Technology management, data mining, data warehousing, e-commerce, internet, knowledge management, optimization, customization, applications, tools systems).

Therefore, the subcategory of Management, planning and strategy CRM is more important for the number of articles published, followed by subcategory Concept and study of the Concept of CRM. Major contribution of this view is given by clarifying the proximate genus as being the

business strategy. The purpose of CRM is consistent with the philosophy of marketing, is to create value for both the organization (in the form of revenue and profits) and customer, as high degree of satisfaction and fulfillment of his expectations.

In literature, the concept of CRM has been studied both at customer and firm level. At customer level [39], CRM involves a single picture of it, as a result of customer knowledge integration in all contact with him. CRM approach at the firm level [17] involves identifying key processes and their main components. However, a holistic approach to customer relationship management is the most recommended [29].

Zablah et al. [39], in their critical review of the literature identifies five major conceptualizations on CRM: (1) CRM as strategy - one that improves the profitability of the portfolio of firm relationships [1]; (2) CRM as philosophy - the firm's focus on customer targeting; (3) CRM as capability - one that reflects the quality of interaction between firm-customer [11], [32]; (4) CRM as a tool for Information Technology - one that integrates sales and marketing systems in order to cultivate relationships with customers [35]; (5) CRM as a process - which includes the entire firm and focuses on creating and maintaining relationships with customers [32], [29].

Some authors [8], [29], [38] believes that there are three levels of CRM: the strategic one, the operational one and the analytical level. In essence, the strategic level refers to the major objective of CRM and the firm's positioning as a strategy, not only as functional strategy. Operational level automation projects targeting different activities of sales, service and marketing, and communication channels with customers. Analytical level is mainly focus on measuring the firm performance related to the relationships with customers and analyzing customer information. Based on this information the firm should adopt the most appropriate marketing strategies and tactics.

According to Freeland [17], CRM strategy include: Customer strategy (The customer that firm wants to attract?); Channel strategy (Through which sales channels will firm contact those customers?); Brand strategy and image (How the firm

ensure that those customers will bring a capital picture?) and Information Technology strategy (What technology tools and capabilities the firm needs?).

Some researchers [39], [36], [38], [23], [33], [12], [29] have developed over the years various process based frameworks of CRM. Of these, holistic approach to Payne and Frow [29] is the most representative.

The processes related to CRM strategy proposed by Payne and Frow [29] are: (1) the development of strategy at both corporate (business vision, industry characteristics and competition) and customer level (customer characteristics, degree of segmentation), (2) the creation of value, which includes three key elements: the value that the firm can provide for the customers, the value that firm receives from customers and maximizing the lifecycle value of customers that firm wants; (3) the integration of multiple channels, that takes the results of the firm's strategy and value creation process and translate them into value-adding activities; (4) information management process, including data warehouses, systems of Information Technology field, analytical tools and front-office and back-office applications; (5) performance evaluation process, which is composed of shareholders results and continuous performance monitoring activities by appropriate metrics.

CRM strategy is successfully implemented when: (1) the firm can provide the same value to customers as competition does, but at a lower cost; (2) the firm can provide greater value to customers than competition offers at the same cost; (3) The firm can provide to customers a higher value than the competition does at a lower cost.

Implementation of CRM processes affects in different ways the financial performance of the firm, depending on the stage of the relationship between customer and firm: initiation, maintenance and termination [33]. Therefore, implementation of CRM process is associated with higher financial performance in the first two cases. Greatest effect on firm performance is felt during the maintenance of the relationship, followed by the initiation phase. In the final stage of the relationship, the effect is insignificant.

Regular assessment of the results of applying CRM strategy needs to be done to see if its implementation has led to positive

results for the firm or if corrective measures are necessary to be done [27]. For that reason, over time, the researchers have been designed various measuring instruments [21], [39] and different indicators like: number of new customers, customer loyalty, loyalty relationship, customer satisfaction, relationship satisfaction, customer profitability and others.

6. Conclusions

Lately massive investments were mainly in the area of Information Technology, "Software before Strategy" which led to a high failure rate in implementing the solution of CRM, hence a very low performance. According to a study by Meta Group [9] this failure rates between 55% and 75%. Many firms consider CRM simply a software application and its implementation as a task of any IT department. This misunderstanding generates a wrong start, which can result in a failure even if the application is properly installed and implemented. What firms need to understand is that the most important change is by no means the technical one. The true change must lie in a change in employee behavior that ultimately use the technology in terms of perception and ability to accept and adapt to the changes inherent in post-implementation.

Customer Relationship Management. Conceptual Aspects and Specific Strategies for Action

Ciobănică Mihaela - Lavinia

mihaelavinia@yahoo.com

Abstract

The existence and functioning of organizations tend to increasingly dependant on their ability to adapt and adjust to change. In front of it, reactivity becomes ineffective, if not useless, to the detriment of proactivitatii and of the level and capacity of anticipation. So, change is the only constant thing in an organization, contrary to common conception, which is defined as the equilibrium stability improvement [5]. Today, mobility, flexibility, the ability to adapt to the requirements and the evolution of the market, the customer's needs and desires are the only weapons that company owns the vigour of change, the only likely to resist, to continue to exist.

Keywords: Adaptability, speed, timeliness, efficiency.

J.E.L. Classification: M30.

1. Introduction

In the present work we started on the premise that the supreme court's assessment, the decision making of the organization they represent resources or, effectively, „the customer”. He is both the most demanding, the most critical quality inspector, most creative copywriter or marketer. He is the symbolic level, give orders and, from the outside. He is an „axis mundi” of the business. Therefore, the new economy requires strong relationships with clients and their management efficiency, customer relationship management and became one of the most interesting and important.

In the context of the unlimited options, always increasing demands, under the hegemony of the fickle customer, we wondered what strategies may fail to attract firms, to meet, to amaze. That's why I

consider customer role arching in the business and I stopped on him. At the same time, in a hyper-tehnicizat universe, computerized, standardized and automated up to the brim, the acute need for resimtim communication and for refocusing on the affective dimension, human, I consider that it is not at all to return to the US surpassed the concept of „relationship”.

Objectives as well as folding on the needs and requirements of the client, personalizing each interaction, exceeding expectations and enthusiasm becomes tangible with the adoption of a vision and a strategy. Fundamental to me seemed so, customer relationship management, that a first contact, uninformed, uncritical, unfounded in theory, a asociam with the ways by which companies will lead, he manages relationships with clients and influence buying behavior. Later, I discovered that such a vision is one truncated, incomplete, which vaduveste the concept of complexity and depth, under the reins of power are often diametrically opposed, pole and the communication ceased long ago to be unidirectional, asymmetrical. Therefore, in addressing the theme chosen, I considered relevant, first, to define the correct pluriperspectivista of the concept of customer relationship management and its related notions delimitation reductionist.

2. Conceptual issues relating to customer relationship management

Customer relationship management, a concept enshrined in the literature under the acronym CRM, according to the English translator to „Customer Relationship Management”, has gained momentum in the early '90, thanks to the growing popularity that a win, at that time, the strategy orientation towards the client.

In terms of the socio-human, customer relationship management is based on the creation and development of personalized relationships with clients, in order to increase their profitability.

At the same time, customer relationship management can be defined as a leap from the orientation on results in the short term to medium term orientation and long, or as a result of the transition from the traditional marketing paradigm to that of relational marketing [1]. Customer relationship management has developed as a distinct area of relational marketing, keeping the same fundamental principles. Gordon called them the dimensions of relational marketing, these being, in essence: creating and providing value for clients, the key role of the customer, the alignment of processes, communication, technology, human resources, in order to get value for the customer, cooperation between sellers and buyers, creating the bond with the so call them stakeholders both inside and outside the organization. In these conditions, the professional training of human resources becomes a stake and a factor of change and continuous training is a requirement that maximizes the value of an organisation [3]. The difference between CRM and relational marketing it is centering on one important category of stakeholders-clients, and of course, the most profitable for the organization.

A second approach to the management of relationships with clients is the sphere of technology relating to the computer assisted management of relationships with clients. Kotler defined the process by „purchasing a computer system (computers and software) to enable the company to capture detailed information about individual clients, the idea of using them for better marketing directed” [5]. By „examining past purchases, and demographic characteristics psychographic profile”, get relevant information about the behavior of consumers, with a view to the needs of their folding. At the same time, informatizata management help company to determine which are the least clients

increased profitability and focus on them, eliminating the cost that you would assume the correspondence or contact. At the same time, computer assisted management help company to determine which are the least clients increased profitability and focus on them, eliminating the cost that you would assume the correspondence or contact.

Kotler [5] suggests even a reversal of the magnetic poles guidelines seller-buyer. In concept, the customer should not be bombarded with offers, such as game, practice what wastes both time and material resources of the company.

It is necessary for the Organization to identify the need for the client to know information about the availability and responsiveness of the customer towards the respective bids, to offer advice, but total freedom in choice. Relevant information received to become the client directly, and not those relating to customer, obtained by buying behavior analysis based on the use of information technology.

Viewed through the prism of this aspect, the management of relationships with clients is „to humanize” relations between the client organization, no way to standardize and automate. Limiting the information solutions lead to the neglect of the actual objectives, major, omitting the customer as complex and unique individuality. Customer relationship management must be supported, indeed, information technology, but without having to deviate from the initial purpose: getting the value both for the organization and for the customer-first of the actors in the form of profit, revenue, for the second form of satisfaction and performance expectations.

3. Specific action strategies in customer relationship management

The concept of customer relationship management is regarded in the literature as tridimensional [1]. There is thus a strategic level, the operational CRM and analytical dimension. Strategic CRM level refers to the orientation towards client prosperity and advancement throughout the Organization, not just in the Department of marketing. Moreover, the proximity to the customer and getting satisfaction and enthusiasm it must become part of the organizational culture. Such a vision, strategies and techniques the

carrier, leads not only to retention of clients, but also to a more efficient internal communication, both horizontal and vertical.

3.1 Strategic level of CRM

The implementation of a strategy of customer relationship management aims to identify potential customers, attracting them through personalized offers, and their retention retaining and increasing their profitability by extending their life cycle. CRM strategies involve monitoring, assistance, advising the client on the entire duration of the life cycle. CRM strategies involve monitoring, assistance, advising the client on the entire duration of the life cycle. Major construction and development, not just their creation. A successful CRM strategy require gathering data storage volume as high as information obtained during each contact with clients, as well as proactive communication, as many horses as possible, with both current ones and those with potential. Without understanding that it is much more difficult and less lucrative to attract new customers than it fidelizezi existing ones, many organizations are focused on quick profit, having only a short and medium term and does not take account of the fact that business expansion occurs only by creating and developing relationships with long-term clients. The current context seems to impose such new requirements and trends: „currently, companies pay more attention to the art of retaining customers because they found out that it can cost them five times more to attract a new customer than to keep an old one” [6].

Customer relationship management enables knowledge of customer behavior, rapid adaptation to the needs and changes and, in the most fortunate case, even anticipating them. CRM strategies is based on „establishing, maintaining, developing and optimizing the relationships between an organization and its customers and focus on understanding and satisfying the wishes and needs of customers, items are placed in the center of the business strategy of any firms performing” [2].

A CRM strategy will effect the three major steps and, ideally, clients ' satisfaction consecutive, their fidelity and, finally, getting their enthusiasm. Starting from the idea that

„satisfied” is not a stage or „satisfied enough is not satisfied enough”, companies should have active clients satisfied, to find clear and strong reasons for having chosen the product or package their services and not a competitors. Passive clients satisfied choosing product accidental due to lack of time, interest, or options, typical reasons or ambiguous and, in consequence, are infidels: at the time of an offer of the best change supplier without hesitate. Therefore, the Organization must provide more than just expect the client to focus on emotions, feelings, to offer its constant reasons to remain faithful to the brand or product. The strategy is not complicated if you follow a few tips companies important and if you would be willing to make the effort and give them to customers. It is summed up in a few words: „Amaze your client!” or „Get the enthusiasm!”

Of course, the most profitable segment for application management strategies of customer relationship we are loyal customers. They constitute the most powerful competitive advantage of a company, as a part of the market is inaccessible, if drivers manage efficiently.

3.1.1 „The scale of relationships”

One of the types worthy of consideration is the proposed by Payne, Christopher, Clark and Peck [2]. The authors set up a „scale of relationships”, from potential clients, defined as the „target market”, the segment on which the organization strives to gain it, and ending with the latest gear, an ideal, in which relationships are based on mutual benefit and defined the concept of *win-win situation*. Thus, the scale relationships include the following stages or steps: potential client client constantly supporter partner occasionally, depending on the degree of interest and loyalty they have for it products or services and company values promoted by it. Indicated would be to adjust its strategies organizations CRM Customer typology they hold in portfolio and streamline its efforts, time, and costs involved in the creation, maintenance and development, in order to obtain maximum profitability.

3.1.2 The typology matrix of relationships between organizations and clients

Another way to define the type of relationship that clients wish to maintain with the organizations it's „The typology matrix of relationships”[2]. According to Piercy, there are four major types of clients:

1. Job seekers, relations defined as those buyers interested in a close relationship with the supplier, but in the short term. The relationship between the two actors can be defined as a partnership, which can continue to evolve, or can be done, depending on the result of the first collaborations and the degree of satisfaction of the two parties involved.
2. The blockade of relationships, those buyers who develop a long term relationship with the organization, but also a low interest. The relationship is distance, whereas these clients take advantage of all the benefits, but change the provider without hesitate at the time of an offer more attractive, in spite of the repeated attempts of the organization to retain them.
3. Casual customers, sensitive to prices and discounts are likely to migrate from one vendor to another. Their relations with the company is short and distant, based on specific transactions.
4. Loyal clients, the nearest of the relational point of view towards the organization. They distinguish by very low vulnerability to competition, bids will assume the values and culture of the organization, identifying themselves with its goals and have a lasting relationship, based on, with the company whose products and/or services are chosen.

Piercy's classification highlights the fact that between the clients and the organization there are different kinds of relationships, according to the desire of the actor and, of course, the efforts of the second. Therefore, efforts must be dosed, folded on the type of relationship that clients and want the company to make the CRM strategies. Obviously the loyal customers are the most profitable category, natural consequence being that they should be given more attention and more interest.

3.2 Operational level of CRM

From the operational point of view, CRM is the automation of the contact with the clients, in terms of the functions of marketing, sales and services [1], through specific software solutions. In other words, the operational customer relationship management refers to focusing on information technology and communications. According to this vision, internal and external information flow, obtained at each contact with the clients, determine the most effective methods of service, satisfaction of their needs. More and more the importance accorded to the *e-business* environment, because through his companies is just a „click” away from their clients. Basically, the virtual environment of the business relationship, the relationship turned classics of organization and the customer. As you point out and Philip Kotler in „Marketing in the digital age: a new vision about profit, growth and renewal”, organizations must adapt to the evolution of information technology: changing markets faster than our marketing activity.

3.2.1 Marketing Automation

Thus, the function of marketing automation includes activities such as customer segmentation, campaign management, communication or answers to clients ' requests. CRM solutions allows the storage of customer information in databases, real „gold mines for the organisation” [2], since they allow the creation of client-related strategies. It is so-called „data-mining” technique, which involves a careful and thorough analysis of customer data in order to identify the profiles of clients and split the portfolio.

3.2.2 Sales automation

CRM software applications also allow automating the sales process, helping to issue forecasts on the basis of information about the behavior of the purchase. At the same time, they contribute to automate management of your contacts (formation of automatic, automatic writing e-mails) and can even generate quotes or optimal customer

solutions, based on previous interactions, consumption registered or based on purchase behavior.

3.2.3 Automation services

Automation services represent the most important dimension of operational level, enhancing the effectiveness of CRM enormous and efficient organizations. A major investment in this respect is the telemarketing centers and contact centers. Interactive voice response (IVR) is just one of the examples which emphasizes the efficiency of automation services. By intermedial, clients can listen to General or commercial information, can find out the current offerings can even make changes to the products or services owned, no longer need to travel to one of the premises of the supplier and nemaidepinzând of working time.

3.3 Analytical level of CRM

At the analytic level customer relationship management deals with the evaluation of the performance of the organization in relation to its customers and to establish appropriate strategies and techniques. In principle, the analytic CRM includes activities such as the collection and storage of data, analysis and interpretation and subsequently use the information about the customer.

3.3.1 Identification of clients

Customer relationship management, looked at both from the technical point of view, as well as information from the human point of view, that strategy, client orientation, in a first phase, the collection and storage of customer identification data. All these information are centralized in a database we do not level the disparate departments and must be continuously updated, on the occasion of any interactions with the client, either at the initiative or on the initiative of the organization. The collection, storage and updating of the data are fundamental for the further establishment of customer profiles, segmentation and to establish appropriate strategies and approach.

3.3.2 Establish customer profiles

On the basis of the data collected and stored in the identification, the organization can develop customer profiles, their segmentation can be achieved and can build specific marketing strategies and sales. In establishing these intervening variables such as profiles, customer value for organization, purchase behavior, communication between the supplier and the customer satisfaction and the lifestyle of the customer [1]. In this sense, are considered the annual shopping performed by the client, all value during its lifecycle, favorite products typology and purchased mainly payment capacity of the client. Relevant in establishing profiles and favorite channels of communication, Internet, face-to-face and analysis of the types of posts that are positive by the client and which bring satisfaction and those who irritate you displease.

3.3.3 Data analysis

In order to develop programs and actions of viable, effective marketing, it is necessary for organizations to identify potential clients, grouped its clients in portfolio in homogenous segments (based on profiles that have been previously implicated and *feedback* provided by them in connection with products, services and business strategies), and later, to identify those groups of clients that could become the target of marketing campaigns. At the same time, the data analysis stage, the organization is required to take into account the probability of the relationship with each of its clients, to quantify the degree of retention and to establish groups of products or services that may be offered for sale or *incrucisate* or *cross-selling*: „The seller add other provider offers its line of products, that might get the same buyers and bring them in their attention” and additional or *up-selling*, as defined „by the vendor to the buyer to see the advantages of replacements or modernizations, in terms of the existence of obsolete equipment or if you need other products” [4].

3.3.4 Assessment of the effects of marketing

A last round of analytical customer relationship management involves assessing the effects of marketing, measurement of results of actions directed by the Organization to its target leader.

It will assess the „effectiveness of the sales process”, from identification of potential clients and their transformation into actual clients before the development stage (virtually throughout the life cycle), analyzing how effective was the selection of clients for marketing campaigns conducted and the neta, aportata by clients from the marketing activities whose targets were.

Conclusions

The customer is considered to be the central part of the business. Supreme in the context of customer relationship management would be targeting all organizational processes and of all financial resources, materials and human resources to it. Unfortunately, customer orientation is done in most cases only the formal level, and its satisfaction is perceived not as the end but as a means of obtaining profit. The attention given to the customer must be implemented, not just discussed. A company that really wants to make the client a priority need to follow a few steps. You must compare the level of satisfaction of our buyers the satisfaction of customers ' competition. You have to draft maps that show the interaction between staff and clients, to jot down in particular points that indicate outbursts and disappointments.

Challenges for Light Industry During the Economic Crisis

Ciorășteanu Gianina
„Constantin Brâncoveanu” University, Pitesti
ciorasteanugianina@yahoo.com

Abstract

Light industry has felt the full effects of the financial crisis. So far only companies that have a good strategy managed to overcome this period, whether they made goods under their own brands or manufacturing production for other brands. Local producers waging a constant struggle to exceed this difficult period. They must overcome a number of obstacles, including difficulties caused by migration of cheap labor force in European countries where earnings per month outweigh revenues per month in Romanian light industry. Another obstacle are: the poor design and implementation of marketing strategies that fail to impose brands created by domestic producers on the European markets, demanding customers or outdated technologies.

Keywords: customers, light industry, students, brand.

J.E.L.Classification: L67, M11

1. Introduction

In the 2000 Romanian light industry experienced a flourishing period followed by decline since 2006. The decline was predicted by specialists in this field. In industries where cheap labor is the main attraction lose market share when the country enters the European Union. The same slope downward had industries in countries where outward processing trade was practice (Hungary, Poland) when countries entered the European Union. Increased utility costs, labor migration, loss of strength of the national currency on the currency market contributed to lower of competitiveness industry.

The decline was accentuated when in the global market penetrated huge amounts of

cheap garments and textile products from China due to the elimination of quotas on exports from this country. Economic crisis has emphasized all these factors and consequences on light industry were multiple:

- diminishing number of producers of garments;
- reducing the number of manufacturers in outward processing system;
- increased production costs;
- reducing the number of employees;
- decrease of earnings for employees in light industry;
- decrease in purchasing power of customers;
- clothing and shoes acquisitions budget reduction;
- market penetration of low quality products;
- market penetration of cheap products.

2. Challenges for Clothing Industry

China's economic prosperity has helped increase wages of garment and thus low the attractiveness of the country for some producers. Institute Francais de la Mode estimated that the average salary in China's coastal areas increased from 240 euro in 2005 to 400 euro in 2011. [1] The consequence of this is the return in Eastern European countries, in Romania also, of outward processing. Apparel market was strongly shaken, many companies went bankrupt. From the market disappeared, companies, especially small and medium enterprises, who did not have the strength to face the very tough competition exacerbated by the crisis. On the market managed to stay firms who were able to adapt to the recession. Survival strategies differentiated from one company to another: reduction of costs, developing new products, finding new clients, dismissing a number of employees etc. Manufacturing companies who remained

had to face many challenges. Among challenges are: lack of qualified staff, low wages in industry or renewal of equipments.

Deprofessionalization of industry

A problem that must be exceeded by manufacturers in this area is the lack of trained personnel. They need to find people who are trained to do all operations of manufacturing a product. Over time one of the strengths of Romanian light industry was the well prepared and highly qualified workforce. Light industry is a traditional industry in the Romanian economy and Romanian workers were able to perform the quality products requested by partners. Economic crisis, low wages and difficulty of the activities have a strong contribution, to diminish the number of young people who want to work in this field.

Table no. 1 Vocational, post high school and foremen education in light industry Pupils enrolled

Type of schools	2005 - 2006	2006 - 2007	2007-2008	2008 - 2009	2009 - 2010	2010 - 2011
Vocational schools	34738	26768	21087	15751	8938	3357
Post high schools	227	118	164	239	242	245
Foremen schools	29	29	54	136	131	120

Source: Romanian Statistical Yearbook, 2011

We notice a dramatic decrease in the number of students enrolled in vocational schools in light industry, from 34738 enrolled in 2005 to 3357 in 2010. In foreman schools the number of students enrolled increase.

Table no. 2 Vocational, post high school and foremen education in light industry Graduates

Type of schools	2005 - 2006	2006 - 2007	2007 - 2008	2008 - 2009	2009 - 2010
Vocational schools	18212	14421	10892	8187	6708
Post high schools	105	77	10	97	77
Foremen schools	-	29	-	47	70

Source: Romanian Statistical Yearbook, 2011

In 2010 only 6708 students 2.7 times less than in 2006, graduated from a vocational school that offered a qualification in light industrial activities. Many of students enrolled drop out. One reason is the lack of perspectives of the field.

To manage the problem of human resources, lack of qualified personnel companies hire unqualified persons and train them on the job.

Low wages

One of the factors that contributed to business development of outward processing in our country was represented by cheap labor. Employees who worked in this area were among the lowest wages in industry. Lack of jobs in other areas, rising unemployment made the job supply to exceed. The existence of excess labor force generated the possibility for employers to tough negotiate wages offered. Entry into the European Union provided an opportunity for more staff to go to work (legal or illegal) in European Union countries for amounts higher than those earned in garment enterprises in Romania. The consequence of all these actions was a dramatic decrease in the number of those willing to work in this field.

In last years the average nominal earnings earned by those working in textiles is among the lowest in manufacturing.

Table no. 3 Average net nominal monthly earnings

Industry	2009	2010
Manufacturing	1146	1237
Manufacture of wearing apparel	773	858

Source: Romanian Statistical Yearbook, 2011

Hard work and low earnings made this area to continue to be unattractive to work force. Manufacturers to meet orders must use different solutions: appealing to workers

outside the cities, hiring workers from other countries, relocation of plant in rural areas.

Necessity for investment in industrial machines

Pre 2007 light industry investors have made numerous investments in equipment to ensure its competitiveness. Joining the European Union in 2007, the end of Multi Fiber Arrangement (MFA) in 2005 which open the markets to textiles and garments from China, and the financial crisis that started in 2008 have contributed to the adoption and implementation of strategies of tightening. Reducing costs and expenses affect technology. The demand for new equipment in light industry decreased. Manufacturers just bought equipment that they considered absolutely essential in attracting and retaining customers. Because many producers purchased second-hand equipments the second hand equipment market increased during this period. [2] Returning off partners is forcing executives to invest in new production capacity in order to be able to meet the quality requirements.

Dealing with customers in time of crisis

Although they do not have a high share in light industry, there are companies that produce products under their own brand. For this firms even more challenges, not just lack of trained personal. Because they create and distribute their own products, managers need to be in constant contact with clients' needs. The crisis has influenced the way people spend their money on clothes. Companies have to deal with two main types of light industry products customers:

- "Choose carefully" customer - this is a demanding customer, buying less but in better quality. A solution to gaining and retaining this customers is making very small series or small series with many models or making unique pieces or small series of very high quality. Prices may be lower, but for this educated customer, responsive to new things, low price is not the main point of interest when a garment is purchase.

- "First price" customer - for this customer price remains the main criteria for purchase. In recent years consumption has decreased due to the lower of purchasing

power. To attract this type of customer the solution is the low price. In the battle for lower prices local manufacturers are struggling with major famous brands that made large series, and have lower production costs and can afford to decrease the price because they obtain profit even when prices are low.

Adapting products to these two main categories of customers is a challenge for many companies.

Brand promotion

In order that Romanian producers to achieve competitive products is required to achieve performance in three main areas: design, production and marketing. Creativity is one of the defining features of the Romanian nation. Talent is not lacking to those who want to be involved in clothing. There are faculties that prepare young talents in fashion design. But creativity can manifest and technologies. Nationwide in 2010 increased the number of employees in research and development in textiles at 36 compared to 28 in 2009, but decreased the number of people working in research development in the manufacture of clothing by 50%, from 12 in 2009 to 6 in 2010. [3] Textiles and clothing industry in Romania is a traditional, well known throughout Europe and worldwide. Numerous partners who have made garments with Romanian employees represent the proof of Romanian producers ability to conduct a competitive manufacturing activity. Know-how gained through the development of outward processing and the return of brands show that in terms of getting production performance is not a challenge for Romanian companies. The weak point of Romanian light industry is the marketing activity. The companies in Romania have experience in manufacturing garments but not in brand development. Establishing a brand on the market requires both financial and time investments. On the market there are companies who have created real brands and distribution networks nationally and who compete with strong brands and international markets. Their success is the proof that the world market is not impervious to brands created in Romania. One way is to increase brand visibility, made it closer to consumers is the involvement in

social media, professionally. A study by Ernst & Young found that consumer confidence migrate far from traditional channels of mass communication channels towards that involves "community".[4] New trend offers tremendous opportunities and advantages to organizations who know can gain the digital consumers. Of this trend Romanian companies could take advantage when they create brands. Virtual promoting allows to the new brands to be known to more potential costumers and much more quickly compared to the period prior to the emergence of social media. Social media can be a very powerful tool for companies who aim contemporary consumers.

3. Conclusions

In the short term textile and garments industry will record growth: production, number of employees, etc. The return of top international brands on the Romanian market will contribute to the advancement of light industry. Although many major brand manufacturers are returning to Romanian we believe that Romanian light industry will not achieve the level registered before the entry into the European Union and the onset of the economic crisis in 2008. Textiles and the garment industry are constantly evolving. To have an important place on the map of garments and textiles production manufacturers need to create products that follow international trends, to create diversified products, to invest in machinery and equipment to carry out high quality products, also to invest in human resources. We believe that, first, the producers should give due importance to marketing activities. Product distribution and promotion of brand image using social media will allow to Romanian brands to be placed as famous brands and consumers need to have it. Neglecting promotion activity will make the Romanian producers to be known only as mere tailors. In the long term the market will remain only the best, those who add value to products or services.

Control-evaluation in NGOs

Ciucescu Nicoleta

“Vasile Alecsandri” University of Bacau, Faculty of Economics
ciucnico@yahoo.com

Abstract

In the frame of the organizations belonging to the public sector, as well in the ONGs are used self-monitoring being in early stage of development, in comparison with organizations working in private sector, which use strictly systems by which these organizations measures performance and effectiveness of the carried out activities. This paper aims to analyze a number of aspects concerning evaluation-monitoring. Methodological approach was based on using direct sociological investigation by mean of questionnaire.

Key words: management, objectives, results, self-evaluation

Clasificare J.E.L.: L31

1. Introduction

In an environment in which the establishment of ONGs has an extremely dynamic character, watching closely the trends of characteristic social needs of a community in evolution, the competition for resources is becoming more and more fierce.

Performance measurement is necessary because through this, ONGs have capacity to determine the measure in which the objectives were met, to evaluate their performance and to elaborate future initiatives to improve their performance.

2. Control-evaluation: definition, stages, typology, functions and characteristics

The control as a function of management is a set of activities designed to verify the performances realized by the organization, or by different compartments of it, at a given moment, compared to the set objectives, in the goal of a prompt intervention in the case of appearing of any abnormalities or

deficiencies in achieving those objectives. In other words, the control actively contributes to the achievement of the objectives of the organization, to the elaboration of the lines of action. The control is designed and developed as a process through which are realized the measurement of the current performances of a productive system or of another nature. [6]

As a function of management, control consists in all activities which compares the performances of an organization or of its various components with its projected goals and then the results are correlated with the pursued aims.

A control is effective when:

- is based on a flow of accurate, precise and clear information;
- uses simple methods of investigation;
- is appropriate and has low costs.

In case the verification of results confirms the goals achievement, then the management process is restarted and if there is a conflict between them, then we need to act in one of the following cases:

- if the results exceed the established goals, the objectives are reassessed;
- if the results are inferior to the goals, the performances are improved.

Expressed synthetically, the exercise of control – evaluation function involves the following steps:

- measuring the outputs;
- comparing achievements with predetermined objectives and highlighting the deviations;
- determining the causes of the constant violations;
- doing necessary corrections.

The control can be classified according to several criteria, such as:

- a) depending on the moment of the realization:
 - preventive (trying to avoid disturbances of the systems of the organization);

- feedback (focusing on correcting economic systems);
 - self-correcting (correcting automatically the appeared problems);
 - non-self-corrective (correcting the appeared problems only by the intervention of the manager);
- b) depending on its nature:
 - hierarchical (is done from the bottom to the top);
 - financial (checks the use of available money funds);
 - budget (uses statements of expected results);
 - technical (checks the quality of products and services).
- c) depending on the subject who launch the control:
 - direct (initiated by the manager);
 - indirect (realized by the manager on the basis of obtained results);
 - self (realized by the executant himself);

Control fulfills five basic functions:

- function of results evaluation- the control activity has the starting point the examination of the organization's concrete situation and performances (quantitative and qualitative);
- recovering function – it provides the opportunity to eliminate the disturbances from the activities of the organization once the flaws were discovered;
- preventive function – it helps to prevent imbalances if it occurs before the occurrence of events;
- informative function emphasizes the role of control in subsequent decisions;
- stimulating function of the human factor – strives to improve the employees' activity and results in order to obtain favorable conclusions after the control.

The managerial control function includes the following requirements:

- existence of an information system to allow rapid circulation of information related to performance standards;
- opportunity to be done directly to the scene inspection;
- analysis of the causes of deviations and their differential treatment according to their importance;

- avoid duplication of control activities and record activities. [10]

Professor Mihaela Vlasceanu that the first major problem faced by a non-profit refers to identifying and defining a clear and precise mission and it involves not only the statement of the purposes for which the organization was created, but also their expression in such a way as to make possible a permanent evaluation of performance.

The high standards and ambitious goals must be achieved at least by at least the best people from an NGO, and the assessment should always begin with positive comments. An evaluation should always begin with what the person did well. You can not build performance with what people do not have. And it is up to each organization to turn the strong parts of its members in actual performance and neutralize human weaknesses. This is the final test. [16]

There are several typologies destined to the evaluators, depending on several applied criteria and the nature of the organizations. Recently, Zeljko Sevic [14] considers that the evaluation can be divided into the following categories and phases:

1. Formal evaluation:
 - a. in the development phase;
 - b. in the retrospect process phase;
 - c. in the experimental phase;
 - d. in the retrospect phase of results;
2. The theoretical approach of decision
 - a. The phase of evaluable feedback (stages:
 - a.1. the specification of the program policy;
 - a.2. the collecting of informations about program policy;
 - a.3. the modellation of the program policy;
 - a.4. the analyse of the evaluability of the program policy;
 - a.5. the feedback for the users of the program);
 - b. The phase of analyse of multiattributive utility (stages:
 - b.1. the identification of the users;
 - b.2. the specification of the problems linked on the decision taking;
 - b.3. the identification of the results;
 - b.4. the identification of of the atributes conferred by the results;
 - b.5. the assigning of the ranks;

b.6. the standardization of of the scale (scales);

b.7. the measurement of the results obtained by the actors;

b.8. the utility calculation;

b.9. the proper evaluation;

b.10. the final data presentation);

Concerning the methodology, Zeljko Sevic examines five indicators of monitoring performance of an organization or of a program of social service delivery or policy: effectiveness (response to needs) and efficiency - the degree to which a process produces an effect with the lowest cost, quality - a producer's best response at customer service expectations, opportunity – delivering/fabricating a product or a service in accordance with standard procedures and exactly when it is needed; productivity - value added by the process divided by the value of labor and capital consumption, and protection - health care for those who produce and consume a good or service being delivered or delivery.

The monitoring-evaluation function is effective only if it has the following characteristics:

- it takes place continuously throughout the course of activities that are conducted, ie it is not carried out from time to time;
- it is preventative, it aims to prevent the occurrence of negative deviations;
- it is fair, it aims the decisions taken that lead to eliminating the causes triggering negative deviations.

3. The case study

The case study had in view the approach of the control-evaluation function in the aim to highlight the degree in which ONGs realize this managerial function and in the aim to identify causes that contribute to a non-preoccupation to the achievement of of self-evaluation of their actions. In this sense was elaborated a semi-structured questionnaire with 20 items that was focused on different aspects of the control-evaluation function, each of them having a scale with seven levels of response.

The case study realized in this paper focused on 14 associations and foundations in Bacau operating in various fields.

The essential pursued aspects made reference to:

- the examination of the particular situation of the ONG;
- the importance of the control in adopting of future decisions;
- the comparing the results with expected objectives;
- the use of a correct, precise and clear flux of information;
- the oportunity of realizing the control;
- the continuity of realizing the control;
- the realizing of the control straight at the place of running the actions;
- the realizing of a differentiated analyse of the deviations according to their importance;
- the realizing of the control by using indicators of efficiency;
- the realizing of the self-evaluation of their actions.

4. Conclusions

Following the centralization of the questionnaires, it was found that in ONGs, undergone to this research, the function control-evaluation is excersed in a measure corresponding to a mean score of 3,25. In terms of achieving self-evaluation of the actions, through open response items from the questionnaires, were identified the following arguments, which lead ONGs to not take actions of self-evaluation, as:

- *The actions for community support are good, because represent more than nothing*

Many NGOs are convinced that contribute to the benefit of the community, even if they sometimes offer services of dubious quality and believe that is not necessary to self-assesment to ascertain it, because they start from the premises that they want to make good. Consequently, these NGOs show a non-preoccupation and disinterest in thr goal to evaluate the infuence they have on the upon the community.

- *The existence of the difference between financiers and beneficiaries*

The evaluations made from the two perspectives, that of the financier and that of the beneficiary, are fundamentally different.

If in the private sector the dependence on beneficiary is maximal, in the public sector and that of NGOs this dependence is minimal, fact which leads to a diminished concern to evaluate the measure in which the beneficiary's needs were satisfied.

Having in view that the beneficiaries of an ONG and of a public organization are different from financiers, it results a differentiation of how are carried out the evaluations. In most cases, NGOs are more interested in the performance obtained through the prism of the financiers about at done actions than of served beneficiaries. So, when NGOs prepare evaluation reports for financiers, it is the trend to put in evidence the success of the actions, it not being the result of a self-evaluation process.

- *The non-existence of some systems which penalize poorly performing NGOs*

The evaluation of the performance at the level of NGOs as well of public organizations is significantly reduced compared with the performance at the level of the organizations practising in the private sector. The record loss of the organizations belonging to the private sector may lead to their bankruptcy, situation which does not occur in the case of NGOs or of public sector because we can not talk about bankruptcy.

- *The necessity of material resources*

Starting from the idea that the evaluation involves unproductive costs, these costs are much lower at ONGs precisely because these organizations are animated to the desire to make as many good things for their clients, and as a result, minimum investment, reduced appraisal and budgeting of all activities involving self-diagnosis and self-knowledge.

- *The lack of time*

When evaluating organizations, a barrier is the lack of time, in the sense that the members of a NGO does not rigourously evaluate their actions because they are too preoccupied to the needs of beneficiaries.

- *The lack of knowledges on how to carry out an evaluation process*

The evaluation process of NGOs involves to put into application of some specific knowledges about this process that should firstly have the board of directors and not at least all members of the organization.

- *The failure to use appropriately the results of the evaluation process*

When modifying or adjusting programs, many NGOs are not able to use their own strategies.

- *The inactivity of the Board of directors*

In a NGO, the Board of directors is the body that should work on watching the performances obtained at the level of the organization, the body which proves that in most cases is inactive or subordinate to the executive.

The Entrepreneurship- an Important Determinant for the Economic Development and Progress

Costin (căsătorită Călin-Costin) Georgiana-Delia
Valahia Univeristy of Targoviste
delia.costin@yahoo.co.uk

Abstract

The main objectives of this paper are: to highlight the important role of the entrepreneurship and of the entrepreneurs and also to identify the main characteristics of this field of study.

The base of this research was the management literature that presents a variety of definitions, characteristics, risks, challenges and benefits of the entrepreneurship.

The entrepreneurship is a science and an activity whose main character is the entrepreneur- a person often associated with the success, the professional fulfillment and also with the fortune.

Considering the result of this research, there was concluded that although this field presents some disadvantages and risks for the main actors involved, its benefits are not insignificant and it has an important contribution to progress, and also were identified the main aspects regarding the entrepreneurship and the entrepreneurs.

Key words: entrepreneurship, entrepreneur, business, economy, progress.

J.E.L. classification.: M13, L26

Introduction

The study of entrepreneurship is one of the reasons that led a number of scientists to devote their time and energy in order to deepen this field, to discover new information and to deepen the old knowledge.

Over the time, the entrepreneurship has been defined in various ways, each researcher trying in his study to capture as accurately as possible the essence of this science and to emphasize its importance not

only for the moral and material benefits that it offers to the entrepreneurs or for the economic development of a country, but also for the general development of society, for the progress of humanity.

The identification of the key aspects regarding the entrepreneurship and of the features of the entrepreneurs contributes to a better understanding of a field that is at the same time science, art and practical activity- the entrepreneurship.

The Entrepreneurship- an Important Determinant for the Economic Development and Progress

1.1. The entrepreneurship- basis of modern economies

The entrepreneurship is a science whose main character is the entrepreneur, an activity that involves the creation, the management and the development of a business, and at the basis of this field is the dream and the idea to start an own business, to see how it grows and to lead it to success. Also, the entrepreneurship is the ability to observe, to use and to take advantage of a number of favorable situations, occasions or events.

The definition of entrepreneurship and the identification of its essential characteristics represented and continues to represent point of maximum interest for the specialists who have noticed in their works that it is "the process of identifying of some opportunities and of transforming them into innovations" [1], but at the same time, the entrepreneurship is "a lifestyle for many people who want to promote their own ideas" [2]. Also, about the subject, authors as Sebastian Văduva [3] mentions that "the entrepreneurship, seen as activity in the service of business goals and subsumed of its purposes- the profit maximization-, it is the subject of the

concerns more and more assiduous of the specialized literature. It is related to a particular type of organization- the small and medium enterprise- causing significant particularities in the process of resources management in relation to the approach taken in the multi- and transnational companies.”

The importance of the entrepreneurship and implicitly of the SMEs, as well as the results of the entrepreneurial activity are materialized in: economic development, creation of jobs, increase of competitiveness, stimulation of the innovation etc are issues that have also been observed by authors such as Delia Popescu [4] who claims that ”the small and medium businesses are the backbone of the European economy. They provide an important part of total employment as the engine of the economic growth and of the competitiveness. In addition, the entrepreneurship can contribute both to the personal development of entrepreneurs and to solve some social problems.”

Although the results of the entrepreneurial activity are not insignificant, it can be said that they depend not only of the degree of intelligence, of the innate or acquired qualities and skills that the entrepreneur possesses and exercises in order to develop its business, but also of certain factors such as: the market where the business is positioned and acts, the state of the national economic situation and therefore ”The small and medium enterprises don’t represent a constant ensemble, but, on the contrary, they are in a permanent renewal. Daily, small businesses disappear, while others are created.”[5]

1.2. The entrepreneur- the main actor of the entrepreneurship

The entrepreneurs are people intelligent, ambitious, creative, optimistic, motivated by the desire to fulfill their professional dreams, to run a business and to be their own boss. They have always existed and will always continue to appear new ones until the disappearance of the human species.

Most of the researchers define the entrepreneurs as one of the major actors for the economy of a country, people that create jobs, contribute to the economic growth, stimulate the innovation and last but not

least, they contribute to the overall progress of society. For example, authors as Tanțau [6] claim that an entrepreneur is „that person who using intuition and creativity sees opportunities where others don’t see them, he turn them into innovative ideas that successfully apply in practice in order to create new jobs and to assume a calculated risk”, and other specialists [7] mention that ”an entrepreneur is primarily a producer of new things, a creator of activities in opposition to classic manager that is in charge of managing and running of existing enterprises. More concretely, the entrepreneur is gifted with the ability to perceive new economic and social prospects and to achieve new things on this basis or to perform previous activities in a different way, thus innovating.”

Also, about the entrepreneurs, certain authors [8] says that ”by its dynamic and concrete characteristics, roles and sizes, the entrepreneurs generates a timely turbulence in society, in every country, especially, in economic and social plan. In the economic plan, the entrepreneurs, through the businesses that they founded and developed, they causes significant movements of capital, simultaneous with their multiplication and of the capitalist and wage income. The economic changes are reflected in considerable changes in social plan, contributing decisively to the change of the social structure configuration and of its individual components. The synergistic effect is represented by the impress of a more consistent ”freshness” and dynamism of society and economy, in their overall. In conclusion, the entrepreneur is a main actor and a symbol of the market economy.

Irrespective of the field of activity in which the entrepreneurs decide to activate (industry, trade or services) and no matter how great is the desire that leads them to choose the entrepreneurial career, they see not infrequently in family, friends and specialists true groups of support that are meant to listen, consult and advise them from time to time.

It can be said that although a general valid profile of an entrepreneur doesn’t exist and to be a successful entrepreneur it has nothing to do with issues such as: gender, physical characteristics, geographical location, but only with moral traits among which there are

a number of inherent and acquired qualities such as: optimism, intelligence, ambition, self-confidence, sociability, ability to learn constantly new things, adaptability and others.

The identification of the reasons that lead some people to choose the entrepreneurial career represented and continues to represent an objective for the specialists in the field. For example, A.D. Tanțău [9] believes that “the reasons that determine a person to become an entrepreneur are endless. The main reason is the desire of many people to get rich quickly, and D. Popescu [10] mentions that the main reasons for a man to have his own business are represented by: the desire for independence, the spirit of revenge, the desire to succeed. So, this author [11] claims that “the most important mobile is the desire of being independent, that it can develop throughout life, but it can also be instilled in the family. This entrepreneurial learning in the family since childhood or adolescence, concerns, beyond technical skills to a range of basic skills such as: the desire of being its own master, of not depend of anyone. Another reason is the spirit of revenge. Starting from sociological trauma or emotional wounds, some entrepreneurs want to prove themselves that they are able to achieve something else that their destiny has reserved. Some family drama or existential crisis can also represent the basis of an entrepreneurial vocation. There are entrepreneurs for which the success in businesses represent their “revenge” for a destiny less favorable. For others, the creation of a successful business is the only way to permanently get rid of a modest social status. The living conditions since childhood may represent the main reason of an entrepreneurial process, primarily seen as a process of enrichment.”

It can be said that like any job, also the profession of entrepreneur involves a series of advantages and disadvantages. So, in the category of the advantages can be included: the independence, the professional fulfillment, the possibility to be his own boss, the possibility to choose the team (the employees) that you will work with, the possibility to establish his own work program, financial satisfaction and others, and in the category of the disadvantages can be mentioned: high degree of risk, high

degree of responsibility, risk of losing everything that it was invested (resources, hopes), less time spent with family, friends and own person.

About the positive and the negative aspects of the entrepreneurial activity, authors such as D. Popescu [12] mentions in the category of the advantages the following benefits: independence of action, financial opportunities, job security, creation of jobs for family and in the category of the disadvantages: the sales fluctuation, the competition, high responsibilities, the financial losses, the labor relations and the risk of failure.

Conclusions

As a conclusion it can be said that despite the fact that a considerable number of specialists have conducted various studies and analysis on entrepreneurship (a field that is at the same time a science, an art and a practical activity) and on its importance, it can be said that until now they couldn't develop a general valid definition of this science because every researcher has his own vision of its.

Although there isn't a general valid profile of an entrepreneur- the main actor of the entrepreneurship, he/ she is characterized mostly as an intelligent and ambitious person motivated by the desire to have an own business and to be his/her own boss. Also, about the entrepreneur it can be said that this individual assumes a number of risks and responsibilities and all these in order to achieve some moral and material benefits, in order to achieve their own fulfillment.

Destination Branding and Rural Tourism: How to Generate Tourist Flows in Mountain Area - the Case of Arieșeni, Alba County

Cotîrlea Denisa Adriana
Babeș-Bolyai University of Cluj Napoca
cotirlea.denisa@yahoo.com

Abstract

The present article was written in order to provide a framework that can boost the sustainable development of rural tourism in mountain area. It is already known that –in terms of natural heritage- Romania has the necessary resources that can meet the demands of mountain tourism development, both for winter sports and for summer. Because of this, the present article addresses the issue of generating tourist flows in Arieșeni, taking into account issues related to destination branding process.

Key words: rural tourism, destination branding

J.E.L. classification: L83, M31, M39

1. Introduction

Tourism has always been an important component of civilization, which has led to the permanent evolution of culture and humanity. Mountain area, one of the three defining components of landscape structure in our country, contributes heavily to the diversity of the tourist potential of Romania, offering a wide variety of touristic original attractions which are highly valuable, while anthropogenic tourism potential complete harmoniously the beauty of the nature.

Considering the rural tourism, it has a particular valence that is translated into a specific appreciation and increasing demand, since it is based on the attributes of the rural areas. Also, because rural tourism „represents a convergence of social and economic interests at local level” [3] and, at the same time, because the simple lifestyle and the opportunity of the temporarily return to nature represents a motivation for all socio-professional categories (because is the result of the tendency of conservation, health,

physical comfort, and not only), is detected - in Romania- the enhance of this type of tourism. In the context of destination branding, perceived as the process of identification of those competitive advantages of a particular area in order to differentiate itself from other similar regions that provide relative similar services and use their own strategies in order to attract tourists, Arieseni compete intensively with other mountain area from Transylvania and needs to enhance its attractiveness in order to attract tourists and to increase its position on the touristic market.

2. Issues related to rural tourism

Rural tourism niche focuses on life in rural communities, affecting those tourists who seek to benefit from the specific intrinsic qualities offered by the closeness to nature, by the sense of continuity and stability, by the living of a vivid and enduring history, by the close familiarization of the local community members - together with the concerns and specific activities (as opposed to irrationalism and anonymity of the human).

The specialists in the field of rural tourism classify it into numerous categories, depending on the specific of the area in which the tourist activity takes place. This is the explanation why there are several different terms, like ecological, thematic tourism or like agro-tourism [8].

The sustainable development of rural tourism plays a significant role and importance in the revival and the economic recovery of a region-especially because it is not characterized by seasonality-, the context in which the sustainable tourism involves the development of all forms of tourism so that the management and tourism marketing respect the natural, social and economic integrity of the environment, ensuring the

exploitation natural and cultural resources for future generations.

Rural tourism appears as a form of tourism focused on destinations from rural areas where activities are based on a close connection with the natural environment and are organized and led by local people - so that the local tourism resources, accommodation facilities, functional structure and other heterogeneous services are valued.

It is clear that the EU member countries have tourism potential, showing a significant degree of tourist attraction - fact that is appropriate to rural tourism development.

The continuous increase of the competitiveness, the desire to resist on the market and to achieve a higher profit leads administrators of the rural tourist pensions to become more and more interested in a continuous monitoring of tourists' needs in order to fully, fast and effective satisfy them.

3. Arieseni and its characteristics

Sourced in the western limit of Apuseni Mountains, Aries stream crosses one of the most spectacular valleys of the Carpathians. The middle and upper sectors of the watercourse form one of the most populated mountain valleys in Romania. Arieseni is located in the foothills of Bihor, in Alba County (Figure 1)

Figure 1 – Arieseni' location

Located in the picturesque scenery of Bihorului Mts, Arieseni shows the specific features of the mountainous landscape, with altitudes ranging from 850 to 1848 m, and covers the entire water source basin of Ariesul Mare. The karst phenomena bring a large variety of forms to the landscape: rocky abrupts, deep valleys and gorges, ridges as well as “negative” (underground) karst phenomena: caves, shafts, sinkholes, karst depressions, underground watercourses.

Arieseni has a remarkable potential for tourism development, the area having multiple valences to practice a varied and complex tourism. The main attraction is the slope Vartop, located on the northern side of Biharia Mt. The northern sides of the mountain allow for the development of the skiing area while the southern sides permit the development of the tourist facilities for accommodation, food etc.

Within some of the caves there still exist large ice deposits, of which the best known is the Glacier in Scarisoara. Also, the natural resources existent in this include nature reserves (*Cheile Gardisoarei, Avenul din Hoanca Urzicarului, etc.*), waterfalls (*Varciorog*), caves (*Scarisoara Glacier, "Poarta lui Ionele"*) and gorges (*Galbenei and Ordancusei Gorges*).

Even if tourism has suffered because of the transition to market economy and the development of mountain area was not a priority for the recovery progress of natural resources for tourism -fact attested in our country by the relatively modest equipment, both qualitatively and quantitatively, both in infrastructure and other areas like accommodation, leisure etc.-, current trends show the sensitivity of tourism to economic and social stimuli. Considering these, some of the strengths of Arieseni are summarized below:

- it is one of the most developed areas in Alba County, in terms of tourism;
- its surroundings represent ethno-folk and agro dedicated areas;
- it is positioned in the proximity of Ponor - Padis area, place of several famous tourist attractions;
- it benefits from the support of tourism development by local authorities (development of promotional materials, strong local initiative in promoting tourism, promotion of new routes, developing the network of tourist information centers);
- tourism activity is conducted both in summer and winter;
- camp students of Arieseni register a constant activity and is appreciated at local level;
- there is a rich tourist offer in relation to other areas of Romania;
- it benefit from a recognized gastronomy;

- many natural areas have remained in good preservation;
- the International Congress of Rural Tourism held at Alba Iulia promoted Apuseni mountains and Arieseni area, so future investments are expected;

4. Aspects regarding destination branding: Arieseni – rural tourism in mountain area

The process of branding helps a region to define its identity, to promote itself, to draw attention and to differentiate from others.

Branding process, which consists of identifying that specific characteristic of the product, service or geographical area is a difficult one, due both to fierce competition and to variable customer expectations.

In order to talk about tourist destination branding, it is necessary to mention what a tourist destination involves. As defined by the International Agency for Tourism, it represents a locality consisting of a set of touristic attraction elements which is equipped with accommodation, food and entertainment facilities for tourists- for a certain period of time. Therefore, mountain tourist resort can be defined as a place that has picturesque mountain surroundings and unpolluted environment that includes specific tourism structures and equipment (ski slopes etc.).

Considering this, it can be said that “[...] destination branding represents the process of developing and utilizing a unique identity and personality that distinguishes from competitors through a positive image, whose aim is to capture the essence of the destination in order to promote its core values” [10].

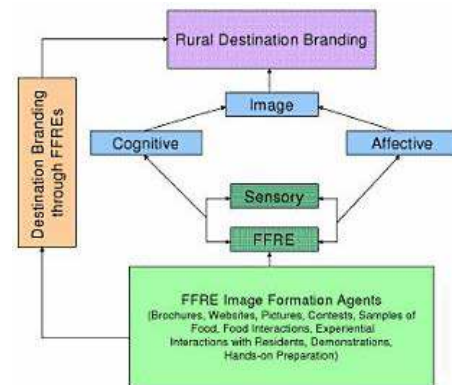

All these have been said, is necessary to mention the fact that “[...] rural tourism services have the specific attributes and can be identified as idea, entertainment, information, knowledge, change of consumer health and expectations, social innovation, convenience, food, security, deed, social event, output for consumption in production place, and etc.” [1].

The local brand of a community is represented by its distinctive features, shared by the main majority of the community. The development of rural tourism in Arieseni villages is supported by the existence of several particularly attractive places in which

customs and traditions preserved for many generations, ancestor festivals and crafts became art and are still alive in the consciousness of local people. Considering this, Arieseni tourism destination brand can be naturally promoted and developed, having as main advantages the undeniable authenticity and originality that contribute to the existence of a powerful symbol that “penetrates” the potential customers’ minds and impel them to buy the touristic product.

Also, the gastronomy specific to the area (FFRE – food and food related elements) represents one of the elements that can significantly contribute to destination branding through sensory identification (Figure 2).

Figure 2 – The role of FFRE in rural destination branding

Source: Kalkstein-Silkes C.A., *Food and food related festivals in rural destination branding*, 2007

Related to the rural character of the area should be noted that -although services or destinations that the tourists opt for are chosen according to the predominant motivational factors, such as: adventure, nature, religion, education and so on-, rural tourism requires a different kind of behavior, an alternative mentality to the prevailing one in classic tourism.

Among the distinctive features of Arieseni local brand, there can be mentioned the surroundings of the area, which offers to those who are interested several unprecedented beauties, activities that bring them back to the tradition specific to this area for centuries and natural phenomenon due to which nature lovers will feel comfortable (since Arieseni is the perfect place for hiking,

climbing, hunting, fishing, outdoor picnic, kayaking, walking and trekking).

Also, another element that definitely contribute to the process of destination branding are the festivals that are organized here year by year, like „Snow festival”, for example.

To the local brand building contributes, on a large extent, the locals, who are known for their patience in manufacturing household objects, craft inherited from their ancestors – “moți”. Therefore, Arieșeni completely soaks of traditions and culture and spreads everywhere its magic, in order to maintain the legend of the place alive. It is thus a sure fact that “the local communities play a pivotal role in rural tourism development as their participation and involvement are critical” [6] to the process of rural destination branding.

Rural tourism –in the context of rural destination branding process- has to essentially contribute to the conservation of natural and cultural heritage, representing a specific kind of responsible tourism, dominated by integrity, cooperation and commitment of all those involved.

It is directly related to its unique specificity based on territoriality - fact that highlights the history of the place, the daily life of local people, the specific customs and traditions; it also contribute to the national pride feelings’ development and rise our attention to the capitalization of local, natural and cultural assets. All these encourage a better understanding for the restoration and protection of the areas where it is mainly practiced.

Since the main function of the destination branding is to arise interest and curiosity in possible tourist’ minds in order to determine them to visit that particular place, it should be mentioned that Arieșeni has several extraordinary resources and picturesque places, hospitable locals, tasty food, dreamy landscapes and fresh air, and the smiles of nature and sport lovers make this region a perfect oases of calm and peace that can be perceived as a perfect destination both during summer and winter.

5. How to generate tourist flows in Arieșeni, Alba County

Marked by its unique specificity based on

the territoriality (community, district, region, micro-region or basin belonging to the rural environment) that highlights the history of the place, the daily life of local people and the specific customs and traditions, the rural tourism wants to contribute to directing some important tourist flows to areas where it is practiced.

Considering the current trend, the future tourist demand can know an ascendant trend because of the tourist facilities of which the tourist can benefit during his/her stay in Arieșeni. Focusing on foreign visitors, we would like to mention that the existence of accommodation facilities with high classification and the diversified offer of services in a preserved natural environment, unpolluted, will help to attract tourists from UK or Germany – tourists who are perceived as being more demanding, but also as being able to spend more than tourists from other countries.

Existing of transport services (that would work regularly and which have an increased frequency at least on the main routes) intra- and inter- regions would facilitate tourist traffic and would lead to increased tourist expenditure, to increased benefits felt by consumers, as well as to a better popularization (promotion) of tourist attractions.

On one hand, additional services needed to be developed in order to attract tourists refer to leisure activities, organized trips and specific events that promote local culture and customs.

On the other hand, uniqueness of Apuseni mountains attractions can lead to the visit of any tourists, not only of those who are passionate by nature. Considering this, it can be taken into account the probability that the visits will be shorter and rather occasioned by some other events. If the mountain tourism or recreational one (winter sports, hiking off-road etc.) addresses to a broad age category, the adventure one is mostly practiced by people under 35 years old, especially with a better and stable financial situation (at least above-average income). Housing conditions should reflect this, so accommodation structures with higher classification is required (3 F/S and 4-5 F/S).

Furthermore, it is necessary to provide additional services (besides the core activities) that aim at diversifying and

improving the range of activities performed. The attraction of a segment of consumers elder than 60 years old in active tourism – considering the actual conditions of Romanian economy- could be achieved by balancing the level of price with the quality of offered services.

Tourism demand in Alba County is particularly high for pensions with superior classification (3-5 daisies). It has also been noticed the necessity of arranging camping zones in Arieșeni. Foreign tourists mentioned on different forums and websites that accommodation services in Arieșeni are, usually, inferior to accommodation services they are used to. Some tourists also mentioned the necessity of more shops (food/non-), as well as better supply of local handicraft shops.

In the case of those tourist who are attracted mostly of cultural sights is also recommended accommodation services with higher classification; touristic products of the area focus a certain type of tourist attractions (fortified citadels, wooden churches, vineyards), fact that implies the existence of specialized guides and other high quality auxiliary services. All of these are valid as far as cultural tourism in Alba County (and in Romania, in general) is practiced mainly by foreign tourists. In addition, many of the historical monuments or archaeological sites need to be renovated or to be equipped with special visitor facilities.

For a higher tourist traffic in the Arieșeni area, we suggest the following: promoting the area and tourist objectives with the help of a tourist guide, specialization of accommodation and food service staff, improving quality/price ratio; developing road infrastructure (the means of transport that reach the area are very few), implementing household utilities, information and support regarding the access to structural funds.

Considering the fact that the World Tourism Organization experts say that almost no activity in the world “*needs a more active, ingenious or aggressive promotion as tourism does*”, we strongly recommend the implementing of a promotional strategy in Arieșeni touristic area, because the zone is well known to the people leaving in the nearby towns, but not discovered by the rest of the country, neither by the foreigners. The

promotional strategy should assert an attractive tourist image of the services that Arieșeni offers, highlighting its natural, cultural and historic attractions.

In order for the rural tourism in the Arieșeni area to grow –and thus this region to become a tourist resort that meets current requirements- we strongly believe that a strategy for tourism development should be implemented [2]; this should include superior enhancing of the tourism potential; the increase of economic and social efficiency of tourism activity; the development of all potential forms of tourism that can be developed in the village and in its surroundings; preservation and conservation of the environment and sightseeing.

In order for Arieșeni to become an equipped mountainous area, is needed to combine good accessibility for tourists with a strong attractiveness of natural surroundings and accommodation, food and entertainment elements [2]. Issues raised by equipping a tourist area, however, are much more complex and the approach should be done in a scientific vision, of marketing, allowing a fair correlation of the tourism product and promotion decisions on both domestic and international tourism market.

In order to reduce the negative impact of the phenomena perceived as nature hazards and to ensure a proper tourism development in accordance with the principles of sustainable development, the creation of a forest belt on the mountain sides close to the slopes is proposed, aiming at soil consolidation against slides.

The natural factors of the area, namely the relief, the climate, the nature monuments, represent an outstanding potential for touristic development. Even if the national road DN75 crossing the village from east to west, along Aries river, separates the Biharia Mts. from Batrana Mts., in order to allow access from DN75 to Arieseni resort and Arieseni skiing area, crossroads shall be developed in compliance with regulations in force to ensure the optimal comfort and safety of the traffic. Roads (streets) to be developed will be of 3rd category, with asphalt cover, equipped with ditches, gutters and bridges, according to the condition of the soil. The roads should be 6.00 m broad.

Measures to increase the safety mountain tourism product need to be much more

developed - between the directions where improvements would be needed, we mention the arranging of mountain refuges, increasing efficiency of Rescue services, training a larger number of mountain guides, appropriate signing and marking of all mountain routes.

There were also identified several investment opportunities, like: hostels, motels and holiday inns; catering units; shopping centers; animal husbandry; slaughterhouses, sausage factories and canneries; woodworking; shooting box.

6. Conclusions

Considering the fierce competition existing between destinations both nationally as well as internationally, is a sure fact that each destination have to try to readjust on the fly, to change its image depending on the global trends. As in political, social and economic environment, is essential to eliminate the practice of "forms without substance".

As rural tourism is a motivation for all socio-professional categories- because of the simple lifestyle and the possibility of temporary return to nature (the result of the trend of preservation)-, mountain and rural tourism activities in Romania intensifies day by day.

It is a sure fact that in order to expand the area of provenience of both foreign and Romanian tourists in Arieseni area is needed to invest in infrastructure and in accommodation facilities, to develop the existent services and to improve them, to provide a better quality with an adequate price, to consider appropriate measures in order to facilitate and stimulate the activity of tourist services providers (fees, taxes), to support their promotional efforts, to promote and assure both environment and consumer protection and to provide training for personnel that develops its activity in tourist domain.

In this respect, public authorities can contribute decisively to the growth of tourism demand, both for national and foreign tourists.

vio.radulescu@yahoo.com,

Abstract

Markets have become far too competitive for organizations to focus efforts only on consumers, so in addition to market and customer analysis, an equally important step in terms of marketing audit, the pre-development phase strategy marketing and its implementation in the future is to analyze competition. This article aims to present the main steps to be used for a comprehensive and efficient analysis competition.

Key words: competition, competitive environment, competitive analysis, marketing strategies

J.E.L. classification: M31

Introduction

Competition in the European market is a challenge for any company. This implies a favorable response from competitors, in other words, speed of adaptation to existing business, ability in capitalizing on existing opportunities in the competitive environment and responsibility for consumer issues and society in general. In other words, the definition and implementation of strategies to meet the overall objectives of the company are not sufficient. It is necessary to assume corporate responsibilities vis-à-vis consumers and society in general.

Competition in the European market requires the development of skills of each competitor, through which the company can prove their uniqueness and thereby significantly differentiate from other competitors. Specifically, the company powers refers to skills and technologies that will enable it to provide a real benefit to its target consumers. Managers of these companies will make efforts to understand

customer needs and actions direct competitors.

Studying the competition is an important factor in formulating marketing objectives and strategies of the organization and at the same time, a reference framework for adopting competitive conduct based on ethical and fair play.

This competitive behavior can be supported by a series of actions, able to lead to the knowledge of existing competitive situation at some point in the reference market. Therefore, the company will initiate analysis of existing competition in the market, activities that will have a permanent, comprehensive and systematic character, as this information will be processed, interpreted and used to develop marketing strategies to be implemented by the company.

Competitive environment

To make the best marketing decisions, the company will be aware of the implications of competition on their own work and take care to build a system of competitive information on a variety of factors specific competition. The purpose of this initiative is to develop competitive skills to ensure the company achieve a strong position in the reference market. Competitive intelligence system must provide relevant answers to a series of questions, such as:

- What are the main objectives pursued by market competitors?
- What are the resources and skills available to competitors?
- What is the intensity of competition on the relevant market?
- What are the strengths and weaknesses of competitors?
- What are the marketing skills held by the competitors in the competitive struggle?

- What are the strategies implemented by the competitors?

To know the intensity of competition is necessary to evaluate the competitive environment in which the company operates. Thus, competitive environment analysis can be used five competitive forces identified by Michael Porter:

- *rivalry competitors in the industry.* Number and size of competitors may influence the intensity of competition in the sense that a large number of competitors in a market increases the rivalry between these. The same thing happens, however, where there is a small number of competing forces approximately equal because they will try a series of strategies and tactics to gain a better competitive position. Also, the rivalry between competitors increases when market share is stable (the market is mature) or declining, if the fixed cost or market exit barriers are too high.
- *threat of new entrants.* New entrants are often a serious threat because they have sufficient financial and material resources, but mostly "psychological" manifested by the desire to occupy a large market share. Entry is subject to a number of entry barriers such as the need for capital, access to know-how, economies of scale and product differentiation through brand loyalty to a product, brand access to distribution channels, legislation, authorization rules / patent etc. Also conditional market exit high cost (depreciation of equipment, training of employees), legislation etc.

Kotler and Keller believe that the most attractive market segments are those where market entry barriers are high and output is low. [3]

When both the barriers to entry and exit are low, firms enter and exit the market easily leaving most of them when the situation is stable. When both barriers to entry and the exit are high, industry is characterized by high potential profits, but companies are facing a very high risk because competitors face bad performance but do not want to leave the market.

The most difficult situation is when barriers to entry are low and the output high, as companies enter the market in favorable situations, but it is very difficult to leave the

industry when things get worse.

- *threat of substitute products.* In determining the number and intensity of competition in a branch / organization must also take into account the indirect competition coming from substitute products, in terms of accessibility difficult in certain products / services, due to their price and distribution, product substitutes is a viable alternative for most consumers, so market segments for which there are actual or potential substitute products are characterized by a low potential default rates and profit organization follow a declining path.

- *bargaining power of buyers* also affects the intensity of competition in a particular field of activity, buyers will try to select those organizations providing the best products in terms of quality, the lowest prices and services. On a particular segment, bargaining power of buyers increases when they become more focused and organized, it is a process of vertical integration thereof, the offer is indiscriminate when buyers are price sensitive, etc..

- *bargaining power of suppliers* plays a decisive role in increasing the level of market competition, which is favored by the small number of suppliers, their concentration or organization to obtain favorable terms, the absence or limited number of substitute products, the quality of commodity to the industry, the high pricing etc.

Competitive Analysis

Competitors analysis is a complex and demanding, but can provide valuable information necessary to make management decisions.

Methods of analysis of competitors must respect the principles of ethics and legality, the only way the company will adopt competitive conduct based on fairness and loyalty.

Competitive analysis involves tracking of successive steps for staying answers to questions above. Specific steps in the analysis are the following:

- identify current and potential competitors,
- analyze the strengths and weaknesses

- of direct competitors,
- description of the profile competitors and work performed by them,
- knowledge of marketing objectives and strategies and tactics for analysis of main competitors,
- Studying competitors in the market positioning,
- benchmarking application,
- creating a competitive information.

Competitive environment analysis leads to identify the main competitors of the company based on product line and market segment concerned. [5]

Moreover, identifying competitors must be done and depending on that market performance, given the area of business, market share and growth potential.

Also, another tool used in competition analysis is the product map outlining the competitors, for all products in the line and the main market segments in which they operate.

Once you have identified the main competitors, the next step is to analyze their strengths and weaknesses. David Parmerlee considers that the measure strengths and weaknesses of competitors have established five basic elements that provide a clear profile as competitors, namely the ability to meet consumer needs and desires, reputation, financial resources, approach market the product, key attributes. [5]

Kotler, Keller considers that the analysis of competitors must be measured three variables: [3]

- Market share - the share of each firm in the reference market;
- The penetration rate - the percentage of consumers who said a contestant was asked to name the first company that comes to mind in that sector;
- Preference - Percentage of consumers who meet each competitor in terms of preference for it.

Companies that gain significant share in terms of penetration and preference will gain significant share in terms of market share and profitability.

In analyzing competitors can take into account a number of indicators expressing their profitability: gross profit, investment, growth rates, marketing costs and so on, the difficulty consists in obtaining this information.

Profile description of the competitors and work performed by them requires the application of appropriate methods for this purpose. A relatively easy way of understanding of marketing activity undertaken by a competitor is observation.

The observation may know that a competitor actions it has taken in product characteristics, price, distribution and promotion.

Knowledge of the most important objectives competitors should be an important point in the competitive analysis.

If these targets are correctly identified, they can be expected actions by competitors.

For example, they enhance their competitive actions, addressing offensive strategies where say they aim to become the market leaders. To increase market share, actions aimed at achieving this objective aimed at reducing prices, heavy investment in advertising, sales promotion, all these actions can be observed by those who follow the activities of competitors. As a result, market behavior may be known and thus can be taken swift action to counter the actions taken by competitors.

Marketing research aimed at studying the positioning of competitors in the market are recommended because they can lead to competitive analysis objectives [2]:

- Identify the main characteristics of the product or brand positioning researched
- The order of these features by importance attributed by consumers purchasing decision-making,
- Assess characteristics of products or brands using an interval scale (semantic differential, Fishbein model - Rosenberg).

Based on research results is achieved positioning map, which is a practical tool through which he can be better visualized position of each product or participant in the market after a series of attributes (product quality, product availability, additional services, sales force, degree of notoriety).

Interviewees give marks from 1 to 10 for each feature; graph is achieved by representing each features one axis, all axes starting from the same point radial size of the angle between the axes is proportional to the frequency of that feature .[2]

On these axes is the average for each feature separately for each product or competitor. This position must be

communicated to consumers because, differentiated advantages will be charged on the supply company. Because the approach strategic positioning involves implementing strategies that are designed to present the company's offer so that it occupy a distinctive place in the minds of consumers.

As we have seen, identifying the strengths of competitors is a necessary objective in analyzing competition. Then, these strengths identified will be imitated. This assessment is known competitive benchmarking and is a competitive analysis method which compares the activities best carried out by those competitors consider "best-in-class" own activities.

Benchmarking can be seen as an instrument capable of improving a company's performance and competitiveness in business. [1]. Benchmarking can also be defined as the process of continuous improvement by identifying, understanding and adapting the best models from inside or outside the organization. [6]

Because these advantages of competitors change constantly, it is required a systematic assessment of the competitors activities. Competitive performance of competitors will be measured both quantitatively and qualitatively, so that they can be properly evaluated by benchmarkers. Comparison of its activity with that of the best competitor can take place regardless of the field of the latter.

Purpose of benchmarking is to improve organizational performance and increase company competitiveness. By analyzing marketing strategies and tactics used by leaders in a particular area and transpose characteristics identified in their company, this goal can be achieved.

Building a competitive information system is necessary because all information should be collated and analyzed previous steps properly. In addition, they will be stored and updated according to the company's needs in this regard.

Usually, in order to obtain information of how to competitor activity, recourse to secondary sources relatively easily accessible and less expensive. As sources of information can be used:

- local, regional or international
- annual reports in some publications,
- newspapers and magazines,

- administrative and supervisory authorities competition
- market research institutions,
- consultant firms,
- specialized exhibitions and fairs,
- advertising and sales promotion techniques,
- sales force of competition,
- personal contacts,
- electronic data banks,
- other.

Regardless of the competitive analysis method chosen, all information obtained about competitors will be processed and analyzed carefully by competitive analysts of the companies. It recommended the creation of a competitive information system capable of providing essential elements for the activity and situation of competitors, so choosing and implementing competitive marketing strategy can take the most beneficial conditions for success.

Also this competitive information system must find their place within the marketing information system, in order to prove its effectiveness in certain situations and to allow key decisions at the managerial level. The foundation of marketing strategies based on strategic planning requires a market orientation, which shows that both customers and competitors are the two essential components for the company.

Marketing management strategy of the planning process is in essence proactive in the sense that it defines and forms the future of the organization and responds to changes in technology, environmental conditions and meets the needs of customers, and also the stakeholders. [4]

Conclusions

Highly competitive environment of the European space, requires companies to develop a proactive behavior in the sense of knowledge of competition in the industry but existing competitiveness. Involvement with responsibility for studying, analyzing and developing an information system is a competitive activity to adapt to the peculiarities of the competitive environment.

Knowledge of real-time information on competitors and the ability to analyze and structure in accordance with the company's

marketing objectives can be essential skills that contribute to competitive advantage in the reference market. Therefore, companies must invest in this competitive analysis by allocating adequate budgets, but also by training specialists.

All results of the analysis of competition and competitors in the industry will be used for the adoption and implementation of competitive strategies capable to lead towards achieving objectives and achieve market vantage point.

Abstract

This article aims to be an overview of what Organizational Justice represents and how the concept evolved in the last decades, highlighting older and newer research on the topic, with the final purpose of showing how important organizational justice is for the management of an organization, in a context of hard competition, showing how important every instrument is in the management process, making the difference.

Key words: organizational justice, environment, organizational climate, employee, organization

J.E.L. Classification : J2, J24, M54

Introduction

No later than 1990, Jerald Greenberg (Greenberg, 1990), one of the most consecrated researchers in Organizational Justice was saying that the 1990s promised to be a decade in which the viability of organizational justice as meaningful organizational construct will be fully realized. The definitional work of the 1960s and 1970s, along with the qualifications elaborations offered in the 1980s, have set the stage for what promises to be an era in which issues of justice and fairness – in many diverse forms – will rise to the top of the field of organizational behaviour’s collective research agenda. For this to occur, there first must be some serious improvements in the way organizational justice researchers operate.

He couldn’t be more right, years to come just confirming his theories, as we will further see.

Researchers today assert that just 20 years ago (and some might say even more recently than this), the study of organizational justice was much more straight forward than it is today. The term “organizational justice” evoked a construct operationalized as employees’ perceptions of the fairness of their outcomes (i.e., distributive justice [DJ]), of the processes leading to said outcomes (i.e., procedural justice [PJ]), or IJ, the social accounts given for processes or outcomes (i.e., informational justice), and the manner in which employees are treated interpersonally by those with authority over them (i.e., interactional justice).

Indeed, surveyed employees’ perceptions of distributive, procedural, and interactional justice were shown to positively influence constructs such as job satisfaction, organizational citizenship behaviour, job performance, and commitment; and negatively influence constructs such as counterproductive work behaviours turnover intentions, workplace hostility, revenge and retaliation. The effects of justice dimensions measured in this way have been confirmed meta-analytically (Cohen-Charash & Spector 2001; Colquitt, Conlon, Wesson, Porter, & Ng 2001), as have interaction effects between justice dimensions (i.e., fair procedural or interactional treatment can mitigate the effects of unfavorable and unfair outcomes; Brockner 2010).

Then

The importance of the justice research conducted across the decades (of which this article is just a small sample) should not be under-estimated. Few would contest the implications for management practices, the implementation of personnel systems, and the

formation and delivery of human resource practice (Gilliland, 2009; Truxillo, Bauer, & Campion, 2009).

Historically, the mechanism driving justice effects was thought to be self-interest (Cropanzano, Rupp, Mohler, & Schminke, 2001). Coined the instrumental model (Tyler, 1987), this perspective assumes individuals are largely motivated by economic rationality (Barley & Kunda, 1992) and therefore will mostly act in ways that maximize outcomes for the self (Bazerman, 1998; Becker, 1971). Employees were said to desire justice because fair practices were seen as best owing of control, and with control individuals might be able to more directly influence the favorability of their outcomes (Thibaut & Walker, 1978).

Now

Taking a more contemporary view of organizational justice takes us beyond self-interest. Therefore, employees care about justice because it is indicative of the extent to which they are valued by the organization, which impacts their attitudes and behaviours at work.

An even more recent theoretical force within the justice literature is one that argues that justice is more than a means to an instrumental or relational end—that justice is an end to itself—an end that is closely tied to our human need for meaningful existence, and an evolved human tendency to punish those who violate the rights of others (Cropanzano, Goldman, & Folger, 2003; Folger, 1998; Folger & Skarlicki, 2008). Referred to as the *deontic model*, this represents a perspective that, to date, had not been explicitly taken—that employees are aversive to injustice for no other reason than the fact that injustice involves a discretionary, unethical act against an undeserving party. This is a unique perspective, in that by arguing for justice motives that lie beyond the self, researchers are able to study how individuals react to observed injustices committed toward others (i.e., third-party justice perceptions; Skarlicki & Kulik, 2005). Indeed, research has shown that third parties can experience strong emotion and seek punishment for transgressors upon witnessing another’s unfair treatment, even when they do not

closely identify with the victims or are unharmed by the event themselves (Turillo, Folger, Lavelle, Umphress, & Gee, 2002).

A different view

How can these various theoretical and empirical advances guide our understanding of recent justice research, and with it, set an agenda for future research? It is reasonable to first claim that employees face fairness-related events at work on a daily basis. Experiencing these events launches a number of processes, including (a) the formation of justice judgments, (b) the holding of others accountable for unjust acts, (c) the development of relationships with parties held accountable for justice-related events, and (d) the development of employees’ subsequent attitudinal and behavioural responses.

Considering justice in this way allows us to recast the various approaches taken in the justice literature according to differences in perspectives as experienced by the employee. That is, employees may perceive themselves as potential victims of injustice, they may perceive their work unit as a target of collective (mis)treatment by upper management, they may act as third-party observers of the justice-related experiences of other individuals and groups, and in the broadest and most outward-looking case, they may judge the actions of their employing organizations toward external communities and environments.

This paper classifies these perspectives according to whether the employee is looking in (i.e., considering their own treatment), looking around (i.e., considering the climate of justice), or looking out (e.g., as a third-party observer of others’ treatment or in judging the corporate social responsibility of the firm).

Looking in

Looking in refers to how fairly employees feel they themselves are treated. At first blush, this may seem to take us back to the historical approach described at the start of this paper—where employees are asked for their judgments of distributive, procedural, and interactional justice. However, a more contemporary

consideration of this issue suggests it is much more.

The employee responds to survey items such as “How fairly am I treated by my supervisor?” and the bulk of past justice research has largely been studied, to use a grammar analogy, in the first-person singular (Kray & Lind, 2002). If justice is to be treated as a broad, cumulative, and dynamic employee experience, these “looking in” perspectives are not enough. Employees also “look around” and “look out” as they form judgments that ultimately influence their attitudes and behaviours.

Looking around refers to how social processes between individuals lead to collective perceptions of justice (i.e., justice climate). Looking out considers third-party observances of justice both internal and external to the organization.

Looking out

The last major component of the employee-centred model of organizational justice proposed in this review involves looking out. This refers to the process by which employees perceive the treatment of others and react accordingly. This perspective is not referring to social comparisons made during the process of determining the fairness of one’s outcomes (e.g., as articulated by equity theory; Adams, 1965). Nor is this referring to social information processing within groups, leading to the formation of justice climate.

Third-party justice.

Only recently has justice considered how individuals react to how others are treated (DeCremer & van Hiel, 2006; Skarlicki & Kulik, 2005). We can look to the contemporary theories described earlier to draw support for the idea that it is not self-treatment alone that drives worker phenomena.

A key feature of this theory, that previous models of organizational justice have lacked, is the notion that the observer need not be the victim of the mistreatment, and that the deontic reaction may be just as strong when

the injustice is witnessed by a third-party observer.

These ideas were brought into the organizational justice arena by Turillo et al. (2002), who conducted a series of four studies that replicated and extended Kahneman et al.’s (1986) results.

This article sought to recast contemporary justice theory according to how justice is subjectively experienced by employees. It is posited that employees traverse through their working lives via the experiencing of events.

The content of the events may vary—they may involve the allocation of outcomes, the carrying out of procedures, communications between people that vary in interpersonal treatment and information sharing, and even firm-level behaviours toward external stakeholders. These events are often interpreted by employees through the lens of justice.

Group Level against Individual Approach

From a different point of view, Despite these scholarly and practical achievements, much of the organizational fairness literature tends to share a common constraint. In particular, it has been conducted at the individual level, with only scant attention devoted to group-level investigations.

This is potentially problematic because, as we shall shortly see, there is sufficient evidence that justice operationalized at the level of the work team, what has been termed justice climate, is an important predictor of organizationally relevant criteria (Ambrose & Schminke, 2007;

Distributive justice pertains to the fairness of the outcomes that one receives (Frohlich, 2007; Sabbagh, 2001, Markovsky & Younts, 2001). Probably the best known theory of distributive justice is Adams’s (1963, 1965) equity theory, which posits that the fairest allocations are those that reward people in proportion to their contributions. In addition to equity, there are other allocation standards, such as equality and need. People often try to balance these rules by using them in combinations (Frohlich & Oppenheimer, 1992). Generally speaking, there is little research on collective perceptions of distributive justice, which is unfortunate

given some recent promising findings (e.g., Roberson, 2006a; Spell & Arnold, 2007).

Procedural justice involves the perceived fairness of an allocation process. According to Leventhal, Karuza, and Fry (1980; Leventhal, 1976, 1980), the following six attributes make processes fair: consistency, freedom from bias, accuracy, representativeness for all stake-holders, correctability, and consistency with ethical standards. As we shall illustrate later, procedural justice has had by far the most influence on justice climate research (e.g., Mossholder, Bennett, & Martin, 1998; Naumann & Bennett, 2000, 2002).

Interactional justice concerns the fairness of the interpersonal treatment one receives from others (e.g., Bies, 2001, 2005; Bies & Moag, 1986). In their initial work, Bies and Moag (1986) emphasized the dignity and respect with which decision makers treated others. Bies (1987) expanded on these ideas, arguing that it was also important for organizations to share information and provide adequate explanations regarding important decisions (Shaw, Wild, & Colquitt, 2003; Sitkin & Bies, 1993; Sitkin, Sutcliffe, & Reed, 1993). Colquitt (2001) treats these two types of interactional justice separately, referring to the former as “interpersonal justice” and the latter as “informational justice.” Notice that Colquitt’s framework creates a four-factor model of justice (distributive, procedural, interpersonal, and informational) that has received empirical support (Colquitt et al., 2001; Masterson, Byrne, & Mao, 2005). Within justice climate research, a few scholars have begun to successfully employ Colquitt’s four-factor model (e.g., Liao & Rupp, 2005; Mayer, Nishii, Schneider, & Goldstein, 2007), whereas others have continued to employ the original three-factor conceptualization (e.g., Moliner, Martinez-Tur, Peiro, Ramos, & Cropanzano, 2005).

Prior to the construct validation work of Colquitt (2001), informational and interpersonal were known collectively as *interactional justice* (Bies & Moag, 1986).

Although this work has been useful and informative, it has tended to be conducted at the *individual level*. As Mossholder et al. (1998) pointed out, such an individualistic approach fails to take full account of the social context within which justice

perceptions are shaped. Within a unit, members interact with each other, observe each other’s behaviour, and engage in *collective sense* making, a tendency that may ultimately lead to the development of shared perceptions on how to evaluate justice-triggering events (Naumann & Bennett, 2000; Roberson, 2006a, 2006b).

Consistent with this argument, recent research has suggested that justice can be viewed as an emergent property formed in the course of interactions among members within the same unit.

The functional approach is different, in that it emphasizes the effects of a unit-level construct within an organizational system. A construct is understood, at least in part, by its consequences; it becomes meaningful when it produces certain effects. When individual-level constructs have similar effects to their group-level counterparts, then this construct is considered to be functionally isomorphic across levels. Although this assumption is not typically stated explicitly, unit-level justice researchers have argued for this sort of cross-level isomorphism.

Conclusions

Team-level justice is a promising area of study, but it is also a young one. In recognition of this, we have here emphasized first principles. Based on the work of Morgeson and Hofmann (1999), we have seen that collective fairness is consistent with both the structural and the functional approaches to group-level constructs. Considerable work suggests that interpersonal interactions of various sorts boost justice climate (e.g., Colquitt et al., 2002; Naumann & Bennett, 2000; Roberson, 2006a, 2006b), whereas other findings suggest that fairness shows functional isomorphism across levels of analysis (e.g., Liao & Rupp, 2005; Yang et al., 2007).

Beyond these important meta-theoretical issues, we then discussed the five compositional models proposed by Chan (1998). Here, we observed a need for greater research.

Scholars now have at least a rudimentary idea of the causes and consequences of justice climate. Finally, and perhaps most

notably, we observed that there were actually two different types of collective justice. Justice climate has amassed a large amount of research (Rupp et al., 2007a). However, intraunit justice climate, the fairness with which teammates treat one another, has also proven to be of value (Cropanzano, Li, & James, 2007). Li et al. (2007) found that intraunit justice climate has incremental validity, and in some cases, stronger effects, than the better known justice climate. Likewise, Li and Cropanzano (2008) found that justice climate exerts its beneficial consequences by prompting higher levels of teamwork quality. This work is still in its infancy, but it is off to a good start.

Theoretical Implications

Given the considerable promise of research on justice climate and intraunit justice climate, scholars have begun to retool their theoretical ideas. In this section, we will briefly review three trends in the literature, suggesting how they may develop in the future.

At the individual level of analysis, organizational justice researchers have long known that procedural fairness has a greater effect when an outcome is unfair or unfavourable. In other words, people care more about the process when the outcome they obtain is not what they would have preferred (for reviews, see Brockner, 2002; Brockner & Wiesenfeld, 1996). Although this finding is well established, unit-level fairness research adds corollary mechanisms that explain how workers might render fairness judgments without personally experiencing a negative event.

- Drawing on SIP, Roberson (2006a, 2006b) found that people discuss events that occur in their workplaces. Over time, these discussions can produce agreement. This process may be further enhanced as emotional information spread through the process of justice contagion outlined by Degoey (2000). Fairness may result from the process of workplace sense making.
- Based on the deontic theory of justice, Folger and Salvador (in press) argue that we care about more than simply how we are treated. We may respond negatively to the treatment of others even when our

own outcomes are not impacted (see Brockner, 1990, for a real-world example).

Consequently, justice may be valued for its own sake, and workers may even punish authority figures that harm their teammates (cf. Lerner, 2003).

For justice research, these are intriguing ideas, as they imply that feelings of unfairness need not be based exclusively on the personal receipt of an unfavourable or unfair outcome. Rather, the sense of injustice could spread through a team, even if the team includes individuals who were not personally harmed. Perceptions of fairness, in other words, can sometimes emerge as a property of a collective. We may simply imitate what others think and feel (Degoey, 2000).

According to Folger and Salvador (in press), we may also be directly affected by the treatment others receive even if we do not directly interact with them (Turillo et al., 2002). Of course, nothing reviewed in this article denies the importance of individual-level justice. However, the work discussed herein challenges researchers to incorporate the collective sense of fairness into their conceptual models. These are exciting possibilities, signalling a fresh look at workplace fairness. Among other things, unit-level justice research links fairness to other important organizational processes. These include such things as work-team effectiveness (Li & Cropanzano, 2008) and the success of business units (Simons & Roberson, 2003).

Counterintuitive reversals

It is interesting that unit-level justice can occasionally turn “good” things into “bad.” For example, Naumann and Bennett (2000) found that group cohesion, which most would view as desirable, produces greater agreement as regards justice climate. This suggests that cohesion might promote a more positive response toward an employer that is generally fair but a more negative response toward one that is generally unfair.

A strong climate could be formed when a cohesive workforce unites against unfairness. From society’s point of view, this is probably a good thing as it may prompt organizations to improve their management

techniques to the benefit of all. Still, it is interesting that efforts to promote group consensus can backfire on a firm that does not accompany these efforts with fair policies.

In their work on multifoci justice, Bashshur et al. (2008) provide another interesting reversal. These researchers assessed both justice climate that resulted from the action of the organization and justice climate that resulted from the action of the immediate supervisor. Bashshur et al. report some evidence, admittedly limited at this point in time, that employee responses were very negative when they had an unfair supervisor inside a fair organization. If these results are replicated in future studies, it suggests that just organizations could actually be harmed unless they also curtail unfairness from managers.

Leadership

In preparing this article, we were struck by how often leadership, or at least supervision, appeared in the unit-level justice literature. Naumann and Bennett (2000) found that a visible supervisor helped to promote a strong justice climate. Liao and Rupp (2005) and Bashshur et al. (2008) reported that supervisors' efforts on justice climate have an impact beyond that of the organization. The most comprehensive leadership model was Ehrhart's (2004). Ehrhart found that servant leadership was an effective means of building a fair workplace. This collective sense of justice, in turn, increased citizenship behaviour. All of these findings fit together, in that they provide specific “action steps” that managers can take to promote fairness. Such actions, besides being worthwhile in their own right, seem to have a positive effect on the organization. Our hope is that the relationship between leadership and justice climate will be the subject of additional scholarly attention in the future.

Closing Thoughts

A sense of justice can, at least at times, result from the collective perceptions of a work group. As we have discussed, this realization provides considerable challenges to an exclusively individualistic

understanding of fairness. However, it also provides opportunities. Organizations that build a strong sense of community based on just treatment are likely to benefit from more favourable worker attitudes and behaviours. Employees, for their part, are apt to experience less stress and more assistance from their coworkers. Such promises, with the potential to benefit supervisors and subordinates alike, should be a priority for scholarly investigations.

The goal of this paper was to provide a sampling of where we have been historically, as well as some of the current trends in justice research, when considered holistically, and together with for moral motives over self-interest or relational trends within organizational climate at large, point toward justice as a lens, not only used to understand organizational psychology more completely, but also used experientially and phenomenologically by employees to make sense of and navigate themselves in a massively complex social system: work.

Case Study Regarding Forecast Management of Human Resource Needed in Railway Transport

Dăneci-Pătrău Daniel

*Spiru Haret University Bucuresti, Faculty of Management Financial Accounting
Constanta*

danusidenima2@yahoo.com

Abstract

Correct determination, in line with the requirements of specific activities, of human resource needs - numerical, qualitative and structural - and after that, providing it, is one of the most important tasks of human resource management. It becomes necessary, under these circumstances, the use of forecasting management of personnel needed as an essential tool of human resource management. This work is considered to be a useful tool for railway managers who, in today's restructuring and reorganization conditions of Romania's railway system are forced to cover effective human resource requirements with qualified railway staff.

Keywords: prediction, rail, necessary human resources

J.E.L. Classification: M12, L92.

1. Introduction

In order to improve global performance, every company must respond to the evolution of all aspects connected to human resources and be aware of their importance. This research is part of the logic and contributes to information enrichment regarding human resources management in railway transport. Given that the quality of personnel entries is lower than the human resources exits in the system, companies are forced to undertake a series of activities regarding design, implementation and monitoring of action plans on reducing in an anticipated manner differences between organization human resources needs (in terms of numbers and skills), determined by strategic option formulated and its availabilities at a certain given moment. These activities actually represent management's forecast in human

resource needs required as a condition and guarantee in an efficient use of human capital in an organization.

By achieving the object of activity, the National Company "CFR" SA, which is the subject of this case study, ensures the performance of public railway passenger, baggage, cargo and other goods transport, based on transport contract in order to satisfy public, social and defence interest. Public railway transport is organized and carried on commercial market principles. CN "CFR" SA administrates the infrastructure of Romanian railway system, public property of the state and holds in its property the goods in its equipment and those acquired in its own name with any title. In order to achieve its object of activity, CFR carries some secondary activities, including commercial supply and foreign trade, import-export, exploiting heritage. The activity of railway stations is carried by well-established rules and procedures to ensure optimal use of transit and processing capacity of trains and wagons in terms of regularity and safety.

Starting from a defined strategy in terms of objectives, management's forecast of human resource needs consists in developing action plans designed to annihilate, in a predictive manner, quantitative or qualitative mismatches between future needs (hiring staff) and human resources (available skills). In specific literature it is stated that successful management of employment and skills forecast is determined by using several essential elements, such as: a set of organizational means, technical, budgetary and human resources as well as the effects of certain factors that influence the development of new qualifications with changes in the organizational structure [6].

According to experts, the forecasting activity „involved a number of factors differentiated by the decision maker can

act on internal or external environment of the organization, leading and successful use of a particular method of prediction” [1].

By examining the content of forecasting human resource management presented in various forms in specific literature, we carried out this research, considering that this essential tool of management must address the following three aspects:

- Analysis of the current situation in the organization regarding workstations and personal resources;
- Forecast of needed staff;
- Adapting on a short, medium and long term staff requirements in relation to existing staffing and the strategic objectives of the organization.

2. Analysis of the current situation in the organization regarding workstations and personnel resources

In order to ensure the best structural premises necessary to achieve the objectives set and achieving higher final performances is required that the top management of the railway company to know exactly the content and requirements of all positions through the analysis of the available activities staff and positions, which is some of the most important and complex human resource management activities.

According to experts “analysing and designing positions fits the definition of functions, which represent an important part of the analysis process and design of organizational structure” [7] and consists in specifying the elements that make the execution of these functions, namely the role, position, duties and their connections. In foreign specific literature, the position/ job is defined as “a group of identical positions and situations regarding main tasks and similar enough in general to be included in that group” [4]. This definition is limited because it does not take into account the responsibilities of the post holder. Defining functions and positions is realized in the context of systemic treatment of the organization's management. In the literature of our country, T. Constantine considers that in general, job and function analysis refer to the same reality: the description of a unit in

the organization that is or will be occupied by a single person who has to fulfil certain tasks, has certain responsibilities and from whom a certain level of results is expected, in line with the training, skills and its personality traits [2].

The activity of a railway station is complex and is conducted continuously within certain working departments which, although differentiated by their functions, compete together to achieve passenger and goods transport. These sections are divided into three exploiting activities in movement, cargo and passengers, as well as administrative and personnel activities that are common to the entire station or separate for each type of activity taken separately [3]. The joint or separate compartments containing positions with responsibilities in handling, technical inspection of wagons, staff training, safety.

In order to ensure an adequate scientific support of this work the following methods and research tools were used:

- Direct observation and self-photographing of indirect activities performed by employees of railway stations railway sections of the Constanta-Mangalia traffic, which is a subordinated section to CFR Constanta Branch within the National Company CFR SA;
- Qualitative analysis of comparative type regarding personnel indicators (scripted number, average number, fluctuation, input - output);
- Brainstorming - creative method applied to human resource managers and engineers specialised in railway technology in order to produce variants of solutions;
- Flow - chart to determine routes travelled by information contained in the documentation provided by the company's management in order to be studied.

The circulation section Constanta-Mangalia, for which this study has been conducted is representative for the Constanta railway branch because it has subunits in which are present all types of specific activities to traffic branch - movement and maneuver, traffic management systems, centralized manual - as well as all executive functions of these activities - moving traffic

controller, needles auditor, pin cushion and guard barrier. Railway stations are exterior subunits to Traffic Division within the CFR Constanta Branch, through which the management and organization of movement and maneuver of passenger and freight trains in the public and private sectors is realized. The graphic scheme of Constanta-Mangalia movement section, shown in Figure 1, consists of eight railway stations, including the first degree station - Constanța, Mangalia second grade station and the other six stations are third degree. The degree of a station is determined mainly by the complexity of movement and maneuver activities performed, by the type and number formed or transited trains in a certain period of time.

Figure 1. Traffic department stations
Constanta – Mangalia

From the analysis of documentation made available to research by the company’s management and related calculations, has been obtained and is shown in Table 1, the existing situation in the railway company regarding workstations and personal resources on the analysed traffic department.

Table 1. Grading railway stations and normalizing operating personnel from traffic department Constanta – Mangalia

Source: Standards Branch personnel "CREIR CF" Constanta

Forecast management of employment and skills currently defines the framework and relationships from which start and are organized the other activities of human resources flow management: recruitment,

selection, integration, evaluation, development, promotion. Through its correct application, railway managers can assess more rigorously all employment consequences in terms of strategic choices in order to facilitate the selection of appropriate measures to regulate the internal market of the organization.

3. Forecast of staffing needed on the traffic department Constanta -Mangalia

Since Constanta-Mangalia traffic department has a special status in the railway company, showing a pronounced seasonal activity by the increase in rail traffic during the summer period compared to the rest of the year when work is suspended temporarily between 22.00-4.00 pm, we found it necessary and timely to realize a comparative calculation of the necessary personnel used to carry out the operation of the railway transport.

In order to highlight the law that is manifested in the relationship between occurrences they should be described by analytical equations of the proper form regarding the relationship between variables [5].

The formula for personnel needed on a post office of IDM from a station with *traffic and maneuver activity temporarily suspended* is:

$$NOP = [N1 \times 24 + N2 \times (24 - s)] / [(365 - FCO) \times 8] \quad (1)$$

$$FCO = CO + FE + ZLC \quad (2)$$

where:

N1 = number of days in a year when they work 24 hours;

N2 = number of days in a year when work is performed with suspended activity;

s = number of hours from a suspended activity in a day;

FCO = number of days in a year that are festive holidays, of rest and free days according to Collective Labor Agreement;

CO = number of days of paid leave in a year, which for the staff worker operating are of: 31 days for IDM position, 29 days for the office of inspector of needles and 27 days for a switchman and a guard barrier;

FE = number of festive days in a year, in calculations FE is used = 104 (52 weeks x 2 days of Saturday and Sunday/ per week);

ZLC number of days in a year that are free according to Collective Labor Agreement (ZLC = 12, for 2012).

According to formula (2) FCOIDM = COIDM + ZLCIDM + FEIDM = 31+104+12 = 147 days.

Under these conditions the number of people needed in a IDM position, calculated using the formula (1) is $NOP = [243 \times 24 \times 122 \times (6.24)] / [(365-147) \times 8] = 4,34$ people.

The formula for calculating personnel needed to a IDM position in a work station with traffic and constant manoeuvring activity is:

$$NOP = (365 \times 24) / [(365-FCO) \times 8] \quad (3)$$

Under these conditions the number of people needed in a IDM position, calculated using the formula (3) is $NOP = (365 \times 24) / [(365-147) \times 8] = 5,02$ people.

It can be noticed the fact that in order to ensure optimal train traffic during the summer period, the company's management must ensure qualified personnel higher in number than in the rest of the year.

This is possible through redeployment of staff specialized in similar stations as degree belonging to other departments and where the completion of circulation is done in the same way. If such an option is not possible, then the same permanent staff of the department is going to be used, but being lower in number than is necessary for a top activity, it will make overtime, which will increase the wage bill (bonuses are paid double the hours of the normal time).

4. Adapting needed personnel in relation to existing staffing and strategic objectives of the organization

Human resources necessary for any organization is decisively determined by the volume of their own activities. Specifically, this amount appears as an expression of the organization's business plan regarding specific human resource needs. An accurate forecast staff requirements must always be correlated with predictable changes in the environment - market conditions, the economy, competition, technology and finances.

Determining future staffing needs is a complex process with two essential

components: personnel demand forecast and forecast regarding future personnel supply.

Future demand for staff on a given planning horizon is estimated based on the company's overall strategic plans. The goal is to specify the workstations that the company needs in the future and how many jobs are needed for each position.

For the railway companies in our country the necessary information is taken from: company's internal information systems (systems of railway transport capacity planning, systems analysis and design of work stations) and external sources - associations of railway operators, governmental statistics, specialized companies which provide access to public databases. Is thus calculated the *gross personnel needed* which represents the number of work stations and estimated on the entire company and staff categories.

The future offer of personnel on the same given planning horizon is estimated starting from current availability of staff - the number of people who have the knowledge and skills necessary to fill a certain position - which is converted to predicted availability of personnel on the planning horizon given by extrapolating tendencies already manifested - retirements, resignations, promotions, transfers.

Net demand in personnel for each position is obtained as a difference between gross demand in staffing and forecasted availability of personnel and may have the following values:

- *positive* - and actions of are required: recruitment, choosing batch of candidates from within or outside the company; *selection* by choosing the right people for each position, *training and professional integration*;
- *negative* - actions of are imposed: restrict staff redundancy, encouraging early retirement or encouragement encouraging voluntary departures.

One of the problems the management of public railway units has to face is the average high age, so many employees which occupy positions with the responsibility of road safety are beyond retirement age. The necessity of maintaining its operation lies in the shortage of suitably qualified personnel in the labour market. This opinion is supported by the recently made employment in the last

period accomplished by private rail operators that employed staff who retired from state railway companies. From this perspective, we point out the need to increase the number of qualified personnel in railway transport.

In the case of the traffic section Constanta-Mangalia of CFR Constanta railway branch, current benefits, which are currently establishing criteria for prioritizing the jobs of motion signalman (both device, outside and localist) have decreased more, following the rehabilitation of Corridor IV pan-European movement in this period being lower than before starting work. This fact is a disadvantage for traffic personnel, meaning that the clerk is requested by other factors that are not currently considered when ranking posts.

5. Conclusions

Following the replacement of existing infrastructure and removal from functioning the traffic safety facilities, a traffic manager must manage circulation considering the large number of line closures (both planned and accidental) and a large number of faults registered at traffic safety facilities. Thus, although the number of circulated trains has dropped significantly, these aspects require greater attention from the railway worker, his work having a much higher degree of difficulty in these situations, which have become almost daily. Also in this case increased - significantly - both the number of circulation orders issued by IDM traffic and the number of checks performed on third parties (by the checking's that are made over the builders working for the rehabilitation of Corridor IV).

Given the presented ones and in order to correct the quantification of benefits underlying the hierarchy of IDM stations, we propose introducing some criteria for prioritizing new and updating existing criteria, namely:

- quantifying the number of circulation orders issued by the traffic manager;
- quantifying the number of closures of lines managed by the traffic manager;
- counting the number of faults recorded in the register of safety circulation, whose remedy must be pursued by IDM device or – with the version of- counting the number of signals, switches, detailers I

handled by IDM, for the quantification of chasing train traffic on IDM desk, and for quantification of faults in equipment and monthly and biannual revision works;

- giving additional scoring for IDM-provision from first degree stations with two IDM provisions, in which the IDM provision fulfils the responsibilities of a localist;
- counting the number of checks made by IDM on private railway operators regarding staff.

Based on research conducted to document this work, we consider as necessary the raise in the number of people participating in training courses in the railway sector. This need becomes urgent to meet future requirements arising from the entry into service of new rolling stock, upgrading various facilities, equipment or elements of railway infrastructure and using a new system of organizing the traffic.

Comparative Analysis of the Accommodation Capacity Evolution in the Black Sea Countries

Dedu Elena Mădălina
Academy of Economic Sciences
madalinnad@yahoo.com

Abstract

In recent years, tourism has become the most dynamic item of Black Sea countries' economy that provides new workplaces as well as constant income.

This paper aims to analyze the dynamics of accommodation units of the six Black Sea countries in recent years, to compare the development of the material base in each country and make some proposals to improve tourism activity on the Romanian coast of the Black Sea.

Keywords: Black Sea Coast tourism, tourist potential, tourist accommodation.

J.E.L. Classification: L83

1. Introduction

Black Sea Coast is a highly dynamic and sensitive area encompassing varied and attractive natural resources, which favors the development of human activities such as tourism, recreation, leisure, etc.

Tourism is considered an important source of income for Black Sea riparian countries: Romania, Bulgaria, Turkey, Georgia, Russia and Ukraine. These countries have rich tourism resources, establishments of tourists' reception with various functions of accommodation, transport, catering or leisure, offering various leisure options for all tourists.

2. Black Sea Coast tourism potential

The Black Sea is the most isolated sea in the World. It is connected to the World Oceans via the Mediterranean Sea through the Bosphorus, Dardanelle and Gibraltar straits and with the Sea of Azov in the northeast through the Kerch Strait. [4]

Due to lack of tides, Black Sea coast

ensures optimal use of beaches and the low salinity of water favors water sports and, especially, those underwater.

The chemical composition of water is particularly favorable to the human body under therapeutic aspect.

Besides the sea water, as the main attraction, the Black Sea provides tourists a wealth of natural resources as reservations, beaches, lakes, fauna, flora, natural cure factors and anthropic resources represented by historical and archaeological sites, museums, historical monuments, religious buildings, economic objectives, festivals, cultural events, etc.

2.1. Romanian Black Sea Coast

As a whole, the Romanian Black Sea coast has a length of 245 km and lies between Chilia branch of the Danube, to the north, and the border with Bulgaria to the south. The Romanian seaside belongs to Constanta County, the Romania's major tourist area due to the beaches, archaeological treasures, novelty landscapes, recreational areas, hunting and fishing.

Tourism potential of Constanta includes both natural tourism resources and tourism anthropic resources. Tourism resources of the county haven't a uniform distribution and they explain tourism development especially on the Black Sea coastal area.

The richness and rarity of elements of flora and fauna and the variety and beauty of the local landscape imposed, for the protection of the natural environment, the creation in Constanța of numerous natural reservations of great scientific and tourist interest. [5]

Romanian seaside is one of the most important tourist areas in Romania as compared to other tourist areas of the country, which is reflected by indicators of tourist flows and accommodation capacity.

Constanta County coastline stretches over a length of over 100 km (from the total of 245 km which is forming the access to the sea of Romania) comprising beaches in resorts: Olimp, Cap Aurora, Costinești, Eforie Nord, Eforie Sud, Jupiter, Mamaia, Mangalia, Năvodari, Neptun, Saturn, Vama Veche / 2 Mai, Venus.

With so much to offer, Constanta County and, mainly, the Black Sea Coast will always be an attraction for both foreign and Romanian tourists.

2.2. Bulgarian Black Sea Coast

The Bulgarian Black Sea coast, situated in the Western part of the Black Sea, has a 378 km long coastal line, 140 km of which occupied by 78 beaches.

The Bulgarian Black Sea coastal zone is 5.21% of the country territory and hosts 8.85% of the national population. [7]

Tourism and, in particular, coastal tourism is one of the fastest developing world industry sectors and Bulgaria follows this tendency. [1] Bulgaria has become one of the leading tourist destinations in Europe over the last couple of years. Bulgaria benefits from the geographical position, which allows the country to offer skiing in winter and sunbathing at the beach and exploring the nature in summer.

The Bulgarian Black Sea coast is picturesque and diverse and is located along the provinces Dobrich, Varna and Burgas.

Here long strips of sand dunes alternate with estuaries, large and small bays and inaccessible high rocky shores. The coast is divided into two sections, north and south of Cape Emine, where the Balkan Mountains reach the sea.

Clean and calm sea with shallow sloping sandy bottom, wide beaches with fine grain golden sands, venerable forest and numerous mineral springs are features that make the Bulgarian Black Sea Coast an attractive place for domestic and foreign tourists.

All along the coast, with several kilometers interval are lying large and small resorts - from large modern complexes to small picturesque villages: Balchik, Kavarna, Varna, Pomorie, Nessebar, Bourgas, Sunny Beach, etc.

Most marine cities and towns were founded millennia ago and they preserve the

rich cultural heritage - remains of the Roman and Byzantine eras, medieval monuments and magnificent architectural examples dating back to the Bulgarian Revival.

2.3. Turkish Black Sea Coast

Stretching 2000 kilometers from the Bulgarian border in the west to Georgia in the east, the Turkish Black Sea coast varies dramatically, from sheltered sandy coves, to soaring green mountains, to dire freeways and industrial ports.

Turkey's Black Sea coast is famous with its humid and green forests, traditional wooden houses, extraordinary plateaus, and also untouched beautiful beaches. The region is very mountainous and is heavily forested, while the highest parts of the mountains are covered with alpine meadows, glacier lakes and glaciers.

The Turkish Black Sea coast is never crowded because cloud is more common than sun, and the seawater is chilly. But that is fine with the adventurous types who come here for a few days to savor its deep history, its dramatic beauty and its special cuisine.

Turkish Black Sea coast is a wild beauty, with many mountainous areas; although it is one of the most verdant regions of Turkey, it is not among favorite destinations of tourists visiting the country. Only a few resorts have sandy beaches: Kilyos, Sile, Sinop, Ordu, Giresun. [8]

2.4. Georgian Black Sea Coast

The Black Sea Coast of Georgia has about 300km of coast stretching from the border with Russia to the border with Turkey. Many of the coastal resorts offer treatments for cardiovascular, central nervous system, functional, joint and gynecological diseases. Some Georgian Resorts on the Black Sea are: Batumi, Kobuleti, Ureki, Grigoleti, Mtsvane Kotskhi, Tsikhis Dziri. [6]

2.5. Russian Black Sea Coast

About 300 kilometers (190 miles) separate the Taman Peninsula steppe in the north and the resort city of Sochi in the south on Russia's Black Sea coast. From May to October, the country's resort life is

concentrated on this relatively short coastline. [14]

Dozens of coastal towns and villages, hundreds of hotels and health resort centers, welcome millions of vacationers from all over Russia, and foreign tourists from different countries to the Black Sea coast.

The cities and towns of Russia’s Black Sea coast are famed for their healing spas and rejuvenating waters. The main Russian resort towns on the coast of the Black Sea are Anapa, Novorossiysk, Adler, Tuapse and Sochi. The Russian Black Sea resorts are situated in Krasnodar Territory. [10]

2.6. Ukrainian Black Sea Coast

Ukrainian Black Sea coastline begins at the Danube river delta on the Romanian border and extends along the Crimean Peninsula to the historic city of Odessa.

Many of the Ukraine Black Sea resorts have been attracting guests for decades, or even centuries. [11]

Most of the Ukrainian Black Sea resorts reside on the western shores of the Crimean Peninsula: Yevpatoriya and Saki are well known for their sandy beaches, healing mud baths, and mineral waters. Some of the resort towns in the cape area include Alupta, Simeiz, Yalta, Gurzuf, and Koreiz, with Yalta being the largest and most popular.

3. Analysis of tourist reception structures on the Black Sea Coast

Valorizing tourism patrimony of a country or geographical region involves ensuring minimum conditions for travel, accommodation and spending leisure time enjoyable for tourists. In essence, the combination of these elements offers visitors the most satisfaction in a trip or vacation.

Tourist reception structures are classified as follows:

1. *Tourist reception structures with functions of tourist accommodation:* hotels, apartment-hotels, motels, villas, chalets, bungalows, holiday villages, campsites, rooms for rent in family homes, river and sea vessels, boarding houses and agro tourist pensions, etc.

2. *Tourist reception structures with functions of public alimentation;*

3. *Tourist reception structures with*

functions of Leisure;

4. *Tourist reception structures with functions of transport;*

5. *Tourist reception structures with functions of spa treatment.*

3.1. Tourist reception structures on the Romanian Black Sea Coast

Tourist accommodation equipments in Constanța are many, because many tourists visit coastal area every year. [12]

Table 1. Number of seats in reception facilities

Unit	Years				
	2007	2008	2009	2010	2011
Total	121717	120944	121723	124643	83751
Hotels & Motels	78287	78583	79201	80173	63929
Hotels for youth	609	495	624	-	-
Hostels	288	288	381	1383	1590
Tourist chalets	40	40	40	40	301
Camping & Tourist halting places	21962	21230	21738	21794	8138
Tourist villas & bungalows	10495	10588	10534	11500	5267
School & preschool camps	8200	7900	7600	7840	3756
Tourist boarding houses	1055	1045	1081	1030	343
Agrotourist boarding houses	781	1045	524	883	233

Source: <https://statistici.insse.ro/>

The chart based on data from Table 1 is given below:

Figure 1. Number of seats in reception facilities Constanta, Romania

From the previous analysis is observed an oscillating evolution of the number of accommodation during 2007-2011, its biggest decline compared with 2007 registered in 2011.

3.2. Tourist reception structures on the Bulgarian Black Sea Coast

On the Bulgarian Black Sea Coast are functioning many accommodation establishments, as hotels, motels, camping sites, other establishments for short-term accommodation with more than 10 bed places. [13]

Table 2. Number of seats in accommodation establishments by regions

Statistical regions	Years			
	2008	2009	2010	2011
Dobrich	24433	21990	22217	23691
Varna	61222	59434	58736	56773
Burgas	98933	106683	101627	105300
Total	184588	188107	182580	185764

Source: <http://www.nsi.bg>

Based on data from Table 2 I obtained the following graph on the evolution of the number of beds in Bulgarian coastal region:

Figure 2. Number of seats in accommodation establishments by regions

Analyzing the data obtained, one can observe an oscillating evolution of the number of accommodation during 2008 - 2009 on the Bulgarian seaside. The decrease of the total number of beds between 2009 and 2010 can be attributed to the global economic crisis that affected the Bulgarian economy, too.

3.3. Tourist reception structures on the Turkish Black Sea Coast

The Turkish Black Sea region is easily

accessible to tourists and provides a wide range of hotels and restaurants at a variety of prices. [9]

Table 3. Number of seats in accommodation establishments by type

Type of Establishments	Years	
	2007	2010
Hotel	20047	23516
Motel	1529	1534
Boarding house	2701	6674
Holiday Village	616	600
Camping	24	206
Thermal Resort	178	383
Total	25095	32913

Source: <http://www.kultur.gov.tr>

Based on data from Table 2 I obtained the following graph on the evolution of the number of seats in accommodation establishments on Turkish Black Sea Coast:

Figure 3. Number of seats in accommodation establishments on Turkish Black Sea Coast

It can be observed the upward trend of the number of places in accommodation establishments on the Turkish Black Sea Coast between 2007 and 2010.

3.4. Tourist reception structures on the Georgian Black Sea Coast

In the Georgian resort on the Black Sea coast are several accommodation units that provide various services to tourists. During 2007 - 2010 the number of accommodation in this area had the following evolution: [2]

Table 4. Number of seats in accommodation establishments on Georgian Black Sea Coast

Years	Number of seats in accommodation establishments
2007	16704
2008	17573
2009	18741
2010	21086

Source: Statistical Yearbook of Georgia

Dynamics of accommodation places on the Black Sea coast of Georgia is shown in the following chart:

Figure 4. Number of seats in accommodation establishments on Georgian Black Sea Coast

Data obtained show that the number of accommodation of Georgia's coastal resorts grew annually in the analyzed period.

3.5. Tourist reception structures on the Russian Black Sea Coast

Sochi is the biggest resort of the Black Sea Coast of Russia. It extends along the shores of the Black Sea for 145 km. The territory of the municipal district of Sochi is divided into four districts: Adlersky, Khostinsky, Central and Lazarevsky. Unofficially, the city is called the summer capital of Russia.

The resort complex of Sochi is the biggest in Russia with over 600 different recreation facilities (therapeutic facilities, SPA complexes, vacation hotels, private hotels, holiday camps), that is, 50% of the overall resort potential of Krasnodar Kray. [15]

Table 5. Number of means of accommodation in Sochi, on Russian Black Sea Coast

Years	Number of means of accommodation
2009	228
2010	238
2011	246
2012 (forecast)	256

Source: <http://megaresearch.ru>

Given the data presented in the table, we see that the number of accommodation units on the Russian coast of the Black Sea had an upward trend.

3.6. Tourist reception structures on the Ukrainian Black Sea Coast

Accommodation on the Ukrainian Black Sea Coast is very easy to find, as there are various types of hotels that offer world-class facilities and amenities. During 2005-2011 the number of accommodation establishments had the following evolution:

Table 6. Hotels and similar facilities for accommodation, by region on The Ukrainian Black Sea Coast

Region	Years			
	2005	2009	2010	2011
Odessa	79	80	81	217
Crimea	78	96	104	651
Total	157	176	185	868

Source: Statistical Yearbook 2011 [3]

Based on data from Table 2 I obtained the following graph on the evolution of the number of accommodation establishments on Ukrainian Black Sea Coast:

Figure 6. Hotels and similar facilities, on The Ukrainian Black Sea Coast

Data presented show upward trend in the number of accommodation units on the Ukrainian coast of the Black Sea.

4. Conclusion and proposals

Comparing data from the statistical institutes of the countries bordering the Black Sea, we can draw several conclusions about the evolution of the number of tourist accommodation facilities in recent years.

First, it notes that, overall, the last five years, the supply of accommodation has increased in countries of the Black Sea, except the one on the Romanian coast which in 2011 fell by 33% compared to 2010.

Also, the Black Sea coastal region has a rich tourism potential natural and anthropic, capable of attracting tourists and satisfying a variety of requirements.

Romanian Black Sea coastline stretches over a relatively small area (100 km) compared to other coastal areas, however, Constanta county holds many resorts equipped with diverse material base offering a wide range of tourist activities.

In order to improve the Romanian seaside tourism activity can be proposed several actions, such as:

- Modernization of hotels and other tourist structures with accommodation functions;
- Diversifying supply of accommodation places by building new tourist resorts;
- Develop special programs to conserve, restore beaches, prevention of beach pollution and bathing water;

- Improving the quality of tourism services in hotel structures with accommodation and food functions within the hotel complex.

With an investment in the region that rely on the upgrading of accommodation and food units, of the access roads and on a campaign to promote coastline and to educate people about the values to be preserved, Constanta county could become soon one of Europe's most important tourist areas.

The Intellectual Capital Statement in Knowledge-based Organizations: The practitioners’ and Academics’ Answer for Reporting the IC

Dicu Roxana Manuela
“Alexandru Ioan Cuza” University of Iasi
rm.dicu@yahoo.com

Abstract

Currently, one cannot dissociate the idea of economic entity of its capital. Whatever form it takes, this constituent element of wealth is seen as the basis of business, whether in the form of financial capital (equity and debt), economic capital (capital employed) or intellectual capital (knowledge, skills, relationships, intellectual property, social attitude). The increasingly ample orientation of the companies towards the intellectual capital is based on the rediscovery of this resource with (almost) unlimited potential, generating economic benefits for a company. Given its importance, the information needs of stakeholders on this line have increased. Thus, in this context, it was put the issue of reporting information related to intellectual capital and the transparency of information published by companies, given that its reporting is not currently regulated.

Keywords: intellectual capital, reporting, European Commission.

J.E.L. Classification: C81, O30, O39.

1. Introduction

The problem of identification, representation, evaluation and reporting of intellectual capital in economic entities exists today in the attention of both academic community and practitioners. If initially it was treated as *theoretical economic resource* which generates future economic benefits, the practice has spoken, the corporate values began to increase on specialized markets, increasing the difference between the accounting value of the entity and its market value. This difference, attributed to intangible elements that were not reported separately in the annual financial statements,

requested, from the members of the business community, a reconfiguration of their attitude towards all the existing resources in companies.

There are authors who see the intellectual capital (IC) as *a change in the structure of investments*, specific to new discovered knowledge based economy [1][2]. Others authors, like Edvinsson [3][4], Sveiby [5], Andriessen [6], known for their preoccupations regarding the intellectual capital, consider this capital as a *source for creating value in the new economy*. Once the 90 were alerted to the existence of intangible assets in companies, subsequently it was established the term of *knowledge-based organization* [7][8][9].

Many studies based on the theory of knowledge-based organization researched the problem of *reporting the IC*. Since the first papers in this direction, the problem of classification and compound of IC [3][10] cannot be dissociated of the problem of its value. In this last situation, there are *three perspectives* in the specialized literature: one, according to which the intellectual capital should be included in the companies’ annual reports [11][12][13][14][15], second, which states that the reporting of IC should be presented separately, so not included in the annual reports [2][16] and, not least, a third perspective, related to *the validation of IC in a managerial context*, related to the decision making process of the investors [17][18][19][20].

2. The necessity for a model for reporting the intellectual capital

Relatively new and widespread term of “knowledge economy” has generated a great interest for the intellectual capital. The very idea of its existence was not enough, stakeholders and managers requesting information on its value, its potential to

generate benefits and its contribution to company performance. The answer to all these questions, in fact, shows how intellectual capital is managed within organizations. Implicit or explicit assumption is that better management of intellectual capital will lead to unique, competitive and sustainable advantage [21][22].

The problem of a statement of intellectual capital was placed amid awareness of its growing importance, this being the context in which it was concluded that conventional management tools, such as scorecards, do not cover anymore the administration of this area. Thus, the project „Intellectual Capital Statement - Made in Europe” (InCaS) started in this particular context, being the result of a Consortium which included 25 SMEs from five European countries, experts, research institutes (“Fraunhofer IPK Berlin”, “London School of Economics (LSE)” and “Universidad Politècnica de Catalunya (UPC)”) and six business associations [23][24].

Since the beginning, the project itself has had as purpose:

- Strengthen competitiveness and innovation potential of European

organizations by systematic enabling of intellectual capital;

- Setting the Intellectual Capital Statement (ICS), as an important and valuable management instrument in knowledge-based economy;

- Integration and consolidation of individual national approaches on European intellectual capital statements.

The researches started in July 2006 [25] and they lasted two and a half years, period in which the statement was implemented in the 25 SMEs, was refined and finally published with the name of European Commission on it. In three fazes, the partners elaborated the ICS methodology, implemented and evaluated it, together with the companies, and, of course, they optimized and improved the methodology according to the requests of the users. Next, we will present the method created by this Consortium for the reporting of IC in enterprises, whatever their size and core operations.

3. The procedural model for the preparation of IC Statement

The procedural model for preparing the IC Statement is presented in figure 1:

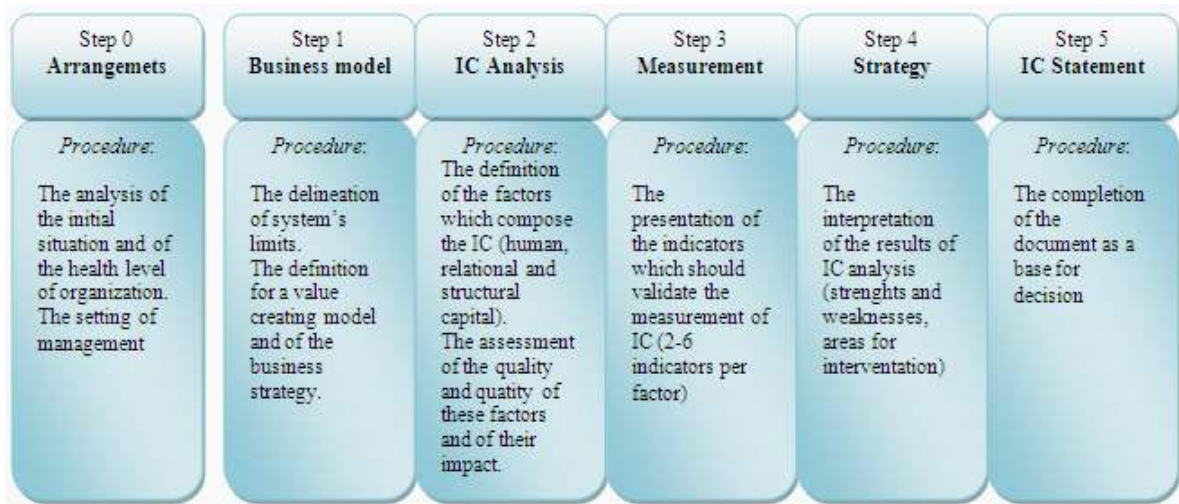

Figure 1. Procedural model for preparing the IC Statement

Source: European Commission, *InCaS: Intellectual Capital Statement. Made in Europe*, available online at <http://www.incas-europe.org/European%20ICS%20Guideline.pdf>, p. 9

Practically speaking, these steps can be described as follows:

- Step 0 includes history, culture, and institutional background of the company.

Also, It also refers to additional information on strategy, market development, trends etc. To finalize next steps, the company

constitutes a management team that has the role of completing steps 1-5.

• Step 1 requires a statement of how the company creates value from the products and services they sell and ending with the main processes taking place in the business. The answer to these questions must relate to the enterprise as a whole or only to a segment.

• Step 2 considers the analysis of the three components of intellectual capital and identifies those factors that compose them effectively. The level of detail should be high. It also analyzes the factors in terms of strengths and weaknesses. For factors such as organizational culture, quantitative-qualitative delineation is reduced, so that they will be treated as a single dimension and described as such.

For each identified factor, three questions must be answered:

1. Is the quantity/volume of this factor sufficient to accomplish the strategic objectives? (quantitative question)

2. Is the quality of this factor sufficient to accomplish the strategic objectives? (qualitative question)

3. There are measures clearly defined to improve this factor? (managerial question). The answers to these three questions appear on a scale from 0 to 100%, where 0-30% is “insufficient”, 30-60% “partially sufficient”, 60-90% “largely sufficient” and 90-100% “absolutely sufficient”.

Thus, for each factor, eg organizational culture, we will formulate the question “How does organizational culture answer to strategic objectives?”, we offer 85% and a reason for that percentage. Finally, factors, grouped into the three components of intellectual capital, are summarized in a table that included the question, percentage and the explanation for the assessment. In this way for each component of intellectual capital there is an adequacy process, overall and for each component.

Also, the analysis of the impact score for each factor is recommender, as follows:

Table 1 The analysis of the impact score of IC elements

IC Type	ID	Factor	The calculated position by every member of the team								Amount	Impact score
Human capital	CU1	Professional competence	5	1	3	2	2	7	3	3	26	7,20%
	CU2	Motivation	4	3	2	5	3	8	2	5	32	8,90%
	CU3	Social attitude	9	5	5	8	5	5	5	6	48	13,30%
Structural capital	CS1	Culture	7	6	8	6	7	2	8	8	52	14,40%
	CS2	IT	6	9	6	9	9	1	9	7	56	15,60%
	CS3	Know how, patents, copyrights, intellectual property	1	7	9	4	6	4	6	4	41	11,40%
Relational capital	CR1	Customers relationship	2	8	4	1	1	6	7	1	30	8,30%
	CR2	Investors relationship	3	2	1	3	4	9	4	9	35	9,70%
	CR3	Relationship with the environment	8	4	7	7	8	3	1	2	40	11,20%
Total			45	45	45	45	45	45	45	45	360	100%

Source: Adaptation after European Commission, *InCaS: Intellectual Capital Statement. Made in Europe*, available online at <http://www.incas-europe.org/European%20ICS%20Guideline.pdf>, p. 32

Each factor is given a score from 1-9 (total number of factors). Horizontally, we calculate the total points given by each team member and the percentage of importance, which may result in a classification of factors, depending on the importance and impact.

• Step 3 call for effective indicators of intellectual capital measurement to represent the factors taken into account. These indicators may vary from the information in absolute size (number of employees, number of managers, the number of patents and trademarks, etc..) to relative size indicators or

qualitative assessment, which are assessed by 1/0.

• Step 4 resumes the percentage of the three questions from step 2, and makes their average, which represents “the medium value” of each factor, the difference to 100% being *potential of improvement*. Also, one can calculate the medium value of each component of intellectual capital.

4. The interpretations for the results of the model

The portfolio of IC management is done in a graphic way, on the abscissa X being noted the impact score, and on the ordinate Y, the average result of questions from step 2. The dial is so divided in four parts:

1. Left down – *Analysis* – includes the factors with low importance for the strategic objectives, but with high potential for development;

2. Right down – *There is no need for action* – includes the factors with low importance for the strategic objectives, and with low potential for development;

3. Left up – *Development* – includes the factors with high importance for the strategic objectives, and with high potential for development;

4. Right up – *Stability* – includes the factors with high importance for the strategic objectives, but with low potential for development.

This graphical representation is a map of IC factors and of strategic development, directly related to these factors. All these conclusions must be processed in step 5, in IC Statement, in two separate versions, one for internal use and one for external stakeholders.

5. The IC Statement across Europe

In the preparation of a statement of intellectual capital, we consider that the example of the European Commission, presented above, is affordable, provide relevant information suitable to all categories of economic entities, regardless of size and, most importantly, based on experience of a relevant sample of companies and professionals. However, is not the only model, some developed European countries

presenting their own models in this respect [26]:

• Denmark – *IC Statements – The New Guideline* – the guide has four parts (The description of knowledge in organizations, The challenges of the management, Efforts and Indicators). Intellectual capital has three components: human, relational and organizational (processes and technologies). The idea is to reflect the components of IC into indicators and to establish strategic targets for them;

• Germany – *Wissensbilanz (Guideline on the preparation of an IC Statement)* is also structured in four steps: the first one aims at preparing a IC statement in a simple form, taking into account the environment, the strategy, and own representation of IC; the second one imposes the identification of the aspects mentioned before, using specific indicators; the third one determines the preparation of a document, with previous dates; the fourth one aims at monitoring the development of the organization, by establishing target-indicators;

• Austria – *Austrian Research Centers IC Report* – combines four elements: goals, intellectual capital (human, relational and structural), knowledge processes and intangible resources. The capital is the input for processes, and, after that, the management establishes targets for results;

• Spain – *Intellectus Model* – facilitates the decisions regarding research and development activities, bringing to the fore a series of factors which can influence the results of innovation (human capital – culture, qualifications of the researcher; relational capital – scientific alliances with specialized centers, associations, collaborations; structural capital – full time employees, ongoing projects, equipments, industrial and intellectual property;

• Sweden – *IC Rating* – is an initiative of a Swedish company, specialized in the assessment and description of intangible assets, not presented in traditional financial statements. It is based on three domains: efficiency, risk, and renewal and development. 230 parameters are measured, to describe IC. Each parameter is converted in a question, which is evaluated from 1 to 8. The answers are grouped for each component of IC;

- Belgium – *ICV calculation* – represents a set of 77 formulas, which are applied to a company and then aggregated, with the inclusion of the result in certain margins;

- France – *IC-dVAI* – is a strategic approach of the intellectual capital, from a dynamic perspective, set around four dimensions of the competitiveness: - resources as inputs for the production process (tangible resources, R&D, acquisition of technologies, etc.); - processes; - the construction of intangibles (intellectual capital is seen as an amount of intangible resources); - outputs – measured in performance indicators and in market share of the company;

- Europe – *MERITUM* – is an European guide for the management and reporting of intangible assets, for the purpose of their identification, assessment and control, for them to become part of the company’s financial performance. Given the fact that the year in which *MERITUM* was published is 2002, InCaS created IC Statement few years later, as an alternative.

European countries and others were actively involved and are still involving in providing solutions for the preparation of a statement of intellectual capital and intangible assets, as appropriate, responding to a need of today's economic entities regarding the reporting of this resource recently acknowledged. Given the wide range of examples, each company must choose the model that best suits its internal structure and external partners' informational interests.

6. Conclusions

Competitiveness of modern organizations, regardless of size and core activities, is based on the strategies applied. Conditioning performance through strategy, in last decades, is evident for companies and managers in most developed countries, and explains the large number of researches, education, training and consultancy in the field. An expression of this trend is the frequent references to strategic management, strategic alliance, strategic control, strategic planning, strategic coordination and so on, which have proliferated especially in the last decade. Passing over these issues, it is noted that the strategy has emerged as an essential component of management, both in theory

and in practice, and are means for the company to move towards long-term objectives by developing good relationships with internal and external environment.

Intellectual capital must become an important part of corporate strategies, regardless of their field. Its components must be identified and exploited to their full potential for the entity to benefit from maximum future benefits embodied in them. In addition, companies must understand that employees as human capital are easily identifiable and are extremely varied ways to motivate them, on a financial line or by social attitudes.

The IC Statement helps entities to follow the quantitative and the qualitative side of their IC, as a result of their attitude and strategies applied.

Based on the foregoing, we believe that management should consider preparing a Statement of Intellectual Capital, especially if the business they manage impose such an approach. The novelty of intellectual capital and its regulatory failure was and is both for practitioners (including the managers) and the academic community, a challenge in terms of quantifying the economic benefits expected from the exploitation of this capital.

Regardless of the methods chosen to reflect, assess or present the intellectual capital, it should not be forgotten that the *elements are evaluated are based on knowledge, therefore they have a high degree of subjectivity*. It is obvious that such an Intellectual Capital Statement can not be achieved within a company, based only on public information. Therefore, access to such a document can only be made by contacting people directly involved in the preparation of it, the report itself being a managerial product.

Trends in Strategic Management of Banking Institutions in Romania

Dinculescu Elena –Silvia
Bursugiu Mihaela
Constantin Brancoveanu University of Pitesti
nataliadinculescu@yahoo.com

Abstract

The integration of Romania in the European Union has determined serious implications on economy and on the national banking system that had to cope with the pressure of a competitive market having higher and higher demands from customers who ask for much more complex products and banking services.

Considering the evolution of the banking environment in the last period, for any institution of credit, aspects such as: diversification, innovation personalization of banking products and services should be priorities.

Key words: strategic management, banking activities, trends, performance.

Clasificare J.E.L.: G21, G24, E59, F33

The sector of banking services involves a specific approach to study the customers demands and to set up the portfolio of the services that the credit institution is to offer.

All these appear mainly due to the particularities of the banking services and products such as: [1]

- banking products and services have a long life cycle- this due to the imaterial character, they are not liable to moral and physical usage. Their process of ageing is very slow, sometimes meeting products and services as old as the banking institution;
- the impossibility to protect the banking services by means of patents, because of the similitude of a banking product created and launched on the market by a banking institution, can be very easily taken over by the other banks in the system. The difference can be made

by emphasizing of some intrinsic qualities and by using a distinctive and personalized name;

- the demand of banking products and services is heterogenous, the credit institution having to consider the needs and demands of each segment of customers in order to attract new and devoted consumers;
- the launching of banking products and services is highly conditioned by the existence of banking and fiscal regulations, the lack of a legal basis braking promotiong new products, as it was the case of leasing operations, that could not be used up to the appearance of a legal basis;
- carrying on the banking operations calls for the customers engagement. In order to get and use some banking products, a cooperation with the beneficiary is necessary, who will draw a personal documentation under the limits of a form frame used by the banking institution. The self-banking services, that are a way of externalization of the banking activity, allow the users to manage a financial situation by means of banking operations such as the bills payment, depositing or withdrawing cash, getting a statement of account, without restrictions;
- atomicity, another characteristic of the banking services demands, brakes carrying on the operations with the customers who ask more and more personalized services;
 - the banking products and services can be offered to the customers only directly, being no possibility of redistributing or reselling. This involves the existence of dispersed units in different geographical areas, determining the

process of developing in territory of the banking institutions. The banking branching is the place where the customers are got or lost. According to the latest evolutions, the structure of the Romanian banking system, that represents the dominant of the financial system of our country, has not been changed over the last two years, including in 2011 a number of 42 credit institutions, among which 32 banks Romanian legal persons, 9 branches of foreign banks and an authorized network of credit cooperatives (CREDITCOOP). Comparing to 2009, the number of the foreign banks branches is lower with a unit while the number of domestic banks is higher.

From the point of view of the countries that hold participations to the social capital of the national banks and of foreign branches, banks with Austrian capital still have the highest quote on the market (25,5%), being followed by those with Greek capital, however being on a decreasing trend.

On the third place, at a great distance those having Dutch capital, that comparing with 2011 registered a significant increase (Table 1) [2]

At the end of 2011, the national banking market was dominated by five credit institutions that were holding together 52,8% of the total assets and deposits. BCR holds its leading position, followed by BRD-GSG (13,9%) and Raiffeisen Bank that ascended four positions. The fourth and the fifth are hold by CEC Bank that did not highly increase. (Table 2)

Source: author's data

Keeping the same degree of concentration of the Romanian banking industry reflects an increase of the competition. The credit institutions in our country can be grouped in three large strategic groups having as clasification criteria the strategic advantages, competences and vulnerabilities, in this way:

The group of banks having a state majority capital made up of CEC Bank and Exim Bank that has the following competitive advantages: a well knowledge of the Romanian economic environment, the teritorial network widely spread and a great number of employees that are providing services to the customers, all these advantages not being correctly used can become negatives aspects.

Besides these, banks having a state capital present some vulnerabilities consisting in the low flexibility concerning the operation and the investing reticence highly produced by the control of the governmental bodies; the limited managerial competences together with the generality of the banking products and services, determines a low quality level and the impossibility to focus future strategies on certain segments of customers;

The group of private banks has the following competitive advantages:

The staff and managers competence and high qualification stimulated by the selecting and motivating strategies, the high flexibility of the operating way, of the investing polcies,

a well knowledge of the economic and social environment, the importance granted to the new information banking technology.

Besides all these, credit institutions having a private capital are vulnerable from the social capital point of view, that sometimes is not enough in order to serve the great companies and from the point of view of the low number of units in the teritory. Commercial banks that are affiliated to this group should develop its strategic area in the field of diversifying the customers segments, but also concerning technology and services offered;

The group of foreign banks branches, that have the possibility to take advantage of the banking experience got by the ” holding” banks from the countries they are from, of an international banking know-how, by a good reputation among customers and of the relations with the correspondent foreign banks.

Another great advantage is setting the capital (in foreign currency) at the fluctuations of the rate exchange generated by inflation. The disadvantages of this group consist in: diminished network in the teritory, the impossibility to take advantage of the leading effects determining important advantages in the origin country, the limited knowledge of the economic environment and of the restrictions of the customers segments.

The competition of the three groups consisted in applying differential strategies considering different aspects such as interest rate, geographical proximity of serving (teritorial network), the level taxes and commissions charged, the fast and safty ways of providing services.

Concerning the level of interests for the deposits received and the credits granted, the competition took place among the banking institutions that are part of the first two groups.

In order to meet the requirements of the customers concerning the serving proximity, banking institutions have developed up to 2008, its network of units in the teritory. This teritorial expansion is highly expensive for any banking institution, the exact price depends on the development level of the bank and on the final target. If it is aimed to get a 10% market quote, then at least 5-6% of the total units in the banking system should be hold, that is about 380 units.

Analyzed in its dynamics, the dimension of the territorial Romanian banking institutions (Figura 1) is in this way: until 2008 when the highest level is reached 6552, the number of units increased, since then a number of units to be diminished, in fact the banking institutions closed 88 units representing about 1,4% of the territorial network, reaching 6464 of units at the end of 2009. [3]

The dramatic diminishing of the crediting process and the significant increase of provisions negatively influenced the activity over the last three years, on the activity of the credit institutions. All these, in order to diminish its expenses and the eventual losses, applied measures to reduce the territorial networks. The effects of this process can be clearly seen, many commercial banks giving up to their presence in different counties.

In 2010, a significant diminishing concerning the territorial units took place, when 294 banking agencies were closed, representing about 4,8% of the total agencies and branches. The territorial network still continued to diminish, so that at the end of the last year, this was made up of a number of 6040 units.

Figure 1. Territorial units evolution of the credit institutions

Source:www.bnro.ro

At the end of 2008, banks registered 6552 agencies, meaning that only in the three years that past since the beginning of the financial crisis, the banking institutions were determined to close a number of 512 units.

CEC Bank can be considered a champion of restructuring, that since 2008 closed a number of 241 units reaching 1177 agencies in 2011.

The Romanian banks orientation towards retail customers since 2002 led to developing a network of banking counters, determining credit institutions no matter the dimensions to penetrate numerous areas of a high banking potential, many of the units opened having modest dimensions of 2-6 employees

(neighborhood units). However, the banking process of Romania is still modest having about 6000 citizens at the banking counter, much above the average of the member states in the European Union of 2297.

The fast development of the Romanian banking system in the first years of the last decade, was accompanied by the fast development of the labour force used in this sector of economic activity.

If at the end of 1999, the average number of the employees in the banking system was of 50784, one year later, as Bancorex closed and some restructuration measures were taken by those banks having a majority state capital, the staff employed in the banking industry decreased up to 44802 persons.

Since the orientation of the Romanian credit institutions in 2002, towards retail activities that requires a numerous staff, the process of increasing the occupied available labour force in banking institutions, thus at the end of 2008 a number of 71622 (Figure2)

Figure 2 The evolution in number of the employees in credit institutions

Source:www.bnro.ro

Since 2009, the evolution in number of the employees registers a decreasing trend, thus comparing to the previous year, 3160 persons were dismissed. Commercial banks continued a slow restructuring last year, by dismissing 61 employees, reaching a number of 66692 persons at the end of 2011.

A higher cut off took place in territorial units that decreased from 6170 to 6040 agencies and branches, banking institutions closing more than 2% of the territorial network in 2011.

The trend of externalization in banking services is more and more evident. This is possible by the broker agencies of the banking services and by franchising system.

Mobile bankers represent the mobile sales component of the banking entities, by which one can obtain high results at low costs. In

case of crediting process, the responsibility of drawing the crediting file is assumed by the broker, so diminishing the queues and the time spent in front of the banking counters.[4]

The costs involved are supported by the banking institution, this not charging further commissions from the customers. A personalization of the banking services produces in this way, by moving the brokers to the branches of economic agents or to the addresses of the individuals, getting a considerable time saving.

Collaborating contracts are concluded between the brokerage companies and the commercial banks.

The first ones are not obliged to provide services to only one bank. This modality leads to a diminishing of costs for the banking entity, this paying a certain amount and a commission proportionally direct to the efficiency of the brokers, also diminishing costs due to paying the staff and providing the necessary conditions to carry on the activity. [5]

The offer in franchising system is another method to externalize the banking services. A training period and instruction is necessary for those who provide such kind of service. The training course will be provided by the branch to be able to use the soft, to check the data and to get used with the labour flow in general.

The deep changes that happened on the national banking market, mainly determined by the international regulations and new information and communication technology, involves new strategic orientations of the banking institutions materialized by changing the methods.[6]

In the future, the customer will have a central role, being more anticipative, more familiarized with the banking services and more authoritative. He will have the control and he will be interested only in those banks able to meet his demands.

The banking activities will focus on basic competences, aiming to identify those target fields and on developing them. Banking competition will take place on strict specialized market segments.

Thus, human resources management, inovative approach of banking products and services, information technology and applying a quality management will be

essential elements for banking institutions to succeed.

Entrepreneur and entrepreneurship education. Entrepreneurship Education in Romania

Dromereschi Maria Irina
Technical College „Anghel Saligny” Bacău
dromereschi_irina@yahoo.com

Abstract

In entrepreneurship research indicates a direct relationship between the level of entrepreneurial activity - the frequency with which an economy is creating new businesses - and growth. It is considered that the level of entrepreneurial activity in a country or region favors the growth of the country or region. The idea behind government initiatives to develop and implement public policies to support and encourage entrepreneurial activity across countries and regions.

In Romania, entrepreneurship education at all levels - primary, secondary, university or professional training - plays a major role in key entrepreneurial skills. Although entrepreneurial knowledge necessary for learning is growing, there are still a number of obstacles in the development of entrepreneurship education, especially in terms of finance and human resources.

Keywords: entrepreneur, entrepreneurship, entrepreneurship education.

J.E.L. Classification: L26, I25.

1. Introduction

Entrepreneurship is manifested in the economy under a multitude and variety of forms, with very different results not only reflect the economic and financial welfare. Equally, entrepreneurship is correlated with technological progress, create jobs and reduce social inequalities or environmental issues.

Globalization and the global crisis in recent years have favored a series of structural changes in plan entrepreneurial deeply felt. Increased competitive pressure on businesses, which resulted in an increase in productivity by using the new technologies

and innovation processes. New opportunities stimulated entrepreneurship and creativity, which are considered engines of economic development in 2020.

It is widely recognized, particularly economic analysts and policy makers, that business is generating wealth in society is a key to economic growth and job creation. Supporting entrepreneurship has become a priority as a solution to the crisis and stop the alarming rate of unemployment. In recent years, governments constantly allocates resources for recovery help businesses in different forms: loan guarantees, tax subsidies, credits for research and development aimed at forcing innovation or to encourage startups.

2. Entrepreneur from yesterday and today

Richard Cantillon (1680-1734) was the first to use the term "entrepreneur" calling him as the one who had to be constantly alert to speculate relationships and opportunities, be confident and willing to take risks [1]. Related Industry in the early revolution, Cantillon sensed no impact technological innovation or responsiveness status on careaceasta one determină.

In 1800, Jean Baptiste Say's vision of the entrepreneur creates new value in that person recognizing him as "transferring resources from one area of lower productivity into one with higher productivity and higher profits "[2].

Alfred Marshall believes that the most important function of the entrepreneur is to provide simultaneous innovation and progress [3].

In the twentieth century, Schumpeter distances itself from classical economic theories, centered on the ideas of balance and optimize and promote "man of action" and the concept of developing the kind of change that only genes within the economic sphere

and not in response to the phenomena produced in response beyond. Entrepreneur or "man of action" [4] has the courage, vision, creative spirit, the ability to initiate a new quality, to recombine or to imagine new combinations of already existing resources. Innovation is the process continually change and progress a natural consequence. Entrepreneur is "man swim against the current society in which he lives" because it is motivated by power and desire for self.

Peter Drucker is one that nearly a century after the first edition (1911), Schumpeter's work makes an observations enlightening demonstration: entrepreneurship is not a "feature either an individual or an institution. It is not a personality trait. [...] Entrepreneurship is behavior rather than personality trait. "Entrepreneur is a person who "always looking for change, responds to it and exploits that opportunity". [5] Therefore the link between innovative entrepreneur and dynamic imbalance of an economy is a direct theory. Moreover, one who "maximize opportunities" that "bring all parties together, integrating all resources (financial, human, knowledge) to transform business invention 'that practice" systematic innovation "(in an institutional sense). Moreover, Drucker lead judgment and addictive behavior in the vicinity of entrepreneurial management.

If Knight's entrepreneur based its ability to raise capital on the ability to handle uncertainty, intelligence, confidence and foresight Israel Kirzner (1982) exploit vigilance, creativity, leadership skills and ability to exploit profit opportunities. Existence of unexploited profit opportunities is a sign that some resources were earmarked wrongly and led to a kind of social waste"[6].

May source of fresh new and in an integrating vision, Adrian Tanțău shows that the entrepreneur is "a person who by intuition and creativity, sees opportunities where others do not see them, turn them into ideas that successfully apply in practice creating new jobs and taking a calculated risk "[7].

In 2007, cooperation between the OECD and Eurostat, the EIP [8] were developed standard definitions and concepts underlying the production and collection of statistical data from different countries. OECD-Eurostat approach combines several conceptual definitions empirical indicators.

Based on theoretical contributions of Richard Cantillon, Adam Smith, Alfred Marshall, Joseph Schumpeter to EIP adopted several definitions on entrepreneurship deliberately focusing on the link between entrepreneurship and business.

Were taken into account three components: entrepreneurs, entrepreneurship and entrepreneurship, defined as follows:

- *entrepreneurs* are those persons (business owners) who seek to generate value by initiating and developing economic activities by identifying and exploiting new products, services and markets;
- *entrepreneurial activity* is the enterprising human action to achieve value generation through the creation or development of economic activity, by identifying and exploiting new products, services and markets;
- *entrepreneurship* is the phenomenon associated with entrepreneurial activity.

Between the three components there is no perfect boundary. Entrepreneurship is one of the key success factors for the EU 2020 strategy, promotion and support of entrepreneurship is provided in a series of actions to smart growth, industrial policy, research, innovation and education.

3. EU policies to support entrepreneurship

EU policies on entrepreneurship guided by three documents: Small Business Act for Europe (2008) Europe 2020 Strategy and Action Plan for the development of entrepreneurship in the EU, 2020. "Small Business Act" (SBA) or the Small Business Act for Europe is the European Council initiative that arises recognition at the highest political level, the role and importance of SMEs in the European economy. In 2008 it was adopted European Industry Commissioner Gunter Verheugen said that "through the Small Business Act for Europe, a Europe full force involved in supporting SMEs by bringing all the resources of Europe to support small businesses in business their daily and to prepare the way for those that will create more jobs and grow "[9]. For the first time, proposes a partnership between the European Union and the Member States to establish a policy framework that is based on the "Think Small First". SBA promotes such a set of 10

principles to guide the design and implementation of public policies in this field, both at EU and Member State level.

Principles found in the 4 strands promoted by the European Commission in 2009, which followed consistently, primarily the implementation of the "Think Small First" by "SME test". SME test, already implemented by some Member States (Belgium, Denmark, Finland and Germany) to simplify accounting rules for micro and reducing administrative burdens for SMEs, introduction of single window operations and completion of one year within the judicial proceedings in the case non-fraudulent bankruptcy.

The second major direction of action relates to access to finance, by simplifying rules on State aid, adopt a manual on rules applicable to this area and adopting a temporary framework for state aid for 2009-2010 in order to counter the effects of the credit squeeze on real economy.

The third course of action is to market access by reducing fee for Community trade mark rights and simplified registration procedure.

The fourth course of action promotes entrepreneurship by organizing major events for the general public, allowing entrepreneurs to present their career paths and enable network activity. Are promoted examples of good practice, European prizes for entrepreneurship, to set up a European Network of Female Entrepreneurship Ambassadors and ERASMUS network supports young entrepreneurs, while a number of Member States have decided to integrate entrepreneurship education into their curricula.

'Europe 2020' [10]. is the European Union's strategy for growth, with the time horizon 2020. In a rapidly changing world, the EU wants to become a smart, sustainable and inclusive growth. Smart growth concerns an economy based on knowledge and innovation. Sustainable development requires competitiveness and resource efficiency. Inclusive growth means a higher rate of employment in the economy to generate economic, social and territorial cohesion in the EU. These three priorities are mutually reinforcing and are able to help the EU and its Member States to achieve a higher level of labor employment, productivity and territorial cohesion. In fact, five major goals

are set on employment, innovation, education, social inclusion and the environment to be met by 2020. Various actions at European and national level in support of the Strategy. The European Commission launched in autumn 2012, an Action Plan [11]. entrepreneurship development at all levels (European, national, regional), which aims to boost entrepreneurship in Europe in 2020, by unlocking the potential for growth and jobs.

4. Entrepreneurship education and training for entrepreneurship

Education is essentially an action oriented purposes. As a modeling activity, socialization, leadership training process of the younger generations, education is always done from the perspective of project personality, a kind of man who embodies the value system that society tends to perpetuate, to promote it and develop it through education.

Existence goals and the need to express their formulation under prospective nature of education, the fact that, by its nature, education is necessarily forward-looking. In this regard, while goals ensure ongoing consistency of educational influences, it prints the current educational activities and projected future destination. Need and importance of taking explicit formulation and enhance education goals for education systems and processes. Goals are, in this context, the central component that gives character planned, organized and systematic education.

In the current global context, policymakers in Europe and the United States believe that entrepreneurship is more than necessary to achieve higher levels of growth and innovation. Empirical research has shown positive relationships between entrepreneurial activity and economic outcomes [13]. Policy makers also believe that increased levels of entrepreneurship can be achieved through education [14] and especially through entrepreneurship education. Therefore, such education is promoted and implemented curriculum in many European Union countries and the United States [15].

The premise behind these programs is that entrepreneurial skills can be taught and are

not fixed personal characteristics. Indeed, it was shown that: the effect of general education, measured in years of schooling on contractor performance is positive [16] and that effort is effective business training is measured in the number of people who applied for microfinance to start your own business [17].

Entrepreneurship is a multidisciplinary field with a broad topical coverage. Shane and Venkataraman (2000) have defined the "the territory of the scientific examination of how, by whom and with what effects are discovered, evaluated and exploited opportunities to create future goods and services". What is the relationship between formal education and entrepreneurial performance? As demonstrated by Van Praag and Versloot (2007), there are enough studies that show the important contribution of entrepreneurs to the economic development of nations. Henrekson and Johansson (2005) shows that successful entrepreneurs are responsible for growth. The latter is supported by levels of competition, job creation and innovation. Private benefits imply positive social externalities. Consequently, many developed countries and regions, including the U.S. and EU, unemployment policies encouraging successful entrepreneurship. One is providing opportunities for people to develop human capital through education. In other words, these policies are consistent with the hypothesis that entrepreneurship involves skills that can be developed through education.

Opportunity cost problem of choosing between being an entrepreneur and take full advantage of this quality, and be entrepreneurial and employee performance measurement reads her idea through income earned and not of individual time. We read stories about successful entrepreneurs who dropped out at various stages of their lives. They include Sir Richard Branson (Virgin), Michael Dell (Dell Computers), Bill Gates (Microsoft) and Larry Ellison (Oracle). Not infrequently some of them said that education is a waste of time if you want to become an entrepreneur. Education would be useful only for salaried employees. Therefore, these statements imply that the skills required of a contractor can not get / can not be developed through formal education. However, the

latest list of billionaires in the world, included 1125 individuals of which only 73 of them, six percent gave up at some stage of schooling.

Inverting hypothesis, we could say that formal education is associated with a greater likelihood to opt for entrepreneurship, the reason being that people with higher education are more likely to see entrepreneurial opportunities. Investing in their education can multiply the number of their future business using superior information processing and with higher degrees of freedom when optimizing the use of labor in their company.

5. Entrepreneurship Education in Romania

In Romania, entrepreneurship education should be initiated and continued in school family. It is a priority one only from a pragmatic perspective (who will produce added value tomorrow?) Nor in terms of alignment with economic standards, but from the perspective of European education or cultivation of a way of being and living compatible with notions of welfare (A. Smith), sustainability and sustainable development in an economic, social and political high entropy.

In 1973, Edgar Faure [18] warn "competitiveness of an economy depends on the wisdom of its decisions concerning education, the ability to make decisions necessary reform, the ability to take on tasks that involve this type of investment. [...] Over the next 20 years, international competition will be linked largely by investment type and intellectual education itself will no doubt make a good international exchange will export >> << educational programs at the same time finished products ".

Characteristics' investment in entrepreneurship education "related to the specificity and magnitude of its economic and social effects:

- multiple and inter-effects - economic, social, cultural, political, educational demos, interpersonal manifest in terms of creation and innovation in the social participation, communication, dialogue and transparency, cooperation and collaboration, initiative and autonomy, participation in society, education and family strengthening social cohesion etc.

- attribute training, dissemination and propagation of individual scale investment: in performances, learning capacity, flexibility in terms of economic knowledge and occupational mobility - training and, ultimately, the size and scale of income and social security by contributing - via competence and performance - to increase the material and spiritual at the family level, there is transfer of knowledge, behaviors, orientation and education of children in the community in which they work, communication, and mutual respect, solidarity and cohesion etc.

- whether theoretically infinite, human resource development through assimilation of new skills through restructuring / reorganization of previously learned, transfer of knowledge, skills, competence;

- character "close" effects with respect to time investment is made, there is a noticeable distance in time when there are changes in education and training and employment patterns (trend of reduction, compression of the gap).

Investing in entrepreneurship education, regardless of the agent that they fund is a long term investment in terms of period (s) of time when it is done, and the short / medium beneficiary of this type of investment and human community of which part, usually expressed in competence, performance and income.

And Romania have made great strides by introducing elements of entrepreneurial culture in school curriculum early learning classes, continue to the secondary. By revising school curricula at all levels approved by Ministerial Order 5097/2009 entrepreneurship is explicitly recognized as cross-curricular goal. Development, the number and content of courses, the recent emergence of educational research and the current situation in education - reflects an apparent consensus in the need to provide adequate teaching entrepreneurship education for purchases.

However, the short history of entrepreneurship education indicate that it is not possible to share another collective experience, knowledge and meanings about how to do this. To move forward, there is a need to combine entrepreneurship studies methods of integration of knowledge into the curriculum and to focus greater dynamics in

the context of the implementation of specific cultural values of each people.

6. Conclusions

Romania should give greater weight to economic education and entrepreneurship, to identify the main factors that may contribute to enhancing the role of education in economic development through curriculum content invoice facilitating economic structural adjustments - the quality of human resources to the labor supply and allowing modeling work according to set patterns imposed by labor demand.

The considerations arise from the very fact that economic education, or entrepreneurship, by extension, means preparation for professional work as the main reaction and adaptation to change. Currently in Romania, entrepreneurial culture crystallizes especially in private companies founded after the creation of free market mechanisms in Romania.

EU employment guidelines work identifies entrepreneurship as a priority in education. Encouraging entrepreneurship involves promoting right thinking, entrepreneurial skills and awareness of career opportunities as an entrepreneur. Therefore it recommends teaching entrepreneurial subjects, inclusion and recognition in the national curriculum and the curriculum for each level of the education system.

dugan_silvia@yahoo.com

Talmaciu Iuliana

Universitatea „Constantin Brâncoveanu” din Pitești

iuliana_talmaciu@yahoo.com

Abstract

Franchise is definitely a superior concept of doing business and it provides the best answer to the globalization tendency, as it has the advantage of distributing risk, which leads to avoiding the danger of general economical crises with devastating effects.

In our country the impact of the economical crisis on this sector has materialized in the year 2009 by a decrease of 30% of the volume of franchised businesses, after which the figures have constantly increased, reaching in 2011 the same level as in 2007. The franchise market in our country is developing, and the specialists of this sector estimate that it will evolve explosively in the field of retail and in that of consulting and training services.

Keywords: franchise, franchise market, crisis, brand

J.E.L. Classification: M16

1. Introduction

Taking into consideration the national and international context of the economical crisis, interest lays upon profitable business. In these circumstances, a franchise business represents a winning bet because franchising becomes the most dynamic and powerful method to develop a business, as well as an economical opportunity and the franchised has the possibility of becoming his own architect of the franchised draft and of work procedures. Franchise provides the best answer to the tendency of world globalization, as it has the advantage of risk distribution which leads to avoiding the

danger of general economical crisis with devastating effects.

Franchises promote the entrepreneurial sense and that of initiative and also encourage independent work activities as an alternative for the job of an employee. The opportunities offered by such businesses are of great help for those who are just starting their careers and intend to become entrepreneurs, for the retired people who want to increase their incomes but also for the unemployed who can thus benefit from a professional reconversion and for those looking for a new job.

2. General considerations concerning franchise

The International Association of Franchise defines franchises as being a commercializing system based on a continuous collaboration between physical and juridical persons, financially independent, through which a person, called franchiser, gives to another person, called beneficiary, the right to exploit or develop a business, a product, a technology or a service in a certain territory.

Briefly, the franchise means putting in practice the fundamental pedagogical principle: “Teach me to succeed on my own.”

The notion of franchise is defined in Romania by the law no. 79/1998 for the approval OG 52/1997 as being a commercializing system based on a continuous collaboration between physical and juridical persons, financially independent, through which a person, called franchiser, gives to another person, called beneficiary, the right to exploit or develop a business, a product, a technology or a service.

The franchise appears in all fields of activity, such as: fast food, restaurants, cafes, shops, beauty, real estate, services, education, Internet, auto, cleaning, security, advertising, finances, training, traveling etc. This business technique could contribute greatly to the modernization of the Romanian economy, especially commerce, by attracting foreign investments to its highest components, brand, know-how, modern technology etc, in a manner convenient for all parties. [1]

The advantages of a franchise in comparison to the traditional business would be the fact that the franchisee benefits from an extended training in developing a successful business, the franchisor guides the franchisee regarding the direction of the business, all franchisees receive training, guidance and planning before setting up the business, minimizing risks, both for the franchisor and the franchisee, the reputation of the product or service is already identifiable for the consumers, such a business does not require previous experience in the franchise field, financial assistance is offered in the form of consultancy, by associating with them the franchisee benefits from instantaneous local recognition, obtaining a business model, diminishing the risk associated with launching a business, rapid extension of the distribution network and other forms of help offered to the franchisee. [2]

On the list of weak points there are aspects such as reduced crediting of the private sector by the banking sector, the extreme long procedure of closing a business, the taxing system that burdens the private sector and the low expenses in the research-developing sector.

3. The evolution of the franchise market in Romania

In Romania, the first commercial contract containing specific elements for the franchise system was closed by HERTZ with the Romanian Auto Club, in 1975.

During communism, in Romania one has intended to annihilate the entrepreneurial spirit.

Starting with the 90's, as Law no. 31/1990 concerning commercial firms passed, developing the entrepreneurial sector became

an important component of the economical restructuring policy. [3]

Starting with 1991 the franchise entered our country through firms known internationally: Coca Cola, McDonald's and Pizza Hut, but the beginning of the accelerated expansion of great international franchisors really started in 2002. According to the data of the Romanian Franchising Network Association – ARFR, in 2000 there were 20 franchises, in 2003 - 103 franchises, in 2004 - 171 franchises out of which 43 were Romanian, in 2005 - 210 franchises out of which 63 were Romanian.

The business environment becomes more favorable for franchises in 2006 when the Romanian Franchise Association is established. The association promotes franchising as a commercial method on the Romanian market and it initiates actions against illegal franchises, counterfeits and to avoid know-how theft.

In 2007 the franchise system brought a new advantage to franchisees. Following the adherence of Romania to the European Union all companies must respect the norms of the Union. Auditing is fairly expensive in Romania and the offer of the franchisor is more advantageous because it is already formatted according to the E.U. In 2007 363 franchises were in function, 12% more than in 2006, the most franchised brand being Fornetti, with over 400 locations open.

The first attempt of a local brand to enter the market outside of Romania through the franchising system was in 2008 when Jolidon had its first exhibition at the Franchise Salon in Paris. [4]

In 2011 there were 385 franchises, 17% more than in 2010. Nowadays in Romania there are over 400 franchises operating with a lower or higher degree of success. The evolution of the number of franchised businesses in our country is synthetically represented in graphic 1.

Graphic 1. The evolution of the franchised brands on the Romanian market

Source: Data processed by the authors

The best known Romanian franchises are: Gogoșă Înfuriată, Elvila, Turabo Cafe, Jolidon, Musette, Tina R, Startonight, Rodipet, Rompetrol, Piritex, Ana Pan, Best Clean, Rent a Benz, Expert Detailing, Mobexpert, Romstal, Fereastră Suki, Perfect Nails.

The best known brands that have entered the internal market by franchising are: McDonald’s, KFC, Broaster Chicken, WU XING, Four Star Pizza, New York Pizza, Pizza Hut, City Wok, Fornetti, Danny Donuts, Burger King, Golden Pie, Wienerwald, Clate, Coca-Cola, Pepsi, Yves Rocher, H&M, Miniblu, Replay, Mexton, s.Oliver, VERO MODA, Veronesse, Gloria Jean’s, New Look, Motor Jeans, Etam, Safety Broker, Mr. Bricolage, Lavazza, Segafredo Zanetti Espresso, Caffè Filicori Zecchini, Caffè Vergnano, Illy Caffè, Julius Meinl, Euroins.

At this moment there are big brands from U.S.A., Canada, Italy and France which are interested in entering the Romanian market. The most sought after franchises remain those in fast food, services – especially gambling, sport bets and beauty saloons but also retailing. [5]

According to CHR Consulting Group data, in 2004 the turnover generated by the franchising system in Romania was of approximately 730 million Euros. In 2005 the franchise has registered a turnover of 890 million Euros, in 2006 it increased to 1 billion Euros, it continued its increase in 2007 and 2008, reaching 1.2 billions and 1.3 billion Euros and it dropped to 900 million Euros in 2009.

In 2010 the income generated by franchises rose again to 1 billion Euros and to 1.2 billions in 2011. Graphic number 2

presents the evolution of the turnover resulted from franchises in Romania from 2004 until 2011.

Graphic 2. The evolution of the turnover resulted from franchises on the Romanian market

Source: CHR Consulting Group

From the graphic above one can notice that in 2009 the impact of the economical crisis over this sector materialized in an approximately 30% decrease of the volume of franchised businesses, less than in other businesses – such as leasing, where the decrease was of 74% during the same year.

The explanations of the development of franchises in our country would be the following:

- the rising competition in all fields of activity which leads to the idea that the faster a firm enters the market the smaller the initial costs, the weaker the competition and the stronger the development will be;
- the current level of the balance between prices and salaries – prices tend to align in a relatively short amount of time to world prices, while salaries align to global ones during a longer period of time;
- the existence of a highly qualified, cheap and easily adaptable workforce;
- the acute lack of quality services and products;
- numerous staff dismissals both in industry and administration;
- the existence of small entrepreneurs who have gained a certain experience and who have been forced, because of

environmental changes, to reduce or close their own business;

- the positive attitude of political parties and of governmental institutions towards foreign investments in Romania;
- the existence of an attractive natural environment that can be valorized effectively in a franchising system;
- the deficient juridic system that determines foreign investors to make investments of intelligence instead of financial ones;
- the franchising system promotes businesses of reduced proportions which imply a small financial effort;

The franchise represents a management school for the Romanian entrepreneurs who benefit of the experience, know-how and research of foreign businessmen, thus providing them with the professional standards necessary to attain success. Romania needs to develop and apply the concept of franchise, a concept important for the reduction of the imports of services and products.

Nowadays, Romanian investors have become more prudent in deciding how to spend their money, in the context of facing a lack of liquidity. On the other hand franchisors are more conciliating, more willing to negotiate certain clauses in the franchise contract. If until now foreign franchises were usually less interested in Romania, now, in their desire to externalize, they are looking for emerging markets. It is a favorable moment for franchisees and master franchisees to obtain certain advantages such as some discounts when it comes to entrance taxes, the level of royalties, dividing payments. Moreover, foreign franchisors are facing with a certain degree of saturation of their own markets and they are looking for other consumers in their wish to expand. At times like these they become more conceding as the potential candidates start from different positions in comparison with previous years, when it was possible for those

wanting to become master franchisee for a certain brand not to be even considered by the franchisor. [6]

Regarding the structure of franchised businesses, it has suffered insignificant changes between 2006 - 2011, its evolution being presented in graphic number 3.

Graphic 3. The evolution of the structure of the franchise on the Romanian market

Source: data processed by the author

An ascending trend on the Romanian market of franchises belongs to businesses in the field of restaurants, including fast food ones. Positive evolutions are also registered in the retail market and in the services market. Franchises in the field of sports betting and cosmetics also have good results. Hence, one of the most dynamic Romanian franchises, GS Bet, sports betting house, targets reaching in 2012 a number of 400 franchisees nationally and it intends to obtain accreditation sell the franchise in other countries. Also, the franchise Biothecare Estetika, of Portuguese origin, opened in Sibiu and it represents a serious competition to franchises such as Nomasvello and Cellulem Block. Another franchise from the cosmetics field, also from Portugal, Depil Concept, aims at entering the Romanian market. A Greek franchise, specialized in developing and implementing modern methods of learning foreign languages has managed, after three years of activity, to reach

impressive figures, the pilot unit being set in Pitesti.

2011 was the year in which well known franchises have come to Romania – for example H&M and Subway – a brand that has recently surpassed McDonald's in the USA. In a global top of the first 10 franchises Subway is on the second position while McDonald's is on the sixth. [7] The secret of the franchise's success was positioning Subway as a healthier alternative in the fast food industry. Other factors have also helped – for example cheaper properties, access to better commercial areas and more agreeable conditions offered by the owners of the commercial spaces. Another important factor was the low tax of the franchise – only 15,000 dollars. The company is now present in 100 countries amongst which Romania, where the necessary investment to open a Subway restaurant is of about 100,000 Euros while in the USA the costs rise up to 250,000 dollars. Another strategy that paid off was choosing nontraditional areas. About 20% of the restaurants of the franchise are set in university campuses, auto dealers' quarters and even churches. At this moment the Subway chain has 36,000 units out of which 2,100 were opened in 2011. [8]

Romania remains a profitable target for the development of franchised businesses even during the crisis, the success rate of the franchised networks being of 89% compared to 93% in 2005. Nowadays the most profitable areas in which one can invest for franchises are alimentation and services.

A significant evolution was registered by expanding franchises in areas outside the capital city. Until now, 75% of the franchises were found in Bucharest, but a medium term expansion of the franchise chain is expected in areas outside the capital, the targeted cities being Timișoara, Constanța, Arad, Suceava or Iași. Moreover, luxury franchises were affected the most by the crisis, taking

constant losses because of the crisis, despite the fact that some of the franchisors have lowered the prices. Another effect of the crisis on luxury franchises is increasing the time in which the investment is recovered. If in past years the time of recovering the investment in a franchise was of 2-3 years, now it has increased to 5 years.

In addition, if in the past the sums of the most sought after franchises were between 75,000 and 100,000 Euros, now the ones that are sought after are those of approximately 30,000 Euros, as the risk for them is smaller and many investors still believe the Romanian market to be insecure thus preferring a smaller investment with a quick profit. In general, the minimum investment for a unit open as a franchise is between 10,000 and 80,000 Euros, depending on the placement and on the field of activity, but it can also reach 250,000 dollars, sum that was invested for the opening of a Musette shop in New York. It is not by far the only example of an exported Romanian franchise, this already being a clear tendency on the Romanian market.

'Native franchising networks represent 45%-47% of the market share of all franchising systems, mainly because of the fact the products and services are adapted to the needs of the consumers, but also because the price and the necessary investments are considerably smaller than the ones for foreign franchises', states Constantin Anton, the president of the Romanian Franchise Association.

Of course there is also bankruptcy among Romanian franchises. One of the examples is Credit Team, a franchise of bank brokers that went into bankruptcy last year, without going through the procedure of reorganizing, only a year after it had received an excellence award for 'solutions for crisis'.

4. Conclusions

The relaunching signs are many more, and investors from a wide range of domains want to bring new franchises on the market. The franchise market in our country is developing and the specialists estimate that it will develop explosively on retail, consultancy services, training. The big franchise chains have entered Romania but there is still place on the market.

Brand Image Perception: Case-study at Volkswagen AG

Dumitriu Roxana Ioana
University of Craiova
dumitriuroxana@aol.com

Abstract

In this paper I studied the perception of brand image within the Romanian consumers. Brand holders want their brands to enjoy a strong awareness and notoriety. Brand image is an important constituent of customer mind-set, the value of the brand belonging to the customers. Various instruments were set up to measure the brand image. I used the customer based brand equity model to measure the attitudes of the Romanian consumers toward the Volkswagen brand. The objective of the study was, at theoretical level, to assess the explanation power of the customer based brand equity model and, for the practical purpose, to see how Volkswagen brand perform for the Romanian public. As a methodology I selected a sample of students from the University of Craiova. The results showed that the customer based brand equity model is useful tool in assessing the brand image and that Volkswagen is an appreciated brand.

Keywords: brand image, brand associations, awareness, Volkswagen.

J.E.L. Classification: M10, M31

1. Introduction

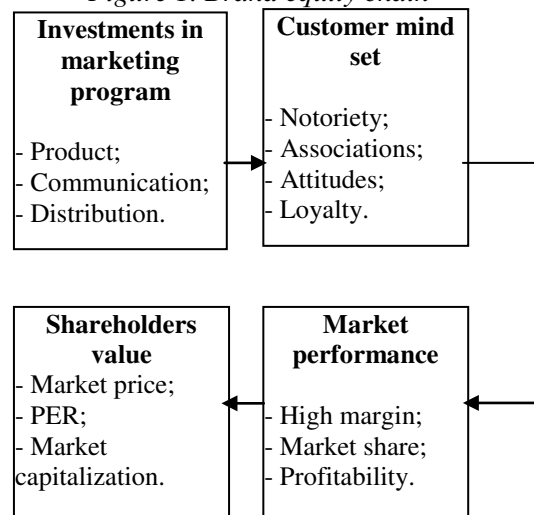

Brands are the connection, the bond between the production and consumption. A product is no longer a sum of functional benefices; it is mostly a symbolic item, with many associations. In order to stimulate the sales of a product it is not necessary to change its utility, but only to slightly modify the emotional connotations that the product generate. It is necessary to change the perceptions of the public and to reinterpret the product. People consume fewer products and more brands. The consumption can no longer be interpreted as the rational decisions

of consumers to maximize the utility. At the moment, the consumption is a social act with strong cultural implications. The brands have a strong importance in the business world, being a sign of the acknowledgments and notoriety. Brands mean respect, quality, leadership, competitive advantage.

2. Literature review

Brand equity is a set of assets and liabilities tied to a brand, to its name and symbol, which adds (or deducts) something more to the value furnished by a product or service. Those assets and liabilities must be in connection with the name and the symbol of the brand, in order to contribute to brand equity [1]. Brand evaluation must take into consideration many elements. Keller (2008) is suggesting a system called the brand equity chain, as a structured approach in order to identify the sources of the brand values and the ways the marketing activities create brand value [2]. The brand equity chain starts from the assumption that the brand value is the mind of the consumer. The process to create the brand value begins with the companies' investments in a marketing program, in order to attract actual and potential clients (figure 1).

Figure 1. Brand equity chain

Source: Adapted from Kevin Keller, *Strategic Brand Management, Person Education, 2008.*

Brand holders try to create a set of associations in the mind of consumers. In this way, they are aware of the fact that brand equity is higher if the brand evocations are numerous. Brands became the must-have thing. Brands became an ideal at which many people aspire. Above the aspiration brands are the identifications brands, with which the people wants to get identified. The dependence is created at various levels. According to Kornberger (2010), the brand equation is as follows [3]:

Figure 2. The brand equation

Source: Adapted from Kornberger, Martin, *Brand Society: How Brands Transform Management and Lifestyle, Cambridge University Press, 2010.*

This equation ensure the formula of success and profit in many industries. It is useless to conclude that the evocations assure the highest part of the brand value. If a consumer has a strong bond with its brand, then this is less inclined to change the brand [4].

A model of brand equity starting from the clients perceptions is the Keller model of customer based brand equity (CBBE) [3].

Developing brand equity is a difficult, complex and sensitive process. The CBBE model approaches the brand equity using the customers perspective. The basic assumption of this model is that the power of the brand is based on what the clients have learned, felt, seen and heard about a brand, based on their experience with that brand over time. In other words, the power of the brand is in the mind of consumers. Keller defines the customer based brand equity as the differentiate effect that the brand knowledge of consumers have on the consumers response to the marketing activities of that brand owner company.

The construction of a successful brand using the CBBE model is realized in a four steps succession; the passage to the next phase is realized only when the previous objectives have been touched. The four phases are:

- The clients must known the brand; they

should be able to associate it to a product or service (brand awareness);

- The clients must to be aware of the totality of significances of a brand, by associating tangible and intangible elements with certain properties (brand meaning);

- To obtain the desired outcome from the clients (brand action);

- To transform this outcome in a active, intense, loyal relationship between client and brand (brand relationship).

The CBBE model can be represented under a pyramidal shape as in table 1. The left side is more a rational way regarding the brand equity development, whether the right side is a more emotional approach. The most admired brands have been consolidated both ways.

Table 1. The CBBE model

Resonance (loyalty, commitment)	
Judgments (considerations, credibility, superiority)	Feelings (love, fun, security)
Performance (basic characteristics, design, price)	Imagery (user profile, personality and values, purchasing experience)
Salience (associations, information gathering)	

Source: Adapted from Kevin Keller, *Strategic Brand Management, Person Education, 2008.*

Keller’s model approach has some drawbacks because even if it does offer an analytical and conceptual description of brand equity development, the approach lacks a firm theoretical foundation. It remains unclear how qualitatively based brand evaluation can be converted into monetary units. Keller’s system is a conceptual strategy for brand appraisal that remains as yet unconfirmed by empirical evidence.

Basically, brand-customer relationship experiences three stages: knowledge, experience and emotions, as depicted in the figure 3.

Figure 3. Stages in brand-customer relationship

Source: author conception

Knowledge is reflected in that a person learns the concrete characteristics of an object, such as its name, its appearance or its physical properties.

Experience is the process of interacting with the brand world, resulting both consumption and networking.

Emotion represents the feelings, positive or negative, brought to mind by an object or idea.

A brand representation that is activated quickly and easily is more likely to influence a decision at the point of purchase. Hence brands with more balanced associations across these three areas are more likely to be strong and primed for continued growth. This is evidenced by elevated levels of bonding leading to brand's future performance [5].

3. Volkswagen company

Headquartered in Wolfsburg, Germany, Volkswagen AG is the biggest car producer in Europe. In 2011 VW sold more than 8.2 millions cars all over the world. The group has a multibrand strategy including among others for example: Volkswagen, Audi, Seat, Skoda. Its main markets are: Europe (more than 4 millions cars sold), Asia-Pacific (2.64 millions) and South-America (0.93 millions). Volkswagen has a strong presence on the markets that generate the highest raise in the selling figures: China, India, Brazil, Russia [6].

Volkswagen cars have a solid technical reputation. The cars are reliable and offer a good price to value ratio. Despite the current economic crises, Volkswagen increases its sales due to a good brand image and reputation. The company is not so interested in offering discounts to its models, such as the competition. Also, the company is interested to maintain the reselling value of its cars.

The group strategy for 2018 is:

- to deploy intelligent innovations and technologies to become a world leader in customer satisfaction and quality.
- to increase unit sales to more than 10 million vehicles a year; in particular, Volkswagen intends to capture an above-average share of the development of the major growth markets.
- to increase its return on sales before

tax to at least 8% so as to ensure that the Group's solid financial position and ability to act are guaranteed even in difficult market periods.

- to become the top employer across all brands, companies and regions; this is necessary in order to build a first-class team.

Volkswagen intends attain its objectives by a judicious allocations of technical and commercial resources. The company has more than 54 production locations in the world. The company invests in hot areas, with greater demand such as: China, India, Brazil.

From the technical point of view the company is investing constantly in new technologies that will make driving a remarkable experience. Making new technologies widely available, Volkswagen democratizes automotive technologies. These new innovations are in the area fuel-emissions reduction, helping the driver to enjoy to manage the cars. The company is engaged in new futuristic projects, such as the cars that drive their self.

Other innovations are realized in order to increase the autonomy of the electric engines. All these innovations are to be found on the new cars releases. Volkswagen invested in 2011 in research&development more than 7 billions euro.

From commercial point of view, Volkswagen continues to engage in new products and markets development. Its strategy is designed to increase the number of cars sold an also to launch new models. The diversification of products is necessary in order to better satisfy the clients needs.

Audi brand is targeted for consumers with high income. The brand's success can be explained by better engine solutions combined with a stylish driving emotion. Volkswagen, “Das Auto”, is appreciated by consumers that want a German car, with a good reputation, and that is still affordable. For the people in the developing countries Volkswagen is an aspiration car. The Skoda brand, “simply clever”, also increased its awareness and reputation on its target markets.

In general, the customers are satisfied with the brands of Volkswagen AG. The results of the satisfaction surveys place the brand on leading positions in Europe, and all

over the world [6].

4. Objective and methodology

The objective of this paper is to investigate the brand image of Volkswagen in Romania, using the CBBE model. For practical reasons, I focused only on the Volkswagen Brand. The survey used a sample consisting in a number of 158 bachelor and master students from the University of Craiova, Faculty of Economics and Business Administration. The sample has no pretention to be representative, but it is useful in two ways:

1) from a theoretical perspective to verify the applicability of Keller’s model on a specific brand;

2) from a practical perspective to acknowledge the image of Volkswagen AG on Romania market.

All the students investigated had a valid driving license and they confirmed to poses a good information on Volkswagen. Potentially they all are future clients of this brand.

For each category in the CBBE model we realized 5 items, asking the respondent to place itself according to a 5 point Likert scale, from 1 totally disagree to 5 totally agree. Then we checked to see if the items were representative. For this reason we used the Alpha Cronbach test, resulting a satisfying value of 0.932 (table 2).

Table 2. Reliability Statistics

Cronbach's Alpha	Cronbach's Alpha Based on Standardized Items	N of Items
.932	.931	25

5. Results and discussion

Then we performed the means for each of the five categories. The descriptive statistics is listed in the table 3.

As we can see from the table above, the highest score (4.26) was obtained by the item: *The products of this brand are well-done*. The lowest score (2.84) was obtained by the item: *I identify myself with the people using the Volkswagen Brand*. Overall, the *Performance* category obtained the highest score (3.98). Volkswagen is appreciated by its technical characteristics and features.

Table 3. Descriptive statistics

	N	Mean	Std. Deviation
Performance_1	158	4.26	.717
Performance_2	157	4.13	.785
Performance_3	158	4.20	.835
Performance_4	158	3.72	.772
Performance_5	158	3.58	1.023
Imagery_1	158	3.39	1.008
Imagery_2	158	4.02	.829
Imagery_3	158	4.08	.743
Imagery_4	158	3.83	.843
Imagery_5	158	4.03	.735
Judgements_1	158	3.52	1.001
Judgements_2	158	3.77	.871
Judgements_3	158	3.69	.811
Judgements_4	158	3.80	.967
Judgements_5	157	3.70	.995
Feelings_1	158	3.09	1.209
Feelings_2	158	3.34	1.045
Feelings_3	157	3.67	.928
Feelings_4	155	3.25	.990
Feelings_5	155	3.45	1.082
Resonance_1	157	3.11	1.270
Resonance_2	158	2.90	1.155
Resonance_3	158	3.04	1.090
Resonance_4	158	2.84	1.202
Resonance_5	157	3.14	1.327

The overall performance is detailed in table 4. We did not check the *Saliency* category, since every body was aware of the Volkswagen brand. As we can see, overall the performance and the judgments are better evaluated by the respondents. Volkswagen is better known for its reliable, good technical performance cars than by the felling its car produce to consumer. The *Performance* (3.98), the *Imagery* (3.87) and the *Judgments* (3.70) obtained good scores. Scores were lower for *Feelings* (3.36) and *Resonance* (3.00).

Table 4. General sores

Resonance	3.00
Feelings	3.36
Judgments	3.70
Imagery	3.87
Performance	3.98

The results for male and female is detailed in table 5. In general, women do exhibit a strong bond with an auto brand, such as the men.

Table 5. Results for males and females

	Male (N = 87)	Female (N =71)
Resonance	3.09	2.89
Feelings	3.45	3.23
Judgments	3.70	3.68
Imagery	3.92	3.79
Performance	3.98	3.96
Average	3.63	3.51

From the table above we can find that there are significant difference between male and female regarding the perception of Volkswagen brand. The males seem to appreciate more the brand, especially in relation with the feelings and the imagery of the brand, while the females are somehow not attracted by the emotions of the brand. Both males and females appreciate Volkswagen in the same manner concerning the performance features and judgments. Overall, men appreciate the brand more than the women. This can be explained to the fact that cars have a much stronger influence and attraction on men.

6. Conclusions

The CBBE model proves to be a solid tool for measuring the brand image, especially the representations customers have. A sound theoretical construction, the CBBE model can be used successfully to capture the customer mind-set and the customers associations toward a certain brand. From the managerial perspective, the CBBE model is a reliable instrument to asses the brand-image perception. Our paper emphasized that Volkswagen has a good reputation, especially regarding the judgments about the brand. Concerning the emotional side of the brand image, Volkswagen is developing positive emotions among young Romanians. The quality of its cars and the positive perception of the public can help Volkswagen to achieve the group strategy.

The Particular Aspects of Intellectual Capital in Romanian Knowledge Economy

Feraru Andreea

Universitatea "Vasile alecsandri" din Bacău

Andreea_feraru26@yahoo.com

Abstract

Knowledge-based economy offers a new vision. This involves the intertwining of all the aspects of information, economic, managerial, social and technological approaches. Implementing the new vision at local level must be of a strong originality, the interdisciplinary approach is evident.

The success of knowledge-based economy requires innovation and creativity, qualities that are especially promoted by the higher education system. Entrepreneurship and leadership development is to include, according to various studies, in the academic training.

It is considered that the knowledge economy will provide a huge advantage for the emergent markets, for the isolated parts of the world economies, or for the countries like Romania.

The society of the third millennium enjoys the benefit of employees who are valuable due to their knowledge. In many companies, worthiness does not consist in tangible assets, but in intangible ones. Intellectual capital is the term attributed to combined intangible assets that allow a company to operate efficiently.

Keywords: knowledge, intellectual capital, human capital, intangible resources

JEL Codes: F15, F50, O10

1. Introduction

At the present it looks increasingly obvious that the world passes through a continuous rapid transition from an economy based on industry to a knowledge-based one. It can be argued that the resulting knowledge and more knowledge. Knowledge is a public property. Once being discovered, it becomes virtually free of charge for all (excepting the

knowledge protected by law). The benefits of the new discoveries will be for the benefit of everyone, sooner or later. It should be noted some important aspects of the new economy as being fundamentally different from those of the old economy, meaning that the economic laws were not changed, but the economy has changed in a radical way.

In the industrial economy the capital is more important than the land. In the new economy, innovation through knowledge is the most important, it underlies many aspects of the economy. In the global knowledge economy, which is promoted, supported advantage of nations will not come from natural resources owned or on cheap labor forces, but in their ability to harness the intellectual capital. Today and tomorrow, "mind" and not "muscle" will be important for the economic growth.

2. Aspects of intellectual capital in knowledge economy

The development of civilization, knowledge-based economy can be regarded as a further step, which presents favourable prospects of a new better way of life. This economy has an economic and also socially important impact, it is based on the use of information in all spheres of human existence and activity.

Time evolution for the concept of knowledge-based economy has led to investigations which have established foundations, as follows:

- Industry of knowledge, which will note that the future will support those industries based on knowledge, innovation, development of the design activities;
- A second approach which preceeded the knowledge economy was the Knowledge Management approach. The first specific international conference

and exhibition held in Brussels on 20- 22 December 2000. The emblem of the conference was "Europe's future is the knowledge economy" and was highlighted by Robert Taylor and Unisys.

Defining the knowledge economy is a difficult goal. First, we consider the wide variety of successful implementation of the concept, and secondly, the specific of the countries which registered recognized significant progresses such as USA, Britain, France, Germany, Finland, Austria, Singapore or South Korea.

During the preparations for a knowledge-based economy, an important factor may be the recommendations elaborated by the World Bank Institute and OECD in a country study published in 2000. It was entitled "Korea and the Knowledge-Based Economy: Making the Transition" where there are presented some lines of action for the transition towards a knowledge-based economy. For example we can remember:

- Strengthening intellectual property rights, promoting exploitation of intangible assets;
- Take the necessary policy measures to encourage competition (competitive firms are more oriented to innovation);
- Managerial and curricular reform in higher education;
- Encourage greater interrelationships between firms, universities and government research programs;
- Allocation of resources to universities.
- European Union efforts should be driven up to build the knowledge society, and to the continuous improvement of the administrative capacity. They are absolutely necessary priorities to support and diversify the labor market.

Only a better exploitation of local and regional potential by strengthening local and regional powers can lead to both a sustainable development of communities, as well as by a coherent sectorial policies and changes, they look feasible because of strengthening trade relationships and inter- and regional changes.

The knowledge measuring assets refer to the evaluation, monitoring and managing business success through a number of increasingly large intangible factors. The

name of intangible (incorporeal) associated with these activities reveals their immaterial form, a characteristic which makes them especially difficult to identify and assess.

Intellectual capital consists of knowledge accumulations and flows owned by an organisation. They can be seen as intangible resources which, together with tangible ones (money and material assets), provide the total or market value of a firm.

Considering the definitions given by [9] author so far, we can infer some characteristics of intellectual capital, as follows:

- it is intangible, even if a material form can be attributed to some elements of the intellectual capital (for instance patents, registered trademarks);
- there is a close connection between the intellectual capital and knowledge under various forms;
- the human capital of a modern organisation, which is a part of the intellectual capital, is represented by professional knowledge, skills, abilities and health status that could contribute to an enhancement of the creative capacity of any person and, implicitly, to an increase in the prospective future revenues, or it represents humans' capacity to produce goods and services in an efficient mode;
- it offers opportunities to achieve superior performance in the future.

The development of the knowledge economy where the investment in human capital is a priority and human resources become an important asset will create prerequisites for the employment policy to build a close relationship between education and training.

Globalization and knowledge economy expansion creates a competitive environment defined by the criteria of efficiency, competitiveness and economic performance where the human capital develops.

Human capital consists of the characteristic abilities of individuals that remain the same in any social environment and can be exploited on the labour market in exchange for any kind of economic resources.

Within the higher education system the human capital refers to all the academics (in

terms of knowledge, experience, skills and their individual talent) and the number of students involved in the educational process. Students' education is done through the transmission and the development of basic and specialized theoretical knowledge.

Human capital concept reflects the investment in education and the development of competencies and skills necessary to perform certain economic activities. Basically, human capital consists of educational capital (skills acquired by individuals while they are enrolled in a school but also the skills acquired outside the school) and biological capital (physical abilities of individuals, most often synthesized as the health status). Universities distinguish from other education and training institutions because they increase knowledge and generate graduates and researchers with creative and innovative potential.

The term *human capital* reflects the investment in education and the development of adequate aptitudes for the labour process. [10]

Economists consider that investment in education produces human capital, by analogy with the investment in physical capital used in industrial enterprises. Human capital develops progressively within the formal frame of the school, in the family, within the organization, and through individual efforts of study and reflection.

Intellectual capital consists of knowledge accumulations and flows owned by an organisation. They can be seen as intangible resources which, together with tangible ones (money and material assets), provide the total or market value of a firm.

3. Conclusions

The evolution of society shapes an era of knowledge, which is equally aimed at by the entire humanity and by the business environment/world. Economy is gradually redefined and renamed, being gradually transformed into a New Economy that gives up its former approaches, seeking to clarify the increasingly complex reality which unfolds for/to us. A major role is attributed to information, which constructs the intellectual capital.

The central idea of all theories concerning intellectual capital and societies based on

knowledge is that the hierarchy of values has changed. Hence, the impact of physical resources has gone one step lower, so as to allow intangible resources to go higher, while the latter become an increasingly important factor for, among others, the development and profitability of a firm.

Knowledge has become the basic resource of the firms, the way they gain power, prestige and wealth in modern society and economy.

The generation, the acquisition and use of knowledge are critical for the sustainable economic, social and cultural development.

This principle equally applies to individuals, organizations, public institutions, companies, regions or even states.

The organisation and the coordination of specific knowledge every organisation has, known as the "knowledge management" plays an increasing role in Romanian organisations. Managers can take the best decision within a reasonable period of time only if they have the necessary knowledge in order to carry out the planning, organizing, coordinating, leading and controlling processes.

Trends of Remuneration Based on Results

Greco Gheorghe
Spiru Haret University

elianro@yahoo.com

Abstract

While time-based wage system has some advantages such as simplicity, low bureaucracy regarding accounting salaries, safety on the amount that employees receive, etc., however we can not observe the shortcomings that this pay system to determine: the need for close supervision, poor incentives employee incentives, low income workers compared with other pay systems (piecework system), unable to establish easy and expected cost per unit of work, prior to work, i.e..

Key words: remuneration based on results, straight piece-work system, standard hour.

J.E.L. classification: M 52

1. Introduction

Wage system employees after work output (piecework or by result) aims to address one of the fundamental drawbacks of direct labor wages and the lack of direct incentives for improving production and productivity. Could cost as by emotional appeals or coercion exercised strict control over workers through other means, we can not ensure the effectiveness of their work performed in excess of 80-90% of their actual possibilities. Impact defines motivation reward with firm performance and employee motivation [1].

To overcome these shortcomings, and optimum use of the full potential of employees, including the company's resources, was used to design and incentives designed to increase productivity and thus lower the cost of labor per unit of product.

The payment agreement was widespread in most industrial countries. There are many reasons for this trend. First, increasing mechanization and specialization of industry have largely removed some of the old

incentives, job pride and satisfaction due to the job and had to be replaced by a financial incentive.

Second, the growing belief developed among employees that are fair for workers to be adequately remunerated work that he performs. Traditional attitude of trade unions were in favor of uniform wages as time worked, but to the best workers wish to be remunerated in relation to their superior qualifications and extra effort made, in most cases unions have agreed, with some reservations, payment after results.

Value but increased incentive payment according to work, payment by results seems to stimulate the desire to excel and introduce an element of interest and competition at work, thus compensating to some extent and its monotony. Simple rules to work fixing agreement sets them a task worker, provide an end, an opportunity to show the importance and superiority, which may contribute to increased satisfaction from work.

Generally, the payment agreement may be applied in good conditions with repetitive work is carried out under conditions allowing more or less standardization, so that ensures that a certain amount of energy and encouragement will lead to results in a certain volume of production.

Even in cases where standardization is not possible, but the product can be easily measured in quantitative terms (e.g. the extraction of coal, ores), using payment system agreement is possible or appropriate. Best results are obtained when the main objective is quantity produced, where quality control can be performed without difficulty and finally, when unit labor costs are going up. Proper implementation of the agreement is not the size of the production speed can result in a great waste that compensate or exceed gains achieved by additional production. The agreement also may be

applied to work in small repetitive in nature random or intermittent work, including work generally called "indirect" or "directly unproductive" - the preparatory work of the production processes, the type of maintenance machinery and equipment, in this work fixing inconveniences precise time are very high. Similarly, the application of this method is specified or where the volume of production (or operations) is determined by the speed of the machine or the process respectively.

1.1. The main forms of performance-based pay

An overview of very complex systems of remuneration in agreement possible and necessary at the start.

Although remuneration systems in the agreement (as results or performance) have common characteristics, they are not totally homogeneous, but differentiated by wage bond strength results of production.

Thus, the overall system of payment by return (in agreement) can distinguish three main subdivisions regarding the extent to which workers receive full or increased production:

a. payment systems that vary directly with production volume in which employees (individual or team) receive the same price for each unit of product (or operation), regardless of their number. In this system, any gains or losses on labor costs per unit, resulting from changes in production that benefit or are incurred by workers. Instead the company incurring losses or gains made changes in general overheads per unit.

b. Payment systems where employees varies proportionally less income than production. Their essential characteristic is that it divides the enterprise worker gains (relating to unit labor costs) resulting from changes in production beyond fixed time, the worker receives only a share of the amount due to overflow.

In this category includes among others: the Halsey, Rowan system, Bedaux system and Barth system with variable participation.

In most cases their application is associated with guaranteeing a minimum wage (after working hours) when production reaches a certain level not specified.

These systems give the company an added

benefit of exceeding production worker, but Western economists argue that they can achieve a "braking action" excessive efforts of the workers, or excessive increase work speed that can be detrimental employee health, or detrimental to product quality and, finally, the quantities of materials consumed per unit of product (waste).

c. Systems that income varies proportionately more workers than manufacturing, characterized in that the worker, in addition to receiving proper rate for each part or process, also participates in some of the savings in overhead costs made by the company after overcoming rules. Usually, in these systems, standards are very high, which pushes the disadvantage of an excessive effort that can be harmful to health workers-drawback common to all systems that accelerated growth rates paid. In practice this framework based on a tariff system (high piece-rate system) which recognizes the increased effort that we must make the worker to increase production. For each increment, for example, 1% of the premium paid production is successively higher (going from 1.1% to 1.25%, 1.33% and so on). The system is generally limited to companies whose management is urgently needed workforce collaboration to increase productivity. In line lies a system based on productivity index, i.e. the relationship between employee productivity and time set for the task to fulfill. The first, which is 57% original commence to be paid to achieving a 5/6 of the time, it gradually increases to 80% for standard performance and achieve 130% of base salary to exceed 33% of the rule set.

We believe that pay systems can not be treated only in a general form, it is necessary to illustrate each of the three main categories of systems models that have been used and are used today in practice developed countries economically.

1.2. Remuneration varies in proportion to yield agreement

These first categories of payroll systems include three types of systems: salary proportional to the number of parts produced, the system time allocated (standard time).

Straight piece-work system or proportional salary crafted pieces, is the system in which payment is made after the number of parts

and operations performed. Is the antithesis of salary after time spent (in direction). Wage is equal to the product of the number of parts (or operations) and the rate (price) established for each of them, in other words remuneration vary directly with production volume. Therefore he defined "full salary bonus."

Salary in direct agreement (or part or full bonus) is the general model, the basic salary in line:

$$s = s_0 A; \text{ and because } s = \frac{S}{t} \text{ and}$$

$$A = \frac{T}{t}, \text{ we have } S = s_0 T$$

It should be noted that the total salary (S) is given by a formula that is similar to that of the salary for time worked, but the time spent is replaced by the allotted time. It can therefore be said that salary is a salary track after the allotted time.

Since the worker's income is directly related to work performed, number of tracks, the worker is determined to produce a large number of parts (or carry out a large number of operations). The system is particularly attractive for experienced and efficient workers.

Since the establishment of full wages in proportion to yield, presents some risks for workers less handy be either due to possible disruption of work for reasons beyond the control of the workers resorted to a form of "softening" of the system. In this case, it was established as part of the salary is based on the time of attendance at work, which is a guaranteed minimum wage, regardless of the realization rule. This should not be confused with the minimum rate below which no worker can be paid, usually about tariff established by legislation. Guaranteed minimum wage in this case is minimum wage which the employee will receive for time worked, regardless of the amount of its production. If time is fulfilled, and especially if it is exceeded, the employee receives an additional (first) equal to the charge per unit multiplied by the number of additional pieces worked. Unit labor costs as part of cost price; reduced by the time you reach 100% production rule set, after which they remain constant, however, the company benefits from reducing overall overhead fixed or

semi-variable. The latter include administrative and sales expenses in a moderate increase of production remain unchanged or vary not strictly proportional increase above a certain limit production volume (as opposed to depreciation of buildings, plant and machinery, which are tasks fixed independently of their use).

The first form of the piece wage system is the time spent or "standard time system" (standard hours). It is also known as the "standard time", considered by some as essentially identical payment agreement the number parts, meaning that in both systems pay is directly proportional to the work performed. The difference is that instead of specifying a price (tariff) for each unit produced (payment agreement), establish a "normal time" (standard time) for the manufacture of certain parts or to perform a certain operation; worker is paid based on its hourly wage, depending on the actual work performed within an hour, which however may exceed labor provided by "time zone". Specifically, if "standard time" is an example of 6 pieces per hour and worker produces 9 pieces, he is paid 50% more than its fare zone. It must however be noted that, unlike treaty payment system in which production is equal to equal pay for all workers in the workers received payment system varies not only by production volume, but also by the basic hourly rate, which usually differ from one worker to another. This method was adopted to remove difficulties arose when some workers salary climbed were put to work based on individual agreement whose price per unit (relatively small) are not allowed to make and of course income equivalent to avoid the difficulties arising from the need for these workers setting (highest paid originally) a higher price per piece. Given these differences, it is considered by some to be a failure to fully assimilate the system of direct payment agreement because it is actually a variant thereof. Applying this system has the advantage of not requiring a review for modification wage rates.

The time standard can be applied in two versions: with or without the guarantee of a minimum wage. In the first alternative, a worker who does not meet the norm is paid on a time basis, as if to fulfill the norm, the second alternative it is paid by quantity

produced strictly based on time spent (time) for each part or surgery.

Another form of wages per piece is the system "Standard minutes" or time per minute. It is a variant of the "normal time" where norms are set in minutes. Minute standard includes the amount of work that an employee has to perform, as a minimum, during the one minute timer. Work to be performed is calculated in a way that takes into account the inevitable time delays at work, fatigue and personal needs of the employee so that the average worker is able to perform an average over an hour, work equivalent to 20 - 30% more minutes than the standard 60 minutes without being subjected to stress or not to accelerate pace of work. In most cases workers are expected to make an allowance for time average of 75 minutes in an hour, which entitles them to a premium of 25% over base salary. In this system the employee's remuneration is directly proportional to the work output. The company does not benefit than reducing overheads per unit of product, as a result of increasing production volume.

1.3. Nonlinear systems link between remuneration and yield

We presented three types of linear systems of remuneration in relation to performance. We believe, however, necessary and nonlinear analysis of pay systems in which pay increases in proportions that vary in relation to performance.

Also multitude of nonlinear systems can be classified into three broad categories:

- Remuneration with gradual progression: pay by time (in direction) plus a fixed premium;
- Pay the increasing progression: first progressive;
- Pay with decreasing progression: first digressive.

Presented graphically, these three categories of remuneration systems also expressed their full coherence to the different situations of economic and social practice.

It should be noted that in these three cases (categories) their pay - performance is not linear, i.e. wage increases at a rate which varies itself with efficiency. One can speak of a double flexibility, both remuneration and efficiency, hence if all other conditions are

the same, the cost per unit will be lower without thereby reduce the motivation of worker. Effort by both workers adjusts parameters: level (s) remuneration and performance levels. Let's examine the major systems of nonlinear compensation.

Figure 1.1. Payroll systems as a result

Source: Les systèmes de rémunération liés aux résultats, Bureau International du Travail, Genève, 1985, pp.11

1.4. Compensation benefits after return (in agreement)

Motivational effects of pay for performance depend largely, as I mentioned, the shape of the relationship between pay and performance, but also have many positive effects extremely important and primarily economic, to stop us below:

- Increased production volume. According to international experience, salary increases consistent production, usually between 25 to 33%.

To determine the correct size of production growth generated by the work agreement must take into account all the variables that influence the overall work environment, namely:

- The number of workers and hours worked are unchanged from the previous situation;
- Workstations are occupied by people with the same level of qualification;
- Structure of the operations performed will not change;
- The calculation of each type of work (content, standard working hours) is similar;
- No changes in the supervisory and management personnel;
- The physical environment of work is the same;
- Technical jobs, cars, plants are the same, unchanged.

In practice it is very difficult to meet all those conditions. But made rigorous evaluations are required to speak the effectiveness of the agreement or its forms. On the other hand, the physical effort of worker decreases as improving production techniques [2].

- Remuneration systems in the agreement have the effect of significant increases in wages and incomes of workers. Thus, if production increases from 25 to 33%, remuneration may increase about 20 to 25%. For these reasons, workers appear interested in removing any obstacles that stand in the way of increasing production and its economic efficiency. Worker effort plus the effort and professional competence and management decisions for the entire organization of production and work to permanently achieve higher gains, increased.

- Payment agreement can not be achieved without fixing the amount (tariff) for products or transactions made or no time dedicated. These requirements may be applied only if the first systematic study of the work is done (organization of production) revealing new directions in practice to improve production processes. Development of production rules is an incentive to increase production and to improve labor management, efficiency;

- Pay for performance stimulates innovative faculties of workers, improving work processes are under their direct control, such as physical organization of labor, minor changes gauges adapting speed work, power machinery etc. Director remuneration system does not have these incentives;

- All factors (benefits) labor agreement mentioned contributes to reduce wage costs per unit of product. This is due to the salary systems varies less than output, and especially for all systems as general overhead costs (fixed and trimmers) is distributed to an increased volume production. Of course, this effect is less agreement if the remuneration system grows faster than labor efficiency;

- Labor system in accordance worker becomes its own supervisor, helping to eliminate the company's staff costs, even if quality protection consistent production work requires a staff increase. If we talk about participatory work systems in which workers make their own quality control, then reduce personnel costs is even greater;

- Payment systems in direct agreement have the advantage of simplicity both for workers and for calculating wages. This element of simplicity of calculation reduces administration costs of salaries, calculating the cost price and production control. The contribution of these systems must be assessed as if coexistence records and systems involving more laborious calculations leads to reduced impact on overall production costs;

2. Disadvantages of remuneration after return (in agreement)

Practice shows that all payroll systems, without exception, in addition to advantages and limitations (disadvantages). Thus, for remuneration after return, we mention the following drawbacks:

- Can not avoid the effects of bad appointments of staff;

- The first can not generate a spontaneous improvement of working conditions, if there is no favorable climate change and innovation;

- First agree not to suppress labor disputes; work environment does not improve, if they are not integrated into policy management, staff training and dialogue with staff.

In theory and practice are recognized worldwide inconvenient three main categories of remuneration after return (in agreement): physiological, socio-economic, and psychological.

Tend to produce more to get higher wages can lead to excessive fatigue of workers, with negative consequences on their health status. Practice shows that man is capable of exceptional work only for short periods, which can not be extended without their harm. Ergonomic studies undertaken over time, a subject treated by specialists is more work capacity (physical or intellectual) considered as a parameter of professional activity. Analysis activities must show, among other things, capabilities or skills body professions and compliance requirements of them, so that activities are performed in biological balance [3].

Fatigue at work resulting in decreased ability to work effectively, psycho-physiological manifestations (sensory changes, metabolic, i.e.). And subjective symptoms (discomfort, emotional and

behavioral changes and so on).

In a physical environment acceptable to work consistent with training and capacity at a level of remuneration for the work submitted, any individual can provide, on average, an amount of work equal to the contribution of optimal.

Remuneration according creates difficulties establishing working time and charges: generates conflicts between management and workers, some want to maintain or even reduce wage costs per unit of product, while others (workers) want to increase wages, employees no certainty that prices (rules) once established, will not change, in some plants, setting labor standards is very difficult and shortly after the accumulation of experience and the promotion of technical changes, technological, these rules require revised. Therefore, some experts declare for eliminating premiums paid based on performance. This would increase the ambiance and spirit of collaboration.

In paid employment agreement results in increased working speeds, which leads to deterioration of product quality. This impact can be minimized by the introduction of monitoring and quality control. Promoting check each piece before moving on to the next operation. But this would increase the number of control staff and hence wage costs. To reduce this cost is often used to control sample quality manufactured parts. Other companies to reduce their costs or expenses, introduced award bonuses for quality, so that the worker himself to achieve an increase in salary after production quality output with respect, knowing that positive incentives are always more effective than negative incentives (penalties). Finally, the same principles, in some countries (Japan, i.e.) remuneration systems by protecting the quality and efficiency by promoting self stimulate increased production quality.

Remuneration according differentiation generates gains made by workers who perform the same work because of the difficulty of achieving equilibrium labor standards, but also due to individual characteristics of workers. For these reasons appear complaints, disputes, complaints, envy, jealousy, damaging the climate and collaborative work, with adverse consequences on production.

The sources of these negative aspects are either insufficiently prepared to pay for return transition, in particular measures necessary for production and labor, but also the various forms of bias, favoritism promoted by some superiors, especially in the division of work favorable to the worker.

3. Conclusion

Remuneration as performance suffers wear conditions generated use it. Most times giving up yield premiums is justified in some cases such as:

- Labor standards diminish their quality until the question of the transition to pay the overhead (time spent);
- Custodial staff (team leaders, foremen) the remuneration is disinterested after return;
- General policy of the company, public personnel management and organization are insufficient;
- Introduction form of agreement was not prepared the necessary corrective measures in the organization of production, in preparation workers without proper training and lower middle management staff, especially staff and supervisory norms.

Remuneration after giving yield maximum efficiency when incorporated into the overall management of the company, department and production workshop.

Variable Pay - a Motivational Factor for Employees

Greco Gheorghe
Spiru Haret University

Faculty of Financial-Accounting Management, Constanta

elianro@yahoo.com

Abstract

In conditions of crisis in which we are finding ourselves about few years, the companies are trying to reformulate their salary budgets. In this way, they are turning to increased variable payments and benefits that reward performance.

Key words: Incentive pay, profit sharing, share option, group bonus, individual bonus.

J.E.L. classification: M 52.

1. Introduction

Due to competitive pressures organizations are continually looking to increase the added value of their employees by encouraging them to increase their effort and performance beyond that which is at a minimally acceptable standard, or reducing labor cost to a minimum [1].

1.1. Variable pay

The system is actually the first application in a form evolved and adapted to modern conditions, the systems used in the past, in which a contractor, hire a subcontractor who, in turn, pay the amount received by all workers use [2].

Finally, the appearance of mixed payroll marks a comprehensive optimization payroll process. If the systems in line, and overhead systems are placed somewhere in the natural history of polar pay, remove this polarity mixed systems, not only because it eliminates the disadvantages of each of these systems, especially systems that blend the benefits of agreement and directing.

Apart from reducing inflation, limiting the variable part of salaries provides a guarantee of a party increasingly higher wages for a period of increasingly longer. It is here a

tendency to pay monthly, eliminating the disadvantages that include both the agreement and directed hourly and daily when calculating licensing rights.

Wage workers are similar in terms of structures. Workers paid in addition to directing the base salary for skill and complexity, receive a supplement (premium) with the collective character (can not measure individual contribution but the contribution of each employee matters, contributing to the tasks and increase the salary). Workers, in addition to base salary for the classification and complexity of work receive a bonus (premium) of individual intake (measured) and a first collective nature of the overall results (team, workshop etc.).

The need for individualization of injection led to the development of scoring systems for services rendered, other elements that may occur in salary structure is not related to individual benefits, but raw shop floor productivity, factory bonuses.

According to a study conducted by Price Waterhouse Cranfield in 1991, on variable pay in European countries reveals that there is an upward trend in terms of flexibility in pay systems. So, the percentage of organizations who have reported increases in various parts of the variable payment of rewards in the total package over three consecutive years in private sector was: in France 51%, in Germany 54%, in Spain 60%, in the United Kingdom 45% and in Sweden 57%. In the public sector the situation it's a little bit change: in France 22%, in Germany 17%, in Spain 57%, in the United Kingdom 56% and in Sweden 48% [1].

Another aspect pointed out by this study highlights the incidence of various incentive-based payment systems such as individual or collective bonuses, profit sharing or equity, differentiated by categories of staff in five European countries (Figures 1.1 - 1.5).

Figures 1.1. Incentive pay in the private sector in France

Source: Hegewisch, A., "European Comparisons in Rewards Policies. The Findings of the First Price Waterhouse/Cranfield Survey, SWP/1991, pp. 7-8

Figures 1.2. Incentive pay in the private sector in Germany

Source: Hegewisch, A., "European Comparisons in Rewards Policies. The Findings of the First Price Waterhouse/Cranfield Survey, SWP/1991, pp. 7-8

From the figures presented, we note that the largest share of the profit-sharing incentives based on one found in France, where this system is strongly encouraged by the government, and in Germany where there is an old tradition in system implementation managers in medium-sized enterprises [1].

Figures 1.3. Incentive pay in the private sector in Sweden

Source: Hegewisch, A., "European Comparisons in Rewards Policies. The Findings of the First Price Waterhouse/Cranfield Survey, SWP/1991, pp. 7-8

Figures 1.4. Incentive pay in the private sector in Spain

Source: Hegewisch, A., "European Comparisons in Rewards Policies. The Findings of the First Price Waterhouse/Cranfield Survey, SWP/1991, pp. 7-8

In Spain the individual first applies primarily, while Sweden prefer collective first, especially for manual workers, confirming the importance of team work and performance in their business culture.

Figures 1.5. Incentive pay in the private sector in UK

Source: Hegewisch, A., "European Comparisons in Rewards Policies. The Findings of the First Price Waterhouse/Cranfield Survey, SWP/1991, pp. 7-8

Profit sharing has the largest share in the United Kingdom, where this system is encouraged by the government.

In Romania, variable pay is more often applied by employers amid financial deficit experienced by many companies. To the management level, the share of variable pay is 13%, while in Germany, for example, is 35%.

The Mercer Salary Survey 2012 assess that this year the value of variable payment is still a widely used means of compensation and policy regarding such bonuses have not been modified, in exchange received by employees are still up from previous years. Also, the variable bonuses represented as a percentage of annual base salary, do not show changes from previous years, they maintained at the same percentage since 2012: 20% top management, mid-management professionals between 15% and 10% - 15 %.

While the variable pay fixed salary plus local market employees can reach the equivalent of three monthly salaries it becomes a motivating factor for employees.

Other trends in terms of solutions applied in different countries to which we referred above may prove very useful in the design, choice of forms of remuneration, as in the transition from one system to another.

2. Conclusion

The conclusion is obvious that the choice of one of these mixed forms, directing and consent, becomes more efficient, is easier and faster, taking into account other factors to the occurrence of mixed forms of pay not could be taken into account in the sizing of wages.

Participatory Management of Human Resources - a Solution for Organizations Success

Greco Iulia

Spiru Haret University

Faculty of Financial-Accounting Management, Constanta

elianro@yahoo.com

Abstract

The gaps between the Romanian and the developed countries in terms of a strong affirmation of the effectiveness of management in general and the participation of human resources in particular have convinced us that our choice might draw attention Romanian companies on the most effective methods management to extend it faster and generally improve overall human resources management in Romania.

Key words: participatory management, efficiency.

J.E.L. classification: M 52.

Introduction

High efficiency and increased participatory management is of great significance for improving the quality of products, labor productivity and, hence, the ability to compete, the economic performance of Romanian companies under a single market.

Choosing participatory management of human resources approaches that follows is, we believe, welcome and for the knowledge society in which mankind came further amplifies the need for participatory management, and a series of restructurings likely to further increase the usefulness and its economic efficiency and social policy.

1. Content and participatory management features

In management methodology in its subsystem world appeared and strengthened increasingly strong participatory dimension, a spectacular evolution and even revolution.

Literature consulted, particularly rich and

valuable, it still contains a definition of participatory management. However, the wealth of existing approaches allows us to venture in a bid to help crystallize the concept of participatory management. Thus, participatory management could be defined as "a set of methods, techniques and leverages more or less special training and professional capacity and scientific exploitation of employees, either individually or in groups, with manager to address and resolve problems or complex functions to meet business objectives, increase its performance, its ability of economic competition" [1].

Elements of involvement, participation and we find authoritarian model created by FW Taylor, under the domination forms of motivation through coercion. What else is in this model using normal work and especially the degree of its fulfillment. In this regard, we can cite even Taylor's belief that technology is not considered sufficient to increase labor productivity, but requires the participation of labor and its exercise in the best possible conditions. In Taylor's model, employee participation was minimal results and possibilities for their individual physical and intellectual, separated from each other, were limited in increasing production and productivity.

Participation in its present form appeared in the previous management models, namely human resource management practice. Its precursors, of participatory management, supported by early needs for more interesting work-attractive, more creative, better treatment for workers, better working conditions to protect the health of their employees and increase productivity firm surveillance over democratic labor etc.

Genuine participation in the contemporary sense of the term is detached from its previous forms since the employee is no

longer confined exclusively to the execution of tasks and procedures of record (description) job, but also extends the scope of design and decision rationale and choice of company objectives.

Consider this process and to discern the main features of participative management even driving style. Reflects its historical development process gradual transition from authoritarian management model to more advanced models (human relations and human resources) to participative management style.

Referring to driving style, Professor Eduard Rădăceanu reserve us a picture of involvement-participation with manager and employees as we present you below:

Table 1.1. Involvement-participation with manager and employees

Decisional involvement of the superior						
Involving performers						
Auth oritat ive	Patr iarc hal	Info rmat ive	Cou nsel or	Coo perat ive	Parti cipat ory	De moc ratic

Source: Eduard Rădăceanu, Management (Generatorul succesului), Editura Bren, București, 2001, pp. 34.

Eloquence in painting the involvement, employee participation, alongside manager is beyond any doubt or question. We should just point out that senior managers always felt the need to promote the start of simpler forms such as reforming, and further forms, such as those of consultation, collaboration (co), so that in decades recent training junior employees and managers take the form of wider democratic, participatory. In fact today, the manager at any level, depending on the branch, sub-branch, and organization or in relation to specific problem involving a decision may take one or more of the attraction, engagement, consultation and participation in decision-making.

Affirmation of participative management, in all its theoretical and practical process is observed more clearly in historical succeeds key management models.

Participatory management has gradually given way, hastening the end of the employee and accelerating the emergence and widespread passive active employee and

partner.

Participatory management continues to evolve today, it will generate and other features and improvements in terms of the knowledge society.

Starting to improve quality and productivity requirements, management tends to get a broad, holistic to Total Quality Management.

It is expected that participatory management with preference to focus on knowledge worker - the only category that creates - innovate and learn. If before participative management is based on the participation of all employees in terms of the knowledge society, it is possible and even necessary for routine workers are to remain in the area of participatory management, but to apply specific methods of participation so that employees routinely to be mobile and to make high pay.

Participatory management in the knowledge society is based mainly on democratic coordinate - one that provides employee access to the act of creation and innovation.

So far, participatory management has a social component generalized almost unique. In terms of the knowledge society, this component could be structured in increasing business flexibility, human resource management, deregulation and reduction could result in rigidities that cause labor laws, unions, negotiation methods and scope of collective bargaining, the practice of using contracts indefinite employment for all or almost all employees etc. Social protection, treatment and motivational Remuneration generally will be large differences in firm knowledge, for knowledge workers.

Promoted in practice especially for the needs of creation and innovation, increase product quality and raising labor productivity, authentic participatory management, modern design eliminates the separation between executive and was imagined and made a part of the growing scale of employees in based on four essential elements:

1. Need to communicate the vision for the future of the company, to its knowledge and acquired by employees. Practice shows that no one can participate without knowing creator-innovator firm vision of the future, the way of confrontation with the internal

and external environment;

2. Enrichment and job duties. The classic Taylor type characterized by a direction opposite action by separating work design and work execution and by poverty and divided tasks;

3. Promoting continuous training to enable employees to perform work tasks, creation, execution, execution or creation. In this way, participatory management not only assume the role of effective realization of human resources, but also the continuous development of human resources, both in the company and outside the company, national and international scale;

4. Empower employees with authority to control tasks. The company's new organizational structures in which coordination is done through various mutual adjustment mechanisms, facilitated by structural decentralization and the emergence of flattened structures, such as "lean management", and teamwork.

2. Forms of participatory management

During the last century of the second millennium, participatory management, according to literature high and new synthesis achieved in Romania takes four main forms [2]:

2.1. Participation in work (running)

Is the potential human targets with a high degree of education and more training for more complete and efficient use of other means of production, so that the company can reduce costs and increase productivity while to improve production quality, increase output and superior ability to achieve economic competition.

These objectives, as discussed below, are equity and other forms of participatory management. It is noteworthy, however, that participation in today's workplace is done according to a number of objective and subjective conditions and peculiarities of industries and businesses, both on a old Taylor by separating design execution and new bases, by redefining jobs and job functions, i.e. by bringing together smaller or larger version with design, physical labor to intellectual labor;

2.2. Participation in management in the decision making and coordination

It is a higher form practiced in upstream participation at work before presented. This form of participation is achieved through the identification and selection of employees able to make a significant contribution in making decisions as representatives of employees in the works council or trade union representatives. This form of participation is achieved not only humanizing relations company-employees, but a "path" through which to stimulate and further polarize the human energy accumulated history of human beings through education and performance desire. This form of participation in decision-making is itself an expression of physical work to eliminate separation intellectual work, work design and work execution, restoring the unity of these two components. As Taylor efficiency type called separation concept execution, today the same criterion, efficiency requires combining, blending with design execution. Finally, it is worth emphasizing that through this meeting in execution and concept was to not only improve decision making, effectiveness, but also another management function, that of coordinating production processes and decision making among all company departments, both internally and in its external environment and customer first, with the market;

2.3. Participation in sharing economic and financial results of the company

It is a form of participation that operates independently of other listed or combined with them. Forms of remuneration, salary growth rate compared to the standard realization with its quantitative performance and quality of products and services, the first workshop for quantity, quality, as well as participation in benefit sharing or profit played and plays a strong motivation both in terms of organization and type Taylor management and participatory management today (denial of Taylor work). The essence of this form of participation could not and can not be even today associated with individual or collective work.

2.4. Participation by association capital of the company

It is a form of participation that recognizes and strengthens the position to which the employee recognizes ownership, the shareholder. It is a form of employee association to "power" the decision in its aspects concerning not only the management side or the other, but the complexity of decision-making.

We note that all forms of participative management contribute to shaping behavior modification and employees to promote harmony and equity in the company to focus their interests and aspirations of the organization, to increase production and quality, reduce time losses and streamline its spending to increase labor productivity enhancing competition in the company.

3. Factors of expansion and diversification of participatory management

Participatory management was born into a long historical process under the influence of a complex of causes, the premises of factors and conditions. Diversity, and participatory forms of management, requires us to classify explanatory factors in several different categories:

- The need to attract adherence and involvement of employees in achieving company objectives. Adhesion and employees with business goals focus - with or without separation of execution and conception - bring substantial quantitative and qualitative contributions, elimination of various forms of waste and loss, increasing the capacity of innovation, competition and firm creation;

- Increasing the role and place of human capital among factors of production. A high level of education and high capacity, unlimited creativity and innovation reduces the role and scope of natural resources and capital on growth significantly increases the quality and efficiency and viability of the firm. Participatory management in all its forms became an important mobilizing creative energies employee's extension among all other forms of general management, concerted growth of health and availability of resources of the planet, blending the interests of generations present the interests of future generations.

Knowledge society in which mankind came along with the involvement of all

employees and therefore emphasizes the role of knowledge worker expansion and diversification of participatory management in all its forms;

- Extension of participatory management is strongly driven by new information technology. This favors the transition from functional organization to organization on processes and products (projects), and the transition to a multi-level hierarchical organization, a networked organization.

All these processes and trends favoring participatory management in all its load factor to which we have referred to so far in the preceding paragraphs, require new and important developments in the field of human resources management of the company on at least three levels:

1. Developments in human resource management function:

- Powerful new technology works towards increasing weight and participatory management;

- Communication management function is carried regarded as top-down and bottom-up as far as it retains some hierarchical levels, but especially is done promptly and efficiently in a horizontal plane in the networked organization, communication becomes important importance in the company. Performance management is not possible without moving power, knowledge, information and earnings to lower levels;

- Recruitment, selection and promotion of staff is conducted complex criteria and requirements in relation to changes in staffing structures and participatory management's new requirements;

- Motivation is based and diversified multi-criteria for each form so as to satisfy individual, group and company;

- Stimulate the emergence of new forms of organization and management of human resources such as teamwork (quality circles and productivity), work remotely at home and so on, all these forms is to supervise the professional capabilities and deep loyalty to the company ;

- The relationship between the employer (manager) and trade unions are deeply restructures. Knowledge worker and other employees will find their needs and aspirations in a complex relationship collaborative partnership, collaboration, creation and innovation and not of

confrontation, conflict;

- Reducing the distance, up to integration between execution and leadership activities promoting teamwork and reducing the number of hierarchical levels;

- To produce a wider process of overlapping formal links informal links are developing strong a release of creative energy;

- New technology requires substantiation increase the quality of decision making while reducing the time, both being crucial advantages in terms of economic competition between firms increasingly sharp;

- Effectiveness of participatory management of labor resources is superior to other forms of management that are associated therein, focus and coordinate direct managerial power (manager), knowledge (know-how), information and motivation;

- All changes that we referred to above and others that they draw after them can lead to achieving progressively the full Japanese model of total quality management.

2. Mutations in human resource structures and their participatory behavior:

- Increasing workforce and employee share knowledge workers while reducing weight routine, producers of goods and services. Knowledge workers who work in complex teams will propel obviously increasingly participatory management;

- Unskilled workers reduce their proportions as unskilled activities will be replaced, removed;

- Repetitive work tasks and low productivity will be replaced by innovation and innovative workers, creators;

- Individual firm authority is not given by the hierarchical position and the hidden battle for it, but what the individual works, creates, innovates;

- Content enrichment labors in the execution (job enrichment) giving individual autonomy on the one hand the execution of tasks, and on the other hand the possibility of exercising self-control, because he knows how well the task was performed. Labor content enrichment and expansion of participatory management fullest human potential and leverages it contributes to better use of all other material resources;

- Active participation of employees in company affairs beyond daily tasks strictly

professional;

- Better working climate in the firm, affirmation and learning ability and fidelity increases attachment individual's desire to contribute the acquisition of a new culture, the higher the firm.

3. Changes in forms of work organization

New technology leads to rediscovery of teamwork. Teamwork is practiced by knowledge workers and other workers. It provides:

- Approximation executive management, i.e. the process;

- Increases the effectiveness of decisions;

- Strengthen the rationality of the whole production chain;

- Promoting informal leaders;

- Reduce the number of foremen and middle managers and lower;

- Blends and harmonizes master team leader, complementing and eliminating rivalry between them;

- Stimulates learning as product project implementation progresses;

- Take some preventive maintenance tasks machinery;

- Stimulate innovation in human resources management;

- Facilitate and promote participatory management;

- Integrates more management components, such as: hiring, promotion organizations, labor payment and quality control and production work;

- Teamwork is the most productive by P. Drucker [3]. The problem is what kind of team is chosen because, in practical life, there are several types of teams. Essential not only teamwork, but also choice of the type of team that they need process that best suits the process. Thus, wrong team "can destroy productivity";

- Teamwork fosters creativity, cooperation increases pecuniary motivation of employees to achieve ever better results;

- Quality circles and productivity are extremely important forms of teamwork. These circles have a participatory role Extreme important because:

- Enhance support and collaboration of team members (6-10 employees);

- Stimulates the growth of labor quality and productivity;

- Reduce material losses and customer complaints;

- Reduce delays in service;
- Team collaboration in decision making;
- Ensure staff responsible for quality control of products;
- Stimulates raising skills;
- Contribute to increased opportunities for advancement in the hierarchy;
- Quality circles are a prelude to achieve total quality management;
- Quality circles are in fact in many cases partially autonomous work groups.
- Business culture, national culture derived from a set of values, the traditions, beliefs historically constituted generates two attitudes towards participatory management, especially compared to the first two forms of it. On the one hand stimulates the use of participatory management (of Japan). Moreover, brake extension participatory management (for North American, European and even South of Central and Eastern Europe, etc.). In this framework may run even conceited behavior manager not to share with anyone driving act, especially those who exercise executive processes.

At the confluence of organizational culture with other factors that promote participatory management results in a variety of versions of participatory management, considerably higher than those to which we have referred in the preceding paragraph. Moreover, the literature would reveal infinitude of participatory management features of the contemporary world.

Fighting cultural factors that hinder the use of participatory management is impossible. It takes under management experience accumulated worldwide, the development of strategies and policies that promote values, norms acting in favor of extending participatory management. It is therefore longer lasting action in the medium term and, if necessary, long term. We believe that, with these strategies, sharpening strong international economic competition will accelerate the learning process by companies' most productive cultural values of nations and peoples of the world [4].

This possibility depends to a large extent by the association which is the motivation for all company activities. Note here that the motivation is strongly influenced by the culture of the organization. Therefore, actions to promote participatory management should not exclude and objectives to facilitate

changing the culture of its own vision of our employees and the forms of reasoning.

Conclusion

Great advantages of participatory management have been highlighted in previous approaches. But here we can not avoid summary of potential benefits of participatory management: stimulates considerably improving the quality and productivity; favors promoting effective work methods; create flexible field work to accomplish tasks; enhances the attractiveness of work; complex motivation, increased fosters harmonization of company employees; raise the qualifications of employees, promoting participation in field work creates solid foundation for a decision.

Participatory management, like any other form traps has negative effects that need and can be avoided by management wisdom throughout the work. Potential negative effects of these possible additional costs related note: insufficient wage growth coupled with high efficiency participatory management; resistance to change so important in promoting new, often manifested by middle and lower level managers; a term sometimes excessively high background process decisions that may lead to missing opportunities.

Avoid these negative effects involving at least meet two requirements:

- Each concrete situation requires specific management solutions and not global models;
- Good correlation empowering manager, knowledge (know-how) information and, of course, motivation (monetary intertwining motivations of non-pecuniary motivation).

HR Outsourcing in Romanian Companies

Greco Iulia

Spiru Haret University

Faculty of Financial-Accounting Management, Constanta

elianro@yahoo.com

Abstract

In this paper we analyze how important it is to outsource some activities of human resource management, the advantages and disadvantages.

We will also study the stage of Romanian companies outsourcing.

Key words: outsourcing, payroll, human resources.

J.E.L. classification: M52.

1. Introduction

In recent years, the literature focuses increasingly on outsourcing strategy when addressing the topic selection variant planning [1].

1.1. What is and what outsourcing entails?

Outsourcing involves delegating some tasks or objectives to organizational segments belonging to external drives, often through a formal agreement.

HR Outsourcing (HRO) refers to the outsourcing of certain activities related to the human resource function of a company. Choose activities that are being outsourced or managed business based on how much control you want to have on the HR function.

Let's see first what the main areas of human resource management are:

1. Work organization and job design

- Project organization and its development;
- Designing stations;
- Job analysis.

2. Staffing

- Forecasting staffing needs;
- Human resource planning (number and structure);
- Recruitment and selection;

- Assessing the qualities and placing staff positions.

3. Development (improvement) staff

- Training;
- Retraining;
- Education and training in line with other requirements (reliability, confidentiality, cooperation, self-help, business success, etc.)
- Promotion functions;
- Vocational careers.

4. Performance evaluation

- Employee performance;
- Potential and costs on jobs,
- Highlighting the current limits of employment and staff
- Education and scientific research.

5. Rewards employees

- Payment systems;
- Payment for qualification;
- Payment for working conditions;
- Payment for labor intensity;
- Payment for quantitative and qualitative results;
- Rewards for loyalty, participation and so on;
- Other benefits for employees.

6. Employee Relations - employer

- Law (rights, equal opportunities and obligations);
- Regulation of organization and functioning;
- Participation-involvement;
- Join a union;
- Informing, advising staff
- Communication and negotiation.

7. Benefits and welfare of employees

- Pension schemes;
- Security systems;
- Payment for time not worked (vacations, i.e.)
- Cultural and sporting facilities and transport facilities and hygiene;
- Transport facilities and hygiene in and out of hand.

8. Employee health and safety
 - Humanization of work;
 - Measuring physical and mental energy;
 - Applying ergonomic work stations - this is necessary to increase the concerns of modern organizations to increase the supply ergonomics in design oriented work environment as major HR implications that will enhance the efforts of managers to make pleasant work workers so that they, in turn, be motivated to improve work efficiency and productivity in general especially without neglecting ensure the safety and health of employees[2];
 - Measures of protection and occupational safety.

9. Administration-management employees

- Employing staff;
- Working hours (flexible);
- Managing job costs;
- Discipline and control;
- Information systems.

HR Outsourcing (HRO) in Romania, for many companies is a taboo. One of the secrets to a successful business is the ability to know what services to outsource. HR can be outsourced, at least theoretically, all services. Should however be taken into account when such an approach is effective.

Benefits HR outsourcing enables companies to focus on key activities. Ability to budget and track you're spending easier for certain administrative tasks. Mitigate risks associated with the correct application of all legislative changes as a result of calling the services of specialized companies and accredited human resources. Increase productivity and simplify employee management staff.

Saving time and money. Flexibility according to the needs constant company - client by preparing the statements and reports in a format agreed by the parties. It is very difficult to apply only method of outsourcing or in sourcing simply at an organization, which involves using them together, complementing each other.

Outsourcing advantages related to lower long-term rates, internal resources more specific and beneficial for the company, but for employees who are not saturated with

various tasks plus faster response. Companies using outsourcing can win long term 20-30 percent of turnover plus employees more efficient, more motivated and loyal.

Disadvantages HR outsourcing: One disadvantage is lack of knowledge about client's outsourcer environment, both internally and externally. Of course, a good collaboration, communication and patience, this impediment can be easily removed.

A second disadvantage, which I mentioned above, it, would be incorrect to define the objective of outsourcing an activity, after a thorough analysis of the outsourcing decision.

1.2. Which activities are outsourced human resources in general in Romania?

In Romania there is so much work outsourced payroll, but more work is outsourced training and recruitment and selection. The training was apparently function HR department outsourced most, followed by recruitment and selection and then pay. The vast majority of firms prefer internal performance assessment to be made as an external resource can not know all the details of the person, its progress, results and partial contributions of individuals to achieve organizational objectives.

Outsourcing is higher in small companies, where salaries and general administrative activities are conducted by third companies. Companies with a large increase in calls for 2.5 to 4 times more outsourced services than those with medium or low growth. Here an important role is held recruitment activity which, because momentum is achieved by specialized intermediary firms.

For a dollar invested in wages and benefits, the company and receives the lion recovers plus 0.7 RON. We nearly five times better than companies in Western Europe and twice better than those of Central and Eastern Europe. But Russia has a return of more than two times higher than Romania. Due to the fact that wages will increase to stay with a high yield companies should increase total revenue and control wage costs.

IT firms have developed recently integrated human resource management, payroll and timekeeping. Using these programs, companies can recruit, select and distribute staff at work and establish methods

and systems staff remuneration and salary calculation.

The advantages of this method are reducing payroll process payroll time allocated, which is very important, especially in organizations with a large number of employees reporting process and adequate accuracy by authorities, but also to management. But the costs are quite significant: the actual purchase of software, infrastructure investment required for installing, maintaining personnel costs application, the update due to legislative changes etc.

At first glance, buying a soft computing is a cheaper solution compared to human resource companies that charge a monthly fee depending on the number of employees. But buying program is not the only expense you have to do those interested. Customer must pay a maintenance fee monthly, quarterly or yearly, which often approach the purchase price.

The trend in the last two years is that large companies with thousands of employees, to use all the companies specialized in leasing and payroll.

Recently, for large companies, the cost of outsourcing solutions seems this service, or hiring a human resources company that provides payroll employees. What in the specialized language called "payroll outsourcing" is thus how companies get rid of the hassle of an accounting department, paying instead a firm dealing exclusively with this activity.

Although experts expected to increase payroll services 15% compared to 2011 and forecast a significant increase over the next three to five years, companies in Romania are reluctant to outsource payroll and wage calculation prefer "in-house". Prices for services outsourcing company is determined by specializing in payroll and company who wants such a service, so it is difficult to set an exact price for outsourcing services wages.

The price is set only after a meeting with the client, which includes exactly the requirements and needs. Market price of Romania is based on two euros per employee, reaching about 12 euros. Companies specialized in providing corporate payroll solutions payroll process optimization, reducing costs, minimizing

effort in the department of human resources and payroll, with special software.

Staffing services are services provided by specialized companies acting as employer for personnel operating companies - customer. By law, this concept implies that temporary employment agency provides a company employee hired through a temporary employment contract. This temporary work can only be done in two situations: either when employees go on vacation or when business needs seasonal labor. Also, customers should be aware that a temporary employment contract has the same value as indefinite contract, grant seniority and require the same financial obligations, both the employer and the employee. Staff Leasing has become a form of labor use more common in Romania, mainly due to entry of multinational companies with fluctuating activities that have hired staff to cover busy sales periods (during holidays Easter or Christmas). Cases (most relevant) which may use personal leasing are few employees: situation often encountered in multinational companies due to internal policies, insufficient number of employees: the period of the leave or medical promotion and organizational changes. Long time to approve a new position: although the need for a new employee is often urgent approval of a new job can take time, budget restrictions: usually they apply to salary budgets or other categories, less budget for contracted services, exactly where the budget falls working with such a company specialized internal resources insufficient or inadequate: can mean either lack a human resources department or insufficient resources allocated to the department to handle a large volume of work required for projects of limited duration. Employment during the test: is a pretty frequently requested by some clients to test the abilities and skills of future employees through leasing companies during the probationary period, then to engage them on their payroll.

Outsourcing recruitment: If there developed a specialized department then you need to outsource recruitment. But if such a department can be discussed working with a specialized company? Most times not. For recruitment simple, everyday there are people who are supposed to ensure the efficiency of the operation. For any complex recruitment

recruiter can provide arguments for which you must choose: sources more extensive search, media job promoting much wider selection tools and so much more refined. A situation that can be counterproductive recruitment outsourcing is that the market is restricted and specialized reporting and as such, the employer is more commonly known candidates than could ever be recruiter. If a large real estate company, for example, look for people who specialize in this area most likely they will either learn quickly or already in its database. No recruiter will be able to identify and attract talent more effectively than companies' representative area of the field, even if not admitting it. This situation makes it superfluous: a good recruiter can provide professional element in such recruitment even though he identified candidates. A good recruiter can cover the identity of the employing company, he deals with the best results most professionals, specialized tools involved in the selection process can get references from several directions, can assist employers in negotiating terms of employment. Generally speaking, may assist selection.

HR outsourcing is becoming more common, integrated external market this year is estimated at 12 billion dollars worldwide, according to a recent study by Gartner Inc.

Why outsourcing business in today's increasingly required?

It is generally accepted that there are five main reasons why companies prefer to outsource HR activities:

- Focus on core business
- Achieve global services
- Permanent access to the latest technology
- Permanent access to specialized expertise
- Tight control over operating costs

Outsourcing was imposed in response to the increasing pressure exerted on the human resources department and the entire organization to improve services and to manage resources and costs efficiently.

Administrative activities and salaries of staff in Romanian companies work three times more people than in Western firms.

However, human resources departments of Romanian companies are not numerous. On the contrary even. According to PwC Saratoga study Human Capital Benchmarking [3], Romania 2007, a human resources specialist takes care of 78

employees, while a colleague in Western Europe dealing with only 66 employees. In this way, the Romanian specialists have less time to provide strategy or policy or retention compensation and benefits.

Outsourcing human indicator calculated as the ratio between the costs of outsourcing human resources and its total cost is 9.9%, similar to Western European companies (11.7%). According to the study [4], "Outsourcing in Central and Eastern Europe" conducted by Accace in Romania, Ukraine, Poland and Hungary in 2012, the most commonly outsourced services in these countries are payroll services (96%), followed by accounting services (93%), tax administration (93%), financial reporting (85%), financial planning and analysis (64%) and IT (57%).

Conclusion

The principle of outsourcing is that always a competent entity specialized in a particular service, can make that work better in terms of cost and quality. Indirect benefits for the customer are: first, removed from the day to day operations unrelated to the core business, secondly, there is no need to allocate resources for secondary sectors.

Outsourcing can provide a high level of service and increased efficiency, reduced response time and data availability can increase employee satisfaction with a direct impact on productivity.

Reputation Management of Romanian Small and Medium - Sized Enterprises under Crisis

Holban (Oncioiu) Ionica

Dimitrie Cantemir Christian University, The Faculty of Tourism and Commercial Management
nelly_ioncioiu@yahoo.com

Abstract

Increasing global competition and e-commerce are trends which reinforcing the pressure to rethink existing intangible value. The good reputation of a company's can be destroyed in a matter of minutes on the Internet by anyone; even a competitor. So, more and more enterprises will realize that concept of the reputation management is a mission critical part of management. Reputation management neither can be ignored nor can be dismissed because in the age of internet it has become more visible especially for Romanian SMEs which face a new challenge. The aim of this paper is to contribute in bringing more clarity into the question: what is the current status of Reputation Management in Romanian SME's? Future business success will depend on an enterprise control the reputation management and managing his brand. The research will establish which constituents are essential for attain high reputation management in the SMEs market.

Keywords: small businesses, reputation management, crisis

J.E.L. clasification: H12, J54

1. Introduction

In changing organizations, information is power and that is why you need to be absolutely sure that the information going out about your company is accurate. A bad review or misleading information from a competitor could mean lost business.

The role of Reputation Management is a growing field which just started to get attention a few years ago. Managing your reputation is critical in today's world because, as billionaire Warren Buffet says,

“it takes 20 years to build a reputation and 5 minutes to ruin it.” [1]

Reputation is the total of a company's perception by all of its stakeholders, but this concept can be separated into three different categories. Obviously, it is managing the reputation of a company, but it can be for a company of any size, whether it is a larger company who wants to self-promote, or a just-established company which wants to get its name out there. Therefore, the Romanian small businesses did not care enough about managing their reputation in an appropriate way.

In the same time, the Reputation Management is needed because picture customers searching the company's relevant keywords and being faced with negative words just next to your company or products names in the first results page. In this case, online Reputation Management is the response for any company to overcome this damaging information and establishes other unexplored information gateways between the company and customers.

Romanian SMEs performances highly depend on the priorities set by entrepreneurs and managers. We should notice that over a quarter of the managers intend to undertake managerial restructures and increased the importance of monitoring, managing, protecting and promoting their reputation. As a result, a user rate of more that 30 percent demonstrates that Reputation Management has already arrived Romanian SMEs. The general understanding is considered as proficient although the term itself is still rather unknown. Summarizing, users are regarded as more vital, less vulnerable and more successful.

The challenge of high volatility in capital needs and company risks Reputation Management would meet with more stability, higher prices and an increasing customer

loyalty. However, this intention requires strategic planning which is not strongly distinctive in Romanian SME's. All the more it is essential that there is an explicit commitment of the entrepreneur and the willingness to drive Reputation Management actively.

2. Literature review

In the international literature there are often used interpretations reflecting a general understanding, but there is still a lack in definition of Reputation Management. All presented interpretations share the view that reputation is an intangible asset, which depends on people's perception. Although the conceptual focus differs it is clear that there is a relation between reputation and economic success. It is also undisputable that reputation contains attributes like trustworthiness, orientation and experience.

The empirical investigation of literature review reveals that to complicate the issue of mix-up, reputation and Reputation Management are often used in a context including terms like corporate responsibility, corporate ethics, corporate governance and sustainability (Bennet and Gabriel, 2001)[2].

To clarify all terms and putting them into relationship would go beyond the scope of this work. Thus, it focuses in the following on the definition of reputation and the delimitation of reputation and image, which is the most commonly misused term.

Following Bauhofer (2004), Reputation Management is the concerted application of activities, which is based on the precondition of a stakeholder-oriented company aiming to create sustainable value. The main difference in his interpretation is that reputation is not an aggregation of several individual images but it represents corporate culture, which is characterized by creating sustainable value [3].

Thielemann (2004) represents the version that Reputation Management is stakeholder--support respectively public perception management, which is first of all opportunistic [4]. He differentiates between ethical activities, which are executed due to their relevance for the higher aim that is economic success and activities, which are executed because they are for the sake of an ethical matter.

Today's Internet culture demands transparent and authenticate communication from organizations (Gonzalez-Herrero & Smith, 2008) [5]. Regardless of whether stakeholder comments have any veracity or the author's identity is obscured, organizations operate in a whole new communication paradigm where not responding is wrought with potentially negative consequences.

Regarding the delimitation of reputation and image, the interpretations are more controversial. Regarding the delimitation of reputation and image, the interpretations are more controversial. On the one hand, the image has a short-term phenomenon and therefore volatile and subject to permanent changes reflecting what a company wants to be regarded as of its target groups. Reputation in the sense of a good record reflects the experience of all market participants with a person or a company. Due to the impact of communication on reputation, it is useful to establish and promote a relevant communication network. On the other hand, image can be modified quickly using unidirectional communication. Whereas reputation aims to grow sustainable long-term company value, image is appropriate to generate short-term value in attracting potential buyers.

3. Methodology

The methodology of research was focused on two directions: first, we tried to identify the elements that constitute the reputation management potential from the firm point of view; second we analyzed outlines differentiate results for various participating groups according to the objectives of this paper.

The method was chosen as it is web-based questionnaire and the survey instrument used in this study was a structured questionnaire for the quantitative study. The questionnaire was made up of two parts and it comprises a total of 25 questions. The first part of the questionnaire gathered background information of the respondents from different Romanian SME's, which filled up the questionnaires and representing Reputation Management users. The second part of the questionnaire addressed the scale items related to the social organizations

(Reputation Management non-users or indecisive). The variables were measured using multiple items. All of the scale items represented in the survey instrument utilized a five – point categorical rating scale. The anchors used included: a) 1 = not at all, b) 2 = few, c) 3 = partly, d) 4 = good, e) 5 = very good.

The online survey system provides a total of 2104 data records.

4. Results

Based on the scoring results in the questionnaire 54 percent of the participants associated Reputation Management with strategy whereas 34 percent regarded the topic as an additional instrument for corporate management and even 19 percent acknowledged Reputation Management as one of the most important competitive advantages in future. Eleven percent identified a current trend and for another ten percent the topic was yet completely undeveloped. This result indicates a general confession of Romanian SME’s to Reputation Management as an important management topic. Considering different sub-groups it is remarkable that micro enterprises assumed with 19 percent an over-average attitude that the topic is only trendy which is intensified with an under-average vote of only 12 percent for the consideration of Reputation Management as a competitive advantage. From those participants considering the topic yet as a completely unimproved land, 82 percent argued that they heard for the first time about Reputation Management in the survey.

The questionnaire survey has demonstrated that 21 percent of all participants committed themselves to the use of Reputation Management, 49 percent were non-users and 30 percent were not sure if it is used in their companies. This is not remarkable because general comprehension expects an increasing willingness for strategic planning and the availability of resources as a function of increasing company size.

The question “Does the Romanian SME’s use Reputation Management?” categorizes the participants quantitatively in Reputation Management users, non-users and indecisive.

According with data the result admits the follow considerations: either the participating Romanian SME’s have a different understanding of managing reputation or they are pioneers in Reputation Management yet before large-sized enterprises which appear unreasonable. This result reflects that the importance and relevance of the topic is associated correctly to corresponding functional areas. It leads to the conclusion that Reputation Management users are aware of a proper integration into business.

In consideration of the figure 1 in average 41 percent stated a good or very good knowledge of stakeholder needs, 31 percent indicated to know expectations partly and 19 percent confessed to few familiarity or do not know needs at all. Comparing Reputation Management users and non-users about 50 percent of users are familiar with their stakeholder needs, stating good or very good knowledge, only 35 percent of non-users agreed to this level. This leads to the conclusion that the use of Reputation Management clearly supports a better understanding of stakeholder behavior. Within different company sizes, micro and medium-sized enterprises dominate the result positively. At the same time medium-sized enterprises show a percentage of 13 percent in the category few to none, which is below the average of 19 percent.

Figure 1: Values perspective at the Reputation Management in Romanian SMEs

According to the figure 2 the influence of Reputation Management in applying Romanian SMEs, participants were asked to state if there are changes of aspects that represent reputational benefits from literature. In average 36 percent indicated an improvement, 47 percent an unchanged

situation. Only one percent stated that Reputation Management worsened things. There is a general agreement among the participants that customer loyalty (65 percent), employee motivation (59 percent) and attractiveness for applicants (51 percent) significantly improved.

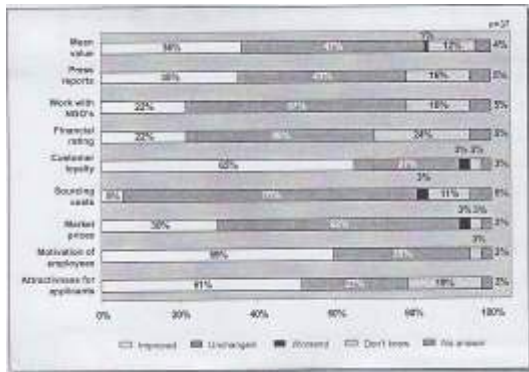

Figure 2: Influence of the Reputation Management in Romanian SMEs

For another point of view, the participants of questionnaire declaring to measure reputation focus on different methods: 65 percent indicated to execute surveys for identifying stakeholder perceptions. The evaluation of press reports was noted by the additional 22 percent as the method of choice. Finally, 13 percent stated to get reputational feedback on customer site through personal contact and common work. Despite of few entries it can be assumed that SME's focus on classic marketing measurement methods like surveys and media analyses are already known. This is not bad because these methods provide a lot of relevant information although they should be completed with reputation specific key figures. Those participants relying simply on their gut feeling have to be explained that this approach might be sufficient for individual case but contradicts a systematic Reputation Management approach as well as strategic planning with a negative impact on business.

As a result, Reputation Management users can be regarded as more active and less vulnerable, which reduces business risk, due to the intensive exchange with their stakeholders. Based on the high correlation it can be assumed that major efficiency issues in communication do not occur among the participants, as it would be expressed in the case of little knowledge despite of high contact.

5. Theoretical and Practical Implications

The important effects on Reputation Management in Romanian SMEs which have to be taken in account is the number of channels which have to be considered increases and comes along with a higher speed on building reputation as well as an additional coverage of publicity.

The results of present study leads to the conclusion that all mean values are over-average, which confirms that Romanian SME's have already a considerable level of proficiency in Reputation Management. The well-balanced best practice shows that it is definitely possible for SME's to use Reputation Management in a professional and successful way. Regarding the mean value it is obviously that, beside of the internal dimension, there is a large potential for advanced optimization. The worst practice shows the example of a company that is mainly market-driven whereas other aspects are regarded of lower priority.

After regarding the influence of Reputation Management obtain with this design, it is useful to confront the expectations of non-users with the experiences of users. As experiences prove that many enterprises introduce Reputation Management as a reaction on a sudden damage of reputation. Practical in the Romanian SMEs case, the Reputation Management is useful to think about an enhanced or modified measurement.

6. Conclusions

From a perspective of size, small enterprises represent the majority of users, followed by micro enterprises and medium-sized enterprises. More than half of the companies are experienced users indicating to practice the Reputation Management for more than five years, whereas the implementation comprises most aspects of stakeholder value perspective and reputation drivers on a high level of activity and over-average results.

Although a percentage of three quarters indicated that Reputation Management has medium or strong influence on business, the reasons for not applying Reputation Management are still not clear. It can be assumed that the topic has not yet reached the

consciousness of decision makers in an adequate relevancy.

The originality value of this research are: considerations regarding the role of Reputation Management as a pivotal instrument to support management in changing organizations and actual concerns regarding the maintain reputation of Romanian SMEs for measure progress because there is no control to anticipate concerted activities or step in if requested.

This study confirmed that the use of Reputation Management in Romanian SMEs improves the exchange with all stakeholders and enhances the knowledge of stakeholder needs. Reputation Management users have a high contact rate with their environment and work intensively on business improvements.

Strategic planning is considered as the most important supporting factor to implement Reputation Management in Romanian SMEs because if this factor is not given, it can be assumed that an implementation.

For sure the implementation of Reputation Management is more difficult in the case of a damage of reputation owing to the management of reputation needs intensive exchange with all stakeholders who require trust and credibility, and both suffer in the case of damage.

The real problem for Romanian SMEs today is managing the information about his company on the web where online reputation management can give their serious disadvantage over their competition. To make sure that the company does not come under one of these unfair attacks the Romanian SMEs should consider hiring a reputation management firm.

In future every Romanian SMEs has to answer to questions like: “Which factors influence the implementation of Reputation Management in your company?”, “How does Reputation Management help?”, “How can activities in Reputation Management are identified in your SMEs?” “When would you expect significant success after implementing Reputation Management?”

So, the Romanian SMEs must be opened for external support in Reputation Management and is better to create a measurement system referring to six beneficial aspects regarding this concept: internal, financial, market, public relations,

political-legal and online. Due to the fact that Reputation Management influence all dimensions and is the most important theme today.

Reputation is a phenomenon which exists and it is helpful to know that the work is dealing with socially constructed interpretations of people and companies. Moreover, the Reputation Management in Romanian SMEs is subject to permanent changes and is influenced by individual perception. In times of crisis, companies must look beyond their corporate borders to manage corporate reputation effectively. In most cases, the loss of reputation is the result of a company's own short-sighted business and communication tactics.

Case Study: a Model of Taking Over of Railway Institute in Bucharest

Humă Elena

Institutul de Studii Doctorale ASE București

humaelena@yahoo.com

Abstract

In the context of the global economic crisis the business environment leads to new mergers and acquisitions. In order to consolidate the economic and financial situation, many companies choose to merge or to be absorbed by stronger companies and to continue their domain of activity or to keep on supplying services. It represents an ideal solution for companies in difficulty, as it is the case often during this economic crisis period.

Key words: current liquidity ratio, acid test ratio, method of compensation

J.E.L. Classification: M49 Accounting and Auditing

The Railway Institute was founded in November 1947 based on a Decision issued by GENERAL DIRECTION of CFR aiming to achieve a unitary concept on the railway operation and development, thus separating the study and design activities from the construction one.

So the new institute could benefit by numerous specialists from the Railways and very soon could be operative and able to create and use the elements of the Railways logistic base.

Even from its starting-up, in November 1947, of the Railway Institute, it was required to be a central and strong organization that will gather all the railway design, attributed till that moment to each department of the railway regional. Up to that moment, all projects were an attribution annex to all CFR units, with no practical guidance or control from the part of General Direction of the railways.

This bad organization become more and more projecting after the finalization of the Second World War, when the rehabilitation works started, sometimes even to new

constructions that had to be performed in that time.

Studies, as well as projects were performed under the pressure of open sites, but without having the necessary documentation or with incomplete documents or documents containing the big errors in measurement, quantities and so on. The situation was even harder when talking about objectives that were related to different activities: finalized constructions, without additional installations, with a superficial specification of the necessary equipment. In such a manner, inadequate workshops, warehouses, centralization cabins, water castles were built. These constructions were not functional and, in the same time they were blocking the investment funds.

The studies and the designs were not elaborated in anticipation, their making-off and putting into operation was superficial, with many delays in the decision making process; with no concern for the financial resources or the importance and emergency of these types of activities of the CFR Company.

In order to fix this situation, the General Direction of CFR decided to separate the execution and design activities. In this favorable context, in November 1947 the Railway Institute were born.

The Institute had to perform the Unitarian of the technical conception upon development of the material means, the best regarding the exploitation of the railway network.

The Government Decision No. 235/1991 and 570/1991 establish the starting up of the National Company of Romanian Railways; with own autonomy and own legal personality, having in its structure the Railway Regional, Direction of Railways Constanta harbor, the Welding Railway Company, Informatics and Computation Center of CFR, Training Center and CFR Museum.

By Government Decision No. 570/1991, the Railway Institute is part of the units that will separate from SNCFR, becoming, based on Governmental Decision No. 692/04.10.1991 a limited liability company under the denomination Railway Institute S.A. Bucharest.

At the end of 2006, AVAS tendered 70% of the shares of ICF SA (the rest of 30% is the SM portfolio) and beginning with 1st of November 2007 the main shareholder of ICF SA became SC AC SA together with a group of persons.

AC is a Romanian Company established in 1994, having as main activity domain civil works and industrial constructions.

Partial privatization

Although passenger railway services are not a state monopoly in Romania, CFR remains the only passenger carrier operating at a national level. However, after the reorganization of CFR in 2011, around 15% of Romanian railway tracks have been leased to private companies. These are known as non-interoperable tracks in Romania. The main operators are: S.C. Regional S.R.L., S.C. Transferoviar Grup S.A., S.C. Regiotrans S.R.L., and S.C. Servtransinvest S.A. which now operate a significant number (especially Regiotrans) of routes <<http://tren.transira.ro/>>. Early transfers to these companies included Zărnești–Brașov, Brașov–Întorsura Buzăului, Sfântu Gheorghe–Brețcu, Sighișoara–Odorheiu Secuiesc, Șibot–Cugir, Blaj–Praid, Galați–Bârlad, Buzău–Nehoiășu, Iași–Dorohoi, Timișoara Nord–Nerău, Satu Mare–Bixad, Arad–Nădlac, Bistrița Bârgăului–Bistrița Nord–Luduș, Arad–Brad, Roșiori Nord–Piatra Olt and many others lines. On these lines, CFR is not allowed to operate its trains—companies which have leased the tracks have a virtual monopoly on their usage. Aside from CFR Călători, 12 other companies provide local passenger services, on non-interoperable tracks, even though none of these services exceed 40 km in line length. 28 private companies, including Petromidia and Servtrans, operate freight transport services on main lines with their own rolling stock, leasing usage rights from CFR. As of 2005, some of the leases have been breached and the tracks have therefore fallen back under the operation of CFR. In August 2005, CFR announced that it

intended to privatize CFR Marfă, its freight division.

The company has a subscribed and paid social capital of 4.582.400 lei.

In the end of 2007 the turnover was of 20.242.260 lei and the company obtained a Net Profit of 77.351 lei.

Revenues made in 2007 amounted 21.686.111 and it come from:

-exploitation revenues from design works, studies, technical assistance, internal partners as well as external partners as well as service activities amounting 21.576.670

-financial revenues added from interest rates and exchange differences, in value of 109.441 lei.

Expenses occurred during 2007 amount 21.608.760.

-expenses coming from exploitation revenues amount 21.562.998 lei

-financial expenses from interest rates and exchange currency differences amount 45.762.

Note that in the Profit& Loss Account both operating revenues and operating expenses are influenced by the adjustments regarding the current assets and the provisions for risks and expenses, litigation.

Operating expenses-on primary elements-are:

-consumables, energy, water, other material expenses 1.388.625

-depreciation 455.894

- gross salaries 11.420.933

-social security expenses 3.143.269

-taxes and fees 292.235

-subcontractors 7.890.797

-adjustments in value for current assets (3.335.519)

-other operating expenses 306.764

The company's debts amount 7.939.186 lei from which the ending accounts receivables at 31.12.2007 was 7.855.747.

At 31.12.2007 are recorded debts in total of 2.598.111, representing debts that should be paid within 1 year, as follows:

-suppliers, collaborators, designing 659.747

-debts to personnel 769.695

-social security funds 341.132

-unemployment funds 27.831

-income on salaries 149.667

-VAT 499.876

Debts to personnel, social security funds, income on salaries, VAT and special funds were all paid during January 2008.

In what concerns the debts towards specific suppliers (as the renting supplier), the method of compensation will be applied as it was done so far.

At the end of 2007 the annual inventory of assets and liabilities was performed according to OMFP No. 1753/22.11.04 for Norms approval regarding organizing and performing the active and passive elements inventory.

During the reported period the economic-financial activity was performed, in average, with a number of 43 employees.

The balance sheet, the Profit & Loss Account, the informative data, the situation of the fixed assets and its depreciation and the situation of the provisions for depreciation at 31.12.2007 are presented according to the legislation in rule established by the Ministry of Public Finance for the year 2007.

Total capital of the company is in amount of 10.363.660 lei.

The result of the year (profit) amounts 77.351 lei.

The management of the company is responsible for preparation and presentation of the financial statements.

Main economic-financial ratios for the year 2007:

1. Liquidity Ratio:

1.1 Current Liquidity ratio (current capital ratio):

$$= \text{Current Assets} / \text{Current Debts} = 12146913 / 2598111 = 4.68$$

$$\text{Debts} = 12146913 / 2598111 = 4.68$$

1.2 Immediate liquidity ratio (acid test ratio-quick ratio test):

$$\text{Current Assets} - \text{Stocks} / \text{Current Debts} = 12146913 - 1509625 / 2598111 = 4.09$$

Quick ratio specifies whether the assets that can be quickly converted into cash are sufficient to cover current liabilities.

Ideally, quick ratio should be 1:1.

Our quick ratio is higher, meaning the company keeps too much cash on hand or has a problem collecting its accounts receivable. Higher quick ratio is needed when the company has difficulty borrowing on short-term notes. A quick ratio higher than 1:1 indicates that the business can meet its current financial obligations with the available quick funds on hand.

2. Risk Ratios:

Debts degree ratio:

$$= \frac{\text{Borrowed Capital}}{\text{Own Capital}} \times 100 = \frac{0}{10363660} = 0$$

3. Activity Ratios: activity ratios are critical in evaluating a company's fundamentals because, in addition to expressing how well a company generates revenue, activity ratios also indicate how well the company is being managed.

3.1 Clients Debts Turnover=

$$\frac{\text{Average credit Clients}}{\text{Turnover}} \times 365 = \frac{7855747}{20242260} \times 365 = 141,65 \text{ approximately } 142 \text{ days}$$

365=141,65 approximately 142 days

Turnover ratio indicates how many times the accounts receivable have been collected during an accounting period. It can be used to determine if a company is having difficulties collecting sales made on credit. The higher the turnover, the faster the business is collecting its receivables. It can be expressed in many forms including accounts receivable turnover rate, accounts receivable turnover in days, accounts receivable turnover average.

3.2 Turnover Supplier's Credit:

$$\frac{\text{Average credit Suppliers}}{\text{Acquisitions}} \times 365 = \frac{620433}{13001385} \times 365 = 17,42 \text{ approximately } 17 \text{ days}$$

365= 17,42 approximately 17 days

The accounts payable turnover ratio indicates how many times a company pays off its suppliers during an accounting period. It measures how a company manages paying its own bills. A higher ratio is generally more favorable as payables are being paid more quickly. When placed on a trend graph accounts payable turnover analysis becomes simplified: the line raises and lowers just as the ratio does. Common adaptations used to calculate accounts payable turnover yield results like accounts payable turnover ratio in days, ap turnover in days.

3.3 Turnover fixed assets:

$$= \frac{\text{Turnover}}{\text{Fixed Assets}} \times 365 = \frac{20242260}{1077695} \times 365 = 6855,77 \text{ approximately } 6856 \text{ days}$$

6855,77 approximately 6856 days

The fixed asset turnover ratio measures the company's effectiveness in generating sales from its investments in plant, property, and equipment. It is especially important for a manufacturing firm that uses a lot of plant and equipment in its operations to calculate this ratio. If the fixed asset turnover ratio is

low as compared to the industry or past years of data for the firm, it means that sales are low or the investment in plant and equipment is too high. This may not be a serious problem if the company has just made an investment in fixed asset to modernize, for example. If the fixed asset turnover ratio is too high, then the business firm is likely operating over capacity and needs to either increase its asset base (plant, property, equipment) to support its sales or reduce its capacity.

3.4 Total Assets Turnover:

$$= \frac{\text{Turnover}}{\text{Total Assets}} \times 365 = \frac{202242260}{13224608} \times 365 = 558,46 \text{ approximately } 558 \text{ days}$$

The total asset turnover ratio measures the ability of a company to use its assets to efficiently generate sales. This ratio considers all assets, current and fixed. Those assets include fixed assets, like plant and equipment, as well as inventory, accounts receivable, as well as any other current assets. The lower the total asset turnover ratio (the lower the # Times), as compared to historical data for the firm and industry data, the more sluggish the firm's sales. This may indicate a problem with one or more of the asset categories composing total assets - inventory, receivables, or fixed assets. The small business owner should analyze the various asset classes to determine in which current or fixed asset the problem lies. The problem could be in more than one area of current or fixed assets. Since current assets also include the liquidity ratios, such as the current and quick ratios, a problem with the total asset turnover ratio could also be traced back to these ratios. Many business problems can be traced back to inventory but certainly not all. The firm could be holding obsolete inventory and not selling inventory fast enough. With regard to accounts receivable, the firm's collection period could be too long and credit accounts may be on the books too long. Fixed assets, such as plant and equipment, could be sitting idle instead of being used to their full capacity. All of these issues could lower the total asset turnover ratio. What if the total asset turnover is excellent as compared to historical data for the firm and to industry data? That means the company is using all its assets - its asset base

- efficiently to generate sales and that is a very good thing.

4. Profitability Ratios

4.1 Return on capital assets=

$$\frac{\text{Gross Profit}}{\text{Owner's Equity} + \text{Long-term Debts}} \times 100 = \frac{77351}{10363660} \times 100 = 0,75 \%$$

The profit percentage of assets varies by industry, but in general, the higher the ROA the better. For this reason it is often more effective to compare a company's ROA to that of other companies in the same industry or against its own ROA figures from previous periods. Falling ROA is almost always a problem, but investors and analysts should bear in mind that the ROA does not account for outstanding liabilities and may indicate a higher profit level than actually derived.

4.2 Net Profit Ratio:

Net profit margin is a key financial indicator used to assess the profitability of a company.

$$\frac{\text{Net Profit}}{\text{Turnover}} \times 100 = \frac{77351}{20242260} \times 100 = 0,38\%$$

4.3 Economic profitability ratio:

$$= \frac{\text{Exploitation results}}{\text{Total assets}} \times 100 = \frac{13672}{13224608} \times 100 = 0.10\%$$

Net profit margin measures how much of each dollar earned by the company is translated into profits. A low profit margin indicates a low margin of safety: higher risk that a decline in sales will erase profits and result in a net loss. Net profit margin provides clues to the company's pricing policies, cost structure and production efficiency. Different strategies and product mix cause the net profit margin to vary among different companies. Net profit margin is an indicator of how efficient a company is and how well it controls its costs. The higher the margin is, the more effective the company is in converting revenue into actual profit.

Net profit margin is mostly used to compare company's results over time. To compare net profit margin, even between companies in the same industry, might have little meaning. For example, if a company recently took a long-term loan to increase its

production capacity, the net profit margin will significantly be reduced. That does not mean, necessarily, that the company is less efficient than other competitors.

Conclusions

The ratios computed above show that the taking over was the clever solution to be adopted by the management of the Railway Institute in order to maintain its activity and to sustain the expenses incurred.

The Effects of Uncertainty and the Asymmetric Impact of the Economic Crisis on Sectors of Activity and Companies in Romania

Ionescu Adriana

Christian University „Dimitrie Cantemir”, Faculty of Tourism and Commercial Management, Constanța, Romania

ioneascaadriana@yahoo.com

Catană Petronela

petronela_catana@yahoo.com

Pîndiche Elena

pindichielena@yahoo.com

Abstract

Economic strategies for today's Romania should be in this time of crisis, more than ever, a priority for both government and main political and professional organizations, economic research institutes and universities in the field but also general business environment. But the economic crisis in Romania full installed at the end of 2008, resulted in dramatic decreases in spending among companies and significant adjustments budgets. In an attempt to keep business afloat, companies looking for effective solutions ranging from monitoring of cash flow, renegotiating contracts with suppliers, rethinking strategies tailored customer service, to more drastic solutions, such as redundancies personal.

Keywords: economic crisis, anti-crisis measures, crisis support, economic decline, the analysis of macroeconomic

J.E.L.Classification: D00

Introduction

In conditions of crisis, the company, the state plays a decisive role in fostering, protecting and strengthening economic and political independence of the country, so must act vigorously and giving priority to local producers providing training, building, operation and Development internal market to meet social needs, with gainful productive activities for both the state and the population.

As a matter of national interest with profound economic and social implications, should develop measures to mitigate the global financial and economic crisis, which may make it possible to avoid a severe crisis in our country and create conditions to maintain or increase the living standards of people through civilian and not military investment.

This goal can be achieved by "turning all natural resources" and especially those in agriculture, where our country has a large unused potential, which means an increase in subsidies and a substantial amount of investment will create a strong impact economic and social development and give rise to other areas of activity: industry, construction, trade, tourism, services and allow time and territorial rural development real and lasting.

To this end must be urgent action at national and regional levels to:[1]

A. Reduction or suspension of import of food products and raw materials that occur or may occur in the country and export of agricultural products and/or virgin forest and allocation massive funds for development of domestic production in these areas;

B. uptake or emergency access to community funds necessary territorial development particularly for agriculture and infrastructure, where there is the possibility of obtaining quick results, multiple major and visible;

C. Establishment and / or working in partnership by the Village Hall or urban small and medium units in private sector activities that meet local needs, such as:

1. Production units or sections and/or service, in each municipalities own, such as construction, repair and maintenance of streets, garbage collection, which currently are paid enormous sums to the state budget,

2. Anonymous-stock companies formed or formed joint ventures, public and private, including a wide range of activities such as:

a) The execution of agricultural works by taking the form of lease municipalities/and/or association of arable land/orchards or vineyards or unkempt worked by owners, for various reasons and the establishment of agricultural units with their agreement with the basic land as private property and the council will be equipped with necessary equipment investment,

b) processing of agricultural products to obtain goods and services supply basic necessities to the population and not only that: mills, bakeries, canneries, compotes and jams, collection, processing of milk and milk products, slaughterhouses/meat sections and meat products obtained from their own farms or from local producers, cutting fabrics, garments and knitwear, manufacture of furniture, bricks and others,

c) Construction, development and maintenance of roads, bridges, drainage, hydro facilities, dams, hydropower plants for farms/stations/industrial workshops, regulation of rivers near the village and the earth formation displaced by dams on the one hand and other paved or concrete, a distance to avoid flooding, directing water to irrigate farmland and channel formation of ponds or ponds for fish farming, greenhouses and vegetable crops of mushrooms, construction of buildings or premises necessary production workshops industrial warehouses, silos, residential buildings, dispensaries, communal bathrooms, schools, etc,

d) Disposal of products of own facilities and/or goods that are required locally for personal or household needs, the grocery, general stores;

e) Arrangement of sightseeing symbol landscape/historical/musical/cultural area and the establishment of characterizing locations for tourism, with pensions, cottages specific local,

f) The organization of fruit tree nurseries, for the establishment of orchards, trees for afforestation of deforested areas, landslide areas / on dams, curtains/selvedges of trees in

addition to national and county roads, city streets and streets.

Implementation and operation of these enterprises will be made based on:

- Financial resources consist of: State and private capital investment will include the state budget - plus subsidies - accessed funds from the European Union-based projects concrete investment funds from individuals in the country, the diaspora and those who return, low interest loans from CEC Bank and not least foreign capital;

- Investment funds from individuals can be achieved through a policy of attracting savings by presenting the importance, necessity and benefits of creating profitable productive activities, both for those taking part with funds that will be guaranteed by the state, and for those who want to work;

- Autonomous stock companies, joint ventures will be the state with investments and subsidies., The earth's population, specific buildings, equipment and funds or savings funds, and how the results will be key: the shareholders (the state and individuals) will receive profits/dividends in proportion to the degree of participation, those who work/working in establishments with payroll.

D. Processing of the entire state-owned underground riches, to ensure energy independence and it can households, exploit, process and distribute the entire society, as a national asset that belongs to all Romanians present and future, is an important source of income to budget the state;

E. To encourage, stimulate and assist farms, small and medium private productive units to obtain the necessary funds to develop their business, supporting existing tourism, the local craftsmen and open to tailoring, cismărie, repair and/or car washes, repairing bicycles, electrical appliances and others.

Macroeconomic analysis of the evolution of Romanian economy by sector in the period 2008-2011

Macroeconomic analysis shows that the evolution of Romanian economy in the fourth quarter 2008, global economic crisis began to unfold in Romania.

In terms of *sectoral developments*, the Ministry show that the gross industrial value added grew by 1.3% over the whole of 2010,

compared to 4.8% in the first nine months, following the decline of industries in the fourth quarter (textile products, Automotive, metallurgy, machinery and electrical appliances, furniture) and reduce growth in the first half, with important contributions in other branches in manufacturing industries (food and beverages, electricity and heat, other mining and quarrying).

The construction sector in Romania is already affected by tightening credit conditions and increased costs that inhibit the development of demand in the residential segment. Reduced demand will be partially covered by infrastructure development and construction works agro-industrial and grants financed by the European Union (EU). Gross value added in construction in 2010 recorded an increase of 26.1% compared to 31.1% in first 9 months.

For services, the effects of the crisis were made mostly felt in business, namely retail and services provided to the population as a result of tighter credit conditions that have led to a decrease in volume of activity in the banking system and limiting the amount of activity in the industrial sector.

In all of 2010, gross value added of the tertiary sector rose by 5.1%.

In the first quarter of 2010, there was a contraction of the Romanian economy for the first time since the early 2000, respectively 6.4% from the first quarter 2009, according to seasonally adjusted statistics.

In the first quarter of 2010, industrial production declined in real terms by 13% (raw number), mainly due to lower processing industry by 15.2%. However, developments show a certain return monthly industrial production in March was 21.5% above the level recorded in January 2010 and 21% higher than in December 2009. As a result, industrial production in March 2010 was only 8.5% below March 2009.

In March, activities that provide 36% of manufacturing industry has achieved a high production level in March 2008, MFP mention of the tobacco products (+23.3%), manufacture of other transport equipment (20.1 %), manufacture of motor vehicles (+7.4%), wood (6.2%), printing and reproduction of recorded media (1.1%), food (+0.5%) . During this period, the volume of construction works increased by 4.4%.

According to data provided by the National Institute of Statistics in June 2011, industrial production declined from the previous period, both as gross series and as adjusted series, depending on the number of working days and seasonality, by 1.5%, 2.2%. Gross decrease of 1.5% causes were due to reduction in all industries: manufacturing and supply of electricity, gas, water, heat and air conditioning (-4.3%), mining and quarrying (-4.0%) and the processing industry (-1.0%).

Also, and in the industrial groups have declined for most categories of goods: durable goods industry (-3.7%), energy industry (-3.3%), intermediate goods industry (-2.2 %) and household goods industry (1.3%).

In Romania, the first economic sectors affected are those related to exports, especially exports to the EU is moving about. 70% of total exports. Intra exports were worth 23.7 billion, representing 70.4% of total exports, while exports were 10 extra billion.

Eastern European states, whose economies have recorded growth rates higher than those in Western Europe will not escape the effects of global economic slowdown and the demand for exports coming from the Eastern European region will decrease.

Intra imports were 38.9 billion, representing 69.1% of total imports, and the extra 17.4 billion. The increase of intra imports was 6.4% and 18.1% of imports outside, obviously a shift to areas outside the Romanian trade.

Reducing consumption will affect global production all over the world, and exporters will be affected first. Metallurgy, ArcelorMittal Galati has already decided to reduce production of rolled and closure of production capacity, ArcelorMittal is the largest exporter in Romania.

Although currently, the statistics do not reflect the decline of industrial production and exports, the effects of international financial market turmoil will be felt in Romania in the future.

International Monetary Fund revised estimates of Gross Domestic Product (GDP) growth rising of Romania for 2011, down from 5.4% to 8.6% advance in April and expects next year's economic advance of

4.8%, slightly over the previous forecast of 4.7%.

In the first quarter of 2010 due to weaker external demand, exports of goods continued their downward trend recorded in the last quarter of last year, decreasing by 19.4% over the same period of 2009, recorded in the lower reduction first two months (-26.0%) due to diminishing exports decline in March to just 6.9%. It said strong growth in exports of goods by 23.0% in March compared to February of this year. In contrast, imports of goods decreased in the first quarter by 35.4%.

In the first quarter of 2010, compared to the previous year, there is a structural improvement materialized in increasing the share of exports of machinery and equipment exports in total exports of goods transport by 6.7% (from 33.9% to 40.6%). Corresponding to this evolution of foreign trade, the commercial deficit FOB - CIF was reduced by 61%.

The current account deficit increased by 1.3% in 2009, reaching EUR 16.9 billion (12.3% of GDP), financed at a rate of 53.8% through FDI, accounting 9.1 billion, compared with 7.3 billion recorded in 2007.

In the first quarter of 2010, the current account of balance of payments has improved its deficit decreasing by 82.1% to EUR 709 million.

The current account deficit was financed entirely by foreign direct investment, which stood at 1.456 billion euros compared with 1.691 billion euros in the first quarter of 2009.

Trade deficit (fob-fob) amounted to 1.337 billion euros, down from the first quarter of 2009 to 67.2%.

In early 2010, the annual inflation rate continued growth manifested since the second half of 2009, falling in July to a level of 9.04%.

Since August noted, however, a change of trend, so that the annual rate of inflation has reached the end of December to 6.3%.

In the first three months of 2010, the annual inflation rate reached 6.71%. In the first four months compared with same period previous year, national currency recorded a depreciation of 13.4% in nominal terms against the euro.

It becomes increasingly obvious that the world of tomorrow will record other global

equilibrium dynamics sometimes turbulent change.

In general, tightening credit and increasing costs, the relative lack of liquidity is already affecting businesses in various economic sectors in Romania.

Falling demand - the main problem of the Romanian economy

The main factor affecting the business environment in Romania is in demand. This however must be seen as part of a complex and independent of factors, including the most important are: availability of credit, exchange rate, the emergence of arrears and liquidity problems, etc. All the effects of public policy too little calculated at the time of their adoption and voluntary contraction of private consumption as a means of protection against the effects of the crisis.

Availability of credit problems come mainly from lack of liquidity existing global financial market in Romania, Romanian National Bank (BNR) increased the reference rate and reserve requirements for banks to discourage the granting of credit too easily. The result is a high cost for working capital and to finance investments for institutional clients. Individuals were tightened credit conditions. 44% of managers in metallurgy, metal constructions and metal products and chemical industry considers 40% of credit availability one of the key issues that lead to lower demand in their sectors.

One of the unknowns in the equation of the economic crisis is the exchange rate. In December 2007 the RON / Euro was 3.53 to reach 3.92 in December 2008, 4.22 RON / EUR for late 2009 and 4.29 RON / EUR at the end of 2010. Panel of experts convened by the SAR expected for the end of 2011 an average of 4.4 course Roni / euro, but dispersion predictions is very high, which reflects the current state of volatility in the short term analysis of Romanian National Bank (BNR) in January 2011, when shows that exchange rate affects 36-45% of companies in metallurgy, textile industry and means of computers.(Figure 1):

Figure 1 - Evolution of exchange rate RON / EURO in 2007-2011

Sourcecode:<http://cursvalutar.clubafaceri.ro/evolutie-curs/?an=2011>

Commitment to adopt the euro in 2015 is maintained and is an important anchor in budgetary and structural reforms necessary to increase the flexibility of the Romanian economy.

In preparation for the changeover to set up a ministerial committee under the coordination of the Prime Minister, which includes NBR, MPF and other responsible institutions. In February 2010 was established at the National Bank, a changeover Preparation Committee, aiming to create technical support, organizational and legal framework necessary to achieve the tasks of the central bank in the process of introducing the euro. Since October, the Committee shall be invited permanent representatives of the Ministry of Finance.

Among the concrete actions undertaken by this organizational structure can remember drafting proposals for euro adoption law, the study of the institutional structure used by other central and east European countries in preparation for adoption of common currency, analyzes the degree of fulfillment by Romania nominal criteria and real convergence criteria, etc.[3]

Emergency application of anti-crisis measures

General Union of Industrialists Romania - UGIR-1903 calls for emergency anti-crisis measures agreed with the Romanian Government. At the anniversary celebration of 106 years of existence of the movement of employers in Romania UGIR-1003 is concerned with limiting profound economic crisis in Romania.

Given the difficult global financial and economic crisis, UGIR-1903 welcomes the opening of the Romanian Government, the Presidency and other central administration bodies for full consultation and dialogue with social partners for Romania's 2012 budget structure UGIR-1903, with other employers' confederations and trade unions, the Government filed a substantial package of measures proposed to mitigate economic crisis effects in Romania, which also measures were accepted and budgeted.

Develop a draft budget of this year Romania has to stay under the sign of realism, the drastic reduction of public expenditure, except expenditures for infrastructure investments have a positive multiplier effect. It is necessary for companies to benefit from tax incentives to help reduce the tax burden and improve their working conditions in an increasingly difficult economic environment, fewer fees and taxes, as well as generated parafiscalității them.

At the same time, UGIR-1903, fully understand the situation of 1500. public sector employees whose income growth will be limited by reduced activity more in the private sector of the economy which should provide the budget with taxes supply the necessary amounts. Becomes obvious in this context that maintaining a job is "cheaper" than creating a new one, or the payment of unemployment benefits.

Union of Romania General Industry also considers that it is fully justified as in the current economic circumstances. Romania to focus the priority use of products and services to those made in the country.

Therefore, UGIR-1903 aims to launch a national campaign to support domestic production with the slogan "Choose românesc100% and keep a job" in the campaign all companies operating production or provision of services within Romania will be invited to get through UGIR-1903 certification under the brand "100% Romanian." This program is to support both producers and service providers that create jobs in Romania and of the population who will find this means needed to mitigate the crisis.[4]

Conclusions

It becomes increasingly obvious that the world of tomorrow will record other global equilibrium dynamics sometimes turbulent change. In general, tightening credit and increasing costs, the relative lack of liquidity is already affecting businesses in various economic sectors in Romania.

Economists problem is that next year will not have nothing to finance consumption: speculative capital left, outside the Romanian workers will not easily find work, and exporters will be more difficult, because demand has fallen dramatically in countries where we sell our products to date (EU). Domestic demand (not just the consumption but also investment) will drop dramatically to the point that can be financed. In turn, domestic supply will be affected by the difficulty of financing capital goods.

Firm's Price Strategies Typology

Ionescu Gr. Ion

"Dimitrie Cantemir" Christian University,

Faculty of Management in Tourism and Commerce, Constanta - Romania,

iionescu_levant@yahoo.ca

Abstract

Thus, the strategies of the firm, are responsible for the harmonization of the results, and for the exigency of the parties concerned in the life of the firm: stockholders, accounts payable, state. We analysed all the specified and typological gamma of diversification strategies, strategic alliance role and of the relational strategy.

As a measure of improve it 's that the firm, but also the specialists in communicational strategy, focuses the efforts for the definition of the best strategical options, in account with the compartiment of the competitors, but also with plenty of sectorial inter and in factor, for the improvement of the business environment.

Key words: firm, strategy, relations, business, competitors

JEL Classification: M31

Introduction

In the specialized literature are found a series of strategy definitions, its first utilization appears to be from 1947 [7] (Neumann & Morgenstern, 1947), when the fast changes from business with the increasing of the instability and competition, determined one hand the dynamism of the companies and on the other hand the evolution of the economy to the new concepts and instruments which outlines the new reality.

Price Strategies

It was considered a long time that the development of some protection strategies of the markets represents the most efficient way

for the protection of the profits obtained by the firm. For a such strategy the essential element is the price or the access barrier in that field.

When the entrance barriers are carefully formed by the competitors from the field with the purpose to limit the others to enter, we talk about the defensive strategies.

These represent the communication to the attacker about the existence of a report between him and the competitors that exist in the field, they group together in defense or the fight takes place by one or by a restricted group of competitors [1] (Dimitriu, 2009).

So the realization of an informational asymmetry [4] (Harrington, 1987) between the attacker and the possible victims from the field constitute an efficient strategy of market protection without using the real forces of the competitors.

1. safeguarding strategy is the lost chance for the defending firm, because it does not have a capacity to form its protection barriers of the market, and the attacker understands this incapacity, resulting that the defending firm is in a situation very vulnerable. In this situation the defending firm has two strategic instruments: partition of the legal rights of the organization between more shareholders and undervaluing the assets. In this way the attacker can be convinced to give up the attack, the victim is not anymore interesting strategically even if is easy to obtain.

2. In the situation in which the perception of the aggressor firm over the defending capacity of the target-firm is weak , but the capacity is important, we talk about the tactic advantage of the defending firm. The defending firm can use its defending power by access interdiction in the field or by reprisal (escalade of prices).

3. persuasion is the defending arm used by the firms with a weak capacity for defending, but the attacker see it as powerful. So, even if the defending power is limited, by creating an impression of lack of interest of the offensive tactic, the attacked firm can reinforce the force perception from the attacker’s mind.

The firms which confronted in a field obtain a reputation depending on their repetitive behavior. By maintaining a reputation of response to the competitors attacks , the firm makes an intimidation of the competitors .

The second way of maintaining a position of the firm in the field, as well as attack or competitive attack, is the applicability of prices strategy.

The price is the element on which the strategy of the market protection focuses and can be [3] (Glais, 1992):

- a threshold price fixed by the firm with higher position in the field
- a ruinous price that a firm adopt hoping to ruin its competitors
- a discriminating price for increasing the profits and the economic power.

The strategy of threshold price and capacity exceedance

This price strategy can be adopted in the fields where are important investments in fixed funds because these generate higher fixed costs and the investment bet is important , none form the investors do not want to lose something from the owned part on the market. This is the case of the ironworks industry, oil-chemistry and electric industry.

To adopt a such strategy, defending strategy, can be transformed from a defending one in an advantage for the competitors because this strategy can be considered less credible for a long term and the firm which will adopt it will lose as a result of the maintaining the prices at a limit-level (being afraid by the competitors) which diminish the profit for a long term and may disappear (because will not have sufficient resources for the next development).

The strategy of ruinous prices

Endorsing an aggressive behavior towards competitors and declaring war to prices assume the existence of the following premises:

- to settle an inequitable level of the price; this strategy is supported by intense advertisements or by market’s saturation with new fake products.

- lack of a direct profit which is temporary and it can be compensated for long term profit, higher and safer.

The strategy of ruinous price is different from the one of threshold price, because the latter remains settled at a level which is superior or equal with the cost of production, while the ruinous price is settled so that the competitors go bankrupt and discourage the possible competitors, sliding here and there in its *dumping* extreme aspect, punishable by law [5] (Heil &.Helsen, 2001).

This can be realized with the help of additional investment necessary to obtain fixed assets (to increase the production capacity above the necessary optimum one).

The purpose of this investment is to support the aggressive company during the war of prices which will be unleashed when the company’s activity is being threatened by present **or** possible competitors, and in order for this additional goods quantity be engrossed by the market, it needs to be accompanied by a big price cut.

Therefore we can see that the aggressive company needs to do a big price cut if it wants to remove easily its competitors because this type of policy cannot be maintained on long term since it implies the allocation of important financial resources (for additional production capacity and for supporting the lack of profit during the war of price).

Consequently, the aggressive company has to be sure that its policy will not be counteracted and that will persist on the market for a long enough period of time in order to retrieve the loss.

An aggressive policy can also have disadvantages; thus we can suppose that the aggressive company will look for having the support of its traditional clients by attracting them with the lowest prices on the market,

which is actually the strategy's essence we are analyzing. However it is possible that these clients, knowing the ominous consequences that the creation of a tradesman's monopoly market can have, to refuse the cooperation, preferring to conclude a delivery agreement with the aggressed company at a higher price than the ruinous one, that is at the normal price corresponding to a medium competition in the field.

Another disadvantage is that such a strategy it is not meant to help the initiator to be more credible because if he manufactures for several markets then it is obvious that he will try to minimize the loss by increasing the prices on the other markets he dominates.

The strategy of discriminating prices

This strategy doesn't necessarily have negative connotations. There are cases when price discrimination makes the product easy to access for certain categories of customers because the price *can be higher for some customers and lower for others*.

In order for a company to be able to use the discrimination, it has to fulfill the following conditions:

- to determine the price on the market, that is the company to activate on a market where is either exclusive producer(distributor or provider) or it vies with one or more competitors with less economical power, so the examined company has a part of the market enough important to allow it to determine the price. We can conclude their favorable negotiation position towards any of their customers.

- to be able to identify those clients that are open to pay a discriminatory price, in other words the company must be able to segment the market with the help of variables such as age, income, hours of consumption, type of consumption etc.

We can give the example of the railway transport which offers lower prices to students, veterans etc. and higher prices for the other categories.

- to manage to control the sale of the product from the one who acquired it at the

lowest price and to the one who acquired it at the highest price.

Thus the company needs to be able to prevent the product's transfer between different categories of customers because otherwise the discriminating prices cannot be applied anymore.

This discrimination can be produced in several ways, such as:

1. thanks to so called *reservation price*
2. by means of *commercial rebate*
3. thanks to *secondary products*

The features of each one are the following:

1. the policy of the reservation price is the one through which the bidder forces the company which needs that product, to pay more so that it can be able to have all the utilities of the desired product. It is possible that even the monopolist desires to determine different prices for each union of products or an initial fixed amount (a kind of permission to enter or subscription), followed by a fluctuating amount depending on the desired quantity of the product or of the desired service. It is the case of mobile company services. You pay a subscription and they give you free minutes, but they also tax in addition whatever goes beyond the subscription.

2. the policy of commercial rebate, when the price is determined depending on the quantity of that product that is being sold, that is each customer is being proposed the same catalogue price but he will be offered a discount depending on the quantity they bought.

3. the policy of using secondary products, when the bidder offers a principal product to the client, but conditions its acquisition on buying another product (secondary). It is the case of those companies that produce cars and also offer their clients the spare parts needed.

Strategies of differentiation

As to the strategy of differentiation, the company determines its competitive advantage according to the *specificity* of its offer, on condition that it should be recognized as such and valorized therefore by the market to which it consigns. This type of strategy limits the

direct competition concerning prices, and costs, promoting the differences that make the company's offer to be hardly compared with the one of its competitors [7] (Radu, 2006).

By choosing to apply the strategy of differentiation, the company seeks to make its offer singular which would allow it to create a lasting advantage in comparison with the direct customers on the market.

For this to happen, we must take into account the features' ensemble that define the offer's nature. It can be outlined the company's offer in a multidimensional way, that is like a sort of resultant of different features' ensemble such as: quality, price, image, localization.

In most of the activity fields, we can notice the existence, through the possible combinations of these features (dimensions), of a base level, which in specialized literature is called reference offer.

This is defined as being that offer's level which most of the customers expect to find on a certain market, for a certain product and at a certain moment. If all market companies want their offer to be placed above the implicit market expectation, they must be able to demand and determine a price superior to the medium one for a certain product.

The ways one can differentiate a product are many, and they mostly depend on the nature of the activity field, starting with the product's features (as mentioned above) and ending with the distribution network or the product's image created by marketing policies [2] (Dimitriu, 2012).

From the company's point of view, the search of the product's originality that they manufacture, shouldn't stimulate high prices which are obtained when selling the differentiated product; if the relation between these two elements is inverted, then the applied strategy is not efficient anymore.

We can talk about differentiation as a strategy only when it was perceived by the market company as such and if its application changes, in a negative or positive way the market's value assigned to the company's offer in comparison with the value assigned to the reference offer, from where it also appears the difference of selling price.

Strategy of differentiation- typology

As the possibilities to modify one or more features of a company's offer are many, it is difficult to classify the strategies of differentiation, but we can determine two coordinates which define them:

- on one hand, the evolution's sense of the '*couple value perceived by market/price*' in comparison with the reference offer *and*

- on the other hand, the existence of a pre-segmentation or post-segmentation on the market where the differentiate offer penetrates. At their crossing point, there are four types of strategy:

Improvement strategies correspond to a perceptible differentiation, valorized by most of the market's receiving factors; consequently, at equal prices, the 'improvement' strategy would definitely be preferred by the customer's reference offer, and sometimes itself becomes the new market reference.

I. Specialization strategies, which we will talk about in the next chapter, encourage the creation of a differential offer addressed *only* to a certain customers' segment previously identified and which is the only one able to value the singular and special feature of it. The 'specialized' offer is conceived so that it can satisfy a certain need of a considered market segment, a bad or not at all satisfied need of the reference offer and only that market segment can manifest.

II. Combing out strategies are those whose product differentiates by degradation from the reference offer (after a certain number of criteria), being offered in exchange at an inferior price to it.

III. Limitation strategies, like the specialization ones correspond to a pre-segmentation of the market, in respect of determination of a customers' segment who perceives a part of the reference offer's features as being in addition to its expectations. In this way, by removing those features, thinking of that segment the resultant offer is not less valuable, but increases because the selling price diminishes proportionally, hence the product's activity increases. Such strategy could be applied, for example in the white products segment by elimination

(concomitantly with price cut) of some features, such as design elements, which have to do less with the product's functions and more with its look, being incorporated in the fashion phenomenon.

The classification of differentiation strategies into four different categories, as shown above, doesn't automatically mean that this typology agrees with a totally tight strategic actions and this is why labeling the company's strategy is left at some point to the likes of the analyst and can be subject to interpretation, especially as the practical strategic thinking must be under the pressure of the economical reality, much more flexible than theoretical pattern

Strategy of specialization

This strategy, often called, strategy of focus or concentration consists in specializing the company on a customer's segment, a type of product or geographical area, by occupying an unassailable position on that segment, either due to some advantageous costs or to the strong differential character of the offered products or to the coexistence of the two features.

This strategy is, most of the times the only path to follow for small and medium size company which activate on an oligopoly type of market, dominated and controlled by big companies. Thus, the company is looking for its outlet on a specific strategic niche which allows it to avoid any frontal competition with the sector's giants; by focusing on this niche, the company has great chances to be protected from the aggression of the more powerful competitors because these are not interested in a such small market portion, where they cannot render their trump valuable (volume effect, cost advantage).

Conclusions

In order to succeed in implementing a specialization strategy, the company has to segment the market in a creative and original way and in addition, to take care that the chosen niche does not engross too much the other powerful competitors attention.

Possibilities of Customer's Loyalty in Tourism Industry

Ioniță Roxana-Mihaela

Universitatea Creștină „Dimitrie Cantemir” București

ionita_roxana2000@yahoo.com

Abstract

Increasing the quality of tourism services must be established as a priority for owners and resorts under management increased competition Powerful tourism market of our country. Competition has become increasingly close in recent years, so providing an optimum quality-price may contribute to attracting an increasing number of tourists and the retention of existing..

Keywords: quality, tourism, services, loyalty, customer

Jel Classification : L83

1. Introduction

Tourist services are dominant and crucial component of tourism, the flexible combination of assets that are characterized by dynamism, mobility and ability to adapt to the growing demands of tourists. They can materialize as held for sale commercial act, which requires the existence of effective travel packages and client's decision to accept the offer of tourism products in the market.

Through their specifics, tourist services to create optimum conditions for restoring the body's natural ability, while instructional spending free time. Consumption services helps ensure active leisure tourists in order to mitigate the negative effects of pollution and stress in large urban areas.

2. Customer loyalty

In tourism, quality of service results in attracting new tourists and losing as few among existing ones. Quality is the main element that creates loyal customers, satisfied customers that chose that unit after experiencing its services, customers will use

in the future to service the unit and they will recommend to others.

As in all fields of tertiary tourism and quality of provision is a competitive, quality is what differentiates a unit other travel service. A tourist service quality is a profitable strategy because it ensures greater price stability in a close competition. If the tour is provided at a higher quality, profit will be overflowing, but this is not all. Tour quality service and satisfaction that is based on building a culture of quality in that unit. Working in an organization that permanently increase knowledge and qualification, employees have a sense of accomplishment, they are interested to use the best qualities because they know they will be rewarded for the work performed.[3]

Thus, we can say that tourism services are an extremely large area, which is often difficult global approach to issues of quality of the services. Quality in accommodation services, for example, involves both receiving quality equipment and quality bedding, furniture, that of plants and ultimately not on the staff. A series of activities such as guides, animators or monitors, promotion or advertising is even more difficult to measure or compare in terms of quality.

Service quality evaluation methods can be common with those of the products, such as cause-effect analysis, also called Ishikawa diagram or Pareto analysis, but may be specific methods. Such product quality assessment is based on a system of product quality indicators that measure the characteristics of each part, the groups of features, and the product that their synthesis. An important role in this system occupies quality synthetic indicator which is quantitative expression characteristics, established according to the conditions of creation, use or consumption.[3]

In assessing service quality, service companies using five complementary

methods, namely critical incident method, complaints management, mystery shopper, list of comments; satisfaction survey.

Another aspect that should be noted about the quality of services is related to factors that directly or indirectly affect their quality, as follows:

- Correctness, or ability to provide an accurate and attentive service to;
- Responsiveness, provider or desire to help the consumer and to provide prompt service;
- Safety, or ability of customers to inspire confidence in the quality of services
- Individualization (personalization), that concerns and efforts to treat each customer due in part;
- Tangible elements, namely the existence of material facilities, equipment, personnel and materials appropriate advertising service.

In recent years, the quality of services between undertakings providing tourism services increased a lot. Tourism market in Romania has clearly developed, which led to increased consumer demands and their selectivity in the choice of services. In this respect, providing businesses become more concerned to maintain customer loyalty through its long-term, focusing their efforts to the fullest satisfaction of customer expectations and requirements through continuous identification and analysis expressed wishes and requirements customers, turning them into ideas for products / services for the development and perpetuation of lasting relations with customers economically advantageous. When the client believes the travel company's ability to provide services of high quality, turn into repeat purchase, customer loyalty occurs. A loyal customer is a stable source of long term income for the company as it recommends providing the firm and other potential customers. However, consumer loyalty is not maintained by itself, it is considered as long as the consumer receives additional value embodied in the value for money compared to another company that offers same services.

Achieving customer loyalty is extremely complex and requires the tourism enterprise and involves the following steps: [7]

- developing a customer loyalty strategy, namely determining how loyalty (for

example customized service offerings, additional services, direct mail, customer clubs, telephone marketing, online orders etc.).

- building a database of customers, to be updated on a continuous basis from which to extract customer data to be used as a measure of loyalty;
- conducting analyzes on customer satisfaction, which involves conducting surveys, especially, customer satisfaction, repeat purchase intentions, referral to other services offer potential customers;
- establish performance standards refers to setting quality standards for customer satisfaction and periodic thereof;
- analyze customer buying behavior envisages determination and interpretation of indicators related to actual and observable behavior, such as rate of return for purchasing, service consumption intensity, the number migrating to other providers of services.

Customer loyalty has positive effects on cost reduction company providing travel services so there is this line:

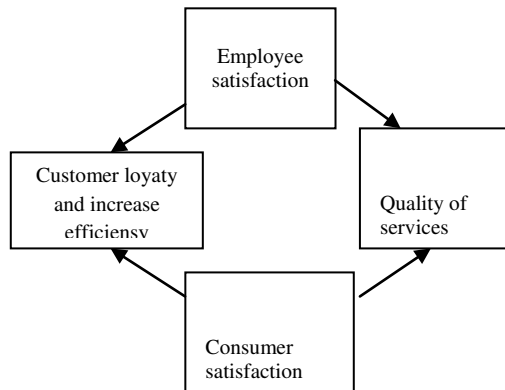

- reduce the cost of running relationships with customers by focusing actions mainly on loyal; customers;
- reduce costs "non-quality" customer involvement in improving services;
- possibility of reducing transaction costs through new communication solutions (for example by making electronic controls services, the Internet etc.).

A systematic management of consumer loyalty is also a positive influence on the amount of benefits achieved and therefore the turnover. Thus, the loyal customers of hotel companies have a certain predisposition to accept higher prices than other customers, creating opportunity for that company practice of higher prices. Also, where loyal customers can see a higher frequency of purchases of services, resulting in positive effects on the amount of benefits made by hoteliers.

A very important condition for achieving consumer satisfaction and their loyalty is the company's employee satisfaction holidays. Provider staff is responsible for providing high quality services and providing customer satisfaction. Thus, it is clear that attitudes and behavior may increase or diminish the

reputation of a hotel service organizations. [6]

Figura 1. The relationship between customer satisfaction and employee satisfaction services company

Source: Zeithaml, Valarie A., Bitner, Mary Jo , op. cit., p.306 .

Effective management objective provider staff - namely the process of performance - can be achieved by practicing successful internal marketing, which aims to develop motivation and stimulation provider personnel in an effort to provide high quality services.[2] By adopting the fundamental company internal marketing strategy aims to form loyal customers of their own employees. Satisfying the requirements of internal customers, the company increases its ability to service successfully meet the needs of external customers.

Relational marketing will not provide the hoped effectiveness hotel but if the quality of the hotel benefits will not satisfy consumer preferences and demands of customers, namely their consistency if the services do not meet consumer expectations.

Service quality can be assessed by the hospitality tourism service providers. Professional hospitality is defined as the process of ensuring psychological and physiological comfort and safety of the client, while consumer requested products inside the units, in exchange for money the customer is willing to cede provider of products and services as consideration received. [5]

Because no tourism service company can not survive long if they lose some of the clients, it is important to recognize the value

assigned to each consumer. Specifically for hotel, restaurant or other hospitality companies involved in operations, business success depends in large measure Guest loyalty than satisfied with the quality service every time attracting new categories of consumers, requiring sustained efforts promotion.

Consumer value can be interpreted in two ways: [4]

- the "present value of the customer" and through the sales of services provided guest who visited the first hotel unit (or restaurant or complex);
- by, the future value of that consumer, namely in terms of potential revenue opportunities that can be obtained in a future period.

Indifferent that is, the status of the social guest of a hotel, the criterion for assessing the expected benefit to the client is based on evaluating quality / price ratio (Value for Money) and the assessment of the value attributed to the quality of tourism services, compared with value assigned amounts of money spent to purchase travel services respectively.

Of course, client assessments may vary from one situation to another consumer, even during the same stay, and as such, the quality / price may take different values, the positive feedback to negative feedback. This once again argue the importance accorded to the hotel management business consistent quality standards compliance—without compromising advanced promises customers.

If waiting is rewarded satisfaction of product functionality hotel purchased by the customer, quality creates a stimulating effect, which enhances future consumer behavior, translated in intention if not the customer's desire to come back to the same resort. Instead, if the company is not concerned with maintaining hotel standards of service and will endeavor not to eliminate situations generating discontent will likely bear the cost of accumulated dissatisfaction among consumers unit.

3. Conclusions

In conclusion, the quality is relative, as a matter of balance, meaning that it requires a multi-layered approach and assessment is

quite difficult and quantified. Offering the best quality-price customers and employee satisfaction leads to customer loyalty that has positive effects on cost reduction company providing travel services.

Economic Affairs Rm. Vâlcea*

iordache72@yahoo.com

Abstract

With the increasing demands of consumers and their selectivity for choosing the services, hotel organizations are becoming more and more concerned about maintaining the customer's loyalty through its term. In this respect, the organizations are dropping their efforts on meeting comprehensive expectations and requirements of customers, by identifying and analyzing continuous desires and requirements expressed by the customers, turning them into ideas for products / services for the development and perpetuation of sustainable relationships, economically advantageous for customers.

Once the customer is convinced about the company's ability of providing high quality services, and it turns into repeated purchase, there it will be the customer loyalty. A loyal customer is a stable source of long term income for the organization because this recommends it to other potential customers. However, consumer loyalty is not maintained by itself, it exists as long as consumers believe that getting additional value embodied in quality/price ratio, comparing to another organization offering similar services.

Keywords: hotel organizations, customer satisfaction, loyalty.

Clasificare J.E.L.: L83, M31

1. Introduction

The interactive nature of hospitality services materializes in the evaluation of the quality the customer makes immediately after its done. A strong influence on the level of satisfaction or dissatisfaction is generated by the memory of previous experiences arising from the provision of similar services. This fact can lead to changes in consumer's attitude towards future performance. This

increase in the level of (in)satisfaction can not be easily identified or controlled by the provider, as long as it is unique and personal to each user at a certain time. This fact places the consumer in a very strong position as long as he can create, sustain or destroy the reputation of the hotel through comments to other potential consumers or through media.

A systematic management of consumer loyalty is also a positive influence for the amount of benefits achieved and hence the turnover. Thus, clients attached to the hotel company have a certain predisposition to accept higher prices than other customers, creating opportunity to practice higher prices for that company. Also, for the loyal customers, one can notice a higher frequency of purchasing services, resulting in positive effects on the amount of benefits made by hotels.

Should be noted that a very important condition for achieving consumer's satisfaction and their loyalty is the organization's employee satisfaction. Provider's staff is responsible for providing high quality services consumer's satisfaction. Thus, it is clear that employee's attitudes and behavior can increase or diminish the reputation of a company providing hotel services.

Hotel companies are therefore interested to seek all possible ways to attract more clients in their units, to preserve and respectively to become permanent.

For maintaining and sustaining the loyal customer, according to analyst Philip Kotler, the best weapon is applying the concept of relational marketing, which involves creating, maintaining and strengthening relationships with customers and other business partners, especially with tour operator travel agencies and distributors of hotel services.

Relational marketing will not provide the efficiency expected by the hotel if the quality of hotel services will not satisfy consumer

preferences and demands of customers, if, through their consistency, the services do not meet consumer's expectations.

Any hotel organization has the same opportunities to perform and distribute quality services, regardless of their category. Each operates on a specific market segment characterized by certain consumer motivations of potential customers. Therefore, each providing unit has an equal chance to meet, to overcome or not to cover expectations of their own customers.

For hotel organization, business success depends to a greater degree of loyalty of satisfied guests than each time attracting new categories of consumers requiring sustained promotional efforts.

Consumer's value can be translated in two ways:

- through the "present value of the client" and through the sales of services provided to the guest who visited for the first time a hotel unit (or the restaurant complex respectively);
- through the "future value of the same client", and that is in terms of opportunities of the potential receivables that could be achieved in a future period.

Identifying expectations, meeting constantly or exceeding these expectations, but by doing such a way that the price to be acceptable to customers and to guarantee an acceptable profit for the organization represents the guarantee of success in hospitality. Therefore, if it will not be able to receive a sufficient number of customers, any hotel organization is likely to fall the business volume below the waterline and, therefore, likely to become bankrupt. In other words, if a customer has left a hotel unit with impressions of satisfaction, he becomes a potential spokesman of future undertaking receivables.

2. Customer's loyalty versus satisfaction

The degree of satisfaction and perceived value resulting from customer experience reflects concept of quality [13]. This statement is supported by various studies whose results reflect the fact that the price and quality perceptions influence the overall customer perception. Also the quality directly affects the purchasing behavior, reflecting in the same time the intentions of customers for making new purchases in the future. The degree of satisfaction depends directly on quality.

Therefore, the satisfaction is determined directly by the level of quality [13]. Specialized studies emphasize the importance of service quality at the expense of price, especially for hospitality organizations and especially the hotels. It is very important to properly promote a concept of hospitality, in order to increase customer loyalty [10]. There is a big difference between satisfaction and quality, this difference must be clearly defined to achieve the objectives.

Quality in hospitality measures the level of the provider's performance, while satisfaction measures the guest's satisfaction from the experience taken [13]. Quality is not included in the values observed, however, it is an important factor and can be regarded as a prediction device for perceived value. However the forms of satisfaction, value and quality are unique, with strong relationships between them. The case studies showed that monitoring the quality concept leads to showing the level of satisfaction and perceived value. Generally customers will be satisfied with products and services whose quality level is very high. Most of the studies on the relationship between value and satisfaction didn't have convincing results, so it is important for hotel organizations to understand how customers perceive and recognize the concept of quality.

As noted by Dube and Renaghan [8], "managing customer value by providing quality services is considered a critical component of corporate marketing strategies. Value is what builds customer loyalty. The orientation towards customer retention, the continuous contact with customers and the commitment to raise customer's expectations are the new strategic rules of the management of the customer relationships that are based on other factors than economic evaluation and product attributes [2].

Consumers have become more willing than ever to transfer their loyalty to those suppliers perceived as offering quality. Customer satisfaction and loyalty, provided by a high quality of products and services that offer value for money, are essential for long-term survival, let alone the long-term success [19].

Satisfaction and loyalty should be analyzed because in most cases, even satisfied customers tend to deviate. According to a research on customer satisfaction [13] it was found that satisfaction provides less than 25%

repeated purchase. Reichhel [14], states that the 65-85% of the customers of a services providing company are actually leaving as satisfied or very satisfied customers. He concludes that there are other factors, excluding the power of satisfaction, that affects the loyalty.

Loyalty involves usually satisfaction, but satisfaction is not loyalty. In a hotel, a guest can be satisfied by his stay, as purchased services amounted to his expectations, but this does not mean that he will repeat the experience or recommend it to his friends and relatives [2] - [22]. Apart from travelers in transit who do not return, generally in the area where the property is located, some people choose different hotels depending on the purpose of travel (for example, they travel for business or with their family), others are seeking for novelty and are willing to try different properties in the same area, others are more sober about the price and are looking for the best deal. Finally, some visitors can not develop loyalty simply because they are not encouraged to return.

While maintaining satisfied customers is important, loyal customers bring more satisfaction than the satisfied ones. They generally show lower sensitivity about the price over the time, they tend to resist in front of the change of the service providers, they identify themselves with the brand and they maintain a strong preference for the service purchased against the competitors [3]. This allows the hotel to reduce the marketing costs and significantly increase occupancy and profitability. According to research conducted in a hotel chain, a 5% increase in customer retention can lead to a 25-125% increase of profits [15].

In order to stimulate loyalty, hotel managers must have a clear understanding of the value represented by the customers and to be aware of how their business contributes or fails to contribute to create such a value [7]. These guidelines may be different, depending on the purpose of travel (for example, leisure vs. business), the type of group travel (single tourist vs. family), culture (for example, a Japanese vs. an European guest), socio-demographic characteristics, income, etc.

3. Customer database - basic component of the loyalty policy

Getting accurate information about the client is crucial to define the attributes of a hotel, to promote innovative services and constantly adapted to customer needs and to develop customer-oriented marketing strategy, the ultimate goal being to acquire and retain valuable customers. Each interaction with the customer can increase or decrease the value of the relationship, but the impact of future contacts can be easily predicted based on the information and the behavior of hotel employees earned over the time. For example, improving interpersonal aspects and services (for example, personalization, personal recognition, fastness, efficient check-in and check-out, etc.) is among the first attributes that make the greatest contribution of the value which is represented by clients in two key phases : at the point of purchase and during guest's stay [7].

Customers provide to the hotel staff general information on the requirements and preferences since the buying decision until their arrival and during their stay also. At their turn, hotel managers and staff provides information on the services provided and communicate their requests to various departments / functions within the hotel (for example, room service, food and beverage, etc.).

Better to centralize information, there must be made a distinction between customers of a hotel [17]:

- **Buyers:** Those who buy services from a hotel for their activities, but may not use them directly. Here there is a buying decision directly, but indirectly a hospitality experience and evaluation. Buyers are generally intermediate distributors (travel agencies, tour operators, professional congress organizers, the organizers of meetings, etc..) and the organizations who book rooms for managers and their staff traveling on business.

- **Guests:** those who use the services of a hotel, but have not bought directly (for example, tourists who purchase packages). In the latter case, the experience is direct, but product selection can be made by other people.

- **Individual customers** - independent tourists, transit travelers or business travelers that are customers and guests at the same time.

This distinction is important in order to maximize hotel capacity to store data, since buyers are the only source of information about their customers until the check-in. Passing data regarding allocation agreements, tariffs and economic outcomes with hotel customer database helps managers to identify the most profitable market segments. In addition, given that tourism agencies and companies often generate most of its turnover in a hotel, the information collected from their customers, segmented by reservation channels, allows the hotel organization to plan specific actions of promotion for buyers.

The main profile of the customer must contain three important parts:

1. Personal information, such as those related to name, gender, contact details, nationality, language, if the person has special physical needs, business office address (if tourist on business), means of payment, etc.. These include primary data (for example date of birth) and secondary (for example allergies, special diet).

2. Information on all aspects of the period of stay in hotel such as those accompanying person, reservation type (eg individual, group, etc.), room type (eg double, matrimonial etc.), length of stay, type of room requested services, food services and beverage and other hotel facilities, etc.. This information includes compulsory data, and also kindly and behavioral data.

3. Complaints and guest opinions on quality standards of hotel services and hotel staff performance that can be collected during the stay or even before departure (customer satisfaction) through online forms or questionnaires that are printed on an interactive TV.

All information collected may be stored and processed in the hotel database, to identify each client registered and recognized online based on details of the prior visit [18].

To be successful, hotels need to take first a customer-centered cultural mentality, which implies a shift in cultural norms, organizational structures, and how employee performance is measured and rewarded. Second, they must develop a cross-functional integration between different functions and information systems (booking, marketing, sales, administration, etc.) to accelerate the process and to facilitate the exchange of information for customers. Finally, they

should have a strategic investment in IT, properly managed and to adopt a broad approach to the hotel on the use and integration of IT systems [20].

Convergence of IT, telecommunications, media and use of data stored or data searching facilitates techniques hotel organizations and customer relationship management and supports the collection and consolidation of data from each point of interaction - before customers arrive at the hotel and during stay [6] - [12]. Call center, e-mail, Web site, central reservation system (CRS), point of sale (POS), and so on, are just a few examples of these applications. Through specific electronic devices (eg pay-per-view system, interactive TV, etc.), hotels can also store huge amounts of information about customer satisfaction at the end of their stay, even before check-out procedure, that are useful whenever the customer returns to the same hotel or another hotel of the same chain and, in general, to help plan marketing actions (frequency of residence programs, special discounts, etc.) for different key market segments.

IT creates valuable knowledge spread, promotes a high level of connectivity between the hotel and clients in hotel departments, eliminates inefficiencies and increases the number of distribution channels available. However, while hotel managers claim to address a customer-oriented strategic focus, their technological initiatives does not support this action [13]. Poor IT system and inability to communicate a shared vision and coherent hospitality technology to the providers are the main causes of it.

However, hotels and restaurants of international chains with computerized information systems have special programs designed to identify consumer's repeated visits to their units, recording behavioral events in a nominal sheet "Customer Profile." Information extracted from file "Customer Profile" allows the provider to come more prepared to meet the applicant's services and to anticipate customer's needs, who repeat the visits as consumers, in this way increasing guest's confidence toward quality services.

By anticipating consumer preferences and habits of nominated customers, providers follow the challenge of an "active psychological shock" that enhances the benefits of professional hospitality reception, just before rendering the services. Therefore,

nominal sheet "Customer Profile" can be considered as a useful operational tool for assessing potential consumer valence, reducing the prospect of losing future business. The potential valence of the consumer demonstrates that when a guest leaves a unit providing feelings of dissatisfaction, he takes with him a considerable body of lost opportunities for future business.

4. Conclusions

The hotel industry is enjoying high profits when led with more intelligence by creative, original managers, direct to consumer and customer needs that have to do with it.

Customer loyalty is one of the major challenges for hotels and other tourism service providers. To achieve this objective one may use tools such as personalized service, discounts for loyalty programs and loyalty cards available in partner networks. But simple repetitive behavior of customers is not enough for them to be considered loyal to the company, repeated purchases are required to be accompanied by a favorable attitude towards the company. Therefore, an adequate conceptualization of the term in question must consider customer loyalty as a complex construction, incorporating both psychological component (attitude) and behavior.

Customer loyalty is a new marketing trend that hotel organizations must follow in order to ensure long-term success. A loyal customer is a very valuable form of capital for the development of an organization. Customer retention and loyalty have many advantages which, on the long term, ensure the company's success: the least expensive method of promotion, the least risky, most consistent with consumer behavior and last but not least, this marketing strategy puts to work personal communicational energy of dozens of people who speak for the organization and provide other clients.

The Role of Maritime University in Specialized Training in Maritime and Port Marketing

Iordanoaia Florin
Maritime University, Constanta, Romania
floriniordanoaia@yahoo.com

Abstract

Important implications because of the competitive conditions and the international business environment, has become a necessity, as the companies in the field of navigation, and port operators, maritime insurance and banking companies to establish specialized departments or increased divisions in maritime or port marketing. Need to train specialized personnel is subject to the problems that arise in maritime market, like the fluctuations and crises, the decrease or increase the amount of freight transported. But there is a question about which institutions can prepare specialized personnel in this field. In Constanta Maritime University has started and runs this preparation for several years. The paper is an analysis of the need for staff training and the state of the Maritime University.

Key words: university, shipping, marketing, manager, training.

JEL Classifications: I 21, M 31, O 15.

1. Introduction

Specialized training in Maritime and Port Marketing must take into account the following aspects, [1]:

A). Appropriate personnel selection:

-Higher education graduates by Marina, economic or transport.

-Intelligent, with outstanding invention or innovation, always adaptable to market conditions, available to travel within the country or abroad.

-Proper motivation to achieve high efficiency, high efficient work.

B). Continue training at work, [2]. Particular attention should be given by the business leaders for ongoing collaboration with them.

C). Providing outstanding technical infrastructure so, [3]:

-With modern communication facilities such as telephone, fax, internet.

-Operating advanced equipment and data recorders.

-Subscriptions to various publications, economic, legal and specialized in country and abroad.

-Unlimited access issues management, orientation, optics and overall vision of the company.

D). Ensuring participation in symposia, conferences, meetings of owners, producers, [4].

Maritime or Port Marketing specialist role is determined by the following aspects:

-Influencing management decisions of the shipping company or the port operator in the following ways.

-Transportation contracts or services, [5].

-Price services (of freight).

-Promote the company services.

-Connections with partners.

-Creating and maintaining relationships with public authorities, port agents, banks, manufacturers, [6].

-Design variants of action, [7]: immediate, medium-term, long-term.

-Knowledge permanently: external-political factor, economic environment,

-Structure, strengths and weaknesses of competitors,

-Maritime market trends, anticipate them, [8].

Some firms, multinational companies and large port operators have reached the stage of establishment of the office of director (manager) for the marketing department. This is having a major role in management. Need to establish such a function is given by the fact that he and his department are designed to model the decisions controllable marketing variables, [9]. These are in relations to maritime market variables that can not be

controlled. Structure of a marketing department, maritime and port can be organized as shown in Figure 1.

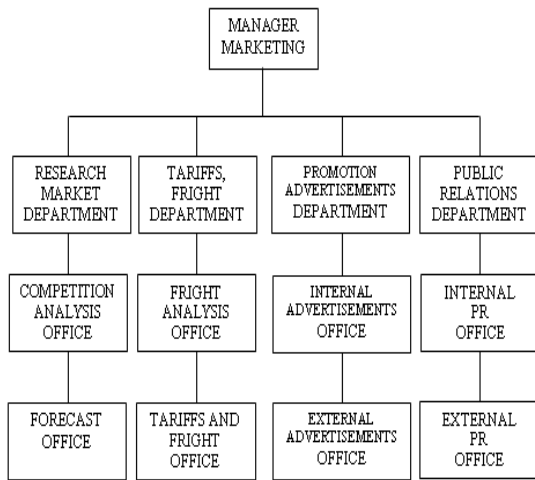

Figure 1. Structure of the Marketing Department.

Source: author, original.

Marketing department is divided into the following sections:

- Maritime market research office.
- Analysis and calculation-part tariffs or comparable rate office.
- Promotion and advertisements office.
- Public relations office.

This scheme can be simplified or expanded depending on business needs, the activities it carries out, the number of ships, etc. Some of the activities may be integrated with other offices or departments, and in other situations when the number of persons is reduced a person may fulfill multiple tasks, [10]. Simplified structure of marketing department is shown in Figure 2, and can have two models.

2.Tasks related to marketing specialists

Staff of the shipping company or port operator working in the field of marketing and they must know their duties very well, but the company's general policy, maritime market developments, to be attentive to all the problems in the field for to learn from everything that occurs at a time to find optimal solutions to concrete problems. Marketing specialist, called “marketer”, [10], may perform work in a function so, [1]:

MODEL 1

MODEL 2

Figure 2. Simplified structure.

Source: author, original.

- Director of marketing.
- Chief of maritime market research office.
- Chief of analysis and calculation of transport costs office.
- Chief of promotion and advertising office.
- PR chief office.

1). Director of Marketing shall:

-Manages department according to the strategy, tactics and the company's general policy, plans and programs based on annual, quarterly or monthly fixed.

-Shall keep the company management about [11]: maritime market situation and its trends; the political situation in the area of navigation; competition situation; emerging opportunities, etc.

-Sets out proposals to assist in decision making by company management navigation in the following ways:

- transportation contracts,
- price services (of freight),
- promote the company services,
- connections with partners,
- creating and maintaining relations with public port agencies, banks, and manufacturers.

-Adopt the most effective measures for the job, getting the best results in all the activities they carry out marketing department.

2). Chief of maritime market research. It is responsible for the following aspects:

-Creation, selection and validation tools for collecting and processing data.

-Writing and testing of survey questionnaires.

-The choice of recording equipment and playback of images.

-Choosing appropriate software study.

-Sizing and training samples used for investigation.

-Composition experimental groups.

-Maritime market research, recording and managing information and data.

3). Chief of analysis and calculation of tariffs or comparable rate has a number of tasks and obligations upon which the success or failure of marketing. Among these are the following:

-Customer-company identification or port operator.

-Obtaining information about their performance.

-Identification of service providers for the company and ships.

-Comparative analysis of quality of services provided by competitors.

-Analysis of tariffs (prices) for services offered by competitors.

-Analysis of port performance through indicators such as: berth occupancy, traffic each berth in hand, residence time in the port.

-Analysis of freight traffic daily, weekly, monthly, quarterly and yearly.

-Analyzing the changes of an economic, commercial, technical and policy in the country and abroad.

-Analysis of global economic trends.

-Analysis of the foreign ports and make comparisons with the port of Constanta.

-Calculating transport tariffs, tariffs for port services and pricing alternatives, with margins and bargaining limits that can be used in negotiating shipping contracts or those of port services.

-Participate in the preparation and drafting of the questionnaire survey or marketing.

Staff of the two departments needs to work together as a team to get the correct data and to analyze, synthesize and process so that the results be used for the intended purpose, to increase the efficiency of the company.

4). Chief of promotion and advertising is primarily responsible for:

-System communication that are put into circulation information, ideas and attitudes of

the company to potential clients, customers, partners and suppliers.

-Planning, promotion, publicity or advertising.

-Calculating costs of the promotion, advertising or advertisements.

-Choosing the most effective means of promotion or advertising.

-Following-up effects used by promotions or advertising company.

-Correction of form, content or changing the mode of transmission.

-Quality promotional, messages, information and data.

5). Chief of Public Relations shall:

-Maintaining the best relations with all audiences inside or outside the company.

-Investigation and analysis of permanent-attitudes, opinions and behavior of the public to be able to provide it with information, data and images may encourage attitudes and behaviors favorable to the company.

-Build, protects and preserves public image of the company.

-Public relations is a form of communication complex organization that involves strategic compromises and controlled by the company, between respecting the need for transparency in communication, discretion and confidentiality shares.

The main audiences are the following: shareholders or members; banks; media; state institutions; political organizations and civil; according to public (external audiences); employees (internal audience). It is known that a number of companies in maritime and port on proper marketing policies have achieved outstanding results, were able to increase the turnover of firms, grow venues from basic and auxiliary. With relatively low budgets for market research, promotion and advertising, results were well above initial projections.

3. The Maritime University role in training of specialized staff in maritime and port marketing

From 2001 to Constanta Maritime University introduced a master on maritime economics called „Maritime and Port Management”, the only of its kind in Romania, [12]. In this master introduced a course on „Naval and port Marketing”.

Initially this course was more intended to inform students on issues of marketing, master of the ship and port than to form marketing specialists who work as market-officers from shipping companies and port operators. Organization of the course was 28 hours per semester courses only read 2 hours each, without hours of seminar or lab and complete an examination. The first set of students enrolled in the Master in this specialization were graduates of the Faculty of Navigation, marine deck officers, who were more interested in management positions at corporate headquarters or navigation related, such as the broker, crewing or chartering i.e. the functions of agent ship crewing operator or broker less than that represented by the marketing companies. Admission consists of determining the order of entry based on the average of the license exam at graduation. Syllabus of the course initially was simple, according to Table 1, aiming at informing graduate students of Navigation specialization, not tied to any economic studies. Upon completion of graduate studies able to choose and prepare dissertation on a topic of Maritime and port Marketing, but their knowledge was very limited and faces difficulties in completion of works. The author of this paper is the one who organized and supported this process from the beginning until now, [3].

After 2005, when the university education in Romania began restructuring under the “Bologna Process”, in Constanta Maritime University has started changing and adapting educational programs, redirecting it to the new demands of university education, but adapted to maritime market demands. On this Master following changes occurred:

-Master studies was introduced in profile “Naval Engineering and Navigation”, specialty “Engineering and management in maritime and port field” form of education for day and the course was called “Maritime and Port Marketing”. This master is accredited by the Romanian Agency for Quality Assurance in Higher Education.

-Number of hours of discipline “Maritime and Port Marketing” increased from 28 to 56 hours, by introducing laboratory hours.

-Completion of the course is made through written examination for the first note and prepares a draft class and its support for the second note.

-Objectives are changed from the previous information specialist to specialist training in this area.

-Was allowed admission to the Master of graduates of other colleges or universities from the country. In this way they came to this Master from graduates of economics, engineering and law. This allows graduates of other majors to work in this field.

-Admission was based on the exam, multiple choice of material taught in the “Commercial exploitation of marine vessel” specialized discipline studied in the third and fourth years at the Faculty of Navigation and Naval Transport, [12].

The current structure of the course is presented in Table 2. Besides syllabus amended, Maritime University has developed specialized laboratories that allow further education and information in this area, most notably virtual campus and laboratory informatics, e-learning, e-marketing and shipping.

TABLE 1. INITIAL COURSE SYLLABUS

OBJECTIVES	Seeks discipline for understanding the formation of theoretical marketing peculiarities of naval transport, the shipping companies, boats and port operators.
COURSE CONTENT	Fundamentals introductory in marketing marine transport. Maritime market. Shipping service. Price of transport and waterways. Promoting the marketing of marine transport. Relationships in maritime and waterways marketing. Peculiarities of the maritime and waterways marketing. Concepts introductory in port marketing. Port services. Tariffs, taxes port. Port investment decisions.
TIME	28 hours (14 courses).
COURSE COMPLETION	Exam.

Source: Constanta Maritime University (2001).

TABLE 2. ACTUAL COURSE SYLLABUS

OBJECTIVES	Seeks discipline for understanding the formation of theoretical marketing peculiarities of naval transport, the shipping companies, boats and port operators. In the discipline will address specific issues that relate to the maritime market, the demand for shipping, international transportation situation, naval ship and port marketing peculiarities. Students will be trained to work as specialists in marketing and naval port.
COURSE CONTENT	Concepts introductory in marketing marine transport. Sea and river market. International conjuncture of the naval transport. Service of the maritime and waterways. The price of transport and waterways. Promoting the marketing of marine transport. Planning, organizing and managing maritime and waterways marketing. Marketing relationships in the maritime and waterways. Peculiarities of the maritime and waterways marketing. Port Marketing. Port services. Port tariffs and taxes. Port investment decisions. Promotion and relationships in the port marketing.
CONTENT LABORATORIES	Marketing questionnaire. Marketing analysis model to service organization. Study design and analysis of marketing at a port operator. Proposals for the reorganization of marketing. Restructuring activity, organizing functional links, people attributions. Marketing objectives and strategies of the company. Database marketing. Access to the database, the database organization of society. Port marketing plan. Strategic marketing plan. Annual general marketing plan. The organization of service of marketing. Weekly activity plan. Plan promotional activities, communication and public relations. Marketing budget. Maritime market research. Models of marketing strategies. Advertise on maritime and port marketing. Errors in marketing. Marketing Specialist "marketer". Present and future marketing.
TIME	56 hours (14 courses, 14 laboratories).
COURSE COMPLETION	Exam. Project.

Source: Constanta Maritime University (2012).

Virtual campus students find all specialty courses, and links to sites enter shipping companies, firms or crewing port operators. Laboratory for e-learning and e-shipping help students from Master studies to learn, to make a commercial site, such as “online shop”, but also to create their own network business, maritime and port marketing.

An important aspect is the ongoing drafting of this discipline, students with the obligation to respect a number of criteria in order to carry out their projects. Students the criteria are:

1). Has been chosen a company operating in the field of maritime transport, inland water transport, port operation, logistics, agency, brokerage, consulting, marine insurance.

2). Contain the following information and basic data:

-Analysis of the company, the model presented in the seminar questionnaire.

-Analysis of Marketing at the company chosen.

-Presentation of conclusions about society and develop quality proposals to increase marketing activities.

-Preparation of annual marketing plan for the company.

-Developing a marketing budget.

-Preparation Plan “Public Relations”.

-Presentation of conclusions and proposals.

3). Draft must be at least 15 pages, format A-4.

4). Draft is submitted in paper form and shall be supported by a Power-Point presentation at the end of semester in the exams session.

Another important aspect is the Dissertation Thesis that student’s background and shows the final examination. Students can propose a topic to study and enter in the exam, but most students ask the teachers to propose topics for their study.

In recent years more and more students were taken issues in the maritime and port marketing. Topics considered were related to:

-Marketing-analysis in maritime shipping companies, the port companies or shipping related activities.

-Promotion freight shipping service, passengers, luxury cruise tourism and others.

This proves that marketing interest in this area is increased. It is realized that the role of

marketing is especially important in situations of economic crisis, when it is less and ship goods more waiting, which makes maritime market is dominated by brokers or charterers (cargo owners).

Thus the role of marketing specialist maritime, like maritime shipping company employee, becomes more important during economic downturns to find customers or cargo transport.

Conclusions

A shipping company which employs people, specializing in marketing, working in this area is considered to be one of “old” with management “classic” can not reach an important maritime market, hold significant precious market share. Large foreign maritime shipping companies have understood the role of marketing specialist and current situation shows that marketing specialist role is increasing in these companies. Thus it seeks solutions to find customers (brokers or charters) to direct advertising to them to specialize this advertisement depending on the specific vessels. But a real problem for shipping companies is that such highly qualified people are hard to find or are formed in a long period of time and with a high costs. Investment in staff training by Master studies is one of the solutions and is more efficient in several ways, including that the person attend classes, seminars and specialized laboratories of them dealing academics specializing in maritime and port domains. Even if a Master study takes more than time, however obtain results show that investment by staff in their preparation is justified for the company. In this context appears the significance of the Maritime University of Constanta, in training specialists in this field. Maritime University assumed this role in the current maritime market and further efforts are made to meet the training requirements of students at the highest quality settings.

Maritime Market Crisis is the Lack of Charterers

Iordanoaia Florin

Maritime University, Constanta, Romania

floriniordanoaia@yahoo.com

Abstract

The global crisis has different effects on the activities of companies. In different areas, the crisis is different, which means that it can be searched and found generally valid solution to address the negative effects of the crisis. Different forms of the crisis involves deep analysis of the causes of the crisis and based on these analyzes must seek solutions to overcome them. Shipping is directly affected by the financial crisis, the crisis of production and the sale. But these are general issues for a major shipping company which is in direct relationships with customers, relationships with brokers, those who are cargo transport. Analysis of corporate customers must be made separately by type of vessels, goods and services. This paper presents the general and particular aspects related to the maritime shipping companies' customers, some solutions for business problems

Key words: crisis, shipping, cargo, charterer.

JEL Classifications: F 44, L 91, M 31.

1. Introduction

Most international marketing professionals consider it particularly important the knowledge of the market and customers [1]. Basically customers are those who are the source of existing maritime and river shipping companies. But they are essentially a source of events, opportunities, threats and uncertainties [2]. Not owner does not enter in the maritime market without having at least one client or broker to help him for to find employment cargo ship [3]. Application of the "supply creates demand" principle [4], is particularly risky in maritime market because investments are very high, and with it the risks. It considers that the potential customers in a market as the sea

must be made based on the following aspects: identification of customers in foreign markets, knowledge and understanding of customers, analyze the relationship between company and customers [5].

A). During the first situation leads can be identified by maritime market segmentation.

B). To be able to know and understand these potential customers need to be researched on their behavior, policies that have them transport the requirements on transport ships, etc.

C). Analysis of customer relationships must be made in terms of the dynamics of these relationships, i.e. the changes that occur in the requirements to transport it self, the way of payment, etc.

Research and analyze potential customers can be oriented to such situations:

1). Maritime market segmentation by seeking answers to the following questions:

- What are the biggest companies that appeals to carriers in this market, area, route or line?
- What are the most profitable companies who are able to pay on time, according to contracts so as to avoid a situation of default?
- What are the risks for collaboration with these customers, these risks can be provided?
- How to share the market so the need for a single marketing strategy?

2). Knowledge of customer behavior by finding answers to the following questions:

- What is their general policy in shipping?
- What are the immediate objectives, medium term or long?
- What they expected from the services provided by shipping companies (port operators)?
- What kind of changes could occur in priorities and positions against shipping companies?

The answers to all the questions are strategic marketing objectives.

2. The charterers

Maritime transport literature deals charterers only in terms of the types of contracts used in hiring ships transport of the goods [6]. These contracts are very important and theoretically everything should take place under the terms of these contracts were standardized so much. But the reality is much tougher and situations experienced by owners and especially crews of ships require some reconsideration of collaboration with them. Ignorance of the customers is a serious error of Marketing and Management of the navigation company leaders'. Ignorance of the charterers, even in the "tramp" navigation where the goods reach at the ship through brokers, represent a great risk for the ship-owner. In this regard can mention many cases where maritime companies had big problems with the charterers who have not complied their contractual obligations. It is therefore essential knowledge, analysis of the situation and their position on the market, ability to pay, history, etc. I.e. not enter into business with anyone and anytime! But who are charterers? The answer of this question is give by the evolution of the world economy and national. Charterers classification can be performed as follows [7]:

A). Economic criteria:

- Producers of the raw materials and semi-finished products.
- Manufacturers of the finished products.
- Travel and tourism (cruise) agencies.
- Commerce companies and forwarding (wholesale).
- Individuals.

B). By the types of the goods transported they are owners of [8]:

Following these types of goods transported they are owners of [8]:

- General goods packed in: bags, bale, links, boxes, cartons, drums, cans, boxes, bales, rolls, coils, etc.
- Liquid and dry bulk goods: oil, ore, coal, grain, etc.
- Goods in the transport units: pallet, packed, container on wheels (cars, trucks and railway wagons), barges, etc.
- Frozen and chilled goods, such as meat, fish, vegetables and fruits, food, etc.
- Hazardous Goods such as: explosives, gases, oxides, etc.
- Livestock: sheep, cattle, etc.

-Goods oversized type: power plants, oil plants, tanks, beams, small boats, etc.

Hence, who are producers, exporters, importers and large trade houses that do business with the goods?

C). Following commercial quality charterers are: sellers or buyers.

D). Since legally they are [9]:

- Stock company: state, private and mixed.
- Limited-liability company.
- Associations and NGOs.
- State-Public Administration, central or local.

In terms of marketing, all can be actual or potential customers.

3. The brokers

Is a form of marine agent with multiple functions as a representative of a shipping company on behalf of employers engaged comparable rate and load goods, acts as an intermediary between charterer and ship-owner load at the end of charter contracts [10]. In shipping business owners and charterers are interested in obtaining information as accurate. Therefore they depend on: the sources of information, personal knowledge, maritime industry and industrial relations, quality and personality of the shipping brokers, ability and ease in negotiating of these brokers, etc. Ship-owners and charterers, as a rule lead negotiations with the help of the brokers. Thus the owner or charterer can to work through: one broker, two brokers, three brokers, many brokers [11].

Broker owner is called "Shipbroker" and broker of the charterer "Chartering agent". Maritime market uses generic term "ship-broker". In negotiations between ship-owner and charterer may be involved in one, two or more brokers depending on the situation. When the negotiations are involved three brokers is therefore considered: one is the owner broker, other is the charterer broker, and another one is called the "competitive broker". When there are more brokers is a category called "cable brokers". They are brokers which working in the major ports and centers of maritime information and dealing with the composition of the list of goods and ships available that they transmit to other brokers in other ports or international maritime center. Brokers perform multiple functions as follows:

-To inform the ship-owners or charterers on: maritime market developments, commodities, ships available.

-To initiate a series of measures and actions to goods and vessels engaging in the best conditions.

-To act in accordance with instructions from charterer or ship-owner.

-To work loyally for the company with which he has the contract.

-Do not hide information or to submit false information.

-To protect the information for his client.

Brokers must actively engage in negotiations, to make a series of recommendations on the establishment offers and counter-offers. In these situations the personality and temperament of the brokers have an important role, leading to a new division of brokers in "charter-party brokers", "freight brokers." The "Charter-party brokers" is broker which concluding negotiations after studying the market and especially negotiation of each clause of the charter contract. "Freight brokers" is the broker which concluding negotiations on a higher level compared to the market, but do not risk losing a commitment to a particular detail from a clause in the contract. Internationally it operates a large number of brokers, corporate, who seek permanent cargo or carrying vessel and are in the fierce competition. The most important global brokerage that operates a large number of brokers have the offices in Singapore, Hong Kong and New York. Centers in Europe with most brokers are in London, Copenhagen, Hamburg, Piraeus, Rotterdam [12].

Their activities are in small firms ranging from 3-10 people, such as limited liability, depending on the size of the business, competition, supply and demand of ships or cargo. In Romania there are plenty of companies that have in the business, among others intermediation services such as brokerage, but in reality the number of those who carry out this usually is much smaller [13]. But in Europe there are a large number of firms with the object of the type "Limited" for all maritime market. So are brokers who specialize in: search for cargo, ships, building new ships, ship sale and purchase "used-second hand" or that handles many types of activities. But the European market emerged and joint stock companies such as holding

companies, consortia or conglomerates that operate in the same way as companies such as "Limited", but have a much greater financial strength, international relations or business partners especially strong.

Some maritime shipping companies have set up their own brokerage houses as independent companies, but with the same owners. The activities of these new types of companies are employing vessels for his "mother" company. Brokerage firm of this type is known as "house broker", i.e. the broker of the main company. Advantages of establishing such firms "by home" are: reduce the number of tasks of the navigation company's top managers; reduced the scheme uses for the staff; can be established in a country "tax haven"; has the decisional independence in choosing solutions to be most profitable.

Another important aspect of maritime market brokers is that some of them have focused on certain types of goods, such as "freight broker" or even certain types of ships, in some way limiting its activity but this is justified by the fact that the activity is profitable, partners are serious and profits are considerable.

4. Price variation of transport, cause and effect

An analysis of corporate customers in the shipping industry is made separately for the two types of navigational: ad-hoc "tramp" and line. The analysis of transport following the price variation to understand the causes that produce these variations and their effects on shipping.

A). Prices (comparable rate) on the "tramp" market is fluctuating, they have evolved over time, often unpredictable. The most important factors which influencing its rate are supply and demand for the freight and tonnage. The following situations are considered to be [6]:

1).Least when there is cargo transport, it follows that:

-More ships are available in port or nearby.

-Freight-rate is small.

-Charterer position is strong and the market is called generically "the charterer".

2).Cargo transport when there is, but:

-Are fewer available ships in port or nearby.

-Freight-rate is high.

-Owner-position is strong, the market is called generically "the owner".

On the owner market are very large variations freight, its evolution is very sensitive to the occurrence of political, economic or military, such as a war (Gulf War), closure of canals (the Suez Canal), restricting the movement of large ships through the Straits (Bosporus Strait) [14]. In this market, owners usually do not publish comparable rate levels on destinations or quantities, sometimes only certain reports are published on this market, which presents the most representative comparable rate on certain routes. Variation freight in this market has a strong seasonal. For the International Trade in the northern terrestrial area the annual change in overall freight is the blue curve which is shown in Figure 1. Freight variation can actually be as shown in dotted red curve in the same figure.

Figure 1. Variation of annual general freight in "tramp" navigation.
 Source: Study author.

On the "tramp" market charterers and ship-owners are most exposed to the maritime market fluctuations often are large variations in the level of freight, which can result in large losses. But in periods of the economic booms the profits can be very high in this market. At the same time shippers may be exposed to uncertainty about the cost of transport. These fluctuations may be interesting to speculate market owners, who buy and sell ships at appropriate times, thus exploiting maximum periods where the comparable rate is high. These owners are speculators and traders and they use their skills, knowledge in an attempt to use market fluctuations for own purpose. The current economic crisis has seriously affected this type of navigation, due to lower quantities of goods transported, leading to lower transport prices and then navigating to the bankruptcy of many companies.

B). The Liner situation is different. In this type of transport prices (freight) are stabilized by the practice of charging the same price to all charterers, offering to transport the same type of goods, provided that the goods to be transported in the same vessel [9]. Prices may vary from one ship to another, but in such situations, this is known by the all shippers. Changing freight (charges) is announced with the long time before their entry into force. These rates are listed in the form of lists calculated values having different destinations and transport various quantities that are available to the charterer, the ship-owner initiative or upon request. When owners are members of a "Maritime Conference", constituted in order to stabilize fares and in this way to standardize maritime market competition, the prices used are changed periodically. Because a number of countries impose tariffs established rules tended by a "Conference" to be less volatile, than those on the market "tramp".

This type of navigation was as severely affected by the economic crisis, many companies taking ships to dock in the waiting shave or conservation. For this reason many contracts for to build the new ships were canceled, which led to a chain reaction and negative at the shipbuilders. But the number of bankruptcies among shipping companies of line was much lower, because many companies have made investments in other areas, such as operating the port, logistics and distribution centers, business centers, etc. In this way companies managed to stay afloat. Theoretical transmission tariff to ship of the Line navigation, is a constant line, as the blue line in Figure 2. In reality this type of navigation can occurs transport tariff changes as dotted red line and cut twice a year.

Figure 2. Liner ship tariffs.
 Source: Author study.

A very important aspect of marketing analyzes and studies at the shipping companies is represent each ship freight study variation over a period of time, usually a year or a certain number of consecutive voyages. Freight variation analysis is relatively simple and is based on actual numbers of each trip individually, travel case are removed from the vessel. This analysis is a management tool that must be made available to managers of shipping companies to understand at all times what is happening in the market maritime shipping line and "tramp".

Conclusions

In the current global economic crisis maritime shipping companies have taken a number of measures that sought to solve problems and remain in business. Among the most commonly encountered measures are: reduce the price of transportation to a minimum; almost without profit [15]; reducing salaries [16]; reduction of staff at headquarters and in ships; replacing sailors and officers from European countries with high salaries with people from South-east Asia who agreed to work for lower wages [17]; dissolution of training programs for cadets on board [18], [19]; moving and changing corporate headquarters and the ships flags in countries called "tax haven" to not pay taxes; cancellation of contracts for the construction of new ships and other investments [20]; reducing consumption on board; reducing travel speed vessels to reduce consumption fuels and lubricants [17]; sale of vessels of greater age for scrap or "second-hand"; conservation were not what ships to transport; switching unemployed employees; renegotiated contracts with creditor banks for financing, reduction of interest rates; postponement of payments; outsourcing of services to third parties at the company, etc.

Many of these measures have contributed to saving sea shipping company, but others, despite cuts made, failed to resist and went bankrupt. The main reason being given the lower demand for all domestic and international markets, which actually resulted in lower quantities of goods transported by sea and thus the loss of customers (owners of goods, exporters, importers or brokers).

However, some maritime companies have resisted and resists further. The question arises: how they did it in the same maritime market, while others have failed? Following analyzes from several companies, the following aspects:

-Majors maritime shipping have large financial reserves, held in several banks in the countries of origin of ship-owners, but also abroad, usually banks were hit hard by the financial crisis, which allowed these companies to resist.

-Had more currency reserves, "no bet" on a single currency. The reason being that mitigate shocks of exchange rate between international currencies.

-They renegotiated contracts with charterers, asked them to accept delivery of freight at a certain level, allowing companies to cover transport costs.

-Made large investments in land, maritime related fields, but also in commerce, logistics and top industries (IT and communications).

-Have invested in scientific research to find innovative solutions to reduce costs and optimize transport bought modern ships with the low consumption and small number of crew members.

-Have sought to engage on board the best officers and sailors on lower wages than before the economic crisis started, because surplus labor in this market, resulting from the collapse of many companies and removal from service a large number of ships.

-Have increased the number of courses and hours of training and retraining of crew in order to reduce fines, damage and naval disasters. Thus aimed at reducing losses generated by checks of the naval and port authorities, and shipping to avoid rejection by charterers or operators charging port.

-Some companies have requested and received aid from governments that supported companies to avoid entry of default, but also issues of transport of goods and persons, excessive unemployment among seafarers.

-A number of companies have sold shares and investors sought and were associated with them, with bigger and stronger financially company, even in other areas, they offered to transport goods or money for supplies, repairs payment of wages, [21].

But still many unresolved issues remain, such as those generated by the price of fuel,

crew salaries, tolls and straits channels, piracy, strengthening labor laws and environmental protection, etc. For the next period expected new challenges for the maritime shipping companies, primarily amend the Convention "Marpol" in the sense it tighter, piracy, terrorism, illegal immigration, etc. But most will be fierce competition between companies.

To survive in this market, shipping companies need to focus the main activities of looking for new customers, reduce costs of all kinds, reducing profits, bringing money "home" for investment, association or holding groups representing chains strong supply, starting and ending with retailers manufacturers. The future will be safer for large companies and industrial groups, especially maritime, which will mean that the group is charterer and ship-owner at the same time. The "tramp" navigation can only revive momentum for economic, demand for ships, the rest will remain the most vulnerable, with more risk of bankruptcy.

Abstract

The paper presents the result of a risk analysis of some companies, which are grouped in three economic sectors: production, construction and tourism.

The main focus consists in the impact the three risk indicators have (risk of exploitation, financial risk, risk of bankruptcy) on the activities that underlie at each economic sector.

The applicative part of this paper is materialized in a scientific approach that includes a number of 27 companies, grouped by sector, from Timis County, Romania, which has in view the obtainment of useful and perspective information concerning the risks, based on the specific behavior of the activity they perform, aiming also the possibility of taking useful and correct decisions.

This approach represents our own vision about the differences of risks within each economic sector analyzed.

Keywords: risk, risk of exploitation, financial risk, risk of bankruptcy.

JEL classification: M, M2, M21.

1. Introduction

In the process of knowledge, analysis is an indispensable research method, through which is created not only the possibility of research things and phenomena, but is discovered the structure, are checked and established causal links, factors that generates them and so decisions can be made for future activities.

Financial analysis is a tool of financial management. It consists of the evaluation of the financial condition and operating performance of a business firm, an industry, or even the economy, and the forecasting of its future condition and performance. It is, in other words, a means for examining risk and expected return. Data for financial analysis may come from other areas within the firm, such as marketing and production departments, from the firm's own accounting data, or from financial information vendors.[3]

The skills of financial analysis are important to a wide range of people including investors, creditors, and regulators. But nowhere are they more important than within the company. Regardless of functional specialty or company size, managers who possess these skills are able to diagnose their firm's ills, prescribe useful remedies, and anticipate the financial consequences of their actions. [4]

There are taking place profound changes in all fields of activity and the implications are felt in the financial situation of each company. To mitigate the risks that can influence a company's activity, we must know what are the pressures factors that may arise from the company's external environment and also the weaknesses within the internal environment of the company.

Assuming a certain level of risk varies from one company to another, depending on the degree of endowment with resources, business objectives, its previous performance and also the performance of other similar companies.

Taking into account the current economic context, the present research is performed

based on risk indicators, in order to identify the weaknesses of these economic sectors and formulate the correct suggestions regarding their remedy.

2. Literature review

Specialized literature abounds in the term "risk" used in various theoretical and methodological purposes, which led, inevitably, the appearance of relative contradictions to the exact meaning of the term.

The term risk has its base word in Greek, „*rizikon*” which means root, later being used in Latin for the word rock. During the Middle Ages, the term „*riscium*” has been widely used in certain situations, primarily in sea trade cases where losses or damages appeared in the quality of goods.

Although the risk was one of the most interesting themes of investigation and research, the first consistent results in terms of understanding, assessment and management occurred only at the end of the seventeenth century.

The word risk is more and more used in various fields, especially in economics and also it is known that within the specialized literature are many definitions of risk. In essence, risk is the probability that an undesired event can happen.

In the economic practice, most frequently forms of risk encountered are: country risk, commercial risk, currency risk, risk of exploitation, financial risk, risk of bankruptcy. We will insist on the last three risk categories, these being the most common risks to which it is subjected the activity of an economic agent.

A. The risk of exploitation (also called economic risk) can be defined as the inability of a company to adapt on time and with the lowest cost to environmental variations. [5]

In order to determine the risk of exploitation which characterizes a particular activity, we will use the threshold of profitability method.

The threshold of profitability method represents the point where the turnover covers the operating expenses delineated in fixed and variable costs, calculated in physical or value units, for a product or for the entire activity. The relation for calculating the threshold of profitability is:

$$CAcr = CF / (1 - CV/CA)$$

Where:

CAcr - Turnover to achieve the threshold of profitability;

CF - Total fixed costs;

CV - Total variable costs;

CA - Total turnover;

CV/CA - Part of variable costs in turnover.

B. The financial risk reflects the resulting variability indicators due to the changed financial structure of the company. [2] The financial risk can be evaluated using the threshold of profitability.

The financial threshold of profitability calculation is similar with the calculation of the exploitation threshold of profitability, but adding interest costs. The relation for calculating the threshold of profitability is:

$$CAcr = (CF + Chd) / (1 - CV/CA)$$

Where:

CAcr - Turnover to achieve the threshold of profitability;

CF - Total fixed costs;

Chd - Interest costs;

CV - Total variable costs;

CA - Total turnover;

CV/CA - Part of variable costs in turnover.

C. The risk of bankruptcy is closely linked to the state of solvency, reflecting the possibility that a company can not fulfill its payment obligations. In this case we can say that the company is in a financial difficulty state.[1]

In the economic theory are elaborated several models based on the scoring method, such as: the Altman model, the Conan-Holder model, etc.. Within our case study we will use the Altman model (Version 3).

The last version of the Altman model, updated and revised, presents the advantage of applicability in case of non-industrial enterprises and those that operate in countries which are under development. [6] The Altman scoring function, in this last version, is as follows:

$$Z = 6.56X_1 + 3.26X_2 + 3.72X_3 + 1.05X_4$$

The model variables have the following meaning:

$$X_1 = FRN / AB$$

$$X_2 = PRI / AB$$

$$X_3 = \text{RBDIT} / \text{AB}$$

$$X_4 = \text{ANC} / \text{DT}$$

Where:

FRN - Working capital;

AB - Total assets;

PRI - Retained earnings;

RBDIT - Earnings before interest and taxes;

ANC - Book value of equity;

DT - Total liabilities.

The critical intervals for the Z function are as follows:

- Level I: safe zone, with very low probability of bankruptcy, practically negligible; creditworthy firms $Z > 2.6$;

- Level II: uncertain zone, firms with temporary financial difficulties, which can be remedied if the applicable strategy is suitable $1.1 < Z < 2.6$;

- Level III: risky zone, bankruptcy firms $Z < 1.1$.

3. Material and Methods

In the next case study, we will calculate the risk indicators and based on the results obtained we will facilitate making the correct decisions on the settlement of existing problems in order to improve this system, taking into account the current economic context.

The data to which we refer within the undertaken study are out of a sample of 27 companies from Timis County, Romania, and are grouped into three economic sectors (production, construction and tourism) to identify the particularities of each sector, on a reference period of four years (2008-2011), from the risk point of view.

Sector 1 - Production;

Sector 2 - Construction;

Sector 3 - Tourism.

4. Results and Discussion

Based on the data held and calculation of risk indicators, we have obtained the following results:

- For **sector 1 – Production**, situation is as follows:

- Risk of exploitation

Table 1 - Results of the risk of exploitation in the period 2008 - 2011 for enterprises in the production sector (RON)

Production enterprise	Time span			
	2008	2009	2010	2011
P1	362160	137507	295546	-948164
P2	-1017917	8388203	10075912	-32237806
P3	10453921	-105726482	3231776	6763553

P7	-4340623	110370226	4139179	5042254
P8	112500369	6528159	3052369	8242949
P9	7121622	5700598	-4479974	-11025811

Source: own compilation

Based on the threshold of profitability and safety index deviation results from the enterprises that operate in the production sector, in the period 2008 – 2011, here are the following conclusions: P2, P3, P6 designates an unstable situation, respectively a high risk of exploitation. At the opposite side, P4 and P8 are enterprises that have a low risk of exploitation. Enterprises P1 and P9 registered in the first half of the analyzed period a low risk of exploitation, followed after that by an increase. For P5 and P7 the situation is similar, in the first two years the risk of exploitation is high, and in the last half of the analyzed period they benefited a reduced risk of exploitation.

- Financial risk

Table 2 - Results of financial risk in the period 2008 - 2011 for enterprises in the production sector (RON)

Production enterprise	Time span			
	2008	2009	2010	2011
P1	1458653	885743	819599	-1915753
P2	-1017917	8388203	10075912	-32863055
P3	12560854	-110566784	4291576	9645173
P4	10369444	46569295	13992583	11211545
P5	-6025927	-7361698	8986077	35820461
P6	-4385914	-10085298	5324157	-1378342
P7	-8416416	168430278	8405097	9283171
P8	114636811	7258550	3577061	9144532
P9	7710396	6974225	-5016448	-13784477

Source: own compilation

At the level of enterprises that operate in the production sector in the period 2008 - 2011 the situation is similar (in terms of

positive and negative values recorded oscillation) with the risk of exploitation, but with slightly higher values due to the inclusion in the calculation formula of interest costs. It is remarked that P2 recorded in 2008-2010 a financial risk value equal with the risk of exploitation, which proves a lack of interest costs.

➤ Risk of bankruptcy

Table 3 - Results of the risk of bankruptcy in the period 2008 - 2011 for enterprises in the production sector

Production enterprise	Time span			
	2008	2009	2010	2011
P1	1.45	4.94	5.09	1.46
P2	-9.91	-10.27	-7.45	-4.66
P3	-0.24	-1.41	1.21	1.53
P4	0.92	-1.27	-0.78	0.31
P5	1.65	2.12	1.95	1.76
P6	2.57	2.69	2.87	-2.02
P7	-0.69	0.42	2.61	4.28
P8	-0.59	0.59	3.57	1.90
P9	2.18	3.05	3.30	2.03

Source: own compilation

In the analyzed period 2008-2011 it is remarked that enterprises P2 and P4 are in a risky area, namely bankruptcy. The enterprises that are in a risky area in the first half of the range are P3, P7, P8 and later in the second half takes place an improvement of them, namely they go into a safe and uncertain area in terms of financial difficulty. According to the data in Table 3, creditworthy enterprises and those who have temporary difficulty that can be remedied if proper strategy is applied are P1, P5 and P9. Can be observed that in the first three years P6 is the only creditworthy enterprise whose values increases systematically from one of the other, but in 2011 is part of a strong downward evolution, which positions her in a risky area (of bankruptcy).

- For sector 2 – Construction, situation is as follows:

➤ Risk of exploitation

Table 4 - Results of the risk of exploitation in the period 2008 - 2011 for companies in the construction sector (RON)

Construction company	Time span			
	2008	2009	2010	2011
C1	8602287	6415368	3673893	9732541
C2	41336226	15135990	315494	-5815115
C3	741100	1325647	905550	-5290365
C4	2711323	5919970	7116697	16024308
C5	6024217	5152356	5232224	101823894
C6	-2056134	171380675	4985479	4126529
C7	1103390	905513	1653705	-8642934
C8	-12949796	1515354	669948	421524
C9	-7401514	2926231	2893335	4179151

Source: own compilation

Given the results mentioned above, it can be observed the situations of companies (C3, C4, C5 and C7) that activate in the construction sector, in the period 2008-2011, is presented in a similar way, namely in the first three years they register a low risk of exploitation, and in the last year the companies show an unstable situation, respectively a high risk of exploitation. In 2008 the risk of exploitation of companies C8 and C9 is high, and in the years 2009-2011 is registered a sharp drop due to safety index offense determined. The risk of exploitation in the first and last year of company C1 is high, in 2009 corresponds to a medium level (relatively a stable situation), and in 2010 this is reduced.

➤ Financial risk

Table 5 - Results of financial risk in the period 2008 - 2011 for companies in the construction sector (RON)

Construction company	Time span			
	2008	2009	2010	2011
C1	8602287	6415368	3673893	9732541
C2	46893272	18030116	-1685652	-7741448
C3	1518650	3608022	2002376	-9019918
C4	2763868	6040353	7200618	18267866
C5	6181627	5368445	5285598	104067660
C6	-241775	111237933	12180146	12916601
C7	1103390	905513	1670480	-8731821
C8	-23166423	4505509	2039047	1559364
C9	-12466393	5347094	5454399	6371394

Source: own compilation

Over the four years period analysis, the situation is similar (in terms of positive and

negative values recorded oscillation) with the risk of exploitation, but with slightly higher values due to the inclusion in the calculation formula of interest costs. Exception to the above mentioned is company C1 which recorded a similar evolution as with in the risk of exploitation, because the interest costs recorded a zero value the entire range.

➤ Risk of bankruptcy

Table 6 - Results of the risk of bankruptcy in the period 2008 - 2011 for companies in the construction sector

Construction company	Time span			
	2008	2009	2010	2011
C1	63.11	10.97	11.03	46.40
C2	-1.09	-1.15	-2.09	-1.15
C3	3.68	1.06	4.04	3.63
C4	4.84	5.78	1.82	1.55
C5	4.42	5.90	7.26	5.89
C6	1.08	0.90	0.57	1.13
C7	6.22	7.08	4.38	4.26
C8	-3.12	2.76	2.98	2.07
C9	3.14	1.89	1.84	1.67

Source: own compilation

Based on the available data, it is remarked that a number of three companies (C1, C5 and C7) in this economic sector, recorded a very low probability of bankruptcy, practically negligible, the entire period 2008 - 2011. We can not afford to overlook the values obtained in all four years by company C1, due to too high values recorded regarding book value of equity in comparison with total liabilities. According to the values obtained, C2 and C6 are the only companies in bankruptcy, but the latter records an improvement in the last year, placing it in an area with temporary financial difficulties. Based on the data in Table 6, the creditworthy companies and those who have temporary difficulty that can be remedied if proper strategy is applied are C4, C8 and C9.

- For sector 3 – Tourism, situation is as follows:
 - Risk of exploitation

Table 7 - Results of the risk of exploitation in the period 2008 - 2011 for firms in the tourism sector (RON)

Tourism firms	Time span			
	2008	2009	2010	2011
T1	1854181	1615769	1718817	2154156
T2	1119822	2727022	1611987	2637963
T3	2844162	-8587784	-1876459	1152533
T4	944794	882239	-739681	2519998
T5	-2842524	-21195453	1957810	-9643907
T6	609347	-497880	436168	-535481
T7	1589114	-1416724	186066	194450
T8	-373153	2662175	-359528	2518869
T9	630699	487787	2168643	1500115

Source: own compilation

For the firms operating in the tourism sector in the period 2008-2011, can be observed highly oscillating values of the risk of exploitation. Firm T1, in the first and last year, then in the second and third year, shows a low risk of exploitation, respectively a medium one. T2 and T9 present a low risk of exploitation the entire analyzed period, compared to the other firms in the same economic sector.

➤ Financial risk

Table 8 - Results of financial risk in the period 2008 - 2011 for firms in the tourism sector (RON)

Tourism firms	Time span			
	2008	2009	2010	2011
T1	2234914	1933225	1908467	2258338
T2	1921940	3898153	2108358	3201478
T3	4598572	-16866966	-3384805	2124294
T4	1124533	902220	-878046	2541616
T5	-3789399	-25296544	2676076	-13109902
T6	609347	-958843	1258249	-1339846
T7	1779796	-1969906	1103057	726190
T8	-713207	4961867	-695014	10770272
T9	931320	653097	2543712	1676545

Source: own compilation

At the level of firms operating in the tourism sector during 2008-2011 the situation is similar (in terms of positive and negative values recorded oscillation) with the risk of exploitation, but with slightly higher values due to the inclusion in the calculation formula of interest costs. It is remarked that in the first and last year, respectively in the second and third year, the values obtained are

approximately equal, while the latter are a bit smaller.

➤ Risk of bankruptcy

Table 9 - Results of the risk of bankruptcy in the period 2008 - 2011 for firms in the tourism sector

Tourism firms	Time span			
	2008	2009	2010	2011
T1	208.47	38.41	38.35	123.78
T2	1.12	-0.34	-0.02	-0.08
T3	-1.49	-2.24	-6.99	-6.57
T4	10.84	12.81	2.24	6.25
T5	1.81	-0.17	0.44	0.42
T6	2.13	-3.07	-3.31	0.58
T7	0.46	-0.14	-0.35	0.99
T8	2.73	-5.17	-1.57	-5.95
T9	4.17	4.00	5.95	7.86

Source: own compilation

Over the whole period 2008-2011, we remarked that a number of three companies (T1, T4 and T9) in this economic sector, recorded a very low probability of bankruptcy. We can not afford to overlook the values obtained in all four years by firm T1, due to too small values recorded regarding earnings before interest and taxes in comparison with total assets. Since 2009 until the end of 2011, most firms (T2, T3, T5, T6, T7, and T8) are in bankruptcy. In 2008, some of them (T2, T5 and T6) have tried to remedy their financial difficulties through some strategies appropriate to the situation, but have not succeeded.

5. Conclusion

Based on the values obtained, by comparing the results between risk of exploitation, financial risk and risk of bankruptcy and as a result of poor management, of some internal dysfunctions and external factors, companies P2, C2, T3, T5, T6 and T8 are in a situation of bankruptcy. Given the direct analysis results of companies, from the economic sectors presented, based on the indicators system which express risk, we can say that the most favorable situation is found in the construction sector, than in the production sector and finally in the tourism sector.

The steps that have to be taken in order avoid critical situations are:

- Understanding risk and its integration into the company's strategy;
- A good knowledge of competitor strategies;
- Adoption of those decisions that can lead to risk avoidance.

Cost reduction is considered to be the most effective way through which can be achieved a competitive advantage, especially in those economic sectors where the market is so bidders.

Regardless of the activity profile, legal status, size and space in which it operates, the company is obliged permanently adapt to risky situations, that can occur in the current activity, as well as in the predicted one.

Nowadays the economic activity is dominated by risk, because of the lack of concern, of managers for knowing and understanding the elements that determine the risk which leads to the appearance of differences between companies in the same economic sector.

Risk approach from the perspective of organizations must be consistent with the type of their activity and with all the characteristics of markets and environments in which they act as economic and social agents.

The success of a company depends heavily on its ability to innovate, and innovation represents taking risks.

Interdisciplinary Research Frameworks of Online Behaviors: Critical Review from a Marketing Perspective

Lazoc Alina

Dimitrie Cantemir Christian University, Faculty of Management in Tourism and Commerce Timisoara
alina.lazoc@gmail.com

Abstract

The present paper sets out to outline the theoretical frameworks and the research methods that may be used in addressing general issues of web behaviors and in formulating new researchable marketing questions. In view of this, we provide a brief literature review in three major areas of web research (marketing, media management and communication studies) and reveal advantages and major shortcomings of each framework considered (the Flow Theory, the Multimedia Convergence Paradigm and the Uses and Gratifications conceptual framework). Drawing on the results of the literature review we finally formulate our future research directions concerning online informational, search and shopping behaviors. Drawing on the selective interdisciplinary literature review we are proposing several steps in designing a research study concerning consumers' online experiences during shopping activities and during product and product information search.

Key words: web behaviors, motivations and experiences, profile development, causal models

J.E.L. Classification: M15, D83, L82, L86

1. Introduction

Web behaviors have been examined under various contexts over the years. One of the most obvious characteristics of web behaviors research is its interdisciplinarity. Web usage studies cover a wide diversity of themes that result in a wide range of methodologies and intellectual approaches specific to the researchers' initial backgrounds (sociology, management,

marketing, media and communication or computer sciences).

Although researchers from all mentioned areas of research have made significant progress, the scope of their studies is rather broad and the research appears relatively fragmented and with contradictory results. We consider it therefore essential to distinguish between the wider issues and concerns related to web behaviors, that may provide the overarching context for a study, and the specific topics, investigation of which offers a real chance to add to what is known already.

2. Web consumption motivations research

One of the keys to the understanding of online consumer behaviors lies in an appreciation of the motivations that lie behind consumer web use. These motives of the consumers are more often assumed rather than investigated.

The uses and gratifications approach is one of the theoretical frameworks in the field of mass communication through which consumer motivations in regards to new media products and services have thoroughly been examined. U&G looks at the ways consumers use media and the utilities they receive from that use. In U&G studies, people are seen as purposive, goal directed, and motivated in their use of the media (and other communication activities) to satisfy their social and psychological needs and wants.

Traditional media researchers have identified some basic gratifications that people receive from consuming media products, among which Lacy and Simon [1] mention: surveillance of the environment, decision making, entertainment and diversion, socio cultural interaction, and self-

understanding. Each of these (and some others) represents underlying constructs of the U&G theoretical framework.

Although widely used to understand other aspects of media use behavior, U&G has been less frequently applied for understanding consumers' use of the world wide web [2] and some researchers even suggest that the theory has not been adequately adapted to the internet [3], [4].

Nevertheless, it has not escaped the attention of researchers [4] that the web is in many ways a unique medium. The time-honoured list of gratifications derived from early television studies [5] has been expanded to explore the unique facets of the internet medium. Among the new factors identified by internet studies we mention *search* [6], *interactive* and *economic control* [7], which together achieve an increase in the variance explained in web usage.

Uses and gratifications profile development in internet research is typically accomplished through a two-stage research design [6]. First, an exploratory list of terms that characterize typical uses and sought gratifications (for example: *information, search, browsing, entertainment, etc.*) is developed; this process allows for the sampling of the domain of the theoretical construct. The second stage of U&G development uses factor analysis to group descriptive terms into profiles representative of specific audience gratifications and intended uses for a medium.

Some U&G studies [8] measure the distinction between gratifications sought (GS) and gratifications obtained (GO) and extend research from description of gratifications to tests of explanatory power of these gratifications. These studies found that GO are stronger predictors of media exposure than GS.

The major shortcoming of the uses and gratifications approach is that it is more a conceptual framework than a theory, and generally it is used to describe and classify audience behavior rather than to predict it.

However, there is a research area that moved beyond the mere classification of motives to identifying complex instrumental and ritualistic user orientations. Studies in this area have required a clear conceptualization and operationalization of

motivation. Rubin [9] [10] was the forefront of this methodological development.

Based on the users' motivations, U&G literature on this topic identify two overarching media orientations (later extended to web orientations as well): *instrumental* and *ritualized* use [10], also seen by others as *active* or *passive* [11], or *utilitarian* and *diversionary* [12]. The media orientations classification in communication research is very similar to the marketing classifications of consumer *intrinsic* and *extrinsic motivations* [13] and their *situational* and *enduring involvement* [14].

3. Conceptualizing web generated market behaviors

Another key aspect in understanding online consumer behaviors is the study of online medium itself and its ever evolving characteristics.

According to the convergence paradigm, internet is, first of all, a convergent medium reuniting and transforming characteristics of computers, telecommunications and television.

Most conceptualizations of multimedia convergence include a technological, a strategic and a functional dimension. Technological convergence affecting access terminals consists of the integration into one device of a set of features performed by several devices. The essence of the functional dimension is that the converging digital technologies empower consumers to decide where, when and on what device they consume whatever media content they want (video fragments, audio tracks, maps, etc). On a strategic level, convergence means allowing business partners, customers and consumers more freedom to manage their own media and entertainment experiences.

The multimedia convergence paradigm is a theoretical approach in media management [15] primarily focused on the strategic issues in the communication industries, which also attempts to describe consumption patterns in multimedia environments (such as the world wide web). Jenkins [16], for example, suggests analyzing multimedia convergence from the standpoint of users' multitasking strategies for navigating the new information environment. The author considers that “convergence is taking place within the same

appliances within the same company ... within the brain of the consumer ... and within the same fandom.”[17]

However, convergence-based research focused on consumer demand is a rather underdeveloped area of inquiry in media management. Scholars in this area focus less on consumer issues than on strategic issues at the industry level, trying to develop an understanding of the extent to which industries (media, IT and telecommunication) are coming together [18] and of the convergence strategies used by multimedia businesses [19].

The major shortcoming of the convergence paradigm is that convergence as a multidimensional theoretical construct hasn't been yet clearly defined, nor operationalized, so that researches are not able so far to measure its impact on other phenomena under study.

4. Causal models of optimal consumer experiences online

Flow theory [20], a very elaborate and consistent social sciences theory, that has been successfully adopted in online marketing [21], attempts to conceptualize and operationalize the process of total immersion (mental and emotional) in an online activity.

Flow models attempt to better explain the factors that make using the web a compelling experience for its users, and of the key consumer outcomes of this compelling experience.

The social sciences construct of *flow* describes a state of consciousness that is sometimes experienced by people who are deeply involved in an enjoyable activity. The experience is characterized by a balance between the challenges of an activity and the skills required to meet those challenges, clear goals and immediate feedback, concentration on the task at hand, a feeling of control, a blending of action and awareness, a loss of self-consciousness, a distorted sense of time and the autotelic experience. The term *autotelic* refers to an activity that is “done not with the expectation of some future benefit, but simply because the doing itself is the reward.”[22]. In other words, while in a state of flow, people become completely immersed in the activity to the point of losing

awareness of time, their surroundings, and all other things except the activity itself.

In the marketing literature, Novak et al. [23] conceptualized online flow as a cognitive state experienced during navigation that is determined by (1) high levels of skill and control; (2) high levels of challenge and arousal; and (3) focused attention; and is enhanced by interactivity and telepresence (a psychological state in which individuals don't perceive the media existence between them and the real world). Studies confirm that many different kinds of web activities can facilitate flow:

- shopping [24], [25];
- searching information [26], [27];
- playing games [28], [29], etc.

The causal models of online flow, such as Hoffman and Novak's [21], Novak et al. [23], Koufaris's [30], Skadberg and Kimmel's [24] or Guo and Poole's [25] models have developed a modality to operationalize flow in different contexts by including antecedents, dimensions and consequences in its measurement. Among the antecedents of flow analyzed in the studies mentioned above there are: the *challenges* of an online activity, the level of *skills* of online users, the intensity of the *telepresence* state, the levels of *interactivity* and *complexity* of the online medium. The main dimensions identified when studying the online flow are: *concentration*, *pleasure*, *a sense of control* and *time distortion*.

Confirmatory factor analysis has been used to evaluate the validity of the measurement models and discriminant validity tests helped assessing latent factors as being separate and distinct constructs. Reliability of measurement scales has been tested using alpha Cronbach. However, taken together, studies involving flow assessment demonstrate that some potentially serious consequences of measurement model misspecification exist, and researchers need to think carefully about the direction of causality between constructs and about their measures.

5. Conclusions and future research agenda

As identified by the U&G literature, search, information and shopping are distinct

and major motivations of web usage and we are particularly interested in contributing to the conceptualization of online ritualized and instrumental shopping and information and product search, and to creating structural models that operationalize these in specific contexts.

Firstly, we are interested in developing operational measures of the three online consumer motives: product information search, product search and shopping, based on the existing U&G empirical studies.

Secondly, based on the online flow literature we intend to develop, test and compare flow models of online product information search, online product search and online shopping. Also based on the reviewed flow studies we are planning to elaborate and validate a measurement instrument for online flow experiences during all three types of online consumer activity.

Drawing on the literature review on flow theory and the multimedia convergence paradigm, and the above-mentioned structural models of online experiences already tested in different web usage contexts we are interested to address in our future empirical studies the influence of the convergent web medium and its interactive, intuitive applications on consumers' decision-making processes and their shopping experiences online.

Therefore we will also try to extend our theoretical research in the area of computer studies in order to identify measurable particularities of the web as a convergent information environment, both from the objective point of view of its technological features and from the experiential point of view of people's perception of these features as well as in the area of experiential marketing in order to identify operational dimensions of online consumer experiences.

Abstract

As a key agent in a competitive pole, intelligent enterprise includes, as well as other organizations that provide goods and services, the various categories of stakeholders. Due to the large number of stakeholders, relationship management of them at intelligent enterprise level presents a high degree of complexity. This involves precisely identifying of relevant stakeholder groups and how relationships with them can be effectively managed in the business model. This paper aims to provide a new perspective of the complex system of relationships that exist between the main stakeholders of an intelligent enterprise within a competitive pole structures and also intends to propose a framework that can support managers of such organization in assessing and estimating the models reactions and actions required to manage dynamic relationships with its stakeholders.

Key words: intelligence, intelligent enterprise, stakeholder relationship, competitive pole, stakeholder relationship management

J.E.L. classification: D80, L50, M10, O10, O30, P40

1. Introduction

The intelligent enterprise success is not determined only by the quality of intelligent infrastructure (technological, structural and human resources), by knowledge management or intelligent behavior, by indicators of competitiveness and overall performance of it, but increasingly depends on how managers succeeds to direct

interactions between the various stakeholders to common goals set by the organization's integrated mission. Thus, the concept of stakeholders has become a key term within an intelligent enterprise strategy.

Intelligent enterprise includes, as well as other organizations that provide goods and services, the various categories of stakeholders. This involves precisely identifying of relevant stakeholder groups and how relationships with them can be effectively managed in the business model.

The intelligent enterprise managers need a better understanding of the dynamic relationships between and among different stakeholder groups as well as the knowledge of divergences or convergences objectives and views of them. In most organizations this exercise is not completed in an explicit way. Although business managers consider different stakeholder behavior and objectives, they rarely have a good overview to emphasize the dynamics that shape relationships between stakeholders. As a result, in this case stakeholder relationship management is ad-hoc in nature and is not based on a frame structure that could help in assessing and estimating models of reactions and actions necessary for managing relationships with stakeholders.

This paper is based on review and analysis of existing research literature, of relevant documents certifying the work of various professional bodies and on personal vision about the results identified in managerial practice. The purpose of this study is to propose a new perspective on the complex system of relationships that exist between the main stakeholders of an intelligent enterprise within a competitive pole, by providing a framework structure that can support managers of such organization in

assessing and estimating the models reactions and actions required to manage dynamic relationships with its stakeholder.

2. Theoretical framework: Conceptual approaches of the relationships nature between stakeholders

In the literature there are several approaches of the relationships nature within and between stakeholder groups. Also, Henesey et. al. (2003) proposed three approaches about these relationships. The first approach refers to the costs and benefits distribution among stakeholders, to the "trade-offs" situations (between economic, social and environmental aspects of the organization) and to the creating of "win-win" situations. A second approach examines the efficiency aspects, such as maximizing results by minimizing inputs, and the latter approach aims to analyze the behavioral aspects such as those relating to deceptive behavior, opportunism and limited rationality. In view of the same authors, the interaction which characterizes the inter-organizational relationships stakeholders can take a physical or tangible form that refers to the physical transfer of goods or intangible asset form aimed at exchanging information and knowledge based on contracts and control. All these aspects can be applied both within formal stakeholders relationships and less formal situations of interaction between them.

Other researchers in the field (Mitchell et. al., 1997, Ulhoi, 1997, Cummings and Doh, 2000, Eden and Ackermann, 2004; Bryson, 2004; Bryson et al., 2007; Boonstra, 2008) developed several methods of stakeholder analysis aims to identify and to categorize the main stakeholders of an organization. These approaches often refers to the specific aspects of stakeholder management, such as identifying stakeholders (Vos and Achterkamp, 2006), assessing their relative importance (Mitchell et al., 1997) or ways of involving stakeholders in organization strategy (Bryson , 2004) . A first step in the analysis is to identify the major groups of stakeholders that may be directly or indirectly affected, or which may affect the formulation and execution of the organization strategy. These groups can be identified by classification into one of four

major categories: organizational stakeholders (senior managers, front-line employees), capital market stakeholders which can affect the availability and cost of capital (shareholders, banks and other financial intermediaries) , industry or product market stakeholders (suppliers, customers), social stakeholders represented by these groups and external organizations that may affect or influence the strategy and performance of the organization (unions, government). All these stakeholders groups can be divided also in terms of demographic and geographic criteria according to the government level or by other relevant criteria.

Based on the general stakeholder approaches and on the intelligence researches, Waltz (2003) identified in the Intelligent Community of United States of America (considered also an intelligent organization) following structure of relationships between key stakeholders of this community as well as metrics by which these actors value the organization:

- The owners (beneficiaries): the public and its elected officials. These stakeholders aimed at identifying threats to national security interests and they measures intelligence value by the degree to which it is maintained.
- Intelligence consumers (customers or users): those civilian, military or national users within intelligence agencies that measure intelligence value according to its contribution to the organization's mission by assessing impact mission effectiveness.
- Intelligence producers (direct users of raw information): intelligence collectors (human and technical), information processing agents and analysts, whose intelligence assessment metrics are based on performance, and refers to information complexity, level of confidence, accuracy, opportunity, and coverage depth.

Based on the above approaches, we may consider that at intelligent enterprise level, a stakeholder is any individual or group who has an interest or which may be affected by the organization decisions and strategies. In

such context, intelligent enterprise can be approached as a contacts and contracts network under which each stakeholder is driven by their own interests and priorities. Thus, in the enterprise intelligent the process of value creation depends on the support of various groups of stakeholders, situation in which each stakeholder group deserve receives due consideration according to the degree of importance given within the existing relationships.

3. Issue: A new perspective on intelligent enterprise stakeholder relationships system

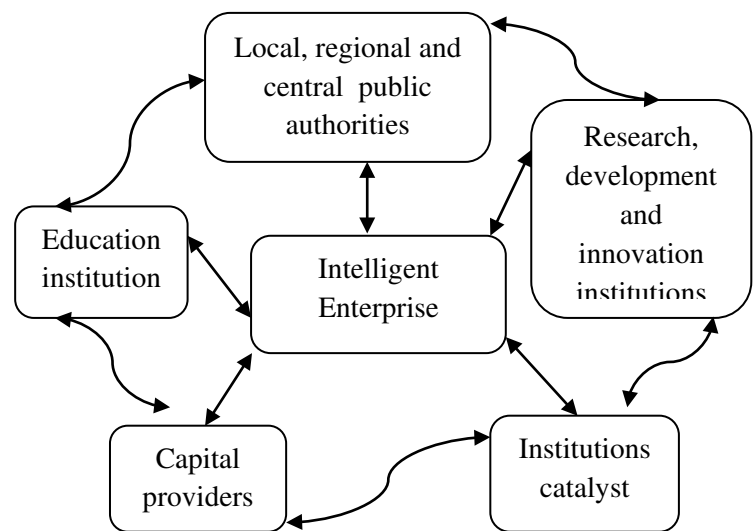

As a key player in a competitive pole, intelligent enterprise includes in addition to traditional stakeholders (creditors, customers, managers, employees, government, governmental and non-governmental agencies, policy makers, owners/ shareholders, suppliers, unions and civil communities) which provides organization with necessary resources to achieve strategic goals, and other key stakeholder groups including: universities and research & development institutions as providers of innovative products and technologies, local and regional authorities and institutions catalyst. Each of these stakeholders has a special interest in the mission of the organization, making it necessary to have a purpose and a value chain to guide specific operations of knowledge management.

Managerial practice has demonstrated over time that stakeholders do not have an equal position in the stakeholders system, can't have the same influence in determining the purpose of the organization and are not affected as much by the effects of its policy and strategy. In this context we can say that stakeholder relationship management (SRM) is an important input in formulating and implementing of intelligent enterprise business strategy, also emphasizing the role of certain categories of stakeholders to create interdependence between its formulation and implementation. Thus, the first challenge in managing relationships with stakeholders is to identify them, to determine how stakeholders can be affected by decisions of the organization and what influence they can have on the implementation of these decisions.

Based on European project CLUSNET researches during 2009-2011, authors Solvell and Lindqvist (2011) consider that at the cluster/ competitive pole level can be identified five major categories of actors: government, capital providers, educational institutions, research institutions and companies that have the central place in this system.

In our view, the major stakeholder categories of a competitive pole, whose interactions are focused on innovation and creating conditions for a superior adaptation to intelligent enterprise business needs, are shown in Figure 1.

Figure 1. Categories of actors / stakeholders in a competitive pole

Source: Made by authors

As shown in Figure 1, intelligent enterprise have a central place in a competitive pole and is considered the most important actor of the pole and the economic side of it, because represent the innovation demand by bringing innovation to the market and by testing on it in competition.

In the enterprises relationships system, business interactions occur between small and medium enterprises with large

companies, but also between local and the multinational organizations, each of them having an alternative role as a buyer, supplier, technology partner, workforce space training, or source of new ideas and inspiration for setting and achieving ambitious goals.

Organizations or research, development and innovation institutions are producing and providing new knowledge and innovative solutions, representing offer products, processes, services and innovative technologies. Education institutions include schools and polytechnics, colleges and universities. The Universities role consist in establishing research groups to obtain knowledge leading in relevant areas and sending them to other actors in the pole, which often confers a dual role: the research institution or educational ones. Colleges provide specialized education programs and graduates with specialized knowledge training as requested in respective pole. Technological, human, knowledge, intelligence and financial capital providers (banks and venture capital organizations) are the ones who provide the necessary resources to exploit inventions and new business models. Capital providers analyze carefully the pole risks and opportunities and provide "smart money", having the role of "experts" in the competitive pole. The last stakeholder category is represented by public authorities at national, regional or local level, and also by public agencies and non-governmental organizations with innovative processes facilitating role. This competitive pole actor is responsible for investments decisions in public infrastructure, regulations and other factors relevant to innovation in order to provide an adequate framework for harmonious development. Both local and central authorities should understand the needs of businesses in order to make better decisions that promote competitive pole and to remove obstacles to its progress. Thus, the authorities are those that should provide business support mechanisms for obtaining and maintaining their competitiveness and growth. Catalyst institutions are entities specialized in technology transfer and innovation, consulting firms, chambers of commerce aimed at aligning the partners' joint vision and facilitating their interaction level by eliminating certain barriers in

communication and cooperation process. Between these main categories of actors is a complex relationship, thereby creating numerous ways in which a stakeholder can interact with each other. For example, a set of paths can be created between research, development and innovation institutions and enterprises, another between the central authorities and businesses.

Thus, a competitive pole, as showed in the figure above, can be characterized through a complex interactions system that contribute to its dynamics, through an increased speed of sharing knowledge, through adequate collaboration that allows most effectively uses of resources and through a coordination that aligning the interests and actions of different stakeholders.

In a competitive pole, the intelligent enterprise stakeholders may have different perceptions and interpretations on the relationships system which makes their perceived interests differing from one stakeholder to another, and also the degree of interest ranging from low to high. In a low interest case, stakeholders may be inclined to believe that relationship system will increase efficiency and lower operating costs due to internal and external technologies can often be inconsistent and may provide insufficient support for basic process control. On the other hand, a higher level of interest reflects the perception that the competitive pole specific relationships system may contribute on achievement of the intelligent enterprise overall objectives.

Stakeholders perceived (dis)interest normally include several elements and often are based on strategic organizational, financial, technological and behavioral issues (Porter, 2001; Chen, 2003; Bendoly et. al., 2004; Golden and Powell, 2004; Günther and Grote, 2006). All these aspects can't have the same relevance to all stakeholders, so that stakeholder perceptions may differ in terms of power and power relations. For example, a stakeholder with a high power and interest can constrain those actors with less power, in spite of their level of interest. In this paper, we define the concept of power as the ability to exercise the own will on others in order to achieve the desired benefits. Since our study concerns on the dynamic relationship of intelligent enterprise stakeholders we should consider two aspects of the concept of power:

the institutional and procedural one. In such context procedural power is based on the interest of social interactions and institutional structures is characterized by an unequal power representing the external components on the basis of which power is shared between organizations of competitive pole. Thus, we can appreciate that in the context of competitive pole, power is a relational projection having many sources in the sense that a pole actor may have more or less power in relation to the others relevant stakeholders.

4. Conclusions

At intelligent enterprise level, stakeholder relationship management present a high degree of complexity, due to the large number of actors which have many and different interests and perceptions. Intelligent enterprise managers must have an understanding and active monitoring of all stakeholder legitimacy aspects, considering different interests of certain categories of stakeholders in decision-making and operational processes. In the certain decisions and actions case, managers should take into account the interests of stakeholders primarily considered as the most important and those involved in decision-making processes.

Although the stakeholder common interest satisfaction is a survival condition for intelligent enterprise there are still many conflicts interest between different stakeholders leading to decrease of community interests. Because of potentials conflict between the stakeholder interests and the intelligent enterprise business objectives, achieving a balance of this in the competitive pole is often very difficult. The objectives of intelligent enterprise and also of other organizations in the same industry are usually related to microeconomic objectives as a mix of shareholder value, of maximizing profit, of growth, of market share and productivity. In such context, the Government may impose socio-economic goals for an active policy of enterprises, but also some restrictions and limitations.

The major contribution of this paper is to provide a new perspective of the complex system of relationships that exist between the main stakeholders of an intelligent enterprise

within a competitive pole structures by providing a framework structure that can support managers of such organization in assessing and estimating the models reactions and actions required to manage dynamic relationships with its stakeholder, having also the confidence that researching of this topic will be continued and developed.

Marketing vs. Fashion Trend – Between Myth and Reality

Meghisan Flaviu
University of Pitesti, Romania
marketing_mf@yahoo.com

Abstract

This paper makes an analysis of the different methods that marketers use to attract the consumers towards their products. The main research purpose is to focus on fashion from the marketing perspective. Fashion represents the process of social spread which has as result the adoption of a new style by several consumer groups. Fashion or style represents a unique combination of attributes. The system of fashion is made of all the persons and organizations that take care of the creation of symbolic significations and transfer them upon the cultural goods.

Key words: consumer behavior, marketing, fashion trend, advertising

J.E.L. classification: M31, M37

1. Introduction

The field of marketing represents a continuous evolving process. [1] However, the marketing term represented one of the most exciting subjects of the business world within the last six decades. *Marketing 3.0* is the stage in which the companies pass from consumer focus to human values while, the profitability is put into equilibrium with corporate responsibility. The consumer defines the value of the product, but the consumers' needs and wants are different one from another and vary within large limits. The company earns from the creation of a superior value for its clients and partners. The company sees its clients as a strategic point, approaching them and taking into consideration all their aspects as human beings, with a special attention towards their needs and wants. Today's marketers try to reach the consumers' mind and heart. The marketing concept can be seen as a counterbalance to the macroeconomic

concept: each time the macroeconomic environment is changing, the consumer behavior will have the same trend, what leads to a change of marketing. [2]

2. Objectives

The main characteristic of the XXI century companies is not the lack of material goods and services, but the lack of clients. The client is the most important arbitrator of our actions on a short term. It doesn't matter if the client is or is not always right. The truth is more subtle, because not all the clients have knowledge on the technical markets and are always rational. The marketing's role is to lead the market, not to follow it. [3] The consumers from the post-industrial economies evolved in a culture with omnipresent brands in the market with companies continuously fighting to gain more visibility and attract the consumers towards them. [4]

3. Methodology

The marketing communications can have an influence to the consumer's level of self esteem. The exposure to advertising can lead to a process of social comparison. The individual tries to evaluate himself by making a comparison with the persons described in these artificial images. This way of comparison is inherent to the human nature and many marketers take advantage of this tendency, proposing ideal images with happy persons that buy and use their products. A study on the social comparison demonstrated that the student girls have the tendency to physically compare themselves with manikins from the advertisements. Moreover, those that look at advertisements with beautiful women declare themselves satisfied with their body, contrary to those that don't look to this kind of advertising. The advertising that makes reference to self

esteem tries to modify the expectations regarding the products, stimulating the positive feelings towards the “I”. For most of the individuals, *the ideal I* is different from the real *I*, but, for some people, the difference is very high: they represent a perfect target for the marketing that appeals to imagination. The imagination represent a self-provoked derive of the consciousness, which often allows compensating the lack of external stimulation or a breakout from the real world problems.

Each one of us is, in fact, different. We have as many “*I*” as the social roles we play. We act differently depending on the situation, using different products and services and have a different opinion about ourselves, depending on the situation. A woman may need distinctive products depending on her role: a discrete perfume for work, a scented perfume for the nights as “fatal woman”. The product that form the “*I*” is: “You are what you consume”. Let’s not forget that the “*reflected I*” leads to the creation of oneself. This means that the people look at each other in the way they imagine that others see them, with their cloths, jewels, car etc.

Two of the main significant moments from one’s life, the marriage and the born of children, have a more important influence on the women acquisition behavior than on men’s. The married women spend more and buy more expensive things – insurance, new cars, open a new account or buy property titles. Nowadays, the women make the most important acquisitions, even in fields addressed to men: 53% of the investment decisions; 55% of the personal electronics; 60% of the interior design articles; 80% of the decisions for the interior design; over 60% of the new cars; 66% of the computers. The unmarried women from USA are the only decision factors, which mean more than one house holding from four. The women are the ones that take care of the cheques and pay the bills in 85% of the American families. The woman controls the highest part of the house holding’s expenses. The women are now more implied at the working place, are more educated than men and often gain the same or more than the men. Thus, the women earn and own more now, than in any historic period. The women control 51.3% of the private wealth on the USA territory; they

represent 40% of all the business travelers and influence 80% of the family and luxury travels. [5]

The sex identity is essential for the “concept of oneself”. The Brand study’s results show the fact that a percentage of 59% of the Gillette clients associate the “masculine” word to the Gillette brand. The kiss between the singer Madonna and Britney Spears during the MTV Video Music Awards 2003 gala was appreciated “the kiss of the decade” by the customers of the famous Selfridges shops from London. The sex appeals represent an advertising accessory since several decades, often used to sell jeans, cosmetics, perfumes, automobile, drinks, food etc. According to the specialists, nowadays we can see a considerable growth of the open sexual calls, compared to elderly advertisings, which were making only a slight reference to sex. Rio Mare pate has the message: „*Voulez vous Pâté avec moi?*”, a words’ game, with reference to the song lyrics „*Voulez-vous coucher avec moi (Ce soir)?*”.

The gender identity (F or M) represents both a mental and body pattern state. The biological gender of a person does not completely determine the situation of having typical characteristics of gender. Masculinity and feminity are not biological patterns. A man can have a feminine behavior depending on the situation. For the women is the same - Ioana d'Arc. *Condé Nast Traveler* magazine deliberated that Singapore Airlines is the best airlines company. The candidates for the stewardess position had to be at least 26 years old, more than 1.60 meters tall, very thin, seductive and have a perfect skin. The selection included a test in swimming suit to verify the lack of scars. At the end of the year 1990, a new flavor named Stefan Floridian Waters was introduced as a part of the flight experience. The flavor patented by Singapore Airlines could be found in the perfume of the stewardess and the hot towels given to the passengers before taking off, having the potential to create recreating memories. [6] The company has the logo „*Singapore Girl, you’re a great way to fly*”. [7]

An ideal of beauty is a particular model of a physical appearance. The ideals of beauty for men and women can include physical characteristics, fashion style, make-up, hair-style, skin tone and the body shape.

Eventhough beauty is only an appearance, the women put much energy for a touch. They spend much time for artificial tanning and sweat doing fitness. Jane Fonda is present on the market of morning gymnastics videos, beginning with 1980. Today the ideal of beauty for women is thin, soft, but with the aid of miracle products, esthetics surgery etc. As a result of this phenomenon and medical problems of “forced weight loss”, the *Elle* magazine won’t publish anymore anorexic manikins.

4. Analyses

A fashion designer affirmed: “The cloths have to be made by instinct, otherwise it won’t last. Marketing is something collateral. Fashion means change and the people that adopt it have to be always ready for it. Every dress has a moment of its own and usually its future means vintage”. [8] Nowadays, the price is less attached to the cost of the merchandise, but more to the value that the buyer attaches to the remember of the experience. However, the companies have to create reasonable responses to the following questions: What do we give back to the society?; What social investments do we make? What noble causes do we sustain? What charity organizations are enjoying our funds?; What social cause do we serve by our activity on the market?; What is our reputation among the clients and our collaborators?

In many countries, many movements against consumption are put into practice. In United States, the *Adbusters* association promised a day without shopping, a weekend without television and a parody of the advertising spots. Despite all the efforts made by the researchers, regulations and implied industries, *the worst enemy of the consumer is often himself*. He is usually described as a rational decision taker who calmly tries to choose products and services that are in favor of his health and personal wealth, on one side, and his family and society, on the other side. In reality, the wishes, choices and consumption actions have sometimes negative consequences on the fellow humans and the society they live in. Among the harmful behaviors, the excessive consumption of alcohol and cigarettes leads to social pressures, while the cultural value of

money encourages actions such as theft and insurance fraud. Dealing with inaccessible ideals of beauty can provoke frustrations of the “I”.

The system of fashion is made of all the persons and organizations that take care of the creation of symbolic significations and transfer them on the cultural goods. We have the tendency to make confusions between fashion and cloths, but, in fact, the fashion processes affects all types of cultural phenomenon, especially music, art, architecture and even science. For instance, some research themes and scholars are on fashion trend at a time being. Even the commercial practices are subject to fashion. They evolve depending on the management techniques from that period, such as, *total quality management* or *just-in-time stocks control*. Fashion can be considered as a “code” or a language, which helps us descript these significances. Different from a language, the fashion depends on a context. Different consumers can interpret the same element, but in a different way.

Fashion represents the process of social spread that a new style is adopted by several consumer groups. Fashion or style represents a unique combination of attributes. To “be fashionable” means that a reference group positively evaluates this combination of attributes. *Fashion is a very complex process, which operates at several levels.* To an extremity, we speak about a society phenomenon which simultaneously affects several people. At the other extremity, fashion has a very personal effect on the individual behavior. The buying decisions of a consumer are often motivated by his desire to be fashionable. The fashion products are also esthetical objects, which have their roots in art and history. That’s why, the points of view are very different regarding the origin and fashion spread. Some researchers suggest that the fashion of naked waist reflects the importance that our society gives to physical shape.

The model of collective selection represents an example for the sociological approach of fashion. This point of view focuses on the initial adoption of fashion (idea, style, etc.) by a subculture and on further spread of fashion for the whole society. Such a spread begins with the youngsters’ subcultures, such as the hip-hop

segment. Another current example is represented by the integration of the gothic fashion within the dominant current. At the beginning, this fashion was a way for the pariah youngsters to express their rebellion, defying the classical styles with their black cloths, often matched with accessories such as Dracula’s cape, trousers with fell down back, collar with buttons and lips with black lipstick. Other examples: *Emu* and *punk* music. Today the Virgin stores propose boxes with food for vampires, while the mall shops sell crosses and black lace mantilla.

The diffusion theory evoked by Georg Simmel (1904) was one of the most influent approaches for fashion understanding. She considers that there are two forces of conflict, which lead to fashion evolution. First of all, the inferior groups tend to adopt the statute symbols of the groups that preceded them, so as to enter into the social scale. The dominant styles have their origin in the superior classes and spread themselves within the downside part of the society. At the same time, the second force comes in; the persons from the superior groups look constantly to what happens in low level social groups, to be sure that they are not imitated. These persons react to the temptations of imitation from the part of inferior social classes by inventing more recent fashion. *These two processes generate a continuous cycle of change, being the engine that makes the fashion move.* The whole range of expressions used by youngsters that entered into our vocabulary shows how people that create models have a resistance to their adoption by the dominant trend. This fact is not so simple in our days. In the contemporary occidental society, this approach has to take into consideration the new mass culture evolution, which has to be changed. A new approach based on the class culture can not take into consideration the whole variety of existing styles at the same time within today’s society. The modern consumers have an individual degree of choice superior to those from the past, due to the technology progresses. It is sufficient to watch TV to be instantly informed with the last tendencies of fashion. The elite fashion was replaced by a mass fashion, because the mass-media exposure allows the numerous groups to be informed by a style-line of fashion at the same time.

We must appreciate the fact that fashion has the tendency to develop following a predictable tendency. The life cycle of fashion is very similar to the product’s life cycle. A product or an idea progresses in elementary phases, from the beginning to its end. To understand the functioning of this process, let’s take the example of the acceptance of fashion in music industry so as to understand the functioning of this process. In the introduction phase, a song is listened by a small number of music innovators. It can be diffused in clubs or transmitted by several radio channels. Thus, “grunge rock” groups appeared, such as Nirvana and the MTV success of the singer, *Inna*. During the acceptance phase, the song has much social visibility and acceptance from vast segments of the population. A disk can be widely diffused on radio channels and constantly lift up into the Top 50 classification. In the decline phase, the song reaches the saturation point, because it has been too much listened and ends up by being forgotten. A title of success can be played every hour on a radio channel for several weeks or months (e.g. Kiss FM or Radio ZU). At a time being, the listeners get bored by the song and focus on new disks. The models are characterized by a slow acceptance at the moment of launch, which (only if fashion “sticks”) rapidly accelerates, reaches the top and then calms down.

5. Conclusion

Many marketers have to confess that if they had to tell the truth, deep in their hearts, on the top of their priority list, the consumers are never present. It is possible that the applied marketing in their company may be guilty for this decline of consumer’s trust, but there is still the marketing (as theory and practice) which has the best chance to solve this shortcoming. [2]

We, as human beings, have autonomous powers that we add value to the world and, at the same time, extract value from this world. Within this context, our moral, individual and collective mission is to cultivate the understanding, to have a job which helps us make a better world that the one we have found, taking into consideration the limits of our creativity and capacities. That’s why the moral initiative through business needs

equilibrium between the practical and moral considerations. [9]

Possibilities for improving the performance of organizations using the Balanced Scorecard

Miculescu Corina

*Christian University „Dimitrie Cantemir”, Faculty of Management in Tourism and
Commerce, Timișoara*
gmccorina@yahoo.com

Abstract

Current economic context in which organizations act has changed a lot, the current environment is characterized by globalization, increased competition, rapid changes, market segmentation, changes in technology, demand volatility, important information. Economic environment influences the organization in various ways, affecting strategy, structure, and control system performance. If for any company is performance, then management tools should pay attention how it is built by the interaction of environment - strategy - structure. In this context, an important system that supports decision-making within organizations is the technique Balanced Scorecard.

Keywords: performance, value, strategy, balanced scorecard.

Classification J.E.L.: D63, L26, M10.

1. Introduction

As a result of changes occurring in the economy, both globally and nationally, process management organizations appears to be the very complex at all levels. In this context it becomes strictly necessary to seek the most appropriate methods to conduct business activity in terms of competitiveness and profitability. This involves carrying out organizational activities suitable to enable the most efficient use of modern management methods and techniques. Such an enterprise management approach can be achieved but only under a suitable information support whereas decision making involves a lot of information to be developed, provided, interpreted and rigorously controlled.

Modern society relations shows that with the development of market economy and its

increasing complexity has to develop appropriate that area, content and efficiency and economic information so that it can provide the necessary decisions, can reflect accurately achieve objectives of financial entities and economic results. Economic information helps us to see the use of human and material resources, to grasp and to critically examine the positive aspects and weaknesses in order to take necessary measures.

In this respect, support decision making, wine tools of performance management. They reflect the organization's understanding of the relationship between the strategic, operational and financial performance skills, serve as communication, implementation and strategy development organization. The most famous system of measurement and performance management represents mainly Balanced Scorecard (BSC).

2. Conceptual Approach to Balanced Scorecard

Balanced Scorecard (BSC) first appeared in the U.S. in the early 90s, the bases being established by Robert S. Kaplan and David P. Norton, who were concerned about finding a performance evaluation tool based and non-financial indicators. This was due mainly to insufficient information provided by financial indicators, on the one hand the historical nature - are oriented entities' past actions, on the other hand provide little information about the future - are useless in cases the financial consequences of a chain of actions underway appear long after the reporting period. For example, managers behavioral consequences resulting from the use of financial indicators can in improving short-term performance but not long term.

Thus, in the early 90s, the concept of Balanced Scorecard approach was the sense

of generating a performance report by grouping of performance indicators by business prospects, of which the most common are: Financial, Customer, Internal Processes, Learning and Growth.

Starting from the fact that the implementation strategy of the organization hangs often when implementing the action plan, the authors proposed to remove this blockage by measuring and monitoring strategic objectives consistent with a scoring tables ("Scorecard") and the implementation of concrete policy initiatives, for each strategic objective, elements are grouped into perspectives that reflect aspects considered key to the success of the organization.

Consequently, the Balanced Scorecard has been constantly evolving from a simple performance measurement tool to a strategic performance management system organizational performance using strategic and operational plans as the basis for individual communication, monitoring and improving organizational performance become one of the most used management tools worldwide.

Currently "Balanced Scorecard is a strategic planning and management system that is widely used in business, government and nonprofit organizations worldwide to align business activities to the vision and strategy to improve communication internal and external and monitor organization performance against strategic goals "(Balanced Scorecard Institute, 2010).

3. Balanced Scorecard - support the organization's performance

BSC was designed as a set of indicators, financial and non-financial, showing building and inter-enterprise performance by balancing the four forces, using a cut-based organization processes and activities. At the BSC are two *principles*:

- The strategy must be known, followed and applied at all levels of the organization.
- Modern organization is a network of relationships between the company and interested partners. They are interested in business performance and act on it.

Thus, Balanced Scorecard considers the entity's ability to adapt to environmental resources and depending on which strategy is defined as a set of interrelated activities and

processes. Are envisaged:

a) connection BSC to strategic intention - is considering in turn the following points:

- *financial perspective* - increasing the value of shares held by:
 - *Increasing revenue* (penetration of new markets, new products, attracting new customers, increasing sales to existing customers);
 - *Increased productivity* (reducing direct and indirect costs, more efficient use of assets by reducing working capital requirements);

The two strategies are explained by the fact that the purpose of any business is profit, thus leading to a focus on revenue and expenditure. The two strategies are merely detailing the potential for increased revenue and reduced costs in order to maximize results.

- *customers perspective* - expresses the target customers and consists of "indicators showing the results of a strategy well formulated and implemented" (Kaplan & Norton, 1996), such as customer satisfaction, attract new customers, retaining customers, their profitability and the target market segments. The target customers are "attributes offered through the company products and services to create loyalty and satisfaction in target customer segments." Made by many implementations of BSC, Kaplan and Norton have identified the following sets of attributes for the target: the attributes of the product/service (uniqueness, functionality, quality, price, time), customer (service, reliable), and image and reputation. Subsequently,, the authors distinguish between value proposition through operational excellence, near customers (customer intimacy) and product superiority (product leadership), companies choosing to excel in one of the three, keeping the others constant. Operational excellence involves low prices, quality, reduced time delivery, customer proximity means quality relationships with clients (excellent service) and product superiority focuses on functionality and features.
- *internal processes perspective* -

identifying processes that entity must excel (creating new products and customers, increase the value provided to the customer, operational perfection and create a social environment free of stress) show processes that an organization must excel to deliver the proposed value to customers and shareholders to meet expectations. This perspective takes the concept of "value chain" from Porter that divides the innovation cycle, operations cycle and after-sales services cycle. The difference between BSC and traditional approaches focus on processes consist of strategic importance, not only improving existing processes. Identified four important processes to be followed in this perspective: developing new products and attracting new customers through innovation, customer value by improving relationships with existing customers, obtain operational excellence and transformation in an organization-good citizen by developing appropriate relationships with external partners.

▪ *development and learning perspective* - expresses the changes and improvements entity must use long term to ensure the achievement of its vision. This perspective identifies the infrastructure you need to build the organization to sustain long-term growth and improvement. Competition and environment features require companies "to constantly improve skills to provide value to customers and shareholders" (Kaplan & Norton, 1996). Learning and development comes from three sources: people (watch for satisfaction, rotation, training, skills) systems (availability) and organizational procedures. This perspective is "the foundation of any strategy" (Kaplan & Norton, 2001), and managers define here competences and skills, technology and climate necessary to support strategy. At the same time, the focus on intangible assets, which are divided into human capital (relevant informational capital (information system) and organizational capital (the firm's ability to mobilize and sustain the change process required by the strategy). The four perspectives provide a balance between short term goals and long term

between desired outcomes and the factors that lead to those outcomes, and between tangible objectives and intangible effects.

b) cause-effect relationship can be explained using constructions like "if - then". These relationships help using concrete terms and strategic mapping (strategy maps). The role of strategic maps is to develop performance targets and indicators related to strategy. Kaplan and Norton (1996) define strategy as "a set of assumptions about cause and effect." Highlighted in "strategy maps" cause-effect relationship requires consideration of the following type of causal relationship:

- Indicators of growth and development;
- Indicators of internal processes;
- Indicators of customer perspective;
- Indicators of the financial perspective.

Be drawn up "strategy map" - complete logical structure that describes an entity's strategy and involves the destination (goals) and trace all routes (actual strategy) that could lead to the destination set.

Cause-effect relationships are built realizing ways that can influence the final results and identifying tools by which they can evaluate the action. Occurs analyze business activities in view, on the one hand, chaining them and, on the other hand, seeking the way of value creation. Identifying cause-effect relationships "translate" strategy and facilitate internal dialogue. Causal relations must include all perspectives and be linked to financial objectives.

c) BSC ability to be used as an instrument to measure strategic management and organizational change involves:

- Transposition vision - gives managers the opportunity to reach a consensus on the vision and strategy;
- Communicating and linking strategy to strategy - allows managers to communicate to all departments in the executive management strategy;
- Integration planning ("business planning") - allows managers to adapt to the chosen strategy plans and budgets;
- Feedback and learning - strategic learning.

To ensure performance measurement function, BSC uses two types of indicators:

- ♦ execution indicators (or outcome, lag indicators) - are measures of the outcome of past actions;
- ♦ indicators flight (or driving, leads indicators) - are financial and non-financial measures that signal (indicating) the result of future operations.

These indicators help identify opportunities and prevent mistakes being called strategic indicators.

To be a strategic management system, indicators should be linked to strategy and, moreover, to provide notification. Indicators provide a balance between financial and non-financial performance and between efficiency and effectiveness for its size.

BSC implementation involves the following *principles*:

- Translated this strategy into operational terms;
- Align the whole organization to the strategy;
- Strategy is the responsibility of all members;
- The strategy is an ongoing process;
- Mobilization executive management to promote change.

Recent studies conducted worldwide by Bain & Company (2009) places Balanced Scorecard in 6th place in a top of the most commonly used management tools globally. According to the same study, 53% of surveyed companies use Balanced Scorecard, with an average satisfaction of 3.85 out of 5.

4. Advantages of Balanced Scorecard in an organization

Balanced Scorecard (BSC) was developed as a tool for strategic management of a company. The biggest benefit offered by the organization that is implementing higher efficiency through consistent pursuit of the objectives set. Consistently advance the organization's goals are achieved by performing step strategy content. BSC can be successfully used for communication strategy and public employees and management team by presenting actual values of performance indicators than planned. BSC can play an important role in motivating employees to implement strategic initiatives as the contribution of each initiative to

achieve targets is clearly defined and transparent. Motivation can be improved by an appropriate system of incentives associated system objectives. It is recommended that this motivational system is introduced after 1-2 years of BSC implementation or after acceptance by employees of the new instrument. Another advantage is that view strategic objectives and relationships of cause - effect relationship between objective supports communication strategy as strategic objectives can be better understood and coherence of the organization is more easily secured, verified and proven. In addition, transparent representation of BSC strategic content strategy fosters acceptance and increase motivation in achieving it. When an organization implements a management tool to control the balance of cost/benefit is vital. The decision to implement a system based on the Balanced Scorecard requires a similar analysis. Costs of implementing a new tool is relatively easy to measure, but often there is a lack of reliable information on the potential benefits. Some of the major benefits that come with a successful implementation of a strategic performance management system based on the Balanced Scorecard are:

- focus on organizational strategy and translate into concrete actions that can be executed;
- improves organizational management by reducing costs and improving productivity;
- helps to align all activities and resources of the organization's strategy;
- improves internal and external communication - communicate at all levels of the institution's strategy and vision and strategy become more clearly delineated for all members of the organization, enabling efficient ownership of the strategy at all levels;
- demonstrate responsibility and generate results;
- help monitor strategy execution and allow - often first real implementation and enforcement strategy continuously.
- visibility provided by the Balanced Scorecard supports better decisions and faster on a budget and control processes in the organization;
- produce information does not produce

- data;
- allow and encourage change;
- provide recognition of individual merit and team learning by facilitating the link between performance and reward and trust.

5. Conclusions

BSC has evolved from a tool for performance measurement to strategic management system and then the tool change. BSC contains a description of what the organization is trying to achieve strategic objectives (medium to reach your destination in time), seen as a model of strategic ties (strategic linkage model) encourages systemic thinking. BSC analyzing characteristics and stages of evolution of the tool, looks like:

- Establishing indicators in perspective is subject to the performance measurement;
- Transformation strategy objectives, declining the organization, strategic allocation of resources and strategic learning management system is a strategic strengths;
- Knowledge management makes it a communication tool.

BSC focuses on how to create value. This guidance is based on a definition of performance to the value. BSC help manage internal and external environment of the organization, ensuring:

- Internal environmental management through continuous improvement through support to implement complex strategies to control an organization with a degree of decentralization by supporting learning and organizational change.
- Managing the external environment by observing demand, competition, the supply chain analysis and relationships with partners.

In this respect, the BSC can be implemented in an organization in one of the following purposes:

- To improve system performance - involves improving performance by managing current processes;
- As a strategic management system - is more than superior results because it provides a better strategy by refining its
- The external accountability tracking system - complete internal orientation of

the first two approaches with attention to the external environment. This system allows better incorporation expectations of external partners and discovery learning.

Given that performance is seen today not only economic, but also social and environmental, BSC can be used in pursuing sustainability, looking surprised by the Sustainability Balanced Scorecard concept. Linking Strategy sustainability principles through BSC determines the traceability performance of four social and environmental dimensions: environmental, health and safety, employment practices and investment in the community.

The Background of the SME - SMP Relationship

Mihu Stefan

Spiru Haret University of Constanta

Abstract

In understanding the role of Small and Medium Practices (SMP-s) in providing business consultancy to the Small and Medium Enterprises (SME-s), it is important to establish the general background against which this important role is played. The SME-s have nowadays a critical importance for most of the developed and developing economies. For instance, in the European Union, the SME-s contribute over 99% of the overall number of enterprises and 100 millions of working places, representing 67.1% of the working places in the private sector. The existing theories and evidence demonstrate that the SME- owners and managers outsource the consultancy and support services, mainly due to lacks in their corporate resources. The prerequisite that the SME-s have certain competencies in order to survive in a permanently changing environment and purchase resources for consultancy and support is the main approach for their surviving and development. This shortage of resources and the ever-changing environment the SME-s must cope with create the role of SMP-s as main business consultancy. The type, nature and future of this role are an issue still open to debate.

Key-words : professional accountants, accounting market, consultancy services, conformity services, accounting regulations.

J.E.L. classification : E 62

1. Introduction– The SME – SMP relationship, defining features

From the perspective of the demand for consultancy and support, it is generally known that the SME-s resort to professional accountants' services in order to conform to the provisions of statutory audit and taxing (IFAC, 2008; Council for Professional

Supervision, 2009). The researches also point to the fact that the SME-s and the dynamic nature of this market (Gooderham et al., 2004). In truth, the evidence shows that the professional accountants are, invariably, the most frequently used source of consultancy among all the consultancy services providers in the public and private sector, even if not necessarily the first choice of SME-s. Although the conformity dispositions vary among various jurisdictions, it is often supposed that the importance of the accountants in the external relationships of SME-s is universal. How universal these outsourcing behavior patterns, remains an open issue. Unavoidably, there will be certain variations among the SME-s. For instance, among the larger SME-s, there often rises the argument that their resources are not so very limited and they do not resort to outsource accountancy very often as they are able to hire their own accountant, for the management remaining only to address other strategic and operational issues.

However, the SME-s market is, also, very dynamic. The market conditions and the regulation environment in which the SME-s operate are perpetually changing and, as a corollary, the demand for business consultancy services as well is to register a development. The modifications of governmental regulations in dispositions of statutory audit are, probably, the main problem, but the demand for consultancy and support services is also influenced by other factors, such as the requirement of observing other provisions, as well as the need to cope with threats and market opportunities. These are new challenges and opportunities for the service and consultancy providers. The accountants have a strong hold of their place in meeting the SME-s needs, however it is important that the consultancy services fulfill their aim, be relevant, opportune and of high quality.

The SME-s form a heterogenic group, with various sizes, ages, sectors, places and

growing tendencies, as well as owners-managers with various skill and motivation. Such characteristics inevitably influence the type of outsourced services they are to resort to. Also, the statutory dispositions and the regulation regimes in which the SME-s operate have changed in time. For instance, in certain jurisdictions, although there have been a relaxing of the provisions on statutory audit, there were modifications of the regulations on the environment. In spite of the actions for relieving the “burden” of regulation on SME-s, the consultancy and support market is substantial. In UK, for instance, it is estimated that the enterprises spend at least GBP 1.5 billions for support on the purpose of conformity with the regulations (Department for Business, Enterprise and Regulatory Reform -BERR, 2007).

The accountants, and mainly the SMP-s, attempt to provide consultancy to the enterprises in this environment and on this dynamic market. Consequently, the consultancy market, derived from the regulations affecting the SME-s, is perpetually changing. Considering the modification of the market conditions for consultancy, many professional accountants have undertaken to provide a larger scope of services for SME-s. This has had major implications for those accounting practices attempting to offer services for SME-s. In time, the scope and type of consultancy provided by the accountants has developed both towards meeting the needs of SME-s, and in accordance with the strategic intents of the accountants.

It is often supposed that an overwhelming majority of the accountants deployed by SME-s are small and medium accounting practices (SMP-s). The SME-s-SMP-s relationship is thus regarded as a necessary relationship, as the SME-s are supposed to produce the documentation required for conformation with the governmental regulations, for instance audited financial reports, and they will resort to SMP-s to have those records compiled. The researches have also proved that the relationship SME-s-SMP-s, established as a result of the conformity works, has as well the potential to generate the provision of other consultancy and support services than those related to conformity.

Although, it is widely admitted that a significant proportion of the clients of the large -“Big Four”- and medium accounting practices are SME-s. The extent of their involvement varies, however, depending on the nature of the accounting market and of other services for enterprises in various jurisdictions. There is a higher likeability that such practices avail of resources and benefit from scale savings for generating the services and products to satisfy the needs for accountancy and other forms of specialized support of their customers. On the contrary, the SMP-s have few resources for supplying all the services and products required in order to satisfy their needs. The objective of this work is represented by SMP-s, as they have a far more restricted capability with regards to providing on their own the human resources required to satisfy the needs of their SME-customers.

Whether or not the SMP-s succeeded in answering the changing demand for consultancy, this remains to be seen. For instance, the SME-s may resort to SMP-s for consultancy in other issues than those regarding the conformity, including aspects related to planning and succession. Also, they may resort to their accountant to help them in other aspects as well, as regulations in the field of health care, of safety or of environment. This may be cost-related as well as relying on an already-formed relationship.

However, the SME-s-SMP-s relations may be underdeveloped, rather the result of a strategy change than a strategy of SMP-s in itself. Thus, there may be room for the SMP-s to develop, in order to expand and deepen their relationship with their SME-s customers, beyond the conformity related services. In other words, as we have previously highlighted, the market for counseling and support is perpetually at change as a result of the market dynamics and the regulation dynamics. The fact that the SMP-s are or are not able to fulfill those new requirements and to turn from supplying the conventional audit and fiscal services towards becoming multilaterally developed business counselors may be a challenge. This strategy turn may be rather an issue of necessity than one of option for the SMP-s, as the market of basic services becomes more and more competitive in some jurisdictions.

The accounting industry has undergone dramatic change in supplying statutory conformity activities. For instance, in U.K., gradually, the number of audit companies registered is in decline. The overall number of audit companies registered in 2008 (8.179) is by 25.7% smaller than in 2003 (11.006). Consequently, in terms of income from fees for many accounting practices, the image has also changed. Again in the U.K., in the last five years, the “Big Four” have registered a constant increase from activities other than auditing for non-audit customers. By contrast, the income from the fees originated in other activities than the audit for the audit customers decreased.

The background of this work is, consequently, the changing environment and the implications for the accounting practices, mainly the small and medium size practices, as being the main sources of counseling and support for the SME-s. Against this larger background, the following section will establish the specific objectives of the work and then provide a detailed analysis of the literature and evidence regarding the relationship between the SME-s and the SMP-s.

2 – Definition of small and medium enterprise (SME)

World-wide, there are several definitions of what is a SME, having the tendency to use the same estimation regarding the working places, turnover and basis of assets. For instance, the European Union defines a SME as consisting of an enterprise which employs less than 250 persons (1-9 micro, 10-49 small , 50-249 medium) and which has a yearly turnover not exceeding EUR 50 millions and/or an annual balance not exceeding, overall, the amount of EUR 43 millions (UE, 2005). In USA, the threshold for the number of provided working places is of 500 persons, the small companies employing 100 persons (SBA, 2009). IFAC has chosen to define the small and medium enterprises (SME-s) as “entities regarded to be of small or medium size referring to quantitative features (e. g., the assets, turnover/employees) and / or qualitative features (e.g. the concentration of ownership and the management of a smaller number of persons). What an SME is, differs depending on the country.” (IFAC, 2010)

2.1 – Definition of the small and medium practice (SMP)

SMP is a less known term than the SME, despite the fact that it is usual among the accounting bodies, especially at international level. Although to provide an accurate definition of a SMP at world level is difficult, IFAC has chosen to define the SMP-s as being those “accounting practices the customers of which are mostly SME-s, mostly outsourcing in order to supplement their internal technical resources and including a limited number of professional staff. What an SME is, this depends on the country.” (IFAC, 2010)

A basic reason for defining the SMP-s is to provide a distinct character and an identity over the small entities and large accounting organizations (the “Big Four” included). The distinct nature of SMP-s ensure a basis for the associative-type organizations, such as IFAC, and the regional organizations, such as the Confederation of Asian and Pacific Accountants (CAPA), which provides resources by services and products for various groups of interest within their organizations and which, subsequently, may estimate the amount of resources supplied by such groups. Moreover, many organizations ensure an important lobby for the profession and counseling in the name of the SMP-s, make at the government and at the regulation bodies at national and international level. In the case of IFAC, the SMP board has been created by the IFAC Council in order to represent the interest of the professional accountants who work in SMP-s and of other accountant professionals who provide services for the SME-s. The board investigates the modalities by which IFAC may meet the needs of the small and medium practices, the customers of which are in their majority, SME-s.

3 – Methods of researching the literature and of collecting the primary information

This work is based on an extensive analysis of the literature, and following an initial identification of a clear basis of “lacks”, on a series of interviews with accountants. Searching the literature which

constituted the main foundation for this informative work, involved the examination of the contents of a series of databases, additionally copies of books, monographs and pertinent reports for the targets of the analysis. The database includes: Google, Google Scholar and the Athens databases, which cover world-wide sources.

The research elements included a variety of term uses: SME-s, SMP-s, consultancy in the field of accounting, services. The researching process was conducted in the months August and September 2009 and involved a large number of iterations and checks in the research. However, using those search terms with regards to the SME-SMP relationship, the literature yielded relatively few items as compared to the large searches achieved for the SME-accountant relationship. As in other studies about the relationship SME-accountant (Samujh and Devi, 2008), the research established that the largest part of the literature was Anglo-Saxon and derived from sources in U.K., Europe and Australia.

The six audio interviews recorded with accountants from various countries were conducted between December 2009- January 2010. They have been conducted on the purpose of analyzing certain issues arising from the literature, to provide additional detailed evidence regarding the points of view of the SMP-s accountants on the changing nature of the relationships they have with SME-s in various jurisdictions. The interviewing practices were undertaken from Brazil, Italy, Malta, Romania, Sweden and USA. All the interviewed persons were partners within their organization and all but one were a small or medium size practice. The interviews took between 45 and 90 minutes. Obviously, the results in such a field should be regarded in a prudential light due to their limitations with regard to the capability to elaborate defined or cogent generalizations. Nevertheless, the interviews allowed for the collection of exploratory-type evidence which was presented in the section intended for study specific questions.

Collectively, the analysis of the literature and the original evidence presented represent the fundament for a summing-up indicating where we are in our knowledge basis, highlighting every hiatus, thus providing

information for a subsequent research agenda.

3.1 – Literature on the SME – accountant relationship

The literature on SME-accountant comprises fields such as academic, governmental and of the specialty. In essence, there is a vast collection of literature which took into consideration the various aspects of the SME-accountant relations. There is as well a large bulk of marketing information and literature from accountants and accounting professional bodies, an extensive part of which is available on the web free of charge. The examples include ACCA (2009) and links towards these websites may be found at the address: http://www.ifac.org/PMM/relevant_links.php.

In the literature, the specific term of small and medium practice (PMM), as previously mentioned, is rarely used and only recently it spread among the professional bodies, and it almost entirely lacks in the academic literature. For instance, a search in Google Scholar generated only 267 results by the search term SME SMP accountant and the largest number of results in this search were irrelevant or tangential to the study. The search generated only 35 results for the period 2006-2009.

Notwithstanding, roundly there is a substantial amount of literature regarding the SME-accountant relationship, covering the devised and empirical analyses. In this analysis, we will classify the literature in the following categories:

- the category attempting to understand the demand for business consultancy offered for SME-s by the accountants;
- the category providing an examination of the consultancy supply from accountants and SMP-s.

Following this analysis, the hiatuses in the literature and the implications for future researches will be determined on the purpose of identifying the need to collect primary data and to develop subsequent research activities.

3.2 - The SME-s demand for business consultancy

In examining the demand for outsourced business consultancy and support for the SME-s from SMP-s, it is important to present the larger picture of the business consultancy which the SME-s look for. There is an increasingly comprehensive literature on consultancy motivations and activities looked for by the owners-managers. Basically, this literature points to the behavior of the owners-managers, which is reticent or circumspect, to the best, in the readiness to resort to consultancy. The causes for this have many valences, thus

Curran and Blackburn (1994) have found that the owners-managers have the tendency to wish to “deal with it themselves” rather than expose their issues to strangers, illustrating the mentality of “fortress enterprise”. The reasons for this were based on the psychology of the owners-managers, a need to, stand on their own feet“, and to avoid any display of weakness; the opportunity cost and the financial costs for resorting to business consultancy; and the often raised point of view on the quality of business consultancy, as being more often than not irrelevant or defective. Such findings are also supported by Shaw (2006).

However, as shown, „...the development of the business services was spectacular in most of the countries“ (Bennett and Robson, 1999: 155), and the market for consultancy and business support is rich – drawing agents from the private and public sectors. It is arguable whether this helped subsequently encourage the demand for counseling. However, it is likely that the scope and quality of the available counseling services be the result of an increasing demand, derived from the need for information of the SME owners-managers on the purpose of fulfilling their day-by-day regulation obligations and their strategic challenges.

Previously, there had been a strong consideration that the SME-s required external support and counseling, following the lack of internal expertise. This is mainly the case when there are changes within the enterprise, such as the growing, the succession or taking-over, or an alteration in the external environment. The research revealed that a major incentive for external counseling of the SME-s was the increase in quantity of the governmental regulation and the demand of SME-s’ customers for

monitoring and quality control. This is not only restricted to the financial conformity. A number of studies have identified an increase in the number of regulation (e.g., the Research Center for Small Businesses, 2005), and this has generated a secondary demand for external counseling and support, as with the regulations regarding the environment (Open University, 2009).

4.- Conclusions

By employing the qualitative approach and by conducting interviews with 16 company general managers and 14 accountants, Marriott et al. (2008), the conclusion has been attained that the SME-s would resort to their accountants for a series of financial management services. However, opposing opinions were revealed, issued by SME-s and accountants, on the usefulness of the financial consultancy for businesses. In this report, the managements of the SME-s would treat the professional qualifications as being less important than the personalities and the opportunity of the consultancy and support.

Burke and Jarratt (2004) have reached the conclusion that, usually, the accountants were employed for fiscal aspects, reporting practices and decisions regarding procurement, but there is the tendency that they be consulted on strategy only after the event had occurred. In other words, the accountants were not treated as credible consultants on strategies issued.

By contrast, Deakins, Logan and Steele (2001) have reached the conclusion that the decisions on financial management are often dynamic processes and are based on the relations with external consultants, accountants included. Such relations are considered to be essential during the initial stages of business development.

Obviously, it seems that there the evidence is mixed regarding the competence of the accountants related to the scope and type of providing conformity or non-conformity consultancy for SME-s. Attempting to reconcile this contrasting evidence basis, it is possible that a number of experiences exists, connected with the diversity of the SME-s needs and with their particular experience in the relationship with their accountants.

This analysis made us infer that, the farther from providing statutory financial services an accountant, the biggest the challenges the accountant faces. Even when there is a previous relationship, the accountants have to convince their customers of their experience and competence in the non-conformity services. Moreover, they will be in competition with other consultancy sources, public as well as private, in the circumstances when they are outside the “comfort zone” of audit and financial consultancy.

Finally, it seems that there are few evidences of the benefits and drawbacks of the SMP-s in point of technical competencies, beyond providing non-conformity services. However, it is likely that this internal capability of theirs to provide technical consultancy for a variety of business operations (for instance, the

management of human resources, planning of succession, marketing) be limited as compared to the larger practices.

Tourism Competitiveness and Destination Branding - A Theoretical Approach

Morar Doriana

Cotîrlea Denisa Adriana

“Babeş – Bolyai” University of Cluj Napoca, Marketing Department

dorianamorar@yahoo.com; cotirlea.denisa@yahoo.com

Abstract

The present article was written in order to provide an overview of the theoretical approaches considering competitiveness and differentiation in tourism industry. Also, it emphasizes the importance of competitive advantages in destination branding, their connection and their influence on the size of tourist flows in different destinations.

Key words: competitive advantage, destination branding, competitiveness

J.E.L. classification: L83, M39

1. Introduction

Considering the present context, in which the globalized economy requires fierce competition both on national and international markets, obtaining economic benefits represents an essential factor for the economic development of a region/country. Relating to tourism industry and taking into account these conditions, it can be said that any differences can represent critical elements in achieving economic advantages over competing regions/countries. Because of this, destination branding should become the main target of local authorities, considering the fact that “[...] place branding is an integral part of contemporary place competition” [8] and, thus, of the regions/nations battle for success, development and economic advantages.

The concept of tourist destination competitiveness seems –at the first sight– easy to understand: it represents the qualitative and quantitative superiority of one destination when compared to the existing and potential competitors. Still, its complexity comes to light when trying to define or measure it.

The competitiveness of a destination represents one country’s ability to create more values, thus enhancing national revenues through asset, process and proximity management in a social and economic model, taking into account the destination’s natural capital and its preservation for future generations. [1]

Some authors define competitiveness as “a country’s ability to maintain their rank on the market and to improve it in time. It is a general concept, including price differences related to exchange rate modifications, the productivity of various tourist industry components and other qualitative factors which affect the appeal of a certain destination” [14].

2. Destination branding through the important factors of destination competitiveness

Understanding the sense of “tourist destination competitiveness” implies the inclusion of the entities participating in the tourist “product” creation [6]. Michael Porter states that “[...] success in international competition depends on economic power under the influence of different factors such as the overall demand, corporate strategies and competition itself”.

In order to create and develop a destination branding process, the local authority needs to:

- delimitate the interest of tourists for that particular geographic region;
- analyze the characteristics and functions of the destination that is going to be branded;
- compare the potential destination brand to other existing similar destination brands and emphasize the differences existing between them;

- understand and anticipate which and what represents the main attraction for the potential tourists, why and how can it be capitalized;
- which are the factors that can influence competitiveness in tourism field and how can their influence be measured.

In order to make an idea regarding the last requirement mentioned, it should be remembered that in their recent research, Enright et. all [6] divided influential factors into six categories: input, industrial demand and the demand for consumption, the cooperation and competition between enterprises, the industrial and regional crowding, the internal and strategic organization of companies, and the social institutions and structures.

On the other hand, other authors mentioned that there are four main factors which influence competitiveness when speaking of tourist attractions:

- *Basic resources and attractions* – the main element according to which tourists prefer one particular destination or another: physical factors (sights, climate), culture and history, connections within the market, special events and the structure of tourism (accommodation, meals, transport and main attractions);
- *Backup factors and resources* – infrastructure, accessibility;
- *Tourist destination management*;
- *Quality determinants* – factors that can negatively modify the influence of the other's three: location, total cost and security; all this are not controlled by the tourism industry, but play an important role in destination competitiveness.

What is easy to see is the fact that all the factors mentioned before lead to differentiation. This can be perceived as designing a particular offer that is unique in a specific domain. Emphasizing the competitive environment in which firms operate in tourism industry, it can be said that quality represents a vital mechanism in order to acquire competitive advantage.

It is important to note that –while products are consumed–, services are experienced. Because of this, taking into account tourist services, in order to differentiate from competitors, an enterprise must fulfill its customers' needs by offering

them high quality services, experiences and feelings. The greatness of tourist services providers is needed in order to brand a destination.

An existent model in the literature sustains that the quality of tourist services must be appreciated taking into account five different factors [2]:

- reliability – the ability to provide professionally and correctly the promised services;
- tangibility – the visibility of the facilities (physical equipment, human resources, practical means of communication);
- promptness – willingness to help customers and provide prompt services;
- safety – employees' professionalism and kindness, but also their ability to inspire trust and confidence;
- empathy – providing individual attention to customers.

Other factors influencing decision making are: the popularity of tourist offers, the increased incomes, and the development of infrastructure, faster airplanes and marketing efforts of new competitors.

In order to be competitive, a destination must utilize its resources, advantages and opportunities within the surrounding environment in order to provide *value*. For evaluating the emerging opportunities from the marketing environment, marketers may utilize the Marketing Opportunity Analysis (MOA) [5]:

- Can the advantages deriving from this opportunity convince the target segments?
- Can the target segments be traced and 'touched' through the use of communication and distribution means at low costs?
- Does a specific destination benefit from resources capable of offering benefits which are of interest for tourists?
- Can this destination provide tourists with benefits better than the existing or potential competition?
- Will the investment return through the number of tourist visits?

Threats can be classified according to the intensity of the potential negative impact and the possibility of apparition.

When analyzing the strengths of a destination, is important to consider the existent threats, in close connection with the

strengths of the competition. Moreover, weaknesses analyzed according to the competition underline the vulnerability presented by a specific destination.

2.1. The importance of determining tourist destination competitive factors

There is an abundance of factors which affect and measure competitiveness in tourism field. Although those factors can be grouped by taking into account various models and sets of values, similarities can be observed. To that extent, it can be stated that the studies and analyses from the literature focuses on the manner in which each individual factor influences competitiveness – and, thus, the appeal of a tourist destination.

Still, it is difficult to determine the importance of the considered factors, because each of them can be associated with a wide series of indicators that are difficult to express. As an example, understanding the relative importance of a destination when referring to “climate” compared to “tourist image” or “the value reflected through costs” still remains somehow unclear.

Even so, researchers have tried to measure the importance of individual factors related to the competitiveness of a particular country.

Gooroochurn and Sugiyarto’s study determined the creation of the *Competitiveness Monitor*. The two authors applied an analysis in order to determine each factor’s share/contribution within their model. The results stated that “social and technological indicators have the largest share, whereas human tourism and the indicators referring to the environment have the smallest shares” [7].

Enright and Newton have classified competitiveness factors related both to tourism and business environment, utilizing one specific case (Hong Kong); both sets of indicators were adapted to urban tourism. The results conferred by the study shows that some factors related to the business environment were perceived as being more important by the participants (practitioners from the tourist industry) than the factors concerning tourist attractiveness. All factors concerning tourist attractiveness were considered to be relevant, indicating the fact that tourist competitiveness models the

researchers embraced are truly consistent in the respondents’ view [6].

Considering their study report, after studying 36 features of competitiveness regarding tourist destinations, the ten most important turned out to be [6]: physical geography and climate; the market connections; culture and history; the tourist body (meaning public or private organizations whose activity is directly linked to the functioning of the tourist sector); safety and security; the cost/value ratio; accessibility; awareness/image; the location; infrastructure.

Six of these ten features formed the group known as *the Core Resources and Attractions*. *Physical geography and climate* proved to be the most important, whereas *culture and history* came in second. While geography and climate underline the “natural” qualities of a destination, culture and history are the primary tourist attractions. The third most important feature turned out to be *the tourist body* (accommodation and reconditioning facilities, transport, recreation, attractions such as theme parks, museums and art galleries).

Considering the current economic context and the advantages (obtained from tourism practices) that can contribute to the welfare of the entire nation, it is imperative for those destinations which do not currently own exploited competitive factors to use all necessary resources in order to develop themselves: to invest in infrastructure and landscape design, to better exploit and capitalize their heritage, to build accommodation facilities and to attract investment in order to develop a sustainable tourism that bring economic –and not only– benefits on the long term.

3. Leads competitive advantages of tourist products from a specific area to destination branding?

The segmentation process allows marketers to learn about the competition existent on touristic destination market, to understand the opportunities and threats of the environment, but also to find out the way to compete more effectively with the competitors.

The competitive advantage for tourism industry was elaborated by Porter in 1990 and was represented as in the Figure 1 [12].

Figure 1. The determinants of competitive advantages of destinations

Source: Vanhove, N., *Tourism policy in Bruges*, 2002

In order to achieve competitive advantage, marketing specialists (from a specific destination) must systematically communicate with the targeted segments of the market place; destination market management should identify, describe and illustrate photos of the touristic potential and facilities offered to tourist within the specific destination. By promoting a particular market product, a destination presents simultaneously its identity and brand.

Brands are important contributors to the construction of regional advantage. As Hall states, “place branding is the development of a place brand and its promotion in order to differentiate a place from other locations so as to gain advantage for its firms, organizations, people, products and services” [8].

Thus, competitive advantages are based on key-products/elements owned by a territory, making reference to the capitalization of natural resources –and not only- in order to attract tourists; also, they determine the differentiation of that particular territory from other similar destinations which address relatively the same target market and offer almost similar products, but use a different strategy.

These have been said, “[...] a destination uses its special features and emphasizes the advantages of its offer in order to attract tourists and to be competitive within the market” [10].

Like in any other crowded market, in tourism industry brand image is crucial: almost no one has the time, patience or

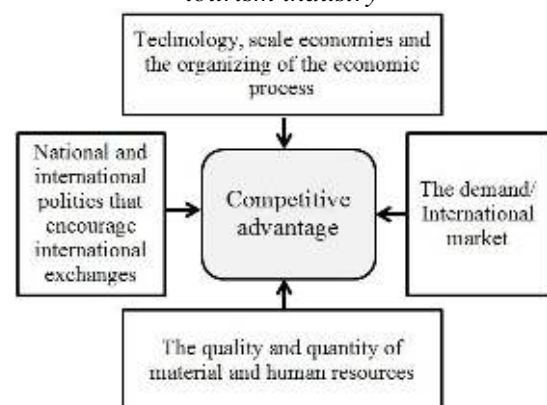

expertise to understand the differences between various offers regarding different destinations, so what really influence tourists’ purchase decision are the beliefs and prejudices regarding a specific destination. Countries with the reputation of being poor, dangerous or corrupted are highly associated with lack of culture and encounter a great difficulty in shaping a positive image among tourists. Because of this, the reputation of a tourist destination plays a key-role in its economic, social, political and cultural progress.

What should also be mentioned is the fact that the economic development of a country influences the process of destination branding, on the assumption that developed countries can offer to tourist high quality services, while the developing countries usually offer medium quality services.

Because of this, what stands out in terms of economic advantages that influence the competitive advantages of tourist products (Figure 2) offered by a specific country is [3]:

- the total amount of human and material resources;
- the effective combination of these two through technology;
- the economic and legal framework;
- the existing market conditions.

Figure 2. The determinants of national competitive advantages that influence tourism industry

Source: adapted after Croitoru, M., “Indicele competitivitatii in turism – analiza empirica Romania vs. Bulgaria”, 2011

Ritchie and Crouch suggested that “understanding the factors which determine success has a fundamental importance, being

classified in resources that represent either comparative advantages or competitive advantages” [9].

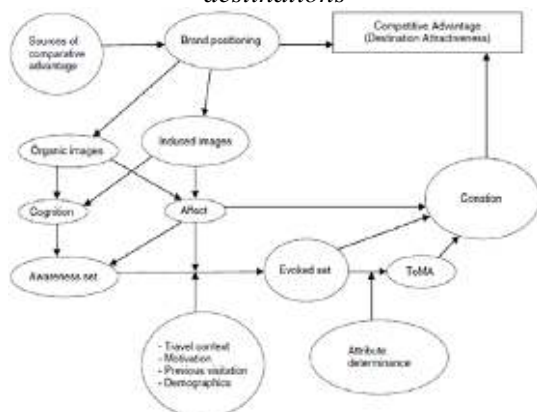

Natural resources of a destination -such as climate or landscape- fall into the category of comparative advantages, while resources created by the destination represent competitive advantages.

Pike also shows more detailed sources of the two types of advantages, as follows [9]:

- The sources of comparative advantages: natural resources, cultural resources, human resources and “goodwill resources”.
- The sources of competitive advantages: development of human, financial, legal and organizational resources; it also involves resources of various relationships existent between the parties and resources for implementing different programs.

Considering brand positioning as a source of competitive advantage in touristic destinations (Figure 3), is imperative to say that it depends on the induced and organic images, which are built considering the travel context, motivation, natural and cultural resources, heritage end overall experience. Because all these are different from destination to destination, brand positioning constitutes a strong competitive advantage in tourism.

Figure 3. Brand positioning as a source of competitive advantage in touristic destinations

Source: Destination Marketing. An Integrated Marketing Communication Approach, p. 220

When it comes to gaining competitive advantages, marketers from a specific destination need to take into account

partnerships with tourism organizations, in order to be united by knowledge, professional expertise and capital resources.

Because of this, what is also important is the information provided by tourist information centers, tourist agencies, specialized websites and journals or newspapers, which aim to promote from a specific area, both in terms of natural/anthropogenic potential and tourist infrastructure. Among their objectives should be included the fact that they:

- provide information needed to tourists that are visiting the area;
- submit the required information to those who are interested;
- transmit all necessary information to travel tour operators and travel agencies (for tourist information centers only);
- organize tourist promotional events in order to attract tourists, to arouse their curiosity and interest;
- keep in touch with similar centers for joint promotion of tourism regions;
- offer realistic information.

4. Conclusions

These have been said, it is imperative for tourist destinations to differentiate their offers through available competitive advantages. This process is overall influenced by:

- current competitors;
- existing threats;
- weaknesses of the destination;
- opportunities of the destination;
- the existence of suppliers and purchase power (through the influence of major hotel groups, airlines and tour operators on the diversity of quality, price and cost structures);
- the existence of complementary entities (like the existence of marketing agreements with other local and regional destinations, with other economic sectors and other providers may increase the magnitude and consistency of the tourism product);

In the context of perceiving destination branding as the process of developing and utilizing a unique identity and personality that distinguishes from competitors through a positive image, whose aim is to capture the essence of the

destination in order to promote its core values, it is impossible to separate a region's competitive advantages from place branding process. More than that it can be said that the fundamental elements on which destination branding is built are represented by competitive advantages and destination's competitive factors.

Abstract

The increasing involvement of different categories of people in education surpasses the traditional boundaries whereas the contents and the electronic instruments used to create, share and develop the information are more and more widespread and accepted. These realities provide opportunities for the development and spreading of a wide range of open educational resources, which implies significant challenges for the concept of intellectual property. As a consequence, increased online access to such resources generates individual study which, correlated with the development of the social networks and collaborative learning creates opportunities for pedagogical innovation.

The present paper aims at offering an introduction into the vast domain of open educational resources which becomes more and more accepted and used both at the individual level and especially at the level of some prestigious international institutions like UNESCO.

Keywords: open educational resources, communication, new media, e-learning, education technology.

J.E.L. classification: M31, I21

1. Introduction

In a global economy based on knowledge, the educational systems at university level play a major role in the social development and the economic competitiveness in each

country. A number of educational institutions associate the information and communication technologies at the level of their own management, in administration and in the educational programs in order to offer them to their students in a far more convenient variant from a financial point of view and in order to train them for the real world practice after they finish their studies.

Our intention is to prove that open resources have a major role in the progress of society, especially in the field of education. This paper comprises a number of ideas related to modern methods of education as well as their importance for all the people involved in the process: students, teachers, researchers, consultants etc.

2. Objectives

We are trying to explain and support the idea according to which the new means of education are used to make this process easier and faster. We rely upon concepts already applied in the field such as: e-learning platforms, new media, discussion forums, blogs etc. We consider that this paper is relevant for the general topic in our section because it provides substantial support for the development and improvement of learning and assessment at the level of higher education.

We will look for answers to the following questions: What kind of materials can be distributed through the system of open educational resources? Who will respond to these materials? Do they raise the efficiency of learning and the socializing process of students, teachers, researchers, consultants

etc.? How and where can we quickly find credible and up-to-date learning materials? How can we profit from the fact that they have been used during both curricular and extracurricular activities? Which are the trends in the field?

3. Aspects of the international expansion of the concept

Multimedia communication is interactive since the user receives the information actively. He can interfere, he can request something or he can change what he receives. Multimedia will remove neither text nor other traditional means of communication, it will only complete, enrich and use them at their real value [5]. As a consequence, pedagogical experiences and the materials for study should be adapted to this environment at the same time ensuring them a high quality.

The great advantage would be that the information and communication technology contributes to the increasing transfer of everything that is new in the field by means of the global transmission systems leading to a boom in the knowledge at the users' disposal.

On the other hand, the transformation of the information in the digital environment combined with its spreading in various domains represents important challenges for the concept of intellectual property [7]. Thus, the protection of copyrights has turned into a great problem hence the emergence of open licenses. This is the reason why open licenses have focused upon the effort of protecting copyrights in those environments where the content (especially the digital one) could be easily copied and shared without permission. Open licenses seek to ensure the fact that the copy and share operations do not need a structured legal framework relying on much more flexibility than the one provided by the “all rights reserved” of the copyright. These licenses allow for the clear transmission of the consent, but eliminate the restrictions of traditional copyright. Open Educational Resources (OER) are part of this process.

3.1. The concept of OER and its brief history

Open Educational Resources (OER) refers to the access to diverse data, studies or analysis in education facilitated by the information and communication technologies with non-

commercial consulting, usage and adaptation purposes of the users' community. The term OER is not synonymous with on-line learning, eLearning or mobile learning.

The open educational resources are the materials used to support education and they can be accessed freely, they can be reused, changed and shared. The purpose of these enterprises is to encourage the decision factors from governments and universities to invest in the systematic production, in the adaptation and usage of the OER in order to make them available on a large scale at the level of high education with the purpose of improving the quality of the programs and of the teaching methods and of cutting costs [9]. More concretely, open educational resources include:

- materials for teaching and learning: full courses/programs, course materials, modules, guides for students, course notes, books, research articles, video materials, assessment instruments, interactive materials such as simulations and role plays, database, software, applications (including mobile applications) and any other useful educational materials;
- open source software – for the development, usage, re-usage, search, organization and access to resources; the virtual learning environments (LMS - Learning Management Systems) and the learning communities are included too;
- licenses of intellectual property which promote the open publishing of materials, design principles and good practices as well as the localization of the content.

The informational technologies allow people in the educational system the online access and exchange of resources. Until a few years ago most of the materials were protected and they needed authentication of users. Nowadays, most of the resources are created and freely published on the Web making use of the Web 2.0. collaborative systems.

The studies reveal the importance of the open educational resources for the compulsory education as well as for lifelong education, for the acquisition of competences and skills which will allow teachers, pupils/students and adults to actively participate in the progress of a society and economy based on knowledge. The open

educational resources generate a fundamental change in an educational process centered on the pupil/student.

Open Education has started since 1972 in England at the first university of this kind - Open British University. Since then, more initiatives have broken new ground for the change of educational resources in a system of free access as it is perceived today [2]. Prestigious universities from the whole world have cooperated in the OpenCourseWare Consortium project allowing access to the text, audio or visual materials of the courses, to the discussion and exam topics. The movement was started by the Massachusetts Institute of Technology in 2001 by means of the MIT Open Courseware project. Being part of the OpenCourseWare Consortium, the Open University launched the Open Learning project in 2006 [6].

Since the number of the institutions which offer free and open courses has increased, in 2002 UNESCO organized the first OER Global Forum when the term OER was adopted. Moreover with the help of the Hewlett Foundation, UNESCO created a global wikki community in 2005 in order to share the information and to work in collaboration to the regulations regarding the production and use of the OER. The OER WSIS community has lately been supported by UNESCO in order to encourage practitioners, researchers, decision factors, teachers and students to bring their contribution to OER [1]. In partnership with important European institutions, UNESCO is a member of the Open Educational Quality Initiative which aims at developing the OER practices meant to improve the quality and innovation in education [10].

3.2. The potential of open educational resources. the certification of studies

It has become more and more important for the educational institutions to carefully and systematically support the following actions [7]:

- the development and improvement of both the curricula and the learning materials;
- the organization of interactive sessions with and among the students;
- the development of teaching and learning materials of high quality;

- the creation of effective instruments of assessment for various environments;
- the development of the relationships with the labor market.

Many of the internationally famous universities have understood that the model of free access can function from an economic point of view and can even bring them more and more students. Once the students take part to an online course they can decide to apply for the university where the course has been conceived. After the teachers at Stanford decided to offer a course upon artificial intelligence more than 100.000 students signed up online, 20.000 have taken all their exams and the first 1.000 students have been asked to send their CV with the promise of finding a job in top companies such as Google [2].

OER can significantly contribute to these processes. Nevertheless, OER do not automatically lead to quality, efficiency and the cost-efficiency relation because many of them depend upon the procedure adopted. The educational potential of OER depends upon [7]:

- the improvement of the quality of the learning materials by means of a peer-review process;
- the emphasis upon the open character and the improvement of quality;
- the need to acquire the ability to create and use OER as a part of the professional development of the academic personnel;
- the attendance to the interests of certain categories of students such as the ones with special needs;
- the attendance to the students' needs in local languages;
- the involvement of the students in the selection and adaptation of the OER in order to actively engage them in the learning process.

We can tell that at present the main objective in the OER is still limited to the facilitation of the access to digital contents under the form of collections without any assurance that technology will support the educational practices, the open education or the promotion of quality and innovation in the teaching and learning domain [3]. Therefore, in order to innovate and break new ground for other innovations in the OER one needs to identify those characteristics which can

support the successful spreading among institutions more than among persons [4].

The success of a kind of learning based on open educational resources is not complete if the certification problem is not solved, but this has not been possible yet. Nevertheless, there are also local initiatives such as, for example, in France where the professional competences are assessed by means of the VAE system (Validation d'aquis d'expérience) which allows residents to profit from every training or professional activity in ECTS credits (each credit means 30 hours of individual study).

In our country there is still not a well-established system but progress has been made through Order 6563/December 2011 for the approval of the Calendar for the activities stipulated in the Methodology regarding the ECTS/SECT validation of the short-term higher education under the form of a three-year college or a three-year pedagogical institute (leading to a Bachelor's degree after the first cycle of university studies) for the teachers in the pre-university educational system. This is not in the least sufficient to be able to extend the connections between the traditional educational system and the foreign environment, especially the business environment.

On the other hand, the open educational resources are better represented in the online environment where there are a number of specialized platforms such as: [elearning.ro](http://www.elearning.ro), <http://www.elearningeuropa.info>, <http://www.elearning-forum.ro>, <http://resurse-video-tice.wikispaces.com>, <http://www.elearningpapers.eu>.

4. Research regarding the use of the OER on a global scale

4.1. Methodological aspects

The main objective of this study was to enhance the way in which by means of well-conceived systems the open instruments of education allow educators and any other person willing to learn to have access to and to exchange online resources. Thus, by means of the qualitative research method one can resort to various sources of secondary information such as: reports of some international organizations, synthesis of certain events, analysis, case studies etc. The

research started from the analysis of the papers of the “World Open Educational Resources Congress” taking place in Paris in June 2012. To this analysis one could add the analysis and interpretations of certain studies regarding different open educational systems representative on a global scale.

4.2. The UNESCO and COL report regarding the OER

From the point of view of the participants to the UNESCO meetings, the free/open educational resources (OER) represent any kind of didactic material available and accessible to the public. Teachers are encouraged to use, copy and adapt the scientific resources to suit their own needs of knowledge as well as the needs of their students. UNESCO and The Commonwealth of Learning (COL) have written a global report regarding the use of the OER by means of a survey sent from the beginning of this year to all the governments and ministries of education of the member states of the OECD (The Organization for Economic Cooperation and Development) as well as to the permanent delegations of UNESCO from Paris and the National Commissions for UNESCO.

The report was presented during the World Open Educational Resources Congress taking place, as previously mentioned, in Paris in June 2012. Over 400 deputies including representatives of governments, teachers, ONGs and universities were present at the Congress which was organized in partnership with The Commonwealth of Learning (COL) and was supported by a generous donation from the part of William and Flora Hewlett Foundation (USA) [11].

According to the data held by the organizers until April only 82 countries responded to the survey [6]. The respondents either filled in the online survey and sent it electronically or sent it on paper to COL and UNESCO. The responses sent by mail or on paper have been introduced by the COL/UNESCO personnel in an application of the online survey type (SurveyMonkey). The results included in the online form have represented the starting point of this analysis.

In Europe, the OER are concentrated at the level of the secondary and higher education. In Austria, for example, the OER are

supported by many departments of the Federal Ministry of Education, Art and Culture. The institution supports a special platform for the creation and free access to mathematical knowledge of all Austrian schools by means of the GeoGebra application (interactive geometrical and algebra calculations). In Finland there are governmental initiatives which promote the public's free electronic access to learning materials by means of the national portal for education as well as other electronic archives and scientific and academic publications at the level of higher education. In Holland, the Ministry of Education has introduced Wikiwijs, an instrument of promoting the development and use of the OER. Although Slovenia does not officially participate to the OER movement, The Ministry of Education, Science, Culture and Sport promotes an electronic basis of pedagogical scientific materials for whose completion it made serious investments.

4.3. The Connexions experiences

Connexions represents a dynamic digital system with educational content and an optimized management system of offering this content. Connexions is among the most well-known sites of open education in the world. There we can find more than 17.000 learning objects and modules and over 1.000 collections (textbooks, articles etc.) which are used by over 2 million persons per month. Its content responds to the educational needs of people of all ages for almost any discipline from mathematics and science to history, psychology and sociology. The platform ensures Internet access to free content for schools, teachers, students and parents. The materials are easy to download on almost every mobile gadget with the purpose of using them anywhere and anytime. Schools can order printed sets of materials (including textbooks) for a low price [12].

The knowledge acquired on the platform could be shared by all users because it represents facilities from the following points of view:

- technological: all modules are saved in a simple and standardized format; the data are easily combined on the platform or with elements of content which belong to other platforms;

- legal: the Creative Commons open licenses allow their authors to share their works – allowing others to legally use and reuse them – whereas they are praised for their efforts;
- educational: Connexions encourages authors to write each module so that the others could easily use it in different collections and contexts;
- collaborative: the global community of authors continuously convert and adapt the information on the platform promoting the communication among the content creators and offering various means of collaboration through the feedback given to authors as well as the shared “Work zones”.

5. Conclusions:

This study is important for all the people involved in education because it provides a set of information used to adapt their work to the actual needs of society. Moreover, the paper helps the educational system to raise the quality standard of the courses and the practical methodology. The conclusions concentrate on the idea that the instruments which ensure the open educational resources – world wide web, email, blogs and others – are included in the category based on free communication.

The digital revolution continues to extend in different ways which were hard to believe a few years ago. Therefore, we can say that we are living in a time when we can talk of „open source”, „open education”, „open science”, when worldwide collaboration and collective intelligence help in the process of taking the right decisions, when global strategies of action could be identified and applied to face the complexity of the present situations.

The individuals' desires regarding education will most likely be easily communicated to the other members of the community and they will react favorably proclaiming their support and help. Likewise, one will easier and easier identify the text, audio and video resources necessary for training as well as the persons willing to learn the same thing.

Faculty of Economic Science, Ovidius University of Constanta

verovnp@yahoo.com

Abstract

In a marketing approach, the first objective of the logistic system is to assure a high level of logistical services, in such a way as to increase the customers' satisfaction. Producers are concerned to assure more and more logistic utilities, on a smaller cost, and the clients want to obtain the products on the quantity, quality, the moment of time and the place when they need. From the producers' point of view, the logistic system involves the following elements: purchasing activities, activities of manufacturing support, physical distribution. For the economic organization, an efficient logistic system means a good correlation between all these components and a good integration with its environment, strong relationships with suppliers and customers' logistic operations and must be integrated and correlated on value chain. One of the most important activities that can increase the competitiveness and contribute to a strong differentiation of the organization's supply is providing a high level of customer service.

Key words: marketing, logistics, customer, service.

J.E.L. Classification: M31

1. Introduction

Considered a very important component of logistic mix, the customer service has a strong impact on sales and profit of any enterprise. The first issue for any competitive organization must be to deliver customer satisfaction. But is very difficult to measure or appreciate the level of customer satisfaction.

From the logistic specialists' point of

view, the logistic service is integrated in customer services and is an important way to increase customers' satisfaction.

2. Conceptual Elements on Physical Distribution, Logistics and Value Chain

In the last decades, marketing specialists used several terms to describe the physical flow of goods and materials from the origin point to the utilization point. In the beginning, physical distribution was understood as the movement of goods from the place of their production, to the place where are consumed or utilized [1].

Some marketing specialists considered that physical distribution involves planning, implementing and control of physical flow of raw materials and finished goods, from the place of origin to the place of utilization, in such way to assure satisfaction for customers and profit for enterprises. In the same opinion a distribution channel is created by many independent organizations which are involved in the process of goods or services deliverance to final consumers or other organization and, in this way, assures the product to pass from the place of production, to the place of consumption [2].

In the last decades, the concept of logistics was more and more used, being considered more complex than physical distribution. In the '90, The Council of Logistic Management from USA replaced the term of Physical Distribution Management with Logistics, considered as an efficient and effectiveness process of planning, implementation and control of the flows of materials, finished product, manufactures, services and information storage and flow, from the origin point to consumption point, corresponding with client's demand [3].

A logistic channel is a major system that

assures customers service because its main goal is to delivery on time and to manage the goods' flow [4].

According to integrated logistic philosophy, the specialists consider that the main objective of logistics existence is to offer the utilities of time, place and possession, on the lower possible level of costs, and today, logistics is a strategic resource of the organizations, an important source of competitive advantages [5].

On a producer's level, the logistic system involves three major elements [6]:

- Physical distribution. In marketing channel, the operations of physical distribution assure for customers the availability of products. The clients' expectation or the fundamental marketing goals for wholesaler or retailers are achieved by offering the utilities of time, place and possession. The physical distribution involves activities such as transportation, storage, inventory management, packaging, information management etc.
- Support manufacturing activities. Inside the enterprise, on the product process, logistics has the particularly task to assure with material flows, such as raw materials, finished or unfinished goods, components etc., in the quantity demanded by production programs.
- Purchasing. The purchasing or procurement activities with raw materials, goods, components etc., necessary to achieve the enterprise's objectives, have a logistical nature. The suppliers are the aim of this element of logistic system.

The logistic efficiency means a strong correlation between those three components.

The logistic operations are correlated with the value chain, an important tool used by organizations to identify new modalities of value creation for the customers. According to the vision of Michael Porter, the value chain includes two categories of activities [7]:

- Primary activities: inbound logistics, operations, outbound logistics, marketing and sales, service;
- Support activities: procurement, technology development, human resources management, firm infrastructure.

In this opinion, logistics is an important

element of value chain, and a major source of competitive advantage in terms of costs and performances. Fletcher, K.P. offers a value provision model, conceptually similar to Porter's illustration of the up-stream and downstream processes which shape a company's productive, satisfaction producing potential [8]. Going from he's point of view, many other marketing specialists consider the firm must be orientated towards the satisfaction of customers' needs and this orientation must embrace all corporate functions and entail management of the relationships among them. On theirs' opinion, in the value cycle model, the following activities are contributing to find and create value: market marketing research and product development; purchasing and production processes; logistics and distribution; marketing and sales [9].

3. Customer Services, Marketing and Logistics Relationships

Integrated component of marketing policy, the distribution policy involves not only the architectural process of marketing channels, but, also the important process of designing the logistic frame and strategy. The significant decisions on logistics can have deep implications on customers' satisfaction, marketing costs, and on the competitive enterprises.

As a constitutive element of marketing-mix, the distribution policy means not only distinctive activities that facilitates the materials or informational flows from producers to clients, but a very important element of marketing policy, integrated in general policy of the economic organizations.

The relationship between marketing and logistics can be understood considering some specific activities of interface: The existence of this interface is the result of the separation of organization's activities in several divisions, corresponding to the organization's functions [10].

An efficient management involves a strong cooperation between the organization's functions, because from this perspective, logistics and marketing can be considered as strategic resources.

From some specialists' point of view, on one hand, logistics must assure the effective satisfaction of the demand generated by

marketing, and on the other hand, the marketing activities that can create demand, could be product development, personal selling, advertising, sales promotion, merchandising, prices settlement. Logistics can contribute to satisfy the demand and to assure a high level of customer services through some specific activities such as storage, inventory management, transportation, unitization, communication and materials management [11].

Specialists consider that between the marketing activities that have a deep impact to logistic area can be specified [12]:

- Settlement of marketing objectives and goals (choosing the target market, sales volume, the level of customer services), operation that decides the dimension of the necessary logistical resources;
- Product designing (that influence the warehouse spaces and transportation);
- Prices' settlement, because the price is the fundamental way to recuperate the investments from logistic area and to assure a logistic infrastructure that can allow a high level of customer service;
- Designing the campaign of sales' promotion, because involves logistics' efforts;
- Selecting marketing channels (number and type of intermediaries).

In the same opinion, from logistics perspective, the interface activities that can be better managed through a good correlation with marketing activities, the following can be considered:

- Purchasing activity (because of its influence on the capacity of enterprise to assure satisfaction's demand from the level of quantity, quality and rhythm of deliverance);
- Warehouse localizing (the placement of distribution centers can influence the rapidity of logistic service);
- Inventory management (the dimension of stock must be correlated to purchasing operations);
- Honoring the customers' order (the medium space between taking order and delivering order);
- Protect packaging of products (a good protection contributes on costs' reducing);
- Transportation of goods (assures time and place utilities and maintains the quality of

products during the goods circulation between marketing channels).

These interface activities have deep impact for the level of customer service and for organizations' competitiveness.

From logistic point of view, the mission of satisfying the customers' needs and realizing benefits for the enterprise is carried out by some specific and necessary activities, which build the logistic mix. The logistic mix involves two categories of activities [13:]:

- Basic activities: customer service, purchasing, transportation, inventory management and orders' processing;
- Support activities: storing, products' handling, packaging, activities concerning the logistic informational flows.

Customer service is critical for the organization because the level of performance depends on the costs generated by satisfying customers demand.

The organization must be permanently preoccupied to assure a high level of satisfaction of customer needs, and in this direction, must fit the level of logistic service with customers' demand.

Analyzing the distribution process system Kotler, Ph. considers that the first step that must be done is to know what are the really needs of potential consumer and this means to know [14]:

- Dimension of the lot of goods;
- Time for waiting;
- Territorial distribution network;
- Variety of goods;
- Supplementary services.

The improvement of customer service is a major goal of organizations and is usually specified as objective in the logistic plan, marketing plan or business plan.

4. Customer Services

Specialists consider that the major elements of customer service process are the following [15]:

- a. Availability of goods inventory (the probability of the existence of goods inventory, on the moments when is demanded by clients);
- b. Length of order cycle (from client's perspective is the duration of time from the moment of order to the moment when the goods are received);
- c. Goods' recall from the market (in some

cases is necessary to recall products, because of quality defects or malfunction, unsuitable package, inadequate condition of storage a.s.o.).

a. The existence of an available goods inventory is a major problem for the organizations.

The level of inventory depends on goods characteristics, estimative level of demand, the specificity of clients etc. and it's important to consider the contribution of stock to sales and profit.

Usually, the basic stock is completed with safety stock, which protects against the demand's fluctuation or uncertainty of suppliers' deliveries. The medium stock directly depends on the number of warehouses.

To measure the inventory availability, it can be used several ways, such as the frequency of breaking (reflects the probability of absence of a product from stock), index of execution (measure the dimension or the impact of stock breaking during the time and correlates the availability of goods with the customers demand), the number of complete orders (it's a way of measurement the availability of inventory, near by the frequency of stock breaking and index of execution and represents the number of situations when the enterprise is capable to deliver the integral order of client).

b. The length of order cycle can be approached from a double perspective: on one hand, for client means the duration of time from the moment of order, to the moment when the goods are received, and for the other hand, for supplier the order cycle begins from the moment when the order is received from client.

The most important steps for the cycle of order are the following:

- Order delivery (is the time period from the moment when the client delivery the order and the moment when is received by the supplier);
- Order processing, realized from the moment when is received the order of client until the moment of notification of store-house for goods delivery;
- Accepting and assembling the order (including all the activities realized from the moment of receiving the order, to the moment of loading goods in the transport facilities);

- Procuring the supplementary necessary stock (it's about the identification of other modalities to satisfy the client's order, in case that the store-house doesn't have the goods);

- Order delivery (the time period between the moment when goods is accepted by the transporter, until the moment when arrives to client).

c. The goods withdrawal (the products recall) it's an unpleasant situation, generated by several causes: unsuitable package or label, goods with vices, inappropriate ways of storage, that can contaminate or spoil the goods etc.

Considered as an important component of customer service, the products recall is a modality to maintain the image of the firm, its' prestige in the eyes of consumers.

The withdrawal of goods from the market is a laborious and expensive process. There are some requirements that must be accomplished, such as:

- Storage of goods (it's indicate to be isolated from the other products, in such a way to not disturb the flow of merchandise and to be not reintroduced by error in the normal circuit of goods);
- Inventory management (in any time and any place, the specialists must know the quantity of goods and the evidence of recall goods);
- Transportation of good (it's necessary to use the most appropriate mean of transport, considering the specificity of goods and the necessity to use the capacity of the transport facility);
- Handling (it's necessary to use adequate way of handling, considering the type and the state of goods).

The interaction between marketing and logistic operational decisions is amplified by the recall product process.

Managing goods recall is important to a company's bottom line.

Marketing specialists appreciate that, from an operational perspective, the enterprises can consider that a way to improve profitability in the face of product returns is to take the return rate as a given and try to minimize the cost of managing the returns process [16].

Because of the strong impact on costs and benefits, it's necessary to conceive a realistic

customer service strategy.

According to the opinion of marketing specialists, the customer service elaboration process for the organization involves several steps [17]:

- Determining the logistic customers' needs;
- Evaluating the own performance on customer service process;
- Evaluating the competitors' level on customer service performance;
- Designing the logistic customer service strategy.

Logistic customer service strategy must be periodically revised and modified to respond on customers' needs.

Conclusions

The customer service is important because has deep impact on sales, costs (such as costs generated by communication, documentation a.s.o.) and benefits of the enterprises.

To achieve the logistic and marketing goals, organizations must conceive an appropriate customer service strategy, which must be integrated in to the logistic strategy.

Logistic customer service strategy must accomplish the process of satisfying customers' needs and appropriating the benefits for the economic organizations.

Interpersonal Disagreements and Contradictions - Implications on Work Efficiency in a Company

Neacsu Gabriela

*Spiru Haret University Bucuresti, Faculty of Management Financial Accounting
Constanta*

gabrielle_neacsu@yahoo.com

Abstract

The study aims to point out the consequences that the malfunctions caused by the lack of professionalism of some managers could have.

The hypothesis that conducted to realising the study was that the appearance of different contradictions and disagreements influences the employees' capacity to accomplish quantitatively and qualitatively, in due time the tasks assigned to them. The study was conducted in two stages:

In the first stage, the existence of some disagreements and contradictions inside an enterprise was identified;

In the second stage, their influence over the employees' efficiency of the enterprise was identified.

Keywords: disagreements and contradictions, interpersonal relationships, work environment, labour efficiency.

J.E.L. Classification: M12, M14.

1. Introduction

The rational use of human resources represents a basic condition of the success of an organisation in accomplishing the tasks. This involves the management's concern regarding the personnel's assurance and selection, its judicious apportionment on jobs, the motivation to achieve goals and their integration in the general objectives of the organisation, Lazar I., shows [3].

The organisations bring together individuals with different personalities; specific needs, behaviour and visions, specifies McGregor D., [5] These specific individuals make that interpersonal relationships established between them have a special significance. Creating an

atmosphere of collaboration within the organisation, some adequate interpersonal relationships have a direct influence over the labour efficiency. Interpersonal relationships are those connections established between people occupying different jobs within an organisation, on one hand, and between these persons and the entire community, on the other hand, sustains Lazar I., [4]

Interpersonal relationships develop being based on work relationships; the problem of these relationships within the organisation must be looked through the light of the fact that they represent the basic cell of the economy. In each unit the social environment is defined by the fundamental coordinates of the system, being in the same time influenced by the fact that each person has a specific psychological structure, a certain personality, which determines the nature of interpersonal relationships that are forming, as Petrescu I. appreciates [8]. The existence of work relationships doesn't automatically involve the existence of some adequate interpersonal relationships, of some easily accepted discipline, of auto control, of a fully involvement.

The study of the role of interpersonal relationships in the organisation activity highlights the following system of interpersonal relationships:

- The relationships established between employees and social groups from the same hierarchic level (horizontal relationships, of cooperation);
- The relationships established between leaders and subordinated social groups or between leaders and subordinates.

The relationships leader-subordinate express the links that the leader promotes in front of his inferiors' personality through which he stimulates or hinders the possibility of individual arising within the groups he is part of.

These relationships established naturally within the functionality of the leading system of the organisation involve, as coming from the leader, specific qualities and knowledge, namely: knowing and understanding the human nature, observing the motivational elements of the subordinates, participatory approach of problems etc.

A healthy work environment requires the application of minimum demands in the relationships between leaders and subordinates:

differential treatment and establishing tasks for each person or compartment in relationship with the importance of the objectives, with the requirements of socio-economic environment, the peoples' qualities, knowledge, habits and skills;

stimulating the collaboration spirit, the reference, introducing a climate of mutual confidence in leading, which determines real and affective participation of the collaborators and the exploitation of their qualities and personalities;

utilising carefully the competences and the responsibilities, ensuring the enforcement in front of the subordinates through knowledge authority, and not through compulsion;

respecting the personality of each person, of his dignity.

When in labour environment the requirements that need to be applied in relationships between leaders and collaborators and inferiors are not respected, strained situations and a working environment less favourable to work appear. The appearance of inadequate interpersonal relationships determined by the developing of some activities that workers don't love, by malfunctions in the unity's activity, by leader's inappropriate behaviour, by the lack of a suitable communication and of a proficient reliance in difficult moments, creates mistrust relationships and contributes to forming some groups with different interests, having as consequence a certain disinterest towards the attributions and tasks assigned to the job that each component of the group occupies, with negative effects over the achievement of the objectives of the economic unity. This is exactly the goal of our paper, of identifying the conflict situations and of studying their influence over the labour efficiency.

The appearance of disagreements and

contradictions doesn't have to be looked only as a negative fact, as a consequence of defective application of management's principles and fundamental methods, but as a natural state, mostly inevitable. The disagreements' sources and causes are numerous and various, as Ursachi I. specifies [9]. From the point of view of their influence over the evolution of the organisation activity, they can be grouped in two categories:

functional – which stimulates the activity's improvement through better solutions for the problems that generated them;

malfunction – which are harmful and which have to be prevented or worked out as soon as possible.

The contradictions have a special influence in forming the individual attitudes and small groups. The emotional state linked to different disagreements and contradictions can be positive or negative as a certain decision causes satisfaction or dissatisfactions.

In their entire diversity, certain types of disagreements and contradictions have been contoured:

1. *Disagreements and contradictions related to the execution of work duties*, which appear in cases like:

- he need of accomplishing the task for whose utility or realising manner, the employee is not convinced;
- he overuse of some employees with work force and capable, surpassing their sphere of attribution and underusing others less capable professionally;
- he manager took the decision without the participation of the person or the group interested, even though they have a great practical experience;
- he lack of clarity in establishing the objectives, the attributions and the tasks, fact that leads to interferences and tendencies of widening the prerogatives of some persons or groups of persons at the expense of others.

2. *Contradictions generated by the manner of appreciating the employees' activity*. The lack of some clear criteria of some special skills of the manager to appreciate the employees' activity leads to dissatisfactions and contradictions among the employees. For most employees, evaluating the credits, attributing qualifiers and rewards have to be

done not basing on their professional qualities and on other general qualities or by comparing with other persons, but rather by comparing the individual results with the exigencies and tasks that are attributed to them on that specific job. The stimulants and the sanctions, as an effect of appreciating the employees' activity are extremely important. Any groundless, subjective or unjust appreciation will often cause rejection towards work and the organisation in which the employee works.

3. *Contradictions due to difficulties encountered in solving some personal problems and the displeasures of family life.* Bureaucratic solving of personal problems of employees, the absolute, rough form of discussions, the absence of necessary explanations, make that shy employees, who cannot clearly express their claiming, leave the management with unsolved problems, fact that reverberates upon their activity, as in the attitude towards the organisation and the manager. Also, a series of events from family life (divorce, disease, death, difficult children etc..) influence the work efficiency and quality of the employee. In such cases, the lack of comprehension from the manager can have as consequences, either the aggressive manifestation of the person in cause, or falling in depression.

Anyhow, no matter the nature of the contradictions and of the causes that generates them, in order to encourage people to express freely their fears, worries and feelings of injustice, the managers must be prepared that such subjects be discussed and listened with common sense and not ignored, sanctioned, bitten or rejected.

2. Materials and methods

The study was realised at a private enterprise (from confidentiality reasons, we won't mention its name), applied in all departments. The study encompassed two parts:

- the identification of contradictions and disagreements;
- their influence upon the labour efficiency, transposed through work productivity.

The hypothesis used in realising the study was that the appearance of different contradictions and disagreements influence the employees' capacity to realise

quantitatively and qualitatively, in due time, the tasks assigned.

In collecting the data, we used direct observation, which implies that the observer get in touch directly with the investigated phenomenon [6].

The methods utilised in the study were:

- **the statistical investigation** characterised by collecting some information through questionnaires. By processing the data collected through the investigation, we obtained some indicative information upon the study that we carried out.
- **the indirect observation** was realised on a documents basis by studying the evaluation sheets of the individual professional performances of each employee.

The research technique utilised was the interviewing. For collecting supplementary information, to which the respondents could not answer because of the limited character of the questionnaire, informal interview was utilised because this type of interview permits the operator to change the questions order, to explain their meaning, to add supplementary questions and even to adapt the questions wording to circumstances and to the person, in front of who, he stands, as Dăneci-Pătrău D. sustains [2].

The research instruments utilised were the two questionnaires “*Questionnaire for identifying the contradictions and disagreements within the organisation*” was utilised in the first phase of the research in order to determine eventual malfunctions within the enterprise studied, respectively “*Questionnaire for identifying the negative influence of contradictions and disagreements over the employees' work efficiency*” managed in the second part of the study in order to determine if the employees' inefficiency in work caused by the malfunctions from the labour environment is present and how much it represents. The questionnaires have included closed questions, their variables being evaluated with different scales of Linkert type.

In order to establish if there is a connection between the satisfaction degree in work and the work productivity transposed through the score obtained at the evaluation, we used the method of “testing the statistical hypothesis”, the test χ^2 which applies to the table of combined group. The study was

realised during 10-30 May 2012.

3. Results and discussions

The first questionnaire “*Questionnaire for identifying the contradictions and disagreements within the organisation*” was given to the 45 employees, among which 40 filled it out, during 10-20 May 2012. The questionnaire aimed the following objectives:

- Identifying the type of contradiction or disagreement within the enterprise;
- The manager’s attitude towards the employees.

The questionnaire contain 14 items, from which 6 factual questions, 2 motivational and 6 of opinion. For the question “Do you consider that there have been situations in which your boss insisted that you realise a certain job that normally somebody else should have realised?” the following answers were given:

Figure 1 The opinion of employees about their overuse

Another question that we analysed was: “Did it happen that you were assigned with tasks that you didn’t fully understand or of which utility you weren’t convinced?”

The questionnaire highlighted malfunctions concerning rewards assignment, which have been awarded equally to all employees; there is a significant percentage (23%) among the employees who don’t fully know their job description; few employees (34%) presented their suspicions concerning the fears related to defective accomplishment of work tasks.

Figure 2 The opinion of employees about the complete lack of understanding of the works

The second questionnaire “*Questionnaire for identifying the negative influence of contradictions and disagreements over the employees’ work efficiency*” was given to the 45 employees, among which 42 filled it out, during 21-30 May 2012. The questionnaire’s objectives were:

- The identification of a connection between the degree of labour satisfaction;
- The mathematical demonstration of the existence of a connection between the two variables.

For the question: “On a scale from one to five the labour’s satisfaction degree would be”, the following answers were given:

Figure 3 Degree of job satisfaction

In what concerns the question “Do you consider that your mood at a certain moment affects your work?”, the answers have been:

Figure 4 The discomfort affects your work

The questionnaire highlighted that 41% of the employees work sometimes overtime, and

19% often. Overall, all those questioned appreciate that there is a good and very good relationships between co-workers. In what concerns the colleagues’ proficiency, the opinions are divided: 27% believe sufficiently in their colleagues’ proficiency, 32% a lot and 12% very little.

The structure of the community studied was the following: 63% men and 37% women; on ages: 25-34 years (21%), 35-44 years (68%), 45-54 years (10%) and 55-65 years (1%). Among those questioned, 42% are married and 56% not married.

The second part of the study referred to the influence of contradictions and disagreements over the work efficiency, transposed through the labour productivity. In order to answer to these requirements, two variables have been chosen:

The degree of work satisfaction – X variable;
The score obtained in evaluation sheets – Y variable. In establishing the evaluation scale of the employees’ performances, “Graphic evaluation scale” [1] has been used, according to which the qualifiers are attributed as follows:

- Excellent 45-50 points
- Over average 35-44 points
- Average 25-34 points
- Under average 16-24 points
- Unsatisfactory 10-15 points.

In order to establish the satisfaction degree of the employees:

- Excellent 5 points
- Over average 4 points
- Average 3 points
- Under average 2 points
- Unsatisfactory 1 point.

In view of the validation or invalidation of Y variable chosen in order to study the correlation between the two variables, its degree of representativeness was determined So, it was calculated:

- Average $\bar{x} = 35.83 \approx 36$
- Dispersal $\sigma^2 = 131.218$
- Standard deviation $\sigma = 11.45$
- Coefficient of variation $v = 31.8\%$

It results that the series is homogenous and the average representative, so that the study can take place, Y variable being validated.

The connection between two or more variables can be studied through methods for verifying the connection existence and analytical methods. The statistics through the

methods of “Testing the statistical hypothesis” offers the possibility of establishing with a chosen probability degree, the existence or the absence of the connection between phenomena, the analytical form and its intensity, as Neacșu G. shows [7].

Table 1. Correlation table

Score evaluation	Degree of job satisfaction					Total
	Excellent	Above average	Average	Below average	Unsatisfactory	
45-50 E	6	2	3	3	-	14
35-44 AA	3	3	2	1	1	10
25-34 A	2	1	3	1	1	8
16-24 BA	-	2	1	2	-	5
10-15 U	-	1	1	1	-	3
Total	11	9	10	8	2	40

The null H_0 hypothesis according to which, no matter the degree of the work satisfaction, the employees are divided in employees with score: E, AA, A, BA, and U.

If the hypothesis were real, then all groups of satisfaction degree would respect the following division:

- 35% - scoring 45 – 50
- 25% - - scoring 35 – 44
- 20% - - scoring 25 – 34
- 12.5% - scoring 16 – 24
- 7.5% - - scoring 10 – 15

On the basis of this determination, the hypothetical repartition H_1 is constituted, meaning that the division on each group in hypothetical unsatisfied employees is applied, according to table 2.

Table 2. Correlation table for hypothesis H_1

Score evaluation	Degree of job satisfaction					Total
	Excellent	Above average	Average	Below average	Unsatisfactory	
45-50 E	3.85	3.15	3.5	2.8	0.7	14
35-44 AA	2.75	2.25	2.5	2.0	0.5	10
25-34 A	2.20	1.80	2.0	1.6	0.4	8
16-24 BA	1.375	1.125	1.25	1.0	0.25	5
10-15 U	0.825	0.675	0.75	0.6	0.15	3
Total	11	9	10	8	2	40

Applying the calculation relation:

$$\chi^2 = \sum_{i=1}^m \sum_{j=1}^n \left[\frac{(n_{ij} - \theta_{ij})^2}{\theta_{ij}} \right] = 10.6107$$

If the value χ^2 calculated is inferior to

spread sheet size χ^2 for (m-1)(n-1) liberty degrees, and a probability P chosen, we can appreciate that between X and Y there is no connection.

$$\chi^2_{\text{calc.}} = 10.6107$$

$\chi^2_{\text{table}} = 7.96$ for (m-1)(n-1) liberty degrees =16 and a probability of error of 0.05.

It results that between the two variables there is a tight connection.

4. Conclusions

The subject treated in this study is up to date, a lot of employees end up working overtime, are often frustrated because their expectations are not the same with the objective reality and they are often put in embarrassing situations in front of their colleagues.

The study highlighted that the majority of the employees have superior studies and that they have a work experience of at least five years, fact that demonstrates the existence of a well prepared and professional personnel. Nevertheless, there are situations which are created artificially, either because of the manager, or by not knowing the employees' rights.

The most often contradictions that we met, were in reliance with the overuse of some employees to the detriment of others, the fact that some employees don't fully know their job description or the fact that the manager is taking some decisions without consulting the employees directly involved in solving those problems.

All these malfunctions lead obligatorily to decreasing the employees' efficiency and so the work productivity, fact demonstrated by applying the “Testing of statistical hypothesis” whose value bigger than spread sheet value has indicated a tight and direct connection between the variables, the degree of labour satisfaction and the score obtained after evaluating the employees.

Labeling in Food Industries – a Marketing Strategy

Neacșu Nicoleta Andreea

“Transilvania” University of Brasov, Faculty of Economics and Business Administration
deea_neacsu@yahoo.com

Abstract

The objective of foodstuff labeling is to guarantee that consumers have access to complete information on the content and composition of products, in order to protect their health and their interests. Other information may provide details on a particular aspect of the product, such as its origin or production method.

Marketers use food labeling as a strategy to attract customers and promote products. In this paper we present role of food labeling for consumers, but also in marketing.

Key words: food, labeling, marketing.

J.E.L. classification: I11, I12, M31.

1. Introduction

Labeling is any written, electronic, or graphic communications on the packaging or on a separate but associated label. Nutritional labeling is often ignored by people, because they don't really know what it is. [4] We don't have the necessary knowledge about proper nutrition, and how we should combine foods in order to take our daily doses of vitamins, proteins, carbohydrates, and so on.

We think we eat healthy, but in the end we die eating. We make this statement because lately so many diseases correlated with bad nutrition appeared. We think that it is not important to regularly calculate our nutrients intake, but we don't realize that the lack of energy is because we don't eat our daily dose of proteins, carbohydrates, etc.

Calories are generating energy, but it is wrong to believe that the quantity of calories is equal with the quantity of energy. For example, we often think that if we eat more than 400 calories (400 calories is the normal quantity for a meal) we would have more energy than if we eat less than 400 calories, but it is wrong. After eating a consistent meal

you always feel tired. This means that a high intake of calories doesn't give you a lot of energy.

In this paper we want to show the importance of nutritional labeling, and the role of it in our lives and wealth.

We will try to define nutritional labeling in a simple way, in order to be understood by everyone.

We will also try to show the effects of nutritional labeling on consumers, the importance of daily doses, and in which countries nutritional labeling is mandatory. [3]

2. Food labeling

By definition, a food label is a list that contains information about the nutritional value of a certain product.

The food label has to have:

- **Product name or description:** It's illegal for food labels to have false or misleading names or descriptions. For example, the flavor of a peach yogurt must come completely, or mostly, from peaches.
- **Net weight (e):** When this symbol appears after a weight or volume, it means that the weight or volume of each pack might vary slightly, but the figure shown will be an accurate average. [6]
- **Ingredients listing:** Ingredients are listed in descending order of their weight, with the biggest ingredient first (except in the case of yogurt where the biggest ingredient, milk, doesn't have to be listed)
- **Allergy advice box:** Food labels have to list all the ingredients and ingredients derived from allergenic foods have to be clearly identified in the ingredients list. For example, on a milk chocolate label, it is highlighted that it may contain traces of nuts. [5]
- **Nutrition Information:** This information tells you about how much energy, proteins, carbohydrates, and fat is in the

food. You may also see information on sugar, saturates, fiber, sodium and vitamins and minerals. You will see this information if a nutrition claim - such as ‘low fat’ or ‘low calorie’ – is made.

- Conditions for storing or using the food: Storage information or instructions on how to use the food (for example microwave information, if it has to be stored in a refrigerator or at what temperatures the food must be kept). [6]
- Country of origin: The true place of origin. (For example if the chocolate is imported from Germany, it has to be specified on the label).
- Contact details: The name and address of the producer, the phone number and e-mail address. These are necessary in the case in which a consumer is unsatisfied with the product.
- Expiration date: The lifetime of a product. On certain products there is other information, such as how to prepare the product, different recipes you can make with the product, etc.

3. The role of food labeling in marketing

The objective of foodstuff labeling is to guarantee that consumers have access to complete information on the content and composition of products, in order to protect their health and their interests. Other information may provide details on a particular aspect of the product, such as its origin or production method. Some foodstuffs, such as genetically modified organisms, allergenic foods, foods intended for infants or even various beverages, are also subject to specific regulations.

Labeling of certain non-food products must also contain particular information, in order to guarantee their safe use and allow consumers to exercise real choice. In addition, the packaging of foods must adhere to production criteria in order to avoid contaminating food products.

The main objectives of food labeling in marketing are:

- Brand Identification - Labeling helps in the identification and principal place of business of the person by or for whom the prepackaged product was manufactured, processed, produced or packaged for resale

- Description - Labels provide the information regarding the food product. It describes the contents, nutritional values, cost, product usage methods, shelf life etc. [1]
- Promotion - Finally labels helps in promoting the product through attractive and bright graphics replacing paper labels glued on cans and bottles. [2]

4. Analysis of nutritional labeling of food

Reading the nutritional label while we are out shopping is not something we are used to do. We find all sorts of excuses to skip that part (such as lack of patience, time, space), and we sometimes “forget” to look for the expiration date. We think we eat healthy until we take a look on the nutritional label. So, in the hopes of still believing in that fairytale, we just don’t read it. And few know how many fats you are supposed to eat in a day. We often don’t have enough time to calculate the intake of proteins, or other things written in there.

But being healthy takes time, and the first step in achieving this goal is reading the nutritional label on all the products we buy.

Lately, more and more people became preoccupied with what they really eat. This means that we have to know what types of food to combine in order to assure all the nutrients we need for a good health.

Nutritional labeling appeared in 1970 in USA, but only after 20 years became mandatory. It is optional on raw fruits and vegetables, however. Nutrition labeling is harmonized throughout the European Union. It is optional, but becomes compulsory if a nutrition claim appears on the label or in advertising. Such as light, natural, 100% fruit, etc. After its adherence to EU, Romania has to respect the same rules as the other countries in the European Union. In Canada the nutritional labeling became mandatory in 2007.

Imported products are required to respect the same rules as domestic products. In Asia, nutritional labeling is not compulsory, but many producers already have products with it. There is therefore increasing interest among authorities in countries in the region to start formulating regulations for nutrition labeling for a wider variety of foods. Australia, New Zealand and Malaysia have

proposed new regulations to make it mandatory to label a number of foodstuffs with a number of core nutrients. Other countries prefer to start with voluntary labeling by the manufacturers, but also spell out the requirements for voluntary labeling.

The Philippine Regulations have prescribed mandatory nutrition labeling for enriched or fortified foods. If foods are to be exported to the United States, they are required to follow the United States Nutrition Labeling and Education Act (US NLEA) requirements. In Singapore, mandatory nutrition labeling is only required for foods enriched or fortified with permitted vitamins, minerals, essential amino acids and fatty acids.

Nutritional labeling is any kind of information about energy value and nutrients (such as: proteins, carbohydrates, fat, fibers, sodium, vitamins, and minerals). [3]

The recommended daily nutritional intake varies from individual to individual, depending on age, physical activity, height, sex, health status, metabolic profile, etc.

The Recommended Daily Allowance (RDA) is the nutrients needed in a day in order to be healthy. Doses are calculated at an average energy intake (about 2000-2500 kcal / day).

In 2008 there was a huge scandal regarding the food sold near schools, kindergartens, or any other educational institution. The problem was that the products sold to children were high on salt, fats, and sugars. They prohibited selling chips, pretzels, sticks sites, snacks, salted nuts and salted seeds, because they contain more than 1.5 grams of salt per 100 grams of product. They also prohibited sweets (such as cookies, cakes, candies) and sodas containing high quantities of sugar.

An "essential nutrient" is a nutrient that your body does not make on its own and that is so important that you can't be healthy without it. [5] There are about 45 essential nutrients that are required for overall good health. If you get those nutrients from diet or supplementation then your body has the raw material it needs to function properly. Without them problems begin to occur.

5. Conclusions

In this paper we've talked about nutritional label and its importance for the human well-being in a period when the obesity became something common and the proper alimentation disappeared, thus, producing many types of diseases.

The nutritional labeling became mandatory since 1990, but still, the rate of obesity is in continuing growing. Some of us are very careful with what we eat and started to consult the nutritional label, which is present (or must be) on the package of each product.

The children and neither the adults don't have the proper education regarding health food lacking in information about how important are Vitamins and the other Nutrients that are important in our life, but not in the quantities we seek for. And maybe starting to read the Nutritional Label will be the beginning of a new life style.

For marketers label has become a way of promoting food products and brand identification.

Marketing strategies for Tourism Development in Harghita County

Nenciu Daniela Simona

*Dimitrie Cantemir Christian University, Faculty of Touristic and Commercial
Management Constanța*
nenciu75@yahoo.com

Abstract

In order to attract in the future a significant number of tourists, entrepreneurs from Harghita tourism should adopt strategies to develop tourism products which they should sell as they can meet the requirements of tourism market currently manifested.

Marketing strategies used should be aimed at creating viable tourism products to harness the best natural and spa tourism potential of the area.

Attracting and retaining good employees should be, for the entrepreneurs from Harghita County, as important as customer loyalty. In this respect, specific strategies should be adopted, strategies specific for personnel policies aimed at increasing the quality of employee benefits, their motivation and loyalty.

Key words: tourism, strategy, marketing, potential, development.

J.E.L.Classification: M31, L83

1. Introduction

Harghita County shall fail to become competitive as long as the area entrepreneurs apply marketing strategies aimed at creating sustainable quality tourism products that meet the requirements of tourists.

Marketing strategy is thus designed to generate demand in the future by specifying those market segments which must be reached, products to be created and which shall be focused on and associated with action programs to achieve the identified potential for these target products: market segments [1].

The challenge for tourism in Harghita is to organize and develop its natural resources

in a range of spa tourism products largely attractive to the public, and the transformation of these attractions in a flow of tourists and area benefits. Such an aspect requires the development of an integrated product and a strategic marketing approach.

2. Particularities of tourism from Harghita

During 2007 - 2011, the number of tourists arriving in this county has seen a slight decrease from one year to the other. Exception was the year 2011 when this indicator increased by 1, 10% compared to 2010.

Graphic no. 1 Number of tourists arriving in Harghita county, during 2007 – 2011

Source: processing data from *Statistical Yearbook of Harghita county 2011, Monthly Statistical Bulletin, no.1 / 2012*, access <http://www.harghita.insse.ro>

The highest average stay was recorded in 2007 (3.33 days/ tourist). There followed a slight decrease of this indicator from one year to the other, so that in 2011, average stay decreased by 18,21% compared with the previous year.

Graphic no. 2 Average stay conducted on the tourists that arrived in Harghita county, during the period 2007 - 2011

Source: processing data from *Statistical Yearbook of Harghita county 2011, Monthly Statistical Bulletin, no.1 / 2012*, access <http://www.harghita.insse.ro>

To re-launch tourism in this country, tourism entrepreneurs should market original tourism products to harness the existing potential. The main strong points of tourism from Harghita concern[2]:

- existence of exceptional cultural and natural sights (Rosu Lake and Bicazului Gorge, Sfânta Ana Lake and Tinovul Mohos, Vârghisului Gorge, lucustrian complex from Sânpaul, Praid saline, Corund ceramic centre, fortified church from Dârjiu, UNESCO heritage, complex of religious monuments and Pentecost pilgrimage to Sumuleu-Ciuc ecc.)

- natural landscape and the relatively good quality of environment, close to nature, mostly mountainous area, temperate climate in summer, abundant vegetation;

- presence of favorable snow cover for winter sports;

- wealth of minerals and emanation pits;

- endemic and relict plant elements, specific ecosystems, many natural reserves;

- relatively rich cultural heritage, both in terms of tangible elements – built, as well as intangible – spiritual (authenticity of ethnographic heritage);

- majority presence of szekler population

- attractive for the tourist market from Hungary, the importance of ethnic and multiple links between the communities from Harghita county and the Hungarian communities from Hungary as well as other neighboring countries (Slovakia, Ukraine, Serbia, Croatia and Austria), settlements and twinning countries;

- the presence of the Romanian cultural elements, to diversify the regional factor,

element of attractiveness for domestic market, but also for the Hungarian market with specific character;

- private investments in the accommodation structures, increase in the share structure of 3 stars, especially urban and rural pensions;

- appearance of wellness services in some hotel units;

- appearance of selected food units in some cities;

- increased interest in the rehabilitation of market walking mountain trails, initiatives of NGOs and local government (APL);

- existence of certain equestrian centers;

- planning new ski areas (slopes and cableway installations);

- initiative to set up tourist information centers or offices;

- participation in exhibitions and touristic fairs from the country and abroad (especially in Hungary);

- NGOs work to promote active forms of tourism (hiking, winter sports), cultural and ecotourism.

3. Market strategies

To identify new ways of increasing effective tourism demand, tourism entrepreneurs from Harghita should adopt stimulating and development strategies. These strategies are viable only if they are part of the coordinates for tourism development in the region.

Many of tourism agencies which carry out their activity in the area apply undifferentiated strategies, which in the present context, where the requirements of the tourists are more demanding and various, find an optimal application, the results being less effective[3]. For tourism products and services sold by the companies from the area to meet the requirements of different consumer segments, specific marketing programs, for each segment, should be made and the differentiation strategy should be adopted.

In order to increase sells in the already existing markets of tourism companies in Harghita, they should apply a reformulation strategy which has the effect of improving the quality of sold products and services:

An example of applying such a reformulation strategy is represented the new

base of climatological spa treatment from Borsec.

In recent years, products and tourism spa services in Harghita were slightly sought by tourists from Germany and those from the Scandinavian countries, who in the past were loyal consumers of such products. To regain these markets, companies should implement market development strategies. This approach involves marketing of quality tourism products to arise interest among tourists concerning these segments.

Also, this area currently requires the adoption of strategies of concentric, horizontal and lateral diversification [4]. The first type of strategy targets the process of launching on the market new tourism products and services (new itineraries, complex thematic trips, ecc.) in order to attract new segments of tourists.

The strategy of horizontal strategy is applied by the companies holding a good position on the tourism market from Harghita and which have been associated with other various companies providing services, managing in this way to develop new products but which serve the same segment of customers.

The strategy of lateral diversification is used by the companies developing new tourism products, different from the products which the company has previously sold and which serve other segments of consumers.

The purpose of market strategies applied in Harghita county should mainly aim at developing spa tourism which shall help increase employment and quality of life of local communities without affecting the sights and environmental status.

When creating tourism offer, it is necessary for development to be made based on local tourism resources with active participation of local people and to be assigned/included into an integrated program of regional development.

To that end, it is necessary to support tourism development of local cultural heritage attractions that are unique in Harghita county. The high-level presentation strategy analysis of regional tourism acquires particular importance, the analysis of training local people and businesses in tourism management and tourism impact analysis related to the society and the environment.

Main ideas of market intervention strategies aim at [2]:

- improving most of tourist routes (the most urgent ones: [Sighisoara] – Cristuru-Secuiesc – Odorheiu Secuiesc, Odorheiu Secuiesc – Bradesti – Zetea – Valea Strâmba), as well as improving the routes visited by tourists within the town and villages;

- creation of software packages and themed itineraries to achieve quality tourism;

- introduction of wellness tourism, by attracting internal or external capital;

- establishment of recreation and winter sports centers at Harghita-Băi, Gheorgheni and Harghita-Mădaraș.

- improving and developing the rural area targeting complex activities of vital importance for Harghita, both in rural dimension expressed by the area owned and the share of population employed in agriculture, social services and socio-cultural activities and tourism.

- exploitation of the rural area in Harghita county which provides optimal conditions for development of rural tourism and agrotourism, arising from specific geographical location, in the area of the Eastern Carpathians, which includes a valuable scenery heritage, with forests, springs and significant monuments of nature. Natural resources are completed with the anthropic ones; archeological monuments, historical monuments, art and architecture monuments, museums, memorial houses, monuments of folk architecture, etc.;

- rebirth of popular customs and traditions, of crafts, of various holidays which can represent tourist attractions.

4. Specific strategies for personnel policy

In their efforts to achieve strategic and tactical objectives proposed, tourism companies from Harghita must effectively manage the resources at their disposal. They should give great importance to the human resource which is essential to the existence and progress of tourism business because it leverages other resources for the effective conduct of the company activities.

The personnel policy has a great importance on the market approach of tourism companies from Harghita. One of the most important challenges of tourism

companies represents the employee's team building, the best to support an efficient use of company resources in such a way as to achieve the objectives that they have proposed.

The personnel employed in tourism plays an important part in anticipating the needs of tourists, in customizing services and in creating new long term relations with consumers, thus contributing to their increase of loyalty. Personnel awareness of the role by tourism companies imposed the level of handling it from its marketing optics perspective, so that it was introduced in literature and professional practice of internal marketing concept.

Internal marketing represents “achieving, improving and maintaining the employees of the company in positions which ensure the maximum and efficient usage of their working capacity and also a system of incentives that allow satisfying material needs and aspirations of a professional personnel”[5].

The crucial role of personnel in providing tourism services requires paying special attention to the way of attraction, selection, retention and promotion of the personnel from the company.

Sustainable tourism development depends not only on the attractive landscape and tourist facilities but also on the competitiveness and quality of personnel. Being one of the most economic competitive activities in the world, tourism requires understanding, professionalism, commitment, organization and efficient strategies in developing human resources [6].

Competitive services can be assured by a highly trained and specialized personnel, with appropriate skills and performance. Creating a skilled workforce in tourism requires basic education, vocational training and continuing education at the workplace.

Tourism in Harghita currently registers a major shortage of qualified personnel. Most entrepreneurs do not hire qualified personnel and neither invests in their professional training. This aspect reflects in the quality of services, services provided by an insufficiently qualified personnel and very weakly motivated by low wages.

Also, the level of competence in tourism is low, due to the lack of performance

standards, labor standards and the standards of education and training.

Entrepreneurs from local tourism, that is from Harghita, should adopt, within their personnel policy, strategies to attract skilled workers in the field of personnel retention strategies, strategies for increasing the quality of services provided by them, by ensuring training qualified courses, personnel loyalty strategies, strategies to enhance the quality of services provided by them, by ensuring training courses and strategies to increase competitiveness by providing facilities to performing workers.

The success of entrepreneurs from Harghita County shall certainly depend on the investment in human resources and the strategies adopted to improve the quality benefits of tourism workers.

5. Specific strategies for the marketing mix

Analyzing the marketing strategies specific to the touristic product it can be observed that a considerable part of the entrepreneurs from the tourist market in Harghita, by their attractive offers have contributed to the increased use of the already existing tourism potential in the area of action.

On the touristic market from Harghita, there are tourism agencies which have understood, first the importance of differentiation strategies. Especially, differentiation strategies used by complementary services which are part of the tourism product.

The advantages provided by differentiated strategies of personnel begin to be taken into consideration by most tourism entrepreneurs. This strategy shall be but a long-term competitive advantage only if training becomes a reality.

Due to the fact the Harghita county has a varied tourism potential both for tourism potential, but also for natural and anthropogenic potential, touristic product and service providers can be identified as applying the differentiated strategy through image.

Diversification strategy and innovation supply strategy are now used by those entrepreneurs from Harghita market operating in areas that have a varied natural and anthropogenic potential such as, for

example, tourism service providers from Băile Tuşnad that benefit from the investment made in order to exploit the potential of the mountain by arranging the ski slope which was inaugurated in 2009.

Harghita County has highly valuable natural and cultural values which unfortunately are not entirely valorized. The experience of other countries shows that an appropriate way of highlighting is represented by initiating major projects. Their achievement does not only depend on the activity of the already existing entrepreneurs, but also on the options of strategic marketing of organizations and central administration, where, of course, the political factor intervenes.

As far as marketing strategies of price policy are concerned, it has been noticed that the effects of the economic crisis had left its mark on the formulation of marketing strategies. Also, it has been noted that certain tourism service providers acting on tourism market in Harghita, have adapted to the existing economic conditions, offering tourism products and services at more attractive prices.

The negative effects of the economic crisis have been strongly felt by tourism companies from Harghita, first of all, due to the strong revenue reduction of the vast majority of consumers of tourism products. It is obvious that in this context, one cannot speak about a high level of capitalization of tourism potential in the county.

On the touristic market from Harghita county suppliers of tourism products and services do not pay enough attention to the distribution strategies. Certainly, the marketing of high quality tourism products,

by intermediaries known nationally and internationally, can contribute to the increased exploitation of tourism potential of this area. Marketing of poor quality tourism products even through internationally recognized tour operators, generates large disadvantages.

6. Conclusions

Long-term tourism in Harghita can become a competitive and sustainable tourism, contributing to meet the present and future needs through strong concern and care towards its resources, resources which must be employed in such a way as to allow their use in the decades to come.

The Young Generation’s Perspective on Ecological Behavior and Education

Nica Ana-Maria

Bucharest Academy of Economic Studies, Faculty of Commerce

ana.nica@hotmail.com

Abstract

Based on theoretical aspects related to the role of education and environmental performance, continuing with market research and ending with conclusions, this paper aims to encourage stakeholders’ concerns in the environmental field. The most valuable part of the paper is the market research among young people in Bucharest, seen as the core of future environmental concerns. It reveals that although young people are perceived as beginners in environmental issues, they are however very aware of their role, and they are ready to support the introduction of environmental subjects in school curricula as early as possible. Young people appreciate organic products, passing the ball into the producers and traders field, who are forced to consider appropriate policies for marketing, because now they know that their products are good, but too expensive. In the future, the authors intend to renew this research, towards new, evolutionary conclusions.

Keywords: behavioral ecology, environmental education, environment, youth research

J.E.L. Classification: Q01, Q56, Q57, M31

Introduction

Concerns for the environment, ecology, sustainable development are becoming increasingly prominent in all countries. Global warming, population demographic boom, lack of food are just some of the current problems economy faces. The new concept of eco-economics, promoted by Lester Brown [1] requires harmony between the economy and natural resources, which is not just a fad but a necessity. We are too many, compared to the amount of resources

available. We are not enough educated, while inattentive to the environment. Theoretically, we are on the wrong track. Consumption exceeding all limit can lead to conflicts over resources and even poverty for other people. In 2005, 1,345 million people in underdeveloped countries lived on less than \$ 1.25 per day [2]. It is hard to believe that this figure changed given the current economic crisis and global population estimated at 7 billion [3].

Thus, concepts which 30 years ago seemed to be only collateral concerns are now hard realities. However, humanity has made leaps through recent years, so one can say that we have the ability to create complex programs in order to stop or mitigate certain negative phenomena.

The ecological field plays an important part, being understood as an effective way to connect man with the environment. Its existence in itself is not sufficient. Steps have to be taken towards understanding these issues by all people, but especially the young generation. In this context, education becomes vital.

On one hand, a proper attitude of world governments towards the introduction and continuity of ecology subjects and topics in the school curricula is one way to reduce negative environmental impacts. On the other hand, based on an adequate education, the probability for a correct attitude and ecological behavior is greater. Thus, the road from the present to a green conscience becomes smoother. Man must regard future issues as recycling, separate collection of waste, consumption of organic products as natural facts. The change is directly linked to the desire for a better and more harmonious living, in a just, clean and peaceful world [4].

Environmental education is interdisciplinary and multidisciplinary. Understanding the processes and phenomena that determine the status of ecological

systems, i.e. understanding ecology provides, for the ones involved, both rights and responsibilities. A special responsibility is given to the mass media, which have access to scientific information. However, in addition to the scientific/eminently pragmatic part, environmental education has also philosophical issues related to ethics, morality, axiology, etc., all of which contribute to human individual position in society, in the frame of civilization and ecosphere.

Ecological behavior is a complex and complicated concept. It requires a constant and correct attitude towards what people generally call environment. In the 21st century, environmental behavior involves a number of actors that contribute directly or indirectly to training, maintaining and improving it. A basic element is the concept of responsibility. Thus, environmentally responsible people are those who are employed often in the category of environmental behavior (including consumption of organic products). Psychology studies have revealed that there are two types of responsibility: moral and conventional. The first is referred to the thinking and the feeling of guilt that one has, while the latter is connected to the social expectations that a person has and to the capacity of being able to meet them [5].

Research on the environmental performance took shape in the 80's [6,7] and was developed in the 90's [8,9]. Currently, the concerns on this matter are present in the work of many researchers, mentioning: Fraj, E., Martinez, E., [10,11].

Aiming to highlight the reality of education, environmental and consumer behavior, the article presents the results of a research on the 15-24 age group, in order to formulate conclusions on the issues mentioned, and a series of useful conclusions for several categories of actors involved in ecological activity.

1. Environmental education, a necessity in the 21st century

Ecology is the science of ecosystem interrelations between living organisms and the a-biotic environment, a science focused on understanding integrated synthetic processes in our environment, being based on

theories of organic evolution. Ecological thinking has motivated the emergence of a set of new disciplines, contained in a complex system of interconnections.

Education and learning begin at birth and continue throughout life. They are an interpersonal transfer of ideas, approaches and fundamental data considered relevant to a harmonious human life. If at the beginning the problem of continuous learning concerned only the developed countries, able to invest in adults' education also, while the knowledge-based society was formed, a series of states in transition understood its role and started encouraging the phenomenon [12].

Through experiments, learning should develop naturally from what the person knows to discovering the variety of forms and phenomena of nature. The essential purpose of environmental education is to enable everyone to express personal attitudes, responsibility towards the environment in which they live. This begins with the family which is an important and relevant example.

The ecological approach of education has certain methodological features. Since the ultimate goal of this educational approach is taking on an appropriate behavior and concrete actions for environmental protection, some ways to move from theoretical information, personal involvement, to concrete activities, depending on the cycle education, can be highlighted.

Since primary school to high school, youth are very receptive to what they are told and shown about the environment and willing to pursue actions in that direction. School's mission is to provide, gradually and according to age characteristics, scientific knowledge to motivate eco-civic norms and conducts, to create and organize educational activities on environmental protection, thus resulting in new knowledge [13].

In Romania, there were and are scheduled to be held activities in an environmentally friendly trend. One example is "Keep the city clean" program which took place during the school year 2010-2011 and is set to continue in the next years [14].

The "Eco-School program", on the other hand, is an international program that started from the idea of students' involvement in dealing with local environmental problems.

With an end to become an eco-school, education units must meet certain conditions, primarily related to the appearance of the school, but also the content of materials included in the school curricula, which should include elements of environmental protection, water and energy saving and selective waste collection. Schools must have a supplementary budget through the recovery of waste and use the money to endow educational means. Not only urban units are concerned, but also rural schools are interested in environmental and ecological education activities.

After obtaining this status, schools that successfully implement the program, following the evaluation procedure are awarded the Green Flag. It is a symbol of environmental education, a recognized eco-indicator for sustainable development education and a certificate of environmental performance of schools.

Through environmental education, there is a substantial contribution to higher understanding of the connection between individual and group activities, social and environmental changes of current and future life.

2. Ecological behavior, manifestation of concern for the environment

Ecological behavior is formed over time. It requires both respect for the environment and taking the according actions.

A category of studies that has great value in today's society is the transnational one. Thus, the Determinants of Environmental Behavior in Societies in Transition: Evidence from Five European Countries [15], brings into question the environmental aspects of behavior in five countries in Eastern Europe, including Romania. Several points have to be mentioned: the defined study, inter alia, responsible environmental behavior of active ecological behavior; the first group included questions related to avoiding the consumption of energy, water, the use of home-brought shopping bags, and the second group actions related to engaging in ecology (financial or non-financial), to the use of environmentally harmful products. Of the five states, Romania recorded the highest score in terms of environmentally responsible behavior and the lowest in terms of active

ecological behavior. Although the study was conducted in 2004, it has relevance now, as one can more easily relate to particular environmental behavior than to the common behavior, such as involvement in organized activities or financial contribution to specialized NGOs.

A good example is diverting 2% of income tax. However, a complex of factors consisting from the lack of education, information and even responsibility, conducted, in 2009, to the following situation: slightly over 50% of Romanian people exercised this right [16]. Environmental NGOs are not the most popular, as most people directed this income to church or religious foundations (29%), SMURD (10%), Save the Children (9%) children in difficulty (6%) and the Red Cross (about 6%).

It is easy to understand that Romania is taking its first steps in the ecology domain. However, joining the European Union provided a number of obligations and many of them were environmental issues, such as the requirement for the existence, by the year 2015, of local systems of waste separation by type: paper/cardboard, plastic, metal, glass. Thus, local authorities will have to implement specific measures to achieve this objective. By accessing European funds, the costs could be reduced.

Another issue concerns the environmental behavior of consumption. It is influenced by a series of internal and external factors. In the category of internal can be included: environmental attitudes, motivation and environmental experience or personality. All these contribute to the decisions every consumer makes when purchasing products and services. External factors which are mostly affecting ecological purchasing behavior in some countries, are the socio-cultural and economic type ones. For countries with experience in the field, the dominant influence comes from politics and law, but also from ecological marketing mixes.

The road to ecological behavior is difficult and needs to be paved with appropriate legislation, with strong sanctions, involving local community, school, media, researchers and all stakeholders. Finally, the reward would be a life in harmony with nature, which is also cleaner, healthier and

certainly more fulfilling.

3. Highlights of consumption and environmental performance in Bucharest

Any discussion about the future, sustainable development, trends, must be linked to reality from the perspective of young generation. In this regard, a research was undertaken among young people aged between 15 and 24, in Bucharest. Total collectivity is accounted for 265,000 people [17]. The methodology for determining the sample size led to a number of necessary queries of 384 people [18]. For safety reasons, 400 people were surveyed, yielding a total of 388 valid responses. The accepted error is 5%, and the questionnaire was applied during the period ranging from May 2nd to May 13th 2012, using direct interview operators (three subway stations, five colleges and four universities). A pre-test of this statistical tool was performed, by applying 10 questionnaires. Subsequently there have been some changes, leading to the final form of the statistical tool.

While drafting the questionnaire, several issues were taken into account regarding content, format and wording. Consistent with the typology of respondents (young, less patience) a questionnaire with 13 questions was developed, mostly of them closed type ones. The first question was part of the filter and was related to the respondent's age. If the person was not within the range desired, the interview ended.

The purpose of the investigation is assessing the degree to which young people in Bucharest resonate in consumer issues and ecological behavior, but also how they see the future on these issues. The objectives were:

- to measure the ecological interest – O1,
- to determine the awareness - environmental behavior relation – O2,
- to establish youth attitude towards ecological aspects, especially consumption and behavior – O3,
- to determine the role of media in environmental behavior – O4,
- to identify perceptions about the role of ecology in society and the trend in this area – O5.

After completing the steps related to data collection and analysis, a research report was

prepared; its results are presented below.

The ecological interest of young people reaches the proportion of 77% for much and very much. It's a promising idea for the future of ecology in Bucharest area. Over half of the respondents, 56%, apply what they consider to be environmentally friendly behavior (52% much and 4% very much). This is a positive aspect. However, it should be noted that a considerable percentage, 40%, only applies what they acknowledge in a small proportion.

In Bucharest, the waste management problem in the public space is very present and it seems complicated, as the authorities have no real solution for now. In this regard, questions were designed to identify youth behavior. Thus, 43% of the respondents does not ever throw away trash on the ground, 42% very rarely throws and 13% rarely. Regarding the selective collection of waste, half of the respondents do so occasionally, while 37% do so always. 13% admitted that they never selectively collect garbage.

Relating to waste collection for recycling, 65% of the young people have appreciated they do not undertake such activities. Of the over 130 that have concerns in this regard, 100 collect only paper. Higher frequencies of occurrence (but in very small percentage), registered batteries and plastic bottles. Oil and appliances are rarely collected.

Consumption of organic products among young people is still very low: only 17 percent said yes. They most frequently purchase eco-food: fruit, bread, milk, more rarely cosmetics and light bulbs. In most cases, the motivation for not-buying organic products is unique, but 40 respondents chose more reasons. From the classic 4Ps of marketing, two are cited by respondents: price and placement.

Thus, 37% correspond to variant a - „is expensive", while the variant c, "are distributed in fewer stores than common products" account for 34% of the options. 19% is relating to the improper labeling of products, that makes differentiation difficult. However, organic products are considered to have good quality by 72% of respondents. 15% of the people questioned consider these products to be of good quality and moderate price. Insignificant percentage (less than 2%) rated the products as of poor quality and expensive.

The information obtained by young people through the media determined their responses: 348 (90%) chose one option - 37% felt that they had become more environmentally responsible, 29% that have learned more about ecology, 17% have started to apply the knowledge acquired. Only 17% appreciated the information that was already known, to not have had any influence on their already eco-friendly behavior. Of the 10% who gave multiple answers, the elections were generally double combinations of variants a, b and c ("I learnt more about ecology," "I became more responsible in relation to the environment", "I began to apply the acquired knowledge").

In aspects of subjects' perception on issues related to ecology, 87% felt as beginners. Only 7% said they were convinced environmentalists, while the remaining 6% are either indifferent or opponents of the field. 69% said that ecology-related subjects should be introduced in the school curricula in school or kindergarden, while only 15% felt that they should appear in the programs of "long life learning" type. Only 5% indicated that environment should not be studied formally.

As for the tendency in ecological behavior, the majority of young people (83%) see it as increasing, 15% perceive it as unchanged and only 2% as decreasing.

The five objectives of the research are considered as achieved, and the research findings are extended to the entire community, as follows:

- young people's interest in ecology is greatly supported by the media, which provided useful information, causing them to behave responsibly in relation to the environment,
- although they do not throw garbage on the ground, its selection is of rather occasional nature, while the collection of waste for recycling is still in the pioneering phase,
- young people see themselves as environmentalists beginners and realize the role of ecology, saying that it should be studied as a subject since childhood.
- although they do not consume organic products, mainly for reasons of price and distribution, they appreciate the quality,
- respondents trust their peers, adding that

society will behave in a "greener" way in the future.

The study's results reveal the Bucharest reality and require certain steps in an EU country. First is the question of fair environmental education, by introducing appropriate subjects from the earliest years of life. Those must be included in learning programs, including those of life long learning type. Man-environment relationships highly degraded in recent years and need to be always in our attention. In the absence of repetitive information we tend to overlook the real dimensions of the negative impact we have in today's society. That's why those subjects are needed.

Another component of the society, extremely present, is the media, whose role should be a threefold: information - education - involvement. Programs should be based on correct information, should be continuous, creative, examples of good practice in Romania and other countries.

To increase consumption of organic products among young people, traders should be extremely creative in the promotion and product policy, so buyers are willing to pay the price, often considered too high.

Overall, the study results are encouraging, young people are interested in ecology, learning and adopting an environmentally correct behavior. Thus, if society through its institutions will collaborate in order to set the right objectives, Bucharest is likely to become a cleaner city, more careful with the surroundings, and why not, healthier, by people who will buy cleaner, fairer and more sustainable products and services.

Conclusions

The most valuable part of the paper "The young generation's perspective on ecological behavior and education" is the research undertaken in order to analyze a very important society group: young people. Questionnaires are meant to reveal a scan related to the situation of the environmental aspects, according to young people. The conclusions of the research are useful for different parts. Thus, environmental organizations have found that young people are interested in this area, schools that they might include in their curricula subjects in the field of ecology, producers and traders of

organic products that they can trust their products, but they must be careful with prices. Also, the media has the duty to provide programs that encourage responsible behavior and use of eco products. A good sign is given by the answer to the last question, related to the trend of the green consumption as rising.

Steps taken in this article should be continued, in order to make a comparison over time. Thus, successive application could set up an environmental profile of the young man who lives in Bucharest. Also, research could be extended to other regions and even in rural areas.

Optimism about the interest in ecology should be supported in every way possible, because young people need education, stability and a clean future.

Abstract

The evolution of quality concepts and their application increasingly higher administrative different industries and led to making quality a proven tool of good management. Evolution mood resulting from the awareness of people directions of action to enhance the role of education, the appointment of a management representative for quality, and so on, self-empowerment drives by all staff and continuous improvement of economic results.

It went so gradually from the simple concept of product quality control, quality assurance for products or services and, ultimately, quality management, which is part of an organization devoted to quality management in the spirit of ISO 9000 family of standards - currently with the reference standard version EN ISO 9001:2008.

Key words: quality management, Internet, management responsibility.

J.E.L. classification: M21, M42.

1. Introduction

International Standard ISO 9000 quality systems has been developed since 1987, due to international demand, especially in the initial defense industry and other production areas such as the nuclear industry, and as such standard was used only by companies in the sphere of production. Later, to make it applicable not only commercial sectors engaged in the production, the standard was revised and formally adopted in 1994 by the

International Organization for Standardization.

Currently, the ISO 9000 family of standards addresses a variety of issues in quality, reference being:

- ISO 9000:2005 - Quality Management Systems. Fundamentals and vocabulary;

- ISO 9001:2008 - Quality Management Systems requirements;

- ISO 9004:2009 - Management of an organization's sustainable performance. A quality management approach;

- ISO 19011:2002 - Guidelines for auditing Quality Management Systems and/or environmental.

Increasing competitiveness and capacity gain customer satisfaction can be best achieved through the design and implementation of quality management systems. Training programs in practice management quality management systems vary from country to country and from one organization to another and depends on market characteristics, professional culture, organizational culture and quality oriented.

Certification of quality management systems standards ISO 9000 series is a inevitable necessity for business support market entry and export. Even for businesses that have developed on the Internet certification of management systems is also entering the EU. Very European quality policy aims to promote an image of quality and European cultures to ensure free movement of goods, but also for the continued growth of competitive products and services. European Commission focuses its efforts to develop a legal framework and

procedures, along with training a conformity assessment system, efficient, competent, transparent, based on clearly defined principles.

2. Quality management in online companies from Romania

In terms of the structural components of an organization, creating and improving the quality can be addressed as a cycle, as shown in Figure 1 appears.

Figure 1. Quality cycle

Source: adaptation from Nicolescu, O., Plumb, I., Pricop, M., Vasilescu, I., Verboncu, I. - *Abordări moderne în managementul și economia organizației*, Vol. 2: *Managementul pe domenii de activitate*, Editura Economică Publishing, Bucharest, 2003, pp. 482

Thus, quality assurance and improvement involves better cooperation between departments of an organization, so, based on consumer needs, to define quality attributes, how to measure their quality standards, methods of testing standards, methods of correcting poor quality.

Quality management principles that express the basic ideas, the thesis is based on appropriate methodology, as defined by ISO 9001:2008 (ISO - Quality Management Principles, ISO Central Secretariat, Geneva, 2012), are:

{ Customer focus - meeting customers' explicit and implicit requirements are

fundamentally support the existence and further development of the company;

{ Leadership - enterprise performance goals can only be achieved through full involvement of leaders in training employees in the application of all the principles on which total quality management;

{ Involvement of people - creating and maintaining a functioning feedback mechanism between operational and managerial echelons amplifies a special way how to improve products and processes;

{ Process approach - the product is the result of activities or processes, the process is a set of interrelated resources and activities and added value that transforms input elements (process) the elements out;

{ Quality system approach to process management - identifying, understanding and managing interrelated processes as a system contributes to the effective and efficient business objectives;

{ Continuous improvement - continuous improvement should be a permanent objective of the company, which operates a quality management system functional and effective;

{ Approach based on facts to make decisions - quality management system uses data and information taken from documents that are implemented procedures for preparation;

{ Mutually beneficial supplier relationships - mutually beneficial relationships between all processes undertaken within the enterprise and between external partners and contribute to an osmosis between internal activities, on the one hand, and between the enterprise and its environment, on the other hand, the Thus, the entities involved increase their ability to create value added.

On the other hand, everything is quality management in a company that operates online can be translated and with a strong business ethics. The manner in which leaders choose to exercise this influence is a consequence of the way of being or may be the result of sustained learning. As in management, so in leadership can speak and native issues. Thus flair of management, the art of knowing how to act in a certain time, it can be in leadership charisma, his empathy. Some leaders, aided by these elements come

more easily to performance. Others get harder status, using various methods such as involving employees in decisions current and other assets. All existing businesses seeking excellence: it is recognition, market position, quality certification. To achieve this level it's requires a suitable leader, a true leader. (Tala, Madalina Lavinia - *Leader's ethics - a requirement for business success*, Amfiteatru Economic no. 23, A.S.E. Publishing, Bucharest, 2008, pp. 97-102).

3. Implementation of quality management in Internet business models in Romania

Implementation of ISO standards in an online business has become a necessity due to deficiencies in the management and execution processes, ineffective prosecution of the work and some negative feed-backs or lack of feedback from the customers.

Leaders establish unity of purpose and direction of the organization. They create and maintain the internal environment in which people can become fully involved in achieving the organization's objectives. The first step in establishing unity of purpose and direction of the organization is to assess each business ideas, regarded in its complexity.

Then it is considering delegating management responsibilities to lower hierarchical levels: for example, a dispatcher notifications (for an online business that deals with the distribution of electronic equipment) is required to track each complaint received from customers and to present at the meeting or whenever necessary, service engineers calculate their own times interventions or referrals service maintenance contracts and carry out their own hierarchy of these appointments and schedule their own sales representatives visits the customer's location or the potential customers, and call them at the office.

Implementation of quality management in Internet business models can be achieved using established methodology, adapting to the specific business model adopted, which generally requires a degree of formalization lower than traditional models - especially if sized organizations large. However, observing the stages and their rigorous approach is essential if the Internet business to adapt the entire structure with focus on quality. In this regard, the following steps are

considered (Oprean, C., Kifor, C. V. - *Managementul calității*, Capitolul 4: *Implementarea sistemelor de managementul calității*, Lucian Blaga University Publishing, Sibiu, 2002):

- Obtain commitment to change by organizing the management team;
- Develop vision and mission;
- Decomposition of the mission critical success factors;
 - Defining key performance indicators;
 - Identify core processes;
 - Basic decomposition into sub-processes, activities and tasks, as well as to improve team building;
 - Integration of employees and processes by developing policy or the transformation of objectives.

Six Sigma vision of an organization that operates on the Internet contains a number of issues that can be applied for businesses operating on the Internet (Pande P., Neuman R., Cavanagh R. - *Six Sigma - Cum își îmbunătățesc performanțele GE, Motorola și alte companii de top*, All Publishing, Bucharest, 2000, pag. 93-94):

1. A real focus on customer attitude that puts customer needs first, while being supported systems and business strategies that serve the client's needs.

2. Management based on facts and data, effective measurement systems that track the results and outputs of the system and processes, and other system entries predictors.

3. The focus on process management and process improvement, as the engine of growth and achieve success. Six Sigma approach ensures that processes are documented, communicated, measured and refined on a regular basis. Also designed or redesigned processes from time to time to remain compatible with the customer and business needs.

4. Proactive management involving skills and practices that anticipate problems and changes, use facts and data, and always check assumptions about the organization's objectives.

5. Collaboration between internal groups and customers, suppliers and partners all logistics network.

6. An impulse to perfection offered the organization's Six Sigma freedom to try new

approaches even when risks are taken, the organization learning from mistakes.

Besides these aspects, taking into account the implementation of Six Sigma in an Internet business is justified especially in oriented approach to performance measurement that correlates with commensurate opportunities offered by the Internet environment in much more than in traditional business models.

The Six Sigma approach, the organization can achieve a number of important benefits, which attract companies to this method. These include:

1. Generate lasting success. Six Sigma method creates skills and culture necessary for continued revitalization of the company.

2. Establishes a performance objective for each. In a company of any size each service, business unit and individual goals and missions are different. However, what connects them all is the delivery of products, customer service information. Six Sigma uses this common framework for business process and client to create a constant goal: Six Sigma performance, for example - performance model so close to perfection.

3. Add value to customers. Focusing on the customer is where Six Sigma method, learning what is value to customers and to plan how products and services can be delivered profitably.

4. Rate of improvement accelerates. Information technologies establish a rate of doubling performance every 18 months over costs, improving customer expectations become even more demanding. Contestant who fails to progress in a rapidly become the best. Six Sigma helps a company to not only improve performance, but to improve their improvement.

5. Promote cross-learning and sharing of experiences. Six Sigma is an approach which can accelerate the development and sharing of new ideas within an organization.

6. Implement strategic change. Introducing new products, launching new businesses, entering new markets, acquiring organizations have become common events for most organizations.

4. Conclusions

Beyond the implementation of quality management and the context in which firms

operate, the profitability of a business requires not only the existence of a superior offer, many clients and a turnover above average, profitable companies operating on the Internet also involves (Baran, R., Zerres, C., Zerres, M. - *Customer relationship management*, Ventus Publishing Aps, Holstebro, 2011):

- A design of e-business and technology architecture;
- Internet Marketing Strategies;
- Online brand management (managing online own brand);
- Positioning Strategies of Internet markets products or prices;
- Online advertising, online promotion, web traffic growth tactics;
- Solutions for customer relationship management and technical support;
- Market research and analysis website its efficiency;
- Analysis of customer satisfaction and solutions for online communication;
- Services and strategies for choosing e-business partners;
- Online Payment Solutions and e-Commerce strategies.

It should be emphasized in particular that, compared to traditional businesses, in business on the Internet, the speed of adaptation to change that is required from firms can be considered as superior and often crucial in achieving profitability.

Profitability, the ultimate goal of a business reason for its existence implies a logical approach, integrated structure, if Internet businesses to focus or refocus the firm's activities, or to integrate within them. Thus, the managers need a strategic approach based strictly in accordance with established principles and steps of strategic management.

Abstract

Social media is a term that reflects the rapid development of technology and the skills and knowledge users, a complex concept for which there is no universally accepted definition.

*The term defines generic, a set of online communication channels, social networks and transmission of information, including social networks, groups, forums, blogs and various content platforms that facilitate transmission and instant communication (Safko, L., *The Social Media Bible*, John Willey & Sons, New Jersey, 2010). Social media includes web tools easily accessible by people conversing, participating, creating, recommends exploit information and react to them online.*

Social media refers to communication, interaction between people, free access to information of all kinds, creating content to Internet users.

Key words: Internet, social media, online business.

J.E.L. Classification: M21, L81

1. Introduction

Social media aimed at a specific target, because, as shown in the literature, some sociological and psychographic characteristics are crucial factors that determine users to engage in social media on the Internet. For example, studies show that users are rather young audience, and personality traits such as openness to new experiences, are positively correlated with

the use of social applications on the Internet. These features can be refined according to age and sex: thus, the correlation between extroversion and social media is especially important for young population, while open to new experiences is a key high especially among population segments mature, by sex showed that men with higher levels of emotional instability are regular users to a greater extent (Correa, T., Willard Hinsley, A., De Zuniga, H.G.).

The concept of social media is closely linked to the concept of Web 2.0, the revision of the technology that allowed the development of infrastructure and the concept of social media. Thus, the main features of social media are given by Web 2.0 features, respectively (Chaffey D., Smith PR – e-Marketing Excellence. Planning and Optimizing Your Digital Marketing, 3rd Edition, Elsevier, Oxford, 2008, p 112):

- ♣ Active participation: most applications are built based on active participation in their development of volunteers.

- ♣ Encourage the creation of web content to each user: blogs are a good example in this direction, and other examples are collaborative encyclopedia Wikipedia and YouTube.

- ♣ Ability grading and classification of online content: This service involves classification and grading of quality content.

- ♣ From millions of blogs available can easily find those in a given category and those that were considered useful by other users.

- ♣ Online advertising: some websites offers advertising in their pages. For example, YouTube provides five alternative ways to address the target audience: display

ads, channels dedicated to a particular firm, contests, advertising videos on YouTube or other video hosted by YouTube.

♣ Web services downloadable or interactive applications: such as Google Maps, Flickr or services like Blogger blogs. A number of interactive applications may involve downloading and installing software or plug-ins. For example, Last.fm is a service that allows publishing lists of your favorite songs or music recommendations to find people with common interests.

♣ Data exchange between sites in XML format: For example RSS - a program that automatically sends alerts when certain web sites provide news - is based on XML. These models promote exchange XML data between users of new services such as learning courses in a standardized format.

♣ Develop applications using technologies such as AJAX (Asynchronous JavaScript and XML) best known application of this is Google Maps which does not require refresh image to show maps.

Simplicity in style and design: many Web 2.0 applications are focused on a predominant activity such as social networking, mapping and sharing photos. To make this activity more enjoyable and appealing to an interface as simple as possible, using, for example, a harmonized color scheme, rounded corners on boxes, etc.

2. Web 2.0 concept

Web 2.0 concept incorporates two basic elements: on the one hand, the emergence, growth and popularity of social media, and on the other hand, changing the paradigm for the sharing of control between suppliers and users, in that users take a greater control over their interactions with the media, various organizations and mutual (Poynter, R. - the Handbook of Online and Social Media Research: Tools and Techniques for Market Researchers, John Wiley & Sons, Chichester, 2010, pp. 161).

Is currently circulating the Web 3.0 evolution, driven by technological advances that outlines a number of trends already visible, among which may include (Chaffey D., Smith PR, op. Cit., Page 113):

- Increased use of web applications and services (such as word processor and spreadsheet Google sites);

- Increased incorporation of content and services from other sites or on a network in a site (using tools like Yahoo! Pipes and XML exchanges between widgets);

- Increased use of video flows (as suggested offered by using YouTube and IPTV services such as Joost);

- Increased use of interactive virtual environments such as Second Life;

- Increased data sharing between social networks that satisfy different needs (as shown OpenSocial by Google);

- Increased use of semantic mark - or the sense of information - which leads to a semantic web. This would increase the number of web pages of interest to users by introducing metadata about them and their relationship, allowing access and achieve different tasks to automated agents. Thus, based on semantic mark will be able to develop applications equipped with artificial intelligence, which recommends web content and services to users without needing them to be actively involved in their search, and apply their own evaluation of the products and brands (for example, a service of automated comparison of tenders).

3. Social media types

Social media experience a wide variety of forms, each with its own particularities. An integrated taxonomic approach can be based on the main elements that characterize the concept of social media, which can be regarded as basic motivations that led to its emergence and development - self-presentation or self-exposure, respectively, in the presence of social complex environment more or less high.

↳ blogs - so-called primitive form of social media - composed of personal web pages, usually including articles in reverse chronological order. Text-based sites are still quite common form, respectively, a Web page, built on a free platform with a standardized (divided into header, footer, content and one or two the bullet on the right), the information is displayed (called stations) generally maintained and written by one person, you can find the widest range of information - from current news and general interest to the author's passions - and where visitors can interact by posting comments. Micro-blogging services enables companies

to conduct promotion and marketing. Examples: Blogger, LiveJournal, TypePad, WordPress, Webblog.ro.

↳ Collaborative projects - allowing assembly in a common and simultaneous creation of content by multiple users, thus allowing users to add, remove and change the content. Other sites let you add common content a user group: links and media collections. Wiki term designates and collaborative software used to create such a website, and among the best-known wikis include Wikipedia and Wikimedia, that offers detail product and company, thus expanding the scope of public knowledge about the product. Other examples are Pbwiki or Wetpaint.

↳ Social networking sites - which allow users to create personalized pages that can be viewed by a network of people with common interests (such as a network of students, friends and customers of the same product, fans of an artist). They also allow you to send e-mails and messages. Personalized pages often contain photos, videos, audio clips and blogs. Examples are: Facebook, Hi5, LinkedIn, MySpace, Afaceri.ro, etc.

↳ Content-based communities - have the common goal of providing users various forms of media: text (Bookcrossing), photos (Flickr), videos (YouTube) and PowerPoint presentations (Slide Share). Usually these sites do not require the creation of user profiles to be accessed, but a picture or movie that site must be approved by the moderator before it becomes visible.

↳ Virtual social worlds - allow users to choose their behavior in a more simplified and live in a virtual world, similar to the real one. An illustrative example is Second Life website, and other examples include: The Sims Online, There.

↳ Virtual worlds of games - are three-dimensional virtual platform where users appear as avatars and interact according to the rules of the games. These worlds have gained popularity with the introduction of Microsoft Xbox and Sony PlayStation consoles. Examples of virtual worlds include: City of Villains Travian, Lord of the Rings, World of Warcraft, etc.

4. Tools used in social media

Social media tools used are: social networks, photos, publications, audio, video, micro blogging, live casting, virtual worlds, games, RSS, search, mobile Internet. In recent years, social media has developed into a surprisingly fast pace and has a very large influence on the lives of individuals and at the same time on business. For example, Facebook attracts more than 200 million new active users per month, about 77% of active Internet users read blogs, 10 hours of video are posted on YouTube every minute, and the average age of a LinkedIn user is 31 years old.

Social media is known mainly through blog type platforms. Can be identified within a number of social media tools that are used both in personal and business level: blogs, wikis, multimedia sharing systems, tagging services, social bookmarking, news-feeds, post-casting services, websites social networking sites.

⇒ The blog is a Web page built on a free platform with a standardized (divided into header, footer, content and one or two the bullet on the right) that information (called channels) are displayed in reverse chronological order in generally maintained and written by one person, you can find the widest range of information (from current news and general interest to the author or gossip passions and views on various topics) and where visitors can interact very simply by commenting. Micro blogging services enables companies to launch a product to promote it, to achieve Customer who use buzz.

⇒ Wikis are a web application that allows users to add their own content and keep successive versions, like the Internet forum, but also allows anyone else to change the content. Wikis are part of the recent phenomenon called Web 2.0. The term Wiki (<http://www.wikipedia.ro>) calls and collaborative software used to create such a website. Between wikis are widespread popularity with Wikipedia or the Wikimedia allowing detailed product and company, thus expanding the scope of public knowledge about the product.

⇒ Internet forum site is an online discussion site where people can participate in conversations in the form of posted messages. This type of website is different from the messages in chats, because in this

case messages are temporarily archived. Also, depending on the access level of a user, a posted message might need to be approved by a moderator before it becomes visible.

⇒ Social networks are a network of people with common goals, such as a network of students, friends and customers of the same product, so fans of the artist. Social networks of the Internet are called "social networks".

In recent years, through a social network and an information network of Internet users often means, within site where they can register and communicate. In this way, they can create and transmit information accessible globally.

⇒ Video and photo sharing are sites where users can upload movies and photos on any field. As with forums, a photo or video that site must be approved by the moderator before it becomes visible.

The tools described above can be used in any type of business to facilitate communication and collaboration between customers and suppliers.

5. Conclusions

Success or failure due to build a presence in social media sites and how they will be assessed the presence, is a major issue to be considered by the management of a business. Most businesses, especially smaller ones, have traditionally taken ICT investments in terms of money. Thus, any investment in information and communication technology has been considered as an adjunct business that helps improve operational efficiency - without necessarily contribute directly to adding value to products or services.

According to a study by market research, analysis and market research Gartner (Bîrzoii V. - Revenues from social media - 16.9 billion dollars in 2012, Business Cover, July 25, 2012), the revenue generated by social media can reach 16.9 billion dollars worldwide in 2012. Component of social media, advertising seems to have the largest share in achieving such income, estimated at a total of \$ 8.8 billion in 2012. It is also expected that the number of users of social media to grow at a moderate pace. New forms of media and entertainment will keep the users subscribe on social media sites, may be able to attract new subscribers. Increasing

competition in social media, each competitor looking to gain as much leisure users, this struggle leading to the formation of new social media entities (web based and especially mobile).

A company's marketing budget directed to building business presence on social networks can be typically up to 20% of the total budget. More companies explore social media to create online communities of customers or potential customers that can interact in various ways and to forward the message on the Internet. In Romania, the most popular Romanian 100 Facebook pages, 23 pages are a company or brand. Multinational companies have made their presence felt in online social environment but so far have gathered a huge number of fans having sustained interaction with them. Impact on sales is likely only to websites that offer discount coupons (<http://www.businessmagazin.ro/media-marketing/efectul-facebook-9012897>) social network where users are attracted mainly offers published, the rest is just the engine occasionally to stimulate sales. Four such deals are found in the top 100 most popular Facebook pages and FunDeal.ro is right first, if account is taken only companies or their products.

As the study by Regus, which included over 17,000 respondents from 80 countries among managers, is deemed necessary connection between the types of online promotion and traditional, to achieve maximum efficiency - 61% of respondents consider global, respectively, 57% in Romania. Among ways to promote online presence in social networks is considered essential - by 74% of respondents globally, respectively, 70% in Romania.

Since the main role of communication and information, social media is being used increasingly as a means of promoting the image of organizations and products and services. Social media provides openness and visibility of products and customers the opportunity to test some products. However, it happens that the products and services presented through blogs, social networks, forums to be ignored, pages are hard to read and aesthetically unattractive. Under these conditions, the impact on users can be negative.

For a product to be successful on the

Internet and therefore on social media, it needs to achieve optimum between function and form, in this case to serve the needs by providing information they need, while having a form as pleasant.

The number of users who use (and also pay for accounts on social networks) will increase, but revenue generated by this form of promotion decrease observed tendency of some social media companies like LinkedIn or Xing. It seems that there will be new opportunities to make money in social media, but reviving income sources by 2016 will be made through services. The highest weight and, in effect, the greatest impact in increasing social media will have intake advertising producers. On medium and long term, social media sites will have to implement "data analysis techniques, to interrogate social networks to provide marketing people a picture as close to reality in terms of preferences and consumer needs. "in other words, it will translate into practice through social media, traditional marketing concepts and principles in order to define a more accurate measurement, the average specific needs and preferences of Internet consumers.

Romanian Political and Moral Crisis. Background of Business Strategic Development

Nicolau Cristina

Foriș Tiberiu

The Transilvania University of Brașov

cristina.nicolau@unitbv.ro, tiberiu.foris@unitbv.ro

Abstract

This paper presents the political crisis that Romania is going through as a result of the derived and interconnected crises that the world economy is experiencing, the international financial crisis which started in 2007 in the USA and rapidly spread above the borders and the global economic crisis which has been developing before 2007 but started to be in the view of specialists as the financial one got more and more importance. In this respect, this paper has two major objectives: on one hand, to analyse and present the causes of the political and moral crisis in Romania and on the other hand, to identify the features of the Romanian mentality during a period of time of crisis.

Key words: crisis, political risk, country risk

J.E.L. Classification: D21, D81, H63, M21

1. Introduction

This paper aims at introducing within economic theory of crisis management the political crisis, the main objectives of this paper being defining and analysing the political and moral crisis that Romania is going through from the point of view of Romanian citizens' cultural characteristics, generically named with the concept of „mentality”. The paper is divided into three parts, the first part being dedicated to a literature review on the political crisis and the organizational culture which aims at defining Romanian mentality according to their features on Hofstede's cultural model, the second part makes a detailed analysis of nowadays Romania and the impact of the world crisis on our national state whereas the third part deals with Romanian citizens' behaviour during the crisis, our conclusions

in the end of the paper highlighting the particularities of the Romanian economic environment that businesses should consider.

2. Political crisis and organizational culture – the Romanian mentality

In this respect, we shall use Geert Hofstede's cultural model elaborated in 1980 as a result of his studies undertaken in IBM's subsidiaries within 50 different countries in the world. The main strength of this study was that it offered a widely accepted definition of the concept of “organizational culture” in a period of time highly dominated by psychologists and sociologists part of a strong cultural school that defined the organizational culture by the means of lists of characteristics; taking into account Hofstede's engineer background in the field of computers, his definition was synthetically stated as *the software of the mind*.

This process takes place within the individual's distinctive evolutionary stages, through his education in family, school and society. As a result of this software of the mind, we as individuals acquire specific thinking characteristics and attitudes, a mutual mentality which represents the resemblance to the other members of the group/region/nation we are part of and which, in the same time, differentiates us from the members of other groups/regions/nations.

Hofstede's studies were made before the fall of the communist regimes in the Central and Eastern Europe within the IBM subsidiaries; as the only ex-communist country where such a subsidiary operated was Yugoslavia, unfortunately Hofstede's model was not applied within any other country of the communist bloc! Hofstede, basing on his personal experience, made a series of appreciations, presenting them on

his personal web page www.geert-hofstede.com. In 2010, Hofstede published his last results of the research on a number of 76 countries in the world, but as regards Romania, the values are still estimated! In this paper, we are to positively appreciate the results of the research mentioned above, but they shall be partially contradicted by the reality in Romania, especially as regards the predominantly feminine character of our mentality (feminine cultures are those situated in the Northern Europe, in the Scandinavian Peninsula).

The studies undertaken by Gallup Romania in 2005 having as a starting point Hofstede’s hypotheses persist in the same error, highlighted by the fact that such studies (two in number) were made on representative samples and not on samples consisting of specialists, as in Hofstede’s studies! From our point of view, the Gallup Romania’s studies shall be appreciated, but the representativeness of the sample as regards age, gender, origin environment or education have no connection with the capacity of people interviewed to make suppositions on the Romanian people’s sociologic characteristics. Furthermore, Gallup Romania / Interact conclude that the low level of competitiveness of Romanians is due to their predominantly feminine cultural character! But the Scandinavian countries, predominantly feminine, are they low competitive too?

Table 1. Romania’s national culture dimensions

Cultural dimension	Hofstede’s research	Gallup Romania / Interact	Our research
Power Distance (PDI)	90	33	95
Individualism (IDV)	30	49	46
Masculinity (MAS)	42	39	80
Uncertainty Avoidance (UAI)	90	61	92

(source: www.geert-hofstede.com, Gallup Romania)

As follows, we will present the results of our own research, undertaken within the Department of Management of the Transilvania University of Braşov starting with 1995, our conclusions being from our point of view, more accurate than the reality

perceived by specialists and their conclusions revealed above, in Table 1.

a. *Power distance* – is associated to the means by which society operates, taking into consideration the differences in wealth and power that individuals inherit at birth. Romania falls within the country category with a high power distance level (PDI=95 points out of 120 = max.), as the other Latin countries in Europe or Latin America, leaders generally adopting authoritative styles of management, high organizational structures with many hierarchical levels, high bureaucracy especially in the field of public services whereas nepotism is a frequent way of promotion within organizations.

b. *Individualism/collectivism* – refers to individual’s relations with the other members of the society. Romania features collectivism (74 points out of 120 = max., IDV=46) as well as the Latin, Balkan and Mediterranean countries where individuals develop highly cooperation relationships and when confronted with making decisions and auctioning, they take into consideration their membership to interest groups. Family is extended whereas relations among individuals are strong. Furthermore, motivation at the workplace aims both at the individual and at his group and different material and moral benefits and compensations are used. In general, individuals are able to provide a high level of loyalty towards their organization and they expect to be consulted in the decisional processes.

c. *Masculinity/femininity* – refers to the social division of roles between genders. Romanian population features a relatively high level of masculinity (MAS=80 points out of 120 = max.) this value being a closer value to Italy’s (70 points). Within organizations, labour division is high and there is registered a continuous tendency of the desire to assert, Romanians being ambitious and combative. People with outstanding success consider image elements as very important, building sumptuous houses, buying luxury cars and starting political careers. Makers of success are to be appreciated whereas there are registered relatively low levels of social protection and environment conservation.

d. *Uncertainty avoidance* – refers to the way society responds to the fact that time evolves in only one direction, manifesting towards it

a higher or lower level of uncertainty generated by the future. According to the research, we determined a high level of uncertainty avoidance index (92 points out of 120 = max.). Individuals permanently struggle so as to influence and control their future; thus, they build systems of regulations and institutions and do not tolerate behaviours deviant from the societal rules. In order to create security, it operates *by technological means* - so as to protect itself from the risks imposed by natural disasters and wars, *by legal means* - using the law system so as to unify individual behaviours and *by religious means* - trying to make uncertainty tolerable by reference to more important realities than the personal one.

All these determining values of the four dimensions rank us near the Latin and Balkan countries; moreover, by repeating the studies in time, it has been demonstrated the special stability of the values characterising the organisational culture of a country, at the level of its generations. This is our motivation to state that there is no reason to take action so as to change mentality as a whole, which is relatively constant, but we should optimize actions on the basis of these cultural characteristics and by influencing some attitudes (towards work, property, civic consciousness etc.). In this regard, we shall re-read the literary work of Caragiale, who died just 100 years ago, to see how actual he is!

3. Romania and the world crisis

The autumn of 2008 is considered to be the very moment the world financial and economic crisis was brought to light through the bankruptcy of the large American investment banks as a result of the disastrous financial policy of George W. Bush's republican governance. He implied the USA in costly wars for the whole world and internally, he speculated the American obsession for properties by stimulating investment at an unprecedented level in the real estate field based on overdraft credits. In this respect, Kotz [1] states that the financial crisis of 2008 is a systemic crisis of a particular form of capitalism, namely neoliberal capitalism, featuring in the USA the following characteristics: deregulation of business and finance (the free market

achieved free mobility of capital), privatization of many state services, renunciation of discretionary fiscal policy, sharp reductions in state social spending, reduction of taxes on business and wealthy individuals, attacks by large businesses and state on trade unions, a shift in the labour process from reliance on long-term employees to increasing use of temporary and part-time workers, unrestrained cutthroat competition and the introduction of market principles inside large companies (a shift from choosing CEOs from among internal career employees to hiring from the outside).

The crisis rapidly spread to all the other economies financially connected to the American one and gradually transformed itself into a global economic crisis highlighting all the flaws of the present economic system. This crisis as well as the Great Recession evidenced a number of troubling dynamics in contemporary capitalism, as Pinto, Macdonald and Marshall [2] present, the most obvious being the instability of national economies and the global economy as a whole, such features highlighting the rarity of the current crisis in magnitude and geographical scope, even if it came after several decades in which the frequency of serious crises that spill across national boundaries has risen to historically unprecedented levels (according to Kindleberger and Aliber, quoted in Pinto, Macdonald and Marshall [2]). Moreover, Zaman [3] considers that the phenomenon of globalization imposes nowadays the creation of a regulation framework of the international financial systems so that they become more sure and powerful, but this should be based on multilateral efforts of cooperation of the implied players and actors.

This crisis was predictable through different phenomena such as exaggerated consumption in all the developed economies and was anticipated as a cyclic event by numerous economists and by Pope Paul II as well, who named this phenomena “consumerism”.

In Romania, this crisis started having no connection with the global financial crisis; at the end of 2008, Tăriceanu's government emptied the country's treasury and by the end of the first quarter of 2009, Romania was managed by Boc's government only from loans, blaming this situation on the world

crisis. Moreover, when Romania’s president gave a public statement on crisis, he advised his citizens to save money, not to spend as difficult times were to come! And they came as Romania dramatically decreased consumption! Thus, it entered an uncontrollable spiral – not consuming, there is no money for production – unemployment increases (see Figure 1), consumption power decreases and so on so forth, at an unpredictable level. Furthermore, as regard unemployment, at a European level we must corroborate it to the workforce age average that is increasing, Europe facing nowadays the phenomenon of active population aging, phenomenon that influences the labour market both qualitatively and quantitatively and has impacts both on macroeconomic and microeconomic levels, as Backes-Gellner, Schneider and Veen [4] state, the average workforce age being negatively linked to quantitative organizational performance, but positively to qualitative organizational performance.

Figure 1. Unemployment rate in Romania in 2010-2012

Speciality literature offers studies on the types of crises – U, V, W, according to their evolution; the current crisis is under the form of “jigsaw teeth” and the moment it ends is difficult to predict– pessimistic forecast shows another 10 year period! As Ramesh [5] concludes, no society is immune from the need for social protection during the crisis, as while in a middle of a crisis, economic and eventually social conditions deteriorate rapidly before they improve, leaving behind lasting long-term effects. Public programmes are very important through the spending on

labour intensive projects, the offer of fiscal stimuli and the income necessary to support the poor. Such public programmes should not be launched only when a crisis strikes, no matter the type, scope or causes of the crisis, but affordable programmes should exist before crises. As Baba [6] states, the present economic situation determines companies to search for solutions to continue their activity in optimal conditions to avoid bankruptcy. In such a risky business environment, the strict control of all the economic operations and the adjustment of the strategies to the new market conditions are a must.

4. Romanian citizens’ behaviour during the crisis

Romanians’ behaviours during the crisis are strongly influenced by their mentality. Studies undertaken on disappeared civilisations, as for instance those on Ancient Greece and Ancient Rome, show suicidal tendencies at macro-social level; thus, cultures which entered their suicidal stage are featuring a negative natural increase - citizen don’t reproduce, they migrate in mass, whereas their elected leaders are among those possessing low morality and precarious education! Such leaders are preoccupied only with their own wealth and development of clan relationships, having no connection with economic or political doctrines. To fulfil their goals, they make use of odious debts, Greece offering the best example nowadays, but as Nehru and Thomas [7] state, there are few examples where this concept has been evoked in law to justify the non-payment of sovereign debts (such cases being classified as war debts, subjugation debts or regime debts), even if odious debt has been a subject of debate for a long time.

An odious debt features three elements: it is accessed by government without its citizens’ agreement, it is used according to its own interests and credit institutions managers seem not to know that! In order to develop and analyse the modern concept of odious debt, there have been identified three categories of odious debt, as Nehru and Thomas [7] highlight, criminal, unfair and ineffective debts. Criminal debts refers to loans involving corruption and kickbacks, the original loans to a country’s government being stolen by officials and businessmen or

used to rescue an economy ravaged by corruption. Unfair debts is a wide concept used for numerous debts used in activities considered inappropriate or containing unacceptable conditions, such are usurious interest rates or debts contracted illegally. Ineffective debts refers to loans not meeting their developmental purpose or directly linked to capital flight, even if there is no corruption and all the legal acts were respected.

The long-term behaviours of different cultures are determined, as all the cultural dimensions, as Hofstede states, by the wealth level of the very country analysed (this statement is valid only for occidental cultures). Rich countries feature low power distance and individualism, the other cultural dimensions, uncertainty avoidance and masculinity being relatively independent of the national wealth, whereas poor countries feature high distance to power and collectivism.

In rich countries, wealth is distributed according to a normal curve, Gauss's, this showing the existence of three social classes – a small class of rich people, another class, relatively small, of poor people and the majority of people forming a middle class – this is a structure offering and ensuring the system with stability. In such a society, *global changes are achieved through evolution*. In poor countries, wealth is not uniformly distributed – a political-financial oligarchy leading by its rotation the large mass of poor population. In such a society, extremely instable, *changes are to be achieved by revolution!*

In such respect, Gini's coefficient has an outstanding importance in measuring the inequality of income distribution, more precisely as the Italian Corrado Gini developed it more than 100 years ago. Its values vary on one hand, from one country to another, on the other hand, in time for the same country. The latest data show a minimum values of 0.23 for Sweden and 0.70 for Namibia, considering the fact that 0 shows absolute equality of income (all the citizens should have exactly the same income) whereas 1 shows maximum inequality (wealth is concentrated with a single individual). A Gini coefficient of 0.50 means that a quarter of the total population possesses three quarters of the national

wealth, and the rest of three quarters of the total population possess only one quarter of the national wealth. Such type of estimation does depend neither on the population number nor on the social or political situation of the country. In Romania, following the year of 1989, the evolution was a descending one, from 0.28 by 1998 to 0.29 in 1999, 0.30 in 2001, 0.31 in 2004, 0.32 in 2008 and 0.36 in 2010, as presented in Figure 2.

Figure 2. Evolution of Gini coefficient in Romania

The crisis strongly accelerated social inequality. In the middle of 2010, Valentin Lazea, the economist-in-chief the Romanian National bank, underlined that we already reached a Gini coefficient of 0.36, located at the top limit of the European Union. He then stated that the vast majority of the population could live better, in a sustainable way, if there were an internal social contract according to which wealthy population was to accept offering a part of their income to poor population. Besides, the poor population should show that it really deserves such a sacrifice.

Such Gini values place Romania in the vicinity of dictatorship economies in Southern America, the situation becoming worse and worse as a result of the measures adopted by governments leading during crisis periods. The only strategy to save its economy is that of creating the necessary conditions for the middle class to develop and of ensuring system stability and its future progress. We are to achieve this by stimulating investment, especially by accessing non-refundable European funds intended for Romania and by stimulating consumption, but under no circumstance, by

increasing taxation. In this respect, Winston Churchill said: “We contend that for a nation to *try* to *tax* itself into prosperity is *like* a man standing in a bucket and *trying* to lift himself up by the handle”.

By integrally accessing the European funds aimed at developing Romania, we could significantly have reduced the gap between our country and the other European countries getting through a real crisis. If this had been done, by 2015 we would have reached a productivity level of 45% of the European average. But, instead of accessing such funds by creating adequate mechanisms, Romanian government and power preferred having borrowed money from the International Monetary Fund and the World Bank that proved to be, in a great proportion, *odious debts!*

5. Conclusions

To sum up, this paper focussed on the analysis of the causes of the crisis that our country is getting through at present and unfortunately, there are no positive changes to be predicted in the future – the crisis in the shape of jigsaw teeth is getting more and more difficult in Romania, but not only, the Central and Eastern European member states do face successive crises, as Onaran [8] highlights, these twenty years following revolutions having to be divided into three periods: the transition crisis, post-transition growth and the crisis episode of 2008-9 which entered these countries in the global crisis leading to employment losses and real wage decreases.

By taking into account the political crisis, companies registered in Romania or entering the Romanian market should determine with high precision the influence of the political risk on their business. Bremmer [9] considers that there are two key elements companies should approach when entering an emerging market country: stability (defined as a government’s ability to implement policy and enforce laws despite a shock to the system) and shock (of many kinds and usually unpredictable). By deeply analysing the vulnerabilities of a country, region or community, managers should implement strategies to face with such political risks.

As future development of political risk, we shall determine in our future research

whether political risk is a part of the large concept of country risk or a separate type of risk. Companies entering the Romanian market should take into account such risks when starting their business in a masculine country featuring collectivism, a high level of power distance and of uncertainty avoidance.

Abstract

In the past three years, the concept of customer relationship management (CRM) is the focus of worldwide business. If not long ago customer relationship management was not considered a priority within companies, organizations today's performance puts customers at the center of all activities and rethinks their marketing and sales strategies, depending on their needs and desires.

In this context, manufacturers of software for business have focused the attention on the development of specialized application programs dedicated to strategies for customer relationship management.

Keywords: Internet, Customer Relationship Management, tennis

JEL Classification: F50, F59

1. Introduction

Customer Relationship Management (CRM) has turned into a major element of the business strategy of many companies and is based on the creation and development of personalized relationships with customers to increase their market share. A CRM strategy allows a business to adapt rapidly to changing organizational behavior emerging market and thus the company can better meet the wishes and demands of its customers. Customer relationship management means establishing, maintaining, developing and improving relationships between an organization and its customers and focuses on understanding and meeting customers' wishes and requirements, elements that are at the heart of any company's business strategy performance.

The link between customer relationship management and new information technologies is not limited to create a simple custom website but extends to all business functions that are responsible for managing customer data.

Software packages and Web applications are addressed for sale force, promotional campaigns planners, to the operators responsible for managing customer issues. An e-CRM strategy offers many web solutions from simple e-mail personalized to "Web Call Centers". The most common Web solutions offered by e-CRM strategy can be summarized as follows:

- Personalized Email
- Window CHAT / interactive dialogue
- Forum / discussion group
- Videoconferencing
- Mailing List / postal addresses list
- Voice Applications Internet / VOIP
- Internet Applications Image
- Web Call Center

Even if companies intend through their commercial web sites to purchase as many email addresses of potential customers, the main goal in creating these sites is retaining existing customers largely determined by frequent return to those web addresses. This is quite natural given the fact that it is 5 to 10 times more expensive for a company to attract new customers than to loyalty the existing ones.

Given that number of Internet users in Romania is continuously increasing, companies are increasingly turning more and more to commercial websites, recognized as the most effective ways for business development as long as the target has access to the "network of networks".

Consumers now have many choices between different existing offerings and

facilities offered by the Internet to find and access a tremendous amount of information, making it increasingly more demanding and careful purchasing decisions. Consumers can easily migrate to competitors' products or services, when they become more favorable, in which case the companies are forced to closely manage customer relationships. It was found that customer loyalty via the Internet has different characteristics from loyalty through traditional marketing strategies, "off-line". Appealing to the Internet, any company must meet ethical code imposed by the web that no one has the right to send neither unsolicited commercial messages ("spam") nor a prospectus without prior agreement.

Another element of differentiation between customer loyalty "on-line" and customer loyalty "off-line", is the speed of integration marketing strategy firm. Traditional loyalty strategies focus on the most profitable customers to exploit their potential purchase. Fidelity over the Internet has a much wider scope of action, costs of loyalty campaigns with the Internet support is much lower.

Customer loyalty via the Internet begins with their confidence, followed by actions to develop all axes loyalty:

- presentation on the website of information on products or services as well as programs to support the use of certain products aimed at retaining relational;
- inserting on the website special offers aiming at strengthening loyalty functional set after first purchase;
- Web site presentation of information and promotional advantages that generates loyalty;
- developing a sense of belonging to a community in which all members share the same values.

Interest of companies for customer loyalty strategy via the Internet is determined by its high profitability potential. The results of research show that increased by 5% customer retention rate from web-marketing activities generate some profit sectors increases by 75% (Reicheld, "The Loyalty Effect").

In Romania, most companies focus most of their resources to exploration and web marketing to customer loyalty, something that we found from visualization and analysis of numerous commercial web sites

presentation of Romanian companies. Increase traffic web sites at the moment seem to be the main concern of web marketing actions undertaken by companies in Romania.

A retention strategy via the Internet aims to: stimulate and boost customer database that allows pointing their behavior, anticipate their needs and finding opportunities to add value relationships through CRM programs.

The Internet is the most abundant in terms of communication possibilities, so the moment when hosting a promotional flyer "on-line" can be planned very precisely and messages can be personalized include sound, images, animation and can generate several measurable actions.

The main strategies of customer loyalty over the Internet can be summarized in subsequent categories:

- Strategies punctual "one-shot"
- Loyalty Strategies "on-line" by analyzing customer behavior
- Retention strategies by analyzing online customer preferences
- Retention strategies based on knowledge of online personal data of customers
- The strategies of the online loyalty sending news letters about loyal customers
- Strategies for attracting and retaining customers using online viral marketing technique

Companies should not apply only one of these strategies, but each of them at different times. Effectiveness of loyalty programs by email should be tested regularly. Specificity communication over the Internet is the fact that the customer services online can cancel them at any time by unsubscribing to on those websites. To avoid such unpleasant events, companies must constantly engage in on-line surveys to observe customer satisfaction.

If a company wants to loyal the online customers, must generate loyalty to Web sites dedicated to this goal. Next, we present 10 factors that determine customer loyalty to commercial websites:

1. Site Content
2. Insertion on site of special price offers for online customers
3. Online service
4. Creation of online virtual communities

5. The existence of initiatives on sites
6. Simplicity
7. Security
8. Interactivity
9. Personalisation
10. Segmentation of customer portofoglio

2. Tennis - Easy, fun and healthy

2.1 History

For reasons related to children's limited capacity to adapt to the rigors of tennis practiced by adults, International Tennis Federation has introduced a series of recommendations to children playing tennis. For the first tennis experience to be one of those little funs and appealing it is recommended that training and competition in players to use three levels of play: Red, Orange and Green.

The "Tennis Play and Stay" campaign supported by the International Tennis Federation focuses on the slogan "serve, rally and score" and wants to athletes aged 4 to 10 years still feel playing tennis from the first lesson (<http://www.tennisplayandstay.com/site/>).

With the launch in 2008 of the system, this revolutionary program development for children 10 years and under 10 years has offered many children the chance to play tennis. In Romania competitive system proposed by Tennis Partner was released in May of 2010. Since January 2012 Tennis10 regulation was formalized by the International Tennis Federation.

The campaign is supported by main countries of the International Tennis Federation, professional players such as Roger Federer, Rafael Nadal, Justine Henin as well as sports equipment manufacturers.

2.2 Concept

Tennis10 system is based on the concept of scaling the elements of the game of tennis. It has three levels of play specific to age, physical development and abilities of each child. Like when players want to develop a range of physical abilities, categories Red, Orange and Green gradually learn tactical and technical elements.

- Red level:
- red balls;

-75% decompressed from the yellow ones;

- field 11 m long and 6 m wide;
- net of 80 cm height.

Orange level:

- orange balls;
- 50% decompressed from the yellow

ones;

- field 18 m long and 6.5 m wide;
- net of 91 cm height;

Green level:

- green balls;
- 25% decompressed from the yellow;
- field 23.77 m long and 8.23 m wide

(standard);

- net of 91 cm height (standard).

Rockets differ in size from 19 inches to 27.50 inches. Choosing rocket is based on height and strength and player age. A rocket too heavy would greatly influence the game; making it too passive at the same time can lead to injury.

Suitable competitions are equally important in the knowledge of tennis and making the sport fun. Competitions have motivational role and stimulate young players.

International Tennis Federation claims that slower balls should be used by all players aged under 10 years, with the aim of helping players to develop advanced technical and tactical.

Some countries have imposed in the competition those 10 years players and less than 10 years to play only slow balls, except highly trained and talented players.

2.3 The users of platform Tennis10

Tennis10 enrollment is based on the platform www.tennis10.ro creating an account. Each player is represented in the system by an adult. This in turn requires parental consent if the athlete is not one of them. Player representative can register up to three children in special cases an additional can be based on explicit request by the head of Tennis 10. Users are represented by e-mail and a password of your choice. Once created, you can then purchase Passport tournament entries you want. It is an easily accessible way. There is now a small percentage of people who do not have Internet access and do not have an e-mail.

2.4 Players

Tenis10 program offers three progressive stages for athletes who may enroll:

Red: for ages 4 to 8 years

Orange: for ages 8 to 10 years

Green: for players over 9 years

After passing the White Test and purchase passport tournament players can be registered. White test is to guarantee that every child has reached a certain stage of his skills before entering in the tournaments Tennis10. The player is tested in terms of overall level of skill and theoretical knowledge about tennis. This test can support any club from the list that appears on the internet right indicator "white test".

In section players, athlete once registered has a profile page with name, age and Statistics tournaments performed. On 30 June 2012, were enrolled in the project Tennis10 1925 players aged 4 to 11 years.

Each player profile includes personal data, participate in tournaments and results. It is obvious that the project aims to encourage children to participate in as many competitions without discouraging following poor results obtained by simply publishing the results without preparing a Ranking.

2.5 Tournaments

Tenis10 tournament series runs from May to October and have as Title Sponsor - BCR. It organizes tours to all regions on Saturdays and Sundays and Fridays rarely. They are published in www.tenis10.ro platform. Registration begins two weeks before the competition.

Depending on the number of participants, the organizing club infrastructura, coverage of awards, there are three types of tournaments: Silver, Gold and Platinum.

Silver tournaments are organized with up to 30 participants in one, two or all three levels of play, tournaments Gold is out for up to 50 participants and a minimum of 30 players and at least two levels of play and the Platinum is held only 4 times per year. Races begin and end on the same day. If the weather is unfavorable the organizers can postpone or cancel the competition.

Organizing club page shows information about sponsors, changes, address and location of the club on the map and contact.

Tenis10 project offers the possibility to organize such tournaments to all affiliated clubs to Romanian Tennis Federation.

At the end of calendaristic, each club shall elect the number of tournaments and their deployment dates for next year. They are sent via e-mail to the contact person in charge of competitions. Currently, 63 national clubs joined tennis program 10.

3. Web solutions provided by an e-CRM Strategy - Case Study

In terms of organization and management of customer relationships, the company is well structured. For more information, notices or other details concerning the competition, www.tenis10.ro platform is based on Web solutions to promote the project and attract customers.

a) The most used method of communication with customers is the personalized e-mail. GP team provides customers three e-mails for questions, problems and possible partnership opportunities.

They respond as soon as possible through messaging. Customer data remain confidential and the company can use this information to send personalized emails with promotions, offers.

b) An accessible and effective communication is Mailing List. Coordinator of the events keep customers informed with news and changes taking place in the system. Thus, the mailing list is entered into the program and the messages are distributed to registered users standardize platform www.tenis10.ro.

c) Image applications Internet or Video Over IP has a strong impact on customers. They can actually see what's going on and what promotes that Tennis10 project. Are published pictures and videos to show how to conduct its contests, news and interviews with players, coaches and parents?

4. Proposals to improve e-CRM strategy Tennis10

Tenis10 system has a modern information platform, represented by www.tenis10.ro site. Users have the support they need through active interaction e-CRM strategies. Without minimizing the effort of the organizers to

create a site oriented towards customer loyalty, today it is characterized by:

a. Tennis10 Site Content - provide relevant information about organized tours for small players. This site is able to provide answers to almost every question that comes from small players, parents and coaches. Thus, accessing the site both a customer of this website and any interested person may quickly find information on the performance of any player, awards, schedule of the competition, the competition fee, the number of tournaments a child is enrolled, the number of tournaments that a player retired.

A big drawback of this site is that data of the results of child tournaments are uploaded by webmaster with some delay, not being set a deadline for submission.

b. Insertion on site of special offers for players who register online to participate in various competitions - is an effective way to attract online network and customer loyalty, but is rarely used by companies in Romania. Tennis10 site does not provide information about possibilities for accommodation and rates privileged accommodation and meals for children who come from other places than the conduct of the competition.

c. Online assistance to the "players" - it is known that the on-line generates a high degree of loyalty. Tennis10 portal does not provide any support for the players and their legal representatives where they want to be assisted in their behavior.

Would be welcomed a nurse at least 8 hours per day on weekdays and 12 hours / day during weekends competition in which the activities to assist small players and their representatives in solving problems

d. Creation of online virtual communities - introducing on site the forum or chat application. This would facilitate interactions between members and coordinators. Thus, they can chat online and set up meetings tournaments in the country. Athletes can also discuss developments and exchange of experiences as well as detailed knowledge of sport for children.

e. The existence of initiatives on websites – always surprises and promotions give wellbeing and attract many people. Tennis10 project is with athletes enrolled in the system and enables them to receive benefits: the chance to become ambassadors

Tennis10 and receive awards by convincing other young athletes to join the system, newsletter subscription to the platform to keep up with the latest news, sites redirecting to sports equipment.

f. Simplicity is one of the basic conditions. A page with a language overloaded or slow, is that future members to distance themselves from the idea of using information systems. In this case, the site is well organized and clear. The format is especially good, with big letters; the expression is as simple as it made for children.

g. Security. In recent years has increased significantly percentage of those who make purchases and transactions online. Tennis10 team speculated the same time and decided that payment be made on the Internet Passport. To provide safety, they forced the creation of personal accounts with secure access. To ensure this competition, participation fee could do online, so the organizer is confident that he will have the full number of players.

h. Interactivity – The website provides information specifically for players and parents. These ones has regulation and also details on how the tournament. It is intended and children, the portal could introduce a series of interactive games that teach tennis kids tennis rules, conduct field tactics.

i. Personalizing personal profile of the individual members is something that attracts both big ones and small ones. In this section, Tennis10 platform provides only the opportunity to make the settings at the entry in the circuit, including attaching a representative picture, and then could not longer make any changes. If the profile is not set correctly must be contact the coordinators to make changes.

j. Segmentation of customers – Portal customers can select and divide into categories as follows: community Red, Orange community and Green community. This can discuss broader topics on forum sites and compare the organizers may propose conducting joint activities or offerings can be customized to address each level.

5. Conclusions

Without minimizing the role of web solutions offered today by e-CRM strategy of Tennis10 platform, in my opinion they are insufficient to meet the full requirements of a modern client. Thus, solutions of email, mailing list and video over IP are currently the only ones used by platform. They are solutions of customer relationship management off-line, the exclusive direct interaction and real-time "consumer" of information willing to always be in contact with the organizers in order to clarify any problems, doubts that arise in the process of enrollment, participation and assessment at one of the tournaments tennis10.

An important detail has always been customer feed-back. It shows how the objectives were met. Application Forum and Discussion Group gives users freedom of expression, the benefits available to event coordinators are: ability to adapt to changes in organizational behavior according to the wishes and needs of customers and market, establishing, maintaining, developing and optimizing the relationship between the organization and members its. Thus, expressing the needs in real time can lead to anticipating the needs of the event coordinators.

The Internet is the most abundant in terms of communication possibilities. By creating a connection, such as a network between these members: parents, coaches, players, organizers, founders develop a sense of belonging to the community. Interactive dialogue IM or Internet Voice or VOIP would be most appropriate to implement the www.tennis10.ro site for real-time communication and socialization, as well as obtaining technical assistance at any time. Internet facilities to access a huge volume of information makes most demanding customers. It's a little old to start a sports complex. Many people have grown sports performance education. Especially now that the parents are the ones who bear children work material, especially the need for additional information is present.

A web-based contact center or Web Call Center would be a good strategy to implement. It is available in a well-defined time interval and prepared in order to provide fast and complete information in real time.

Also a profile of each athlete by parents could be an extra point and a way to attract

more users. The more time they spend on the site, the more we can emphasize customer wishes and requirements.

Compliance with e-CRM strategy and investment in this system brings many members, loyal customers and profits as.

Abstract

CRM is an essential business strategy that integrates internal processes and functions with external networks, to create and deliver customer value target, given the profit. It is based on high quality customer data and on information technology. (Buttle, 2006). This definition highlights the bivalent customer relationship management scope, respectively creating and delivering value to both customers in target segments and for the organization. Also, an advantage of the definition is that it is taken into account both strategic side and the operational one, based on software solutions.

The CRM goal is consistent with the philosophy of marketing and consists in generate value for the organization both in the form of revenue and profits, and customer value, as high degree of satisfaction and fulfillment of expectations.

Key Words: CRM, relationship management, information technology,

JEL Classification: M10, M21, M 16, M30

1. Introduction

In implementing a CRM strategy, information technology plays a fundamental role in order to maximize profitability by fine segmentation of the market. We are in the era of information technology involving a strong link between a company and its customers due to the databases occurrence, embedded systems, data warehouses, internet facilities, etc.. All these technologies determines the share and customer profitability increase.

Information technology assist different data and knowledge management processes aimed at understanding customer needs, so

the most effective CRM strategy can be adopted. In addition, use of information technology makes possible the collect of needed data to determine profitability of acquisition and maintaining customer.

New web services allow users to combine the activities of real life with the support offered by the Web. User-centered services change the way people use the Internet and influences how they organize their lives.

When the web became commercial in the early '90s, there was an explosion of the Internet, the amount of information available on the Web taking impressive proportions. At that time most pages were generally static. This period was later called Web 1.0.

Web 2.0 is not the second version of a software or web techniques. Web 2.0 means (rather vague) new ways to find and exploit organizational possibilities of the web. According to these, web content and information is no longer offered to visitors only by the media, governments and private firms, but also by individuals, bound by informal networks based on the Internet.

These Web 2.0 features, combined with current CRM system, are giving rise to a new business strategy, Social CRM (SCRM). Social CRM creates a two-way interaction between the parts and gives to customers ownership right of the conversation with the company.

2. CRM objectives pursued in organizations

The general objectives

Business objectives for CRM software implementation are:

- increasing the number of customers and their profitability,

- identifying high-risk customers and right adjusting the services;
- Increasing market segmentation;
- Increasing the feed-back in campaigns;
- maximizing customer relationships lifetime through cross-selling;
- A higher percentage of customer satisfaction;
- facilitating immediate action to preserve the most valuable customers;
- a greater number of customers who return to visit the website;
- fostering a long-term customers loyalty through building relationships with it;
- a more streamlined internal organization (restriction workflow, shortening cycle activities and eliminating unproductive information flow);
- re-focus personal relationship with the client;
- Creating the possibility to meet customer needs with the right offer at the right time;

For example, in an analysis performed by the Conference Board on the adoption of CRM programs by questioning of 96 corporations, 52% of companies surveyed have implemented CRM solutions. Among other things, the first three statistical reasons were:

- maintain and increase customer loyalty;
- response effectiveness to competitive pressures, and
- build competitive advantage, differentiation based on competitiveness in terms of superior customer service.

The specific objectives of different departments

The specific objectives of the departments are:

Customer Support - obtaining basic information about customers and their complaints, monitoring customer satisfaction and faster resolution of claims in order to enhance their maintenance, self-service efficiency and

attenuation of the need for personal assistance.

Marketing - achieving dynamic customer segmentation to initiate a communication strategy and campaigns better targeted, adequate marketing campaigns, customer satisfaction by analyzing the segments, monitoring the feedback generated by the campaign.

Sales - Sales automatic development by region, guest history tracking, streamlined and efficient sales process and customer qualification based on past experiences.

Customer Relations - monitoring customer complaints history and their resolution.

3. CRM Benefits for organizations

A good CRM will help a company to acquire new customers, to serve old customers, increase the value of the latter, to keep and to determine which customers are loyal and which of them are interested in more complex services.

A professional CRM strategy can improve customer service by facilitating communication with them in several ways:

- increasing the efficiency of interaction with customers through all channels of communication;
- facilitating client-provider collaboration via the web, thereby reducing the costs of customer relationship management;
- provide information about the product and its use, technical assistance websites that are accessible at all times, 24 hours a day, 7 days a week;
- Identify how each customer defines quality, and then creating a service strategy for each customer, based on its individual requirements and expectations;
- a rapid mechanism of management and follow-up schedule - to find customer opinions from a purchase and to determine trends in purchasing new goods, the time of purchase and frequency of purchase;
- a mechanism for tracking the points of contact between a customer and the company - does it in an

integrated manner so that all the resources and types of contact are included and all system users have the same picture on the consumer, thus likelihood of confusion;

- Participation in the rapid identification of potential problems before they happen;
- a friendly mechanism for registering customer complaints (complaints that do not reach the company can not be resolved and become an important source of customer dissatisfaction);
- an effective mechanism for solving problems and complaints (complaints that are resolved quickly, increasing customer satisfaction);
- Internet use cookies to track customer interests and personalize product offerings;
- a mechanism for managing and scheduling maintenance, repair and ongoing support, improving efficiency.

Thus we can say that the benefits of CRM for companies are: increasing fidelity, lower acquisition costs, more revenue from existing customers.

4. Quantifying the success of CRM within organizations

Although success factors are different, at the end many companies choose ROI (return of investment) as the sole factor, although this method of calculation caused controversial discussions.

Sometimes CRM systems measure ROI only as a residual income or profit margin derived from implementing CRM technology. But it has only limited application because it does not provide a sufficient analysis to serve in decision-making. Also, evaluates the problem only from a business perspective and considers the customer only as a source of income, while CRM ROI should integrate both revenue and customer satisfaction.

A study led by researchers at the University Dayton highlights four key indicators for successful CRM:

1. CRM's ability to influence corporate strategy - 25% of respondents;
2. Successful integration of technology - 23% of respondents;

3. Enhancing strategic partnerships - 20% of respondents;
4. Technologies assimilation related to CRM - 18% of respondents.

Another indicator of financial success is customer lifetime value (CLV).

It allows companies to do analysis beyond a period of time and a client, and combines both financial flow reduction with activity-based cost and real probability of a customer retention to help understand the impact of various scenarios of CRM. Profitability results of most likely scenarios that can be implemented must be compared to find the best way to increase overall profitability.

5. Customer relationship management using information technology

In implementing a CRM strategy, information technology plays a fundamental role in order to maximize profitability by fine segmentation of the market. We are in the era of information technology involving a close link between a business and its customers due to the emergence of databases, embedded systems, data warehouses, facilities offered by the Internet, etc.. All these technologies determines rate and customer profitability increases.

Information technology assists various processes of data management and knowledge aimed at understanding customer needs, so the most effective CRM strategy can be adopted. In addition, use of information technology makes it possible to collect the data needed to determine profitability and maintaining customer acquisition.

The research shows that an increase of 5% in customer retention increases profits in net present value terms, between 20-125%. Although managers know the importance of keeping customers, few knows the impact on profit of close relationships with customers. As a result, they often adopt the most effective strategies for acquisition and customer loyalty.

Because the beneficial effect of keeping customers on profitability, organizations are increasingly turning to information technology to increase customer loyalty. To improve customer retention requires three steps: measuring customer retention rates, identify the causes of customer

dissatisfaction and implementing corrective actions.

To measure customer retention rate, a group of researchers from the Institute CRM Cranfield (UK) has developed a model which they called "Retention Gram" that allows managers to determine the impact of factors on customer retention profitability: cost of acquisition, the number of new customers conquered, apprehended customer profitability and customer retention rate. To facilitate the processes in this model requires sales force automation and creation of contact centers, web based and client-server technologies.

Retention Gram model involves creating an IT platform consists of computer networks, databases, data warehouses and integrated CRM software solutions. The ultimate objective of this model is to identify new opportunities for finding and loyalty the customer.

Another model that describes the relationship between employees attitudes, customer retention, their loyalty and company profitability, is the chain " service-customer-profit" developed by Harvard Business School. Under this model there are highlighted five key elements: customers, employees, innovation, financial performance and values of the organization, and the obstacles that arise in relation to the organization - customers.

Companies need to know what management actions should take (ie. investments in sales force training in IT, e-CRM call for action on a Web Call Center, etc.) to improve customer satisfaction and to retain their loyalty. This model was applied to Roebuck & Co. company, where the results were impressive: there were identified links between customer satisfaction as a result of e-CRM solutions applied and company profitability indicators. Attitude of employees towards the company was considered critical to approach customers, while customers impression, due to e-CRM strategies positively affected their retention. The model is used as a revenue growth forecasting: an increase of 5 units of employee attitude leads to a growth of 1.3 units in customers impression and 0.5 units in revenue increase, and if the system database customers can be integrated, it can lead to an

increase of 4 units in customers feeling which determines an increases in revenue.

6. Design and implementation of a CRM system within the organization

In a CRM project will participate employees of Sales, Marketing, Technical Support, Finance and Accounting departments, and IT professionals within and outside the organization. The organizational structure of the company will be held some temporary changes, creating a matrix structure specific to project management.

Team involved in CRM project will interact actively with customers, giving them the support they need.

On the basis of a CRM strategy is client-server technology with which it can quickly be distributed digital information between team members participating in the project. As IT support, there are used software for facilitating teamwork and different web applications.

Sales department benefits of a sales automation tool with which are identified potential customers, based on their needs that are not met or only partially met.

Marketing department uses information technology on sales and cross promotions, business presentations on the web as ways of promoting effective. Offers customization strategies are becoming prevalent. For example on the website www.nike.com customers are given the opportunity to create their own sports footwear, choosing his favorite color, the damping, etc..

Technical Department collects in a database the technical problems that customers sends, by providing necessary technical assistance quickly. It is known that rapid after-sales service is an important factor in selecting an offer by customers.

Department of Finance - Accounting provides reports on customer profitability, the cost of CRM strategy, coupled with expected revenues, costs of training the human resources involved in the process, etc..

Specialists in IT infrastructure creates customer interaction system and are responsible for the proper functioning of the system and for the flow of information carried.

In order to assess the effectiveness of CRM strategy, an important role is the feedback provided by customers, showing how the objectives were met.

The collaboration of these departments with the specialists in IT should not lose any sales opportunity, and each client must promptly receive the ordered products and services, support both during purchase and after purchase, suggestions and personalized loyalty programs .

Bill Gates proposes to CRM project managers: "Spend information and buy time in share. Use digital tools to help customers to solve their own problems and book your time devoted to personal contract in response to more important customer needs. "

A company with good management realize the importance of customer who expect a personalized treatment that can be easily accomplished with a CRM strategy.

If we consider the triangle of project within a CRM strategy we highlight its limitations of time, budget and objectives.

Duration of a CRM project plan can decrease as the manager of the adopting company of this project decided to reduce the third part of the time dedicated to CRM system implementation, to quickly get a competitive advantage. You will need to increase the budget for the project or goal to be reduced.

If CRM project budget decreases, the project manager will need more time to complete the project and will require a reduction of project objectives.

CRM project budget can be reduced for various reasons: either reflect a company's financial situation worsened or the manager decides to relieve some of the own personnel burden on CRM, and to transfer it to a specialised contact center.

If the project goal increases, the project manager will need more time and more resources to perform the work generated by the extended goal. For example: the initial goal of the project was CRM sales force automation, extended target attached to the original objective is to achieve an integrated electronic communication with customers.

7. Conclusions

It is estimated that the success rate of IT projects in the field of CRM, of implementation

of software solutions for customer relationship management, does not exceed 30% (Hoekstra, 2001). The main cause of many failures is that calling an IT solution is unable to produce the desired results as long as the organization has not created a philosophy and a culture focused on customer, oriented to development of long term customer relationships. Increasing customer loyalty is possible only when all resources and processes have in their center the customer needs and his expectations.

Consequently, the conceptualization of customer relationship management involves consideration of the following major coordinates:

- a) strategic nature - CRM is a business strategy. Customer relationship management is relevant and profitable for the organization project only to the extent that they contribute to the objectives of the organization to generate value for the customer and the organization.
- b) the role of IT solutions - Information technology help in developing and implementing capable strategies of meeting the objectives of the organization on customer relationships and develop their loyalty. However, CRM solutions help in performance measurement regarding the applying strategies and programs in customer relationship management.
- c) The purpose of CRM - Elaboration and implementation of strategies to develop customer loyalty and to develop a preferred provider profile for the organization applying CRM strategies aimed at creating value for both major partners of the relationship, supplier and customer. To be recognized and adopted by the client, the value should be meaningful and relevant from his perspective.

Many experts consider three levels of customer relationship management: the strategic, the operational and the analytic level. In essence, strategic level refers to the major objective of CRM and its position as organization strategy, not only as functional strategy. Operational level is targeting the different automation of sales activities projects, service and marketing, and communication channels with customers. Analytical level consists mainly of measuring performance in customer organization, analysis of information about customers and reliance on the

information, analysis of the most appropriate marketing strategies and tactics.

In other words we can say that CRM is the process of continuous adaptation to market demands, marketing decisions improvement, optimizing sales, primarily aimed more detailed knowledge of customers and, hence, its satisfaction by delivering superior quality products and services and at the lowest possible price.

CRM is the technology assisted process by which is collected informations that enable companies to treat customers as individuals, not as consumer segments and cultivate relationships with them as such.

CRM is a strategic management solution for continuously improving client and buyer relationships in a competitive market where success is not only to provide a variety of products, but at the same time to differentiate the services they provide.

CRM is not just automation of sales in a call center but it means enabling an approach cross-channel to customer interactions.

It is a concept of root and branch to ensure that all customers are treated in the same way across all channels and that the institution can learn from interaction with consumers and therefore act wisely based on this interaction.

From a strategic perspective, CRM mobilizes resources rather around customer relationships than around some product groups, and encourages activities that maximize the lifetime value of the customer relationship.

From an operational perspective, CRM is linking the business processes in the "supply chain" from back-office functions to all customer contact channels ("contact points"), enabling the continuity and consistency of customer relationship.

In terms of analytical, CRM provides resources that enable organizations to fully understand customer segments, evaluate and maximize the value provided during the life

cycle of each customer, to model scenarios such as "what if", to provide consumer behavior, to design and implement effective marketing campaigns.

Abstract

Social CRM tools provides us with the means to capture data about profiles and to create the maps of customer experience which contributes to the development of real perspectives to customers, that offers what is really a personalized experience for individual customers. Based on history, CRM could not do it. It might be gathered all transactional data, but emotional and behavioral customer information that the profiles and the maps of experiences with the customers provides, were not part of the CRM value proposition given before.

The strategy behind Social CRM is to be opened with the client, to be visible to them, and give them the needed space and information to make smart decisions for themselves about how to interact with the company. By following this strategy, the company can learn from its customers because they have more freedom in their interaction with the society and with other customers.

Continuous interactions with customers, the ones that have good results, reduces the bad and increases the good relations between the company and the customers.

Key Words: social CRM, CRM, strategy, organization, management

JEL Classification: M10, M21, M 16, M30

1. Introduction

There are many points of view on conceptual clarification of customer

relationship management. Until now, experts have opted for a single definition of CRM, which proves that this area is still in a phase of exploration and development of its essence.

However, an undeniable aspect is the particularly important role that effective management of customer relationships has in the sustainable development of the organization. One of the most relevant arguments that support the interests of managers and businessmen for CRM is that the reduction of 5% in the number of customers lost by the organization can result in an increase of 25% to 85% in organization profit. (Reichheld, Sasser, 1990). This reflects the importance of increasing customer loyalty for the existence and development of the organization, emphasizing, by default, the need of design and implement appropriate strategies for customer relationship management.

2. CRM - a key element of organizations in the current business

CRM is a business philosophy that describes a strategy that puts the customer in the center of the process, activities and culture of an organization. This strategy is implemented through IT applications, and the new developments in IT helps an organization to adapt their strategies regularly.

The main concept of CRM is relatively simple. For years companies have greatly focused their efforts on lowering costs and improving efficiency within the organization.

They focused more on internal process, often automating their functions elements of back office, such as production, logistics and finance. By contrast, management effort invested in customer-related activities such as sales and marketing are often left behind.

As the market consolidates and suppliers become more efficient in providing services or products, the rivals offers are becoming increasingly difficult to differentiate. For example, what is the main difference between two toothpastes? In the same time, as the quality of services and products improves, customer expectations and demands increases. As long as the client is able to change his supplier, it is becoming increasingly difficult for a company to maintain loyalty. It is therefore very important for a modern company to have a system to shorten the response time to customer requests, providing quality and support to their services.

For many industries, the evolutionary process of how to do business is not new. Suppliers of consumer goods in large quantities fought over the years to create brands based on quality and price. What is changing is the impact of increased customer decision-making power. Now, in an environment dominated by the Internet, where suppliers can change with just a few mouse clicks, the problem becomes even more complex. It affects every organization, whether it focuses on customer or business.

It turned out that maintaining old customers costs significantly less than buying new customers. Therefore, as companies expand their customer base, must not lose sight of keeping and multiplying the best of them. Increase of "customer action" - in other words, the amount of business that each client offers - becomes as important as increasing market action. Through good management with good customer relations can increase profitability. And this is essentially Customer Relationship Management.

3. Strategies of SCRM

Social CRM strategy and associated business models are defined by customer engagement, not customer management. While traditional CRM uses database to track customer transactions - be it sales data or

services data, the focus was on 360° angle of view of the client. This is a recording of a single client, with all the data relating to the customer - regardless of department - which is made available to all those who needs to see it. But while this was considered optimal realization of a traditional CRM implementation, it is now a prerequisite for a truly successful CRM effort - although only 38% of companies reporting that they have it.

But Social CRM has a different pivot. Than one that is easily traded and that manages data, rather this new center is a "company like me". This is actually a customer engagement strategy.

What is important is that every client has the products, tools, services and experiences that he needs to carve a personal interactive relationship with the company in a way that meets each of their personal agendas. This means that the company is willing to be sufficiently transparent and sincere quite to be trusted by the client. So, the company becomes a "company like me". The experience that the customer has with the company is positive enough to make that client become at least a loyal one, and in the best case, a supporter, an advocate client.

When a customer engagement strategy is efficient with the support of Social CRM tools and processes, there is a mutual benefit derived, planned from the beginning. Success is characterized by a fundamental change in the relationship between company and customer, from manufacturer to customer-partners. This is not a little effort. This is a major cultural and behavioral change in the way customers interact with a company. If they see themselves as partners, they feel having a contribution and an interest in its success. They are taking their commitment to company in ways that exceed their satisfaction, becomes advocates for the company, engages in community development and can even act as an extension of the company's sales team. These customers expect a reward.

They expect that they will have a degree of access to the operating mode of society, so that they can make intelligent decisions. They expect to receive personalized treatment and privileges. This could take the form of higher discounts, loyalty points program, other forms of recognition, even access to management is not out of the

question. They are also expect honesty, which may seem easy – it’s not easy for most companies, and they know it. Until 2009, higher corporate management have not even thought of knowing its customers, or deserving their loyalty.

Strativity, a consulting firm regarding the customer experience, led by Lior Arussy, perform an annual survey of what companies top management believes about their customers. The findings are often shocking.

This perspective implies something rather disturbing, something that reinforces distrust between CEOs and marketing departments. A very high percentage of executives does not trust their own efforts enough to believe that they deserve a commitment from their customers and are desperate enough to say and do anything to get a paying customer. Again, customers know this.

Add to this the customer already existing mistrust, and the obstacles get larger. This is why the creation of an interactive relationship, transparent and authentic, between a company and a client is not an easy thing to do.

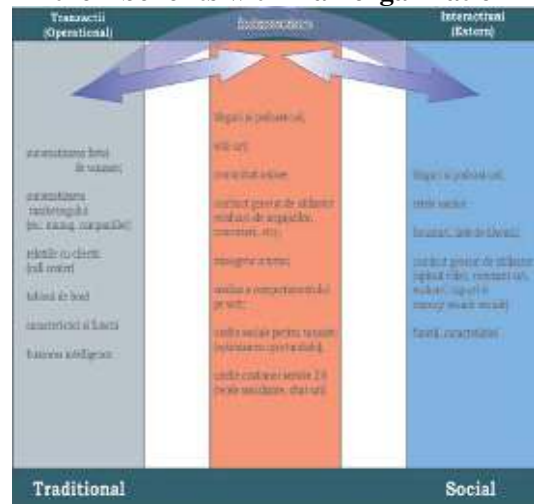

4. Social means and their benefits within an organization

To fully engage customers and to increase the chances of success, either to business to business (B2B), or business to consumer (B2C) customers, both customers and employees has to believe that tools are an integral part of effort. If customers trust any company, it is because of social tools.

But because it’s much more than a brand commitment or even customer loyalty, what a business should consider, the combination of traditional CRM and integrated social tools exist where the real benefits begin to show. The figure below shows the types of tools for Social CRM and social infrastructure, and technology platform needed for support. It combines the operational strengths of traditional CRM tools with the capture power of external customer interaction, then connect directly with customers. But Social CRM tools adds an additional feature. If we focus on the middle pillar we see that the traditional sales force automation, marketing automation and customer service tools (which appears in the left column) are replaced by social selling,

social marketing, and 2.0 customer service tools. Rather than on replacement, we talk about development, a consolidation of these elements. The instruments that appears in the middle column are oriented towards the success optimization of the various departments of the enterprise.

Figure no. 1- Social means and their benefits within an organization

Source: Social CRM Comes of Age, by Paul Greenberg

Social sales

Automation tool of traditional sales force has been a tracking tool. Usually, this tool aims accounts, leads, contacts, opportunities, and gave to sales management an insight to each sales channel, and, depending on the methodology used, the chance for success. But these were appropriate formulas based on realised experiments. Social sales tools exceeded this phase. They are designed to optimize the success rate in business closing, giving you the feeling of the best choice.

Social Marketing

Social marketing tools are still in their early days.

1. The outreach - This tool is designed to interact with Facebook, MySpace and other online communities with huge volumes of activity. The instrument is focused on optimizing the supply, which is based on how it is interpreted not only individual activity on the social network, but the data in his profile.
2. Mobility - This instrument has an incredible insight. There are companies that offer to prospective customers access to the catalog of products and services offered by

the sales department directly on their mobile phone, smartphone, or any other means of communication with internet access (anytime, anywhere, on any device). Not only do they have access to other customer reviews and ratings for each item and they can add and theirs, but their activity is tracked in real time and an optimized offer is sent with a message, based on their history and their activity in real time. All these things take place on a mobile device.

Customer Service 2.0

Traditional customer service is easy to identify. It begins with a complaint to a customer service representative through a phone call to a call center full of automatic features menu or via Internet. Even if the problem can be solved in the end, the customer is usually more unhappy than when he made the claim. It could be that the automated system was a hindrance rather than a benefit, or the person who spoke was inappropriate educated. One way to solve this CRM problem is to reduce the waiting time in queue calls. Customer service tools 2.0 is based on a significantly different archetype:

1. Services which scans the communities of different sizes, from Facebook to Twitter, to find customer complaints, and then, using analytical tools, determine the emotional depth, good or bad, of the complaint. Based on business rules and workflows that are built into the application service, the result triggers an alert that will be sent to the appropriate person in the chain of command.
2. If a customer has a problem and is willing to allow another customer communities to help solve the problem, it is exposed to the community that can be a possible solution provider. If an answer is found, it becomes part of the knowledge base of customer relations department.

5. Conclusions

Social CRM gives us the tools to a real customer insight that can be used to facilitate successful sales and improve customer relationships. It also provides opportunities for customers to interact with us in a more efficient way, which transforms the way the client sees us and what he expects from us.

Social CRM tools provides us with the means to capture profiles data to create

customer experience maps which, at their turn, contributes to the development of real prospects to customers, that offers what is really a personalized experience for individual customers. Based on history, CRM could not do it. It might gather all transactional data, but emotional and behavioral customer information that the profiles and the maps of experiences with their customers provides were not part of the value proposition offered by CRM ever.

If used properly, the gained perspective will provide what a sales person in particular, but also any staff member who interacts with a customer, generally, wants. That means an increased reputation, which can lead to increased influence, which then could allow an honorable and influential salesperson to be more convincing, because these traits are more reliable.

General Principles Regarding the Relationships Among the Environmental Cost Accounting, Environmental Performance Measurement and Eco-efficiency Indicators

Olaru Olga

Radu Andreea Lorena

Banacu Cristian Silviu

The Bucharest University of Economic Studies, Faculty of Management

olga.olaru@gmail.com

Abstract

The scope of hereby paper is drafting a proposal on the environmental cost accounting, environmental performance and eco-efficiency indicators. The paper briefly presents the main trends on the environmental cost accounting. Having in view the material flow expenses and their impact on environment, the eco-efficiency performance measurement is recommended in the costs accounting for measuring the indicators. The complementary relation among the environmental costs accounting and the environmental performance indicators, especially with the eco-efficiency indicators, and with environmental performance measurement, requests the integration of them on the global level. Therefore, this article suggests that the environmental cost accounting and the environmental performance indicators are to be integrated within the decision-making process. The paper concludes with various comments on the integration of the environmental costs accounting with the environment indicators.

Key words: environmental cost accounting, environmental performance measurement, eco-efficiency indicators, sustainable development

JEL classification: E01, F63, Q01, Q56

1. Introduction

The environmental management, through its activities that generate various costs within an organization, can assist in avoiding certain expenses and can generate benefits.

The environmental management accounting objective is defined by the above mentioned functions. The main activity of the environmental cost accounting, part of environmental management accounting, represents the expenses occurred and the related costs that can be avoided and not directly related to the environment performance improvement benefits. The latest is defined by another activity within the environmental management accounting, focused on environmental performance measurement [1].

By issuing an appropriate documentation, this article presents a general view on the environmental accounting concepts, environmental performance indicators and eco-efficiency indicators, and their importance in improving the environmental performance. The environmental cost accounting focuses on the specific costs related to material and energy flows and their impact on the environment, which represents the integration of the economic indicators with the environment indicators and calculating the eco-efficiency level of an organization. The eco-efficiency indicators provide useful information to the environmental cost accounting and during the decision making process.

2. Environmental cost accounting

Environmental cost accounting is defined by the International Federation of Accountants (IFAC) as part of the environmental management accounting [2]. Presently, there are five methods of calculating the environmental costs, differentiated based on the definition of the environmental costs and costs accounting method, defined by the enterprise. Some of

these methods were created for stand alone calculations, and not for integrating them in the accounting system of the organization, and some were designed as part of the management accounting system of the enterprise: full cost accounting, direct costing, process costing, target costing. The last two have been implemented only by few companies [3].

The environmental costs are expenses related to the environmental protection, material and energy flows involved and which have to be reduced when implementing the sustainability concept. The environmental costs are expenses related to those activities of environmental protection and “end-of-pipe” technologies. This type of “end-of-pipe” technologies are used for controlling the pollution level and are related to impacts generated by industrial pollutants disposal/emissions. It has been agreed that this approach represents only a temporary postponement of environment issues, focusing more on “pollution containment” than on their reduction. As per this principle, the pollution is reduced after it was generated. It has to be admitted also that this approach involves additional resources and costs and it is not following the sustainable development vision. The environmental costs can be defined as the total amount of direct and indirect costs, generated by the material and energy flows, and of the expenses as a result of the impact of these flows on the environment. These costs include all the expenses occurred from: taxes, fines, materials purchasing, administrative expenses with environment provisions, which can occur if the materials and energy flows consumption is not reduced [4]. All the current, past and future costs must be considered.

Taking into consideration all the materials and energy flows costs and the environmental issues that may occur, and the present trends in the environmental costs accounting field, a tight relationship between material flow information and costs information is mandatory. Also, the benefits that the environmental management activities could generate have to be considered, regarding the environmental performance improvement of the enterprises. The environmental performance measurement, environmental performance indicators and eco-efficiency

indicators influence the present trends of the environmental costs accounting. The paper further describes these elements and if they can be complementary to the environmental costs accounting, in order to improve the performance measurement through eco-efficiency.

3. Environmental performance and environmental performance measurement indicators

The environmental performance concept was generally defined as “the results of an organization’s management of its environmental aspects” [5]. According to ISO, an environmental performance indicator is a “specific expression that provides information about an organization’s environmental performance” [5]. Bennett defines the environmental performance measurement as the interaction measurement between business market and the environment [1]. In our opinion, all three definitions are rather dim. We believe that the environmental performance represents the actual reduction that an organization succeeds to obtain in time of its impact on the environment. Thus, the environmental performance can be measured by using the following indicators: total gas exhausts and gas emissions, compared to the turnover or to the overall production output, for improving the environmental objectives of an organization in a given period of time.

According to Schaltegger and Burritt, the concern of certain stakeholders resulted in developing the environmental performance measurement [4]. The environmental performance is calculated based on objectives. The question might be if these objectives have to take into consideration only the organization, or they should be exclusively focusing on improving the environment conditions, or if they should have in view the sustainable development or should improve on a short time basis. Given all these aspects, we wonder if the environmental performance measurement should or not be an approach that takes into consideration the overall lifetime process or should be targeting only a single aspect. Another question, in addition to the others above mentioned, is if the environmental performance measurement should be related

more to the external or to the internal organization stakeholders benefits. The issues regarding the environmental performance measurement and their impact on the environmental cost accounting must be clarified accordingly.

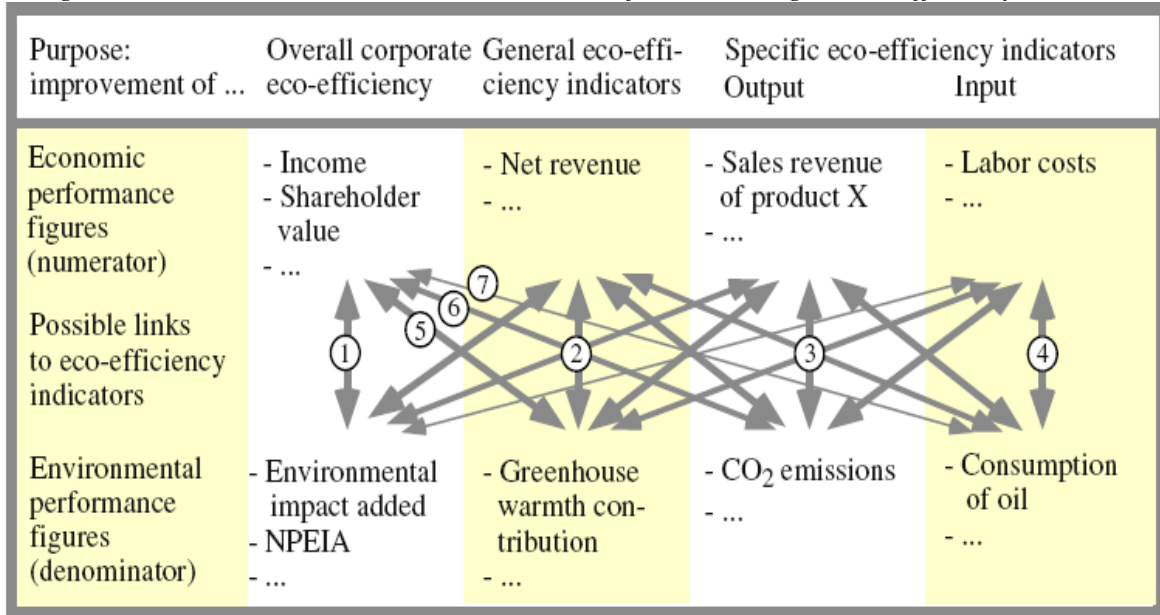

4. Eco-efficiency indicators

The concept of eco-efficiency was the result of the ecologic-economic efficiency and was further developed by Schaltegger and Sturm [6]. Starting from these studies, Schaltegger and Burritt (2000) have conducted various researches on environmental performance indicators. They suggested that for measuring the eco-efficiency of an organization, the available economic and ecologic information have to be converted in information indicating the eco-efficiency [4]. Thus, the economic data, given in currency units, and environment data, given in ecological indicators, have to be integrated as an eco-efficiency indicators system. The integration of the economic efficiency indicators (numerator) together with the indicators that define the environmental performance (denominator) determines a ratio that measures the economic-ecologic efficiency (eco-efficiency) and allows certain environmental issues to be taken into consideration within the decision-making process, and economic matters. An eco-efficiency indicator is a parameter having the same meaning of an environmental performance indicator, defined by ISO 14031 [5] or in the GRI Guidelines [7]. The results showing the economic and environmental performance are different, based on the way the economic indicators are combined with the

environmental ones and on the level of their integration. The result is the general indicators defining the eco-efficiency in an organization and specific indicators that provide detailed information on the processes that take place at different levels of the organization. Figure 1 mainly presents the economical performance on various levels (from a general level to a more specific one), and secondly the environmental performance. The middle row presents the calculation methods of the eco-efficiency by combining the economic indicators with the environmental indicators. Mathematically speaking, and keeping in mind that the eco-efficiency is a concept that needs to be related to a specific event, an unlimited number of combinations can be obtained from the economic data and environment data. However, Figure 1 recommends those combinations that generate advantageous eco-efficiency indicators (the arrows width shows the efficiency of the calculated indicators; the larger, the more advantageous combinations).

Most general eco-efficiency indicators are: short run income, based on the environmental impact added value or, on a long term, the shareholder value, based on the net present environmental impact added value. The net present environmental impact added value, as well as the shareholder value, is strongly connected to the net present value and residual income, and can be used for calculating the long term eco-efficiency indicators. The net present environmental impact added value represents the discounted aggregate future environmental impact added value and also a long term accounting indicator for calculating the future impact on the environment.

Figure 1. Economic and environmental indicators for calculating the eco-efficiency indicators

Source: Schaltegger and Burritt, 2000 p. 362

Other general eco-efficiency indicators can be defined by the ratio of net revenue and free cash flow, as economic data, and the greenhouse gas exhausts that increase the global warming, the gas emissions that affects the ozone layer and which results in photochemical smog, as ecological data. The free cash flow and the product's net revenue can be directly affected by the financial consequences of a specific environmental issues, which generate additional specific costs.

The specific eco-efficiency indicators include indicators related to output, as the income resulted from selling a product/1 kg of CO₂ emissions, and to inputs, as the labor-related expenses/1 consumed fuel unit. Understanding and developing the general indicators are rather simple operations, while the specific indicators involve their integration within a wider frame to be correctly calculated.

By combining all the possible general/specific economical indicators with the general/specific environmental indicators, the eco-efficiency indicators are obtained, offering interesting information for all the involved stakeholders. Having in view the connection between the financial consequences of some environmental issues and materials and energy inputs, many stakeholders will be interested in these indicators. The investors are concerned with calculating indicators as: the shareholder

value/greenhouse gas emissions quantity ratio, shareholder value/unit of CO₂ emissions ratio; or they will be interested in the shareholder value/1kg of consumed fuel. These indicators offer to the investors the information regarding the financial sensitivity of an organization to a possible insourcing of the external costs with greenhouse gas emissions, which can worsen the global warming or determine a possible raise in the fuel price, resulted from, for example, applying a greenhouse gas emission tax.

Defining and clearly assigning the eco-efficiency indicators are very important, thus the economical and environmental data are to be comparable and to take into consideration those activities that are in the stakeholders' benefit. For example, if a stakeholder has a long term vision, then the economic indicator has to be chosen also on a long term basis, as shareholder value, and which has to be related to an environmental indicator also on a long term basis, as the net present environmental impact added value. On a short term, calculating the ration between the return on capital and environmental impact added value is very useful. If the organization is interested in the impact on the company and community, it will determine the eco-efficiency by calculating the ratio between the value added and the environmental impact added.

It is well known that the internal stakeholders have different views than the external ones, and that they are interested in different indicators, but all the stakeholders focus on the financial evaluation of the investment. For the shareholders the appropriate eco-efficiency indicator for this scope will be the ration between the shareholder value and the net present environmental impact added value. The government and the top level management are concerned with evaluating the general impact on the community, the appropriate eco-efficiency indicator for calculating this effect being the ration between the value added and environmental impact added value. The top management is also interested in evaluating the annual performance that can be calculated with the following eco-efficiency indicator, given by the ratio between income and the environmental impact added value. The divisional management, for example, is interested in the economic and environmental impact of the business strategic units. The middle management is focused on the product and the production stages. The eco-efficiency indicators have to be carefully assigned, based on the related activities characteristics.

For most involved parties, the economical, environmental and eco-efficiency indicators make sense when these indicators are related to the specific activities under the responsibility and control and which they can improve. Therefore, an eco-efficiency indicator is determined based on the interest of the involved party and has to be related to certain controllable and relevant comparing standards, within the organizational level to be applied on. For example, for the investors, the denominator of comparison could be the invested currency unit (euro, dollars), and for the production management, the number of the products.

Taking an investment decision, that is to include also certain ecological aspects, requires designing a project which involves both financial and environment information. The indicators for preventing pollution, for example, can include next costs, scrubbers costs/cubic meter of polluted air, sewage plant costs/cubic meter of sewage caused. The calculation of the eco-efficiency indicators ensures a very good practical control of the ecological concerns. The

current eco-efficiency level is evaluated, estimations are carried out and targets are fixed to be compared with certain benchmarks. The indicators that are correctly calculated can offer important information related to the current situation on the eco-efficiency level and improvements directions in the future. Still, even if the eco-efficiency indicators usage can result in more benefits to the involved parties, presently this usage is rather low for certain reasons.

One of the reasons could be that the eco-efficiency indicators can be taken into consideration in the decision making process and can improve the quality, only if based on real information and if correctly calculated in the accounting, using well established methods. As in the environmental accounting there are no generally accepted standards, when calculating the eco-efficiency indicators, internal comparisons are carried out between the enterprise business units, and comparisons at different moments in time. It is about enterprise performance and comparative analysis.

Another angle to have in view is that even if the provided data are real and of a high quality, the eco-efficiency indicators have to be carefully considered. The indicators and data used in this process can be inaccurate, as being too specific or too general when taking a certain decision, and this can create an inappropriate image of the situation. Therefore, any definition of a eco-efficiency indicator has to be carefully analyzed. Also, in most cases, the data indicating the eco-efficiency level cannot underline all the matter aspects for which a decision is necessary to be taken. They are necessary, but not sufficient within the decision making process and, thence, additional qualitative and quantitative information are furthermore required.

5. Conclusions

Lately, the environmental management accounting, especially the environmental cost accounting, is gaining more practical importance. There are various implementation methods of it, and for the managers it is difficult to choose the right method or combination of methods. Also, managers find it difficult in practical situations to appropriately implement these

methods. Moreover, this action needs allocating additional resources.

These reasons led to a stronger focus on the environmental performance indicators, disadvantaging the environmental costs accounting. However, we need to take into account that these two concepts are complementary and are related one to each other. The environmental cost accounting offers important information for correctly calculating the environment indicators. The eco-efficiency indicators are the result of modern approaches of the costs accounting and they combine the economical indicators with environmental indicators. For successfully reaching the targeted strategy, the consistent system of environmental indicators will assign a particular importance to the environmental accounting. The environment indicators, calculated based on a consistent environmental accounting, offer useful information for the decision making process. Basically, the discussion regarding the environmental cost accounting, environmental performance indicators and eco-efficiency indicators needs to focus on their efficient implementation.

Romania's Tourism Brand – a Critical Analysis

Pavel Camelia

“Dimitrie Cantemir” Christian University,
Faculty of Touristic and Commercial Management, Bucharest, Romania
camipavel2003@yahoo.com

Abstract

Today the tourism is the fastest growing industry in the whole world. In comparison with other countries that have been taking advantage of these phenomena of travelling, Romania is lagging behind in terms of tourist arrivals. To capitalize our potential tourist destinations, the Romanian government launched a series of promotional campaigns in order to obtain a competitive advantage over their rivals.

The article provides conceptual delimitations about tourist destination branding. Also, the paper intends to approach in an exploratory manner how Romania has been presented in the communication campaigns over the years and what efforts has been made by authorities to promote the country as a tourist destination. Finally conclusions were outlined that highlight why failed all campaigns that promoted Romania as tourist destination.

Keywords: tourist destination, promotional campaign, Romania;

J.E.L. Classification: M31, M38, L83;

1. Introduction

In comparison with other countries from Western Europe, Asia, and North America, little research has been conducted into the destination branding of Romania. This article aims to help fill this gap in the literature, by examining the contrasting approaches and strategies used by Romanian authorities in their respective attempts to develop a strong tourism brand. The most countries only clearly brand themselves for tourism purposes, so much so that tourism branding tends to be confused with nation branding. This is the case for what happened with

Romania branding.

2. The importance of tourist destination branding

The concept of branding has been traditionally associated with corporations and their products and services. Today branding knows no boundaries. Branding is now applied to people, institutions, political entities, places, destinations, cities and even countries or nations.

If creation, development, employment and positioning of brands are relatively easy to understand for the tourist products and services, in the case of the tourist destinations such activities tend to be more complex [8]. Thus, developing a brand for a tourist destination becomes more difficult as a result of the multidimensional nature of the destination itself, the different interests of the stakeholders present in the tourist market, the differences between the theory and specific decision-making process involved, on the one hand, respectively the consensus of the involved community, on the other hand, a concrete way of measuring the loyalty to the brand and, last but not least, the problems associated with the financial support of the brand.

Brand consultants [4] concluded that, for products and services, principles of branding are common and brands must be developed as the link mirroring the set of functional and emotional values created by the company.

The conditions that support branding in tourism has been defined as: easy identification by consumers, perception of good value for the price, easy maintenance of quality, a large enough demand for the general product for a chain and the existence of economies of scale [6].

A brand as the core element of the process of branding embodies a whole set of physical, social, psychological, traditional attributes, perceptions and beliefs associated

with the place – country, nation, region, city. In other words, a destination brand is something distinctive through its positioning in the competition through its personality comprising a unique combination of functional attributes and symbolic values.

A tourist destination branding is claimed to include selection and strategic combination of a consistent mix of brand elements to identify and distinguish a destination through positive image building. These elements, similar to the consumer products, are proposed to include terms, names, signs, logos, designs, symbols, slogans, color, packages, architecture, typography, photographic styles, as well as heritage, language, myths and legends [3]. All of these have their contributions to identification and differentiation a tourist destination. Due to them, tourists may have holiday memorable expectations which are associated with a unique set of values that create, in time and voluntarily, positive associations with tourist destination. The elements of tourist destination brand serve to consolidating and strengthening the emotional connections between the visitor and destination, and reduce the *searching costs* of the consumers and *perceived risk*. Together, these activities serve to creating a unique distinct *image of a destination* in the minds of the consumer that influencing positively the *choice of the destination*.

3. Communication campaigns of Romania's tourism brand

The Romania's brand story started at the beginning of the 1990s, when a Commission for the Improvement of the Image of Romania Abroad was created.

First promotional campaign was in **1996**, when the government granted 6 million dollars for the publication of an album entitled „**Eternal and Fascinating Romania**” intended to improve Romania's image as a tourism destination abroad. Theoretically, the Eternal and Fascinating Romania should have arrived in 96 countries worldwide. Thus, the album should have promoted Romania all over the world.

In March 1998, of the 97,000 albums only 10,000 were made and only 4,200 reached in Romania. The press pointed out that an album cost 600 Euros, a sum considered

exorbitant.

Then as now, the country promotion was politicized and it became the victim of domestic politics, especially when there is no agreement among the different political parties about how or by whom the country's reputation should be managed abroad. In 2000 the “Eternal and Fascinating Romania” launched a scandal into the Romanian political arena and the Romanian Presidency has been associated with this scandal and with a Romanian-French businessman that has been accused of money laundering, depositing Romanian funds in a group of French businesses.

The scandal has escalated, spreading like wild fire and highlighting more and more corrupt practices within Romanian politics. A scandal of such magnitude has not been publicised in Romania since the collapse of Communism and had far-reaching implications for Romania and her political image abroad.

The second promotional campaign was launched in 1998 – 1999 under the slogan “**Come as a tourist, leave as a friend**”. Its aim was to increase awareness of Romania's tourist attractions and to market Romania as a year-round tourist destination for Americans and Canadians. The campaign slogan was not original one, being used by Greece in 1994 for the same purpose. Finally the promotional campaign was abandoned because the state was unwilling to allocate sufficient funds for marketing and promotion.

The third promotional campaign was entitled “**The 1999 eclipse**” and was connected with the total solar eclipse from 11 august. With this occasion Romania promoted what experts have called the best vantage points for the last eclipse of the millennium.

The purpose of campaign was to take our country out of darkness. The budget for this campaign was of 1.5 million dollars which 140.000 dollars were spent on a commercial spot broadcasted on Discovery, Eurosport and Euronews channels. Other 500.000 USD were spent for the participation to the fairs and exposition, including the printed materials [5].

The results of campaign were disappointing, both for tourists because of the slow privatization, and for authorities who estimated that 500.000 people would be

interested to come to see the total sun eclipse from Romania. But the total number of foreign tourists which expressed their interest to come in Romania for the total solar eclipse was around 3.000 peoples [5].

Tourists were also very puzzled by the almost complete lack of entrepreneurialism around the eclipse. This event has been seen as the greatest influx of foreign tourists that Romania ever saw. Yet, hardly anyone was seen selling eclipse tea-shirts, posters or other souvenirs, something that even the smallest event elicits in the West. It's almost as if as a people we've forgotten how to make money and thus improve our situation.

Another glaring example with regard to one of the government's few eclipse initiatives was — the issuing of a beautiful eclipse commemorative 2,000 Lei banknote (worth about U.S. 12 cents). Tourists had read about them before arriving in Romania and were anxious to pick some up as souvenirs. None were to be found — anywhere. Some tourists even asked if they were real and available. A superb entrepreneurial opportunity was completely missed by our government.

The next campaign that promoted Romania as a tourist destination was initiated in **2001** when government started realized that Romania had „image problems”. This was the first real international campaign meant to improve the country's image abroad and encourage tourism.

The promotional campaign had several steps. In 2001, under the slogan “**Romania – always surprising**”, campaign was commissioned by the General Direction of Tourism Promoting and her achievement was attributed to the agency Ogilvy & Mather Advertising, following a tender. The result of tender was contested because the price offered by Ogilvy was considered by competitors extremely low. The commercial spot contained a story that was inserted main tourist attractions.

During the period, 2000-2003, other numerous programs were proposed and launched by the Ministry of Tourism, such as: “Super ski in the Carpathian Mountains”, “Salvamont”, “Romania – Country of wines”, “Cruises on the Danube”, “Blue Flag”, “Q Mark (Seal) Program”, “Romanian Casino” and “Infoturism”. For internal tourists were launched social programs,

directed at Romanians with low incomes: “May 1st on the Black Sea Coast”, “One week at the Seaside”, “The Littoral for all”. Other program ideas were: “Mamaia – Riviera of the East”, “Europa Resort”, “National tourist parks”, “The rehabilitation of burnt lodges”, “Old trains”, “Cultural and religious tourism”. All those interesting and modern ideas were, unfortunately, lost because the main characteristics weren't anchored in reality: the large number of launched program and their diversity; the time horizon established for implementing the programs (2-3 years) was unrealistic; the sources of funding were not indicated and no special budgets were allocated; no implementation guidelines were established. The absence of a strategy created the false belief that a good idea was enough; transpose it into practice would be easy. This proved not to be the case as for all the announced programs lacked the real communication between the central tourism authorities, local authorities, and local business communities which would have the most important role in the implementation of those programs.

In **2004** was started the second step of campaign initiated in 2001 (“Romania always surprising”) and same agency obtained the contract because had no real opponents [7]. The new slogan was “**Romania – simply surprising**”, with the declared scope of improving Romania's image abroad and attracting foreign tourists. One of the spot presented virgin nature and the Danube Delta as an image for one of the world's greatest wildlife sanctuaries, authentic villages which is easily connected to nature, and Romanian hospitality. Aimed primarily at foreign tourists (20-55 year-old, having an average income, interested by new experiences, culture and history), the first significant series of advertisements aired on Euronews, Eurosport, Discovery, CNN, and BBC in the summer of 2004. The Government-sponsored “Romania Simply Surprising” campaign begun in May 2001 and has since cost the state around 20 million USD.

Although professionally produced, they were criticized for having failed to distinguish Romania from other countries. Part of their criticism is labelled at the adjective “surprising”: Singapore was surprising in the 1980s, Rwanda was

surprising in 1991, Bosnia was surprising in 1995 and Chile was surprising in 2005. “Being surprising per se is not potentially enticing” [2].

The project, “Romania, simply surprising” was cancelled in 2007. The World Tourism Organization criticized both the campaign and the slogan of the project and proposed that serious measures should be taken to enhance Romania's visibility abroad. Richard Batchelor, the chief of international consultants' team from World Tourism Organization said that slogan „simply surprising” didn't communicate the essence of Romania for any potential visitor.

In 2005 the Ministry of Tourism invested 8 million US dollars in Romania's image around. Half of this money was spent on promoting the country abroad through Romania's 18 tourism operators. In the same time, the Agency for Governmental Strategies and the National Authority for Tourism began getting involved in the issue of country branding by ordering research studies on Romania's image. In this context The Agency for Governmental Strategies has conducted several studies in order to draw a comprehensive image about Romania and Romanians abroad. The surveys were performed in several countries of extremely high relevance for Romania: Finland, Sweden, Germany (July 2006), Italy (March – April 2008), and Spain (May 2008).

The reasons which was the basis of choosing these countries for in-depth perception-studies was as follows: on the one hand, during the communist period a lot of people from Germany and Nordic countries was interested by Romania as tourist destination; on the other hand, in Italy and Spain Romanians constitute a large minority of immigrants and also in both countries Romania's image in mass media is preponderantly reflected in a manner which can be situated somewhere between negative and strongly negative. This fact is considered a constant threat to Romania's nation-image, not only in these two countries, but, by extension, in others as well.

After these studies, the Ministry of Foreign Affairs, organized between September – December 2008, a public diplomacy campaign in Italy and Spain, entitled “The Romanians in Europe”, in order to prove that there are more things linking the

Italians and Spanish to the Romanians and less those that seem to separate them. In Italy, the campaign “**Romania: piacere di conoscerti**”, takes place under the slogan “Romania: un mondo da scoprire” and in Spain the name of campaign was „**Hola, soy rumano**”.

Both diplomatic campaigns had opened the series of public actions which were carried out in Italy and Spain, in order to promote Romania. For the entire diplomatic campaign, the Ministry of Foreign Affairs spent 7.9 million euro.

In July 2006, was launched the national campaign “**A journey is a lesson of life. Choose domestic tourism offer**”. The campaign promoted the intensification of domestic tourism around five themes: Littoral; Danube Delta; Mountain tourism; Cultural tourism and Spa tourism. The budget for this campaign was of 800.000 EURO. Despite the fact that was the first promotional campaign dedicated to Romanians, the number of those who travelled abroad continued to grow dramatically.

One of the most important attempts to promote Romania as a tourist destination was the “**Romania – Fabulospirit**” project, designed in December 2006 and initiated in February 2007 after the evaluation of Romania's perception among foreigners. Through this project, Romania decided to valorise the spiritual dimension of its people and brought forward a new slogan “**Fabulospirit**”.

Since its birth, the project raised various scandals involving its financing and the agency that took over the concept, Gav Scholz&Friends. Only the slogan “**Fabulospirit**” which had not any meaning in any language (it is a combination of two words: fabulous and spirit which has some meanings), but had the quality of being unique, was paid for 110,000 euro.

In the same year, the project was cancelled after the resignation of the Minister of Foreign Affairs, and the new leadership Adrian Cioroianu was promoted. He decreed its inapplicability and the importance of a sound project that would not hurt Romania's quasi-inexistent image abroad.

In 2008, the discussions related to branding Romania started to take a shape and in June it was announced the intention to use

a budget of Euro 75 million euro to promote Romania. The Romanian advertising organizations got involved in helping the Tourism Ministry to write the brief for “Romania’s tourism brand” international pitch. After the pitch, in 2009, the Romanian Tourism Ministry selected THR– Taylor Nelson Sofres to realize Romania’s tourism brand as a way to communicate Romania as a tourist destination. Although a pitch was started, the Tourism Ministry launched an intermediary slogan to be used until the new brand was ready.

The new campaign “*Come to Romania, The Land of Choice*” was launched in April 2009, in order to promote Romania. On 1st August 2009, Eurosport has broadcasted for the very first time the video of promoting Romania as tourist destination. To mark this debut, the clip was simultaneously run on both TV as well as on the largest digital media facade in Europe located in Bucharest. During the period August – December, and CNN broadcasted the ads that used the tagline ‘The land of choice’, revealing the concept of „one country, so many experiences”. The logo was common one, undifferentiated because it contained no specific symbol for Romania, and, only emphasized the country’s varied landscape, a feature of most Central and Eastern European countries.

The video’s unrealistic portrayal of the country drew heated debate about national identity and harsh criticism for tourism minister Elena Udrea. It also generated a series of viral response videos with titles such as “The Truth about Romania”, “Come in the summertime, when we are abroad” and “We are the End of Choice,” which sarcastically foreground the dire conditions that the ad concealed about Romania. The conclusion is that Romanians prefer to travel abroad because “it’s cheaper in Turkey and Greece”. Even worse, the ad was promoted by a “tourism anthem” encouraging travellers depressed by the predictability of global tourist hotspots to head for Romania. The daily Cotidianul [1] described the song which praises Romania as a “land of choice” and cost 10,000 euros, as a “very bad joke.” “The real question,” the newspaper noted, “is what sense such a song can make for a sector that really deserves a requiem or a funeral march?”

In this case, was commissioned a new series of ads to run on CNN and Eurosport, which had three Romanian sport legends as protagonists: Nadia Comaneci, Ilie Nastase and Gheorghe Hagi. This campaign focused on the idea that foreigners know nothing about Romania. One of these spots challenges potential tourists to admit the surrealistic projections associated with Romania. It begins with the image of a happy bride in the company of four men. “This is Romania,” Nadia Comaneci playfully comments, “the only country where a woman has the right to marry four men at the same time!” “Discover Romania, the country where people are riding zebras,” urges Ilie Năstase. “Come to Romania and test the fish fruit!” Gheorghe Hagi concludes, leaving us with the image sardines that grow on trees. The campaign tells the audience about itself, but fails to say anything about the content of its own brand - except surrealist images which seek only to confuse the potential tourist further.

Statistics reveal that these ads have been ineffective at attracting tourists. Despite the two million Euros used for the Land of Choice campaign, the number of tourists in Romanian hotels decreased by 21.9 % in 2009. Newspaper articles with headlines such as “Romanian Tourism in Free Fall” and “Romania, the European Country with the Lowest Number of Foreign Tourists,” reported a shrinking number of foreign visitors. Foreign marketing experts, and even some critical scholars, tend to blame the strategy itself. Statistical data for January-May 2010 show a continuing decline in arrivals, of 3.5% year-on-year in those five months. The total number of tourist nights in all accommodation establishments fell by over 3% year-on-year in January-May 2010, with nights by foreign and domestic tourists declining by about 1% and 4% year-on-year respectively. Foreign tourists accounted for nearly 21% of total overnight stays [9].

The most recent promotional campaign for Romania as a tourist destination was presented in July 2010 during the “Day of Romania,” celebrated at the World Expo in Shanghai. Romania’s new tourist brand was officially launched at the Romanian pavilion through the “*Explore the Carpathian Garden*” communication campaign. The new logo and slogan under which Romania is

promoted as a tourist destination, in the coming years, have been also presented.

But the event was shadowed by controversy back home as bloggers revealed that part of the logo is almost identical to a logo up for sale online at 250 US dollars. The leaf which at the bottom of the controversy was claimed to have been produced and had its rights marketed by a Belgian designer through an online library, and has already been utilized by several European companies.

Another huge aspect of the scandal was the price – THR is supposedly getting 900.000 Euros to develop Romania’s tourism brand strategy not only for a logo which was broadly criticised for looking like it been taken out of a stock image bank. A brand strategy involves aspects such as how and where to use the logo, how to communicate the message, which channels to reach, etc.

Business people in the travel sector and branding consultants say the slogan's message is hard to decode by foreign tourists and can generate confusion considering that the Carpathian mountain range crosses several countries.

On the other hand, launching a promotional campaign with a plagiarism scandal is not the most orthodox way to attract clients. But in Romania, maybe work.

4. Conclusion

After the fall of communism, Romania sponsored several large-scale campaigns promoting the country as a tourist destination. Only in the last five years, Romania tried to re-brand itself for three times in tourist purpose, as a reaction to the negative comments generated by the campaigns. Although almost all campaigns primarily have focused on tourism, they had not a resounding effect because touristic brand of Romania has not managed in an organised, continuous, consistent and proficient way. The national logo years by years was modified concerning the shape of letters, colours and connotations. Moreover, were the source of funding scandals be used either plagiarized existing ideas from others. On the other side, a lot of money was paid for slogans that were criticized for having failed to distinguish Romania from other countries.

But creating a slogan and logo is only a

small part, because even the most brilliant logo and slogan is powerless if it is not backed up by a comprehensive branding system. A precarious gap has emerged between the reality of everyday life in Romania and how it is perceived by the outside world - most people either know nothing about the country or harbour half-formed and negative perceptions. This image problem is not just one of recognition, but also of differentiation from other Central and East European countries. Romania needs to present a deliberate and coherent tourism brand image of itself to the outside world to better compete in tourism and to differentiate itself from the other EU countries.

It is clear that the tourism has collapsed, the infrastructure is antiquated, access is worse than it was a generation ago, everyone qualified has gone to places where tourists really go, and prices are higher than everywhere else. Promotional activities are connected with touristic offer, that not corresponding with European standards.

Observing Insurance Companies' Customer Complaint Management in the Online Environment

Petrișoia Carmen
Pop Nicolae Al.

Academia de Studii Economice București, Departamentul de Marketing
carmen.petrisoaia@yahoo.com
nicolae_al_pop@yahoo.com

Abstract

The strategic importance of an efficient customer complaint management is recognized nowadays by the practitioners as well as by the academic literature.

The hereto paper is focused on the online environment and on the instruments used to allow a direct communication through various channels of the complaints addressed by the customers to the insurance companies.

The descriptive research of the online secondary sources revealed that most of the insurance companies are transparent concerning customers' complaints and have implemented at least one instrument for their collection. However, most of the times, the instruments found on the companies' sites, have the same features for all the customers and are rarely adapted to business customers.

Key words: relationship marketing, customer complaint management, business customers, Internet.

J.E.L. Classification: M31

1. Introduction

The development of the Internet technologies is regarded as one of the factors that have enabled the fast economic growth in the 1990's and it is considered responsible for changing the way business are made [1]. The appearance of the sophisticated telecommunication technologies allows a direct interaction with the customers, and the real success of online banking, online investment and online book selling or even cars, are proving the growing interest of the consumer to maintain direct relationships with the marketers [2].

Nevertheless, in the insurance industry, the potential customers believe that the procedure for signing an online insurance contract is rather complicated and the online insurance policy sales are low [3]. On the other hand, the relationship marketing's key component [4], the customer complaint management, is carried out in the online environment, throughout the insurance companies' sites. It has been proved that an efficient customer complaint management through e-mail improves customer satisfaction and helps building a long term relationship with customers [5], [6].

Beyond the relationship aspect described previously, the transparency and the correctness in customer complaint management have become a legal obligation since the Insurance Survey Commission Order number 11/2012 was adopted. More precisely, the insurance companies are compelled to publish on their sites all the decisions concerning the complaints registered by the aforementioned commission.

This study's objectives are: to observe the degree of transparency in the online customer complaint management, to observe the instruments adopted for customer complaint management in the online environment by the insurance companies acting on the Romanian market, to observe the way in which the individual customers are being differentiated from the business customers by the instruments used in the online customer complaint management.

2. Literature review

Virtual communication – in general – and especially the Internet – has determined essential changes in the business architecture [4]:

- The plenary implication of all the stakeholders in the business process;
- The development of an integrated communication in the businesses' marketing [7];
- A new way of managing time in the business economy;
- The customer's awareness about the possibility and the necessity of its involvement in the projection and the execution of the performance that he desires for a complete satisfaction of his demand;
- The efficient customer complaint management.

Customer complaint management occupies a central role in the relationship marketing and has become a strategic instrument considered to be very important for all types of firms [5]. Using efficient ways to solve customer complaints is seen as a sure way to gain customer's attachment to a product, a service, a brand or a company [8], [9].

Strauss and Hill's study [5], has demonstrated that a prompt answer given to an e-mail complaint determines a higher customer satisfaction with the response and an increase of customer perceptions of the company concern.

The academic literature focused mostly on customer complaint management for individual consumers, but the business setting didn't receive the same attention, although it represents one of the cores which formed relationship marketing [10]. The importance of implementing a customer complaint management adapted to business customers is underlined by several studies that have shown that this particular category is less likely to follow a complaint than the individual consumers [10].

3. Methodology

The direct research methods used in the marketing studies are divided according to several criterias [11]: the place where the information was collected: desk research methods, and field research methods; the awareness of the information source: methods which are involving consciously the information source (free talks, experiments, projective tests, marketing simulations) methods in which the information source is

not aware that it is being analyzed (the observation).

Lately, the observation through technological instruments has become very popular because its reliability and data objectivity [12] in new research fields such as neuromarketng. The aforementioned represents a group of investigation techniques for the uncontrolled reactions of an individual exposed to different stimuli – such as colors, smells, shapes, images – with the help of a sophisticated equipment [13].

In order to fulfill the objectives previously established, a descriptive research was carried out through the simple observation method of the secondary sources in the online environment.

With the help of the specialized site www.lasig.ro there have been identified the sites of 30 insurance companies that are working with individual consumers and with business customers as well. A first observation of the sample was carried out in November 2011, and the second one in November 2012. For the data collection, a contingency and observation table was designed.

The study's hypotheses were: I. The insurance companies are totally transparent concerning the complaints registered to the Insurance Survey Commission and they are publishing all the required information in this matter. II. The insurance companies are using at least one instrument for the customer complaint management in the online environment. III. The instruments that are visible in the online environment have elements which allow the differentiation of the individual and the business customers.

4. Results

In order to test the first hypothesis, we have verified the degree to which the Insurance Survey Commission Order Number 11/2012 is being respected and we have gathered information about the number of complaints received for each observation unit during the last three reported months. Hence, 86,20% of the visited sites are using a pop-up window which tells the user that this information is available on the site and offers him a direct link that remains active for about ten seconds before charging the homepage. However, as one can notice from Table 1,

there are companies that are not sharing yet the aforementioned data. It can also be observed that the minimal complaints number is 0 and the maximum is 1218. During the last three reported months there have been 3459 in total, which means an average of 138.6 complaints per company.

Source: personal research

Com* = number of complaints

ni** = no available information

The second hypothesis was aiming the observation of the instruments used in the

online environment for the customer complaint management. After having analyzed the collected data from 2011 and 2012, we reached to the conclusion that the most frequently encountered instrument is the online form, present on 93% of the sites in 2011 and on 90% in 2012, followed by the call center and the e-mail. The instruments that are appearing rather rarely on the companies sites are the fax and the postal address. Moreover, compared to last year, the number of firms that have a call-center and an e-mail address increased.

It is important to underline that in 2012 there are still sites that don't use any instrument for customer complaints. Nevertheless, 7 out of 30 companies are offering to their customers, four distinct instruments, namely the online form, the call-center, the e-mail address and the fax or the postal address. The 7 companies have different market shares and are not homogeneous from the point of view of the turnover, but they all have a low level of complaints registered to the Insurance Survey Commission during the last three reported months.

Table 2: The presence of the customer complaint management instruments in the online environment

Customer complaint management instruments	Site presence	
	2011	2012
Online form	93%	90%
Call center	37%	57%
e-mail address	37%	63%
Fax	10%	27%
Postal Address	7%	3%

Source: personal research

Because of the fact that the last hypothesis refers to the elements that differentiate the complaints online form for the business customers, this instrument was analyzed. The simplest structure for this kind of form has the following fields: Last Name, First Name, Address, e-mail, Phone Number, Complaint Description. However, in most of the cases, the form is also asking for the number of the insurance contract, the number of the identity card and even the favorite way to be contacted the insurance firm representatives.

Although all the insurance companies included in the sample are also addressing to business customers, only 5 of them have an adapted form dedicated to this particular category. Hence, the third hypothesis is rejected, as the majority of the analyzed forms have a general structure.

5. Conclusions

From the analysis of the sample, one can conclude that the importance of using efficient instruments for customer complaint management is properly understood by a significant percentage of the managers. In most cases, the link to the page named „Suggestions and complaints” is easily found on the homepage and the customers are invited to use one of the discussed instruments in order to communicate directly with the company their dissatisfaction.

90% of the sites have integrated a complaint online form easily to access, but only 5 of the companies chose to adapt it for the business customers. Because this is an important and profitable category, it is recommended that the form should have a special, customized structure with specific elements such as: CUI, The Department Function, Contact person etc.

With four exceptions, the observation units are presenting the complaints registered to the Insurance Survey Commission, many of them through the form of a pop-up window which is launched instantaneously when the site is being opened. If we take into consideration the results of the first CSA report in 2012 according to which after a series of verifications carried out in 2011 [14], they have noticed the lack of an efficient, integrated IT system and the ineffective complaint solutions for some of the insurance firms, one can conclude that the degree of transparency and customer orientation has improved.

One of the study’s limitations is that it did not evaluate the use of the online instruments by the customers who want to communicate their complaint. Hence, a future research should focus on the analysis of the impact of the aforementioned instruments on the customer’s satisfaction, especially in the case of business customers.

Economic and Financial Analysis of an Intelligent Organization

Podasca Raluca

The Bucharest Academy of Economic Studies

raluca.podasca@yahoo.com

Abstract

The emergence and development of new technologies, in which information and knowledge play a crucial role, the transition from industrial economy to modern society and then to postmodern society have led to compression of time and space and to the intensification of economic, social and politic relations.

It becomes increasingly emphasized a new trend: the orientation towards lifelong learning organization or in other terms the intelligent organization.

To analyze the overall situation of intelligent organization is necessary to analyze the economic structure by studying the structure of assets and liabilities, the liquidity and solvency of the organization.

Key words: economic analysis, financial analysis, intelligent organization

J.E.L. classification: G00, M10, M21

1. Introduction

Economic and financial analysis serves diagnosis and control of the enterprise business system. Organization is seen as a complex and probabilistic system. Diagnosis involves research of the functioning of the system using status information. These are critical points within the system and approves the decision centers to take appropriate measures.

2. Intelligent organization

Organizational changes have led to new concepts such as intelligent organization (J.B. Quinn, 1992), learning organization (P. Senge, 1990), networked organization (P. Keen, 1991), democratic organization, expressive organization (M. Shultz, 2000), generally about an organization that

leverages more than in past knowledge, innovation, talent and motivation. The success of these organizations depends on effective use of talented people.

The causes that led to organizational changes are: the emergence and development of globalization and mondialization, the increasing competitiveness, the increasing environmental turbulence, the introduction of new information of knowledge that emphasize the importance of knowledge and innovation, major demographic changes at the population level in general and human resources in particular.

Ratner defines the learning organization as “organization in which people at all levels, both individually and collectively, continually increase their ability to get the results they want.”[3].

Learning organization is “organization where people continuously develop their capacity to create the results they truly desire, where new and enhanced models are powered thinking, where collective aspiration is freely accepted and where people continuously learning how to learn together.” [1].

3. The economic and financial indicators

The rates of patrimonial structure provide opportunities for comparative analysis in time and space by identifying major structural features of the balance. Balance sheet structure analysis aims to determine and track the patrimonial elements share of assets and liabilities.

3.1 Rates of asset structure

The value of the asset rates are influenced by the economic, technical and legal aspects of the company. The main rates that characterize the structure of the asset are:

a) Rate of fixed assets:

$$R_{FA} = \frac{FA}{TA} * 100\%$$

where: FA are fixed assets and TA are total assets.

a1) Rate of intangible assets :

$$R_{IA} = \frac{Ia}{TA} * 100\% ,$$

where Ia are intangible assets and TA are total assets.

This rate reflects the share of intangible assets (patents, licenses, trademarks etc.) in the total assets of the company. In case of Romanian companies the value of this rate is very low while in other countries such as USA, intangible assets ratio exceeds 50%.

a2) Rate of tangible assets:

$$R_{Ta} = \frac{Ta}{TA} * 100\% ,$$

where Ta are tangible assets and TA are total assets.

The values of this rate are different from one branch to another, with very high values for firms that use an important infrastructure or expensive equipment (production and distribution, transportation etc.). This rate indicates a company's ability to withstand economic crisis as a high rate of fixed assets entails a high risk of failure to transform the assets into cash.

a3) Rate of financial assets:

$$R_{Fa} = \frac{Fa}{TA} * 100\% ,$$

where Fa are financial assets and TA are total assets. This rate has high values for financial investment companies because it reflects the intensity of financial relations and connections that the company has established with other firms for external growth (loans, portfolio investment etc.).

b) Rate of current assets:

$$R_{Ca} = \frac{Ca}{TA} * 100\% ,$$

where Ca are current assets and TA are total assets.

b1) Stocks rate:

$$R_S = \frac{S}{TA} * 100\% ,$$

where S are stocks and TA are total assets. This rate has higher values for firms with production activity, with a long production cycle or for firms with distribution activity.

b2) Trade receivables rate:

$$R_{TR} = \frac{Clients + Assimilated_Accounts}{Total_Assets} * 100\%$$

This rate is influenced by the customers' type and the payment term that companies gives to its partners.

b3) Available funds and placements rate:

$$R_{AFP} = \frac{Available_funds + Placements}{Total_Assets} * 100\%$$

The interpretation of this rate should be used with caution because significant liquid assets may change over short periods of time.

3.2 Rates of liabilities structure

a) Financial stability rate:

$$R_{FS} = \frac{PC}{TL} * 100\% ,$$

where PC is permanent capital and TL are total liabilities.

This rate is a global indicator of funding sources stability. Permanent capital consists of equity, provisions, medium and long term debts.

b) Financial autonomy rate:

$$R_{FA} = \frac{E}{PC} * 100\% ,$$

where E is equity and PC is permanent capital. It is recommended that this value is greater than 0.5. Financial autonomy rate indicates the share of own sources of funding from the total capital of the firm with different values depending on the company's profitability and financial policy.

c) The rate of short term debts:

$$R_{STD} = \frac{STD}{TL} * 100\% ,$$

where STD are short term debts and TL are total liabilities. This rate signifies the share of debts with chargeability term less than one year in total company sources.

d) The rate of total debts:

$$R_{TD} = \frac{TD}{TL} * 100\% ,$$

where TD are total debts and TL are total liabilities. This rate signifies the share of short, medium or long term debts in total company sources.

4. Solvency and liquidity indicators

Solvency is the ability of the firm to face

the outstanding obligations arising either from previous commitments contracted or compulsory levies. The main indicators used in the analysis of bankruptcy risk are working capital and liquidity rates.

According to the accounting theory, a firm is solvable if the following equalities are observed:

- fixed assets = permanent capital;
- current assets = debt service.

Compliance with these conditions requires a perfect balance of revenue and payments, which in financial practice not always happen.

When permanent capital is greater than current assets, the difference between the two indicators is called working capital. Working capital is a very important indicator for assessing the financial situation of the company representing the part of the permanent financial resources to provide financing current assets which renew continuously.

The most important indicator that measures solvency of a company is the overall solvency ratio:

$$R_{os} = \frac{TA}{Td},$$

where TA are total assets and Td are total debts.

Liquidity is the degree to which an asset can be converted quickly and without additional expense means in immediate payment. To analyze the risk of bankruptcy is important to analyze liquidity ratios.

The most important liquidity ratios are:

1. General liquidity rate:

$$R_{GL} = \frac{Ca}{Cd},$$

where Ca are current assets and Cd are current debts. Normally this rate has to be greater than 1, which confirms the existence of working capital. It is estimated that overall liquidity position is satisfactory, according to some sources, when is between 1.2 and 1.8 and according to other sources between 2 and 2.2.

2. Current liquidity rate:

$$R_{CL} = \frac{Ca - Stocks}{Cd}.$$

According to the American theory, this rate is called the acid test. It shows to what degree firm's total liabilities can be covered

in a short time without taking into account existing stocks. The interval considered satisfactory for this rate is between 0.65 and 1.

5. Economic and financial analysis of an intelligent organization

Based on data presented in the balance sheet of the company S.C. MED S.A., I have made an analysis of the economic and financial overall condition (the name S.C. MED S.A. is conventionally attributed, data were obtained from a real company that belongs to the medicine production).

Table 1. The Balance Sheet of S.C. MED S.A.

Indicator name	Sold at 31.12.2010 (lei)	Sold at 31.12.2011 (lei)
A.FIXED ASSETS	168.483.874	173.363.858
A1. Intangible assets	1.989.252	1.652.572
A2. Tangible Assets	166.413.201	173.690.051
A3. Financial Assets	81.421	21.235
B. CURRENT ASSETS	223.940.478	273.646.635
C.EXPENSES IN ADVANCE	327.246	302.678
TOTAL ASSETS	392.751.598	449.313.171
TOTAL DEBTS	110.652.469	142.722.089
TOTAL CAPITAL	262.612.444	287.058.407

Source: The Ministry of Public Finances

Studying the data in the table above are obtained the following asset structure rates:

Table 2. Asset Structure Rates

Structure rate (%)	2010	2011
1. Rate of fixed assets	42.90	39.03
1.1 Rate of intangible assets	0.51	0.37
1.2 Rate of tangible assets	42.37	38.86
1.3 Rate of financial assets	0.02	0.004
2. Rate of current assets	57.02	60.90
2.1 Stocks rate	10.29	9.33
2.2 Trade receivable rate	45.78	50.38

Source: made by the author

It is noted that the rate of fixed assets is closed to the rate of current assets because the company belongs to the productive sector. The rates of intangible assets are low in both years analyzed. The rates of financial assets are very low because the company has a limited financial investment activity, not being its area of activity. It is noticed an increase in current assets in 2011 (60.90%) compared to 2010 (57.02%), increase that has been achieved on account of receivables whose rate increased to 50.38% in 2011 compared to 45.7% in 2010. The rates of liabilities structure are presented in the following table.

Table 3. Liabilities structure rates

Structure rate (%)	2010	2011
1. Financial stability rate	70.42	67.14
2. Financial autonomy rate	94.97	95.16
3. Rate of short term debts	28.17	31.76
4. Rate of total debts	28.17	31.76

Source: made by the author

It is noted that the organization has a high, relatively constant financial stability in 2010 and 2011. The organization has also a high rate of financial autonomy, with an increasing trend over time. Total debts ratios have relative constant values in 2010 and 2011. The situation is very favorable because the risk of subsequent difficulties due to different debt maturities concentration is low.

Table 4. Solvency and liquidity indicators

Indicator	2010	2011
1. Overall solvency ratio	3.55	3.15
2. General liquidity rate	2.02	1.92
3. Current liquidity rate	1.66	1.62

Source: made by the author

The general liquidity rate reflects an equilibrium situation of the organization on short term. The company has the ability to pay its current debts from current assets (working capital). The overall solvency ratios have very good values, indicating that the company has the ability to honor debts on short, medium and long term.

6. Conclusions

In a competitive economic system, the major objective of an organization is to maximize its value. This involves the development of business activity in conditions of high profitability and at the same time maintaining solvency and financial stability.

Economic and financial analysis of an organization is only one stage in performance and competitiveness analysis of the organization, having a key role in establishing strategies to follow.

About Knowledge Management

Pop Viorel

„Vasile Goldiș” Western University of Arad,

Faculty of Economics

leroivpop@yahoo.com

Abstract

The beginning of the new millennium finds the world in a process of inter-connectivity increasing, of data flows acceleration and of temporal and national borders compression. The necessary power for these transformations at global level is represented by the technologies from the information and communication IT&C domain.

The social structures transformation through knowledge and knowledge management considered as an essential resource of economical increasing and as the main factor of production, constitutes a reason and in the meantime a sufficient justification for defining the modern advanced societies as „societies of knowledge”.

In a society based on scientific knowledge, the old competitiveness measurements, like the manpower cost, like the structure of the appropriation and the infrastructure, are over fulfilled as importance and signification by new economic-social indicators, such as knowledge, knowledge management, knowledge capital etc., key indicators that raise the market value of firms.

Key words: economy, knowledge, information, management, knowledge management, industry, development.

J.E.L. classification: O32.

1. Introduction - Knowledge revolution

With the "industrial revolution" scientific knowledge has become the determining factor of progress of human society in general and economic in particular. Mankind has progressed rapidly in the industrial domain (secondary sector of the economy)

quickly became the most important economic area, thanks to new advances in mathematics, physics, chemistry sciences etc. applied in technology (technology) but also due to the emergence and evolution of management science with its creative traits.

Knowledge revolution - is based on the crucial role they play in the modern economy. In essence, the "knowledge revolution" has made a fundamental change from an economy based predominantly on natural resources (land, technology, workspace, mineral resources etc.) to an economy based predominantly on knowledge.

The richness and power of the 21st century will be derived mainly from knowledge resources (intellectual and intangible) otherwise said, the knowledge capital. The result of the knowledge revolution will be the knowledge economy and a wider dimension - the society based on knowledge. [1]

Of course, we are already familiar with "new" concept "computer revolution" based on information technology, which allowed the amplification and unprecedented speed of collection, storage, processing and use / distribution of information.

Computers are an extension of our intellectual possibilities, which made possible the unprecedented acceleration of research, design and development activity.[2]

In the knowledge society, knowledge becomes the essential element of achieving high performance (productivity / competitiveness) in the economic domain.

2. The evolution towards knowledge

If over time, science was intended only to explain those encountered / seen in nature and current practice (different physical phenomena, some mechanical issues, etc.), and progress, extremely slow, was made only

after lengthy comments due to the understanding of some people, with the development of science, which has taken practical activities before, proposing innovations derived theoretically, calculated and sized correctly, accurately, before applying them in practice, a well-known example being the mid-20th century, the enhancement of nuclear energy. [3]

So, science of the last century has come to be the engine pulling itself after technical and technological progress.

Present computer simulations allow for including "piloting" airplanes and helicopters, industrial facilities design and their virtual control, simulation of geological phenomena, meteorological evolution etc. All these represent a major step, from unpredictable to knowledge, and thus bringing under control the unpredictable.

3. The need to know

During the period in which we live, the industry is the defining element of society. Relating to this element, the world has experienced three types of societies:

- pre-industrial society,
- industrial society,
- and now, post-industrial society.

The differences between them are determined by the importance of different industries, defining for the three types of societies, and in this context, are the main productive prestations change.

Thus, in the pre-industrial society, the priority element of the economic organization is raw material; the industrial society is of the machines and huge mass production number; and the postindustrial society is dominated by information and services sector. The next step will be toward the postindustrial society of knowledge. [4]

For the first time, after centuries of conditions and living standards have remained relatively the same, in the industrial society hundreds of millions of people have come to the material and spiritual standards, like the top class, holding all the comforts of modern homes, cars, shifting to spend holidays around the globe by plane or other means of quick and comfortable transportation, communication and economic transactions over the Internet, have equal access to education etc.

Also for the first time, this society was the one that required the necessity of educating the masses. Education came to be established as required by law. The population had to be literate and educated in order to be able to work in technical and industrial enterprises dominated by increasingly sophisticated technology. The population began to open horizon towards knowledge. With the industrial society, has begun a new world.

Postindustrial society - will impose itself gradually amid the unstoppable progress of science and technology - which has become more intelligent.

Industrial processes will be characterized by a high level of programming, automation and robotics, which will determine quality and extremely high productivity in the production of goods, in a more limited degree of human labor utilization. [5]

Postindustrial society will be dominated by information and communication technology.

4. Economy and management based on knowledge

Labor productivity - has been and will be an essential parameter of economic efficiency. But the future economy - informational, post-industrial knowledge - will greatly reduce the employment level and the labor share in input system, in the economic growth process. A higher importance will gain new workforce productivity, the knowledge workers, knowledge becoming the workforce.

In the information society, where information and knowledge will be the main economic resource, knowledge formation will be the main investment in developed countries. Income derived from knowledge, will become increasingly a decisive competitive factor.

Productivity and knowledge management - will be decisive in achieving economic performance especially that they already exist and will continue to maintain, differences between countries, industries and firms, in these two categories of performance.

Knowledge-based management - can be defined as the management of human capital, through the knowledge they carry, represent the most important and dynamic element in a

more efficient economy induced by globalization.

Society of the future will develop so much, that the basic economic resource (the means of production) to use the term used by economists, will no longer be capital or natural resources, not work, but will be **k n o w l e d g e !** Another feature which is already well felt, is the rapidly increasing pace of changes, scientific and technological developments. [6]

Transformations currently occurring in a period of only 30 - 40 years due to technological advances are greater than those recorded in human evolution, from ancient times until the beginning of the industrial age.

We can really talk about an acceleration of changes, even the acceleration of history. Of course, these changes will have to be managed by an advanced knowledge-based management.

In terms of value, there is the belief that this will primarily grow through knowledge and less through work (physical). Accordingly, "value theory" promoted by Marx will gradually lose its validity, being replaced by a new theory of value, based on knowledge.

In time, the value will increase due process knowledge, value that can be created or destroyed. Knowledge is synergistic, the whole worth more than the sum of the parts. Information and knowledge are in a direct relationship.

While information provides us data about the economic reality, about production and research, knowledge is much more, enabling us understand this reality, and by analyzing the information we can decipher trends and directions of development of economic reality.

Through knowledge, information receives concrete and real meaning arising from human activities, accordingly gaining a much wider content, which makes it possible, if we speak in the economic, the acceleration of the progress.

The signal that indicates an informed observer the fact that he is in front of an economy that is evolving toward a structure / function based on knowledge management, is dematerialization and virtualization increase degree of the share capital of companies and products on the market - goods or services.

Globally, the stock of knowledge is growing much faster than in the past, generating annually information equivalent of several hundred million books, knowledge becoming of the main capital of firms. Thus the last 2-3 decades, in developed countries of the world, there was a 20-25 % decrease of tangible assets in value creation. [7]

The main processes in terms of knowledge management are: Obtaining knowledge, by looking in different publications etc.; Knowledge creation in the form of inventions, projects, management systems; Use of knowledge by creating new products and services and of other knowledge; Preservation and protection of knowledge in databases, systems etc.

Currently, economic performance is more and more conditioned by the efficient use of the capital of knowledge held by each firm. OECD experts from the Institute of Knowledge Management Williamsburg - USA define for the economic domain, four categories of knowledge, as shown in Figure 1:

Figure 1. The main types of knowledge

Source: Authors' processing.

Know what - to know what others are doing, and therefore what you should do;

Know why - to know the main laws and principles of nature and physics, to understand what happens ... as it happens, and not otherwise;

Know how - based on applied research, find out how we can proceed to accomplish what we wanted;

Know who - to know with whom we can achieve what we wanted, how we get access to specialists that we need.

The role of knowledge: raw material, input, product, capital... the capital of knowledge has an increasing share in the overall value of modern and performant firms.

Knowledge held by employees of companies are called "intangible capital", knowledge in the form of technology, marketing know-how, managerial etc. represent the competitive advantage that allows the company to maintain itself on the globalized market.

Figure 2. The roles of knowledge in economy

Source: Authors' processing.

We know that those companies that have a high knowledge capital, such as: Microsoft, Intel, Nokia and Erikson, Boeing and Airbus, Bayer and Aventis etc. their market value (stock market) is a few times higher than the land owned, the buildings and their equipment.

Currently, for example, the book value of U.S., Japanese or European firms, is on average only 20-25% of their market value, the difference of 75-80%, representing an intangible assets.

Intellectual work has become the majority in developed countries. In the U.S., Japan and Western Europe since the '60s intellectual work became the major, when the number of persons in positions of leadership, the professionals and officials - has exceeded the number of workers.

The main characteristics of knowledge-based management are: [8]

- knowledge management requires high costs, but higher costs are due to his ignorance
- to be efficient, knowledge management require interdisciplinary work collective and more sophisticated technologies
- politics is increasingly attracted to and involved in issues of knowledge management
- knowledge management is increasingly avoiding hierarchies, try not so much to respect hierarchies
- within firms, knowledge sharing among certain categories of employees is

necessary to accelerate the process of obtaining performance

- cooperation between firms is necessary to achieve the same competitive product
- knowledge can be sold, their value depending on the degree of novelty and their productive potential.

The characteristics of knowledge management are:

- Knowledge is the basis of company performance
- Using multivalent and multidimensional knowledge management
- Increasing scale use in the management of information and communication technologies
- Promotion of staff who have advanced knowledge of IT & C
- Stimulating employees to produce, exploit and protect the company's knowledge
- Stimulating employees to disseminate knowledge within the company
- Knowledge management requires managers motivated by the desire for self-improvement
- Ignoring knowledge management orientation will decrease competitiveness of firms, leading to negative consequences
- Company must adopt the concept of permanent learning organization
- The body of managers of the firm, will protect with priority individual knowledge of their employees and the one at the organizational level
- Firm performance are based on the quality and experience of company managers
- Stimulation of employees and departments that produce and use new knowledge.

Certainly, the rapid evolution of society "in the industrial age" and then "IT society" and now became "knowledge society" this way was based on development of education, mainly technical and informatics at the university level.

Finally, we can say that neglecting the orientation to knowledge management will lead to decreasing the competitiveness of firms, with all negative consequences, competitive market exit and their bankruptcy.

5. Conclusions

Knowledge revolution - is based on the crucial role they play in the modern economy. In essence, the "knowledge revolution" has made a fundamental change from an economy based predominantly on natural resources (land, technology, workspace, mineral resources etc.) to an economy based predominantly on knowledge.

The richness and power of the 21st century will be derived mainly from knowledge resources (intellectual and intangible) otherwise said, the knowledge capital. The result of the knowledge revolution will be the knowledge economy and a wider dimension - the society based on knowledge.

In the knowledge society, knowledge becomes the essential element of achieving high performance (productivity / competitiveness) in the economic domain.

Human Resources Management

Popa Marius Florentin

Facultatea de Medicina, Universitatea “Ovidius” Constanța

Abstract

Any organization needs a good management of human resources. In this article we will refer to the ranking of managers and their main functions. The manager must have a good job systematization of all the stages of the hiring process resulting, having as a final result the job description. To obtain performance manager must provide continuous employee training and development, and for a better perform he should periodically evaluate the skills of its employees. Another important factor is the motivation without which no employee would give maximum efficiency at work.

Key words: management, human resources, performance

J.E.L Classification:

Introduction

The organization represents two or more persons who develop joint activities, in order to fulfill one or more goals and all the organizations have human resources in their composition.

The development of the organizations represents the main mechanism through which goals beyond the individual power can be achieved in a deeply differentiated society.

Managers hierarchy

Managers are situated on three levels of the hierarchical pyramid, namely superior managers, middle managers and inferior managers. Each manager, regardless of the hierarchical level on which he is, has three categories of responsibilities:

- a. of strategic orientation, by which he will orientate the organization he

directs in conformity with the established mission and goals

- b. of orientation of inter-human relations, by which he will work with people and create a climate favorable to the development of the activity
- c. to act as a specialist, having performant professional knowledge and skills.

The fact that the three categories of responsibilities have a different importance from one hierarchical level to the other and consequently the qualities and skills required from a certain manager are different, depending on the hierarchical level where he is ranged, must be underlined.

Manager functions

In the professional literature there is a multitude of points of view for defining the functions of management, regarding their number, their specific denomination and content, thus the majority of specialists considers as essential the planning or provision function, organization function, resource administration function, management or supervision function and control and assessment function.

The functions of human resources management are based on four desiderata, namely the provision of personnel, training and development, motivation for performance and continuity of employees.

Personnel provision is realized by identifying the necessary work quantity, the force of men employed and their essential qualification and by integrating the necessary personnel in the organization. The importance of job analysis has the role of helping the manager in defining the responsibilities and tasks necessary for that position, validates the methods used in making the decisions regarding the employment, offers a reasoning for the existence of the position and shows where it matches in the structure of the organization,

will allow the identification of hierarchical relations and identifies the excess of employees being reliant on the decision of supplementing/reducing the number of employees, will establish the elaboration of professional development programs, will orientate the employee on what he/she must do and will offer an estimation of the time necessary for activities.

The stages of job analysis must consider labor cost analysis, in which we will monitor the clear description of what and how must be done, on what purpose, with what resources and results, the analysis of job demands, where we will consider the level of responsibility, effort, necessary abilities, the level of training, education, experience, physical requirements, labor condition analysis (temperature, noise, pollution) and sociological data (communication availabilities, if he/she works alone or in group, promotion/gain possibilities).

We will have to gather information, evaluate the existent personnel, estimate the imbalances and seek for solutions to balance labor force, by elaborating an evolution plan of the personnel. In recruiting the personnel we will take into account the identification and attraction in the organization of a group of capable persons interested in occupying the job vacancies, these being potential candidates. During the entire recruitment we will follow a communication in double sense, which consists in the transmission of signals referring to the employment relation in order to be able to make the comparison between the interests of the two parties.

Based on the systematization of the information obtained, according to job analysis, we obtain the job description, which is very useful especially when the applicants use a standardized application form; it is annexed to the labor agreement and is signed by both parties. The component parts of the job description are realized by the detailed description of the main responsibilities and of the standards for their fulfillment, responsibility limits, special mentions, work terms and conditions, as well as the annex of the job description, which will include physical aspects, other general aspects, degree of professional training, necessary special abilities, major preoccupations, individual and circumstantial particularities, considering that the discrimination depending

on sex, ethnic, environmental, religious etc., is forbidden in our country.

Personnel recruitment is realized by various means: media advertisement, direct contact, advice office in employment procedures, interim, spontaneous candidacies, exploration of networks or internet. In personnel selection we follow two stages: pre-selection or initial "screening" and the actual selection. Pre-selection methods are curriculum vitae, letter of intent / motivation, application form, recommendation and interview by phone and in the actual selection process we will take into account the tests / psycho-tests, assessment centers, interview, group interview and test. At the end of the selection process we will get the actual post installation and integration of employee.

Any activity aimed at acquiring knowledge and skills specific to practicing a profession or achieving an operation is called training, and the development is any learning activity directed toward future needs rather than immediate and which deals more with career advancement than actual performance. Training and development are the two goals of training and development in human resource management.

Performance is the sum of the degree of fulfillment of the tasks that define the position held by the employee and the contribution that they make to the fulfillment of the objectives of the organization. Work performance will be followed by top marks in annual evaluations, exemplary work attitude and behavior, proven skills regarding teamwork, professional development and communication. Employees will profit by this evaluation through a retrospective of their past performance, it gives them ideas and guidelines for their future behavior, managers - are the basis for decisions on promotion or dismissal of personnel and human resources service through performance evaluation, provides information about the effectiveness of their own work. The utility of performance evaluation plays an important role in highlighting the effectiveness of human resources service, errors in defining the job, confusions in the circulation of information and highlighting of external influences.

Motivation is the process of selection, orientation and maintenance of human behavior and the process in which people

choose different forms of behavior to achieve personal goals. Motivating factors are represented by labor capacity, labor desire, aspirations, education, training, system of values, leadership, relationships, reward system, precision of tasks, the control system and organizational culture. Increased quality, the effort to be satisfied, positive attitude towards the organization, meeting deadlines, reducing staff fluctuation, reduced absenteeism, increased creativity, taking responsibility are the advantages of motivation, and between work performance and employee motivation relationship Victor (Vroom) relation is achieved:

$$P = f (Me, A, M)$$

Where: P = performance

Me= environment/work climate

A = ability

M = motivation

The professional literature lists several ways to motivate employees, among which the most important are: those of social type (coffee breaks), work environment (office supplies), those related to the position (increased responsibility, rotation in the activity), specific recognition (diplomas and trophies), the money ones (cash, shares, insurance), or those not directly linked to the activity (holidays congratulations).

In maintaining labor force many factors, such as inadequate wages, poor selection and integration, inadequate supervision style, discrimination, lack of promotion or too severe discipline intervene and thus some ways to ensure the maintenance of workforce have been developed. These methods, in a short list, are represented by the knowledge of employees' work motivation, good management of teams, stimulating and performance benefits for the employees, ensuring safety at work (employee health concerns), creating a pleasant climate, design a career development program, tolerating unions, etc.

The team represents any workgroup formed with a purpose.

The *primary* goal of the team is to facilitate communication between individuals and to coordinate interdependent tasks. Goals can be: temporary (project team) or permanent (patient care team). In creating the team several stages intervene: forming, norming, task execution and dissolution.

Factors involved in effective team work have a close relationship with team size, with the purpose and clear objectives (understood and accepted by all), the selection of members, roles within the team (defined and understood correctly) with the external environment, careful control of the time, listening and respect for the views and a relaxing, friendly atmosphere.

"The work team is a group of people who exchange experience and opinions, they respect one another's roles and functions to accomplish a common goal."

The team is a group of people who know each other and interact regularly and often, have a common goal or task and completing the task involves collaboration between members and coordination of their activities. Teams are formed for different purposes, adapting their form depending on the purposes: there are intervention teams, in which new leadership strategies or methodologies are implemented, or management teams consisting of senior managers, project teams responsible for projects or the operating team that has a role in the execution of various functions (surgeons, anesthesiologists, medical assistants, nurses).

Conclusions:

The features of the team must pursue a common goal, be based on the cohesion of members, coordination of activities and complementarity of skills.

The development stages: formation, eruption, normalization, functioning, unraveling are closely related to the factors that influence team effectiveness, namely: size, nature of the task, the selection of members, access to resources, 'leadership' and members' ability to successfully fulfill their roles within the team influence its effectiveness.

Abstract

Research and development is defined as a set of actions aimed at discovery of new elements, laws, technology or services and applying this knowledge to create a product or service improved, technological processes, which responds to market demands. Current economic crisis, should have made us understand that research and development is not an option or just a fad, but an acute need for a society wishing to advance itself, in order to continue to exist. Innovation requires adaptation of our world to the new realities around us, solving the problems we face daily. Developed countries have realized the importance of this activity and significant funds are channeled towards this direction. In turn, companies have understood that within the situation of fierce global competition, only an intense and efficient research and development activity can help to distinguish from a great businesses that offer the same good or service.

Keywords: innovation, research, development, evolution

J.E.L. classification: O3, O32

1. Introduction

Scientific research management is described as all the elements of organizational nature, informational, motivational and decision with which scientific research is conducted and ensures efficiency. Scientific research also called research and development, is "a systematically and creative activity intended to increase the volume of knowledge,

including knowledge of mankind, culture, and use this knowledge for new applications." It is based on the creative potential of people who are trained in innovation, research and last but not least the researcher[1].

Scientific research produces science, which incorporates a good deal in technology products. Research, development and innovation is the engine for the economic and social development of any country. To illustrate the veracity of statements before we chose to present the findings of a research made over the best 100 companies listed on the London Stock Exchange, the study published in the "Financial Newspaper", edition of 3 November 2003 and supports the fact that companies that spend more than 4% of its turnover for research and development activities had a better performance than their average. Also it should be noted that the shares of companies that have made notable investments increased by 50%. Based on this study by the Department of Trade and Industry in the UK, investment in research leads to greater benefits than those made by buying new equipment[2].

This situation should not surprise us. If a company wishes to assert and maintain on the market, continuous innovation is a sine qua non. However, regardless of where ideas come from, how many and valuable they are, their translation into new products and technologies is the task of specialized department of the company, namely research and development[3].

2. General presentation of the Farmec company

Farmec, a brand whose history began more than 120 years, is with its over 400 items, not just cosmetics market leader in Romania, but also a strong brand, presented and appreciated all 5 continents.

Today S.C. Farmec S.A. ranks among the largest industrial companies in Europe, through the quality of the products and technologies and by investing in its analysis laboratories that are known worldwide.

According to data from research agency Nielsen, in 2011, SC Farmec S.A. has been the market leader in the segment of facial care products, with a market share of 21.8% in terms of quantity and leader segment of hair treatments, with a market share of 28.35% in value and 16, 05% quantitatively. Almost half of the market and face care products eye is divided by 5 big brands (Nivea, L’Oreal, Gerovital, Vichy and Garnir), summing them a market share of 54.6%.

Below it is presented the evolution of the main economic indicators of profit and loss during the analyzed period:

Graph 1: Evolution of main indicators of profit and loss

Source: own processing based on annual reports provided by Farmec

Based on the graph previously presented we can say that S.C. Farmec S.A. managed, despite the global economic crisis to keep turnover high, up from 89.85 million in 2008 to 95.5 million in 2010 and the first half of 2012 continued positive evolution, percentage being 16.9%.

Regarding the income, in 2009 there was a decrease due to the financial crisis on the one hand and, on the other hand, negative results of financial activity, a result that can be attributed to investments made, but not only. In 2010 the situation improved, revenues registered a positive trend.

Profit was down during the period taken into consideration, due to the financial loss registered in the reference years and an increase of operating expenses.

Next, in the analysis we follow the evolution of the number of employees in the Farmec company. First, it should be noted that this company is one of the largest Romanian company, a true competitor not only on the national market, but also at an international level.

Graph 2: The evolution of the employees during 2006-2010

Source: own processing based on annual reports provided by Farmec

In figure 2 we illustrated the evolution of the number of employees of SC Farmec S.A. during 2006-2010. Based on these data we can say that the number of staff has decreased continuously, even dramatically over the past two years taken into account, particularly as a result of the economic crisis and the need to reduce costs and optimize business. Thus there was an adjustment in the number of employees and better adapt to the new company on the market.

In terms of personnel structure, in 2010 the situation is as follows:

Graph 3: Departmental staff structure

Source: own processing based on annual reports provided by Farmec

Based on chart number 3 we can deduce that the largest share in total company is occupied by logistics employees and salespeople (254 posts), followed at a great distance by the directly productive staff (140 positions) and the indirectly productive (52

stations). Thus we can say that SC Farmec S.A. grant a significantly importance of the commercialization process of its products[4].

3. Research and development activity at SC Farmec SA

The company Farmec Cluj-Napoca has international quality certificate ISO 9001-2008 and boasts an advanced system of continuous development and 25 patents. Everything starts at conception, research and formulation and is based on strict adherence to the following responsibilities: strict enforcement of European legislation in the field of cosmetics and household chemical; development of new active principles cosmetics, cosmetic effects maximum efficiency proven by tests and professional; use of safer materials and environment for human use and environment; harmonization of formulations with the requirements of target markets (North and South America, Asia)[5].

Envisaged objectives are to develop a line of organic cosmetics, certified organic, achieving a range of household chemical products certified organic.

To create innovative products company invested substantial amounts in acquiring brands, licenses, equipment manufacturing, refurbishment, upgrading laboratories, purchase technological equipment, as behind the finished products reaching the shelves sit research work of the company’s specialized department. Without this company could not exist, because human resource is an active and decisive factor of production activity.

Graph 4: Evolution of investment activity (patents, licenses, refurbishment, upgrading laboratories) at SC Farmec S.A.

Source: own processing based on annual reports provided by Farmec

Based on chart number 4 we can deduce that in the analyzed period (2008-2011) the company has started an intense investment and modernization process, with the aim to

diversify their range of products, to purchase brands (SC Framec SA paid about 1.2 million for the acquisition Gerovital brand) to improve their technology and process, to streamline their research. In 2012, according to the general director’s statements, the amount of investment will reach a value of 0.6 million euros.

In order to make a clear image of how these investments have helped increase company revenue and gross profit, we have built the following graph (figure 5) illustrating the evolution of increased revenues, gross profit at 1 ron invested .

Graph 5: Evolution of increased revenue and gross profit of ron 1 invested in 2008-2010

Source: own processing based on annual reports provided by Farmec

As can be seen in figure 5 both indicators registered a decreasing trend during the reference period, except 2010. This is because on one hand the global economic crisis affected the demand for goods and services in all areas of activity, due to reduced purchasing power of population, ron depreciation against the euro, but also the massive investments made by the company, from investments which have not been collected fruit at their true value[6].

Regarding the structure of gross fixed assets at the end of year 2010, it is shown in the graph below:

Graph 6: Structure of gross fixed assets at December 31, 2010

Source: own processing based on annual reports provided by Farmec

As can be seen in figure 6 at the enterprise level intangible assets share is about 4.81%(5,097,223 USD), concessions, patents and inventions represents approximately 81.2%(4,087,168 USD). This analysis should not overlook the fact that Farmec S.A. since 2008 has full rights to use the mark Gerovital, the company paid for it about 1.2 million[8].

In the company are involved directly in this work, over 30 specialists, representing approximately 5% of total staff. Three products are launched annually. The new products provide most of the success of a business. Refresh existing product ranges is an essential aspect to attract customers[7].

Annual reinvestment of 5% from the profits in research, substantial funds allocated in recent years for investment, make the analyzed society a true pillar of innovation at nationally level and is an example for other Romanian companies wishing to emerge from anonymity and to occupy a leading position in their field of activity. Without research there is no progress and no future progress. Research is not just a fad, but an acute need for a society that respects itself and wishes to endure over time.

4. Conclusions

Our country deposit serious effort to get out of the shadow cone it is found, as evidenced by its attempt to increase the percentage of GDP allocated to research, desire to limit "brain drain" and to attract foreign specialists that help reduce the gap in relation to other EU countries.

As any desert has its oasis, Romania also has a number of companies that occupy a leading innovation position, being allocated financial resources not only consistent, but also hard work, dedication, passion and soul not last. SC Farmec S.A. is a reference point when it comes to research and development, innovation in our country.

It demonstrates that, despite the difficulties, despite the gap to the world's leaders, in Romania there are still a number of oases, oases which give us confidence in the ability of this country to progress and to be competitive even at European level if not

at a global level. The large number of patents, designs, trademarks, awards both nationally and worldwide, SC Farmec S.A. demonstrates a continuing concern for improving products, a focus on consumers needs, a long-term vision of beauty. Clay, flower-of-corner are natural elements that form the basis for a number of creams and other skin care products.

Company market share (21.8%), was superior to other brands stronger financially, demonstrate that creative force, the ability to adapt to market needs and expectations, hard work and dedication is the key to success. Although turnover has fluctuated in recent years (it dropped from 89,849,975 ron in 2008 to 86,821,198 ron in 2009, but noting a positive trend in 2010 when it reaches the figure of 95,929,015 ron), the company has managed to cross safely this time more difficult. Farmec SA understands that in this contemporary economic conditions and strong competition, only an intensive investment process and a well planned research and development activity could bring market success in acting, which is why the company invested in the years 2007-2010 about 12 million in modernizing and upgrading its laboratories, in purchasing brands – Gerovital, in improving its products and creating new formulas.

Thus we can say, without a doubt that research and development is an extremely important constant of the new millennium, constant that offers our society more dynamism, accelerating the innovation process. Innovation is what will help us to overcome this difficult period through which the global economy is passing by, and therefore it is necessary to give its rightful place in the budgets of all states and companies, in this way it won't be seend anymore as a Cinderella of the society.

The Influence of National Culture over Organisational Culture in the Globalisation Context

Remeş Eugen Florin

“Vasile Goldiș” Western University of Arad, Faculty of Economics

eugenremes@yahoo.com

Abstract

The study approaches a very up-to-date set of issues within the current globalization context that is the role the culture plays in the life of a nation and the implications of the national culture over organisations and the manner of conducting businesses.

Existent links between national culture, organizational culture and organisations management are seen through the perspective of the shifts which currently take place in the global context of trading businesses.

Nowadays organisations have surpassed the national action frames and they operate globally, being in the position to approach problems on a completely different level.

One of the issues faced by multinational companies is the one related to cultural differences which arise at the time of starting a business in various countries; they have managers and employees belonging to different nationalities and cultures.

Keywords: national culture, organizational culture, multinational company, manager, globalisation

J.E.L. Classification: M14

1. Introduction

The relation between national culture, organizational culture and organisations' management is extremely complex.

A nation's culture is a defining issue in what concerns the way in which it can be characterized. Culture is a core element, influencing everything that takes place within a nation. The way, in which individuals act, their perception over things and life in general, derive from the culture they belong to.

A nation's culture reflects upon all elements of the social life, including upon

businesses conducted by individuals in such country or in other countries.

Based on the national culture, companies build in time their own organisational culture, adopted by their members and which defines the manner of conducting economic activities within such.

In the following pages we shall try to highlight the way in which national culture influences organisational cultures of companies within a certain country and, implicitly, the management style adopted within such companies.

This study is not intended to be an exhaustive presentation of the national culture issue and its relation with organisational culture, it merely deals with certain aspects from the plurality of possible approaches, pointing out the implications which consist thereof.

2. National culture and its defining elements

Culture is a rather abstract notion, relatively difficult to define and which may be perceived from a multitude of modalities, irrespective of whether we relate to each particular individual or to the nation as a whole.

The term *culture*, with ancient origins (coming from the Latin word *cultura* = to farm), currently has a large variety of senses related to education, anthropology, agriculture, biology, medicine etc.

By making reference to modern meanings, from which the notion of national culture derives, we may define culture, according to The Explanatory Dictionary of the Romanian Language (DEX), as the *totality of material and spiritual values created by mankind, and the institutions required to communicate such values.*

At the same time, in the sense referring to the individual as member of a nation, culture

may be defined according to DEX, as *the fact of possessing substantial knowledge in various areas of interest; the totality of such information; (high) intellectual development level a person has reached.*

By trying to define culture, both from national culture perspective, and from that of the individuals belonging to such culture, we wish to point out its role in the life of a nation and society, the influence it has over economy and the manner of conducting business, within the present day global context.

As a whole, national culture possesses a set of specific characteristics such as language, religion, ethnic and racial identity, history, traditions and practices. National culture influences the family life, education, political and economic system, and last, but not least, the way in which businesses are conducted.

Perception of a certain culture derives from the manner in which it was established. It emerges as three overlapped layers, each displaying a set of specific characteristics which become rather difficult to detect and to understand as we penetrate it from the outside to the inside.

The exterior layer refers to cultural symbols and practices, easily noticed ever since the first contact of a foreign observer possessing a certain degree of culture (language spoken, garments, architecture, art, eating and drinking habits of the local people, the manner in which they buy groceries).

The middle cultural layer comprises the rules and values of the society which show, on one hand, how individuals of that particular nation should and actually behave and, on the other hand, their perception of what is good or wrong in their society.

The inner cultural layer is rather difficult to perceive and it refers to the basic ideas and beliefs of a nation's individuals about existence, about what is true or false in life. In order to access this cultural layer, an outsider shall have to observe for a long while such society and, in spite of all that, he may come to have an insufficient understanding of the meanings of certain mentalities.

3. National culture, premises for organisational culture

Nowadays, the concept of national culture represents a major concern. It is not only a scientific concern of anthropologists or sociologists to understand a nation's culture, but also concern of the ordinary people, willing to know members of other national cultures and, especially, a concern of the multinational companies operating worldwide.

Why is it important for multinational companies to notice the differences between national cultures? The answer to this question may be relevant within the globalisation context and giving the fact that national boundaries seem to be more open than ever before.

The expansion of businesses in various parts of the world and the necessity to operate in different economic contexts, to have employees of various nationalities, ethnicities and religions, to sell on different markets, urge the managers of multinational companies to be more and more acquainted with the cultural specificity of the nations and individuals with whom they get in contact, to build an organisational culture adapted to current requirements.

From a scientific perspective, there have been numerous concerns on behalf of specialists with regard to defining culture and identifying certain patterns, which should be able to shape some general cultural characteristics for various nations.

Edgar H. Schein defines culture in one of his works as being *a pattern of shared basic assumptions that the group learned as it solved its problems of external adaptation and internal integration, that has worked well enough to be considered valid and, therefore, to be taught to new members as the correct way to perceive, think, and feel in relation to those problems* [1].

Edgar H. Schein developed a pattern by which he tries to explain the basic elements of cultures. Edgar H. Schein's pattern resembles other patterns implemented by various theoreticians of cultural approaches such as Geert Hofstede and Fons Trompenaars, and it may be used to analyse all culture types, including national and organisational cultures.

All these patterns derive from the presumption that any culture may be explained and comprehended by observing its core values and assumptions.

The core values may show the visible elements of cultures, such as behaviours, anticipated reactions, dressing code, architecture, eating habits etc. Edgar H. Schein defines these visible elements of cultures as espoused values and artefacts.

Artefacts are a culture's visible elements which may be easily recognized by outsiders: dressing code, art, furniture, labour status, legends, organisational structures etc. They can easily notice them, but they may not understand the reasons which lead to adopting such symbols. In order to understand them, an outsider should get to know the espoused values of this culture.

Espoused values are the values imposed by representative figures of a nation's culture, for example: philosophies, strategies and ways to reach the objectives. If espoused values proposed by the leaders fail to agree with the assumptions adopted by such culture, contradictions may arise.

Assumptions reflect values accepted on a large scale by the members of a culture regarding human nature, human interactions etc. However these values are sometimes insufficiently defined, thus they are not visible for all members of such culture. Assumptions and espoused values may not always be correlated; espoused values may not be rooted in current values of the culture. This fact may generate great difficulties in society, manifested as frustrations, immorality and social inefficiency.

Being familiar with Edgar H. Schein's cultural pattern, leaders shall be able to understand cultural elements, to analyse the connections between the beliefs deeply rooted in society and usual business practices within organisations.

Also, leaders may try to change the basic beliefs of a given culture and as a consequence, they may improve company's efficiency. This process may be seen as a cultural change, if basic beliefs are modified to match desired espoused values and cultural products of the organisation.

Cultural change may be necessary when the organisation's environment is changing. Competition and new regulations may impose a new organisational culture, situation in which a new set of values is needed for the organisation.

At the same time, beliefs also have to be changed, so that the organisation may survive

and develop and, as a consequence, new values proposed by leaders are accepted by all members of such organisational culture.

Beside Edgar H. Schein's approaches, other significant approaches concerning national culture and its influence on organisational culture were made by theoreticians like Geert Hofstede and Fons Trompenaars, who identified various cultural dimensions, which may be used to evaluate the differences between various cultures. They started from the premise that these differences between cultures may have an effect upon the way foreign employees are managed, the manner of satisfying expectations of external stakeholders, and the way in which managerial problems are solved for multinational companies which work with persons belonging to other cultures.

Geert Hofstede has identified culture, in his vast researches as being *the collective programming of the mind distinguishing the members of one group or category of people from others* [2].

Hofstede's concerns regarding the national culture approach and its influence on the values of organisational culture start from an empirical research carried out in the USA, between 1967-1973, which documents the attitude of employees comprised within a database taken over from IBM. Initially, such research comprised employees of various nationalities, coming from over 70 countries.

As a result of the research on a large number of national cultures, based upon a representative sample within each culture, Hofstede reached the conclusion that a national culture may be characterized by four cultural dimensions:

- Power Distance - PDI;
- Uncertainty Avoidance - UAI;
- Individualism vs. Collectivism - IDV;
- Masculinity vs. Femininity - MAS.

Subsequently, in 1991 Geert Hofstede introduced a fifth cultural dimension, perspective on time (Long-Term Orientation vs. Short-Term Orientation - LTO), by the contribution of Professor Michael Bond, who performed an international complementary study, based on the research of the attitude of a significant group of Chinese employees and managers, which later on was extended to a larger number of employees from different countries.

Power Distance – shows the perception on the degree of inequality of power between the one holding it and the one who is subject to it. This dimension shows the extent to which employees with less power expect and accept that power is unequally distributed.

Power distance may be explained by means of value systems of employees with less power, and the way in which power is distributed is related to the behaviour of members with greater power. The studies which have been conducted pointed out a ranking of several countries, on a scale from 0 to 110, which was considered the estimation range.

In countries with great power distance, power represents a defining element of the society, the ones holding it imposing a set of rules which have to be strictly complied with. In these countries authority based on constraint is manifested, while in countries with small power distance authority based on competence is manifested.

In countries with great power distance, there is a latent conflict between the ones holding power and the ones who are subject to it, while in countries with small power distance, a greater understanding can be seen between leaders and employees.

Uncertainty avoidance – shows the way in which members of a national culture react when they feel threatened by insecure or unknown situations. This cultural dimension measures a tolerance level in relation to the anxiety caused by certain uncertain future events. The greater this level is, the less the uncertainty avoidance is and vice versa.

In certain national cultures, individuals manifest the tendency to accept uncertainty as an element which is part of life and which, to a great extent, it can not be influenced. In such case, uncertainty avoidance is much reduced. In this type of national cultures, employees usually work in large organisations, take few risks, a large amount of stress is manifested in the work place, they prefer written and precise instructions, a more aggressive behaviour is accepted and unanimity is encouraged.

In other national cultures, individuals have the tendency to try to conquer the future, to fight in order to control it, thus manifesting a high level of uncertainty avoidance. In such type of national cultures, employees prefer smaller organisations, they

do not hesitate to change their job for better conditions, take more personal risks, and they do not tolerate aggressive behaviour, works under less stress conditions.

Individualism vs. Collectivism – it is a cultural dimension which shows the intensity of connections between individuals of the society. From the perspective of these connections there are two types of societies: individualized societies and community societies.

Individualism belongs to societies in which connections between individuals are chaotic, where it is expected that each person looks after himself, take care of his own family, to have a greater freedom in organising his own work and professional achievement.

Collectivism belongs to societies where individuals are integrated from young ages, in powerful groups, with well-defined relations, which carry on protecting them throughout their entire life. It becomes essential to create good working conditions, by means of which individuals may reach the objectives that were jointly set.

Masculinity vs. Femininity – shows the differences existent in various national cultures in what concerns the equality of sexes. The distribution of roles in the society based on sex criteria is not performed in the same manner, in all cultures, which leads to cultural differences.

If there is a great difference between the roles of men and women in the society, such culture is characterized by a higher degree of masculinity, in which the prevailing values are success, money and possession. If the roles carried out by men and women in the society are less differentiated, such culture is characterized by a larger amount of femininity, being dominated by values such as concern for the others, quality of life.

A large number of nationally identified characteristics may also be applied to organisations. Thus, the organisations may be permanently related to the five dimensions of organisational culture defined by Hofstede.

Perspective on time – shows the two possible approaches, a long term and a short-term one.

The long term perspective on time implies that all members of the organisation accept the idea that in order to reach the targets and to achieve high performances in business

activities, it takes a longer period of time. Also, the employees intend to have a long term professional relationship with the company, with an ascending evolution of the career.

The short-term perspective on time implies that the objectives are clearly established, and the achievement of the results corresponds to a relatively short time span. Employees regard the relationship with the company as a temporary stage of their career, frequently changing their working place, in the pursuit of new opportunities.

Hofstede assigns to the organisational culture concept a series of defining features:

- It has holistic character, in the sense that it represents more than the totality of its constituent elements;

- It may be historically determined, reflecting the company's evolution in time;

- It is connected to a series of anthropological elements (myths, rituals, practices, symbols);

- It is substantiated from a social point of view, being the result of the creation of individuals which make up the organisation;

- It is difficult to modify, due to complex human elements involved in it.

Another concern of Geert Hofstede was that of making a reference book which may solve a series of problems which arise due to cultural differences between national cultures during the leadership process, in the case of multinational companies or companies which hire personnel of other nationalities [3].

Within the same context, the author proposes several ways in which companies may homogenize their organisational culture, in the sense of regulating employees' behaviour for the purpose of solving problems which arise due to cultural differences.

Geert Hofstede considers that the differences between various national cultures are mainly found in the deeply rooted values of such cultures. These different cultural values may shape the way in which individuals expect that the organisations they belong to are managed and the way in which the relationships between leaders and their subordinates should evolve. Ideally, these expectations should balance the relations between employers and employees, but in many cases, existent great cultural differences are reflected in long distances

between the expectations of the two categories, fact that may cause problems in the management of multinational companies.

Companies with employees belonging to different cultures may benefit from the homogenization of organisational culture. Also, multinational companies may create a unique organisational culture, mindless of national borders of the countries in which they operate, despite existent cultural differences.

As a result, employees belonging to another national culture may be integrated in such organisation's culture and may internalise the practices of such culture, even though they are different from traditional practices of their originating culture.

Companies that wish to homogenize organisational culture may use a series of methods which consolidate the integration process of all employees: hiring individuals who possess a system of values similar to the organisation's values; hiring individuals that have not been yet integrated in other organisational cultures; creating a strong feeling of belonging to the group represented by such organisation.

Not all organisations shall record positive results by imposing a unique organisational culture, some of them obtaining this kind of results by accepting and using cultural differences existent within them. Such organisations shall seek to impose, not necessarily a unique culture, but rather a unitary leadership style, a standardization of product quality, a unique image irrespective of the geographical location.

Another interesting approach regarding differences between national cultures is that of Fons Trompenaars. The same, in collaboration with Charles Hampden-Turner, developed a pattern which establishes seven cultural dimensions, pointing out the way in which persons belonging to different national cultures interact [4].

The seven cultural dimensions included in Trompenaars's theory are:

- Universalism vs. particularism – What is most important - rules or relationships?

- Individualism vs. collectivism – Do we function in a group or as individuals?

- Neutral vs. emotional – Do we display our emotions, or do we hide them?

- Specific vs. diffuse – Do we handle our relationships in specific and predetermined

ways, or do we see our relationships as changing and related to contextual settings?

- Achievement vs. ascription – Do we have to prove ourselves to receive status, or is status given to us

- Sequential vs. synchronic – Do we do things one at a time or several things at once?

- Internal vs. external control – Do we believe that we can control our environment, or do we believe that the environment controls us?

Trompenaars tests this pattern in over 55 national cultures based on questionnaires, trying to illustrate the way in which the answers to each question concerning these dimensions may be used by managers in order to obtain an overview on the conditions under which individuals belonging to different cultures may act within the same organisational culture.

4. A managerial dilemma within the organisational culture

A special issue related to cultural differences within a company is the one of imposing managers. Thus, at least four possible situations may be identified:

- Appointment of a local manager, with professional training and experience acquired within the local culture. In such situation, the manager has the advantage to be familiar with the peculiarities of the national culture, making him more easily accepted by the employees, but he shall face the same difficulties as the majority of employees in adapting to the new organisational culture;

- Appointment of a local manager, with professional training and experience acquired within the organisational culture of another subsidiary of the company. In such situation, the manager has multiple benefits generated, on one hand by the affiliation to the local national culture and, on the other hand, the affiliation to the organisational structure. He has the advantage to understand why sometimes the employees do not accept certain values of the organisational culture, which are different from the values of the national culture and he might balance such discrepancies;

- Appointing a foreign manager, with professional training and experience acquired within the culture of such organisation in another country. Such appointment may

generate certain conflicts due to cultural differences existent between the new manager and the employees, which have to be settled in time;

- Appointing a foreign manager, with professional training and experience acquired outside the culture of such organisation. In such situation the company may be subject to the greatest challenges, due to the fact the employees should adapt to the organisation's culture, and the manager has to face both a new organisational culture and a new national culture.

5. Conclusions

The approach of each of the situations presented leads us to the idea that irrespective of variant where it stands, a multinational company assumes such situation and, implicitly, a series of risks. None of the variants presented display certainties for a complete success.

No theory, irrespective of its complexity, shall be able to offer solutions to solve cultural issues, but rather a frame of understanding particular phenomena.

It is the company's management ability that is responsible for surpassing national cultural differences, for imposing appropriate the organisational culture, for creating a pattern within which each member of the group may integrate as fast as possible and to the highest performance level possible.

The cultural disparities which become deeper in a tumultuous global environment should not obstruct the achievement of the company's challenges concerning management and high performances.

Abstract

The necessity for assistance In a transition economy emerges from the analysis of the constraints which limit or slow down the process of small and medium enterprises formation and growth. The unsafe economic climate for entrepreneurs due to the low incomes, the low purchasing power, the resistance of financial blocking, and the high inflation rates, etc.

The process of companies launching and surviving takes place in a period of economic crisis and instability which grow up the environment unsafe and the risks of business actions. Moreover, they emerge many bureaucratic impediments related to the relationship with state enterprises, local administration, and governmental entities.

Key words: phase, growth, company, small and medium enterprises, approach

J.E.L. classification : M10, M20, M51.

1. Introduction

The approaches based on organisational development are the most common, providing the chances of better understanding regarding the small and medium sector rise. The starting point for elaborating the models is the fact that enterprises are confronted with common problems in the same phases of growth. By passing from one phase to another one, we will face a new enterprise, the entrepreneur having to solve the problems related to the necessary changes and crises appearing within the company. These problems' solution can be facilitated if there is an active managerial behavior, dominating compared to the passive.

2. The main approaches specific to the companies' growth in the Romanian economy

The approaches based on organisational development are the most common, providing the chances of better understanding regarding the small and medium sector rise. The basis of this analysis is the concept according which a new enterprise will pass a number of phases during its existence and the phase an enterprise is passing some time can be used as a criterion to differentiate it from the other ones. The starting point for elaborating the models is the fact that enterprises are confronted with common problems in the same phases of growth [1].

The approaches based on enterprises management consider that the company's growth may be analysed according to the managerial skills for performance and maximum efficiency, using strategic operational planning and control elements, especially in the costs area [2].

The researches have proved that enterprises, in which an efficient management is practiced, including its strategic site, show a better availability for growth. Under the conditions which the enterprises are confronted with another types of constraints excepting the managerial one it is doubtfully that the managerial problems solution will lead to the growth in conditions which the other restrictions are not solved. The approaches which try to quantify the influence of the external elements from a macroeconomic and sectoral perspective are faced to the difficulties of a rigorous evaluation of these elements 'impact.

Analyzing more than 25 typologies of enterprise's growth, Lorrain and Dussault (1987) had noticed that they vary in a significant degree depending on the number of the proposed phases. For example, Smith and Gannon – 3 phases (1987), Buchele – 7 phases (1976) and Parks – 11 phases (1977).

These models had used very different criteria for classifying enterprises within a certain phase [3].

We must consider that some of these models are pure theoretic constructions, given that they are never practically validated. For example, Smith and Gannon's (1987) three phases show that the enterprise develops from a small dimension to a fast growth, and then to maturity. According to this model, in the second stage we already deal with a big enterprise.

3. Models of growth specific to the small companies into the Romanian economy

Miller and Friesen (1984) have studied different models of enterprise's growth, identifying five common phases for different life cycles:

- birth – the achievement of a sure, stable position and the surviving after launching;
- growth – the exploitation of market opportunities;
- maturity – the structures and the activities coordination which have fast grown up;
- revitalization, rebirth – the adaptation to a more complex medium;
- decline, stagnation.

McGuire (1963) has provided a model according to which the enterprise passes through five phases during its development:

- traditional small enterprise;
- planning for growth;
- development;
- professional management orientation;
- mass production.

Christensen and Scott (1964) have focused on the development of organizational complexity in an enterprise.

Thus, they have formulated three stages:

- a managerial unit without specialized organizational parts;
- a managerial unit with functional parts such as marketing and finances;
- independent operational units which act in their own name in the market.

Greiner (1972) has proposed a model of evolution within the enterprise passes through five phases of growth and which realizes the transition from small to big,

depending on the sales and the number of customers.

Each phase is distinguished through an evolution from the previous phase and later through a crisis preceding the step to the next stage. Each evolution phase is characterized by a certain managerial style and every period of revolution by a certain management problem the enterprise is confronted with.

Kroeger (1974) considers that the small and medium enterprise's cycle of life is composed of five phases, to each of them corresponding to a certain managerial role:

- initiation: initiator – inventor;
- development: planner – organizer;
- increase: development – implementation;
- maturity: administrator – operator;
- decline: successor – reorganizer.

The author underlines that these managerial roles' achievement is essential for the company's survival and increase. If the roles have been accomplished in an adequate manner, the cycle of life will continue in the next phase. Otherwise, the entrepreneur will be confronted with the fail, a higher risk existing during the early stages.

Perry (1982) and other authors recognize the limits of the lifecycle. Most of these theories claim that a new enterprise turns into a mature, diversified one. Still enterprises may survive without disappearing, even if they do not turn into a big enterprise.

Often they pass through early stages; after that, because they assure living means to the owner, they stop increasing for lack of necessary motivation. More, enterprises are going to be confronted with static periods which are necessary in order to facilitate the use of information achieved during the precedent period.

A Swedish research has underlined that about 40 % of entrepreneurs had declared that they do not intent to develop the enterprise even if market opportunities had existed. Also, in France is considered that there is a lower aspiration for the enterprise's growth than in U.S.A., one of the main causes being the differences between the cultural French model and the American one (Institut d'Etudes Bancaires et Financieres, 1989).

Many times, the entrepreneurs consider that the enterprises which have been developing are confronted with many

problems. The small and medium enterprises are characterized by a unipersonal management, entrepreneurs trying to avoid to lose the total control of enterprise under an increase determined by using professional management, under the use of external resources for financing the increase. In the same time, the enterprises' increase could eliminate some advantages of this type of enterprise [4].

It's still possible that the growth to maintain the company's entrepreneurial values. Some entrepreneurs' adversity towards growth within the companies may offer an empirical explanation of company's small dimensions advantages. Anyway, a growth model of company must be known in every phase in order to know the impact of every phase on the company.

Some of the models of growth existing in the specialty literature analyze the company's growth through the internal factors first of all, the external factors being neglected or underappreciated most frequently.

The growth has also an important qualitative side referring to the capacity to diagnose and to deal with the structural changes which appear in the external environment and with the changes within company's own values system.

4. The main development phases specific to the Romanian companies

By passing from one phase to another one, we will face a new enterprise, the entrepreneur having to solve the problems related to the necessary changes and crises appearing within the company. These problems' solution can be facilitated if there is an active managerial behavior, dominating compared to the passive. The graphic form and the speed the company passes from one phase to another one will vary from one company to another depending on different internal and external factors.

- *The first phase – The company's launching*

Within this phase, the main problems are related to the achievement of the production factors' efficient combining in order to obtain a competitive product, its launching on the market and making a satisfactory basis of customers. These elements are fundamental conditions for creating a sustainable

company.

In the same time, the entrepreneur must deal with the financial demand from this phase. In conditions which the launching takes place within rather small dimensions, the main financial sources are usually assured by the entrepreneurs and family, being a continuous pressure for investments and under these conditions the cash flow is negative.

The entrepreneur can make use of a limited market and distribution channels, the company's supply and demand being also limited.

The company's organizing is simple, the entrepreneur exerts the complete control, and the strategy of the company focuses penetrating the market. In conditions which there are not attracted enough customers, it's not achieved a successful launching of products and services and if the entrepreneur has not additional resources he will have to liquidate the company. In other situations, the entrepreneur's abdication can happen due to the pressures that business exerts over time and financial resources or due to the fact that they consider the decision to become an entrepreneur is not an appropriate one. The enterprises remaining in the market during this phase will pass to the next phase.

- *The second phase – The surviving*

By passing to this phase, the enterprise showed that it can function, the business being a viable potential one. The surviving key problem is about the relationship between incomes and expenses, the company having to generate enough incomes in order to reach to the breakeven for assuring the necessary resource to restart the cycle of production and to finance the growth until the dimensions of market opportunities. Anyway, for a longtime within this phase, the cash flow continues to be negative. Some enterprises can stay for a long time within this phase for recovering the invested capital although, in conditions which the competition enhances, they will be forced to pass to the next phase [5].

If the market has good opportunities, it may appear the temptation of an emphasized growth even in this very phase. Loosing control over the company's growth can lead to some serious financial managerial problems, emerging the risk of the company's fail. The organizing is still

simple, the company has a limited number of employers and the planning is reduced to cashing prediction. The company's main aim is surviving and the entrepreneur identifies himself with the business.

- *The third phase – The consolidation*

The entrepreneur must choose between two action options, meaning either to strengthen the obtained achievements and to prepare the growth for the next phase, or to consolidate the achievements by maintaining the company stable and profitable. Thus, the key problem is if the enterprise is used as a platform for growth or as a support tool for entrepreneurs [6].

From this point of view, we may have two possibilities:

a. Consolidation – maintaining. The company is big enough and has a good position in the market for making profit. It can stay a longtime on this stage by making sure that the environmental changes do not threaten its current position and it is not forced to pass to another phase. Organizationally, it is possible that the company has been growing enough so that it needs a professional manager in order to take some of the entrepreneur's tasks. The managers' potential and their values system are directly influenced by the entrepreneur's objectives. The fundamental strategy is about consolidating and maintaining the company. Also, we should consider that they emerge some situations in which the growth is not possible due to the fact that the market, with its limits, does not allow the increase (for example, a niche-type market with a little potential of growth, some small local markets, etc.). Thus, the option for this alternative can be the consequence of the entrepreneur's values system (subjective reasons) or of the market conditions (objective reasons) [7].

b. Consolidation – the growth's preparing. The entrepreneur consolidates the company by maintaining the actions control, but, in the same time, he prepares the growth. The cash flow is usually positive but the benefit is reinvested. Additionally to its own resources, the enterprise calls in a greater degree for attracted resources, enjoying a better accessibility to the credits market. It must develop new products and services, extended activity in the new markets, elements which will support the growth in the next phase. The managerial structures develop and they

apply a strategic management for building the future growth of enterprise. If the success is not got during this phase, the entrepreneur can use the consolidation – marinating phase of growth.

- *The fourth stage – The growth*

The key problem of this phase is about how fast to be conceived the growth to maintain a permanent control over this and how to be financed this process.

A decisive element for success in this phase is related to a managerial competence for growing having a more and more complex internal and external environment as the enterprise is getting to the dimensions of a big company.

The enterprise must focus more and more over the external factors because the increasing competition towards increasing sales and products distinguishing is possible to become stronger. In these conditions, it must be emphasized the customers' needs by adapting production. The fail's causes may be determined either by the attempt to grow too fast and by the inadequate financial resources, or by omitting authority delegation or performing an insufficient delegation. Consequently, the enterprise may face with the turning back to the third phase or, if the problems are more serious, to the second phase or even with its disappearance.

- *The fifth phase – The maturity*

Opposed to the classic concept of cycle of life, the enterprise can grow up during the maturity phase. The most important problems are about the achievements' consolidation and the controls brought by the growing up process and about keeping the advantages the small enterprise take (flexibility, entrepreneurial spirit, the lack of bureaucracy, etc.) taken that it is possible to have been attained the dimension of a big enterprise. They must be eliminated the possible discrepancies the growth had created and must be applied management modern methods which can be fully used now. The cash flow is positive and it assures the dividends for the entrepreneur and the other investors. The entrepreneur has stopped dominating the company, leaving space for managerial structures. If the enterprise keeps the entrepreneurial spirit, keeping distance from bureaucracy, inflexibility, risk avoiding, non-innovation, it will show itself as a real force in the market.

In the transitory economics, the small and medium sector is at the beginning of cycle of life (they are dominant the launching, the surviving), especially in the Romanian economy which has been started the process of developing this kind of enterprise by 1990.

5. Conclusions

The researches have proved that enterprises, in which an efficient management is practiced, including its strategic site, show a better availability for growth. From the analysis of the company's growth models existing in the specialty literature, including of one of the most known and pertinent models, elaborated by Churchill and Lewis (1983), of the concrete situations of small and medium companies from Romanian economy and form some market economies. The enterprises remaining in the market during this phase will pass to the next phase. The managerial structures develop and they apply a strategic management for building the future growth of enterprise.

Leadership Style and Organizational Culture

Rus Mihaela

Faculty of Law, Administrative Science and Sociology

psiholog_m@yahoo.com

Abstract

Clearly the world is developing in new directions, social, political, and environmental. Now is the time, more than ever, for those decision makers who control training budgets to adopt a framework of practices, behaviors, attitudes and values that address every aspect of an organization's success.

We must ask ourselves: is making decisions according to situations in which we are based leadership? In practice, all those in a position of some responsibility decisions, but this behavior is leadership? In fact, leadership requires a range of skills, behaviors and values.

Secondly, in the current situation, leadership is not seen as something that is done only by the person in charge. Leadership exists at all organizational levels, regardless of the company. We need to move the focus from how the person "the top" lead and focus on how all employees can show leadership.

Key words: organizational culture, leadership, employees, globalization, influence

J.E.L. Classification: A1, A14, D2, D22, L2, L25,

1. Introduction

"Leadership is one of the factors that condition substantially the activities, processes and psychosocial phenomena in synthetic Organisations expressing how relatively stable and a specific leader ..." [1] Leadership occurs whenever a group of people together and harmonize their efforts to achieve a common goal.

As in any enterprise there is a formal organization and informal organization,

which often vary considerably informal leaders can not identify with managers, those with leadership in enterprise hierarchy. In these circumstances it is obvious that a good manager will always be a good leader, but a leader is not always good manager. In this regard, K. Davis says suggestively: "Leadership is a part of management is the ability to persuade others to seek defined objectives enthusiastically achieve." [1] It is the human factor that ensures consistency group and motivates you to achieve goals. Management activities as: planning, organization and decision making are "cocoons" inactive until the leader triggers the power of motivation in people and guide them to specific purposes. "[2]

Leadership can be defined as a person's ability to exert such influence on others through communication, directing them to meet certain goals.

Exercise influence on others is the essence of leadership. Formal leadership, which refers to the managers of an organization, formal or legitimate is their right to influence others by virtue of their hierarchical position in the organization. Informal leadership is not an official right to influence others, but lies in the intrinsic qualities of a person to exercise influence in an informal group.

Can exert influence over others on a wide range of ways that extend from the friendly to the coercive.

Thus, D.Kipnis, S.Schmidt, C.S.Smith and I.Wilkinson believe they can be identified on these types of strategies to influence people: [3]

1. Reason-use situations, events, processes and data and information that reflects the development of logical arguments.

2. Friendship-search support, use magulirii, creating goodwill.

3. Coalition-mobilizing others in the organization.

4. Fall-negotiate a deal based on the use of rewards.

5. Aggression-use direct approach and strength.

6. Superior authority-winning support higher authorities of the hierarchy to increase "weight" applications.

7. Punishment.

The study by the authors quoted on a representative sample of managers revealed that most strategies used are based on reason and aggression, and the least used refers to the use of higher authority and sanction. Also, the study showed constant concern of managers to exercise a strong influence on subordinates as their awareness that they can not be limited to traditional strategy of exercising power within the organization exclusively on hierarchical position held.

1.1. Approach in terms of leader traits

Early studies on leadership have made this approach coordinates emphasizing the differences between subordinates performance leader traits are due. Studies in this approach were based on comparison methodology representative examples of leaders and nonleaders, in order to emphasize the physical and personality traits that differentiate them on top of mates sensitive. The main features considered were:

a)-physical characteristics, age, height, weight, appearance;

b)-basic characteristics, social class, education, experience, professional mobility;

c)-spirit personality introvert / extrovert, independent, self-confident, determined character, authoritarian tendency, spirit friendly / aggressive inclinations of dominance / subordination;

d)-intelligence, knowledge, judgment, intellectual mobility;

e)-social characteristics, prestige, tact, diplomacy, cooperative spirit, charisma, popularity, management skills;

f) - "spirit work" - responsibility, initiative, spirit completed tenacity[4].

Reference in other investigations, E. Ghiselli[5] studied eight personality traits (intelligence, initiative, ability surveillance, confidence, passion for workers, the spirit decided masculinity-femininity, maturity)

and five traits of motivation (need for job security, rewards need cash, need for power over others, the need for self-actualization, the need for occupational fulfillment). Based on research conducted authoritative hierarchy of features mentioned in the following groups:

1. important features in order: surveillance ability, need for occupational accomplishment, intelligence, self-actualization, self-confidence, spirit decided;

2. moderately important features, in order: no need for security, affinity for workers, initiative, no need for cash rewards, maturity;

3. Characteristics unimportant: masculinity-femininity.

1.2. Approach in terms of leader behavior

If previous approach was focused on responses to the question: What should be effective leader? This second approach is faced with the question: What is the effective leader? In other words, how they exert influence on others.

Behavior of effective leaders enroll in antonym pairs autocratic, democratic, permissive and directive oriented toward task-oriented people. Although expressed differently, the three pairs means essentially a dominant leader behavior: behavior focused on accomplishing tasks, production[6].

Implications of his theories on leadership-D. McGregor [7] practiced in an economic organization are highlighted below, and that which reveals how subordinates assumed that a leader will act according to the assumptions of the latter on their attitude towards work.

If subordinates meet assumptions Theory X / Theory Y assumptions If subordinates meet: If the leader believes that subordinates meet assumptions Theory X: subordinates acting under provisions is dependent on leadership and creativity manifest low. Subordinates are frustrated because of leadership based on control and coercion, does not allow display of their actual possibilities and creative work.

If the leader believes that Theory Y assumptions correspond subordinates: Subordinates achieved modest success as they have the necessary maturity. High performance because subordinates realize their needs find their full satisfaction in the organizational environment.

Once again, absolutization a type of behavior or another has proven leadership does not correspond to existing methods in reality, in which are combined in different proportions, concerns Leader tasks with dedicated people.

2. Socio- organizational aspects of culture

The issue of globalization is the internationalization of social research. Acceptance Schein's organizational socialization (1986) and Louis (1980) is the process by which a person shows employment in order to assess its value, skills, behavior and knowledge expected to assume a fundamental social role in that organization and to participate its membership to achieve a set of objectives.

Economic factors that require globalization, and travel becoming increasingly of interest to knowledge management, socialization issues updated four employees (Baurer & Taylor, 2001): [8]

1. A number of employees of the organization can work in another country than the native. For example, the international company GE, only 200 of the 23,000 employees from the U.S.;

2. Investment strategies and decision-making responsibilities are excentralize, that decisions are made directly to company subsidiaries, the most involved in solving these problems. There are many companies that have branches outside a country, which raise important issues about the socialization of employees;

3. The emphasis on knowledge as the basis for competitiveness, ability to socialize employees has become a key issue for attracting and retaining talent. So, recruitment and selection gained much in importance;

4. Globalization has stimulated emigration. U.S. workforce is composed of 12% immigrants, in Germany, 8.7 in labor is not German.

Organizational leaders are those who have great emotional impact on subordinates. Their ability to channel their emotional intelligence to the direction best suited them "help" to work and act according to the highest standards, I positioned the expert level, senior leaders, professionals.

The author also notes that "emotional intelligence has applications in all areas of life as knowing how to work and communicate with people is a skill that one can not do without" and more so it is very useful organizational management level . "... For the organization to work well it is necessary to pay attention to emotional skills of its members. "

Of course, globalization issues currently receiving connotations new phenomenon has accelerated dynamics, covering areas increasingly wider labor psychology, industrial and organizational. It is estimated that the areas of application of psychology in organizations, according to experts will reshape the very first moments of the millennium when I started. [9]

3. Conclusions

Organizations that adopt long-term strategies promote stability, personal prestige, show respect for the tradition and practice a reward system based on reciprocity. This organization is the opposite, based on a short-term orientation, associated with a management-oriented resistant to change and immediate success. [10]

In terms of organizational climate, prevails an atmosphere tense work environment is pressed. Organizational environment can be likened to an extended family, and the leader is not a mentor and a role model for employees

Adopted authoritarian leadership is based on control and coercion.

Developing leaders around us, take personal leadership one step further, showing how to identify and prepare potential leaders and climate create a productive team spirit.

Manager's style or manager must help others to reach their full potential.

In terms of leadership style in the organization studied, it follows that the manager adopt a management style based on excessive authority. One of the most frequent aggressive behavior and orientation towards profit.

Of all known styles in management practice, it follows that there is no perfect driving style because effective leadership style depends on the adequacy of the management situation and the personality hand-frost.

But in this company members said they would like to driving a democratic manager, resourceful.

A leader not only practice one style of leadership and that no style is not suitable for all situations faced by a leader. Therefore, the most realistic approach is to consider leadership style depends on the situation as it is exercised, the personality of the leader and his subordinates capacity, leading to the same leader to use different leadership styles. If you want to be a leader, you must develop and other leaders around you. Must form a team. You have to find a way to make your vision seen, implemented and others increased. The leader sees the big picture, but needs the help of others to make this picture a reality. [11]

Influence of Gender Differences on Leadership Styles

Rus Mihaela

Faculty of Law, Administrative Science and Sociology

Ovidius University, Constanta, Romania

psiholog_m@yahoo.com

Abstract

Studies support the idea of differences between men and women managers regarding leadership style, are quite hard to find because almost all research in this direction have been made in terms of groups of male managers. If there was evidence in the sense similarity between the leadership style of men and women managers this problem would not exist. There have been some studies, mostly in the U.S., which dealt with the nature of leadership and demonstrated that there are many differences between management styles of the two sexes.

Usually when we make comparisons between managers, the dialogue is framed by men tend to control, against the tendency of women to build a team and to reach an agreement. Women want more to consider compromises and seek advice from others, as opposed to this, men often believe that if they ask for advice, will be perceived as insecure.

Key words: organizational culture, leadership, gender, influence

J.E.L.Classification: A1, A14, D2, D22, L2, L25

1. Introduction

In a study of men and women leaders, J. Rosener[1] found that men preferred management style and described as "transactional leadership" is concerned with providing rewards and sanctions based on performance. Men tend to use the power given their position in the company. Women behave very differently. They prefer to use "transformative and interactive leadership" [2] that encourages participation and power sharing information and creating situations to help people feel about themselves. Unlike men, who want to keep the information they

share and women prefer to seek solutions together with staff, not to act as if they have "expert." Women tend to admit I do not have all the answers, unusual behavior in overall, for men. "Transformer style adopted by women is related to organizational morale with team cohesion, commitment and measure success with the team and the organization." [3]

Another study conducted in the UK this time examined leadership style of male and female managers described the construction and for their service qualities. The survey shows that there are differences similar to those of the U.S. trial.[4]

Alice Eagly and Blair Johnson, [5] analyzed a study comparisons were 370, 289 on natural background activity in business, 56 in evaluating situations and 25 research laboratories. Examining the 370 comparisons the authors came to the following conclusions:

1. The strongest evidence of gender differences on driving style is the tendency of women to adopt a more democratic and participatory and men to adopt a more autocratic and directive. 92% of comparisons went to the observation of a more democratic style in women than in men. The researchers attributed this difference observed in firms, evaluation and laboratory situations, primarily interpersonal qualities and complexity of women.

2. Situations and laboratory evaluation made by men managers proved to be more "task oriented" being able to organize activities for them perform. However, in studies in business no differences were observed between managers on orientation tasks.

3. In laboratory evaluation studies and women managers tend to be more oriented towards "interpersonal relations", for moral and human welfare. However, businesses find that there are differences in orientation

toward solving tasks and interpersonal relationships. However, these differences are found primarily in the laboratory and by assessment centers and less in real business managers office. However there is a difference that is maintained in all studies: women are more democratic or participative style of management and a more autocratic men. [6]

1.Social aspects of gender differences in leadership

In support of the idea that women have a different leadership style of men, a study by Cranfield School of Management[7] using Myers Briggs type indicator, based on personality types described by Jung discovered that the most significant difference between male managers and female managers is that the size of intuition / reason.

Rational people tend to prefer practical problems, systems and methods are a matter of routine patient and care for details, standard solutions looking for problems.

Intuitive people prefer ambiguous problems, the routine bother, often ignoring facts and seek creative approaches. Women managers tend to be more intuitive, 70% of male managers were included in the study Cranfield rational, while 40-60% of women were intuitive, based on professional knowledge.

Gary Johns noted that in this case there are two opposed logics. "On the one hand, different socialization experiences leads men and women to learn different ways to exert influence over others. Moreover, men and women should be equally able to revolve around the most appropriate style for a given circumstance, which would result in the absence of an overall difference of style. "[8]

Image of women as more intuitive manager by nature, more emotional, more "specialist" in interpersonal relationships and emotional experiences is considered by some authors one stereotype, it also believes that these qualities are not necessary in an administrative, Furthermore, we are very undesirable. This raises the question whether these qualities are necessary in the management and I am not valued enough? I mean, if it be expressed and used in this type of activity would enhance the effectiveness

of leadership? This idea is supported by a number of contemporary studies, which states that the most effective leadership style is permeated with feminine qualities and style that suits the new types of organizations, less bureaucratic and hierarchical. In addition, this style of leadership would create a wide range of management strategies regardless of gender.

"The manager has qualities intuitively reasonable manager, but also something more. Intuitive modern leader or manager is actually a type <soft> leader who does not need to resort to brutality or <weight> power stripes to be respected, he is as good proof of technical competence, management capacity and method, and the faculty of vision, motivation and creativity. Each leadership style favors after some qualities more than others, but all must be present in it. "[9]

2. Methodology of research

2.1.General objective: to establish the existence / nonexistence of differences in leadership styles of women and men on the assumption that because gender stereotypes and prejudice, women develop their leadership style different from that of men.

2.2.Participants of study

Practical work was done on two groups-one for managers, representing main study group, which will be further analyzed and one of the employees, who had the task to evaluate the 40 managers.

The first group consisted of 40 managers, statistical characteristics of the lot is described jos.Ponderea female managers in the group analyzed is 57.5% compared to only 42.5% of male managers, subject to examination 23 women and 17 men respectively manager[8].

Variable "age" is a balanced distribution between 20-53 years analyzed, higher frequency 2, equivalent to a rate of 8%, is characteristic extreme ages 20-29 years and 53 years for the remaining percentage being constant interval of 4 %.

In terms of the independent variable "type management", it appears that the study group to show a higher proportion of middle managers, although lots are nearly homogeneous in number according to the

label. This finds its explanation in organizational reality, which meet more frequently middle managers against top managers.

The second group consisted of 40 employees who were tasked with assessing lot of managers.

2.3 Tools

A. Investigation of management is done by questionnaire of 100 items Questionary Descriptive Behavioral Leadership - leader behavior descriptive questionnaire (LBDQ) contains 100 items assessing 12 dimensions of leadership behavior

B. To measure self-esteem was used a confidence questionnaire (Filaret Santion), which measures different facets of self-esteem.

C. To measure social perception of the employees and that they develop prejudices against sex managers have built a scale with behavioral descriptors for women and men managers manager.

2.4 Data analysis and interpretation

Consideration - as to which leader is concerned about the condition and status of subordinates - is average, even lower, with the frequencies 10 and 11 to 84% of the total batch analyzed. Only 16% of managers have concerns over average employee welfare. Investigated plot we see that the average is less than the median and mode distribution is asymmetric statistics are grouped around the median.

Making comparisons of the top managers about the same distribution managers see women and men managers. Consideration is perceived differently at middle management level, especially in the percentage of female concern is double the top management feminine and masculine to any level.

Fig.1_Comparative chart variable
"Consideration" to the top managers

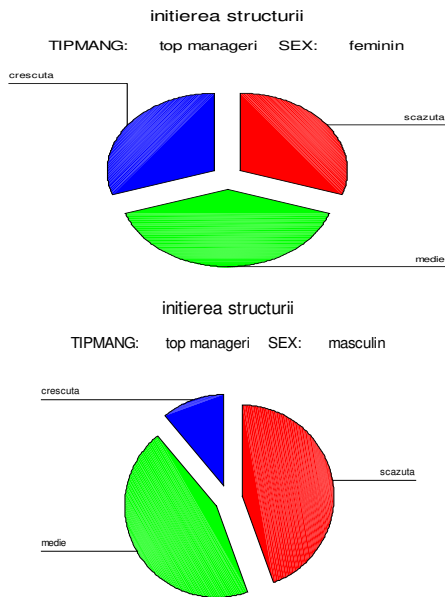

Initiating structure dimension, a number of 20 managers show an average of initiating structure, compared to 12 who have this low level and only 8 managers are judged higher levels.

Statistically speaking, a significant share is held by the average appreciation of this size (50%), while 30% of respondents were low, while 20% of managers have a high level.

In the diagram containing the weight values for the size indicator "initiating structure" prevailing average size is 56%, which means that there are concerns from management to define its leading role and also to inform employees through dialogue, information on the progress of their work. They are informed of the decisions taken by management and the organization's internal regulations are enforced and respected by employees, and decisions regarding work activity are taken at optimal levels by management.

Fig.2. Comparative chart variable "Initiating structure" from top managers

A total of 19 managers are perceived as having a poor representation capacity as a leader, while 15 of them are appreciated by environmental representation level, compared with only 6 subjects who are considered by employees as the best organization out.

Statistically speaking, employees are considered underrepresented in proportion of 47.5%, while average share of 37.5% consider this dimension, and 15% of them believe that they are better represented by leadership.

Fig.3 Comparison chart structure variable "representation" to top managers

Persuasion means the action exerted on someone in order to induce him to believe or do something. Persuasion is used every day by the teacher skilfully suggesting a certain conduct, the doctor who reassures the patient or retailer who wants to sell a new product. One of the means of persuasion used in commerce is to provide a sample. Driver is talking to you "grab a finger" asking less (free use of the new product), he hopes to get more (increasing its customer).

In terms of persuasion, a total of 18 leaders are characterized as non persuasive, while 15 of them have a capacity of persuasion average, while a number of 7 managers are high this size.

Statistically speaking, prevails employees who believe that the leader has a capacity of persuasion lower (45%), while 37.5% are assessed as having an average capacity of persuasion, and 17.5% positive that it valorizes view.

Fig.4. Structure comparison chart variable "persuasion" from top managers

A total of 16 managers have a low level of low prediction accuracy compared with 17 managers, which employees consider it average. A total of 7 managers are considered to have a high capacity for analysis and problem solving.

Statistically speaking, 40% of managers are considered to have a low capacity prediction accuracy, while 42.5% are assessed as having a medium capacity, while 17.5% is the proportion of managers that considers that the prediction accuracy is represented at a high level.

Fig.5. Diagrama comparativa structure variable "accurate prediction" from top managers

Summarizes esteem enhancement, confidence in their own resources, their use in the service of community, emotional

control, emotional, independent of others, autonomy, self-defeating bad opinions, validating their actions, their creative potential, strengths.

Of the 40 managers, 15 of them have low self-esteem, 17 self-esteem average, while 7 subjects manifested higher self-esteem.

Prevalent in the group of subjects analyzed represented a share of 42.5% of subjects with self-esteem average, compared with 37.5% subjects with low self-esteem, while 20% of them show a high self esteem.

Fig.6. Structure comparison chart variable "self-esteem" to top managers

3. Conclusions

From the following conclusions processing synthetic confirm the assumptions on which we assumed at the beginning of the research.

- consideration is perceived differently at middle management level, especially in the percentage of female concern is double the top management feminine and masculine to any level;
- there are concerns from management to define its leading role and also to inform employees through dialogue, information on the progress of their work;
- Managers surveyed lot, which thus effectively using the power of persuasion, discussion, dialogue for expressions of

strong, compelling and beneficial management activities;

- Women managers are perceived as having significantly increased self-esteem than men manager, but enjoy a lower consideration than men;

- Women tend manager to a higher status than men and are more dominant managers.

- Men are characterized by a significantly increased decisional capacity than women.

- Social tags assigned to women are related to the fact that they are smart and nondominante and men managers are perceived as aggressive and dominant.

Abstract

The firm possesses unique resources and capabilities. The firms have different behaviors on the real market. The analysis of firm development in a competitive environment is essential for the reassessment of the business simulation. Starting from these ideas the present paper intends to identify the role of business simulation in developing students’ practical skills. The last part of the paper includes numerical simulations using TOPSIM and conclusions.

Key Words: the firm, theory of the firm, capabilities, entrepreneurial.

JEL Code: D21, D22, M13

1. INTRODUCTION

R. Coase (1937) examines in turn the natural reasons for the existence of the firm, as well as the implied contract costs, the law on transactions on the market, the costs of market use, etc. [2].

Machlup (1947) argued that firms use established routines in decision making. Alchian and Demsetz (1972) argue that the hierarchical structure of the firm’s control does not minimize transaction costs, only monitoring costs. [5] [3].

The need to integrate the two approaches related to business theory – the contractual perspective and the one based on capabilities – is emphasized by some researchers focusing on the firm theory, stating that for a better understanding of the company, more attention should be paid to the problem of

knowledge distribution regarding production between companies, and especially on their character. The corporation is not only a contractual entity, it is also an entity that learns and innovates, seeking competitive advantages from economies of scale and scope based on superior capabilities[7].

Continuing the idea of knowledge coordination, a number of identify the firm with a communication network formed to minimize both the cost of processing new information and the cost of its communication between agents.

2. DECISION SIMULATION BASED ON TOPSIM APPLICATION

TOPSIM is a simulator of business management that serves as an effective platform to learn/develop business management skills, thereby enhancing the theoretical knowledge of the participants.

The simulator shows a realistic model of corporations that are competing in a virtual marketplace. The participants are divided into teams of 4-5 persons, each team representing a corporation. At certain times of the simulation they must take business decisions at group level for their company to gain a larger market share than the other participants and to increase profits. Thus, they develop the ability to make business decisions, taking into account multiple parameters that influence the success of a company.

All risk-free conditions through a competitive and dynamic game. The game sessions are divided up by theoretical “scenarios” presented by the instructor.

TOPSIM is an effective means to strengthen the participants' financial and business skills; in short - it teaches business by practicing business.

TOPSIM is a software simulation platform – interdisciplinary learning and analysis in the economic and social environment can be considered one of the best applications in the world.

The role of the TOPSIM application and of its specific working tools (strategies, decision forms, activity reports, concepts, indicators, simulation tools) resides in the understanding by the student of the functioning of the application and the learning of skills needed to use it in good conditions.

3. NUMERICAL SIMULATIONS USING TOPSIM

The research aimed at the evaluation of students of the West University in Timisoara on the participation and involvement within the TOPSIM process of simulation. The final grading took account of criteria on both the performance of the team which the student was part of (assessed by reference to the place in the final classification results obtained during TOPSIM simulation) and the complexity of the final analysis on the evolution recorded by the group during the period of TOPSIM simulation (assessed in the form of the PPT presentation, taking into account the degree of detail contained in the presentation presented at the end of the TOPSIM simulation).

Thus the assessment of the students watched the following criteria:

1. Participation in the decision-making groups, criterion accounting for 50% of the total of 10 points, respectively a maximum of 5 points, including the performance of the group assessed on the indicator Share price (Banking/ Commerce – international business) /customer satisfaction (Tourism), a maximum of 3 points (3p. 1st place, 2p. 2nd place, 1p. 3rd place, 0p. 4th place); attendance, involvement, motivation, a maximum of 2 points

2. Individually written essay by which the student describes the development (based on the calculated indicators) registered by the company which he/she was part of during the TOPSIM simulation , criterion of a 30%

share of the total of 10 points, respectively a maximum of 3 points

3. Individually written essay by which the student explains the strategy pursued by the company he/she was part of, highlighting the strong points and the weaknesses of the decisions taken in the context of strategies brought about by the TOPSIM simulation, criterion of a 20% share of the total of 10 points, respectively a maximum of 2 points
For master students, the assessment pursued the following criteria:

1. The ability to coordinate the activities of the groups of students, involvement, motivation, criterion accounting for 50% of the total of 10 points, respectively a maximum of 5 points, of which: the ability to coordinate the activities of the groups of students, a maximum of 3 points; attendance, involvement, motivation, a maximum of 2 points

2. Individually written essay by which the student describes the overall development registered at destination level within the TOPSIM Destination Management simulation. The changes induced in the competition environment due to company/ banking activity within the TOPSIM General Management / TOPSIM Universal Banking simulation; criteria having a share of 30% of the total of 10 points, respectively a maximum of 3 points

3. Individually written essay by which the student emphasizes his/ her personal contribution to the company's projects during the simulated enterprise of which he/she is partner / manager, including: website development, shaping and creating promotional materials of IS; criterion accounting for 20% of the total of 10 points respectively a maximum of 2 points.

The assessment of graduate students/ master students was made by allotting points on a scale from 10 to 0, expressed in full numbers starting from 0 points.

The research aimed at evaluating 240 graduate students and 24 master students assigned 80 for each of the 3 areas of the TOPSIM simulation: banking, trade and tourism.

The research focused on 2 assessments achieved comparatively so that the overall average of the two assessments for the master students ranged between 8.75 (banking) and 8.88 (trade), and for tourism the level was of

8.82. The purpose of the analysis is twofold it aimed at showing that the two assessments are complementary; therefore there is no regression between the scores obtained by the students.

The analysis was done on each domain of the TOPSIM simulation it aimed at demonstrating that the assessment was made differently, so there is a tendency for the overall average of the assessment of the three areas of the simulation to be relatively close.

The Banking field: the two were average rating assessment were 6.22 (assessment 1) and 7.5 (assessment 2). The minimum levels were 3 (assessment 1) and 5 (assessment 2), and the maximum level 10 (assessment 1) and 10 (assessment 2). The regression between the two data series regarding both evaluations is 0.11 (coefficient of determination R²).

The lack of correlation of average type between the frequencies of the two assessments and the ones of the overall average is due to the reversed gliding between the four intervals. A graphical representation of the distribution relationship between the two assessments is shown in Figure 1.

Figure 1. Graphic representation of the student's distribution frequency Regarding the two assessments, Banking UVT, 2011-2012

Source: own processing

As can be seen in Figure 1 there is a strong relationship between the scorings registered for the two assessments.

The lack of correlation of average type between the frequencies of the two assessments and the ones of the overall average is due to the reversed gliding between the four intervals. For the first

interval there is no frequency for the overall average.

A graphical representation of the distribution of the relationship between the two assessments is provided in Figure 2.

Figure 2. Graphical representation of students' distribution on the two assessments, Tourism UVT, 2011-2012

Source: own processing

Figure 2 shows the existence of a strong link between the scoring registered for each of the two assessments.

4. CONCLUSIONS

Comparatively, evaluations 1 and 2 are relatively close and the coefficient of determination registered a similar level for all three areas of the TOPSIM simulation. This shows a unitary level with respect to the acquiring of entrepreneurial practical skills for students who used the TOPSIM simulation software.

The need to integrate the two approaches related to business theory – the contractual perspective and the one based on capabilities is emphasized by some researchers focusing on the firm theory, stating that for a better understanding of the company, more attention should be paid to the problem of knowledge distribution regarding production between companies, and especially on their character.

Acknowledgments. The research was supported by the project with the title "Real access to the real market by the simulated firm", POSDRU 90/2.1/S/63442.

Strategies of Risk Management in Banking

Sisea Dana-Gabriela

Ecological University of Bucharest, Faculty of Economic Science
danasiseea@yahoo.com

Abstract

In the conditions of the economies globalization, the economic and financial crisis, it is amplified the uncertainty degree of banking institutions, it is widening the number of events which generates risks associated with these entities. One of the determinants of vulnerability growth of the banking activities, it is very its particularities, an risking activity by definition, operating with money drawn from a third-party, with a numerous and widespread network of high complexity and dynamism, in a comprehensive relationship with all economic, social and cultural sectors involved in the development of new products, services and techniques.

A specific characteristic of banking risks is that they can be monitored, identified and mitigated, but never removed completely. In this uncertain context the banks must be permanently concerned with the development of specific methods and procedures, and effective and rigorous risk management. The essence of this area of research is treated in the following lines.

Keywords: sovereign debt, deregulation, provisioning, prudential regulation, risk of moral hazard.

J.E.L. classification: H63, G32

1. Introduction

For economic activities in general and the financial and banking in particular, risk is a decisive factor, because any economic phenomenon has to be approached, studied and analyzed in terms of uncertainty. To act under the uncertainty it means to admit that in a specific activity there are unknown causes and effects. To act under the uncertainty it means, moreover, identifying of the risks generating events, evaluation of

their effects, in order to take grounded decisions.

2. The necessity of risk management and the factors which require protection strategies of banks

Typically, the risk connotation is negative, both investors and company managers are only interested in the risk that the results obtained are lower than expected. In a correct mean, the risk represents the likelihood that the actual results of the activities to be better or worse than expected, in other words, to be different from those expected.

Understanding risk as the probability of a result real, different from that expected, the theory considers the financial the economic operators as being willing to take risks in the hope of a win. There are, however, situations where bearing risks brings with it the possibility of obtaining a profit.

From this perspective can be identified two important categories of risks: risks that are assumed by the companies because they incorporate the probability of obtaining a gain, category in which fall the banking risks; risks that do not imply the existence of perspective a gain, but only that of a loss (case of an accident, a fire and others) also called "pure risks."

In the conditions in which the risks can be identified, monitored and reduced, but never completely removed, banks must develop a mix of strategies and specific processes of reduction, covering and management. Like banking activity, risk management activity in this a continuous process that presumes certain specific stages: risk identification, risk assessment, the establishment of specific risk management procedures; implementation procedures; reassessment of the risks after implementing management methods and techniques, the result being a residual risk. [8]

The problem of building a strategy for management of banking risks, prevention and mitigation of the adverse effects of the materialization of the risk lies in the choice of the most effective ways and means of giving a maximum and a minimum of costs. The option for specific ways to protect against the risks of the buyer must be motivated by the negative impact of certain factors on the activity of the Bank, the most significant of these are: the peculiarities of banking activity; the current state of development of the banking system in Romania; risks specific to banking institutions; the presence of foreign banks on the Romanian banking market; increase considerably the role of the State in the banking sector during the economic and financial crisis; the process of Europeanization and globalization of economies with major impact of diversity on the bank financial; the political factor that can have a marked influence in taking risk management strategy. [7]

Risk management strategies should correspond to specific requirements, as follows: to include in their architecture a full range of methods, procedures, and others; the components of risk management strategies to provide the necessary degree of efficiency, so that through their application to contribute to minimizing the likelihood of risk and potential exposure of the credit institution; the strategies constituents must be selected after the viability criteria, taking into account the probability of materialization of the risk related to the future; risk management strategies should be reviewed from time to time, the requirement imposed by the mutations involved in the banking business: (restructuring, modernization, operation of new markets, changing the political situation, the increase in competition, the emergence of new risks and others)

3. The main components of banking risk management strategies

Risk management strategies and its various components of regard the quantifiable risks, such as those in the "financial" category. The "non-financial risks as well as operational risks arising from internal malfunctions presents difficulties

related to management because the measurement it is not suitable. [9]

There is no a "universal" risk management but a plurality of them, so each bank assumes both the risks and the appropriate management strategies.

In the following lines are analyzed the main components of risk management strategies utilized in the most banking institutions in Romania.

➤ **The restructuring of the banking system** is a strategic measure of national and international importance, initiated by the European Central Bank (ECB), having as its objective the creation of banking systems safer and healthier by using, among others, to the current economic crisis and lessons. In essence, the restructuring of a bank involves the organization on new bases in order to increase the Bank's performance and goals aimed at increasing performance, and optimization risk - profit relationship. [2] The restructuring of a bank involves the following two areas: area regulations area aimed at creating the legal framework of banking operations and the organizational structures area that provide among others, departments, services, involved in the supervision and monitoring of risk.

For European banking and financial systems, including the Romanian, there are imposed long-term reforms generating mutations. [1]

This goal can become a reality through: policies to control the risky behavior of the big banks; policies aimed at reducing the moral hazard and fiscal costs of caution of banks in difficulty; higher capital requirements and liquidity for financial and banking institutions; the future role of central banks to control and defuse the speculative bubbles; more radical reform of the international monetary and financial policy that contributes to the prevention of future crises; the degree of State intervention in the economic and financial affairs; the interconnection reduction of the financial system in order to be less vulnerable to the systemic effects in the chain, which can ultimately result in a wave of bankruptcies; multidimensional adaptation strategy banks to the new context of economic and financial crisis. [5]

➤ **Recapitalization of banks** is a problem whose importance goes beyond the

interests of risk management within certain sectors of the National Bank. The European Central Bank (ECB), not so long ago, associated the need for recapitalization of the banking crisis with the systemic nature of the Europe. The high degree of interconnection of the financial system of the European Union has led to the rapid growth of the risk of contagion that may threaten the financial stability of the EU and beyond its borders. In this context, the European Central Bank urged Governments and European authorities to act to solve the problem of banks' recapitalization, after first they will be subjected to the stress test. [3]

There are two ways of financing the recapitalization of banks: funding from national budgets or obtaining financing from the European financial stability Fund (FESF) at which Governments can call in case of lack of financing from own money.

Funding from national budgets to increase the Bank's capital would lead to a worsening sovereign debt to increase them significantly as a percentage of GDP. If you use the capitalized banks, FESF eliminate moral hazard but there will be a socialization of losses at the European level, Germany will take over part of the costs.

Development of business environment it represents the economic support of the banking activities, between this and the micro and macro activities being a tight interdependence. Only in an economic healthy environment, especially banking institutions that have experienced losses in the crisis period can strengthen the work; ensure the profitability and optimization methods and processes to optimize the risks. [4]

➤ **Risk management**, component of the Bank's management, has a decisive role in the banks' strategy to minimize risks and capitalize on opportunities. [8]

The major aim of performing management lies in the location of the banking entity within an area between those limits in which the risk is tolerable and the cost is reasonable. According to international standards, risk management, considered "Science of risk, must meet the following requirements: to be permanently integrated into the strategy of the institution; to include all risks faced by the banking entity; to

translate the strategy into tactical and operational goals of risk management. [6]

The concept of risk management at the global level is dictated by two main requirements: the need for any entity to monitor and manage in a holistic manner all the risks they face; the need to ensure that the methods and techniques of risk management must take into account not only the probable risks or recurring, but also the risk of catastrophic events.

As a whole, risk management in the Romanian banking system has evolved to a profession with authority which has proved its viability and competence. However, banks have registered and some cases of mismanagement, especially at the beginning of crisis.

We can mention some errors of banks risk management: the acceptance of a high degree of indebtedness, with the consequence of excess lending and the trend of bad loans; tracking by most banks, to gain the short term profit, under-evaluating the longer term risks at which were exposed to; stimulating consumption by banks, which itself it is not a bad thing, under the condition not being encouraged the request of those who not permit; oversized network of some banks, ready only for retail; establishment of delayed provisions, which could generate a sudden depreciation of the Leu; substantial reduction in the number of deposits as a result of multiple causes which is reducing interest on deposits in correlation with taxation; the disincentive character of new products and services; the lack of transparency in dealing with customers, and unfair terms, interest increased in excess and others; keeping unjustified at a high level, the monetary policy interest by BNR, followed of harmful effects, such as: the appreciation of the national currency which encouraged excessive lending in foreign currency, attracting speculative investors by the good yields offered by Leu.

➤ **Measures of monetary policy adopted by the National Bank of Romania (BNR)** between the high importances is keeping key interest to 5.25% per annum as well as "repo" operations, represents among others effective ways of prevention and in particular the liquidity risk and the currency risk.

➤ **Monitoring of the banking institutions**, is a necessity in the context of the risks management and follows the achieving of the main objectives: limiting the liquidity risk, according to the procedures of the European banks; reducing vulnerability in securing liquidity and capital adequacy; maintenance by each credit institution to an solvability pointer threshold of 10%, the limit required by the regulations in force is 8%; diminishing operational risk.

The situation of the Romanian banking system is kept under control being monitored including the channels through which sovereign debt from Greece would be able to expand in Romania.

For the monitoring of banking institutions, particularly complex, especially as regards the management of the risks those entities are faced, some optimizations, of which the following are deemed to be representative: the launch of the trading operations of the securities that allow them to convert a portion of the Receivables in negotiable securities and illiquid; the location of the higher level of surveillance and operational risk management; prioritize risks within each institution; subjecting all banking institutions stress test after test the European banks; adaptation strategy of the supervision of credit institutions to the new realities resulting from the financial crisis and Stockholm. [7]

➤ **Optimization of the legal and regulatory framework for credit institutions** is the way with the highest scope in the field of banking risks management, given that all sides are subject to banking regulations. In the literature there are many opinions regarding the importance of the appreciation of the rules as a way of managing risk. In this respect, the opinion of the American economist Ben Bernanke, recorded in early 2010, reflects a great truth, that a more strong regulation could prevent the crisis. Are also founded the allegations of those economists who considers that deregulation of the financial activities may contribute to the development of a banking system more flexible and more adaptable to the economic cycle.

In Romania, the behavior of relative stability, specific to the Romanian banking system during the recent financial crisis is largely the result of **prudential regulations**

and monitoring of the risks taken by the Central Bank, mainly with reference to: capital adequacy at the risks incurred by credit institutions in accordance with the provisions of the Basel II Agreement; large exposures of credit institutions and investment firms; reporting exposures to persons in special relationship with the credit institution; mitigation techniques credit risk used by credit institutions and investment firms; treatment of credit risk related to securitized exposures and securitization positions; technical criteria concerning the organization and treatment of risks, for verification and evaluation; provisions relating to the management of the liquidity risk; preventing and combating money laundering and financing of terrorism; pursuit of and prudential supervision of the business of electronic money institutions; the formation of credit risk provisions.

➤ **Determination of specific risk provisions** has a high importance within the framework of the strategies of managing banking risks, the constitution of these provisions by the banking entities having as goal to cover eventual losses recorded from the loans. Reduce costs with the provisions are reflected directly in the profit of the bank institutions.

➤ **The security of Bank Information represents in the present and in the future** one of the important ways of prevention and mitigation banking risks that can be posed by certain endogenous or exogenous factors, including theft by skimming (stealing from ATMs), the new computer virus Trojan, internal fraud, money laundry and others.

4. Conclusions

"Moral hazard" management of the risk has in view the morality of banking institutions and imposes the State intervention in the management of this risk especially during periods of economic and financial crisis. The moral hazard refers to the availability of bank to take excessive risks that normally you would have be avoided if it had known that someone else (the State) it will help her or even to a rescue by the negative consequences of the risk. The financial sector in most countries develop some problems of moral hazard which can

amplify the expected risks ignoring and even lead to new risks.

It is well known the way of solving by USA the risk of moral hazard in September 2008 when they refused to rescue Lehman Brother letting it to collapse with a view to enforce discipline on the financial market.

Energy Efficiency in Supply Chain Management

Stet Mihaela
Technical University of Cluj Napoca,
North Centre of Baia Mare
miha9s@yahoo.com

Abstract

The paper is focused on the issues of optimization of the activities in logistics channel, considering reducing energy costs. Although a number of studies have been made over time regarding the optimization costs in the supply chain, few of them were directed towards reducing energy costs or increasing energy efficiency in logistic channel.

The study highlights that increasing energy efficiency in the supply chain knows a variety of ways given that, on the one hand, the large numbers of activities and, on the other hand, the variety of forms of energy carriers and logistics channel.

Key words: logistics, energy, costs, supply chain

J.E.L. classification: R41, M21

1. Introduction

Even though across the logistic channel there are involved a large number of energy consuming activities, as well as a variety of energy forms, there are however quite a few studies dealing with the problem of reducing costs in the logistics channel.

Need to find solutions to reduce these costs is justified by the fact that in some fields an industries the energy consumption in supply chain equals and even exceeds that of production activities for delivered goods. Therefore, the design of a logistics channel has to take into account, besides other categories of costs, the costs of energy.

In last few years in Europe has been developed several projects in the field of energy efficiency of logistics channels, such as ‘Dryport’ project, funded under the INTERREG IVB North Sea Region programme, involving stakeholders from

Sweden, Germany, the Netherlands, Belgium and the UK which has as objectives increasing energy efficiency and reducing costs in supply chains.

Logistics of distribution comprises a set of activities necessary for physical transfer of goods, such as packaging, handling, storage, transportation, each of them requiring at least a category of energy expenses. Among them, the most energy consuming are transport and warehousing activities.

Global optimization of freight distribution supposes, therefore, the management of distribution centers by optimizing locations of spaces with different functions within them, organizing transport flows, handling and picking operations, assembling orders and packaging.

2. Energy efficiency in transport of goods

In freight distribution, energy efficiency of transportation activities can be expressed in different ways:

- consumption per ton-kilometers;
- consumption per shipped parcel;
- consumption per kilometer per vehicle;
- distance per vehicle per consumption weight.

The share of fuel costs in total costs of a transport company is on average 25 – 35 %. Consequently, an increase of fuel prices, e.g. 10 %, causes an increase of about 3 – 4 % of total transportation costs.

But, transport companies can work towards reducing energy costs by investing in more efficient vehicles, with lower consumption and by optimizing transport routes. Thus, a reduction in energy costs by 20% results in about 5– 7% reduction in transport costs.

In 1994, Demker et.al [3] reveals the effect of load on energy consumption. It shows that energy consumption increases linearly with increasing load, while the effect

of vehicle speed on fuel consumption has a parabolic shape.

Reducing empty trips increase energy efficiency, but for small transport companies it is difficult to ensure load vehicles flows on all routes. For a large company, the large number of customers and their diversity, the load factor is much higher, which can significantly reduce fuel cost per ton of cargo.

Routes optimization leads to a reduction of a distance traveled by trucks, but in addition, also to a decrease of the emissions determined by vehicles.

Also, the reduction of the fuel consumption can be achieved by using of intelligent transport planning.

More, it is necessary to train drivers for use driving techniques to reduce fuel consumption, such as anticipation or smooth acceleration.

Energy efficiency in freight transportation across the supply chain can be achieved also by a modal shift to a more energy-efficient means of transportation such as rail and shipping.

3. Ways to reduce energy costs in warehouses

In some warehouses or distribution centers energy costs represent more than 20% of the total costs, which mean that a 20% decrease of them determine a reduction by about 4% of total costs.

On average, electricity consumptions are between 60 - 80% of total energy consumptions. Consumptions of electricity in a warehouse are primarily due the need to ensure lighting, ventilation and cooling, refrigeration, space heating, for operation of office devices and packaging equipments. Electricity is used also in operating the electrical driven forklift trucks and conveyors.

But taking into account that the price per unit of equivalent energy (kWh) for electricity is about twice the thermal energy, the amount of electricity cost is significantly higher than the heating energy costs.

Therefore, in designing a warehouse or a logistics platform it is necessary to choose cost effective solutions. Also, buildings and facilities should be made on energy efficiency principles.

Regarding the lighting, it can be considered solutions that can better value natural light over a longer period of the day. Also, it will be taken into consideration energy efficient illuminators.

Optimizing the lighting of different spaces can be achieved, also, by setting the correct, optimal position for lighting devices.

Dimensioning the number of lighting fixtures has to take in account national standards for lighting of spaces and requirements for storage spaces. There are analyzed their location, the light intensity, the direction, reflection and color of light.

Lighting control systems can reduce energy consumption in some cases up to 20%. It may be taken in this regard one or several control modes: light sensors, motion sensors, working hours based control.

The amortization period for such investments is relatively lower, up to 3 years.

For existing buildings solution is to modernize the existing lighting systems. For lighting shall be considered energy efficient lighting systems.

Regarding costs in storage systems, internal transport and handling of goods are important factors in the total costs associated with storage space. Operating costs for collecting orders for dispatch is approximately 45-55% of the total operational costs of a warehouse [5].

Basic functions of internal transport consists in moving goods within the warehouse, decomposition of the arrival flows in multiple flows of different components and composition of flows of goods in batches for shipping delivery.

The variable costs determined by these activities include energy costs and fuel necessary for the operation of such vehicles and equipment.

Determining energy costs can be achieved by using computational relations emphasizing the dependence on the number of hours of operation, and technical parameters of these vehicles and handling facilities.

Optimization of energy consumption for AS/RS systems can be achieved by automating the processes, through a speed control and a reduction of it during periods with a lower level of activities or even turning them off.

In warehouses, use of energy saving

technologies for handling equipments represents a solution that enables also the optimization of processes.

Reduction of electricity consumption can be achieved, also, by using energy retrieving brake systems.

Intelligent forklift guidance system is another solution that can be used for routes optimization in warehouse, increasing load and reducing empty trips of handling equipment.

An example in this sense is SmartKanban system, which based on correlation of forklift position and material position provides an optimization of the forklift routing. SmartKanban system is characterized by an efficient ultra low-power wireless network technology, as well as an ultra low-power sensor technology [1]

Packaging supposes a series of fixed costs and variable costs proportional to the quantity of goods subject to this process. Between them there can be highlighted the fuel and energy costs for packaging equipments.

Characteristics of some types of products determine additional consumptions. For example, distribution of frozen or chilled food products requires special packaging for transport and storage. In these cases, an increasing energy efficiency of containers can be achieved by using scroll compressors which use about 35- 40% less energy than other systems.

More, for warehouse spaces, using natural cooling systems based on lower temperature during the night which can provide cooling during the day can reduce also the energy costs.

In case of high power equipments, to reduce their load and to increase their energy efficiency it can be compensated reactive power by installing an automated equipment.

To avoid energy losses, another solution consists in doing the repairs and maintenance operations on time for heating, ventilation, refrigeration and cooling systems, as well as for handling equipments.

Heating energy is provided, in general, by natural gas, used also for hot water.

To ensure heating can opt to use heat pump solution, whose electricity consumption is about one third of the energy consumed by a conventional heating system. Furthermore, it has the advantage of a double

function, depending on the ambient temperature in relation to soil temperature, in the summer being able to provide cooling function in the warehouse.

But the investment is still expensive for Romanian business environment. For example, taking into account a warehouse with a surface $S = 10.000 \text{ m}^2$ and taken in account the heating requirement for such a building, the heating pump is about 400.000 euros more expensive than a classical solution. The long period for investment recovery, about 10 years or more, makes it a solution difficult to be implemented by a Romanian logistic company.

Another solution of using renewable resources consists in installing photovoltaic panels on the roofs of the warehouses. High initial investments, with a relatively long period of amortization, more than 10 years, makes this solution still extremely expensive for many Romanian companies.

Use of renewable energy can reduce electricity or heating bill, but it is effective to adopt such a solution only when the initial investment can be recovered within a reasonable period, not exceeding 5 years.

Elimination or reductions of heat losses are among the solutions that can be considered, to diminish the effect of air infiltration during the loading and unloading operations. In this regard a good insulation, seal closure systems, their automation, use of the quick locking/unlocking devices are possible solutions adopted in the case of a warehouse.

Furthermore, in the case of use of the radiant heaters they should be controlled by timers or occupancy sensors to minimize their operation when areas are unoccupied.

One of the solutions that can be adopted by companies operating in logistics field is the use of an energy management system.

Energy management system is based on measuring, monitoring, controlling the energy consumption.

Introduction of an energy management system allows tracking the values of consumption, identifying areas of inefficiency and optimizing these operations, which can reduce energy costs up to 10%.

Such a system consists a set of tools to measure different energy consumption: electricity, heating, gas consumption and an energy management software that facilitates

storing and processing the data collected and their analysis.

For example, in the case of electricity, the main elements that have to be managed are: the consumption in kilowatt-hours, load factor, reactive energy usage, real power and apparent power demand.

To obtain a first set of data it is required an energy audit [6]. Making an energy audit for a logistics company, create the opportunity to reduce its energy costs, and consequently, the total cost in supply chain.

A production company that realizes, also, the freight distribution, with its own facilities, when it makes energy audit for its production activities, can include also the distribution activities in this analysis.

Based on collected data it can be made forecasts of future energy consumption and estimations of energy costs of different activities. An analysis of consumption data offers the possibility to take some corrective measures to optimize energy consumption and increase energy efficiency.

Use of the energy management system offers, in addition, the possibility to track the qualitative characteristics of energy and to quickly identify any electric disorders and, as consequence, taking immediate measures to eliminate them. Thus, it can be avoided disruptions in operation that can lead to energy losses.

For successful implementation of such a system management has to imply and motivate the personnel to apply the measures for reduction of energy consumptions.

In developed countries, increasingly, those that operate in logistics field are viewing energy management as a potential strategy for cost savings.

In analyzing the energy efficiency of a warehouse it can be used some specific indicators:

- total energy per warehouse;
- total energy per 1000 shipped parcels;
- energy cost per warehouse;
- energy cost per shipped parcel.

To summarize, energy saving methods can be grouped in four categories [4], obviously with certain features in logistics channel:

- a) Housekeeping measures, when energy savings result from better maintenance of equipments and vehicles and their operation;
- b) Equipment and process modifications –

e.g. vehicles design or routes; handling equipment;

c) Better utilization of equipment;

d) Reduction of losses in the buildings shell – e.g. in warehouse or in a logistics platform.

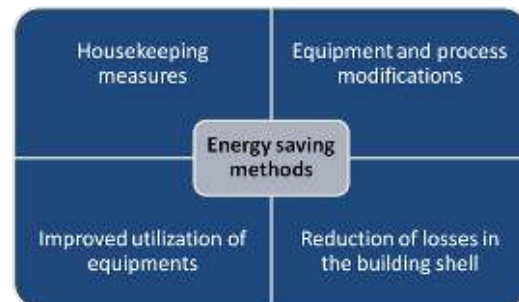

Figure 1 Energy saving methods

4. Conclusions

Increasing energy efficiency throughout the entire supply chain can be achieved by using and combining the most effective transport modes and a wide range of measures for reduction energy costs in warehouses and other facilities.

Among passive measures for increasing energy efficiency there are building insulation, use energy-efficient appliances and equipments that can reduce consumption, selection of the most suitable electrical equipments.

It can be taken into account, also, a series of active measures automation of processes, adjustment of heating, cooling systems or different devices, optimization of equipment and devices, their interruption when they are not used.

Human Resources Audit. Is It Significant in Evaluation of Management Performance?

Susmanschi Georgiana

The Bucharest University of Economic Studies

georgianasusmanschi@yahoo.com

Abstract

Human Resource Management can be defined as a set of measures designed interdisciplinary regarding recruitment, selection, employment, ergonomic use of the organization of labor, material and moral stimulation of employees.

HR audit should be considered a diagnostic tool for identifying strengths and weaknesses of an organization. An effective audit can be useful in stimulating constructive thinking, identifying positive aspects and organizational deficiencies and providing recommendations for improvement.

The HR audit is defined as a complex activity monitoring and information collection manager assures that activities are carried out according to plan, measuring progress towards objectives and detecting deviations from plan to take corrective action.

This paper aims highlighting the importance of human resource auditing in today's working environment as a factor in maximizing the efficiency of activities performed by employees of an enterprise.

Key words: management, performance, human resource, auditing

J.E.L. Classification: M12,M41

1. Introduction

"Man is the measure of all things," said the Greek philosopher Pretoqoras. This means that man is able to integrate any current or future applications in his work.

Human importance in managing a successful business is what makes human resource management, a set of competencies,

skills and attitudes essential for all managers. This is directly related to the supreme values of the company / organization.

This responsibility is not only related to providing services to people, guide them how to work and record their performance, although managers must do so. On top of that human resources management is considered to be an investment having as purpose: *giving people the power to work efficiently and effectively.*

We consider we are not mistaken when we say that man is the most valuable asset of an organization.

A company's success is determined by the quality of human resources, the procedures to attract and retain the brightest employees capable to make the most difficult tasks with the same enthusiasm they make the easy ones.

2. Concept of HR audit

The Management function has emerged as a necessity for people to organize their working time and activities, taking into account the magnitude of activities in an organization so that processes within an organization to give maximum of efficiency, following the main objective. [4]

Human resources have become a strategic production factor, and at the same time the main component of performance for all domains and all organization levels. Such evolution allows us to appreciate that human potential is extremely important for the management of the organization both according to the efficient use, and quantitative and qualitative assurance. [1]

Amid continuing economic change, HR function has evolved to complex tasks with a direct impact on organizational strategy.

Why it is necessary to perform a HR audit?

First of all we have to point that human resources are an important source of increasing the quality of organization, of the company's performance. The company's efficiency is crucially related to the quality of the human resources in the company.

Other factors proving the necessity of a HR audit are given in the following lines.

A Human Resources Audit is a comprehensive method to review current human resources policies, procedures, documentation and systems to identify needs for improvement and enhancement of the HR function as well as to ensure compliance with ever-changing rules and regulations.

Human resource audit in its scope is beyond the conventional audit. The human resource audit is more clearly defined as “a method to evaluate the efficiency of human resource at all levels throughout the organization, in order to ascertain whether sound management prevails throughout, and to recommend its effectiveness where such is not the case” [7].

Derived from monitoring the output of human resources, auditing has evolved over time and has become a basic function of human resources management. Besides being able to reveal the true dimensions of human resource activities, auditing helps the manager in all stages of management decisions from information provided by a well-founded audit.

HR audit should be considered a diagnostic tool for identifying strengths and weaknesses of an organization. An effective audit can be useful in stimulating constructive thinking, identifying positive aspects and organizational deficiencies and providing recommendations for improvement.

HR audit is not mandatory, but it is undeniable the need for such an audit for an effective management of human resources.

Evaluation and critical review of HR is no less important and significant for the company's management than that of accounting and finance function.

3. What is involved in an HR audit?

There are a lot of elements that reflect why is important a HR audit. One of the most important is the following:

- Routine can be a negative factor.

Performing some operations over and over (repeatedly) ensures not only a good fluidity and knowledge of the activity, but also a tendency to error because of these habits. The employee may get overlooked certain things, being sure that he is not mistaken, based on I did this many times, I know how to do it, I cannot be wrong. Still, sometimes the habit turns into an enemy, because self-confidence can sometimes lead to inattention, hence to mistakes;

- aligning HR objectives to business objectives;
- ensure consistency between the rules established and legislation.

A HR audit involves summing up and analyzing all the skills, abilities and limitations of the employees. [2]

A human resources audit usually involves review of all HR policies, practices, and procedures, whether or not they are formal. It includes reviewing documents, interviewing human resources professionals from different areas of the organization, interviewing some managers at different levels of the organization, and possibly interviewing in-house employment counsel. [8]

The purpose of an HR Audit is to recognize strengths and identify any needs for improvement in the human resources function. A properly executed Audit will reveal problem areas and provide recommendations and suggestions for the remedy of these problems. [9]

Audits must be performed in order to determine whether different elements of the subsystem are effective in achieving the objectives set by management. The basic idea of concern in formulating a model in the field is that human resources audit evaluates the work of human resources in an organization in order to improve activities. Audit provides feed-back regarding personnel function.

Concisely, HR audit is a qualitative control, a review of the human resources activities of a department or entire organization, as well as how these activities support the organization's strategy.

HR audit must cover the activities of the department and extend beyond, because the people's problems are not confirmed to the HR department alone. Thus, the audit should be broad in its scope. It must evaluate the

personnel function, the use of its procedures by the managers and the impact of these activities on the employees.[7]

Specifically, a HR audit covers the following areas:

- Audit of human resource function
- Audit of managerial compliance
- Audit of the human resource climate

HR audit methodology requires numerous sources of information to be verified, such as policies and procedures, employee records, job descriptions, job descriptions, job specifications, internal reports, individual and collective labor contracts, relationships with unions, relations with government bodies, professional accident statistics, interviews with staff, and interviews with human resources staff.

A HR audit must be:

- proactive
- reactive
- informative

A human resources audit evaluates human resources activities performed in an organization.

Leading audit team will need to use a variety of approaches, methods and tools to assess human resources activities. Along with internal comparisons, the audit team will have to compare the efforts of the organization to other companies or standards developed by national authorities and statistics. In other cases, the approach will need to assess integration and strategic objectives set by management tactics.

Data are obtained through interviews, questionnaires, checking internal documents, external sources, experiments or target groups. Using these sources, the audit team will be able to prepare an audit report.

The audit report provides feedback to senior management, executive managers, human resources specialists and human resources manager. With this information, human resources manager can develop plans to ensure a better contribution to human resource activities to achieve organizational goals. [5]

As it regards the steps used in a mission of HR audit we present on short how a HR audit is developed.

The auditor begins the HR audit project through detailed analysis of human resources functions, existing procedures within the

company. One after another, are checked all the procedures that refer to planning human resource needs, developing job descriptions, recruitment and selection of candidates, system performance evaluation, wage policy and rewards system / non-material, training policy of the company, planning elements and career development of employees.

A special attention must be directed to an analysis of the company's organizational chart seeking to discover and identify the so-called "overlapping responsibilities" or "false responsibilities."

An important indicator in HR diagnosis is represented by motivational level of employees. Employees can be motivated or demotivated by certain factors, decisions.

4. HR audit. Advantages

Some of the advantages offered by human resource audit are as follows: [6]

- highlights the contributions of human resources within the organization;
- enhances the professional image of the department of human resources;
- encourages assume greater responsibilities within the same department;
- discover critical issues of human resources;
- reduce the cost of human resources through effective personnel procedures.

5. Conclusions

HR audit can be a powerful lever in departmental and organizational change. In time, the HR audit will be enriched by a better definition and a higher level of performance expected.

Employees are an asset to a company and play a vital role in the achievement of the goals and objectives.

The senior management, therefore, needs to understand how efficient its human resource department functions are. Most companies work to ensure the minimum employee turnover. The retention of employees is a key role played by the human resource department. The human resources department should ensure that skilled employees are recruited, trained and

developed. An audit of human resources brings to light the success or the weaknesses of the human resource department in an organization.

The Necessity of Risk Management Programme in Organizations

Tilea Maria Doina

Dinu Ana-Maria

Christian University of Dimitrie Cantemir

alinat75@yahoo.com

anadinu13@yahoo.com

Abstract

In the current economic context, risk management is very important, because the risks are becoming more difficult to identify and especially to control. The company objectives achievement requires the knowledge and multiple risk taking.

Risk management is a process conducted by the management organization and consists in identifying and assessing risks that may affect the organization and activities taking place therein as the business environment changes are taken into account. Risk management also involves defining the strategy to be applied and control the risks so that they fall would within the limits of risk tolerance. Monitoring, reviewing and reporting the continuous risks situation, regardless of their nature ensures that the organization's objectives will be met according to schedules made.

Key words: risk management, organizations, strategies, risks.

J.E.L classification: D81, G3

1. Introduction

Economy is a complex game where the players' expectations influence their future events and probabilities. The issue of risk analysis enables the proof of experience, a better understanding of the socio-economic context and it especially reveals challenges that the company must meet if it wants to remain on the market. Zero risk doesn't exist.

2. Why a risk management programme?

Risk is the condition of success in all its stances.

Risk management may be defined as a very similar process to a medical examination: patients exhibit symptoms, physicians diagnose, recommend treatment and after cure, the patient comes back to the medical examination.

Figure 1. Risk management programme

Source: marsh.com

There are some reasons to implement risk management in an organization, such as:

a) Risk management requires the management style change

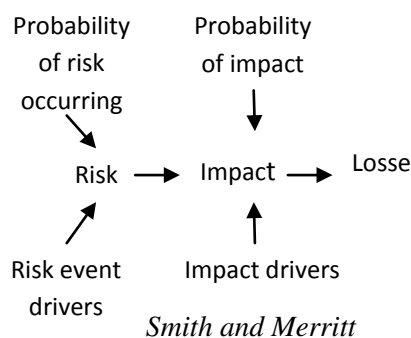

The managers of an organization should not be limited to always treating each time the consequences of events that have occurred. The treatment consequences do not improve the causes and therefore the already materialized risks will also occur in the future, usually with a higher frequency and a high impact on objectives. Managers must adopt a **reactive management** style, which

means that it is necessary to design and implement susceptible measures to mitigate likely risks manifestation. Future oriented response allows the organization to master the listed risk, within acceptable limits, which means increasing the opportunities to reach the goals.

In the terminology adopted in some countries, the above mentioned yet improperly managed risks may occur in the future and are called **real risks**. These risks are easier to identify, but that does not mean they are as easy to treat. Mastering real risk is a guarantee that internal control systems are effective. In other words, the real risk treatment allows the organization to avoid facing the previously encountered risks in the future. Unfortunately, it is a quite common concept that the action of effective risk management is to limit the effects of materialized risks.

Limiting to the reactive management is still insufficient for management. No organization can be conducted only according to the "*seeing and doing*" principle. Equally important is the identification of possible threats before they materialize and cause adverse consequences on the objectives. This means adopting a **proactive management** style. Proactive management is based on the principle of "*it is better to prevent than to realize a fait accompli*".

Figure 2. Proactive risk management

The organizations that benefit from good management, "*observation horizon*" is not limited to the immediate future, but considers

more distant perspective. In these situations, proactive management becomes a **prospective management** where management attempts to identify those risks which may arise as a result of changes in strategy or environment. The organization must be prepared to accept the change.

In the terminology adopted in some countries, risks that have not occurred yet, but that may materialize in the future are also known as **potential risks**. Identifying these risks is not quite easy, yet it is somehow approachable.

Initially, for any organization is its handy the experience of other organizations which already faced such risks. There are also specialized studies developed by specialized organizations on "*observation of the horizon*."

In conclusion, risk management rules expectation and promotes action and foresight.

b) Risk management facilitates the efficient and effective organizational objectives

Naturally, the threats acknowledgement allows their classification according to their materialization event, the extent of the impact on the objectives and the costs involved in measures designed to reduce the chances of developing or limit undesirable effects. The establishment of hierarchies is introduced as support an order of priorities in resource allocation, in most cases limited by analysis the "*cost-benefit*" or, more generally, the "*effort-effect*". It is essential for the organization to focus its efforts on what is really important, and not to disperse resources in irrelevant for its aims. However, regular review of risks, as set out in standards leads to reallocation of resources according to changing hierarchies and hence priorities. In other words, risk management requires concentration on the resources in of current interest areas.

c) Risk management provides the basic conditions for an healthy internal control

If internal control is a whole set of management measures to obtain reasonable assurance of the objectives achievement it results that risk management is one of the important means to accomplish this as risk management targets precisely the threats administration that could have a negative impact on objectives.

In conclusion, if they aim strengthening internal control, is essential to implement risk management programme. The action plan (activities to be undertaken to achieve the objectives) must be assisted by the plan that includes the measures to mitigate risks and the plan to handle the difficult situations (materialized risks).

3. Conclusions

Risk management is a necessity for every organization. Although it may seem complex and time consuming, developing a comprehensive risk management plan is essential in any organization.

Companies face various types of risks. Some may be external in nature, which are not under the direct control of the management, like the political environment, the changes in exchange rates or the changes in interest rates. The others may be internal in nature which the management can control to a great extent, for example risks associated with non-compliance in financial reporting or non-compliance with labor laws.

A company would need to identify the risks that it faces in trying to achieve the objectives of the firm. Once these risks are identified, the risk manager would need to evaluate these risks to see which of them will have critical impact on the firm and which of them are not significant enough to deserve further attention.

Evolution and Trends of Logistics within the Economic System

Vlad Florea

*Christian University „Dimitrie Cantemir”, Faculty of Management in Tourism and
Commerce, Timișoara
octo2012tim@yahoo.com*

Abstract

Modern logistics integrates the strategic planning of companies together with functions of marketing and sales, with the growing support of information technology. Thus, a management field that is currently under intensive and extensive development appeared – Supply Chain Management-SCM.

Keywords: evolutions, trends, logistics, economic system.

Classification J.E.L : M21, M10.

1. Introduction

In order to understand the function of logistics, as it is perceived nowadays, as well as the trends in this field, knowledge of its framework of development, respectively knowledge of companies' evolution is necessary. In the last 40 years there have been significant changes in the orientation and functioning of companies that activated on the market economies.

If by the 60s of the last century, the main issues companies paid attention to were the production and sales, the study of work and its efficiency increase possibilities, by the 80s, the main preoccupations were the extension of markets, the increase of technology's role and the development of logistic rational approaches of management .

Later on, the interest moved towards market globalization and implementation of information technology in all the procedures of a business. This took over and supported part of the modern management responsibilities, and tends, through the expert systems and holistic approaches, to standardize business management and to replace, for cost reduction and efficiency increase, more and more productive and managerial processes of the business, and

human force labour.

2. Theoretical Groundworks

Obviously, the logistic function developed together with the companies it activated in. If by the 60s, the logistics functions were fragmented, they started to integrate within the materials management and the physical distribution. After the 80s, one can observe the total integration of these two fields into what logistics represents, both theoretically and practically (figure no. 1).

Furthermore, modern logistics integrates the strategic planning of companies together with functions of marketing and sales, with the growing support of information technology. Thus, a management field that is currently under intensive and extensive development appeared – Supply Chain Management-SCM.

3. Method and results

We will insist upon two categories of trends that are currently dominant the theoretic and applied research in logistics:

1. Internal and external integration of logistics and its impact on logistic systems

2. Development of information technology and its impact on logistic systems

Our researches show that we cannot speak about them as uniform and complete yet. However, they represent, in our vision, two great trends in logistics, which are not divergent but they support mutually in the role that logistics has and will have in economic systems. The factors mentioned above are just a few of the ones that support the above mentioned.

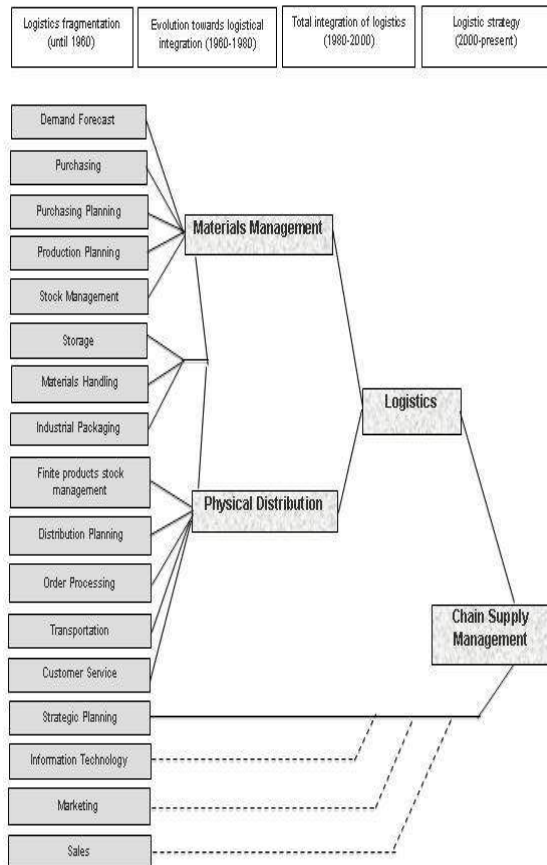

Figure 1 – Evolution of logistics within the economic systems
(abridged after WILSON, Rosalyn, DELANEY, R.V., - *Managing Logistics in a Perfect Storm. 12th Annual "State Of Logistics Report"*, National Press Club, Washington, D.C., June 4, 2001, p.35)

Besides these factors, integration in logistics is supported by a series of endogenous factors at company management level. The subdivisions of materials management (purchasing, stock management, distribution and logistics) integrate in SCM and allow the valorisation of advantages of combining a centralized management:

- Avoiding issues regarding responsibility dilution;
- Avoiding conflict between objectives and priorities;
- Avoiding double efforts;
- Improving communication within the organisation;
- Improving the representation of materials management functions in order to comply with the company's policy;
- Increasing professional development

opportunities;

- Cost savings; with the advantages of a decentralized management:

- Valorising opportunities regarding functional specialization;
- Valorising opportunities regarding the geographic specialization;
- Increasing flexibility.

In such conditions, the integrated organization and establishment of the materials management functions and of the physical distribution within the SCM suppose the derivation from the company's general development strategy and the definition of the integrated strategy of logistics, the choice of the strategy's implementation framework, the management of system restructuring and of organizational change, the identification, monitoring and control of logistics performance criteria.

4. Discussions

The logistics and distribution management from the SCM perspective integrates, in our vision, the logistics and distribution field, on the one hand, with purchasing, exploitation active and passive assets management (stocks, debts) and on the other hand, as a strategic vision, the interferences with production and financial management and marketing, and as a method of designing, monitoring and decision support with the information technology.

This integration trend corresponds to a holistic approach to logistics. This approach together with the fields integrated by a logistic system and the interferences of logistics with the other fields of management, as well as the role of IT.

As a first big category of trends, this integration is already a reality for many international companies. For others this concept is on the way of being implemented, while in the case of Romanian companies it is rarely met.

It is certain that this approach proved feasible and efficient and thus we can state that sooner or later the majority of companies, international and national, will follow this trend.

Further more, developments or extensions of this integration concept take place in other directions too :

- Internal integration
- Upstream vertical integration
- Client oriented vertical integration
- Performance assessment integration
- Technological integration
- Relational integration

Of these integration forms, the partnership marketing (a vertical integration form), the inverted logistics (a form of flux integration from the consumer towards the producer), the visibility of the logistics system (a form of relational integration) are concepts that are already successfully implemented by transnational companies.

The second major trend category in the evolution of logistics is the one related to the impact of the information technology on logistic systems. Evolutions occurred on three main directions:

Systems for operational support that provide:

- Physical operations
- Registered operations
- Accounting operations

Systems for decision support that provide:

- Decision support
- Assisted planning
- Assisted system design

Systems for electronic data exchanges.

Certainly these systems have evolved in time and will evolve in the future as well. Table 1 briefly presents the evolution of information systems for the support of logistic activities, from the point of view of the main characteristics for each generation, of the application types they generate and of their functionality for the logistic and distribution management.

5. Conclusions

If at an international level, companies have implemented 3rd generation information systems or try hard in this direction, a wide offer being provided by hardware and software companies, in the Romanian economy the 2nd generation systems predominate, being either imported or created by specialized companies. Most of the times these systems have integration dysfunctions, many times being used as 1st generation systems.

Table 1 - The evolution of systems for the logistic management support

GENERATION	CHARACTERISTICS	APPLICATION TYPE	FUNCTIONALITY
I	Primary applications	Stock registration	Operational support
	Post-factum registries	Debt registration	
	Accountancy	Account book generating Automated generating of accounting functions	
	Extended applications	Client reliability verification	
II	Transaction processing systems	Generating information for lower and medium management	Operational support Decision support
	Real time registrations	Simulators of decision effects	
	Integrates the operational support with the decision support		
III	Integrated applications	Applications for all logistic functions	Operational support Decision support Tactical support Strategic support
	Adapted to electronic data exchanges	Applications for resource planning Applications for budgets, cost calculation	
		Applications for logistic systems design	
	Real time integrated operation	Applications for optimizing decisions through mathematical methods and optimization techniques

Principles of Modern Logistic Strategies

Vlad Florea

*Christian University „Dimitrie Cantemir”, Faculty of Management in Tourism and
Commerce, Timișoara*

octo2012tim@yahoo.com

Abstract

Logistics has a growing role in companies' activity, being in permanent connection with production, sales, marketing and customer service.

Keywords: principles, strategy, logistics.

Classification J.E.L : M21, M10.

1. Introduction

There are numerous factors that transform logistic operations into maximum importance operations. Each company has its own methods of increasing its logistic operations efficiency. Production and distribution cost cutting, together with improvement of quality and services offered to the customers, makes an objective of the majority of managers.

Visible improvements in the cost, quality and services field are essential for the contemporary competitive market. In the present globalized market economy, such improvements often determine the survival of a company. Logistics can be vital in the implementation of integration strategies that should create this advantage.

2. Theoretical groundworks

More and more top level managers are aware of the importance of logistics for the success of the company's strategies. John L. GATORNA identified ten main principles common to all efficient logistic departments.

3. Method and results

We present below these principles that, applied together, can create the premises for the successful deployment of the logistic activity:

1. Providing a connection between logistics and corporation strategy – all aspects of the logistic operations must be directly connected to the company's strategic plan. This is the first and most important rule in order to attain the profit increase potential that logistics provides. Managers coordinate the logistic function in order to support the company's strategy to gain competitive advantage either through cost supremacy, through services differentiation or both.

In order to gain the competitive advantage, the company's activities must be synchronized. Thus, on schedule delivery imposes the coordination of activities grouped in operations, external logistics, services and sales. Since the same task can be accomplished in several ways, with different costs and performances, the assessment of the activities and of the connections between them is essential for the understanding of the impact of logistics on the company's profitability.

Cost efficient logistics has a great impact on maintaining companies' position within the consumer goods production sector, where even a small advantage regarding costs is essential.

One of the most frequent approaches concerning the gaining of the competitive advantage is the creation of a superior service provider reputation. The emphasis on client orientation and quality in operations represents a decisive element for this trend. Also, innovation in logistics contributes to holding the supremacy in the cost field and the differentiation through services. Certain companies prefer to come up with new approaches than to become competitive through traditional methods. Once these approaches succeed, the management will use them as a competitive advantage.

2. Establishing a global organization – the second principle supports a global organization of logistics, through which all logistic functions can be controlled by only one department within the company. The materials management, transportation, storage, distribution, internal logistics must be unified through an adequate combination of centralized and decentralized management.

Providing adequate logistic services needs a careful coordination of all operations with the company's strategy. Despite the advantage given by the centralization of all logistic functions that are connected, there is a relatively small number of companies that apply this strategy.

It is encouraging that companies start to integrate two important fields – materials management and distribution. These companies run the entire logistic channel as a unique integrated flux that uses a complete range of support structures and available assets. Companies recognize the essential interrelations between logistics, production, marketing, sales and finances. They seek to stimulate cooperation for the accomplishment of common objectives, by using the synergetic possibilities to the utmost extent.

3. Valorising the power of information – the logistic departments fully benefit from the advantage of information and of information processing technologies. These departments perceive the systems based on transactions, as well as the ones based on decisions, as essential resources for the obtaining of the potential profit of logistics. For example, the electronic data exchanges with the customers can be a source of competitive differentiation and of increase in the company's market share.

As a consequence of the fact that information is one of the few business sources to have significantly dropped costs, companies invest more and more in information management systems as an alternative to the expenses for other more conventional logistic resources. Certain managers research those systems that provide support for decision making. The networks for the support of decision making will evolve towards „expert systems” which will have an important role in decision making regarding logistics.

A number of companies already use sophisticated computer patterns meant to provide help with tactical and operational decision making. For a maximum efficiency, these systems must be regarded as an evolution process rather than a revolution one. Companies start exploiting considerable facilities that the information systems provide. The companies' knowledge in this field is rapidly improving, while in the future the rhythm of innovation and implementation will be expected to accelerate.

4. Emphasizing human resources – human resources management is vital for the obtaining of superior logistic performances. These performances are obtained within an environment that admits that people are the most important resource of the department. The management must repay the personnel for productivity improvement, and in certain situations, it must establish incentives which should encourage the accomplishment of the logistic function in good conditions.

The logistic departments need a new type of managers, and recruiting could become a real problem for the department management. As more and more companies close long-term strategic alliances with other companies, human resources management becomes a common preoccupation.

Quality is closely related to human resources. If the company does not impose a quality-based orientation, its products and services will remain behind the competition; that is why quality must represent a daily priority.

Many companies send their managers and the personnel of the logistic department to do training courses that are meant to improve their knowledge and allow the introduction of new concepts and techniques. Nowadays, well-known companies see the investment in personnel training in a new light. These companies have had important cost reductions and increased the number of services by the improvement of operations and the way they have been preoccupied with human resources management.

5. Establishing strategic alliances – this principle refers to the establishment of partnership relations with other participants within the product or channel chain.

Generally, companies change their

perception on business alliances. They stop considering these relations as short-term efforts meant to provide cost control. They try to cultivate strategic alliances with suppliers, customers and transporters more often – even by including these alliances in their plans for the establishment of new companies.

Planning and concluding advantageous alliances is not easy, especially with transnational companies. It is an objective that requires a careful approach, coordination with customers and suppliers, support from the employees and their previous training. Alliances can have expenses for the support of operational changes. But the most necessary thing is the active involvement of the company's management. However, the reward can be significant. Certain companies gain cost savings from the improvement of the operational process and the increase of market share because they become their customers' favourite suppliers.

Companies that will best cultivate strategic alliances with the suppliers, transporters, distributors and customers will obtain higher profits than the companies that do not take into consideration such alliances.

6. Emphasizing financial performances

– in order to measure its performances, the logistic function should use indicators such as the efficiency of using assets, the added value, the operation costs and standards. Knowing the financial consequences of the logistic activity is essential for planning.

In order to reduce its investments in logistic active assets, more and more companies address outsourcing logistic services providers like using public storehouses. At the same time, activities like transportation, storage and customer service will be managed as profit centres. Thus they encourage entrepreneurial attitude among the managers of logistic departments.

7. Establishing the optimum level of services – companies that want to establish the optimum level of services will improve their profitability. In order to establish the optimum level of services, companies must quantify the extra income obtained from the provision of quality services for the customers and to measure the proportion cost-profit in order to establish different

levels of service. This implies understanding the expectations of customers and the types of services they are willing to purchase. This can lead, for example, to the establishment of layered prices where the different levels of services should be associated with prices adequate to the necessary costs (for example, delivery period).

Most big companies recognize the competitive importance of customer service. They have established service parameters and closely monitor the accomplishment of services.

8. The importance of details solution – the fluidization of operations and procedures is important for the companies' profitability, but the attention paid to details may lead to significant savings. When they pass to operations' improvement, the simple solutions will give the best results.

A key element of fluidization and simplification of logistic operations is represented by the valorisation of the workers' knowledge, experience and creativity. Much progress made by companies in the product field is due to the active involvement of the employees.

The attention to details is not the sole condition for obtaining quality and profitability. Without an efficient control of minor daily problems, all other effort will be thrown away. When everything goes well and every detail is under control in a company's logistic department, then the company's services will be of high quality and the profit satisfactory.

9. Optimizing the merchandise volume – the successful logistic operations will have to unitarily manage the transported merchandise volumes, the stocks and so on for service improvement and cost reduction.

One of the most known optimizing methods is the loading arrangement. In order to dynamically unify transport services they have come to use state-of-the-art software applications.

Another element would be the reduction of the number of transporters and the conclusion of regional strategic alliances with the accepted transporters. Also, there must be good coordination between the volume of the merchandise sent inside and outside the unit.

Lately, the concept of third party or of contracting logistic operations has won popularity. It has become common practice for companies in Europe to contract third parties for transportation and storage services. Third parties that provide logistic services, like public storehouses, can often provide better and less expensive services than the ones provided by the producer company.

10. Assessing and exceeding performances – the logistic activity efficiency will have to be supported in order for performances to be long-term. The companies must measure their logistic performances and dynamically react to the obtained results.

4. Discussions

The most efficient logistic operations are the ones that directly connect the operation methods and the overall logistic strategy. The logistic strategy is obviously connected to the company's strategy.

Without a permanent attention and preoccupation for accuracy, performances measurement will not give the expected results.

When discussing performances measurement with the logistic departments managers, two essential objectives are established:

- coordination of logistics with the company's strategy so as to fully support the company's objectives and to allow the accomplishment of the objectives in the most profitable manner

- concentration of logistics on the efficient customer service so as to obtain an optimum profit from the alternative service strategies.

Regardless of its origin – external or internal – the more and more intensive competition has become a reality. Therefore, all companies must use their energy and resources in order to purchase information and make progress in the current competitive conditions.

5. Conclusions

In order to accomplish the objectives reflected by these principles, companies will

have to implement global management. In the current business environment, as well as in the future one it is not recommended for companies to apply and execute those strategies that intend only to accomplish the marketing plan with the lowest costs possible.

Logistics has an increasingly important role in the companies' activity, being in a permanent connection with production, sales, marketing and customer service. The challenges that companies have to cope with refer to the obtaining of a full advantage from using logistics as a competitive weapon.

Abstract

Quality is a component of organisational culture that is expressed by positioning, competition, cooperation and satisfaction. The industry of tourism and hospitality can become a driving force for the Romanian economy through the level of services quality. Together with the practical experience it is aimed to adopt, implement and enforce the codes of good practices, of international standards for quality, safety and environmental protection.

In a competitive economy, the differentiation of the tourist performance is made by the “Q” mark - the guarantor of reaching the level of excellence and of the existence of certain modern management systems.

Keywords: tourism, quality management, certification, guarantee.

J.E.L. classification: L83

1. Introduction

In the context of the insufficient promotion of the Romanian tourism and of the non-compliance with the quality and safety standards by some tourist services providers, the desire of many Romanian tourists to choose destinations abroad stands out.

Therefore, the approach of quality from a new perspective imposed itself as an objective necessity. The respect for the client, the attention for his/her health and safety are guaranteed by introducing a set of requirements concerning the quality management system in tourism.

2. Defining elements on quality in tourism services

In a competitive economy, a company’s success depends on the management’s ability to harmonise the quality of the services and products offered with the dimension of the allocated costs.

In the field of tourism and hospitality industry, quality represents the compliance with the standards and with the customers’ requirements. It is to be noted that this concept has two aspects:

- the objective quality, as emphasised by the quality of the serving process;
- subjective quality, result of the client’s satisfaction level [2].

In quality management, the human resource is a top concept. The relationship between the staff’s behaviour and the customer represents an important criterion for assessing the quality of the performance. The relational quality becomes a competitive advantage whereby all the staff of the organisation performing services must work for the people in the front line, the customer [2].

The strong competition on the specific market, the changing of the laws and regulations in the field, the increase in the customers’ demands, as well as the developments of the tourism companies’ strategic objectives represent improvement factors for the quality of the processes, activities and outcomes obtained by these companies (fig. 1).

In this context, the Tourism Ministry Order no. 1051 of 3 March 2011 stipulates the classification criteria of the tourism accommodation structures with accommodation functions on certain

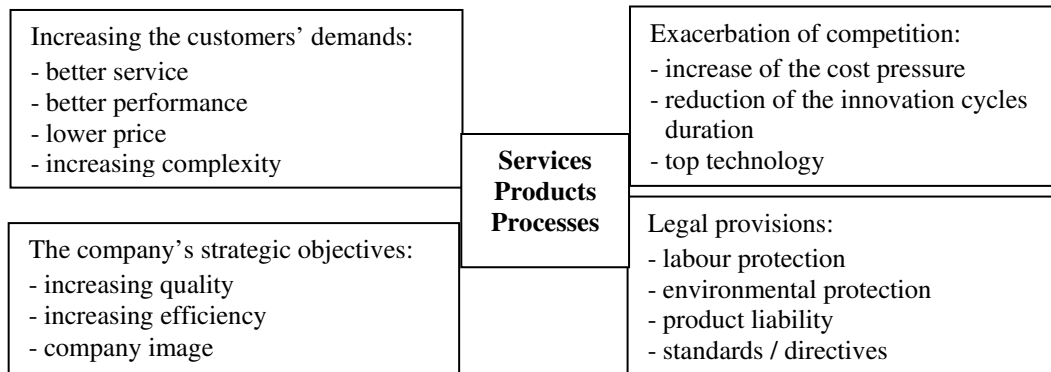

categories (stars or flowers or daisies), according to:

- constructive characteristics;
- facilities;
- quality of the services.

By virtue of the same order, managers must ensure a wide range of additional

services included in the accommodation price or paid separately. While for the 4-5-star hotel units the insurance of at least 15 services is required, for the 2-star hotel units the provision of at least 8 services is required.

Figure 1. The causes of increasing the quality requirements

Stănescu, D., Voicu, O.-L., Sztruten Gilet, G.,
Particularități tehnologice în serviciile de alimentație
(Technological characteristics in catering services),
 Ed. Universitară, Bucharest, 2008, p. 91.

3. The strategy for improving the service quality in the tourism and hospitality industry

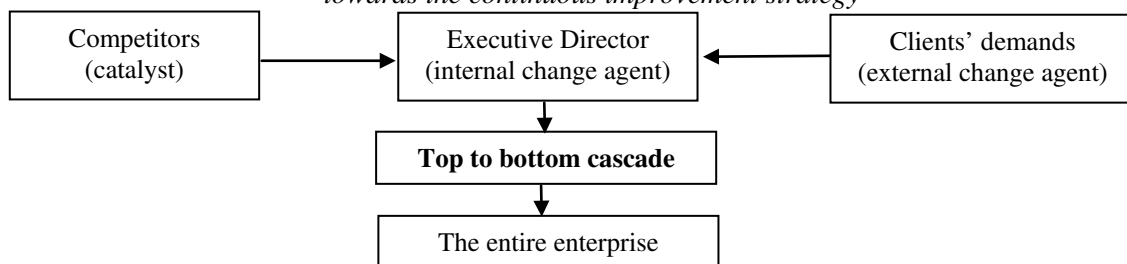

The improvement of quality aims at achieving higher levels of performance as compared to the ones provided by the standards. In an organisation the implementation of this strategy depends on a number of factors:

- orientation towards results;
- management through processes and facts;
- staff involvement and creating an appropriate culture for each employee's

- participation in quality improvement;
- training-innovation and development of partnerships;
- public accountability by using an “ethical approach” which involves the long-term satisfaction of the organisation and of its staff [4].

If the strategy of continuous improvement becomes a state of mind for each employer, the high level of tourism products quality will be felt in a relatively short period of time [1].

Figure 2. The role of the market in directing the organisation towards the continuous improvement strategy

Ciobanu, V., *Cum îmbunătățim calitatea. Ghid practic*
(How to improve quality. Practical guide), Ed. Economică, Bucharest 2009, p. 13

On a strongly competitive market, the tourism service organisation is motivated to adopt the continuous improvement strategy (fig. 2).

The satisfaction degree felt by a tourist while using travel services depends to a large extent on:

- the skill of firms in the tourism and hospitality industry to offer and perform services at the right place and time;
- the serving staff's professional ability to distinguish the tourist services through an individual mark;
- the existence of the adequate conditions for performing the services required (natural conditions, material basis, equipment used);
- creating the conditions to facilitate the active participation of tourists in the consumption of services.

The national programme of increasing the quality of hotel services and of launching the “Q” mark had an important role in fostering

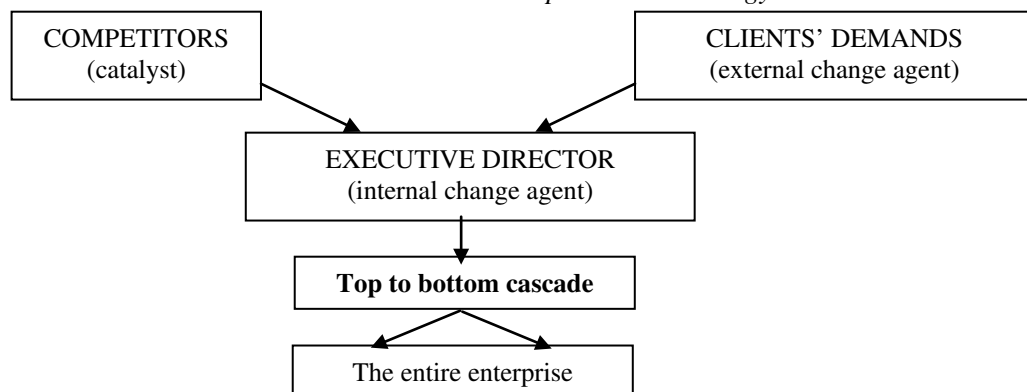

the improvement of the tourist services quality.

The actions included in this programme implemented in 2004 by the Ministry of Tourism were directed towards:

- printing the quality certification criteria for the hotel services and their dissemination towards the economic agents;
- preparation and printing of the good practice guides in order to implement and certify the quality of tourism services;
- empowering the structures necessary to grant technical assistance to the economic agents working in the hotel industry in order to obtain the “Q” mark.

The implementation in Romania of the hotel quality certification system aimed at increasing the competitiveness of the respective companies and achieving a high level of customer satisfaction.

Figure 2. The role of the market in directing the organisation towards the continuous improvement strategy

Ciobanu, V., *Cum îmbunătățim calitatea. Ghid practic (How to improve quality. Practical guide)*, Ed. Economică, Bucharest 2009, p. 13

4. Qmark – method of certifying the excellence level in the hospitality industry

AJA Registrars Romania, certification and training body in the management systems, accredited internationally, has directed its efforts towards developing new standards, namely “Quality marks” in various fields [7]. The standards are designed for the companies

which want to reach the level of excellence in terms of their own management system.

Thus, we notice the importance of granting the “Q” mark to the hotel units that prove management, technical and financial abilities, but also dispositions for qualified and competent staff that shows respect for the client (fig. 3).

Figure 3. The graphic image of the quality certification mark for hotels and accommodation in hotels

<http://www.qmark.ajaregistrars.ro/turism/>

The principles underlying the granting of the Qmark take into consideration:

- consumer protection against practices that place first the price and then the quality;
- health and social responsibility;
- safety and concern for the natural environment.

Moreover, quality brands in tourism exist throughout the world: *Qualmark* (New Zealand), *SATSA* (South Africa), *Qualité Tourisme* and *Hotel Cert* (France), *Quality Rose* (UK), *Q Calidad Turística* (Spain), *Authentic Bulgaria Quality Mark* [7].

In Romania, hotel units must meet a set of requirements applicable to their own management systems in order to obtain the “Q” mark, namely: very critical requirements, critical requirements and uncritical requirements. These requirements are expressed and ranked in relation to the definition and implementation of the following elements:

- management (planning, organisation and administration of resources, marketing, quality control and quality continuous improvement);
- accommodation (general and specific requirements, human and material resources, booking, permanent relationships with the customers, billing and departure);
- food services (catering supply planning, handling, preparation and serving);
- events and entertainment;
- maintenance and cleaning;
- supply.

Thus, in order to meet the requirements at least in a minimum of 85% out of the maximum score the *QMark Approved* is granted, and in order to meet the requirements between 70% to 85% the *QMark Applicant* is granted [7].

5. Conclusions

Tourism and hospitality industry can become an important part of the Romanian economy if a level of awareness directed towards the selection of the local services is created.

The positive feedback and the tourists’ satisfaction may represent key elements in promoting the Romanian tourist products. The consumer will knowingly choose the services package that will meet his/her standards and that will even exceed his/her expectations. This becomes possible in the context in which the operators from the tourism and hospitality industry agreed to implement an efficient quality management system in which all activities are focused on quality and continuous improvement.

Qmark, guarantor of the management system certification, reflects the tourist’s requirements and demands, policies of quality, environment and safety, responsibility of the service provider and the awareness of the law enforcement bodies that tourism must become a driving force of the national economy.

Directions for Improving the Quality of HealthCare Services in Times of Economic Instability

Zanfir Adriana

The Bucharest University of Economic Studies

zanfir.adriana@gmail.com

Marinescu Mihai

The Bucharest University of Economic Studies

mihai.marinescu@adpharma.com

Abstract

At international level, the economic and financial crisis has created strong imbalances in any activity field. Just like the rest of the developing countries, Romania has felt the most negative effects, especially that failed to develop a coherent anti-crisis strategy. In this context, the services had registered a significant decline, becoming one of the most affected sectors.

Unfortunately, no area of public services has been spared by the financial problems, the most serious deficiencies were recorded in the healthcare sector. Superimposed over an existing financial deficit, the economic crisis has accentuated the old problems and created new ones. Therefore, we consider it is essential to draw attention over the directions for improving the quality of health services to prevent the collapse of the Romanian healthcare system.

Key words: economic crisis, health care services, sanitary system, the healthcare quality improvement.

J.E.L. Classification: I12, I15

1. Introduction

Strongly affected by the economic crisis and weakened by political tensions in recent time, the economic situation of Romania has serious signs of instability. National currency depreciation is one of the most important indicators that show that the financial sector is in a down trend. Economic forecasts for 2013 are not at all encouraging, most analysts think that the real

economic growth prospects have diminished in a considerably way. In the context in which the direct investment decreased from the same period last year, even the most optimistic economists dare not to hope for relaunch and economic progress.

There are some sectors of the economy that still feel the repercussions of the economic crisis and facing financial difficulties. The drastic situation will be prolonged by inability of the National Bank to make substantial capital inserts in these sectors. It is noted that the services field still has time to suffer. The end of 2012 is characterized by restructuring the budget, but funds are insufficient even for key sectors of the economy. Unfortunately for the population of the country the health sector is by far the worst affected.

For the medical field, financial and economic problems have become a real stress factor. At the macroeconomic level often appear many warning signs of a possible crisis of the health system. Financing beneath the system necessities, the current personnel deficit, labor migration or overloading the health professionals, are just a few elements that show us the possibility of a crisis in the health system.

2. Impact of economic crisis on health systems of the European Union

The global economic crisis has created a series of financial setbacks that have hindered the proper functioning of health systems. Shortly after beginning, the crisis has been a strong threat to health systems, especially for the countries with emerging economies. No country from the

community space has escaped from these repercussions.

Romania is not the only country member of European Union affected by imbalances from the system. Just as the analysts from the medical field had anticipated, in countries with low-income, where a devaluation of the national currency has been registered, there was an increased risk of onset of medicinal products crisis because of high prices of imports. The states where the population has a high aging level, have registered higher spending in the health sector.

Many other countries, including those with sustainable economies, have been forced to make significant efforts to respond to the financial pressures in the health system (Table 1).

Table 1: The main effects of the economic crisis on the health system in some EU countries

Countries	Effects
Austria	overall decline in financial resources
Belgium	appeared the need to save funds
Estonia	lower wages: negative impact on the collection of contributions for health (98% of revenues of the Health Insurance Fund are from wages)
Denmark	health budget showed the smallest increase in three years
Finland	effects of the crisis were very small because the budget was built largely from taxes
France	the lowest budget for social security
Hungary	negative impact on health determinants

Source: Report of European Hospital and Healthcare Federation. 2011. *The Crisis, Hospitals and Healthcare* [6]

Rising unemployment and the pay cuts have reduced the contributions for the health budget and the number of private insurance.

The shock was quite high especially since it came after a period of growth and economic stability, in which the health funds were designed to ensure the sustainable development of the sector.

Therefore, a fast intervention of National Governments was required to reduce the risk of some vulnerabilities of health systems (Table 2).

Table 2: Measures taken to reduce the effects of the crisis in the health system

Countries	Measures
Austria	lower expenses for the healthcare sector of approximately 1.7 billion euro
Belgium	healthcare budget was not reduced, but increased by a rate equal to the rate of inflation
Estonia	orientation to primary health care services
Denmark	reducing healthcare expenses
Finland	improving management of health system
France	limitation of healthcare expenses
Hungary	particular attention in using the EU Structural Funds on “New Hungary National Development Plan”

Source: Report of European Hospital and Healthcare Federation. 2011. *The Crisis, Hospitals and Healthcare* [6]

However, a retrospective look at the health systems of the European Union show us that the measures taken to overcome the difficult situation had some negative effects for the community space citizens (the cost of hospitalization and care significantly increased, medicinal products prices became higher compared to previous years, direct payments for different treatments have increased, the co-payment for some services was introduced, etc). European countries with strong health systems had approached economic crisis in a strategically way. Long-term vision comes from the fact that these countries were not quick to implement austerity measures in the health system, but have tried wherever possible to reduce the expenses and improve management processes.

Basically, those countries adopted an opposite strategy from that adopted by Romania. Recent research has shown that the main causes of the crisis deepening in the Romanian health system were too small amounts allocated annually for health and inefficient management of the whole

system [4]. These had started from the idea that the health of the population is extremely important and is directly reflected in the remaining areas of activity. Some researchers see a relationship of mutual conditioning between health and economy of a country which means that “*whereas economic development determines the development of new sanitary objectives while medical units contribute to improved performance in production processes by providing work capacity*” [1]. During the recession, all countries above were mainly directed towards identifying ways to improving the quality of health care services provided to patients. With more or less both reaping of the negative effects of economic crisis, developed countries have realized a fundamental thing, that some authors do not cease to sustain: “*our needs have diversified in a continuous technological development and it became more and more difficult to satisfy them with the help of traditional means*” [2].

It is obvious that this way to approach the difficult situations will give a lot of benefit in the long run in a so sensitive field, in which non-quality means important losses.

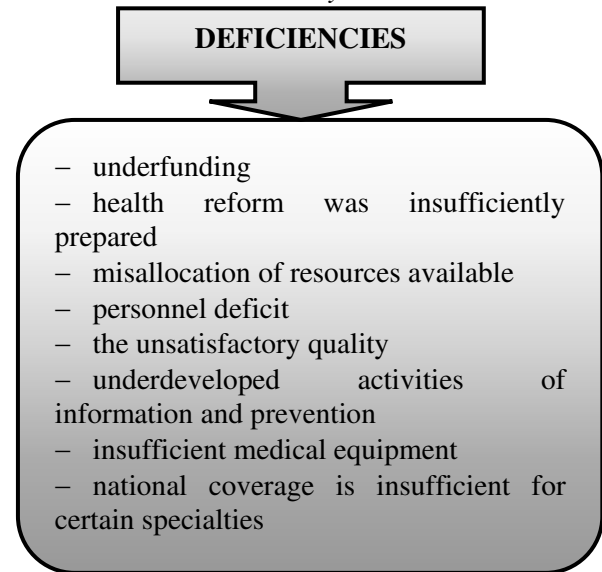

In the new economic context, attention was directed to the hospitals, the largest consumers of system resources. Thus, the legislative changes and most current reforms were aimed at a clear goal - efficiency of the activities. Pressure on hospitals has increased considerably, being forced to provide superior health care services in terms of quality (to meet the needs of patients), but with the lowest cost (to be able to budget).

Some analysts of the Romanian health system believe that the repercussions of the economic crisis on developed health systems from the EU were presented in an exaggerated form, since all these countries are over Romania in any statistics related to services quality, supply funds, working conditions, medical equipment, etc ...

A comparative analysis of the EHCI Index (Euro Health Consumer Index) achieved annually at a European level, focused on the respect for patient rights, accessibility to health services, the results of the health system (number of deaths from heart attack, infant mortality rate, number of caesarean operations, etc..) and on the preventive medicine, etc... Following the accumulated score (489 points), Romania ranks 32 of the 34 European countries analyzed [7].

It was impossible for the Romanian health system to occupy one of the top positions since we have a large number of deficiencies (Figure 1).

Figure 1: Deficiencies of the Romanian healthcare system

Source: Academic Society of Romania: Report “*Crisis and reform in the healthcare system*”, 2010 [8].

Whether it was the programs or projects initiated by the Ministry of Health that were not carried out successfully, or the goals of the last years reforms have not been met, but it is certain that in order to reduce the deficiencies, those were further strengthened. So, a quite legitimate question in this context arises: What can we do to reduce deficiencies in the system?

3. The Romanian healthcare system - Directions for improving the quality of healthcare services

Statistics show that in Romania there has been a decrease of 18% of funds from compulsory health insurance, that affected the health budget which was anyway below the European average. Due to limited resources the hospitals were left without a large number of beds, employment was blocked for a period, patients had to buy themselves their medicines or medical supplies that should have been received freely way in the hospital. President of European Health Forum Gastein, an institution which is oriented to the implementation of health policies and cross-

border exchange of experience in the medical field, said recently that there is not a viable solution to reduce hospital budget and the measures should be aimed to a better use of existing resources, rethinking structures and creating of a more efficient system [5].

Even in this period of economic instability, we can apply various measures to improve the quality of health services:

➤ **standardization of medical practice** – to improve the hospitals` activity. Personal deficit correlated with the increasing complexity of medical cases require the standardization of medical practice, where possible. Internationally, the most used standardized tools are the medical practice guidelines and the therapeutic protocols. The medical practice guidelines contain recommendations that help the doctor to decide which healthcare and treatments are the best. Some authors define the guidelines as a "*set of rules about the diagnosis and treatment of certain diseases*" [3]. Therapeutic protocols are more standardized and include registration in time "*of some processes (medical exams, medication, treatment) needed to obtain a desired outcome from a patient who has undergone a particular procedure or treatment*" [3]. For our country the efforts to standardize activities officially began in 2005, quite late compared to developed countries. Methodology for developing the medical practice guidelines is quite complex and must follow a series of well determined steps. A quite large period of time was necessary until the Ministry of Health was able to provide the necessary guidelines for practitioners. Regarding therapeutic protocols, the situation is slightly more complicated. Most times, our protocols are different from those used by developed countries, being confused with the medical practice guidelines. The protocols content, instead of being very strict and with a clear evidence of treatment, is designed just for guidance, that means a low efficiency. Preparation of clinical protocols in a similar way with those used by countries with strong systems will significantly contribute to the activities efficiency and quality improvement in hospitals (especially, because they are constructed from the results of evidence-based medicine).

➤ **create a comprehensive legislative framework (including application procedures)**

for private health insurance. With high financial potential, the private health insurance sector should be regarded with more interest. Also, there is a need for a good regulation with clear application rules. Encouraging of private insurance will bring multiple benefits such as reducing the pressure on public hospitals, stimulating competition between suppliers, improving quality of care, increasing patient satisfaction, etc...

➤ **medical staff motivation** – has become a mandatory requirement for improving the quality of health services, in the context where the staff deficit is quite high. Although the medical staff is a key element of the health system, we lack a human resources policy clear contoured. This is reflected in the increasingly large number of doctors who choose to leave the Romanian system which they consider completely unattractive. Working conditions and wages below the EU average are only two things which amplifies the migration phenomenon. Is absolutely necessary to increase the wage of medical and auxiliary staff. Obviously, the financial situation does not allow that this to be done suddenly and with a high percentage. But, we have to conceive a gradually increase strategy, so we can get in the coming years to have comparable salaries with other European countries. Otherwise, we risk that the situation from rural areas, where we have many uncovered specialties, to be a general one.

➤ **implementing a quality management system in all hospital units.** Country membership of the European Union requires us obtaining, assuring and continuous improvement of quality. Quality management aims at providing health services that meet the needs of patients, improve health and increase satisfaction for all stakeholders. The sanitary units which wish to obtain performance in the medical field must have a certified quality management system.

Implementing a quality management system according to ISO 9001:2008 in all hospital units would produce significant changes in the conduct of activity. Adapting quality management principles to the specific of medical field is a first step in building an organizational culture where quality is the strongest value. Implementation of ISO 9001:2008 will implicitly lead to a better performance of the hospital management indicators and increase confidence in that unit.

Part of the general management system, quality management system, includes all management processes based on structured documentation, the main goal being orientation towards quality of the units.

4. Conclusions

Building of a solid healthcare well-formed system should be the main priority of Romania in the near future. The imbalances had deepened the crisis and had created new financing problems in the system, a chapter where we already were deficient. At this point we are very near to the in collapse of the health system if there will not be taken urgent measures.

The directions to improve the quality of health services above are just a few ideas to draw attention to the fact that reducing funds is not a way out of the crisis, but adopting a viable strategy to reduce deficiencies from the system, so as to strengthen it.

Abstract

Annual financial statements represent an accounting instrument of great importance in the management activity, being necessary for both the substantiation of decisions on allocation, financing, use and recovery of funds and the organization of control over the implementation of the decisions taken, as well as for the establishment of certain rights and obligations, liabilities arising from the management and development of the patrimony. The fundamental condition that annual financial statements must meet is to reflect reality, regarding both the elements of active and passive at the disposal of economic operator.

Importance of financial statements is given by the usefulness of the information provided by them, which often are the only ones that users have access to and on which they must base their economic decisions and justify the use of their financial resources..

Keywords: annual financial statements, the entity's performance, economic indicators, financial analysis, balance sheet.

JEL Classifications: M40, M41.

1. Introducere

In the context of reform and transition to a market economy, every enterprise, regardless of size, sector or form of ownership, is facing a number of issues concerning the environment in which it operates improvement of its economic and financial performance and competitive ability compared to other companies. Economic and

financial analysis plays an important role in achieving these objectives, contributing to acknowledgement of the status of various phenomena, identifying the factors and causes that determine some failures and taking the appropriate steps to adjust and optimize the economic and financial results of each enterprise by all the methods and techniques used.

Objectives of financial analysis derive from the fundamental objective of the business. Over many years, the fundamental objective of "maximum profit" has dominated the economic thinking and this has brought havoc to mankind both environmentally and socially. Nowadays, in market economy countries, the wording about fundamental objective is "increasing company's value," which means increasing shareholders' wealth for non-listed companies, on the one hand, and growth rate of securities for the listed companies, on the other hand. Such an objective implies a higher return, but at the same time ensuring liquidity, solvency and financial balance. The purpose of financial analysis is reflected in the financial diagnosis, which is part of the economic and financial diagnosis, oriented especially toward profitability and its related risks. Diagnosing the health of the company is a preliminary stage in its evaluation process.

2. Importance of analysis

The current global economy is characterized by a complex process of globalization, leading to an increased sensitivity and instability of markets and business environment that are generally

manifested by a deep economic - financial crisis in present days. Thus, many business entities are in difficulty, facing especially the weakening of their economic activity, along with the sharp drop in demand, financial bottlenecks in chain, more increased cost of credit, a volatility of exchange rate. In this respect, substantial changes are required in the macroeconomic management, but also within each economic entity.

The basic role of a company's financial management consists of making strategic financial decisions that would solve the problem of effectively managing the enterprise's process of optimum, balanced and proportionate growth. This is why it is necessary to make an objective and imperative analysis in order to establish the company's economic and financial diagnosis and its management control, which are key issues in any enterprise's orientation towards performance.

Manager needs accurate, complete and timely economic information to make the best decisions for a correct management of the entrusted resources so as to increase the performance of the entity.

Economic and financial analysis represents the general method used for the research of objective processes and phenomena based on their decomposition into parts and studying each of them. This contributes to raising the level of knowledge from the particular to the general, from the concrete to the abstract.

During the economic and financial analysis, information sources designed to ensure the achievement of a complete diagnostic of the researched entity are used. However, the information provided accounting, and in particular general accounting, remain the essential material used due for the diagnosis. Production of accounting information answers some strict legal stipulations, which are requiring economic entities to inform internal and external partners, even if, exceeding these requirements imposed by law, entities tend to assimilate their production of accounting information for a genuine financial communication strategy.

Financial analysis is in fact the assembly of procedures used for researching how business funds are purchased and used and financial results are obtained and used, its

final aim being to reveal the extent and intensity of the influence exerted by the determinant and conditional factors of the financial activity.

The purpose of financial analysis is to diagnose the financial position of an enterprise, namely to identify strengths, weaknesses, opportunities and risks manifesting at the enterprise's level from financial perspective.

The purpose of financial analysis is to:

- Identify ways to improve resource management;
- Be the basic source of information and decision when taking or granting a loan;
- Be the information source when buying or selling securities;
- Be the source of information for studying business partners (customers and suppliers).

Users of financial analysis are:

- company's management that aims to identify situations of financial imbalances that could affect the company's financial security;
- company' owners (shareholders) who want to know the evolution of their wealth and what gain to expect;
- Banks with which the company is in relationships. They are interested to know its reliability, meaning the security posed by the enterprise to recover loans from it;
- business partners (clients or suppliers) who change their strategic options depending on enterprise's financial situation;
- competitors who are interested in a company's financial status to strengthen their own positions on the market;
- central and local administrative bodies that are interested in the patrimonial and financial situation of a company, because it represents a source of income and a means of solving economic and social problems;

Unions, interested in the financial situation because it is the basis for negotiation of salary increases and conclusion of collective agreement.

3. Analysis based on the balance sheet itself

The balance sheet is a very important instrument in the management process, used

for decision making on the allocation, financing, use and recovery of funds, organization of control over the decisions, establishing rights and obligations, as well as making decisions regarding continuation of enterprise's activity. The balance sheet is also the most important synthetic document providing data centralization in a systematic and consistent form, allowing an overview, a detailed analysis and a control of the economic activity performed and of the results obtained at the end of each reporting period.

Balance sheet is the official document used in the patrimony's management, which should provide a fair, clear and complete image of its financial position. Using the monetary standard, it highlights the balance between economic goods and their sources of funding. Based on this, a number of economic indicators can be analyzed, such as:

Analysis of the assets' structure rates

- a) **Rate of fixed assets** measures the degree in which the capital is invested and is calculated as the ratio between the total of fixed assets and the total assets.

$$r_{Ai} = Ai/At * 100$$

where: Ai = Fixed assets
At = Total assets

- b) **Rate of current assets** expresses in relative values the level of the fixed capital in the operating process, which, due to the fact it is renewed after each cycle of operation, is called working capital.

$$r_{Ac} = Ac/At * 100$$

where: Ac = Current/Circulating assets
At = Total assets

The following relation exists between the rate of current assets and the rate of fixed assets:

$$r_{At} + r_{Ac} = 100$$

Analysis of Liability's structure

a) **Financial Stability Rate** reflects the permanent/fixed capital's share in the total of financing sources. Permanent capital consist of equity and capital borrowed for longer

than one year, which is why they are also called stable source of funding.

$$r_{sf} = Cpm/Pt * 100$$

where: Cpm = permanent capitals
Pt = total liabilities

Company's financial stability is even greater as the rate is closer to 100.

b) **Rate of financial autonomy** highlights the extent to which funding sources belong to the owner. The own sources have an important share in the total of financing sources, the company's financial autonomy is higher. There are two types of financial autonomy, namely:

- Global financial autonomy when company's own sources are compared to the total of financing sources;
- Financial autonomy at term when company's own sources are compared only with the permanent sources borrowed.

c) **Leverage Rate** expresses the debt that the company has in relation to total financing sources or with its own sources.

Creditworthiness Analysis

Liquidity refers to the ability to cover short-term obligations, while solvency is to cover long-term obligations.

Liquidity is defined by two principal characteristics:

- Specificity of assets, which have the capacity to transform into money to a greater or lower extent;
- Destination of liquidity; in this regard, liquidity is defined as the company's ability to cover from its most liquid assets the short-term obligations.

The assessment of liquidity level is most commonly done, according to the specialized literature, by using three indicators (ratios):

- Current Liquidity represents the ability of the company to cover short-term obligations using current assets, calculated as the ratio between average current assets and average current liabilities:

$$l_c = Ac/Pc$$

Ac= average current assets;
Pc= average current liabilities.

- Quick Liquidity represents the ability of the company to cover short-term obligations using current assets that can be quickly converted into cash, calculating the ratio between average liquid current assets and average current liabilities:

$$l_r = (Ac - St) / Pc$$

where:

Ac = average liquid current assets

Pc = average current liabilities

St = Stocks

- Immediate Liquidity represents the ability of the company to cover short-term obligations from its availability, being calculated as the ratio between the average availability and current liabilities:

$$l_i = Disp / Pc$$

where: Disp = Average availability;

Pc = current liabilities.

Patrimonial solvency reflects the company's ability to honor its obligations on medium and long term, to provide the financial resources able to support long-term continuity of its activity.

SP = Social Capital / (Long and Medium Term Loans + Social Capital)

4. Performances of a company

The concept of economic performance includes several elements that characterize the finality of lucrative activities such as: profitability, productivity, competitiveness and economic growth. To synthesize all these elements it can be said that "an enterprise is theoretically efficient when it is productive and effective at the same time."

By the analysis of its results, two components of the economic performance status can be resolved:

- Economic growth, seen as the company's ability to increase its workload, fact reflected by the analysis of all results expressing volume (value of physical production, turnover, value added);

- Profitability, regarded as the company's ability to effectively carry out its economic

activities.

In order to deliver relevant considerations regarding these aspects of performance status, it is necessary that analytical work to be oriented towards the following objectives:

- analysis must be complete, meaning all relevant elements of the situation analyzed must be taken into account, problems and opportunities must be identified, alternatives must be submitted and evaluated;

- analysis involves evaluating and interpreting from economic perspective the situations and events that are being analyzed;

- fill in the lack of information is achieved by reasonable assumptions;

- competent analysis is the one which avoids the confusion between symptoms and problems, opportunities and actions;

- analysis should be the basis for setting some realistic goals and ensuring the recognition of all possible alternatives to achieve these objectives.

5. Conclusions

The main role of the analysis of information provided by annual financial statements is to assess the performance achieved at a given time by a company, to identify factors that lead to failure of achieving the predetermined performance level and to determine the intensity of their actions, so that unfavorable factors can be eliminated and factors with a favorable influence can be maintained.

Merger Strategies of Economic Entities: Fiscal and Accounting Consequences

Baba Camelia Mirela

“Transilvania” University of Brasov

Faculty of Economic Sciences and Business Administration

mirela.baba@unitbv.ro

Abstract

This paper addresses the issue of economic entities' mergers, in legally terms, and especially in terms of accounting and taxation. With the help of the analysis of twenty merger projects, initiated during the year 2012, there were identified and highlighted features of this reorganization strategy in the economic activity in Romania.

Key words: merger, taxation, accountancy, strategy

JEL classification: M41

1. Introduction

The paper, through its approach, brings into discussion the strategic view and foundations of economic entities' mergers, a form of reorganization commonly encountered in Romania over the last decade. Merger is presented as an alternative for companies in financial difficulties as a way to financially rescue their businesses. Also, there are presented theoretical and practical aspects related to the recognition of each phase of the process, in accounting.

The development and spreading of the financial crisis (crisis characterized by economic and financial problems and lack of liquidity) and the instability of the business environment led the economic entities to find solutions for their business reorganization in the form of national and cross-border mergers and acquisitions.

Especially small companies, left without funding, are required to find alternatives to restructure and reorganize their business in order to survive, so they are usually absorbed by other larger bodies which are stronger from an economic point of view. The law

regulating trading companies stipulates that merger is the process by which an economic entity extends its business by combining two or more entities into one. The newly formed society can be founded in two ways: absorption and combination.

Absorption merger is achieved when a company called absorbing company absorbs one or more companies, called adsorbed companies. In the case of merger by absorption, the company that absorbs acquires all the rights and obligations of the company that is absorbed. Combination merger occurs when two or more companies decide the establishment of a new society through assets and liabilities transmission on to the newly established company. In case of combination merger, the rights and obligations of the companies that shall cease to exist pass on to the newly established company.

All details of the merger are included in the project of merger, from the description of the parties involved (name, ownership structure, office etc.), the conditions in which the merger takes place, the valuation of assets, liabilities, equity, exchange ratio, merger premium and the rights assigned to implied parties.

2. National and International Regulations regarding Mergers

Merger operations of economic entities in Romania are legally regulated by Law no. 31 of 1990 regarding trading companies, republished, in which there are provided the general conditions for conducting a merger. The Ministry of Public Finances develops rules concerning the merger, division, dissolution and liquidation of trading companies, as well as the withdrawal or exclusion of some associates of the trading companies. The order governing the

accountancy and taxation of reorganization operations of businesses is Order of Public Finances Minister 1376 of 2004. Accounting implications regarding the merge of economic entities in Romania are set out in Order of Public Finances Minister 3055 of 2009, accounting regulations being in compliance with the European Directives. The European Directives related to mergers represent the legal framework at EU level for this type of business reorganization. Article 3 of Directive III (October 9, 1978) regarding the right of trading companies, defines absorption merger as Article 4 defines combination merger as well. Taxation of mergers in Romania is provided by the Taxation Code and covers issues related to: profit taxation, dividend taxation, fiscal losses and value added tax.

From a fiscal point of view, on the 23rd of July 1990, the Council Directive 90/434/EEC was adopted, regarding the common system of enforcement applicable to mergers, divisions, transfers of assets and exchange of shares involving entities from different Member States of the European Union.

3. Fiscal and Accounting Aspects of the Mergers in Romania

Excepting legal and commercial issues/implications of mergers, the partners in this process should also emphasize on how these operations are reflected in accountancy, respectively in the financial statements.

According to the methodological norms regarding the Recognition of major merger operations, the steps that are followed in the case of a merger are: inventory and valuation of assets, liabilities and equity of companies to merge, preparation of financial statements before merger by the companies which are to merge, the overall assessment of companies and determination of net assets, determination of exchange ratio of shares or of the social parts, determination of number of shares or of social parts to be issued in order to pay the net contribution of the merger, the merger premium calculation and recording in accountancy of the economic transactions specific to mergers.

For assessing the companies that have entered the merger, one of the following methods can be used: patrimonial method or the net asset method, stock method, the

method based on results (return value, yield value, supra-profit value), mixed methods and the method based on financial flows or cash flow. The overall value of the company established by one of the methods mentioned above represents the value of the net merger assets of each company in the merger. This value is determined based on the exchange ratio. To highlight the transferred assets and their removal from administration, result accounts are used (in case of using outcomes method) or off-balance sheet accounts (in case of using accounting net worth method). The increase by value of the assets is shown in the income statement or 121 "Profit or loss" (method result) or account 105 "Revaluation reserves" (net worth method of accounting). Transmission of equity elements is performed using the account 456 "Settlements with shareholders/associates regarding the capital" and of the liabilities elements with the account 461 "Various debtors" (method results), or off-balance sheet accounts (net worth method of accounting). The increase of assets value, in the case of absorption merger, is highlighted with the help of the account 207 "Goodwill". The acquiring company highlights the merger premium as the difference between the value of the acquired company's contribution and the amount of the capital increase in the acquiring company.

Accounting regulations in accordance with the European Directives, approved by Order of Public Finances Minister 3055 of 2009 provide that the revaluations made during the reorganization of companies (mergers/divisions) will not be understood as accounting revaluations, but as circumstances under which financial transactions are carried out, in this way a revaluation during the year in case of a merger/liquidation is not recorded in accountancy. In this context, the evaluation results will not be included in the financial statements. The exception applies only if the data compiling the annual financial statements comply with the one of the financial statements prepared for the merger.

Negative accounting net assets of the acquired company may be acquired by the acquiring company through the retained earnings account, thus leading to a reduction of equity held by the latter (absorbed

company) and an increase in the degree of indebtedness.

Fiscal aspects

In case the companies involved register losses this may have tax consequences at the level of the involved entities. According to regulations (effective from 1 October 2012 Government Ordinance 15/2012 amending and supplementing Law 571/2003 regarding the Fiscal Code) the fiscal loss recorded by taxpayers which cease to exist as a result of a merger or division are recovered by the new formed taxpayers or by those who take the patrimony of the absorbed or divided company. Recovery is proportional with the assets and liabilities transferred to the legal beneficiary, according to the draft of merger/division.

Revenues from the transfer of assets (account 7583 "Revenues from the disposal/transfer of assets") are not taxable under the provisions of the Fiscal Code. Similarly, the expenses regarding disposed assets (account 6583 "Expenses concerning disposed assets") are non-deductible expenses. In accordance with the provisions of the Fiscal Code, reduction or cancellation of any provision or of the reserve that was previously deducted at the determination of the taxable profit is included in the taxable incomes of the acquired company, unless the absorbing company takes over that provision or reserve. According to the Fiscal Code, the acquired company must submit the tax statement and pay the income tax 10 days before the date registration of the end of existence at the Trade Registry. The acquiring company uses in determining the taxable profit the fiscal values of the assets and liabilities submitted by the acquired company. For the depreciable fixed assets the acquiring company will have to apply the same regime of depreciation that would have been applied by the company being acquired if the merger would not have occurred.

In case the amount of the legal reserve provided by the Fiscal Code, resulting from the merger, exceeds one-fifth of the subscribed and paid capital of the acquiring company, the difference is not treated as a taxable income as long as this reserve is maintained at the resulting value.

The transfer of assets is subject to VAT, so that the legal person transferring the assets in case of a merger could be required to pay

VAT on those assets transferred (when it's not registered as a VAT payer).

4. Research Methodology

This paper, through its study, seeks to answer a series of questions about the reorganization of economic entities through merger, namely: What are the reasons for which companies merge? What are the advantages and disadvantages of merging companies? What are the financial, accounting and taxation effects of mergers? The aim of the study is to identify the conditions, reasons and the means by which economic entities in Romania merge, the analysis took place in the late 2011 and the first half of 2012. There were analysed 20 merger projects submitted to the NTRO (National Trade Register Office) of Romania between 2011 and 2012. The purpose of the analysis of merger projects was to obtain information regarding: links of participation of the entities involved in the merger, their ownership, field of activity, considerations of the merger, the financial results of the companies involved and the consequences of the merger.

5. Merging Decisions

The decision to merge is taken after a series of analysis have been made: of the financial health of the company (analysis of financial statements), analysis of the degree of compliance with laws, business management analysis, analysis of accounting and taxation consequences involved in the merger process. Certain aspects regarding disputes with third parties or debts to them, possible violations of law, sudden changes in turnover, termination of certain collaborations with expert accountants or auditors, may influence the decision to merge. In order not to expose themselves to unpredictable risks, accounting professionals will analyse financial statements to determine the financial health, management work will be reviewed to draw conclusions on the reliability of the entity and the quality of the work, and they will examine the records and transactions and analyse the degree of compliance with accounting and tax legislation in force.

The merger represents the result of the objectives proposed by the management of the entity and usually targets: strengthening the market position and the elimination of competition, survival of entities facing difficulties, long-term profitable growth, cost reduction and other objectives.

Advantages and disadvantages of the merger of economic entities

National practical experience revealed a number of advantages and disadvantages of the merger of economic entities, weaknesses and strengths, summarized and presented in Table no. 1.

Table 1. Advantages/disadvantages of the merger

Advantages	Disadvantages
<ul style="list-style-type: none"> ☞ Increase of market share and of the number of customers; ☞ Opportunity of market penetration in new geographic regions; ☞ Competitive advantage, avoiding hostile competition; ☞ Diversification of the existing business and of the product portfolio; ☞ The opportunity to benefit from new technologies; ☞ Rationalization of production and distribution techniques; ☞ Greater opportunities to invest in research and development (thus leading to increased quality of products and services); ☞ The opportunity to gain a better trained staff and a better management; ☞ Increased ability to contract loans; ☞ Improving efficiency by reducing costs and increasing profitability and profit; ☞ Shares of larger companies are more 	<ul style="list-style-type: none"> ☞ Merger may lead to the loss of some employees, there is the risk of job loss as well; ☞ Reorganization can decrease the productivity of the existing employees (working climate changes); ☞ Interest conflicts may appear; ☞ Keeping the same management team may not involve large changes in the new created society.

<ul style="list-style-type: none"> marketable than the ones of the smaller societies; ☞ The opportunity to benefit from fiscal advantages; ☞ The possibility to rescue entities that are in financial difficulty.

Source: original

6. Research Results

The data concerning the merging projects has been collected from the publications made on the website of the National Trade Register Office, and the data regarding the financial position and performance (financial statement) were taken from the website of the Ministry of Finance. The financial statements of the companies involved in the merger have been produced at the end of 2011 (three of the merger projects), and most were made in mid-2012. All the 20 merging projects dealt with merger by absorption of economic entities. These projects assumed the involvement of 20 absorbing companies and 33 absorbed companies.

The conducted study also presents some limitations because of the fact that the available technical or financial data were not sufficiently detailed.

The objectives of the research have some main aspects, presented below:

1. Ownership links between entities

From the analysis of the 20 merger projects, we found that the companies which have entered a reorganization process through merger have at least a common associate/major shareholder and the acquiring company holds securities in the company being acquired (there is a relation of participation between entities). Only two of the cases analysed take into account companies which have no links or common associates between them. The acquiring companies usually have control over the acquired companies, so that the merger motivation is to simplify the decision making process, to streamline the process of execution and reduce administrative costs by forming a single structure in which all the forces of the companies involved are engaged.

In most of the examined cases, in the merging process were involved just 2

companies (75% of the cases) as involving several entities is more difficult to achieve and hinders the coordination of the activities. Most entities that merged are limited liability companies, and most mergers were made between companies with the same legal form of ownership (70% of the cases are made between limited liability companies, 10% between joint-stock companies and 20% of them have different forms of ownership).

2. Fields of activity of the merging companies

The identity of the primary or secondary activity objective of economic entities often represents the reason of their merger. Complementary activities carried out by the companies that have entered the merging process enables them to strengthen their market position, thus becoming a significant presence on the market of their activities, being able to successfully compete on the national level with the leading companies in the field. The acquiring companies are usually looking towards companies that have the same field of activity in order to join forces in the same direction and face competition.

The fields of activity of the analysed companies, involved in the 20 merging projects herein presented, are quite different, such as: hotels and accommodation facilities, business consulting activities, trade of pharmaceutical products, trade with meat, beverage and tobacco; construction, furniture manufacturing, waste treatment and gambling. But the most encountered ones are: trade with alimentary and non-alimentary products, tourism activities, business management services and business consultancy.

3. Considerations of the economic entities' merger

From the analysis of the merger projects, it can be seen that there is a variety of reasons that may lead to merger. The merger is made by the simplification of the decision making process, the reduction of parallel structures and of management and by an increase in the efficiency of the managerial decision. In other cases the merger is motivated by the reinforcement of the two or more companies competing in relation to other entities. Companies operating in the same field of activity and that produce the same economic goods decide to merge in order to win market

share, to control the market, the prices and the amount of products.

Besides the reasons presented above, the base of the merging process is also represented by the following economic, financial and strategies reasons: occupying a leading position in the relevant field of activity; cushioning the impact of the financial crisis; improving the efficiency of the acquired company which on the date of the merger recorded losses; extending the activity of the absorbed company; increasing financial and technological power by sharing the resources and the knowledge; simplifying the accounting; saving human and financial resources by eliminating bookkeeping operations regarding reciprocal transactions and simplifying financial reporting; reducing administrative costs (the number of executives and administrators) by the simplification of the administrative structure; increasing the financial power necessary to take bank loans with lower interest rates; for the company being acquired the chances to get cash dividends increase; increased profitability and efficiency (cost reduction, growth of capital, etc.); merger would help the companies to save money by making common various activities, etc.

4. The financial results of the entities involved in the merger

Financial and economic benefits that the acquiring company pursues, through merger, are more difficult to obtain provided that the absorbed companies record a negative net contribution or if they register losses. Of the 33 absorbed companies that were analysed, 54% recorded negative net assets and 69.70% have recorded current losses, meaning that they faced with financial difficulties in the analysed period. Some of the absorbed companies said (drafts of merging projects) that they encountered financial difficulties which made them unable to pay, which is why they turned to this form of reorganization.

In most cases the acquiring company holds an economic and financial power higher than the one of the acquired company. After the merger, the acquiring companies receive, in most cases of merger, important values of the merger premium and reserves. Thus, from a net contribution taken over from the absorbed companies, a small part corresponds to them in the form of titles and the biggest part goes

to the absorbing company in the form of merger premiums. The merger premium represents a payment from the shareholders of the absorbed company in order to become shareholders of the absorbing company.

5. Consequences of the merger

In most of the analysed cases, the merger involved neither redundancies nor changes in the working conditions. The employment contracts of the employees of the absorbed companies continue their existence and applicability. Merger may have as a consequence a change in the ownership structure, as well as a change in the legal form of the ownership.

Gugler K., and al. (2003) analyzed the effects of mergers around the World, over the past 15 years, and the results of their study show that “Mergers, on average, do result in significant increases in profits, but reduce the sales of the merging firms, and conglomerate mergers decrease sales more than horizontal mergers” [1].

7. Conclusions

The aim of the study was to identify the characteristics of merger projects initiated in late 2011 and the first half of 2012. From the conducted analysis we can conclude that the cushion of the financial crisis and the financial difficulties faced by entities were not the main reason for the merger, but their main focus was driven by the desire to gain as much market share as possible and to streamline the entire activity (to simplify the decision making process). Companies involved have decided to initiate the merger process in order to ensure a unique and coherent approach to their activities.

The merger is also seen as an alternative for the recovery and rescue of financially fragile entities. In order to handle the lack of liquidity, companies seek for different solutions in order to reorganize the business they manage. Economic entities are subject to a whole series of factors acting at all the levels, both inside and outside the firm and that they have to deal with, otherwise they are threatened with their removal from the market.

An important effect of the merger is represented by the significant decrease of the administrative and operational costs, with implications for the company profitability,

which will lead to an increase in their sources of financing investments. By reducing administrative costs we understand reducing management costs, by reducing the entire administrative system, resulting in a simplified administrative structure that will lead to a facilitated coordination and administration of the entire business.

Abstract

International problems generated by the phenomenon of double taxation appeared for the first time during the Middle Ages. Situations of double taxation were most often caused by the juxtaposing of two or more jurisdictions. The first record of these situations dating since XII century and it is reported on the fees charged in France and Italy.

Key words: globalization, double taxation, model treaty.

J.E.L. Classification: M41

1. Introduction

Corresponding to the existing legislation at the time, when the owner of some properties located in France was living in Italy, taxes were charged in both states. The first attempts to solve these aspects were realized only in the second half of XIX century and are divided according to international literature opinions in three stages:

- the stage of measures to eliminate double taxation in relations between federal states of the same union (ex.: German federal laws in 1870 and Swiss constitution in 1874);

- the stage of measures to eliminate double taxation in relations between quasi-independent states of the same empire (ex.: relations between states of British Empire);

- the stage of measures to eliminate double taxation in relations between independent sovereign states (ex.: Dutch law in 1819

granting exceptions from maritime taxes with the condition of reciprocity for Dutch ships). As a result of these stages in order to develop measures to eliminate double taxation in relations between states, the first bilateral treaty to eliminate double taxation on income was signed in 1899 with the signatories of Prussia and Austro-Hungarian Empire [1].

2. OECD Model Treaty to eliminate double taxation

In 1958, following the efforts of League of Nations, Fiscal Committee of the Organization for European Economic Cooperation has started to elaborate a new convention project, designed to contribute to the elimination of double taxation in the international financial relations. The Organization for European Economic Cooperation was extended through the Convention from Paris in 14th December 1960 and continued its existence as Organization for Economic Cooperation and Development (OECD).

The objectives of this organization were established according to the international collaboration and cooperation requirements in economic, trade and financial, to ensure the economic stability and growth of member and non member states. In the center of OECD concerns was realizing the efforts started under the League of Nations and continued after by the Organization for European Economic Cooperation.

Thus, in 1963 the convention project, started in 1958, was published as: “Convention Project to eliminate Double Taxation, OECD 1963”. The Convention Project in 1963 was actually a revision of

London Project and kept the same characteristics and the same structure. The most important characteristic of this project is the allocation of priority tax right of the residence, so the position adopted by London Project was totally maintained. In 1974 were published by OECD new proposals for amending the Convention Project in 1963, and in 1977 was published “OECD Model Treaty to Eliminate Double Taxation”.

Elaboration and publication of this treaty by OECD was the moment of hard work carried out for a period of over 50 years on international level in order to solve the double taxation’s problems. Applying “1963 Project” and then “Model Treaty” in elaborating the treaties to eliminate double taxation was a big success. Indeed, the best proof of the viability of imposed solutions in “Model Treaty” was the big number of treaties that follow the structure and orientations offered by the convention.

From these results, OECD published in 1992 “Model Treaty to Eliminate Double Taxation”, that is a revised “Model Convention” in 1977 [1].

Taking in consideration the general conditions to eliminate the double taxation in international financial-commercial relations, the structure of Model Treaty is complex, and solutions offered in order to achieve this goal are numbered. In this context, however, it is required highlighted the flexible, open character of the Treaty preventions, but especially the possibilities offered to signatory states of bilateral conventions, elaborated after the Treaty in order to complete and adapt its provisions in accordance with the specific of national legal systems. This character is relevant when the actual bilateral conventions on international plan are analyzed comparatively with OECD Model Treaty provisions.

In terms of structure, Model Treaty includes seven chapters [2]:

1. Chapter I- Scope and aims of Treaty;
2. Chapter II- Definitions and basic concepts;
3. Chapter III- Income Taxation;
4. Chapter IV- Capital Taxation;
5. Chapter V- Methods to Eliminate Double Taxation;
6. Chapter VI- Special Provisions;
7. Chapter VII- Final Provisions

In the first two chapters (regarding Scope and Aims of Treaty and Definitions of basic concepts) is realized an identification of taxpayers for who will be applied the provisions of the Treaty and taxes that will be covered under these provisions.

Also, o series of concepts such as “dividends”, “interests”, ”immovable property” are defined in separate articles. In Chapters III, IV and V, regarding elimination of double taxation, Model Treaty establishes two categories of rules. First of all, the articles 6-20 taxation way (by the source state of income or by the state where the taxpayer is resident) of different categories of incomes, and the article 21 establishes the same type of rules, but regarding the capital [7].

For some categories of income, the taxation right is given to the source state, and for others categories of income, the taxation right is given to the resident state. In this way, the second state (for which is not given the right of taxation on income) doesn’t have the possibility to tax the income and so, double taxation is avoided.

Usually, the exclusive right to tax certain categories of income returns to residence state.

Second, for other categories of income, the right to tax is not given only to one state but it is divided between the two states.

In these situations, the two solutions to eliminate double taxation are applied: exemption from taxation and credit method (included in the articles 23A and 23B, referring to methods to eliminate double taxation). Thus, depending on allocation of tax rights between the two states, incomes and capitals of taxpayers can be classified in many categories [7].

In the first category are incomes and capitals that are taxed only from the source state. These incomes are exempt from any taxation in residence state. As examples of such incomes are immovable properties incomes (article 6), incomes from sports and arts in that state (article 17), wage income of managers of companies from that state (article 16), etc. In the second category are included incomes that are taxed in the source state, but limited. Here are covered only in the situation when the results from activities performed in a permanent office of a foreign company. Otherwise, source state must limit

taxation to 5% of the total dividends if the taxpayer holds 25% of company's capital and 15% in any other situation [3].

In the last category are included incomes that cannot be taxed in the source state but only in the residence state. As example of such incomes: private pensions, incomes from selling shares of the company, capital invested in company's shares, etc. after this short presentation we can observe the fact that when taxpayers residing in a state get incomes from sources located in the other state, incomes that according to rules of Model Treaty are taxed only in the residence state, the danger of double taxation doesn't exist, because the source state will always offer exemption from taxation. Otherwise, for incomes that can be limited or unlimited taxed in the source state, the residence state may choose for the two methods to eliminate double taxation: exemption from taxation and credit method. Exemption from taxation method means exemption from taxation in the residence state on incomes taxed in the source state. But according to specific variant chosen to apply this method, incomes taxed in the source state may or may not influence the tax rate in residence state on global income taxation. Credit method means to use paid taxes in the source state as a credit in calculating the taxes owed in the residence state. Choosing the right method belongs entirely to signatory states of bilateral conventions, developed after the structure of “Model Treaty”.

In the last two chapters of the Treaty are included specific provisions related to changing data and common procedures, nondiscrimination system (articles 24,25 and 26) and also final provisions related to entry and exit effect (articles 29 and 30).

These solutions are based on the idea that the benefits of bilateral treaties to eliminate double taxation are really mutual only in the situation when investments between the two signatory states are in equilibrium. This is not the case in relations between developed and emerging countries, because the movement of goods and capitals is primarily in one direction, namely from developed countries in developing countries. For this reason, “Model Convention” of U.N. offers the priority right (but not exclusively) of taxation to the source state of the income and not to the residence state. By this provision, is

aimed offering the possibility to tax incomes by developing countries realized on their territories by citizens and companies of developed countries.

3. Types of international treaties to eliminate double taxation.

In all international financial relations, treaties to eliminate double taxation fulfill an important role. This statement is justified in many beneficial consequences, caused by elimination of double taxation!

In this case falls balanced distribution of taxation rights between signatory states of the Treaty, encouraging the development of commercial and financial relations between the two countries and not at least, prevention of international tax evasion.

In order to achieve goals, two fundamental types are on international plan: multilateral treaties and bilateral treaties [6].

Before the Second World War the idea of using multilateral treaties was dominated, argues for this orientation refers to the broad scope of coverage of these treaties, indeed, in multilateral treaties the possibility of harmonizing the legal measures of income tax on international is higher, but the results of this harmonizing are better. On the other side, the advantages offered by bilateral treaties proved to be stronger on international practice [4]. The explication of this phenomenon is that these treaties provide the chance to regulate all details referring to these solutions that correspond to national specific systems. Another argument in favor of bilateral conventions is their high degree of flexibility in application or in the event of changes and amendment and also the fact that do not require the establishment of special institutions to ensure their uniform interpretation in different countries (as in the situation of multilateral conventions).

In this way is explained the change of two multilateral conventions projects:

1. the project of League of Nations in 1933 and
2. the project of Organization for European Economic Cooperation in 1958 and their publication as bilateral conventions in 1935 and 1963 [4].

The option to conclude a bilateral or multilateral treaty belongs to states interested

in elimination of double taxation in relations between them, thus, multilateral conventions, as Andean Pact and Nordic States Convention are used by certain states that have chosen this type of solving the problems of double taxation.

In Andean Pact, for example, member states decided to give the taxation right to source state of incomes and thus they solved the conflicts regarding the taxation of resident trade companies in one of the states, but having branches in another member state of the pact.

Regarding Nordic States Convention, it respects the general structure of “OECD Model Treaty”, of course with some specific features determined by the specific of their legal systems. To note the provisions regarding income taxes by exploiting natural resources of North Sea and also those referring to property tax on companies that have the object of aviation and maritime transport [3].

Also, Belgium, Netherlands and Luxembourg have concluded a special convention referring to levying and double taxation. The largest share in the actual period of time on international relations is held by bilateral treaties to eliminate double taxation, the majority being elaborated according to solutions offered by “OECD Model Treaty”. Through these bilateral treaties were realized the harmonization of orientations that existed on national level, regarding the problem of double taxation. The big number of bilateral treaties concluded in relations with member states of OECD (over 200 bilateral treaties) but also in relations with nonmember states is an evidence of the success of “Model Treaty” and the viability of its solutions [7].

4. Perspectives of tax conventions

Globalization has led the fight against increasingly difficult tax evasion on international level, and the 27 member states of EU, with major differences between them, are particularly affected. These factors are favorable to a good and efficient cooperation on international level within the European Union. The EU considers that a significant number of multinational companies were structured in order to avoid taxation in different jurisdictions in which they operate.

Different treatments of taxation in different jurisdictions favor big, international companies with tradition at the expense of small, local or new companies. The ability of multinational companies to the intensive use of fiscal havens and off-shore centers, as strategy to avoid taxation conflicts with the principles of loyal competition and corporative responsibilities.

European Union prepares an important number of legislative proposals regarding income tax from economies, administrative cooperation and multilateral assistance in recovering taxes. Anti-avoiding General Principles offers to the authorities the possibility to evaluate the main goal of certain transactions is to reduce or avoid taxation so, to charge additional taxes to counteract the avoidance or reduction.

So, we can conclude that there are international accounting and audit standards but there are not global fiscal standards. However we can appreciate that the OECD measures could be considered a step (weak) to international tax standards.

Abstract

The paper aims the analysis the investment strategies adopted by the private pension funds in OECD countries and the relation between the level of development of the financial system and the impact pension funds have on the capital market in these countries. On the short term, in the countries characterised by a developed financial system, pension funds generate an increase in the market capitalization as well as in the transactions volume. For the countries with immature financial systems, the positive effects estimated are less sustainable. Further, the paper underlines the changes generated by the global financial crises in the assets administrated by the pension funds in OECD countries and shows the fundamental role funds have in increasing the activities of the capital markets.

Key words: pension funds, capital market, financial assets, crises

JEL codes: J32, G23

1. Introduction

The financial globalization process has generated an increase in the importance of the pension funds, due to their positive effects over the capital market. The prudential legal rules of pension funds investments diversification made these financial entities extremely important players on the capital markets.

In this context, various studies have proven that the pension funds' investments can have a contribution in the stabilization of

the financial system [4] or in the liquidity increase of the equity and bonds markets [1, 6].

The way financial capital is attracted through the redistribution of a part of the compulsory employees contributions allows pension funds to design their investing process for very long periods of time so that the pension funds could benefit from the adjustment periods for the assets' prices at the levels that are justified by the economic theoretical fundamentals[5].

A series of studies have tried to set a relation between the capital market development and the development of the pension funds. Catalan, Impavido and Musalem [2] have studied 14 of the OECD countries and 5 emerging countries for the time period 1975-1997. They concluded that there is a relation of causality between the capital market development and the development of the pension funds, the capital market development being generated by the evolution of the pension funds. The pension funds investments influence the evolution of the market capitalisation but not the volume of transactions on the market. Why? A possible explanation is the investment long term horizon for which the investment funds design their investment strategies but also the conservatory approach of the portfolio managers that do not use speculative strategies that could lead to the increase of liquidity of the capital markets.

Other authors such as Channarith Meng and Wade Donald [3] have studied the impact of pension funds over the development of the equity and bonds markets, taking into account a sample of 32 mature and emerging capital markets, between 2003-2007. It is noticed that there is a relation between the level of development

of the financial system and the impact pension funds have on the capital market. On short term, in the countries characterised by a developed financial system, pension funds generate an increase in the market capitalization as well as in the transactions volume, while the positive effects estimated for the countries with immature financial systems are less sustainable.

In the present paper we aim to analyze the role pension funds have in making capital markets more active, underlining the changes generated by the global financial crises in the assets administrated by the pension funds.

2. The Impact of the Financial Crises upon the Pension Funds' Assets

In the last decades, on the capital markets, an increase in the total assets administrated by the pension funds was noticed. For example, at the level of the OECD countries, for the period 2000-2011, an increase rate of about 96% was registered, reaching 30.90 trillion USD in 2011, which represented 90% of the OECD countries GDP (graph 1).

The impact of the financial crises over the assets administrated by the investment funds was strongly felt in 2008, when there was a decrease of 17% in respect to the previous year. It is to be noticed the fact that in the last decade the total value of the assets administrated by the pension funds has doubled.

Graph 1.

Global pension assets

Source: *The CityUk, Pension Markets, 2012, OECD Pension Statistics*

At country level, one can identify an important development of the pension funds in Netherlands and Iceland, the administrated assets value being over 100% of the 2010 GDP (table 1) (134.9% in the Netherlands and 123.9% in Iceland).

By the end of 2010, the level of the pension funds in respect to the national economies in OECD has increased if compared to the level in 2008 (when it was of 60.3% of GDP) but has slightly decreased if compared with 2007 (when it was 78.2% of GDP), reaching a level of 71.6% of GDP on average.

At OECD level, the asset-to-GDP ratios increased in most countries in 2010, in comparison with 2009. A decrease in this ratio was registered for Japan (-1.4%) and Portugal (-2%). At world level, UK, Finland and USA overpass the level registered in the OECD zone and register higher levels, between 70 to 90%.

Source: OECD Global Pension Statistics

Regarding the use of assets administrated by pension funds, one can notice a preference for investments in riskier assets for most developed countries. In the USA, investments in equity add up to about 50% of the total investments, which means an acceptance of being exposed to losses in case of a higher volatility of the capital market. On the contrary, pension funds in Germany, Italy or Spain have reallocated their assets on the bonds markets, reducing their participation on the equity markets (table 2).

Institutional investors as well as banks were highly affected by the equity holdings in investment portfolio, these holdings becoming an important channel through which financial turmoil was transmitted. This has caused a fall in the value of the portfolio holdings of institutional investors and banks.

In the case of OECD countries, as bonds are the dominant asset class and not equity (being about 50% of the total assets), this transmission channel has generally been mitigated for pension funds, especially in those countries where equity holdings do not make up for more than 30% of the overall investment portfolios.

Problems due to this transmission channel arise in countries like USA, Australia, Chile or Finland, where the portfolio allocations to equities is still very high, adding up to 40-50% of the total investments.

The differences in performance between equity holdings and bonds holdings, not compensated by rebalancing policies, has generated a significant shift in the allocation of capitals between equity and bonds in countries as Austria, Finland, Poland or the Netherlands. The weight of equities in portfolio increased with 6-7% from 2009 to 2010 and the bond allocation fell by a similar percentage.

The differences in performance also resulted in reduced bills and bonds allocations for the pension funds in Germany, Estonia and Korea, but in their cases, this reduction was not compensated by increased allocations towards equities but towards other classes of assets.

The investment strategies of the pension funds in Greece have significantly changed in 2010, when there was a sharp rise of 12% in the percentage of cash and similar assets held by the pension funds, in the detriment of allocations towards equity.

The large pension funds try to use a rebalancing strategy, buying more equities when their price is falling in order to keep the targeted level of investments in equities or selling these equities if their price has significantly increased. At a macroeconomic level, this strategy reduces the upward and downward movements on the equity market, increasing the financial stability.

Table 2.

Note: 1. The "Other" category includes loans, land and buildings, unallocated insurance contracts, private investment funds, other mutual funds (i.e. not invested in cash, bills and bonds or shares) and other investments.

Source: *OECD Pension Statistics*

In the context of very unstable and very changeable market conditions, allocation remains a challenge. Even though financial markets are recovering, pension funds and sponsoring companies need to take strategic decisions regarding the asset allocation mix.

Under the aspect of geographic distribution of the assets administrated by the investment funds, the leading position is held by the United States pension funds that were having (at the end of 2010, about 55% of the total assets held by the OECD countries pension funds, which means 10.587 million USD (table 3).

Table 3: Geographical distribution of pension funds' assets in OECD countries, 2010

	As a % of total OECD	
	Total assets In millions of USD	In %
United States	10,587,679	55.2
United Kingdom (1)	1,943,110	10.1
Japan (2)	1,388,329	7.2
Netherlands (p)	1,056,769	5.5
Australia	1,089,723	5.7
Canada	1,017,672	5.3
Switzerland (3)	551,450	2.9
Other	1,541,740	8.0

Source: *OECD Pension Statistics*

Between 2001 and 2010, the US' share of OECD pension fund assets (in relative terms) shrank from 67% to 55%.

The most important OECD countries in respect to their pension fund system are the United Kingdom with assets of 1.9 trillion USD (representing 10% of the OECD pension fund market), Japan with assets of 1.4 trillion USD (representing 7% of the OECD pension fund market), the Netherlands and Australia

with assets of 1.1 trillion USD (representing 6% of the OECD pension fund market), Canada with assets of 1 trillion USD (representing 5% of the OECD pension fund market), Switzerland with assets of 0.55 trillion USD (representing 3% of the OECD pension fund market). The other 27 countries have in 2010 a total pension fund assets of 1.5 trillion USD which represents approx. 8% of the total OECD pension fund market.

Looking at the data regarding the pensions fund asset levels, we can notice that they have gone over the crisis and continue to register a strong growth. The trend is towards reaching the pre-crisis levels and in 2010, financial and economic indicators show signs of further recovery.

Graph 2: Pension funds' real net rate of investment returns in selected OECD countries, 2009-2010 (%)

registered better results, some have registered worst results. If in Netherlands the net return on investments was 18.6%, in New Zealand was 10.3%, in Chile was 10%, in Finland was 8.9%, in Canada was 8.5% and in Poland was 7.7%, in countries as Portugal

or Greece, the rate of investment returns was very low and sometimes negative. The worst case was that of Greece where the rate of investment returns was -7.4%, due to the collapse of the Athens Stock Exchange Market and the significant drop in the price of Greek bonds. The adverse capital market performance in the domestic markets explains the negative performances registered in the case of the Portuguese pension funds.

3. Conclusions

The investment policy of the pension funds is essential in reaching superior performances and in setting pension funds in a leading position on the capital markets, in comparison with other investors. The time horizons, the objective, the investors characteristics have a high impact upon the chosen portfolios and upon the accepted risk levels, the pension funds' managers are setting.

Also, the financial turmoil that has affected the capital markets was a strong determinant of the present investment policy used by the pension funds.

These aspects have made pension funds' managers identify new investment alternatives or opportunities that can generate a better result than those of the capital market.

The data used in the present paper shows the fundamental role pension funds have in increasing the activities of the capital markets. Nowadays, the transparency level reached by the great majority of pension funds regarding the investments structure, the risk level and the evolution of portfolio performance, give anyone interested the possibility to evaluate the level of interest in such investments and to choose the pension fund that is most adequate for its purposes, the impact being over the volume of assets administrated by the pension fund and therefore on the capital market.

The VAT Hike in 2010 and Its Effects on the Romanian Firms and their Reaction

Beca Marușă

Bucharest Academy of Economic Studies

marushabk@yahoo.com

Abstract

This article's goal is to highlight the main microeconomic and macroeconomic effects of the 2010 VAT hike in Romania and the Romanian firms' response to it. At 1st July 2010, the Romanian Government raised the Value Added Tax from 19% to 24%, causing chain increases that delayed with nine months the Romania's exit from recession. It intended to increase its receivables in a period in which the state budget had problems in collecting taxes. I have concluded that the main microeconomic effect was the plunge of the firms' sales and the macroeconomic one was the decrease of the Gross Domestic Product (GDP). Regarding the Romanian firms' reaction to the VAT increase, most of them have ignored the VAT hike and they did not have an important response to such a modification.

Key words: VAT, inflation, Romania, tax evasion, GDP

J.E.L. classification: E26, E31, H25, H26

Introduction

At 1st July 2010, the Romanian Government raised the Value Added Tax from 19% to 24%, causing chain increases that delayed with nine months the Romania's exit from recession. The hike of the VAT has been considered the greatest economic blunder of the Romanian Government.

The increase of prices and taxes for the basic products and services triggered a chain reaction that led to a drop of the population purchasing power and, in consequence, the reduction of the demand for food or non-food products' manufacturing companies.

The declining consumption reversed the upward trend engaged by the economy in the first half of the year 2010, pushing again

Romania into recession for another nine months. Both firms and Romanian families had only to lose because of the increase of the VAT. On the other side, the state, that decided this measure in order to protect its own „business”, sacrificing the entire economy, had only gained shy increases of the VAT receivables, amounts that do not countervail for the sufferings caused to each individual or legal person. [1]

1. Short history

From 1st July 2010 the standard Romanian VAT rate increased to 24%. This move took most businesses by surprise. Although rumored in the past to be an alternative to cutting public pensions by 15%, which has been ruled as unconstitutional, the Government Emergency Ordinance only published the increase in VAT on 28 June 2010, just three days before coming into effect.

The hike in VAT to 24% was introduced by the Romanian Government as an alternative to the proposed 15% reduction in the pensions to cover the gap between state budget revenues and expenses.

Businesses only had 3 days to prepare their systems and decide on their pricing policies to be compliant with the increase. Companies with limited or no VAT deduction right (such as banks, insurance companies, and healthcare clinics) will feel the effects of the increase in the VAT rate directly in their costs and will need to think of ways to maximize their VAT deductions wherever possible.

The change in the VAT rate also raises a series of administrative problems, especially for transactions where invoices were issued or advances were cashed in prior to 30 June 2010, but where the transaction will be finalized after 1 July 2010. Producers and retailers granting or receiving volume

discounts at year end will also need to carefully link those discounts to each two semesters of the year, as the VAT rates applicable for those discounts are now different (19% for the first semester and 24% for the second semester). [2]

2. Microeconomic effects

The main microeconomic effects are the following:

1. crowding in stores, where people wanted to buy the products that were still at a "low price";

2. changes of the invoicing software and of prices from store shelves. Some stores had to "re-price" thousands of ranges of products in tens of hours;

3. the time remaining till the 1st of July was very short. Those equipped with cash registers faced the inability to use them in the first days of July, because those who provided the service would not cope with it; [3]

4. the above mentioned effects determine the increase of costs of the Romanian firms' and, as a consequence, a drop of the recorded profit;

5. the reduction of the consumers' purchasing power determine the decrease of the demand and so the cut of the firms' sales and therefore the fall of the recorded profit.

3. Macroeconomic effects

Increases in such a tax should normally lead to the following macroeconomic effects:

- a number of consumers give up consumption as a result of the increase in the lowest priced products;
- it amplifies the spread of prices among different quality segments so there would be two categories of producers that should be mostly affected: the producers positioned at high pricing segments and the producers positioned at low pricing segments with highly price-sensitive consumers; [5]
- increase of the inflation. The NBR governor's counselor, Adrian Vasilescu, stated that it is likely that inflation will rise to 10%. This will determine a chain reaction:
- decrease of the population's purchasing power. The drop will be directly

proportional with the inflation, and also with the chain reactions that will generate: bankruptcies and job losses.

- raise of the underground economy and the decline of the level of collected taxes by the Romanian state; [3]
- a drop of the consumption determined a plunge of the firms' sales and so a decrease of the Romanian GDP;
- inflation could generate the depreciation of the Romanian currency and this means the export could increase.

After the sudden increase of the annual inflation from 4,3% in June to more than 7% in July and in the next months, the inflation rates exceeded the threshold of 8% in the spring of 2011, at 8-10 months from the moment of the VAT hike. In May 2011, food recorded an average increase by over 11%, record that had not been reached from the period April-June 2008. The food prices increases above the affordability of larger layers of population – the situation that we face now, as a consequence of the VAT raise – determined the Nomura Bank Japanese experts to rank Romania on the first place in Europe for vulnerability to food crisis.

This crisis does not come from lack of food, but from the more difficult access to the products of basic necessity, caused by their higher prices. Another negative effect of the raise of the VAT can be seen on the Gross Domestic Product (GDP) statistics.

In 2008, after entering recession, the gap between prices and volume increased, caused by the diminishing demand, but it began to reduce by mid 2010. After the 1st of July, these gaps increased again, leading to a population's consumption lower by 1% in the third trimester 2010 in comparison with the same period of 2009, but the prices had risen by 8%. The VAT raise forced Romanians to consume 1% less, at prices by 8% higher, caused by the sustained loss of incomes. A decrease of the purchasing power at the households' level falls upon business, taking into consideration the fact that the manufacturers lose clients because of the high prices. This is another negative effect of the VAT hike, experienced at the companies' level. Away from this vicious circle of lower demand and purchasing power, the industry and the export companies had profit in 2010 and 2011.

The president of the Unions Federation from the Food Industry (UFFI), Dragoş Frumosu stated: „In the last two years, the food sales declined by 30%, of which 12%-14% are the decreases of the last 12 months. The state did not gain from it, because a diminished consumption brings lower receivables, and the tax evasion increases with taxes.

“The tax evasion would not serve any purpose if we will have a reduced VAT rate of 5%, at least in the case of basic food”, said the union leader. Sorin Minea, the president of Romalimenta union, observed that the raise of VAT lead to a drop of sales, doubled by an increase of tax evasion.

The VAT hike increased the budget receivables, starting the 1st of July 2010, in a period in which the state collected increasingly less. „Apparently the incomes’ situation has been adjusted, on the moment, but in reality, the things are quite different. The only engine that helped the economy to recover, i.e. the export, it also created a number of vulnerabilities”, the lawyer Gabriel Biriş, partner of the Law and Fiscal Consultancy firm Biriş Goran stated.

The authorities can not rely only on the export in order to boost the economy, taking into account the fact that the situation depends on the foreign markets and the exchange rate leu/euro and leu/dollar. That’s why it is necessary to activate another engine that helps to increase the GDP, i.e. the domestic consumption, adds Biriş. Precisely the consumption – that already was going down in the crisis period – was strongly affected by the VAT increase.

The most recent data published by the Ministry of Finance shows that in the period 1st July 2010 – 31st May 2011, the state collected 40,71 billion lei from 24% VAT. This means almost 1,3 billiard euros (5,3 billiard lei), more than in the period 1st July 2007 – 31st May 2008, when in the state budget entered 35,34 billiard lei from 19% VAT.

Biriş says that the increase of VAT receivables is not due exclusively to the raise of the rate from 19% to 24%, the measures against smuggling taken by the authorities at the IMF pressure also contributed. With the 5,3 billiard lei collected in addition, the state covered less than half of the expenses for goods and services, in the first five months of

2011. [1]

"There is not a proximity store that gives tax receipt. Otherwise they couldn't face the increase of VAT. In Romania, the lack of taxation is serious, thousands of firms are established and then they disappear depending on season", the Romalimenta president, Sorin Minea, stated. [6]

Since the 1st of July, people turned to those who were selling black because they were cheaper. The small merchants adapted quickly and they have given up to cash registers, but the bigger stores had to lower prices and they were going in loss for a period of time in order to not lose the clients. The increase of prices because of the hike of the VAT diminished the consumption with 5%, according to recent appraisals.

"The continuous service providers invoice monthly the previous month consumption, the applicable rate is the invoice date rate, not the one of the consumption period", explained the Braşov Water Company's economic manager, Teodor Popa. This happened in every situation that implied a payment in July for something done in June. For example, those who hurried to buy cheap cars before the 1st of July were lucky only if they had all the money and if they were satisfied with what they had found on the stock. Those who failed had to pay more than the amount from the contract when they have received their car. The final invoice had 24% VAT, and the initial one was rectified. "The state did not take care for the contracts signed before the 1st of July to have a certified rate of VAT 19%", pointed out Mihai Grinzeanu, sales counselor at Dacia AMG dealer. [7]

The leu depreciation because of a big inflation is a danger and the VAT hike to 24% could bring inflation to 10-12%. "There could be two moments from the point of view of the effects on inflation. Firstly, more expensive foods with 5% will bring inflation to 10%. Secondly, the panic and the greed of the merchants could determine a raise of the inflation with another two percentages", Vasilescu said. Rozalia Pal specified that the acceleration of the inflation will diminish very much the margin of maneuver of the NBR, taking into consideration the fact that the Central Bank wants to stimulate lending, but its main focus is the price stability. [8]

"The increase of the VAT to 24% will have an important impact on the evolution of

the economy and the inflation rate. The inflation will be 8% at the end of 2010, with 4 percentage points over the current forecast", the UniCredit Tiriac Bank chief economist, Rozalia Pal, stated. She anticipates that the measure will have as an effect a drop of the GDP beyond current expectations.

"A growth of the VAT will have consequences on the citizens' purchasing power", the economic analyst Aurelian Dochia said, member of the BRD Administration Board.

The government said that this increase of the VAT will be coordinated with the National Bank in order to limit the inflationary risks. [9]

4. The reaction of Romanian firms to VAT increase

The vast majority of Romanian producers have ignored the VAT increase and they did not have a significant reaction to such an indirect tax modification. However, the decision of Romanian authorities to increase the VAT from 19% to 24% starting with 1st of July 2010 is one of the largest VAT hikes in Europe. Romania became a member of the group of European countries, together with Denmark, Sweden, Hungary, with the highest rate of VAT. Despite this qualification, the vast majority of Romanian firms have ignored the VAT increase as they did not have a significant reaction to such an indirect tax modification. The most probable cause of such a situation may lie in the firms' opinion that such a tax hike remains however low from a competitive positioning perspective (5% of the final price). But this is not a comfortable assumption and denies competitive positioning theory.

Among the producers that did react to such a tax increase, the bulk of them opted for two approaches: A. "my word is my bond": some firms have kept the "old prices" constant based on the argument that their pricing catalogue was a firm offer to the consumers so they observe the terms of a contract. This is however a transitory reaction and fundamentally lacks substance (the level of taxes is not a contractual obligation so any Court would waive the liability of the sellers) but highlights the "respect" of the firms towards its clients. This is the case of IKEA (for its entire

catalogue) and Metro (for its promotion catalogue); B. "hit and run": some firms have used the situation in a tactical way to tie the tax modification to a marketing hit. They also used the reduction in pre-tax price on a transitory basis as it was offered only on short term (usually 1 month) with no promise for further pricing repositioning. This is the case of EMAG in the electronics field and FIAT in the auto distribution (only for some models like Linea). [4]

For example, EMAG has offered any client that purchased a product in the two months following the tax increase the option to get a voucher for the 5% increase. The voucher could be used in the following six months in order to buy other products (with a certain minimum order). The campaign was branded "EMAG gives you back 5%" and generated "viral" answers in the blogosphere, where clients reacted positively.

What can be however noticed is that the quasi-totality of firms which chose to react to VAT increase came from budget / value segments or from distributors targeting narrow profit margins. These are obviously the most sensitive competitors to after-tax price increases.

The Romanian experience confirms the fact that competitors are not fully aware of the consequences of such regulatory measures. They lack a strategic approach in their process of competitive positioning. The existing reactions of firms to the 1st of July increase in VAT in Romania were exploratory and intuitive, which sometimes contradicts the theory of marketing.

In the case of the 2010 VAT increase, the most striking aspect is the lack of a significant reaction from the part of luxury brands' producers or distributors – arguably the most affected - which could be caused by their own marketing strategy. [5]

Conclusions

As a conclusion, I can state that the 2010 VAT hike to 24% brought to the Romanian firms and households a lot of economic problems finalized in bankruptcies and loss of jobs. The measure had the expected effect, an increase of the receivables to the state budget, but at the cost of postponing the Romania's exit from recession.

The VAT increase caused a vicious circle consisted of inflation, depreciation, food

crisis, tax evasion and recession, and the only ones who managed to obtain profit were the exporters that benefited from the leu depreciation.

Romania should not rely only on exports in order to achieve economic growth, because the foreign markets are unstable due to debt crisis or military conflicts or other social or economic problems.

Some people tried to find a solution to the VAT modification in order to adjust it or to moderate its negative consequences.

Concerning the VAT hike, the union leader Sorin Minea concluded “The solution could be the implementation of differentiated rates of VAT and the protection of the food industry with several tools as all civilized countries do”. [1]

“The impact of the increase of the VAT on inflation could be reduced in case it would not be transmitted entirely to the consumers or if there will be some exceptions to the growth application”, Rozalia Pal said. [8]

Mihai Lungu, the chief of the Muntenia Cooperative, said that in case the tax evasion would not be stopped, all the subsidies will be useless. “The tax evasion could be eliminated in one month, if we want. We have 70%-80% tax evasion in comparison to 2%-3% as other European countries have”, added Lungu. [6]

Regarding the Romanian firms’ reaction to VAT increase, Musetescu concluded “the vast majority of Romanian companies do not have a strategic approach to pricing. With few exceptions, even those which did have a reaction used pricing measures for a smoothing of the seasonal demand

variations.” [5]

Pricing General Insurance in a Competitive Market

Burcă Ana-Maria

PhD. Student, Academy of Economic Studies, Bucharest

burca.anamaria@yahoo.com

Bătrînca Ghiorghe

Maritime University, Faculty of Navigation and Maritime Transport, Constanta

gbatrinca@imc.ro

Abstract

In insurance industry, the lack of a proper pricing policy will generate suboptimal results. The price has to be competitive and actuarially adequate in order to reflect the dimension of risk.

In a competitive market, the pricing policy of insurance companies acquires the capacities of a dynamic process. In this pricing war, the insurance company must analyze each component of pricing.

Insurance companies use various statistical methods to set prices, taking in consideration the interaction between premium and risk. In this paper, we try to illustrate the method of historical claims and sums insured, used by actuaries in general insurance.

Key words: risk premium, insurance pricing, pricing model, general insurance, competitive market

J.E.L. classification: G22, C13

1. Introduction

Pricing represents the cornerstone of each insurance company. Without a proper pricing policy, the insurance company would not be capable of consolidating its market share and meeting its liabilities. However, computing the proper price of an insurance policy is only one element of the entire pricing process, being necessary to take in consideration overall expenses, other loading factors and profit margin. Also, competitors' analysis becomes vital, because in practice there is no concept of "fair price": competitors may focus on particular market segments or they may conquer market share in loss. In this context, in order to reverse the

actions of competitors, the pricing policy of an insurance company acquires the capacities of a dynamic process in a competitive market.

Along the years, the pricing of general insurance has been extensively covered in the actuarial literature: Bühlmann (1970), Gerber (1979), Goovaerts et al. (1984), Bowers et al. (1986), Hürlimann (1997, 1998), Wang et al. (1997), Young (1998), Denuit et al. (1999), Hofmann et al. (2007), Chessa (2011) and Emms (2012).

Most modern principles of pricing general insurance are presented in a framework based on expected utility theory, that involves defining decision-making situations as ideal models of a situation in which participants aim to achieve benefits that can be obtained through several strategies.

2. The pricing process of general insurance

The underwriting of risks represents the core activity of general insurance and it generates the secondary activities of the insurance companies. The risks underwriting requires a process of pricing based on a risk-price adjustment, by using actuarial modeling and past experience.

Insurance represents an intangible product, which makes pricing a process that cannot be accomplished through traditional deterministic models applied for tangible products. Also, in general insurance industry, the actuarial modeling of losses is very important for estimating premiums, and the uncertainty of losses' frequency and severity amplifies the difficulty of the pricing process. In this respect, in order to estimate the potential number of losses and their average size, insurance companies use stochastic models which are based on probability theory.

The origin of the pricing policy of general insurance is represented by the equivalence principle. According to this principle, the present value of expected premiums is equal to the present value of expected losses and expected cost. Since future losses are random and the premium is set ex ante, the pure premium may not be adequate to cover all estimated losses and costs with a certain probability. Therefore, insurance companies add a loading factor that can be proportionate or fixed and depends on the distribution of losses[1].

In general insurance, the equivalence principle requires extensive statistical information comprising reliable and relevant data. The considered time horizon depends on the risk nature. The higher the time horizon is, the higher the degree of accuracy in determining premium rates will be.

In the pricing process, the cost of the loss represents the dominant component and the most difficult to estimate. In addition, the pricing process should take in consideration inflation. Also, premium rates depend on the terms and conditions of the insurance contract, specific guarantees and the insured risk.

In general insurance, the pure premium is often set on the basis of certain features of the insured object. These features must be objectively quantifiable, measurable and legally accepted.

The pricing policy of the insurance companies must be in accordance with the business, regulatory, economic and social environment. Balancing has to be done to make the price competitive on the one hand and actuarially adequate (risk – price adjustment) on the other hand. Since actuarial modeling is based on past statistical data and simulation, the insurance company must have an efficient IT system capable of providing quality and relevant data. The price should encourage loss control and factor margin for adverse deviation. The pricing philosophy of insurance companies must address the concern of adequate, non-discriminatory and non-excessive tariffs, which also have to be stable over a period of time[2].

The pricing policy reflects the attitude of the insurance company regarding risks. In the process of setting the premium rates, the insurance companies also take in

consideration the forecasts of investment incomes. Therefore, there is an interaction between premium, risk and investment income. Premium rates are set at a higher level when the insured risk is large, but an increase of the investment income allows cutting premium rates.

One of the objectives of the insurer’s activity of charging risk is to set premium rates so as to accurately reflect the dimension of risk[3].

From the insured point of view, premium rates represent a differentiating factor when making decision to buy the policy and, from the insurer point of view, they represent a vital factor of their long-term financial health and performance. In order to understand the mechanism of pricing insurance products, it is necessary to identify its key elements:

Figure 1. The elements of the pricing mechanism

Source: R. Qaiser – General Insurance Business Underwriting

The pricing policy of an insurance company cannot ignore certain commercial aspects such as inflation, interest rate, exchange rate and price competition from other players. In this pricing war, the insurance company must examine each element of pricing to ascertain as to the extent to which they can maneuver with them to bring down the price to the level at which they are competitive and fulfills adequacy criteria also[4].

3. Pricing and competition

For the insurance companies, the pricing process represents a strategic decision. Therefore, if the pricing process doesn’t take into account the competitors’ options or how

they react to changes, the results will be suboptimal.

In insurance theory, the simplest approach of premium rates computation is the expected value principle, which sets the premium equal to the expected claim size multiplied by a loading factor. However, this principle ignores the variability of the underlying risk. Consequently, various principles have been proposed which are based on the utility theory. However, all these principles do not take into account the competitive nature of the pricing process. All these mentioned inconveniences have led to the formulation of models based on both the demand law and the distribution of claims[5].

The pricing policy of the insurance companies takes into account various factors including market and demand issues, current and historical prices and estimated costs.

It is not enough for the insurance company to set the premium rate at the level which covers claims, due to the fact that if the other companies reduce the price, the income will be inadequate for the objective of remaining viable.

In general insurance, the actuarial price of an insurance policy is computed using a premium principle, which relates the premium charged to the potential claims. Insurers add a loading factor to the actuarial price to cover their expenses and generate a profit. In many lines of insurance, there is often a cycle that includes periods during which insurers set premium rates below and then above the actuarial price. Many lines of general insurance are highly competitive in nature, being often dominated by a few insurance companies. In such a situation, each insurance company monitors and tries to predict each other's pricing strategy[6]. Since time delays are an inherent part of actuarial processes, the modeling of the precise financial situation of a competitor becomes difficult and thus, it is unlikely that the market reaction to price changes to be instantaneous. As a result of this competitive nature, in practice, the loading factor is critically dependent on the tariff set by other insurers for similar policies[7].

4. Statistical models of pricing

Using statistical models to determine premium rates in the insurance industry has a

long tradition. Nowadays, more and more insurance companies began applying generalized linear models in order to identify a proper structure of the premium rate.

Insurance companies store vast amounts of information regarding policies and claims. Information is kept in databases, which represent the primary sources used by actuaries in the pricing process[8].

The gross or commercial premium represents the amount of money paid by the insured and comprises net premium and net premium margin. Net premium is set on the basis of statistical data and includes the risk premium and the loading factor. The risk premium, also known as pure premium, is used to cover losses and is determined separately for each risk. The loading factor serves to mitigate fluctuations or errors in premium computation, to ensure profit and to maintain insurer's solvency. The net premium margin is used to cover administrative costs, commissions, to create reserves and to remunerate shareholders.

Figure 2. The elements of gross premium

Source: Constantin Anghelache, Oleg Verejan, Ion Pârțachi – *Analiza actuarială în asigurări*

The risk premium can be estimated through several statistical methods. In order to illustrate how the risk premium can be estimated through the method of historical claims and sums insured, we consider that the insurance company has statistical data regarding historical claims and sums insured, based on previous experience. For necessary computations, we consider the following indicators[9]:

- Average sum insured in year “k”,
 $V_k, k = \overline{1, m}$

- Number of insured goods in year “k”, $N_k, k = \overline{1, m}$
- Average claim in year “k”, $v_k, k = \overline{1, m}$
- Number of indemnified goods in year “k”, $n_k, k = \overline{1, m}$

where “m” represents the number of years of the considered time horizon.

On the basis of these indicators we can compute the claims index which represents the amount of claim per unit of sum insured:

$$I_k = \frac{n_k * v_k}{N_k * V_k}, k = \overline{1, m}$$

The relative frequency of the claims index in year “k” is computed by using the following formula:

$$f_k = \frac{n_k}{\sum_{k=1}^m n_k}$$

The claims index I can be defined as a random variable:

$$I = \begin{pmatrix} I_1 & I_2 & \dots & I_m \\ f_1 & f_2 & \dots & f_m \end{pmatrix}$$

The average claims index is represented by the mean of this random variable:

$$M(I) = \sum_{i=1}^m f_i * I_i$$

Since the annual claims indices present deviations to the average claims index, the latter is adjusted by a risk margin determined through standard deviation:

$$D(I) = \sqrt{D^2(I)} \text{ where}$$

$$D^2(I) = \sum_{i=1}^m (I_i - M(I))^2 * f_i$$

Therefore, the rate of net premium for general insurance has the following formula:

$$cpn = M(I) + D(I)$$

To illustrate numerically, we consider the following data regarding agricultural cultures and livestock insurances for a particular insurance company:

Table 1. Historical statistical data

k	N_k	V_k	n_k	v_k
2007	420.320	56.230.443	156.320	12.230.459
2008	398.250	78.997.340	178.980	18.945.400
2009	450.987	110.223.214	202.345	32.340.342
2010	410.230	189.298.230	155.987	39.067.040
2011	549.980	230.340.220	278.554	40.030.204

The average claims index takes the form of the following random variable:

$$I = \begin{pmatrix} 0.080892 & 0.107780 & 0.131643 & 0.078473 & 0.088019 \\ 0.1607 & 0.1841 & 0.2081 & 0.1604 & 0.2865 \end{pmatrix}$$

The mean of the claims index is $M(I) = 0.09806$, and standard deviation is $D(I) = 0.01974$. Therefore, the net premium rate is approximately 11.78%.

5. Conclusions

In insurance industry, the pricing methods take in consideration the interaction between premium and risk. Each insurance company chooses to apply one method or other according to its objectives, available data relevance and accuracy and the experience of the actuary. Nevertheless, insurers must take in consideration their competitors' options due to the strategic nature of the pricing process.

The Concept of Risk and its Assessment Methods

Căruntu Andreea Laura
Căruntu Roxana Corina
“Constantin Brancusi” University
andreea.caruntu@yahoo.com
r_caruntu_28@yahoo.com

Abstract

In a world dominated by incertitude it is necessary to acknowledge the importance of discovering at the right time the risks that affect companies.

The aim of the paper is to provide important insights to economic agents concerning theoretical notions about risk and its assessment.

It is important for any company to take into account the changes that occur in the environment and due to this a risk management view is necessary.

Companies that want to survive the business environment must be ready to evaluate all the time their activity, give important not only to traditional methods but also to modern methods. In the end it depends not on what happens with other companies but only with the company using the methods.

Key words: risk, risk assessment, risk management.

J.E.L. classification: G32

1. Introduction

The necessity of approaching the risk problem has become one of the most important issues taken into consideration by managers who want their business to survive the unstable economic environment. The economic and social environment has passed through many changes in the recent years and the speed of these changes affect the activity of many companies.

The possibility of avoiding these risks or of using some methods to diminish them represents a crucial factor for all economic agents that wish to find the best strategy to accomplish such a desire.

In Romania not all companies tend to pay importance to such a factor and that is why many companies had gone into bankruptcy or have problems with liquidities being obliged to lay off employees.

The key to solving risk problems is the existence of a specialized department, a risk management department specific to all types of companies which are interested in continuing their activity on long term and even increase their turnover or profit.

The importance of identifying and analyzing risks is crucial for the success of any company.

2. The risk concept and types of risks

The performance of any activity must take into consideration the possibility of a risk to take place. The evolutions recorded on the international financial markets, the changes in the most important stock exchanges; show that there have appeared a series of new situations that can affect the activity of companies in a negative way, having serious implications of its long term objectives.

Unfortunately, in Romania there are not many companies that take into account the possibility of tracking and managing risks and when we say this we mean using different methods and models to identify these risks and to do something in improving the profitability of a company.

The risk is presented also as a result of failures or wrong judges or of some uncontrolled events [1] or as the possibility that a future action will generate losses that will affect the capital, interests, activity and results of an economic agent.[2]

We cannot forget to remind the presentation of risk as „an element of incertitude that can affect the activity of an economic agent or the performance of an economic operation”. [3]

When talking about risks we must not forget to take into account the concept of incertitude, the two concepts could not exist one without the other.

The factors that lead to the appearance of risks are different and can appear from the business environment, from the actions of the Government or can appear from what happens inside the company.

Risks can be structured and analyzed from different point of views, taking into account the fact that they appear in all the socio-economic activities and at all levels of companies. A first classification of risks must take into account the level of organization of the economy and we find here politic risks, social, economic and natural risks.

Figure 1. Macroeconomic Risks

Source: own processing

Risks must be understood as precisely so that the causes that have determined them can be identified in order to make sure what the probability of their appearance is and to try to reduce them or apply proper strategies so that these kind of risks will not appear.

The existence of certain periods which are characterized by economic and financial instability must be a start point for the elaboration of some action plans and strategies that have been clearly established performance objectives, applicable in the

manifestation of all kinds of risks.

It is hard to find a solution to eradicate a risk from the activity of a company but companies should try, if they want to have profitability, to reduce the degree of risk to happen so a set of correct measures could resolve such an issue. Of course, such measures should be adopted only if they take into account the activity of the company not to implement what other companies have done without having any resemblance.

The key of reducing risks is that of discovering them at the right moment and finding the best strategies to implement.

Even the fact that we find different definitions of risks makes it hard for some managers to implement an efficient risk management.

At the microeconomic level we find risks as economic ones, commercial, financial, exchange, politic, contractual.

According to the nature of risks we have[4]:

- Economic,
- Commercial,
- Financial,
- Exchange,
- Political,
- Calamity;
- Contractual.

According to how they are build, we have the following[5]:

- Economic,
- Financial
- Bankruptcy

According to the type of risk, we have[6]:

- Pure,
- Speculative,
- Of non-payment,
- Of innovation.

According to the provenience of the determinant factor, we have:

- Internal,
- External.

We have presented some important criteria, which allow the identification of the most important risks that can take place, so that there can be followed the way of action of these risks and try to identify the methods, techniques and instruments that can offer a guidance.

3. Techniques for identifying and assessing risks

The implementation of an active management of risks is based firstly on the identification of risks. The process of identifying risks must be realized in accordance with the objectives that can be affected by the existence of risks.

The identification of risks regards highlighting the threats and possible dangers, a complex of events, phenomena and processes that can generate losses, having as aim to offer clarity to possible problems before they come into existence.

Companies must firstly take into account the potential sources of risks which can be found in the external environment but also in the operational environment and they must also consider the fact that some information used in the process can be wrong or not enough in order to control possible actions.

The methods used in the identification of risks can be traditional and modern ones. Those traditional are:

- The identification through questionnaire: a questionnaire is used, allowing the identification of assets exposed to risks and of potential losses caused by the action of risks. The questionnaire must include questions regarding external and operating risks. There can be taken into consideration categories of risks like: politic, social, economic, financial, risks regarding suppliers, investors, debtors, competition.
- The analysis of the financial and accounting statements: is done by using the data recorded in the financial and accounting statements that are recorded in previous periods. This method allows the identification of a limited category of risks due to the specific information used.
- Direct observation : It implies the use of information collected directly from the level of activities performed. The advantage is that risk can be identified easily.
- Brainstorming: Is a method which is realized by reuniting more experts in a meeting moderated by a person having as aim the exposure to certain ideas.
- Delphi: Is a combination between brainstorming and the questionnaire method. A group of experts are reunited

in order to identify possible risks afferent to a project or an activity with the difference that they do not meet in a meeting. A questionnaire is given by the coordinator, it will be completed by experts with ideas regarding the most important risks.

- SWOT analysis: Is performed by identifying strengths, weaknesses, opportunities and threats regarding an activity. Risks can be identified more easily, they come from the company or outside of it.

While the modern ones cover the:

- **Process mapping:** This method regards the fact that any economic entity has inputs and outputs and there are build diagrams which highlight the way the activity is structured. The main factors aimed in the process of realizing the mapping are: the dedication of the management team; effective communication; the development of a systematic approach; the training of people involved in the methodology; the supply of good resources in the identification process of time and money[7]
- **Profile of risks:** method used when risks that have appeared in previous cases are found here. It allows a relevant assessment of risks that affect a company.
- **Risk scoring cards:** A method which uses ordinal scales to evaluate risks. These are classified according to some established criteria and the ranking represents the base for adopting decisions when managing risks.

In the specialty literature we can also find the methods like the quality and the quantitative one. Each of them presenting some advantages and some disadvantages. The qualitative one appears to be subjective while the quantitative one is objective.

The difference between the two methods regards the fact that the quantitative one takes into consideration numerical values while the qualitative one regards non-numerical values.

The quantitative analysis has as objective the identification of the risks that have the most important influence of projects. There can be used not only data from the risk management domain but also from the process of identifying risks. Some risks have

a higher probability of appearance while others have a small one.

4. Conclusions

The unstable economic environment faces companies with numerous challenges and managers that want their businesses to survive the economic crisis must give the proper importance to the identification of risks and to their assessment.

Companies that have a proactive risk management attitude are more capable to overcome the appearance of different risks.

Managers must be capable to identify not only financial risks but also commercial ones, risks coming from the fact that currencies can be depreciated. In Romania the currency risk has affected many companies that had not known how to manage their liquidities.

Taking all of these into consideration, we must state that it is crucial to give importance to the identification of risks, to their assessment and to always try to have risk management strategies if companies want not to go bankrupt.

Analysis of the Company’s Performance Based on the Profit and Loss Account

Căruntu Constantin

Lăpăduși Mihaela Loredana

“Constantin Brâncuși” University of Tg-Jiu

Faculty of Economics and Business Administration

caruntu_ctin@yahoo.com, lapadusi.mihaela@yahoo.com

Abstract

The complexity of economic and financial operations of a company has as consequences positive or negative results, which are reflected in the financial statements. One of these statements that play an important role in the analysis of the company’s performance is the profit and loss account. Through this document we shall have an overall view on the performances recorded by a company in an accounting period, performances that can be followed from a dynamic, structural point of view and also through the margin rates.

The profit and loss account is a part of the financial statements set that forms the informational basis of any company reflecting its performances, informational basis well known on internal plan, but also on the international area.

The aim of the research is that of highlighting the structural and dynamic analysis of the results reflected through the profit and loss account, and also through the margin ratios.

Keywords: the profit and loss account, performances, structural analysis, margin ratios

J.E.L. Classification: L2

1. Introduction

In the specialty literature, there is not a unitary vision on the performance concept, finding either particular definitions of it, surprising certain sides, or general definitions that are hard to quantify: [10]

- M. Porter considers that the company’s performance depends on its capacity of

creating value for its clients;

- A. Bouguignon defines the performances as reflecting the accomplishment of the organizational objectives;

- Elie Cohen assimilates the performance with efficiency, tracking the results obtained by the company in comparison with the resources used;

- Philippe Lorino states that the performance for a company is what helps the couple value- cost, and not only what contributes to the diminution of cost or the increase of value;

- C. Marmuse considers performance as the one maintaining a distance, on long term, from competitors, through a powerful motivation (by using the reward systems) of all the organization members.

The professors M. Niculescu and G. Lavalette define the economic performance of a company as representing the unstable equilibrium resulted from the evolution of the concepts of efficiency and efficacy. [5]

P.A. Samuelson, winner of the Nobel prize states that:” it is absolutely indispensable for the modern human to initiate a little bit in the accounting elements. All those which work in the economy must be able to understand the two essential conditions, to understand the balance sheet and the profit and loss account.”[9]

The profit and loss account is a financial statement concluded at the end of the financial exercise, respectively on its performances. On its basis there can be calculated a series of indicators with informational value important for the company, indicators which can be compared with other indicators of the companies from the same activity sector with the view of establishing the level of performance of the company at branch level.

Also, on the basis of the profit and loss account there can be determined the results afferent to the three categories of activity, respectively of operating, financial and extraordinary, and starting from their results there can be determined the weights of the three categories of results (operating, financial and extraordinary) in the gross result. This type of analysis is called structural analysis and has the role of establishing which of the three results has the biggest share in the formation of the gross result.

2. The performances analysis on the basis of the Profit and Loss Account

In our country the profit and loss account is found in a list form where company's revenues and expenses are presented according to their nature. Thus, revenues are divided in three categories: revenues from operating, financial revenues and extraordinary revenues, and expenses in operating expenses, financial expenses and extraordinary expenses.

The simplified form of the profit and loss account can be presented as:

Table no.1

	INDICATORS	ACCOUNTING PERIOD	
		N-1	N
1.	Operating revenues		
2.	Operating expenses		
A.	Result from operating (1-2)		
3.	Financial revenues		
4.	Financial expenses		
B.	Financial Result (3-4)		
C.	Current Result (A+B)		
5.	Extraordinary revenues		
6.	Extraordinary expenses		
D.	Extraordinary result (5-6)		
7.	Total revenues		
8.	Total expenses		
E.	Gross result (7-8)		
F.	Tax Income		
G.	Net Result(E-F)		

Through this form of presentation of the profit and loss account is explained the way in which is formed the global result of the financial year, on its basis being derived a series of conclusions regarding the evolution and level of performances according to the three types of activities: operating, financial and extraordinary.

3. Profitability analysis by using the profit and loss account

3.1. The dynamic analysis of the result indicators

Through the dynamic analysis of the profit and loss account are researched the results reflected by this, respectively those from the operating, financial and extraordinary activity, results which are in a permanent change from a financial year to another, showing their position in a certain time period. Through the detailed analysis, in dynamic can be explained the modifications of the results through the modifications of the different categories of revenues and expenses.

In the dynamic analysis for the appreciation of the way in which the company's results evolve, and also the elements of revenues and expenses there can be used the indexes that can be expressed either as simple ratios between current values (realized) of the economic indicators and previous values (planned) of them, either under the form of the percentage ratios of the two values: current and previous.

3.2. The structural analysis of the result indicators

The structural analysis of result indicators follows their evolution according to the types of results highlighting the structure modifications that appear from a period to the other. A structural analysis allows the establishment of the elements regarding revenues and expenses that contribute to getting the result, and also to the identification of the factors that have influenced it.

The weight of the operating result in the gross exercise of the period:

$$G_{RE} = \frac{RE}{RBE_x} \cdot 100 \quad (1)$$

The weight of the financial result in the gross period result:

$$G_{RF} = \frac{RF}{RBE_x} \cdot 100 \quad (2)$$

The weight of the current result in the gross result of the period:

$$G_{RC} = \frac{RC}{RBE_x} \cdot 100 \quad (3)$$

The weight of the extraordinary result in

the gross result of the period:

$$G_{RExt} = \frac{R_{Ext}}{RBE_x} \cdot 100 \quad (4)$$

By performing the structural analysis of the results we shall determine the weight of each type of result in the total result of the period, observing the positive and negative influences of the three types of results.

3.3. The profitability analysis by using the margin ratios

3.3.1. The analysis of consumed resources ratios

The profitability analysis by using the consumed resources expresses synthetically the efficiency of the activity performed by using the ratio effect/effort. It can also be calculated the analysis of the following ratios: [2]

a) profitability ratio of consumed resources it expresses the gross profit realized at one unit of total expenditure (100 units if it is expressed in percentage) and it measures the capacity of the consumed resources to generate gross profit. It is calculated as:

$$RPRC = \frac{\text{The gross result of the exercise}}{\text{Total expenditure}} \cdot 100 \quad (5)$$

» the growth of the ratio in dynamic expresses a favorable situation for the company and it takes place when the index of the gross result of the exercise brings forward the growth index of total expenditure.

b) profitability ratio of current resources expresses the profitability of consumed resources in the current activity (of operating and financial) and it is calculated as:

$$RPRC = \frac{\text{The current result}}{\text{Current expenditure}} \cdot 100 \quad (6)$$

»this ratio eliminates the influence of the extraordinary result on the gross result of the exercise, meaning the efficiency of the activity performed in general. The increase in dynamic of the ratio has the same significance as at the previous ratio.

c) profitability ratio of the consumed resources in operating activity expresses the profitability of the operating activity and is relevant especially in the situation in which the financial and extraordinary activity influences greatly the gross result of the exercise. It is calculated as:

$$RPRE = \frac{\text{The result of the exploitation}}{\text{Operating expenses}} \cdot 100 \quad (7)$$

3.3.2. The analysis of the ratios of realized revenues

The profitability analysis regarding the realized revenues expresses the economic efficiency through the ratio effect/effect and it shows the capacity of revenues to generate profit. It is used for the following ratios: [2]

a) gross profit margin expresses the weight of the gross result of the exercise in total revenues and it reflects on this basis the global efficiency of the activity. It is calculated as:

$$RPVT = \frac{\text{The gross result of the exercise}}{\text{Total revenue}} \cdot 100 \quad (8)$$

»the growth in dynamics of the ratio reflects a positive situation and can be realized through the increase of the gross result of the exercise in a superior rhythm to the increase of total revenues, which means actually the reduction of expenses per revenue unit. It results that the total revenues profitability ratio is complementary to the consumed resources profitability ratio.

b) the profitability ratio of current revenues reflects the efficiency of the operating and financial activity, elimination the influence of the extraordinary activity which sometimes can influence the gross result of the exercise. It is calculated as a weight of the current result in current revenues as it follows:

$$RPVC = \frac{\text{The current result}}{\text{Current income}} \cdot 100 \quad (9)$$

» the upward dynamic of the ratio reflects an improvement of the operating and financial activity and can be performed through the reduction of operating and financial expenditures in parallel with the growth of revenues realized from the respective activities.

c) the profitability ratio of operating revenues expresses the profitability of the main activity of the company, meaning of the activity that performs the object of activity. This ratio eliminates the influence of the financial activity which influences greatly through its financial expenses the

profitability, diminishing considerably the profit. It is calculated as:

$$RPVE = \frac{\text{The result of the exploitation}}{\text{Operating income}} \cdot 100 \quad (10)$$

d) the operating margin ratio characterizes the economic efficiency from the point of view of the final stage of the economic circuit. It is calculated as:

$$RRC = \frac{\text{The result of the exercise}}{\text{Turnover}} \cdot 100 \quad (11)$$

4. Case study regarding the profitability analysis by using the profit and loss account:

Firstly, in order to form an image on the evolution of the results of a company we shall have to use the following data:

Table no.2

NO. CRT.	INDICATORS	EXERCISE	
		N-1	N
1.	Operating revenues	1.066.796	1.907.010
2.	Operating expenses	577.262	1.015.742
A.	Operating result(1-2)	489.534	891.268
3.	Financial revenues	131.402	109.391
4.	Financial expenses	1.861	6.912
B.	Financial result (3-4)	129.541	102.479
C.	Current result (A+B)	619.075	993.747
5.	Extraordinary revenues	0	0
6.	Extraordinary expenses	0	0
D.	Extraordinary result (5-6)	0	0
7.	Total incomes	1.198.198	2.016.401
8.	Total expenses	579.123	1.022.654
E.	Gross Result (7-8)	619.075	993.747
F.	Income Tax	96.161	158.999
G.	Net result of the Exercise (E-F)	522.914	834.748

Taking into consideration the data from above, we analyze the evolution of the result indicators as:

Table no.3

No. CRT.	INDICATORS	EXERCISE	
		N-1	N
		Change (+/-)	Index N/N-1*100
1.	Operating revenues	-840.214	178,76
2.	Operating expenses	+438.480	175,96
A.	Operating Result(1-2)	+401.734	182,06
3.	Financial revenues	-22.011	83,25
4.	Financial expenses	+5.051	371,41
B.	Financial result(3-4)	-27.062	79,11
C.	Current Result (A+B)	+374.672	160,52
5.	Extraordinary revenues	0	0
6.	Extraordinary expenses	0	0
D.	Extraordinary result (5-6)	0	0
7.	Total revenues	+818.203	168,29
8.	Total expenses	+443.531	176,59
E.	Gross Result (7-8)	+374.672	160,52
F.	Income Tax	+62.838	165,35
G.	Net Result of the exercise(E-F)	+311.834	159,63

From the calculus performed there can be detached the following conclusions:

- the operating result has recorded a growth of + 401.734 lei, respectively with 178,76% in the year N in comparison with the year N-1, this thing is due to especially to the growth of other operating revenues, respectively to their increase with 921.722 lei;
- the financial result has decreased with 27.062 lei in the year N in comparison with the year N-1 due to the growth of the financial expenses with 5.051 lei, but also the decrease of financial revenues with 22.011 lei;
- the current result is the same with the gross result of the exercise due to the fact that the extraordinary result is null; the current result records a positive evolution, growing with 374.672 lei, situation appreciated positively for the company;
- the extraordinary result is null, due to the fact that the company has not been confronted with extraordinary events during the two financial exercises;
- the gross result is positive not only in year N, but also in the year N-1, meaning the company has recorded profit for the two financial exercises, and as evolution this has increased with 374.672 lei in year N, in comparison with the year N-1;
- the net result, respectively net profit, records also positive values, increasing in the year N in comparison with the year N-1 with 311.834 lei.

Together with the dynamics analysis of these results, an important role is had also by the structural analysis which helps at following their evolution from the structural point of view. Through the structural analysis we shall measure the contribution of each intermediary result to the formation of the gross result. Thus on the basis of the calculation of the weight of the four types of results in the gross result of the exercise we shall obtain the following data:

$$G_{RE_{N-1}} = \frac{R E_{N-1}}{RBE_{N-1}} \cdot 100 = \frac{489.534}{619.075} \cdot 100 = 79,07\% \quad (12)$$

$$G_{RE_N} = \frac{R E_N}{RBE_N} \cdot 100 = \frac{891.268}{993.747} \cdot 100 = 89,69\% \quad (13)$$

$$G_{RF_{N-1}} = \frac{R F_{N-1}}{RBE_{N-1}} \cdot 100 = \frac{129.541}{619.075} \cdot 100 = 20,92\% \quad (14)$$

$$G_{RF_N} = \frac{R F_N}{R B E x_N} \cdot 100 = \frac{102.479}{993.747} \cdot 100 = 10,31\% \quad (15)$$

$$G_{RC_{N-1}} = \frac{R C_{N-1}}{R B E x_{N-1}} \cdot 100 = \frac{619.075}{619.075} \cdot 100 = 100\% \quad (16)$$

$$G_{RC_N} = \frac{R C_N}{R B E x_N} \cdot 100 = \frac{993.747}{993.747} \cdot 100 = 100\% \quad (17)$$

$$G_{R E x_{N-1}} = \frac{R E x_{N-1}}{R B E x_{N-1}} \cdot 100 = \frac{0}{619.075} \cdot 100 = 0\% \quad (18)$$

$$G_{R E x_N} = \frac{R C_N}{R B E x_N} \cdot 100 = \frac{0}{993.747} \cdot 100 = 0\% \quad (19)$$

The data obtained can be summarized as follows:

Table no.4

NR. CRT.	INDICATORS	EXERCISE	
		N-1 G %	N G %
A.	Operating result	79,07	89,69
B.	Financial result	20,29	10,31
C.	Current result	100	100
D.	Extraordinary result	0	0

From the synthesis of the obtained calculations it can be seen that the operating result had the decisive contribution to the formation of the gross result.

In order to deepen the results' analysis based on the profit and loss account we will achieve the profitability analysis based on margin rates given the two aspects, namely: the analysis of the consumed resources rates and the analysis of the achieved revenues rates.

The analysis of the consumed resources rates:

a) the consumed resources rate of return:

$$R P R C_{N-1} = \frac{\text{The gross result of the exercise}}{\text{Total expenditure}} \cdot 100 = (20)$$

$$= \frac{619.075}{579.123} \cdot 100 = 106,90\%$$

$$R P R C_N = \frac{\text{The gross result of the exercise}}{\text{Total expenditure}} \cdot 100 = (21)$$

$$= \frac{993.747}{1.022.654} \cdot 100 = 97,17\%$$

b) the current resources rate of return:

$$R P R C_{N-1} = \frac{\text{The current result}}{\text{Current expenditure}} \cdot 100 = (22)$$

$$= \frac{619.075}{579.123} \cdot 100 = 106,90\%$$

$$R P R C_N = \frac{\text{The current result}}{\text{Current expenditure}} \cdot 100 = (23)$$

$$= \frac{993.747}{1.022.654} \cdot 100 = 97,17\%$$

c) the operating consumed resources rate of return:

$$R P R E_{N-1} = \frac{\text{The result of the exploitation}}{\text{Operating expenses}} \cdot 100 = (24)$$

$$= \frac{489.534}{577.262} \cdot 100 = 84,80\%$$

$$R P R E_N = \frac{\text{The result of the exploitation}}{\text{Operating expenses}} \cdot 100 = (25)$$

$$= \frac{891.268}{1.015.742} \cdot 100 = 87,75\%$$

Summarized, the data is:

Table no.5

NR. CRT.	INDICATORS	EXERCISE	
		N-1 (%)	N (%)
1.	Consumed resources rate of return	106,90	97,17
2.	Current resources rate of return	106,90	97,17
3.	Operating consumed resources rate of return	84,80	87,75

Because the extraordinary result is null, the current result coincides with the gross result of the exercise and the consumed resources rate of return is identical to current resources rate of return.

The analysis of the achieved revenues rates:

a) the total revenues rate of return:

$$R P V T_{N-1} = \frac{\text{The gross result of the exercise}}{\text{Total revenue}} \cdot 100 = (26)$$

$$= \frac{619.075}{1.198.198} \cdot 100 = 51,67\%$$

$$R P V T_N = \frac{\text{The gross result of the exercise}}{\text{Total revenue}} \cdot 100 = (27)$$

$$= \frac{993.747}{2.016.401} \cdot 100 = 49,28\%$$

b) the current revenues rate of return:

$$R P V C_{N-1} = \frac{\text{The current result}}{\text{Current income}} \cdot 100 = (28)$$

$$= \frac{619.075}{1.198.198} \cdot 100 = 51,67\%$$

$$R P V C_N = \frac{\text{The current result}}{\text{Current income}} \cdot 100 = (29)$$

$$= \frac{993.747}{2.016.401} \cdot 100 = 49,28\%$$

c) the operating revenues rate of return:

$$R P V E_{N-1} = \frac{\text{The result of the exploitation}}{\text{Operating income}} \cdot 100 = (30)$$

$$= \frac{489.534}{1.066.796} \cdot 100 = 45,89\%$$

$$R P V E_N = \frac{\text{The result of the exploitation}}{\text{Operating income}} \cdot 100 = (31)$$

$$= \frac{891.268}{1.907.010} \cdot 100 = 46,74\%$$

d) the commercial rate of return:

$$RRC_{N-1} = \frac{\text{The result of the exercise}}{\text{Turnover}} \cdot 100 = \quad (32)$$

$$= \frac{619.075}{1.051.378} \cdot 100 = 58,88\%$$

$$RRC_N = \frac{\text{The result of the exercise}}{\text{Turnover}} \cdot 100 = \quad (33)$$

$$= \frac{993.747}{969.870} \cdot 100 = 102,46\%$$

Summarized, the data is:

Table no.6

NR. CRT.	INDICATORS	EXERCISE	
		N-1 (%)	N (%)
1.	Total revenues rate of return	51,67	49,28
2.	Current revenues rate of return	51,67	49,28
3.	Operating revenues rate of return	58,88	102,46
4.	Commercial rate of return	45,89	46,74

From these data it can be seen that the total and current revenues rate of return declined in year N to year N-1, the operating revenue rate of return recorded the highest growth while the commercial rate of return increased slightly.

From the two tables we observe that the resources rate of return registered higher values than the revenues rate of return, except the operating revenues rate of return that increased with 100% in year N compared to N-1.

5. Conclusions

The profit and loss account is and always will be the informational base necessary for any user interested in the results, the performance recorded by a company during a financial year. Of course, an analysis on the company's performance is not based only on the profit and loss account, but in conjunction with all of the other financial statements of the company.

Practically, the profit or loss account is a picture of revenue and expenditure of a period of time having as a balance the net result. This result is determined in cascade, on the following levels: the operating result, the financial result, the current result, the extraordinary result, the gross result of the exercise, the net result of the year. [7]

The result of this research has resulted in a case study that is a proof that through the dynamic, structural analysis and based on the margins of the profit and loss account we can get an overview of the development results

achieved by the company during the financial years.

Also, the case study also provides information that can help decision making process regarding the economic and financial area from a company's management.

The objective of the financial statements is to provide information regarding the financial position, the financial performance, the changes in the financial position and cash variation, their progress being tracked on at least two years.

Most of the information contained and provided by such financial statements and implicitly by the profit and loss account is required for a variety of users of financial statements (shareholders, employees of the company, creditors, suppliers, current and potential investors, customers, managers, competitors, state, and so on).

Analysis of the Government and Local Public Debt in Romania

Căruntu Roxana Corina
“Constantin Brancusi” University
Faculty of Economics and Business Administration
r_caruntu_28@yahoo.com

Abstract

The concept of public debt is a complex one and it has been analyzed many times throughout the years but the current context influenced by the global financial and economic crisis highlights the importance of prudent public debt management.

The term of public debt is based on the financial obligations of central and local public authorities towards their creditors.

The article focuses in observing the evolution of total public debt and of its components in the period 2004 - August 2012. The purpose of the article is to highlight the current values of the public debt in order to show the state of the public finances of the country.

Key words: public debt, government public debt, local public debt.

J.E.L. Classification: H62; H63

1. Introduction

The effective management of public debt is based on the achievement of state funding and payment of its obligations at a lower cost and risk. In conducting the activity of attracting financial resources, the State creates relationships with internal and external creditors which lead to the increase of state debt.

A detailed analysis of public debt shows its evolution and the one of its elements of structure in the period considered.

Public debt may be useful in financial development until a certain threshold; past

this threshold it may actually prove harmful. Furthermore the possibility of public debt adversely affecting financial development has to do with the financial system itself which can be repressed or free.
[1]

The need for public debt management in good conditions is based on the Government's priority to reduce exposure to risks in the medium and long term.

In order to fit into the requirements of the Maastricht Treaty regarding the public debt, Romania intends to reach a level of below 33,5% during the period 2013-2015. Also, the importance of managing properly the public debt appears from the fact it influences the future of the citizens that have to refund the debt.

2. The evolution of public debt

Public debt is the indicator showing the financial obligations assumed by the State from its internal or external creditors. These obligations arise from loans obtained directly or guaranteed by the Government or local authorities and refer both to loan repayment and payment of interest and fees related to it.

Public debt includes all amounts borrowed by government, the administrative-territorial units and other public entities, from individuals or legal entities from a domestic market and abroad and that are to be repaid at some point. [5]

As shown in the above definition of public debt, the total public debt has two components: the government debt and the domestic public debt.

In turn, the government debt and the local public debt are structured by several criteria. In this article we focus on their structure depending on their type, referring to the direct or guaranteed government debt, respectively to the direct or guaranteed local public debt.

The direct government public debt represents the obligations of the state at a time, arising from reimbursements employed on a contractual basis by the Government through the Ministry of Economy and Finance; according to GEO no. 64/2007,

including those contracted by the central public administration authorities until the entry into force of the Government Emergency Ordinance. The guaranteed government public debt includes all obligations of the state at a time, from reimbursable funding guaranteed by the Government through the Ministry of Economy and Finance; in accordance with the provisions of this emergency ordinance, except those contracted by the central public administration authorities until the entry into force of this emergency ordinance. Direct local public debt shows all obligations of the territorial administrative units at a time, from reimbursable funding employed by them, on a contractual basis while the guaranteed local public debt represents all obligations of the territorial administrative units at a time, from repayments guaranteed by them, under the provisions of this emergency ordinance and of the Law no. 273/2006 on local public finances, with subsequent amendment. [2]

In order to analyze the total public debt we tried to follow the evolution of its level (Figure no. 1) and of the components of its structure (Figure no.2).

The analysis performed on the total public debt of Romania in 2004 - August 2012 looks like it had an upward trend.

Figure no.1. The evolution of the total public of Romania during 2004 – August 2012(millions RON)

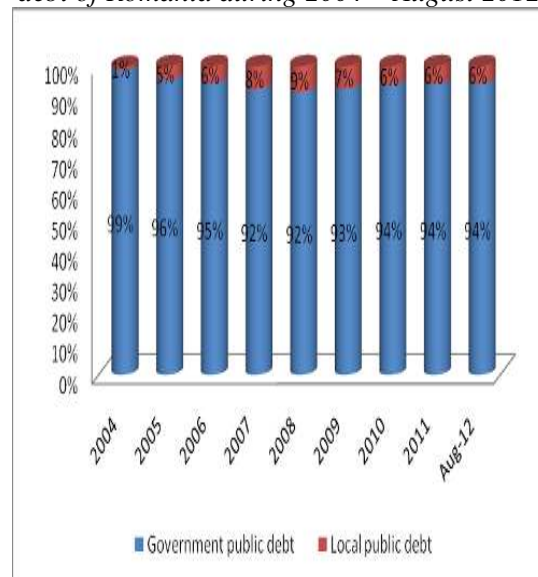

Source: Personal contribution based on the data from the Ministry of Public Finance

We notice that in August 2012 the total public debt registered an increase of 3,76% compared to 2011. Based on the figure we observe that between 2004 and 2006 the

increase of this indicator was a slow one, while starting with 2007 the debt suffered a significant growth annually. The high value of the total public debt is determined by the macroeconomic situation that the country is facing.

For a better understanding of the evolution of public debt we follow the evolution of its forms. (Figure no.2)

Figure no. 2. The structure of the public debt of Romania during 2004 – August 2012

Source: Personal contribution based on the data from the Ministry of Public Finance

Regarding debt structure in Figure no.2 can see that the largest share in the total public debt is held government debt, while total public debt has a very low weight. Thus, the government public debt, in August 2012, has represented 94 % of the total value of the public debt while the local public debt had a share of 6%.

Starting from the government public debt value from 2004, when it represented 99% of the total public debt, we notice a slight and insignificant decrease its share in public debt.

3. The government public debt

The government public debt is the debt component showing the financial obligations of the state arising from the loans contracted or guaranteed by the Government.

The Government is authorized to engage in the name and on behalf of the state obligations in the nature of the government public debt only through the Ministry of

Finance, for the following purposes:

- financing the state budget deficit, temporary financing of deficits from previous years of the state social insurance budget, up to the money allocation to this destination, temporary financing of the deficit of the state budget and of state social security budget in the current year;
- refinancing and early repayment of government debt;
- always maintain a proper balance in the Treasury General Account, established by the Ministry of Economy and Finance, in accordance with the methodology developed according to the art. 12 paragraph (1);
- financing based on the law of programs / projects and other priority needs for the Romanian economy [4].

It registered an upward evolution during the analyzed period, from 55147.3 millions Ron in 2004 to 218464.4 millions Ron in August 2012. (Figure no. 3)

Figure no. 3. The evolution of the government public debt of Romania during 2004 – August 2012 (millions RON)

Source: Personal contribution based on the data from the Ministry of Economy and Finance

The high levels of government public debt are due to the increase of the budget deficit. Thus, in 2008, due to the increase in the budget deficit, the Ministry of Finance decided to launch new issues of government bonds and new borrowings. This decision resulted in the increased value of government debt.

From the above figure, we notice that it has registered an increase of 3,83% in August 2012 compared to 2011. Also, based on the figure we can see that between 2004 and 2006 the government public debt has registered a slight increase. Starting with 2007, its increase was a significant one as it started from 76149.6 millions Ron in 2007 and reached to 218464.4 millions Ron in August 2012.

Based on the public debt structure presented above, we analyze the evolution of its components. (Figure no.4)

Figure no. 4. The structure of the government public debt of Romania during 2004 – August 2012

Source: Personal contribution based on the data from the Ministry of Public Finance

Based on the above figure, we observe that the highest share in total public government debt is held by the direct government public debt. Also, we see that the level of this rate, as part of the government public debt, has an ascending trend during 2004 – August 2012, increasing from 77% in 2004 to 94% in August 2012.

In what concerns the guaranteed government public debt, its share in the total government public debt is continuously decreasing, reaching from 23 % in 2004 to 6% in August 2012. However, the figure shows that in August 2012 the guaranteed government public debt increased by 1% compared to the previous year but it is an insignificant increase.

4. The local public debt

Local public debt is the financial obligations of local administration authorities arising from loans contracted or guaranteed by them.

Administrative territorial units are denied access to loans or to guarantee any loan, if the total annual debt representing annual installments due on loans contracted and / or guaranteed, interest and fees related to them, including those of the loan to be contracted and / or guaranteed in that year, exceeds the limit of 30% of total revenues stated by art. 5 paragraph (1) point a. [3]

Figure no. 5. The evolution of the local public debt of Romania during 2004 – August 2012 (millions RON)

Source: Personal contribution based on the data from the Ministry of Public Finance

Local public debt recorded significant growth in the period under review. Thus, it increased from 672.4 millions Ron in 2004 to 13199.4 millions Ron in August 2012.

In the period 2011 – August 2012, the increase was a minor one of 2,6% and between 2008 - August 2012 it recorded a constant increase.

As in the case of government public debt, for highlighting the local public debt structure we monitor the evolution of direct and guaranteed local public debt. (Figure no.6)

Figure no. 6. The structure of the local public debt of Romania during 2004 – August 2012

Source: Personal contribution based on the data from the Ministry of Public Finance

Based on the figure above, we can see that the direct local public debt represents the largest share in the total local public debt. In the analyzed period, 2004 - August 2012, the direct local public debt level had a value near that of the guaranteed local public debt only in 2004. In the other years, its value maintained between 91% and 96%.

5. Conclusions

Based on analysis achieved throughout the article, we can conclude that the public debt of Romania, during 2004 - August 2012, showed an upward trend because of massive lending contracted by Romania, especially in recent years.

Due to the need for payment of wages and pensions, Romania was forced to seek loans from the IMF, European Commission and other banks in the local market which resulted in high levels of public debt.

From the structural analysis of public debt results that the largest share in total public debt is registered by the government public debt.

For Romania to record a slow growth rate of public debt is needed that the Romanian economy to record growth and the budget deficit to be reduced.

New Customer Demands – Challenge for Accounting Track in Business Faculties

Chersan Ionela-Corina
„Alexandru Ioan Cuza” University of Iasi
macov@uaic.ro

Abstract

For many years business schools were perceived as providers of educational services only for students. Now, can be identified many other customers: internal (students, faculty - teachers, and administrative staff – who do not teach), external (futures employers, other universities, suppliers, the government, and various communities). In this context, all business faculties face new challenges and new approaches of school management. For this reasons we try to identify the impact of the labor market transformations and the new access rules to accounting professional organizations on the demands for accounting track in business faculties.

Cuvinte cheie: Business faculties, accounting, higher education, professional organization.

Clasificare J.E.L.: I23, M40.

Introducere

Trying to produce a map of the customers of business faculties, it can be identified two categories: internal (students, faculty - teachers, and administrative staff – who do not teach) and external (futures employers, other universities, suppliers, the government, and various communities) [1]. Both categories of customers are acceptable in this contest if we define customers as beneficiaries of works efforts or purchasers of products and services.

The customers appreciate a good product or a good service if it answers to their expectations, preferences, and requirements. But the expectations, preferences, and requirements are different from a category of customers to another one (e.g., students expect to acquire knowledge and solid

working skill; employers expect more practical education, foreign language skills, and a focus on teamwork). In this context, all business faculties face new challenges and new approaches of school management.

Changing characteristics of learners, making higher education more diverse, dispersed and decentralized, self-learning, developing virtual and hybrid, customizable and characterized as cross-disciplinary, cross-institutional and transnational delivery mechanisms, adopting national and international requirements for education in accounting are the new challenges for faculty management.

The accountants of tomorrow will face much more daunting challenges that did the accountant of yesterday. In addition to these changes, Bologna process has significantly modified the economic higher education. It is an obligation for faculties to adopt new curriculum and new teaching methods to accomplish the new expectations of different customer types.

Purpose of study

The purpose of this paper is to highlight how internationalization (globalization) of business education, as well as its standardization, higher education reform initiated by government, and new regulations in accounting profession are source of changes and challenges for accounting track in business faculties.

In order to emphasize this, we will present below a number of elements regarding the environment in which the faculties of economics act, the rules that represent the benchmark in training the current and future accounting professionals and the way the Bologna process has influenced the higher education.

When taking into account the higher education in economics, a very clear reality is

that its position within the academic community is not one to be envied. Although not valued at their full potential by the academic community, the faculties of economics managed to earn respect by means of the consistent revenues they brought and still bring for the public or private universities, though rarely being considered as important structures in universities or as determinants contributing to the society development [2]. The matter of reputation can also be raised. Thus, some authors [3] state that a big number of subjects contribute at the academic debate regarding reputation; among them we can find economics, strategic management, marketing, sociology and accounting. Although the last in the list, accounting contributes more and more to the reputation increase and to the bigger number of students that enroll in faculties of economics, for bachelor degree, as well as for master and PhD degrees. In some countries (e.g., France, Romania), the master and PhD degrees in accounting and audit offer important capabilities for accessing the professional accounting organizations.

From the student perspective, both the studies in economics, as well as those in accounting and audit, must have a practical component. The requirements of the professional accounting organizations from some countries contribute to the students' opinion, because they impose to faculties interested in signing agreements for study recognition some conditions regarding the content of study and subject programs, as requirements for profession access.

Under these circumstances, the faculties are more and more interested in having professors that are capable to develop the students' practical abilities, paired with the delivered technical knowledge. Among the abilities ever more necessary for future professional accountants, that faculties are preoccupied to help the students develop, are: oral and written communication skills, teamwork, research, time management etc. However, we cannot say with certainty that obtaining theoretical knowledge under various forms of education ensures their correct use in practice. That is why, at a global level, the International Federation of Accountants (IFAC), through the International Accounting Education Standards Board (IAESB), develops and

publishes documents that represent the referential in professional accountants training [4]. The relationship between the pieces of knowledge obtained through study and the ability to use them in practice is emphasized correctly in the table below.

Table 1. Relationship between capabilities and competence

Capabilities	Competence
<i>Key concepts</i>	
Attributes Potential Possess <i>Can be expressed as learning outcomes</i>	Action Actual Demonstrate <i>Can be expressed as performance outcomes</i>
<i>Types of capabilities</i>	<i>Types of competence</i>
Professional knowledge Professional skills Professional values, ethics and attitudes	Includes the range of performance outcomes related to practice standards Includes the range of performance outcomes related to behavioral standards

Source: IFAC, *Handbook of International Education Pronouncements*, 2009 Edition, New York, pp. 23-24

Although these documents are purely informative, the faculties that offer study programs in accounting and audit are directly interested in what they state because national organizations of professional accountants determine their access requirements and continuing education programs for their members according to these recommendations.

This situation also raises a question: does the higher education in accounting and audit come close to the professional area or the academic environment? In some countries, from the standpoint of the regulatory bodies of university education, these faculties should have an important research component and thus be oriented more and more on research activities.

The so-called Bologna process has significantly modified the economic higher education. This refers to an increase in the study period, but also a structural modification. A noteworthy increase of the number of masters and PhD students led to

added quality for the economics faculties. But it is too soon to make an evaluation of the advantages and disadvantages brought by this process. Nevertheless the reform of the faculties will continue in order to make the results more visible on the long run. Some of the objectives have been achieved: the students, professors and administrative staff mobility was increased / facilitated, a transferable credit system was established and the inter-institutional cooperation has significantly developed[5].

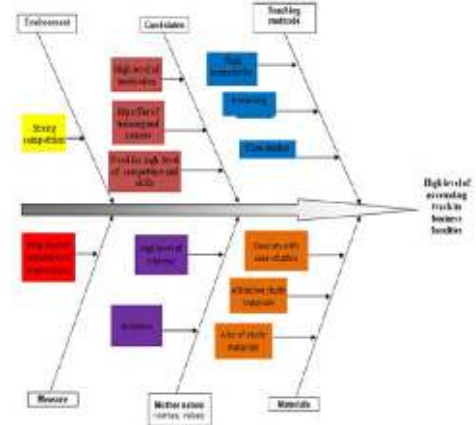

Methods

The accounting track in a business faculty should survive only if on the market exist demand for accounting services. But, there are a lot of costumers who demand educational services (in accounting track). In addition, accounting services market depends on national and international rules. In this context, we focused on the forces and factors affecting internalization, harmonization, and development of higher education in accounting track. Using Fishbone Diagram and Pareto Diagram, can be highlighted the main contribution of some forces and factors in a high quality accounting track development.

As an initial step, we have tried to identify the determinants for maintaining a high study level in accounting and audit. For this, we have developed a Fishbone diagram, (also known as Causes-Effect diagram) that emphasizes the contribution of the identified causes to achieving the pursued effects. All of the causes are grouped in six main categories: candidates, teaching methods, environment, materials (courses), measure, Mother Nature (values, ethics, etc.), and each of them is split into components.

I continued this analysis indentifying the main causes of these results (I presented them in the table below) and I realized, using for data compilation Vertex 42, a Pareto Diagram which highlight that 78.22% of effect is generated by so-called vital causes and the rest of 21.78% is generated by rank 2 causes.

Figure 1. Fishbone/Causes-Effect Diagram for a high level of accounting track development

Source: Own processing

Table 2. The causes of accounting track development and their significance

	%	Causes	%	Total
Candidates	30	High level of motivation	10	3
		Big offer of training and courses	50	15
		Need for high level of competence and skills	40	12
Environment	20	Strong competition	100	30
Teaching methods	10	High interactivity	20	2
		E-learning	40	4
		Case-studies	30	3
Materials (courses)	10	Attractive study materials	40	4
		Courses with case-studies	40	4
		A lot of study materials	20	2
Measure	10	High level of complexity of exams topics	100	10
Mother nature (values, ethics)	20	High level of interest	60	12
		Ambition	40	8

Source: Own processing

The Pareto Diagram presented below has starting point the table above.

Figure 2. Pareto Diagram

Source: Own processing

In developing this analysis we have observed that there are numerous causes that influence the development of higher educational studies in accounting and audit and that the most important depends on market, meaning the competition between various providers of such programs or alternative programs.

We observed that the complex business environment makes new demands on the professional accountant. Users expect a high level of competence of the profession and this level can be reached through some form of specialization. The professional organizations must be pro-active in this area. There are some factors which would serve to enhance the expertise of the professional accountant and hence the service to business. These factors are listed below: to improve and maintain the skills and competence of members who operate as specialist in fast changing business community; to provide guidance for those who may wish to operate in a specialized area; to create a framework for the interaction of members who share a common professional interest; to lessen the danger of fragmentation within the profession.

In the same time, specialization is already widespread among professional accountants, whether they are working in a public practice, in industry, commerce or the public sector. This specialization is a necessity because the professionals operate in a dynamic environment. In recent years, the knowledge required by the professional accountant encompasses not just matters

relating to accounting but includes knowledge of taxation, information technology, internal audit, company legislation etc

Findings and results

From my study resulted that 78.22% of effect is generated by so-called vital causes (5 in my analysis) and the rest of 21.78% is generated by rank 2 causes (6 in my analysis). Unfortunately, most of the causes that influence the maintenance and development of study programs in accounting and audit do not depend entirely on the organizing institution, but on the competitors represented by faculties of economics, as well as other types of organizations that offer courses and training programs in these fields of study. We can state that there are second rank causes that depend on the organizing institutions and about which we can say that more and more of them have worked on developing (E-learning, attractive and diverse courses, interactivity).

Conclusions

The accountants of tomorrow will face much more daunting challenges that did the accountant of yesterday. The role of the accountant in a changing environment should be multiple: adviser, specialist, and even business partner. It is an obligation for faculties to adopt new curriculum and new teaching methods to accomplish the new expectations of different customer types. The business faculties must decide if the higher education in accounting and audit will come close to the professional area or the academic environment. Nevertheless the reform of the faculties must continue in order to make the results more visible on the long run. This is more necessary as, in the recent times, some authors have suggested that accounting research has become insufficiently innovative and increasingly detached from practice and society[6], [7].

Others authors (Deppe et al., 1991) considers that accounting students must develop competencies in seven areas: communication skills, information development and distribution skills, decision-making skills, knowledge of accounting, auditing, tax, knowledge of business and

environment, professionalism, and leadership development.

The employability sits on graduate attributes like: communication skills, good interpersonal skills, teamwork, self-management, problem solving, technological competence, etc. So, business school must develop curriculum that cover all this attributes and open a dialogue with employing firms and accounting professional organization for change the future of accounting profession.

Abstract

In our attempt to understand the causes and consequences of the most critical international financial crisis of the 21st century which, besides crushing world economies, questioned the bases of the mainstream economic theories, we focused our attention on the solutions provided by the Austrian School’s representatives (in doing that we have nevertheless tried to avoid prejudices). According to them, the reckless policy of artificial credit expansion promoted by the monetary authorities represents the major cause of the economic and financial crises as well as of recurrent recessions. Our study aims to provide an enumeration (of course, not an exhaustive one) of the causes of the financial crises, from the Austrian School perspective, but also draws attention to the inevitable political and social consequences of the interventionist policy in the economy, in general, and in the banking system, in particular.

Key words: the Austrian School, financial crisis, central banks, monetary policy.

J.E.L. classification: B25, B53, E40, E50, E52

1. Introduction

The occurrence of the most critical international financial crisis of the 21st century brought back into the spotlight the economic ideas of the Austrian School, thus questioning (and even criticizing) the validity of the *mainstream* economics theory. Among the first representative exponents of this school we mention: Carl Menger, Eugen von Böhm-Bawerk, Friederich von Wieser, Ludwig von Mises, Friedrich von Hayek etc.

and among contemporary representatives we may consider: Israel Kirzner, James Buchanan, Murry Rothbard, Jörg Guido Hülsmann, Jesus Huerta de Soto etc.

According to the representatives of the Austrian School, the policy of artificial credit expansion, promoted by monetary institutions, is the main cause of the economic and financial crises as well as of recurrent recessions. As for the financial crisis which broke out in the autumn of 2007, it is worth reflecting on the five errors (three general diagnostics and two specific recommendations) emphasized by the economists of the School of Madrid: Rodríguez Braun and Ramón Rallo [9]. Their five points of view, incorporated in a message oriented against the mainstream economics theory are: 1) the political culprit for the international financial crisis which deeply undermined the mainstream economic fundamentals is the liberalism; 2) the moral responsible for the crisis is the greed of human nature (this opinion was skeptically regarded by the two economists due to the ethics of this issue); 3) the economic responsible for the crisis is, according to the two economists, undoubtedly, the free market (with a stress on money and finance); 4) the fourth perspective is built on the rejection of the so-called necessity to save the banks in difficulty; 5) the last issue approached by the two is focused on dismantling one of the most popular economic policy strategy, that is, the necessity to increase public spending with the purpose of creating new jobs.

Our paper is structured as follows: in the second section we concentrate on an incursion in the Austrian economic literature in order to emphasize the events preceding the break of an economic-financial crisis. Due to the fact that the origin of the current

international economic crisis was a financial one, the third section is meant to define the role of Central Banks (which represents the top of the pyramid of the banking system in most economies) in the view of the Austrian School. Section four comes to complete the previous one and is entirely dedicated to the problematic of the „natural” interest rate versus the „artificial” interest rate. The final section of the research paper highlights the main findings of our work.

2. The Austrian School’s vision with regard to financial crises

According to Austrian economists, the artificial increase of the monetary mass and the credit (explained in detail in the Austrian business cycle theory) causes serious economic imbalances (at the level of microeconomic and macroeconomic indicators) which distort the real structure of production, thus affecting the private agents’ perception with regard to profitable investments and pushing them into taking considerable risks by getting involved in malinvestments.

In order to clarify the chain reactions which occur up to the moment of the outburst of an economic-financial crisis, from the Austrian School’s perspective, we shall deal the following topics: voluntary savings, real credit versus artificial credit, profitable investments versus malinvestments, the collapse, and finally, the denouement.

2.1. Voluntary savings

Voluntary savings represent the type of behaviour by which a person stops the immediate consumption of a large amount of goods in virtue of subsequent consumption of the same amount [7: 487]. In this way, the person transfers the purchasing power of his savings to the debtor, allowing the latter to purchase different goods.

The savings process is based on the *deposit contract*. According to the Austrian economist, Jesus Huerta de Soto, it is compulsory to make the distinction between the *irregular deposit contract* (in cash) and the *loan contract*. The *deposit contract* is „a contract signed in good faith by which a person – the depositor – entrusts another person – the depository – a mobile asset

which the latter is to guard, protect and return at any moment if demanded by the depositor” [5: 42]. By referring to a fungible asset, the deposit contract (irregular) imposes that „the *tantundem* (the disposal right on the goods) not be transferred”. To conclude, in the particular case of cash (fungible goods), the person receiving the deposit is obliged (according to the institution of irregular deposit) to permanently maintain at the depositor’s disposal 100% cash reserves. The cash deposit contract is applicable in practice to the so-called „visible current accounts, savings accounts and to deposits, any time the last two enable the client to actually withdraw balance at any moment” [5: 196]. As for the *loan contract*, a transfer of full disposal of the goods (or money) takes place from the lender to the borrower for a certain period of time and, normally, with an agreement regarding interest payment.

2.2. Real credit versus artificial credit

Mises [8] proposes, before opening any discussion regarding credit expansion, to draw a clear line between two types of credit: *commodity credit* and *circulation credit*.

Commodity credits (or *credits with coverage in real savings*) involve the transfer of financial resources from those who saved towards the ones who wish to use them productively. The debtor, owner of the financial resources transferred by the lender, (creditor) has the purchasing power necessary to buy the goods for future production. In conclusion, the amount of commodity credit is strictly limited by the previously achieved amount of savings. Supplementary credit can be acquired if additional savings are created by reducing present consumption.

Circulation credits (or *artificial credits*) require transfers of financial resources from „especially created banking funds [8: 124]. The moment the bank offers such a credit, it prints money thus resulting in a simply accounting entry.

According to Huerta de Soto, demand deposits offer bankers the possibility to „create bank deposits (that is, money) and in turn, loans (purchasing power transferred to borrowers, whether businessmen or consumers) from nothing; these deposits and loans do not result from any real increase in

voluntary saving by social agents” [5: 199]. To conclude, according to the Austrian School’s vision, the banking system is abusive in that it creates fiat money „on paper”, the amount of money substitutes is increased, thus providing the opportunity to be used as if proper money. With the purchasing power artificially increased, debtors manifest increased demand on the production factors market which naturally leads to an increase in the price of goods and the level of wages.

2.3. Profitable investments versus malinvestments

In any economy, economic agents plan their future activity according to the information received from such indicators as *price levels*, *salary levels* and *interest rates*. We aim to approach two scenarios: a free economy and an economy in which the state intervenes in the financial-banking system.

In the case of a free economy, the economic agents use the information received from the above-mentioned indicators and establish the extent to which an investment project is profitable or not. If the analysis reveals a configuration of indicators which draws attention to the fact that he is dealing with a *malinvestment*, the economic agent becomes aware of the fact that his project is of no interest, at least at that particular moment, to the consumers. In this context, the consumer is the one who, by expressing his preference for a product/project forces the economic agent to focus his resources in a particular direction.

In the second case, the state distorts the signals sent by the configuration of indicators by direct intervention. Due to this, the economic agent performs miscalculations and erroneously estimates a malinvestment as a profitable one. In this way, instead of directing the economic agents’ resources towards real needs, they are recklessly invested.

Through the expansionist policy of circulation credits, the state intervenes on the market and indirectly modifies the interest rate, thus distorting reality and encouraging taking supplementary risks by becoming involved in investments which used to be considered unprofitable.

2.4. The collapse

The unlimited number of loans provided by banks by means of the circulation credit mechanism lead to major imbalance in economy by: the increase in prices of goods and services, the increase in salaries, the fall of interest rate below the level of the „natural” interest rate (increasing the spread).

On the short term, the expansionists’ interventions, as the inflation advocates call themselves today [8: 126], produce *booming business* but despite that Mises draws attention to the fact that „such an artificial prosperity cannot last and will inevitably end up in a *slump*, a general depression” [8: 127].

Once the economic agent is attracted by the cheap and easy money policy mirage and once he becomes involved in bad business, in the context of the factors of production price increase (as a consequence of the overflow of liquidity), he becomes dependent on the bank’s constant money „injections” (if he refuses to give up on his initial plans). This euphoric state, dominated by bigger and bigger salaries and the possibility to earn money without considerable efforts, becomes fragile in time and ends in a collapse. The natural consequence of this artificial economic boom is, as we are about to see, an adjustment process in the shape of an economic crisis and recession.

2.5. The denouement

Within the first scenario, the expansionist credits policy spiral is fueled by banks which provide economic agents with the cash they need. The chain reactions continue: the credit demand is bigger and bigger as well as the credit offer, the amount of banknotes and deposits (artificially produced) increases uncontrollably, the production prices and costs as well as salaries increase etc. In a moment of lucidity, people become aware of the situation and „run away” from money and focus their attention on more tangible goods and purchase them irrespective of price or of whether they need it or not. Consequently, the purchasing power of the currency falls rapidly and its decline culminates in economic and/or financial crisis.

In the second scenario, it is supposed that banking institutions become aware of the situation created by the credit expansion

policy and therefore refuse to perform financial liquidity injections (artificially created) thus managing to deny access to credit addicts to their only source of finance. In this case, as well, we witness a series of chain reactions: the phenomenon triggers panic, interest rates increase rapidly, prices fall abruptly (as a consequence to the generous stock offer on the market due to the economic agents' attempts to recover their invested money), unemployment rate increases as a consequence to activity restriction etc.

The Austrian economists' solution is a painful but necessary one. According to them, the economic crisis and recession are necessary since they „reveal the fact that a significant number of investment projects financed with the newly-created bank credits *are not profitable* due to the fact that they do not meet the consumers' real needs” [5: 283]. Once the artificial credit expansion has been initiated, we are warned that the economic crisis will inevitably happen. Despite all these, „the outburst of the crisis and recession ultimately represent the beginning of the *recovery*. In other words, economic recession represents the beginning of the *recovery* stage... Similarly to the drinking hangover which represents a normal reaction of a healthy body against alcohol aggression, an economic recession, which marks the beginning of the recovery period, is healthy, necessary but painful at the same time. The result of such a period is a production structure adapted to the consumers' real needs” [5: 444]. The period marked by economic crisis, followed by depression, ends „the moment the free market balance is reestablished and the expansionist distortion is eliminated” [10: 860].

The remedy to these economic mutations (crisis and recession) that Huerta de Soto proposes consists in applying a *maximum economic flexibility* policy able to „focus on the microeconomic objective of flexibility and liberalization of all market factors, and especially of the labour market” [5: 446]. This policy generally refers to: a) readjusting the production structure and adapting it to the consumers' real needs in terms of savings; b) abolishing erroneously initiated projects and the massive transfer of production factors towards the consumption stages and companies, where consumers require them.

According to Mises, *the depression* (as a

consequent phenomenon to crisis) is „the necessary process to structurally readjust production activities according to the real configuration of the market data, that is, to the capital goods offer and to the public assessments” [8: 130-131]. Thus, according to Mises, the depression represents the first stage in the return of normalcy, economic recovery and real prosperity fundamentals reestablishment (by eliminating the prosperity illusion artificially based on credit expansion).

As far as the current situation is concerned, Rodríguez Braun and Ramón Rallo [9] think that the role of the state in solving the financial crisis should be null and they consider the prospects of fast recovery to be conditioned by the following terms: adjustment of relative prices, production factors reallocation and stimulation of savings.

To conclude, state intervention and manipulation of financial-banking activities according to political interests (and not according to profit criterion) prevents the micro and macroeconomic indicators from receiving and transmitting objective market information. In this way, the system becomes unsustainable and incapable to maintain the initial welfare on the long term.

3. The Central Banks' position and role in the view of the Austrian School

According to the representatives of the Austrian School, the current two-level-structured banking system (central banks and commercial banks), based on fractional reserves of cash deposits, represents the basis of disequilibria which ultimately cause financial and economic crises.

As far as the financial-monetary sphere is concerned, Austrian theorists criticize the central planning maintenance (performed by central banks), their massive interventions in economy (by deciding interest rates and introducing regulations) and state monopoly (by legalizing forced exchange which obliges citizens to accept payment in the government-issued fiduciary currency).

Central banks, in their desire to stimulate economy and thus enhance production (beyond the capacity of its normal parameters) follow the Keynesian monetary policy recommendations and allow the artificial increase of credit volume and monetary mass. As a consequence, central

banks are indirectly responsible for:

- *reduction of interest rate*; in this way the activity in different economic branches is stimulated and therefore, production stages are multiplied and entrepreneurs' risk aversion is decreased, an aspect which clearly contributes to their involvement in unprofitable projects.
- distortion of the market signals issued by the configuration of indicators such as interest rates, price and salary levels;
- the occurrence of malinvestments; these are „projects which will never be realized and which will ultimately be abandoned by their promoters” [2: 5];
- the increase in the price of production factors and in the costs of commodities production;
- the outburst of the economic crisis (and/or of the financial crisis which occurred as mutations/bubbles in the financial sector) and its consequences: bankruptcies, high unemployment rate, low standard of living etc.

If economy is not left alone to recover by going through the painful crisis process and central banks continue to interfere (eg. by providing loans without coverage in real economies in order to maintain the value of a currency), it will not be long before the economic crisis will break out at a much larger scale (in terms of duration, loss and intensity etc.).

In the financial-monetary sphere, the Austrian School's advocates propose the application of the principles of liberty and private property on condition that the following compulsory measures are implemented in banking [2: 8]:

- the elimination of fractional reserves and restoration of 100% obligatory reserves for the banks which receive deposits from the public and for all similar institutions ;
- central banks should no longer hold the last resort financing and the central financial planning agency roles.
- The privatization of the fiduciary media issued by the state under monopoly and its replacement with a monetary system which cannot be manipulated by people (the competition principle); at this moment, Austrian theorists recommend a gold-based standard system.

In the current context, the financial crisis

does not ignore, by any means, the regularities of the Austrian School advocates; it is simply the „effect of the U.S. government interference at all levels of the real estate and financial markets” [3: 13]. In Mises's opinion, the banking system, together with its toxic assets is artificially „kept alive” by liquidity injection in economy and thus it transfers loss to state budgets, both current and future. What the state is actually doing at present, through its „manic-depressive” interventions, is transform financial-banking crises into public debt crises thus aggravating, with its every intervention, the seriousness of the matter. And when „sovereign” entities fail they call the superstate European and international financial organisms for support (see the FMI, CE, BM interventions etc.).

4. The natural rate of interest versus the artificial rate of interest

The Swedish economist Knut Wicksell was the one to introduce the concept of *natural rate of interest* (or *neutral rate of interest*) in the economic literature, in order to refer to that particular rate of interest which „equals savings and investments” [4: 6]. If the interest rate had been lower, the money offer in the shape of savings would have been below the investors' demand for financial resources as well. If the interest rate had been higher, the funds demand for investments would have been lower than the savings offer. It is only in the case of a natural rate of interest that the money demand and offer could have been balanced.

According to Mises, the neutral rate of interest „expresses the population's willingness to eliminate the consumption of a percent of the earned income in order to allocate it to the production process extension” [8: 131] or, in Soto's terms, „the market price of present goods as compared to future goods” [5: 306]. Cerna shares their opinion: „the rate of interest which is neutral in relation to the prices on the goods and services markets or the rate which is equal to the demand and offer on the real market” [1: 594].

Despite all these, we would like to draw attention to the fact that, according to the Austrian economic literature, the concept of „neutral interest rate” has a three-fold interpretation: 1) it is a rate for which the

level of voluntary savings is equal to that of investments and therefore, there is no supplementary amount of money created ; 2) it is a rate of interest for which prices remain constant (there is no inflation); 3) it is a rate of interest which corresponds to the real (physical) productivity of capital goods. The interpretation of the interest rate according to the above-mentioned definitions is carried out according to the economic typology: stationary or in course of increase.

The moment the state intervenes on the market and starts to generate *ex nihilo* credits according to the Keynesian monetary policy recommendations, it indirectly manipulates the rate of interest (as an essential element of monetary policy of most central banks) and turns it into an „artificial” rate which is no longer reflected in the economic reality. The decrease in interest rates performed by monetary authorities is a strictly technical action which increases the present value of capital goods and distorts the entrepreneurs’ calculations by creating the illusion that certain projects can be profitable while they are nothing more but malinvestments (unapproved by consumers).

To Mises, the artificial interest (also named „monetary interest” or „gross interest on the credit market”) represents the „product of the manipulations of a group of unscrupulous exploiters” which creates the premises „of a different evaluation of present goods as compared to the future ones” [8: 131]. By modifying the natural rate of interest, the monetary authorities and banks bear the responsibility for the resulting *expansionist orgies and artificial economic explosion*.

5. Conclusions

What we are witnessing today is one of the most devastating artificial (“man made”) phenomenon of the capitalist era. The peculiarity of such an event is that problems keep bouncing from the private propriety to the public one and back (thus having a crisis of firms, banks, markets and sovereigns). The representative economists of the Austrian School blame the *mainstream* economics theory. According to the Austrian thinkers the main culprits for the economic and financial crises as well as of recurrent recessions are the monetary institutions and their policy of artificial credit expansion.

Therefore the artificial increase of the monetary mass causes serious economic imbalances which distort the real structure of production, thus affecting the private agents’ perception with regard to profitable investments. Other representatives from the same school of thought highlight five important errors of our time: a) liberalism is the political culprit; b) the greed of human nature is the moral responsible; c) the free market is the economic responsible; d) the rejection of the so-called necessity to save the banks in difficulty; and e) the so-called “necessity” to increase public spending with the purpose of creating new jobs. In our readings on the economics of the Austrian School we identified five important stages that describe the collapse of an economy: 1) the period of voluntary savings; 2) the separation of the artificial credit from the real credit; 3) the distortions of private agents’ perception with regard to profitable investments thus encouraging them to make malinvestments; 4) the collapse of the economy, and finally 5) the denouement of it.

Abstract

Education plays an important role in civil society, nowadays becoming an essential tool for training “actors” in the market economy. Worldwide currently it manifests the idea according to which educational systems must begin, continue and sustain changes and social progress, ensuring the quality of education, preparing individuals for the future and also to develop capacity to adapt to scientific and technical changes, to be able to create the new[1]. Neither the European Union nor Romania is an exception to this trends recorded by the higher education system at a global level. To continue to be a worldwide force, it is important that through balanced educational policies aimed at performance and quality, this region manage to succeed in a world marked of constant changes.

Key words: analyses, public finances, perspective, quality

J.E.L. classification: H52, H75, I21, I23

The problem of financing the higher education system was always a delicate problem because it is affecting all the countries that aim at achieving a performing educational system. In order to create value, such system needs consistent investments, its result cannot be seen only in the medium and long run. This situation regarding financing sources, size and destination it's a problem that was and is highly debated at the national and European level. Taking this into consideration, in this paper we will create a

comparative analysis regarding the structure and characteristic of the university system at the European level and Romania from the perspective of the measures and laws that EU created at a global perspective.

After the European Union was created, it was clear that the European learning system had to be modified. At the European level the idea of a continuous learning program and was adopted. This would contribute to a healthy development of the modern society and to a long term development of the economy. Because of the variety of learning systems at the European level, the idea of a new model that would adopt the values and qualities of all the countries involved and to create a new university system that would be unitary for all the countries of the EU soon arose.

In this context, the EU encouraged states to collaborate, to work together, to learn from each other in order to create a common path regarding the university system.

A first step in this direction of a uniformization and creating a unique university system at the European level was at 25 of May 1998 at Sorbona when a group of ministers responsible with the higher education system in France, Great Britain, Italy and Germany signed the „Declaration of Sorbona” regarding “the harmonization of the higher European university system architecture”. The primary elements were[2]:

1. Recognizing the „positive potential” of the existence of a European common area of the higher education system;

2. A "progressive harmonization" of the general frame of reeling-off study cycle through "strengthening the previous experience of unifying diplomas, pilot initiative and of dialog " started with the Lisbon strategy;
3. Encouraging student mobilization, researchers by using the hole support of the European Union

The Declaration ended with an appeal to all the European States to join the objective of creating a common european spouce of higher education in which „the national identities and common interests can interract and develop in the benefit of Europe”

The most important step that was made in order to achieve this European Union goal was in 1999 once the „Bologna Declaration”was adopted. In 18-19 of june 1999, at Bologna, at the United Confederation of Rectors of the European Union teh declaration was signed by the ministries of education of 29 European states regarding "European space of higher education system". Until now, the Bologna System was installed and mplemented in 47 European countries.

Romania is not an exception from this system and with the beginning of the university year 2005/2006 the national university system suffered a lot of changes once with the implementation of the European higher university system. So, with the beginning with the fall of 2005 Universities from Romania offered study programs structured on three levels:

a) Undergraduate studies – *Cycle I*. The normal length of the university undergraduate studies is between 3 and 4 years. The length of technical learning system (including agricultural), law and technological is 4 years. The first generation that graduated was in 2008. They received a graduate diploma according to the specialization they followed.

b) *Graduate studies- master – Cycle II*. The normal length of the graduate studies is 1-2 years. The total length of cycles I undergraduate studies and cycle 2- graduate studies must correspond to at least 300 credits. The graduates receive master diplomas in the specialization they followed.

c) *Doctoral studies – Cycle III*.

These studies are usually 3 years long. In special cases, when the research needs a longer period of study the total period can be prolonged with 1-2 years. The graduates receive doctoral diplomas in the field they chosen.

In order to implement exactly the directions of the university system, European Union insisted on education when elaborating the strategy “Europe 2020”. So, the program Education and professional formation was founded (ET2020). This is a strategic European cooperation program in the field of education and professional development and it sets strategic objectives for all the member countries including a set of principles in order to achieve this objectives. It also sets common work procedures with priorities for every academic cycle.

Through this program there are 4 strategic objectives set: [3]:

1. Practical learning along the life and student mobilization;
2. Improving the quality and efficiency of education and learning;
3. Promoting equity, social cohesion and active citizenship ;
4. Stimulating creativity and innovation, including entrepreneurship at all levels of education and teaching

In order to measure the progress in fulfilling these objectives a number of indicators and references criteria were establish. Regarding the higher education system it was established that all the member countries by 2020 had to meet the following criteria [4]:

1. On average, at least 15% of grown-ups have to attend learning program

Fig.1 the share of adults that participated in universities program of learning in Romania compared with EU 2002- 2011 (%)

Source: Authors calculation based on Eurostat

As we can see in figure 1, at the EU level in the entire period analyzed, besides 2002, more than 15% of adults followed a university learning program. This is not the same in the case of Romania where the higher percentage of the population involved in this type of learning program was in 2011-3,9%, way beyond the EU average of 16.1%.

When it comes down to the rate of enrollment in study programs at the level of all learning cycles, not just university ones, the percentage is way lower not just for Romania, where in the last 10 years the percentage was 1.6%, the same value as in 2011.

2. The percentage of people with the age 30 and 34 years old that are attending tertiary sector has to be at least 40%.

Fig. 2 evolution of student with the age between 30 and 34 years old in România and UE 27, in the period 2002-2011(%)

Source: Authors calculation based on Eurostat

As we can see from the figure above, at the EU 27 level for the entire period analyzed, the percentage of students with the age between 30 and 40 rose from 23,5% in 2002 to 34,6% in 2011. This was also the case in Romania when this indicator was 20.4%.

3. The percentage of people between 18 and 24 that drop out of school has to be above 10%

Fig. 3 The percentage of people between 18 and 24 that drop out of school in Romania and EU 27 in the period of 2002-2011

Source: Authors calculation based on Eurostat

The 10% figure that EU stated regarding drop out from school between the ages 18 and 24 is still way beyond realization. Although that through the measures adopted the value of this indicator dropped at 13,5% in 2011 in UE 27 and at 17.5% in Romania there is still a long way to go in order to achieve 10 % by 2020.

4. 20% of the graduates must spend a period of the studies abroad.

At this last point, the statistics are not very encouraging. According to Eurostat in Romania and EU this indicator does not reach 5%. This is because of financial reasons but also because of the lack of synchronization of the learning programs at the EU level.

Another aspect that has to be analyzed is the one regarding financing the university system. In order to get the results that “Europe 2020” set up regarding higher education there has to be significant investments. Education is a priority for EU but it is still insufficiently financed. At the European level, the investments in higher education is only 1.3% of GDP, compared to USA where is 2.7%. In this context, the annual budget of the EU (2014-2020) is set up to be substantially increased for education, professional development and research [3].

Fig. 4 The evolution of public expenditures with university education in Romania and EU 2001-2009 (%)

Source: Authors calculation based on Eurostat

From this analysis we can see that also Romania and EU pay about 1,2% of GDP for financing university education. In case of Romania, we can see something above 0.6% of GDP in 2003 not the same we can say regarding the evolution of the EU level among 1,1% and 1,2 % of GDP.

In order to be competitive the budget has to increase considerably. Not even a doubling of this amount is not sufficient with the Lisbon goal. In nominal terms, this amount will increase based on the economic rise that is foreseen if we take into account the statistics of IMF and World Bank, regarding the GDP growth. And if the percentage for financing higher education will stay the same, then by 2017 the budgetary allocation in absolute figures would have to rise with 32% in Romania and 14% in case of EU.

At this moment, in our country the state financing is little above 3400 dollars per student and at the EU level it is 10600 dollars.

In order to for an educational system to be competitive, there has to be set the necessary conditions in order for students to give the best. So, the sums that state directly gives to the student as a learning scholarship or other scholarships gives a great advantage. The students are attract by the quality of education and are helped to achieve more by this sums. .

In Romania the financial aids for students as a percentage of total budgetary expenditures with the higher education is 7% compared to 17% in EU. Analyzing this data, we see that in Romania in 2011, the financial aids given by the state was 240 dollars. The European average was 1800 dollars.

Fig. 5 Number of students as percentage of the total population in Romania and EU (%)

Source: Authors calculation based on World Bank

As we can see from the figure above, although in Romania the financial situation is difficult regarding the higher education financing, the number of students willing to study is increasing year by year. In 2009, when was the highest number of students registered compared with the worst year of 2001 it was a 40% increase. For a short period of time, Romania was also above the EU average 2008 and 2009.

Although the number of students registered rose it is essential to further discuss the problem of absorption of the market. If we discuss about the quality of the university studies, it is not enough to state the number of students that attended the courses but also the number of people that receive the graduate diploma. We have to analyze the performances and also the value added to the work market. At a macroeconomic level, we have to identify the the best policy in order to obtain an efficient mix between the number of students that enter the university and the capacity of the program to create the best specialists.

Fig.6 Trimester evolution of those unemployed with higher education in Romania and EU 2005-2012(%)

Source: Authors calculation after Eurostat

In the first years of the period analyzed, we can see a drop in the number of unemployed with higher education studies this trend is maintained until the middle of 2008 when this number started to rise. The main reason was the global financial crisis. The high number of graduates along with the crisis made that the absorption rate to be limited which led to a higher unemployment rate.

Conclusion

Higher university system is the most important instrument that a country has at its disposal in order to influence in the long run the development of society, socially, economically, military, politically. It is also true that this system is very expensive not only for the state, but for the students also. But these investments, along with a series of educational programs viable and adapted to the need of every student can contribute in the long run at creating a society valuable that can face all challenges that a global economy can bring. In order to be competitive the higher education system in Europe, through its common policies has to combine with harmony all the factors that can create stability and balance. Considering the diversity of the countries involved in this global process it is very difficult to find a

unique recipe that can produce these beneficiary effects at every country level. Considering that there are a series of different policies that have to be applied taking into consideration every countries member of EU needs and possibilities, then this policies have to enforce the university system of every country. It has to become more successfully , more attractive for students willing to follow the higher education courses competitive so that in the end, from a powerful system of every nation to gain a unitary and successful system for all the EU involved in this reform.

Establishing precise and measurable objectives, allocating the necessary amounts for financing and establishing successful policies adapted to every country needs would bring Romania and EU the competitive advantage needed to become a successful economy in the long run. This process also involves a lot of patience, awareness and involvement and value added. This investment is measurable in the medium and long run, only when through the output

generated, the graduates by knowledge and aptitudes gain, could make a difference in the real economy.

The Evolution of Seigniorage during the Crisis

Clipici Emilia

University of Pitesti, Faculty of Economics Science
emilia_clipici@yahoo.com

Abstract

In developing countries, governments are tempted to, and they often do finance their budget deficits by issuing currency. This leads to inflation, and ultimately, the source of the incomes to the budget are the inflation tax and the seigniorage. The mechanism that is used is the direct loan, from the Treasury (the Government's cash desk) from the central bank, which means creating an additional monetary base. Basically, seigniorage is not different from the financing of the budget deficit, by the central bank, by buying government bonds, and the effect of this practice is the emergence of the phenomenon of taxing inflation, by deteriorating the value of the financial assets owned by banks and non-banks.

This paper is structured as follows: conceptual aspects concerning the seigniorage in section 1, section 2 showing the models for calculate the level of seigniorage, section 3 estimates the evolution of Seigniorage during the crisis.

Cuvinte cheie: seigniorage, inflation tax, crisis.

Clasificare J.E.L.: E31, E58, E62, G01.

1. Introducere

The seigniorage is the increase in the real monetary base, its purpose being to finance the budget deficit (through the monetization of the public debt) and it is the income obtained by the state by issuing currency.

While most economists agree that seigniorage is one way governments finance deficits, there is less agreement about the political, institutional and economic reasons for relying on it.

2. Concept of seigniorage

In order to cover budgetary expenditure,

constantly increasing from one year to another, the Government should find methods to increase budgetary incomes and this desideratum can be accomplished by various methods: increasing taxes and duties, their quantity or number (disadvantages: an unpopular measure and it is less used due to the fact that, at the next elections, politicians would have fewer sympathizers and would thus lose the elections); issuing bonds, securities or other government bonds (may generate or increase inflation should be carefully used and by the authorities); selling assets (when the Government owns various goods, especially fixed property and it is not a long-term solution, because, in a capitalist economy the property is preponderantly private).

Due to the fact that these strategies have obvious disadvantages, a method that was often used in the past to cover budgetary deficit was monetary issue, a process by which the state, through the specialized institutions, increased the economic liquidity. It is a well-known fact that by covering the deficit by monetary issue the inflation is increased, but in certain authors' opinion (Sargent, Wallace, 1981), financing a budgetary deficit by public loan leads, on long term, to a higher inflation rate than its financing by monetary issue. The argument of this theory would be the fact that covering the budgetary deficit from public loans drives only inflation. The assumption of this argumentation would be that the government undertakes to pay interests for the borrowed amount, and has two options at the due date: to use monetary issue or to borrow again, thus creating a new payment liability. However, at a certain point in time, the Government will have to stop contracting loans and to start financing by monetary issue. Interests will increase constantly if the Government delays this moment, and the relative amounts put into circulation in the economy may lead to price increases and

implicitly to the increase in inflation. However, the practice proved that, in most cases, the effect of such method is the increase in the inflation rate.

The first country that stopped seigniorage was England (where William the Conqueror coined the first coin in the 11th century) in 1666 through Queen Elisabeth. However, the system was bimetallic, i.e. gold and silver, with the corresponding divisions. But the difference in parity between states (the gold-silver ratio varied between 1:15 and 1:17) allowed for speculation with the two coins (at the beginning of the 18th century, the ratio was 1:15 in the USA, and 1:15.5 in France – the American golden coins passed to Europe.) The gold-coin standard that eliminated the silver in the coinage, also emerged for the first time in England, in 1821. without directly legislating the standard, England renounced coining in silver, and thus the first monometallic system emerged.

We can find the financing of the budgetary deficit exclusively based on monetary issue in Germany in the 1920s (Mishkin, 1998); in the period 1921-1923 this country care had to resort to monetary issue to finance public expenditure, because the increase in taxation was deemed an unpopular solution. As a result of the fact that public funds were necessary for the reconstruction of the German economy after World War I and, consequently, the reduction of public expenditure was not recommendable, and loans could not have been contracted because the financing needs exceeded the borrowing capacity of the country.

Against the background of social torments (strikes, the invasion of the Ruhr area by France as a result of the failure to observe the treaties for the reconstruction of Germany, etc.), his method of financing the budgetary deficit led to the increase in inflation that reached the level of 1.000.000 % in 1923. A more recent example in this respect is constituted by the states in South America that had, in their turn, to finance high budgetary deficits by monetary issue. An analysis of the situation of the countries in South-America reflect the fact that, if these countries had issued government bonds in order to finance budgetary deficits, the amount of issued bonds would have been so

large that the capital markets would not have been able to manage such an offer of financial instruments (Mishkin, 1998).

In terms etymologically, “seigniorage” from the French Seigneur: Sir, God, Landlord) denominates the capacity of (state) authorities to finance expenditures by money printing and it is associated with its sovereign monetary monopoly. Seigniorage revenues come from the fact that the Central Bank does not pay interest on the issued money, but the respective money is lend to the banking sector in exchange of a corresponding interest. A part of seigniorage revenues is used by the government for financing its budget; once the seigniorage disappears at national level, this source of revenue for the budget is not anymore available.

For exemple, in Romania, the seigniorage is the right granted by the Romanian State to the National Bank to coin. The difference between the printing costs and the nominal value of the coins is a source of income for NBR. NBR’s object is not to make profit, but to provide the stability of the prices in economy, i.e. the financial stability that provides an inflation within the target limits. Although BNR – *the National Bank of Romania* – is an independent institution, its profit is taxed by 80%, the conclusion being that the money obtained by the central bang also go to the government budget.

Because the profits from central bank operations are intended to be returned to the taxpayer, it is important that a central bank be careful with how it uses its power to create money.

For example, central banks often come under pressure to create money to provide loans to insolvent banks. But a central bank that makes loans to insolvent banks and then writes them off is creating money to bail out bank creditors, instead of to acquire assets that can make a return for all of a country’s citizens.

It is important, then, that central banks be regularly audited to ensure their money creation activities are in the public interest. It is also generally considered important that central banks be free from pressure from politicians to abuse the money creation power.

3. Seigniorage calculation models

There are several definitions that might be used and many calculation models for the seigniorage:

- the difference between the face value of a coin and its costs of production and mintage (Buiter, 2007). In fiat money economies, the difference between the face value of a currency note and its marginal printing cost are almost equal to the face value of the note – marginal printing costs are effectively zero. Printing fiat money is therefore a highly profitable activity – one that has been jealously regulated and often monopolized by the state.
- opportunity cost of money cost (Barro, 1982), that is, the money base multiplied by the nominal rate of interest:
$$S = d_n \times B_m$$
- according to Aise and Veiga (Aise and Veiga, 2008) as the change in reserve money as a percentage of nominal GDP and secondly the change in reserve money as a percentage of government revenues (most popular).
- the product of reserve money by the inflation rate divided by either GDP or government revenues (Cukierman et al., 1992). Authors have shown that these two additional alternative measures of seigniorage provide similar results.
- the change in the monetary base as a percentage of government spending (Click, 1998).
- The economists Nina Budina, J. Hanousek and Z. Tuma (Budina, Hanousek, Tuma, 1998) carried out a survey concerning currency demand and seigniorage in 4 countries in Eastern Europe (Romania, Bulgaria, the Czech Republic and Poland) and defined seigniorage as the real the real created base money and calculated it as a percentage of GDP.
- according to IMF (IMF, 2011), the seigniorage can be decomposed into “pure seigniorage” and an “inflation tax.” Pure seigniorage is not inflationary; it is derived from the increase in real base money associated with increased demand for such money as a consequence of economic growth and

other factors. The inflation tax equals the amount of additional nominal money the private sector needs to accumulate so as to off set the impact of inflation on the real value of its stock of money over time. It is like a regular tax, because it requires agents to forego consumption in order to increase the nominal (and maintain the real) value of their stocks of money.

- Fischer, Sahay and Vegh (Fischer, Sahay, Vegh, 2002) calculate seigniorage as the change in the real money stock by comparing the base money variation to GDP (both values are nominal):

$$S = \frac{\Delta B_m}{PIB}$$

- “Inflation tax” after Friedmann: $\pi * m$ (π , inflation rate; m , real monetary holding); it measures the costs of inflation by which the economic agents that retain money are loaded. Some definitions of the inflation tax also include the erosion in the real value of government debt that arises from higher inflation. The unexpected rise in the inflation rate would lead to a substantial reduction in the real value of public debt in advanced economies, where debt is long-term, nonindexed, and in local currency. However, this would also result in higher long-term rates, therefore increasing the cost of new borrowing (Cottarelli and Viñals, 2009).
- the real growth of the monetary mass, such as it is used, for instance in the inflation study done by Cagan: $\mu * m$ (μ , growth rate of monetary mass offer); it measures the profits resulted out of money creation.
- opportunity costs of monetary action (Phelps/Marty): $i * m$ (i , nominal rate of interest); it measures the expenditures that are created due to the fact that the economic agents cannot make investments out of the detained money mass in other asset values, which bear interest.

By assuming the validity of the quantity equation (for a constant speed of monetary circulation) and of the Fisher equation with perfect foresight, the following relation results:

$$\pi * m = (\pi - g_y) * m = (i - r) * m$$

for slight changes, where g designates the growth rate GDP and r the real rate of interest. When g_y , respectively r are positive, the measured seigniorage for item 2 and 3 exceeds the one measured according to item. When $g_y = r$ is valid, than item 1 and 2 are equivalent.

- according to Aisen and Veiga (2006):

$$St = \alpha PIt-1 + \beta SPt + \delta PSt + Ecot + EcPt + et$$
 where St is seigniorage, $PIt-1$ is a proxy for political instability, SPt is a proxy for social polarization, PSt is the Polity Scale, $Ecot$ is a vector of economic structural variables, $EcPt$ is a vector of variables accounting for economic performance and external shocks, et is the error term.

- according to Aise and Veiga (2008) as the change in reserve money as a percentage of nominal GDP and secondly the change in reserve money as a percentage of government revenues (most popular).
- Fischer (Fischer, 1982) calculated seigniorage in the 1980s as the change in high-powered money (line 14 in the IMF's International Financial Statistics) in GDP:

$$\% B_m / PIB = \left(e_y \frac{\Delta \gamma}{\gamma} + e_p \frac{\Delta P}{P} \right) \times \frac{C}{\gamma}$$

where:

e_y = real income elasticity as function of currency demand (assumed to be 1 or 1.5)

e_p = price elasticity (assumed to be 1)

- A survey (Hochreiter, 1996) performed in three countries (the Czech Republic, Hungary and Romania) fuses the following elements to calculate seigniorage:

$$S = H + H' + EK$$

where: $H + H'$ = the money base made of currency and the residents' deposits be they remunerated or nor; EK = accumulated reserves of the central bank exceeding 10% of the quantity of money.

While most economists agree that seigniorage is one way governments finance deficits, there is less agreement about the political, institutional and economic reasons for relying on it.

4. The evolution of seigniorage during the crisis

Central banks have expanded their balance sheets significantly in response to the

crisis, mostly by stepping up purchases of sovereign and bank debt.

On average, this expansion has been financed by an increase in base money, which nearly doubled as a percentage of GDP over 2007–11. Substantial purchases of assets by the central bank to provide liquidity to financial markets have two consequences for the government. Such purchases support demand for sovereign bonds and also boost government revenues through the collection of higher seigniorage—the revenue from printing money (Anand and van Wijnbergen, 1989; Buiters, 2007). Seigniorage revenues have been sizable as a result of quantitative easing strategies in the context of the crisis, with little impact so far on inflation expectations. However, governments cannot rely on these revenues indefinitely, as the central bank may need to unwind its positions as market conditions improve and money demand returns to more normal levels.

Seigniorage revenues have been sizable as a result of quantitative easing strategies in the context of the crisis, with little impact so far on inflation expectations. However, governments cannot rely on these revenues indefinitely, as the central bank may need to unwind its positions as market conditions improve and money demand returns to more normal levels.

In the aftermath of the global financial crisis, seigniorage revenues have risen rapidly as central banks have expanded their balance sheets through quantitative easing and bank support to counteract the impact of the crisis. In advanced economies, the total cumulative seigniorage revenue collected during 2008–11 reached 8 percent of GDP—more than five times the precrisis level. Most of the expansion took place in the form of pure seigniorage, whereas revenues from the inflation tax were limited. This can be explained in part by the surge in demand for reserve currencies (mainly the euro, the Japanese yen, the Swiss franc, the British pound, and the U.S. dollar) amid flight-to-quality effects following the crisis.

With impaired credit markets, the inflationary risk posed by such deficit financing is very low in the near term. The relationship between seigniorage revenues and changes in one-year-ahead inflation expectations has weakened since the onset of

the crisis. A predominant part of the expanded balance sheets has accumulated as excess reserves, which are either nonremunerated or remunerated at a very low interest rate and as a result, central bank profits have increased substantially (for example, the U.S. Federal Reserve transferred to the Treasury profits amounting to about ½ percent of GDP in 2011). Most of these revenues will disappear once central banks shrink their balance sheets to their normal level.

In advanced economies, the inflation tax accounted for less than 0.7 percent of GDP, a level comparable to the inflation tax collected in the precrisis period.

*Graphic 1. Selected Advanced Economies:
Seigniorage (Percent of GDP)*

Sources: IMF, *International Financial Statistics*; and IMF staff estimates.

Note: Weighted averages based on 2011 GDP at purchasing power parity; includes Australia, Canada, the Czech Republic, Denmark, the euro area, Japan, the Republic of Korea, New Zealand, Sweden, Switzerland, the United Kingdom, and the United States.

5. Conclusion

Seigniorage refers historically, that is, in a world with commodity money, to the difference between the face value of a coin and its costs of production and mintage. In fiat money economies, the difference between the face value of a currency note and its marginal printing cost are almost equal to the face value of the note – marginal printing costs are effectively zero. Printing fiat money is therefore a highly profitable activity – one

that has been jealously regulated and often monopolized by the state.

The issuance of fiat money is an extremely profitable monopoly and the Eurosystem can collect a sizable amount of seigniorage revenue while maintaining inflation of two percent. A back-of-the-envelope calculation puts yearly seigniorage collection at EUR 40 billion. Buiter and Rahbari (2011) estimate that the Eurosystem can collect seigniorage revenue with a present discounted value of about three trillion euros.

A straightforward way that the ECB can use its seigniorage to support illiquid but potentially solvent sovereigns is to buy their debt outright in secondary markets as it has done in the Securities Markets Programme. However this is less efficient than purchasing their debt in primary issuer markets and includes no conditionality that would promote good fiscal behaviour.

Abstract

Satellite accounts can respond to specific data requirements. They extend the central accounting framework by adding non-monetary information.

Using alternative concepts may give rise to partial complementary aggregates, the purpose of which is to supplement the central system.

Changes in some concepts and aggregates of the central framework may be introduced, but this is not the primary intention, nor is it intended to give a different picture of the overall economic process.

In the case of Romania, the introduction and use of satellite accounts still represent a nice “future step”.

Key words: satellite accounts, EU, Romania.

J.E.L. classification: A10; H50; M40; M41; M49.

1. Introduction

For some specific needs in terms of data, the best solution is to have separate satellite accounts.

Satellite accounts can respond to specific data requirements: they provide further details, where necessary, and eliminate unnecessary details; they extend the accounting framework, by adding non-monetary information, for example, information on pollution or environmental assets; they change certain basic concepts,

for example, extending the concept of capital formation while introducing the expenditure on research, development or education.

Satellite accounts provide the opportunity to make links between such non monetary statistics and the standard framework of the national accounts. The link is possible by using for these monetary statistics, where possible, the classifications applied in the standard framework, for example, the classifications by type of household or activity branch. In this way, we reach to a consistent extended framework. This framework can serve as a database for analyzing and evaluating all types of interactions between the variables in the standard framework and those of the extended framework. [1]

A number of the complementary or alternative analyses may modify the main aggregates as shown in the central framework either directly or indirectly. Examples of direct modifications are the increase in output and value added when final consumption of household services for own use is included within the boundary of production, or the increase in fixed capital formation if human capital is considered an economic asset. Other aggregates are indirectly modified; saving in the latter case, disposable income in the former. [2]

In some types of analysis the objective is to focus on one specific field of concern, such as education or tourism. Changes in some concepts and aggregates of the central framework may be introduced, but this is not the primary intention, nor is it intended to

give a different picture of the overall economic process. [2]

In the standard version, headings at a given level are mutually exclusive. For example, teaching in hospitals must be classified as either education or health expenditure but not both. Consequently, for an education or health account, it might be desirable to reclassify a number of transactions. In order to preserve as great a degree of consistency with the central system as possible, any reclassifications should be treated as removing an item from one heading and placing it in another rather than allowing double counting. Double counting would mean that transactions classified by purpose were no longer additive since some of them would appear under two or more headings. However, even without double counting, it should be noted that different satellite accounts, each with a different focus, may not be consistent with respect to other headings. For example, if an education satellite account treats some teaching done in hospitals as education rather than health, the measure of health in that satellite will differ from that in any other satellite where such a displacement has not been made. [2]

2. Characteristics of satellite accounts

The document entitled „Proposal for a Regulation of the European Parliament and of the Council on the European System of National and Regional Accounts in the European Union” offers a general introduction for satellite accounts. Union citizens need economic accounts as a basic tool for analysing the economic situation of a Member State or region. For the sake of comparability, such accounts should be drawn up on the basis of a single set of principles that are not open to differing interpretations. [3]

Although still in the proposal stage, it describes and analyzes how the central framework of national accounts can be used as base system to meet several important particular needs for specific data. Satellite accounts might develop or modify the tables from central framework in order to meet the necessities for such specific data. [3]

Satellite accounts can meet specific data needs by providing more detail, by rearranging concepts from the central

framework or by providing supplementary information, such as non-monetary flows and stocks. They may deviate from the central concepts. Changing the concepts can improve the link with economic theoretic concepts such as welfare or transactions costs, administrative concepts such as taxable income or profits in the business accounts, and policy concepts such as strategic industries, the knowledge economy and business investments used in national or European economic policy. In such cases, the satellite system will contain a table showing the link between its major aggregates and those in the central framework. [3]

Broadly speaking, there are two types of satellite accounts. One type involves some rearrangement of central classifications and the possible introduction of complementary elements. Such satellite accounts mostly cover accounts specific to given fields such as education, tourism and environmental protection expenditures and may be seen as an extension of the key sector accounts just referred to. They may involve some differences from the central system, such as an alternative treatment of ancillary activities, but they do not change the underlying concepts of the System of National Accounts in a fundamental way. The main reason for developing such a satellite account is that to encompass all the detail for all sectors of interest as part of the standard system would simply overburden it and possibly distract attention from the main features of the accounts as a whole. Many elements shown in a satellite account are invisible in the central accounts. Either they are explicitly estimated in the making of the central accounts, but they are merged for presentation in more aggregated figures, or they are only implicit components of transactions which are estimated globally. [2]

The second type of satellite analysis is mainly based on concepts that are alternatives to those of the System of National Accounts. It includes a different production boundary, an enlarged concept of consumption or capital formation, an extension of the scope of assets, and so on. This second type of analysis may involve, like the first, changes in classifications, but in the second type the main emphasis is on the alternative concepts. [2]

The wide range of satellite accounts illustrates that the national accounts serve as a frame of reference for a variety of statistics. They also illustrate the merits and limitations of the central framework. By applying the concepts, classifications and presentations such as the supply and use tables of the central framework to a wide range of topics, the flexibility and relevance of the satellite accounts approach for these topics is demonstrated. At the same time, additions, rearrangements and conceptual modifications illustrate the limitations of the central framework for the study of these topics. For example, the environmental accounts extend the central framework to take account of environmental externalities and the household production accounts extend the production boundary to include unpaid household services. In this way, they demonstrate that the central framework's concepts of product, income and consumption are not complete measures of welfare. [3]

Major advantages of satellite accounts include the following: a) based on a set of clear definitions; b) application of a systematic accounting approach; c) linkage to the basic national accounting concepts; and d) linkage to national accounts statistics. [3]

A major characteristic of many satellite accounts is the inclusion of non-monetary data, such as data on CO₂ emission by industry in the environmental accounts or number of treatments by type of health care in the health accounts. The linkage of such non-monetary data with monetary data can provide key ratios, such as CO₂ emission per billions of euro of value added or the costs per treatment. Two other major characteristics of satellite accounts are extra detail and supplementary concepts. [3]

3. Functional satellite accounts

Functional satellite accounts focus on describing and analysing the economy for a function, such as environment, health, and research and development. For each function they provide a systematic accounting framework. They do not provide an overview of the national economy, but focus on what is relevant for the function. To that end, they show detail not visible in the aggregated central framework, rearrange information,

add information on non-monetary flows and stocks, ignore what is irrelevant for the chosen function and define functional aggregates as the key concepts.

The central framework is mainly institutional in nature. A functional satellite account can combine a functional approach with an activity and product analysis. Such a combined approach is useful for many fields, such as culture, sport, education, health, social protection, tourism, environmental protection, research and development (R&D), development aid, transportation, safety and housing. Most of these fields refer to services; they generally spread over a number of activities and they correspond in many cases to subjects that are related to questions of economic growth or of social concern. [3]

Some services may appear in two or more satellite accounts. For example, research in health services in higher education institutions is a product relevant for satellite accounts on Research and Development, as well as education and health. This also implies that the national expenditure on various functions may partly overlap; simple aggregation of these expenditure to arrive at a total as a percentage of GDP may involve double-counting.

The concepts in the satellite account may deviate from those in the central framework. For example, voluntary work may be included in satellite accounts on education and health. For a satellite account on transport, the ancillary transport services can be shown separately. For a satellite account on development aid, the loans which are given at preferential conditions are accounted for. Benefits or costs resulting from rates of interest lower than the market ones are recorded as implicit transfers. [3]

4. Special sector accounts

Special sector accounts provide an overview focused on one industry or product, a regrouping of various industries or products, one subsector or a regrouping of various subsectors. Three types of special sector accounts can be distinguished: a) those linked to industries or products; b) those linked to institutional sectors; c) those combining both approaches. Examples of special sector accounts linked to industries or products are agricultural accounts, forestry

and fishery accounts, tourism accounts, ICT accounts, energy accounts, transport accounts, residential building accounts and accounts for the creative sector. Examples of special sector accounts linked to institutional sectors are government finance statistics, monetary and financial statistics, balance of payments, public sector accounts, accounts for non-profit institutions, household accounts and accounts on corporate activity. Tax revenue statistics can be regarded as supplementary tables to government finance statistics. [3]

The key sector accounts can be presented in the framework of integrated economic accounts. A column or group of columns is introduced for key sectors and other columns are renamed where relevant, such as “other non-financial corporations” or “other households”. This makes it possible to see the respective shares of the key sector and other sectors in transactions and balancing items. The precise format of such tables depends on the objectives pursued. One more step may consist in showing in additional tables the “from whom to whom” relationship between the key sector and other sectors, including the rest of the world. [3]

5. Conclusions

"The 2008-2010 multi-annual national statistics program", developed by the National Institute of Statistics of Romania provides in the chapter of the satellite accounts solely: environmental satellite accounts, natural resource accounting and health satellite accounts [4].

In terms of environmental satellite accounts, INS program includes: the current implementation of satellite accounts of expenditure for environmental protection, development of methodology and data collection for National Accounting Matrix with Environmental Accounts - NAMEA; the development of methodology and data collection for “environmental industries” accounts. The satellite accounts of natural resources refer to actions for 2008 (exploration of administrative and statistical data sources for the calculation of environmental accounts; development of data collection on material flows and providing standard tables to Eurostat; development of the methodology and building of the

indicators: resource productivity and material intensity of their use) but also for 2009 (development of methodology and data collection for the accounts of natural resources - coal, oil, natural gas; development of methodology and data collection for water flow accounts). Furthermore, the program also includes actions on health satellite accounts for 2008 (implementation of data collection on health expenditure, harmonized with OECD methodology and with the most recent methodological recommendations of Eurostat), yearly (for the collection of health expenditure of the three areas: funding sources, health functions and services, health service providers; an additional field is the collection of expenditure on health human resources in the standardized format), for 2009 (review the national methodology of the System of Health Accounts, following the preparation and publication of the second edition of the OECD-EUROSTAT-WHO methodology) and for 2010 (dissemination of statistics on health expenditure). [4]

Premiums in non-Life Insurance: on the Property of Iterativity

Covrig Mihaela

The Bucharest University of Economic Studies, Faculty of Economic Cybernetics, Statistics and Informatics, Department of Statistics and Econometrics

mihaela.covrig@csie.ase.ro

Abstract

This paper presents the premium calculation principles related to an insurance risk together with the desirable properties that should be satisfied. The main result concerns the iterativity property of the principle of equivalent utility (or the principle of zero utility). We compare two loss distributions through their calculated premiums.

Keywords: non-life insurance, insurance premiums, principles of premium calculation, principle of equivalent utility (or principle of zero utility), iterativity.

J.E.L.: C02, G22.

1. Introduction

In non-life insurance, one important issue is the principle based of which the premium is calculated. A premium calculation principle is a functional that assigns a usually loaded premium to any distribution of claims (or a rule for assigning a premium to any insurance risk).

We present the premium principles known from the literature and the properties that a premium principle has to verify. We focus on the property of iterativity, giving a result concerning this property for the principle of equivalent utility. In the end, the numerical illustration compares the premiums calculated for two types of loss distributions: discrete random variable and a continuous light tail distribution.

2. Premium principles

Let V denote the set of nonnegative random variables on the probability space (Ω, K, P) . V is the collection of insurance-loss random variables, also called

risks.

Let H denote the premium principle, or function, from V to the set of nonnegative real numbers.

$$H : V \rightarrow R_+,$$

$$X \mapsto H[X] \in [0, \infty),$$

$$H[X] = \Pi \text{ or } H[X] = \Pi[X].$$

The interpretation is that the insurer is willing to receive Π and in return accepts to make a random payment of X .

Further, we list some well-known premium principles [2], [6].

a) *Net Premium Principle* (or *Principle of Equivalence*): $H[X] = E[X]$ or $\Pi = E[X]$.

The use of the Net Premium is justified in the case we consider a large and homogenous portfolio with risks $X_k, k = \overline{1, n}$,

independent and identical distributed with expected value $E(X_k) = m$. According to the Weak Law of Large Numbers,

$$\lim_{n \rightarrow \infty} P\left(\left|\sum_{k=1}^n X_k - n \cdot m\right| < \varepsilon\right) = 1, \text{ for any } \varepsilon > 0,$$

so the premium $n \cdot m$ could cover the aggregate loss $\sum_{k=1}^n X_k$ with probability 1.

However, from the ruin theory, it is known that if the insurance company does not apply a loading to $E[X]$, i.e. a positive amount $H[X] - E[X] > 0$, for certain there will be a moment in which the insurer will not be able to cover the losses.

b) *Expected Value Premium Principle*: $H[X] = (1 + \theta)E[X]$, for some $\theta > 0$; this principle includes a proportional risk load $\theta E[X]$.

In practice, are used premiums depending on the first two moments of the random variable risk, such as the following two principles.

c) *Variance Premium Principle*:

$H[X] = E[X] + \alpha \text{Var}[X]$, for some $\alpha > 0$.

d) *Standard Deviation Premium Principle*:

$H[X] = E[X] + \beta \sqrt{\text{Var}[X]}$, for some $\beta > 0$.

e) *Principle of Equivalent Utility*: We present this principle from the insurer point of view as well as from the buyer of insurance point of view.

- The buyer of insurance point of view: Let u and w represent the utility and wealth (initial endowment) of a buyer of insurance. We suppose that u is a strictly increasing concave utility function. The maximum premium that the buyer of insurance is willing to pay for coverage of risk X is the solution $H_u[X] = \Pi$ of the equation

$$u(w - \Pi) = E[u(w - X)]. \quad (1)$$

The resulting premium $\Pi = \Pi[X] = H_u[X]$ is the indifference price for the buyer of insurance: he is indifferent between buying insurance at the premium $\Pi[X]$ (the left-hand side) and not buying (the right-hand side is the expected utility of the person who does not buy insurance).

- The insurer point of view. Let \tilde{u} and \tilde{w} represent the utility of the insurer and the initial wealth (initial endowment). We suppose that \tilde{u} is a strictly increasing, concave utility function. The minimum premium the insurer is willing to accept in exchange for insuring the risk X is the solution $H_{\tilde{u}}[X] = \tilde{\Pi}$ of the equation

$$\tilde{u}(\tilde{w}) = E[\tilde{u}(\tilde{w} - X + \tilde{\Pi})]. \quad (2)$$

This relation states that the insurer is indifferent between not accepting the insurance risk (the left-hand side) and accepting it (the right-hand side is the expected utility of the surplus that results when X is insured in exchange for the premium $\tilde{\Pi}$) [8].

f) *Exponential Premium Principle*:

$H_{\text{exp}}[X] = \frac{1}{a} \ln(E[e^{aX}])$, for some $a > 0$.

This premium is obtained from the previous principle for the case of exponential utility

functions $u(x) = \frac{1}{a}(1 - e^{-ax})$ or

$u(x) = -e^{-ax}$, $a > 0$, both strictly increasing

and concave functions, where a is the constant coefficient of risk aversion.

g) *Percentile principle* [7]: the smallest amount payable such that the probability of loss for the risk X is at most ε , i.e. $H_{\varepsilon}[X] = \inf\{x | F_X(x) \geq 1 - \varepsilon\} = \text{VaR}_{1-\varepsilon}[X]$.

3. Desirable properties

We list the desirable properties of the premium principles that should be satisfied. We consider only the insurance payout and refer to that as the insurance loss random variable [1], [7].

i) *Invariant to the distribution law*: $H[X]$ depends on the risk X only through the cumulative distribution function of X , namely $F_X(x) = P(\{\omega \in \Omega | X(\omega) < x\})$, or on the survival distribution function $p_X(x) = 1 - F_X(x) = P(\{\omega \in \Omega | X(\omega) \geq x\})$; if two risks X and Y follow the same distribution, then, their corresponding premiums are equal.

ii) *Risk loading* (or *nonnegative safety loading*): $H[X] \geq E[X]$, for all $X \in V$; in this way, the business of the insurance company makes sense, otherwise it will go bankrupt.

iii) *No ripoff* (or *maximal loss*): $H[X] \leq \text{ess sup}[X]$, for all $X \in V$.

iv) *Consistency* (or *translation invariance*): $H[X + c] = H[X] + c$, for all $X \in V$ and all constants $c \geq 0$.

v) *Scale invariance*: $H[bX] = bH[X]$, for all $X \in V$ and all constants $b \geq 0$.

vi) *Additivity*: $H[X + Y] = H[X] + H[Y]$, for all $X, Y \in V$ independent risks.

vii) *Iterativity*: $H[X] = H[H[X|Y]]$, for all $X, Y \in V$. This property has the interpretation: the premium calculated according to the principle H for the risk X can be obtained by applying the principle H to the conditional premium of X , given Y . The conditional premium is a function of the random variable Y [5].

4. A theoretical result

Among the listed premium principles, the Net Premium Principle satisfies all the

properties i)-vii) mentioned earlier.

The Exponential Principle verifies as well all of them, except the scale property, v).

The Principle of Equivalent Utility verifies i), ii), iii), iv). Regarding the iterativity property vii), Gerber [3], [4] says that a Principle of Equivalent Utility is iterative if and only if it is an Exponential Premium Principle or the Net Premium Principle. In reality, we noticed much more than that.

We state and prove the following proposition [1]:

Proposition: The Principle of Equivalent Utility H_u verifies the iterativity property for any $u \in C^2$, $u' > 0$, $u'' < 0$, a strictly increasing, concave, utility function, i.e.

$$H_u[X] = H_u[H_u[X|Y]],$$

for arbitrary risks $X, Y \in V$.

Proof: We prove first from the buyer of insurance point of view.

By the definition of the Principle of Equivalent Utility, for a risk $X \in V$ we have $u(w - \Pi) = E[u(w - X)]$.

As $u' > 0$, u continuous function, then there exists u^{-1} the inverse of the utility function.

Then we obtain:

$$w - \Pi = u^{-1}(E[u(w - X)]) \\ \Rightarrow \Pi = w - u^{-1}(E[u(w - X)]).$$

Let $Y \in V$ an arbitrary random variable (risk) and denote $\Pi_Y = H_u[X|Y]$. So, we have that $\Pi_Y = w - u^{-1}(E[u(w - X)|Y])$ and $w - \Pi_Y = u^{-1}(E[u(w - X)|Y])$.

Let us denote $\Pi^* = H_u[H_u[X|Y]]$ or

$\Pi^* = H_u[\Pi_Y]$. So, we have:

$$\begin{aligned} \Pi^* &= H_u[\Pi_Y] = \\ &= w - u^{-1}(E[u(w - \Pi_Y)]) = \\ &= w - u^{-1}(E[u(u^{-1}(E[u(w - X)|Y]))]) = \\ &= w - u^{-1}(E[E[u(w - X)|Y]]) = \text{(here} \end{aligned}$$

we use the iterativity property of the expected value for a random variable)

$$\begin{aligned} &= w - u^{-1}(E[u(w - X)]) = \\ &= \Pi = H_u[X]. \end{aligned}$$

That is, we proved that

$$H_u[H_u[X|Y]] = H_u[X], \text{ for any } X, Y \in V.$$

For the insurer point of view, we perform the transformation $w = \Pi + \tilde{w}$ and the proof goes analogously.

5. Numerical illustration

Let us consider two types of distributions for the risk variable: a discrete one and a continuous one.

The individual risk in a given portfolio covering losses for one year is modelled by the random variable $X: \begin{pmatrix} 0 & 2,05 & 6 & 11 & 157 \\ 0,6 & 0,2 & 0,16 & 0,025 & 0,015 \end{pmatrix}$, where the values are the possible losses in monetary units, $E[X] = 4$, $Var[X] = 363,3605$. The large and very large values occur with quite small probabilities.

For a discrete random variable X with the distribution $X: \begin{pmatrix} x_j \\ p_j \end{pmatrix}_{j=1, \dots, m}$, and for $\varepsilon \in (0,1)$,

we have $H_\varepsilon[X] = VaR_{1-\varepsilon}[X] = x_{k_{1-\varepsilon}}$, where $k_{1-\varepsilon}$ is the unique index such that $\sum_{j=1}^{k_{1-\varepsilon}-1} p_j < 1 - \varepsilon \leq \sum_{j=1}^{k_{1-\varepsilon}} p_j$.

Let us consider also a light tailed distribution for the individual risk, namely the exponential distribution $X \in Exp(\lambda)$ with parameter $\lambda > 0$, i.e., with probability density function $f_X(x, \lambda) = \lambda e^{-\lambda x}$, $x \geq 0$, expectation $E[X] = \frac{1}{\lambda}$, variance

$Var[X] = \frac{1}{\lambda^2}$, and cumulative distribution

$$F_X(x) = \begin{cases} 0, & x \leq 0 \\ 1 - e^{-\lambda x}, & x > 0 \end{cases}$$

$VaR_{1-\varepsilon}[X] = -\frac{1}{\lambda} \cdot \ln \varepsilon$, for $\varepsilon \in (0,1)$. For $\lambda = 0,25$, then $E[X] = 4$, $Var[X] = 16$, $VaR_{1-\varepsilon}[X] = -4 \cdot \ln \varepsilon$.

We chose these losses such that they have the same expectation and we want to compare their premiums.

The following tables present the premiums calculated according to principles

a), b), c) d), f) and g) for some parameters, for the two distributions considered.

Table 1. Premiums calculated for the discrete random loss.

Principle			$H[X]$
a)			4
b)	θ	0,10	4,4
		0,25	5
		0,4	5,6
c)	α	0,10	40,3361
		0,25	94,8401
		0,4	149,3442
d)	β	0,10	5,9062
		0,25	8,7655
		0,4	11,6248
f)	a	0,24	139,5012
		0,20	136,0015
		0,10	115
		0,01	7,1430
		0,001	4,1910
g)	ε	0,10	6
		0,02	11
		0,01	157

Table 2. Premiums calculated for the exponential random loss.

Principle			$H[X]$
a)			4
b)	θ	0,10	4,4
		0,25	5
		0,4	5,6
c)	α	0,10	5,6
		0,25	8
		0,4	10,4
d)	β	0,10	5,6
		0,25	8
		0,4	10,4
f)	a	0,24	13,4119
		0,20	8,0472
		0,10	5,1083
		0,01	4,0822
		0,001	4,0080
g)	ε	0,10	9,2103
		0,02	15,6481
		0,01	18,4207

We notice that the premiums calculated according to c) show large differences explained by the value of the variance. Also, we see again significant differences for the same values of the coefficient of risk aversion a . Another remark is that as a becomes smaller and closed to 0, the value of the premium approaches the expectation.

6. Conclusions

This paper presented the main premium calculation principles and the desired properties, pointing out the property of iterativity that the principle of utility exhibits. The numerical example highlighted the fact that two risks, modelled by two random variables with the same expectation, can generate premiums with quite large differences for the same values of the parameters.

One of the ways of quantifying risks means to convert a random future loss or claim into a certainty equivalent. Premiums principles realize this requirement: given the probability distribution of the risks involved, they return prices. In exchange of them, the insurance company agrees to take the risks. This is the actuaries' point of view. However, the insurance company should consider also the market conditions, when assuming a risk.

Controversy and Convergences in Defining the Concepts of Accounting Policies and Options

Dima Florin-Constantin

“Constantin Brâncoveanu” University of Pitești

dimaflorin_constantin@yahoo.com

Abstract:

The accounting policies have an important role in defining the loyal image of an entity. That is why we must distinguish clearly between accounting policy, accounting option accounting estimate.

Keywords: policy, option, accounting estimate.

J.E.L. classification: M41-Accounting

1. Introduction

The definitions given to the concept of accounting policies welcome the achievement of an accountancy that provides a loyal image or, in other words, of an honest accountancy.

2. Theoretical approaches on the concept of accounting policy

The accounting policies are the specific principles, bases, conventions, rules and practices applied by an entity in preparing and presenting financial statements [1].

The accounting policies are defined in the Accounting Dictionary of Oxford University Publishing House [2] as “the specific accounting bases and constantly used by an organisation in drawing up the financial statements, these bases are considered and determined by the organisation as the most appropriate for the loyal presentation of its financial results and operations; the policies are focused on specific topics such as the pension schemes, the goodwill, the research and development costs, the operations denominated in foreign currencies, and so on.”

Another definition, more nuanced, was given by Christopher Nobes [2]: “Accounting policies are detailed methods of assessment,

measurement and recognition (observation) that an entity has chosen from the generally accepted ones by the law, accounting standards or business practices. These policies must be used permanently and they must be published. An entity’s annual report will include “an annex on the accounting policies” that have been applied in the financial statements. For example, a publication of the policies could mention whether the entity has used the linear method or the diminishing balance method of depreciation, whether in the stock assessment the FIFO or the CMP methods were used, the way of calculating and recording the provisions for the future pension payments.

The Accounting Standards Board: ASB in the UK published in late 1999 the Financial Reporting Exposure Draft 21: FRED 21 entitled “Accounting policies”, which was to replace the SSAP 2 standard “Publication of accounting policies”. The draft defined the accounting policies as being the specific principles, the bases, the conventions and the practices applied by an entity in order to reflect the effects of the transactions and other events by the recognition (observation), selection of the measurement bases and the presentation of assets, debts, earnings, losses and the evolution of the owners’ funds. This draft, just as IAS 8 “Accounting Policies, Changes in Accounting Estimates and Errors”, as we shall see below, makes the distinction between accounting policies and estimation techniques.

The International Accounting Standards Board (IASB) by means of the IAS 8 standard “Accounting Policies, Changes in Accounting Estimates and Errors” [3] defines the accounting policies concept in the following way: “the accounting policies represent the specific principles, bases, conventions, rules and practices adopted by an entity in drawing up and presenting the financial statements”.

The Fourth Directive of EEC defines the accounting policies similarly to IAS 8 “Accounting Policies, Changes in Accounting Estimates and Errors” and it states that liability regarding the accounting policies adopted by an entity for the operations carried out belongs to its management. The Directive also envisages that in the development of the accounting policies the general accounting principles stipulated within it must be respected, as well as the fact that the accounting policies should be developed given the specificity of the activity by the specialists in the economic and technical fields, who are familiar with the activity carried out and with the strategy adopted by the entity.

Concerning the selection and application of the accounting policies, IAS 8 stipulates that when a Standard or an interpretation specifically applies to a transaction, to another event or condition, the accounting policy or policies applied to that event will be determined by applying the Standard or Interpretation and by taking into consideration any relevant guidance on the Implementation issued by the IASB for the Standard or Interpretation.

The IFRSs (International Financial Reporting Standards) establish the accounting policies about which the IASB (International Accounting Standards Board) has concluded that they lead to financial statements that contain relevant and reliable information about the transactions, other events and the conditions to which they apply. These policies must not be applied when the effect of their application is irrelevant. Nevertheless, it is inappropriate to ignore or to leave uncorrected irrelevant deviations from the IFRSs in order to achieve a particular presentation of an entity’s financial position, financial performance or cash flows.

In the light of the standard, any omission or erroneous reporting of the items is significant if it can influence, individually or collectively, the users’ economic decisions taken based on the information from the financial statements. The significance threshold depends on the dimension and nature of the omission or erroneous reporting judged in the context. The dimension and the nature of the elements, or a combination of both, could be the determining factor.

An entity shall select and apply its accounting policies consistently for similar transactions, other events and conditions, except for the case a Standard or an Interpretation requires or explicitly allows the classification of the items for which different accounting policies may be suitable. If a Standard or an Interpretation requires or allows such a classification, an accounting policy shall be selected and applied consistently to each category.

In the absence of a Standard or of an Interpretation that specifically applies to a transaction, event or condition, the management shall use its professional judgment in developing and applying an accounting policy that leads to information that is:

- relevant to the users’ needs to make economic decisions;
- credible, in that the financial statements:
 - exactly reflect the financial statement, the financial performance and the cash flows of the entity;
 - reflect the economic substance of transactions, other events and conditions, not only in terms of the legal form;
 - are neutral and free from bias;
 - are prudent;
 - are complete in terms of all significant aspects.

The terms from the Fourth Directive of the EEC on developing accounting policies are similar to those of the standard, and in terms of the changes in the accounting policies the Directive’s provisions are similar to those of the above-mentioned Standard.

IAS 8 “Accounting Policies, Changes in Accounting Estimates and Errors” enables changes in the accounting policies only if the change:

- is required by a Standard or by an Interpretation; or
- it leads to the financial statements providing reliable and more relevant information about the effects of transactions, other events or conditions on the financial position, financial performance or cash flows owned by the entity.

Both the Standard and the Fourth Directive show that the following are not considered changes of the accounting policies:

- applying an accounting policy for transactions, other events or conditions that actually differ from those previously produced; and
- applying a new accounting policy for transactions, other events and conditions that did not occur previously or which were irrelevant.

The changes in the accounting policies shall apply when:

- an entity shall take into account a change in the accounting policy resulting from the initial application of the Standard or of the Interpretation in accordance with the specific transitional provisions, if they exist, from that Standard or Interpretation;
- when an entity changes an accounting policy upon the initial application of a Standard or an Interpretation that does not include specific transitional provisions applying to that change, or it changes an accounting policy voluntarily, the entity shall apply the change retroactively.

When the retroactive application is required, a change in the accounting policy shall be applied retrospectively, except the case in which either the effects specific to the period or the cumulative effects of the change are impossible to determine.

Concerning the financial information presentation, IAS 8 “Accounting Policies, Changes in Accounting Estimates and Errors” provides that when the initial application of a Standard or of an Interpretation has an effect on the current period or on any prior period, it would have had such an effect apart from the fact that it is impossible to determine the value of the adjustment, or it might have an effect on the future periods, an entity shall present:

- the title of the Standard or Interpretation;
- where appropriate, the fact that the change in the accounting policy is made in accordance with its transitional provisions;
- the nature of the change in the accounting policy;
- where appropriate, a description of the transitional provisions;
- when appropriate, the transitional provisions that may have an effect on the future periods;
- for the current period and for each prior period presented, as far as possible, the adjustment value;

- the value of the adjustments relating to the periods before those presented as far as possible;
- if the retroactive application (above-mentioned) is impracticable for a particular previous period, or for periods previous to those presented, the circumstances that led to the existence of that condition and a description of the way and of the moment in which the change in the accounting policy was applied.

The financial statements of the subsequent periods do not have to repeat these presentations.

When the voluntary change in an accounting policy has an effect on the current period or on any other previous period, it would have had an effect on that period apart from the fact that it is impracticable to determine the adjustment value, or it might have an effect on the future periods, an entity shall present:

- the nature of the change in the accounting policy;
- the reasons why the application of the new accounting policy provides reliable and more relevant information;
- for the current period and for each previous period presented, as far as possible, the adjustment value;
- the amount of the adjustments relating to the periods before those presented as far as possible;
- if the retroactive application is impracticable for a particular previous period, or for the periods before those presented, the circumstances that led to the existence of that condition and a description of the way and the moment in which the change in the accounting policy was applied.

Neither in this case is it necessary for the financial statements of the subsequent periods to repeat these presentations.

In case an entity has not applied a new Standard or an Interpretation that has been issued, but which has not yet entered into force, it shall present this fact, as well as the information known or reasonably estimable, relevant in the assessment of the possible impact that the application of the new Standard or Interpretation will have on the entity’s new financial statements in the period of the initial application.

3. Accounting policies and accounting estimates

One important thing that should be mentioned is that the accounting policies do not include accounting estimates.

As a result of the inherent uncertainties occurring in the performance of an entity's activities, many elements of the financial statements cannot be assessed precisely, but only estimated. The estimation process involves judgments based on the latest available credible information. For example, one may request estimates for:

- the uncertain clients;
- technical obsolescence of the stocks;
- the fair value of the assets and financial debts;
- useful life, as well as the expected pattern of consumption of the future economic benefits incorporated in the depreciable fixed assets, etc.

In order not to undermine the credibility of the financial statements reasonable estimates should be used when they are drawn up. An estimate may need revision if changes occur in the circumstances on which it was based or as a result of new information or subsequent experience. The revision of an estimate is neither related to the previous periods nor does it represent the correction of an error.

Both the accounting policies and the estimation techniques presuppose that the entity in question could have used one or more measurement (assessment) bases.

A change in the measurement basis applied represents a change in the accounting policy and does not represent a change in the accounting estimates. In case it is difficult to distinguish between a change in the accounting policy and a change in an accounting estimate, the change is treated as a change of the accounting estimate.

The existence of several accounting policies and estimates for solving a problem leads to the accounting options. The option involves, therefore, a choice.

The choice of an accounting policy or of an estimation technique, including those accepted, must be made in such a way to ensure the best information for making decisions. The best and useful information must be consistent with the most loyal image concerning the financial position, the

financial performance or the financial position and financial performance trends.

The accounting options appear both at the level of the individual financial statements and at the level of the consolidated financial statements. Pierre Lassègue uses a brief inventory of these options in his accounting lexicon [4]:

- examples of options for the individual financial statements: the extent of development of the jobs and headings; the presentation of the annual accounts as account or list; the choice of an accounting system; the possibility of a cash accounting for the small entities; the choice between asset and expenditure and between debt and income; several assessment methods (procedures) of the confusable property (CMP, FIFO, LIFO); the use or non-use of the indexed historical cost; the use or non-use of the replacement value; classification of expenditure (by nature or by function) and of the income (by nature or by origin); accounting of the bad debts at operational or exceptional level; amortisation (amortisation legislation: must the goodwill be amortised or not?, the difference in the purchase?, the intangible assets?); the re-assessment of the balance sheet items (prohibited, optional, mandatory, fiscal conditionality); capitalisation or not of the assets financed by financial leasing; subordinated debt for an indefinite period (qualified or not in the category of equity); the translation differences (their integration or non-integration in the results); the long-term works (observing the result during progress or upon completion); financial expenses (their integration or not in the production cost of fixed assets or of certain stocks); value compensation of the ups and downs on certain categories of securities, etc.
- examples of options for consolidated financial statements: the consolidation methods and criteria; the treatment of difference from the point of view of consolidation (capitalization and amortisation, duration of amortisation, the immediate disappearance through the integration in the result of the exercise or in the equity); the converting method of the foreign subsidiaries accounts; the processing of the conversion difference;

the assessment of the amortisable tangible assets at the replacement value; the classification of the expenses by nature or by function; processing of the deferred taxes; etc.

4. Conclusions

The existence and presence of options in accounting raises the issue of the selection criterion of an accounting policy or of another, of an estimation technique or of another.

Regardless of the possible options, the accounting referential to which various entities appeal, whether national or international, must possess the characteristics of a modern referential in order that both the policies and the estimation techniques applicable can circumscribe in the perimeter of a fair representation of the financial position, of the performances and of the financial position evolution whose reality is modelled by accountancy.

Premises and Obstacles to International Accounting Convergence

Dima Florin-Constantin

“Constantin Brâncoveanu” University of Pitești
dimaflorin_constantin@yahoo.com

Abstract

This article aims to analyse the main aspects of international accounting convergence. Therefore, the issue is the analysis both in terms of factors that favour the international accounting harmonisation and in terms of factors that prevent achieving this desideratum.

Keywords: normalisation, harmonisation, accounting convergence.

J.E.L. classification: M41

1. Introduction

International and even global accounting normalisation has become an increasingly pressing requirement because of the more and more numerous and sensational financial scandals. Therefore there is a need to develop accounting standards as uniform as possible worldwide.

International accounting harmonisation is a process that aims, as much as possible, at improving and reducing the differences between the national accounting practices and regulations. The harmonisation process aims to develop general principles and rules leading to the comparison of the information offered by the content of the financial statements. In other words, harmonisation aims at reducing the differences between the accounting regulations of different countries.

2. Normalisation, harmonisation and accounting convergence

Starting from the undeniable reality that in a market economy accounting harmonisation and normalisation mainly aim at determining the rules for operation of the accounting information market in order to optimise the financial communication, we conclude that the existence of this market

requires a product. The product exchanged on the accounting information market is the accounting information itself. This product only exists according to the rules and regulations that define it, leading to the need for accounting normalisation.

The need for harmonisation and uniformity in accounting requires its normalisation. The normalisation process leads to accounting harmonisation and convergence by formalising and materialising the objectives, concepts, methods, rules and procedures for the production and use of the accounting information. Normalisation involves determining a reference framework to which fundamental purposes can be attached, such as:

- obtaining information and a homogenous image on the entities by the public power;
- obtaining accounting information comparable between entities in time and space;
- ensuring a better allocation of the financial resources in a national economy.

Accounting normalisation is the way through which the presentation of the summary documents, the accounting methods and the terminology are harmonised. The normalisation effort as well as its product aim at [1]:

- defining the concepts, principles and accounting rules based on a precise terminology identical to all the producers and users of the accounting information;
- their practical application to ensure comparability in time and space, the relevance and reliability of the accounting information.

Internationally, the accounting convergence/harmonisation effort involves the development of accounting principles and standards applicable, entirely or partially, to a set of countries, entities or by a group of experts in the accounting profession. This

implies an authority to develop rules to be imposed and which have the authority and coercive power to sanction their non-compliance.

Currently, the institution through which international accounting normalisation is achieved is the “International Accounting Standards Board” (IASB), which is an organisation specialised in developing accounting standards. Although the institution exists, it neither has competence in the application of the rules developed by it, nor has it the coercive means to enforce these rules.

If until a quarter of a century ago accountants lived in a world of their own, in which not only did they speak different languages or used different languages, but they also gave different interpretations to the same events and transactions, today the watchword for most accounting professionals from all the world’s countries is internationalisation.

3. The premises for achieving international accounting convergence

International accounting convergence / harmonisation is, first of all, a necessity arising from the needs of the financial statements’ users.

In summary we could consider that the main pressure factors in favour of harmonising the international accounting normalisation are:

- increasing financialisation and globalisation of national economies (can be considered the main factor but not the only one). Financialisation involves financial concentration (or concentration of capital) through conglomerate integration and it consists of re-grouping the entities performing similar or different activities. The goal of the capital concentration is purely financial, namely improvement of capital development through dispersing the risks into more similar or different activities, but located in different regions of the world. Internationalisation is a strategic objective of the big entity because it provides access to new funding sources, new outlet markets, it leads to obtaining fiscal advantages and to reducing the costs through the access to production

factors that have lower costs. The entities operating on the international financial markets pursue diverse aims, from investments in foreign securities to issuing shares and bonds. At the basis of grounding the investment decisions within the entity, the greatest part of the information is provided by accountancy. Therefore, accountancy has become nowadays a kind of universal language of business and under the pressure of capital markets internationalisation a harmonisation and normalisation phenomenon of the accounting bodies has started worldwide. The process of international accounting normalisation and convergence can take place regionally or globally, as desired.

- the European Union expansion process (together with the European Union expansion we also witness the establishment of a growing number of multinational companies). Although there is a single market and a single currency in the European Union, in the given context, there cannot be a single accountancy in Europe without appealing to the referential IASB, the idea of conceiving an independent harmonisation no longer being current at present when we witness the globalisation of businesses worldwide.
- increasing globalisation of the capital markets and the increasingly acute competition between these markets;
- privatisation of large state enterprises that require significant capital that cannot be provided by the market or by the capital markets of a single country;
- the need and the desire of multinational corporations leaders to reach an optimal convergence between the internal and external information system.

Accounting harmonisation and normalisation are also necessary due to the diversity of the entities that contribute to defining the accounting information demand and supply, but also because of the imbalances that may exist between supply and demand.

The need for international accounting normalisation also derives from the entities’ desire to apply a uniform accounting system based on the International Financial Reporting Standards. If the entities are

required to draw up the financial statements according to various accounting referentials (international rules to inform the investors on the various financial markets in which they operate and the local rules for the local market, especially due to fiscal reasons), besides losing their credibility before the would-be investors, the use of two or more types of rules represents a difficult operation, but especially a costly one because restatements are necessary.

For these reasons, as well as due to the desire of the entities' leaders to achieve optimal convergence between the internal and external communication system, most entities plead in favour of international accounting standards.

The modern world has as main characteristic the fact that among its components there are interdependencies whose intensity is amplified ever more. Communication is vital, but its effective implementation brings into discussion the issue of understanding the messages that are sent. In accountancy there are several languages since the accounting systems have developed rather independently, within the tight background of the national economies. Nowadays, international trade and capital movements beyond the borders of the origin countries have taken huge proportions.

For example, at present, the purchase of Japanese shares by European, American or Australian investors is considered commonplace. However, a problem arises: in order to invest, they must compare various Japanese companies or they must compare them to others. They need documents to reflect the economic situation of the entities and the most important thing is that they must understand exactly the information provided by these documents. Thus there has appeared the need to bring all the accounting systems to a common denominator, something which can only be achieved through international accounting convergence with the aim of reducing the differences between the national accounting regulations.

From this point of view, harmonisation should allow the elimination of the main obstacles in achieving comparisons internationally. Multinational companies are now required to prepare two sets of financial statements: consolidated financial statements

according to the country's rules, to the parent company (for the needs of the capital market) and individual financial statements for each subsidiary, according to the local regulations. Therefore, if the parent company is listed on more than one financial market, it is necessary to draw up a second set of consolidated financial statements for the foreign capital markets. But the very lack of uniformity and comparability of the accounting information often represents an obstacle for the investors on the international markets.

Today multinational companies endorse the diversity of the accounting systems in various ways. They may first establish several sets of financial statements. At present, a private entity that issues shares in the U.S. will have to draw up its financial statements in accordance with the General Accepted Accounting Principles – U.S. GAAP, to annex to the financial statements a detailed reconciliation with U.S. GAAP or to present a comparative statement between the net assets and the results established according to the origin country's principles. This requirement, in addition to being very expensive, also has the inconvenience of leading to two different assessments of the own capitals and results. This does not generally mind accountants who are aware that profit is a relative concept whose dimension depends on the assessment rules, but it is quite difficultly accepted by the financial analysts who tend to ask themselves which is the correct dimension of the profit on which they can count. Thus, harmonisation becomes a major imperative.

Another motivation that determines accounting systems harmonisation is the desire to “unify” the conditions of competition between countries. If one or more states within an economic union have a permissive or favourable accounting system, the entities are tempted to transfer their registered office, thus changing competition.

In terms of accounting information for a good financial communication, the quantity-quality-price relationship should be optimised. The communication process aims at the balanced state of this report, but the balance is also evolving as new information needs occur, new financing techniques, new legal contexts or new problems are individualised. From the above it follows that

the balanced state in this report is not easily achieved nor maintained in the contemporary economy, which has a dynamic character.

4. Obstacles to achieving international accounting convergence

The limits of international accounting harmonisation can be mainly analysed by taking into account the historical context and the cultural differences between peoples. But international accounting harmonisation also faces other obstacles such as: the financing system, the legal system, taxation, accounting information users' characteristics, age and dimension of the accounting profession, the features of the local economy (inflation rate, economic growth rate, the cash flow and the balance of trade situation, citizens' education level, and so on).

Accountancy can be seen as a tool that allows the communication of economic information, in other words, a universal economic language, and yet it remains a particular tool of a national culture since it is influenced by the economic, social, legal and even political and religious developments in each country.

In order to show the influence of politics on accountancy we appeal to history and we can take as example the influence of the Marxist ideology on the accountancy of the entities in the former communist countries. Thus, the theory of double entry was reinterpreted based on the Marxist theory of the value-labour, a theory considering that the value of a commodity has an objective character and it is determined according to the quantity of labour contained in the commodity. In fact, socialist accountancy, which was based on the Marxist theory, was supposed to be a control tool for fulfilling the centralised plan and of state property integrity. Moreover, in China, during the '60s when the so-called Maoist Cultural Revolution was taking place the double entry accounting practice was abandoned in favour of the accountancy based on the “addition/subtraction” recording mechanism (if it can be called so). Later, people returned to double-entry bookkeeping.

Accounting is not only influenced by the political ideology, but also by religion, seen as a cultural component. The religious component has a great influence on

accountancy, especially in Islamic countries where it influences the Mohammedan business people's ethics and that is why it represents an important element to be taken into account in the globalisation process of businesses and in the harmonisation process of the accounting systems.

Starting from the influence of religion on contemporary financial and accounting practices we can speak about two types of companies:

- the Western world based on the Judeo-Christian tradition in which religion does not have a direct and noticeable influence on the conduct of business;
- the Islamic world in which the way of doing business must conform to certain religious precepts.

In the case of the Islamic countries we deal with a cultural intrusion of religion in developing businesses and in the accounting and financial practices. If in the Western countries the business ethics is imposed through the codes of the professional associations, the Muslim business people's ethics is subordinated to the Islamic teaching requirements which prescribe what is allowed and what is prohibited in businesses. That is why the business practices of the Islamic countries do not automatically accommodate to the accounting and financial practices in the Western countries and religion becomes a limiting element, or in the best case, it conditions international accounting harmonisation.

These aspects concerning the accounting and financial practices specific to the countries from the Islamic world draw attention on the fact that international accounting rules have a limited application within the companies from these countries. Also as a differentiation, worth to be mentioned, between the Western accounting practices and the ones from the Islamic countries there is also the fact that in certain Muslim countries accounting audit is doubled by a religious audit. The religious audit checks the compliance with the Islamic precepts by those conducting businesses.

A limitation of the international accounting harmonisation is also given by the fact that besides transnationals which are adherents to drawing up and presenting financial statements according to the IASB rules, there are also small and medium-sized

entities which represent an important segment in the economic “tissue” of each country. In general, they retain the economic, financial, social and cultural characteristics of the country in which they exist and operate. These are not interested in drawing up financial statements in accordance with the international accounting standards and they represent a highly resistant segment to the influences of the contemporary phenomena.

Another objective limitation of the international accounting harmonisation is the fact that IASB is a normaliser without coercive power, the enforcement of its rules is optional, despite the current trends manifested by the world’s countries in order to harmonise the national accounting systems with the international accounting standards.

5. Conclusions

Taking into consideration the previous presentations, we can say that the

international accounting harmonisation process is on the right path, but there is still much to do until reaching the ultimate goal which is represented by an international accounting system applicable internationally and governed by uniform rules and principles.

The Improvement of the Standardized System of Reporting to Suppliers in Order to Comply with the Stipulations of the Order Of the Ministry of Public Finances no. 1248 from 2012

Dragu Gabi Georgiana
University “1 Decembrie 1918” Alba Iulia, Romania
georgiana.dragu@yahoo.com

Abstract

At European Union level it was taken the initiative of creating a system of prompt payment, which becomes relevant under the conditions of the present economic crisis, through adopting the legal dispositions of fighting the delayed payments for the transactions closed among economical agents or between them and public authorities.

The authors of the present paper aimed to design an improved system of reporting to suppliers, that answers both to the requirements regarding the subsectors' reporting procedure and the need to establish whether these debts are due or overdue.

The research aimed at assessing the practical utility of the solution proposed for the improvement of the procedure of reporting to suppliers and especially for the overdue payments in order to enhance the correctness, promptitude and quality in delivering accounting information to its users, representing a refinement of the efforts to present standardized reporting solutions outlined within subsequent studies.

Keywords: European System of Accounts ESA 95, subsector, debts, financial statements, arrears

JEL Classification M41

1. Romanian background

In order to illustrate the national situation, I analyzed the national and communitarian legal framework in force. The aim was to verify the hypothesis according to which the fluctuations of the legal framework influence the organization of accounting and the accuracy of the information provided.

Regarding the economical account, in many European Union's states the financial account is referred to as accrual due to lack of data and is characterized by the registration of revenues and expenses' commitments, ratified as to integrate the financial dimension of economical values based on the management of the economical accrual. Using the single-entry strategy, the Romanian public institutions register the revenues and expenses automatically based on the economical accrual for the reference period.

In the case of Romania, national accounting is attempted to be positioned between two accounting cultures – the traditional continental accounting and the Anglo-Saxon accounting. Due to the communist indoctrination, customs and the many legislative changes, the Romanian accountant that works in the public system demonstrates an aversion to change and he still needs to be said what/ how/ when to act.

Therefore, as article 20 illustrates (weak points) in the chapter regarding the analysis of the “Internal Environment” of the “Strategic Plan of the Ministry of Public Finance 2010-2013”, approved by the Order of Ministry of Public Finance no. 19/2010, there are “Relatively frequent changes to the financial-fiscal regulations within the public accounting domain, State Treasury, revenues administration and information system”.

The International Accounting Standards (IAS/IFRS/IPSAS) bare a cultural knowledge difficult to assimilate, they are based on the professional reasoning (that was not taken into consideration during the centralized period) based on principles which can lead to multiple valid solutions for the same issue (a fact that might generate controversies with the control authorities who could have another option).

Since the International Accounting Standards, regardless of their form, are constantly changing, becoming more and more complex, the Romanian accountant must become an international accountant, mastering the international accounting terms and principles.

Therefore, the Government’s efforts to adopt the International Public Sector Accounting Standard (IPSAS) are welcomed and must continue and be consolidated in order to achieve a complete conformity within a reasonable time. If by any reason the endorsement of IPSAS becomes unachievable for a couple of years, all the reasons must be recorded within the financial statements’ entries – especially those regarding the accounting policies.

The budgeting, recording and reporting of capital expenses must be clarified and simplified. The Fiscal Responsibility Law (FRL) defines the investment expenses as representing the capital expenses and transfers for development expenses. However, the term “capital expenses” is not defined and there might be a confusion regarding what should or should not be considered a capital expense. Likewise, the term “development expenses” is not defined either.

The budgeting classification and the chart of accounts must be analyzed in order to make a distinction between different types of information. Among others, this measure would facilitate a better budgeting and reporting system for capital expenses. For example, there is a certain confusion regarding the accounting recording of capital expenses financed through different sources. The main reason appears to be the use of economic classification for the identification of the financing sources and occasionally for the projects’ too. These issues must be analyzed and furthermore investigate the possibility of introducing a distinct code for the financing source and for a project. The economic classification must be used to describe the type of the purchased asset, e.g. buildings, so that the source code indicates whether it is financed by European funds for example, or by general national revenues, and the project code should indicate the project for which the respective expenses are made.

The overdue payments represent a threat for fiscal discipline and for the control of expenses. The arrears represent a loan measure for financing the current year expenses, which must be reimbursed the next year – from the following year budget. At this time arrears constitute a particular issue and they must be carefully supervised in order to prevent a deterioration of the situation. Arrears represent only a part of the overdue payments as they are illustrated in Annex 30 (30b).

Arrears constitute a subcategory of the liability payments / creditors. Internal arrears are defined as liability payments / creditors which have not been paid during 90 days period or within the deadline indicated (regardless of any grace period stipulated through contract). In case there is no stipulation regarding due date, arrears are defined as liability payments / creditors which have not been paid within 90 days period or more starting with the invoice or contract date.

We can draw the conclusion that the hypothesis stated in the beginning of this chapter is sustained considering the fact that frequent legislative changes influence the quality of the provided accounting information due to the necessity of constant changes in the information system of public institutions.

2. The standardized reporting of debts, overdue payments and arrears to suppliers

The hypothesis of the current issue is derived from the following question: is there a need to improve the standardized reporting system to the suppliers following the European System of Accounts ESA 95 due to legislative changes? If the answer is yes, how can this be achieved?

In order to provide a solution, the legal framework was initially analyzed, as well as the standardized reporting system according to the requirements made up until the introduction of the Order of the Ministry of Public Finance no. 1248/2012, outlining the reporting solutions in correlation with the accounting informatics system. The process thus involved both empirical and historical research following the specific model of documents’ investigation.

According to the position document no. 11 “Economical Monetary Union”, Romania has committed to report after the European System of Accounts ESA 95.

The classification of public institutions is necessary in order to circumscribe the Public Administrations’ area, its division into subsectors, but is also necessary for defining the modalities of the financial statements’ aggregation.

The ESA 95 handbook divides the public administrations’ sector into four sectors

- Central Administrations (S.1311)
- Intermediate Administrations (S.1312), do not exist within Romanian subsectors
- Local Administrations (S.1313)
- Social Insurance Funds (S.1314).

Analyzing the structure of S.13 sector is necessary for evaluating the classification of the institutions into the above mentioned subsectors and assessing the transactions made by/ within public administrations.

The delimitation of the public administrations’ area is essential for the elaboration of the sector’s and public administrations’ consolidated reports according to the identified standards at European and international level.

It should be noticed the difference between public sector and public administrations resulting from the modalities of institutions’ classification. According to ESA 95, an institution is included into S.13 subsector based on its financing modalities and on its commitment to the so called 50% criteria. Since this criterion is strictly statistical, the inclusion or exclusion of an institution into the public administrations’ list is not entirely based on its economic and legal profile.

In the case of Romania, the institutions are included into the public administrations’ area based on two elements:

- Financing modalities
- Legal statute

According to the stipulations 1.3 and 1.4. for the approval of the methodological Norms for the application of stipulations in art. 49, paragraph (13¹) of the Law regarding local public finances no. 273/2006 and the modifications and addenda on methodological Norms for the elaboration and deposition of public institutions’ trimestral financial statements, as well as

several 2009 monthly financial reports approved by Order of the Ministry of Public Finances no. 629/2009,

“Starting with the application of the present methodological norms, for the public institutions entirely or partially financed through owned revenues/ activities entirely or partially financed through local subordination owned revenues, code 49 is no longer used for overdue payments, and is replaced in the completion of the form with the following codes, depending on the situation:

51 – for overdue payments of public institutions, entirely financed through owned revenues (the functioning section and the development section);

52 – for overdue payments of public institutions financed partially through owned revenues / activities entirely financed through owned revenues (the functioning section and the development section).

The balance accounts from the beginning of the year afferent to codes 51 and 52 must correspond with the balance accounts from the beginning of the year reported for code 49.

The balance accounts afferent to previous month for the reporting on September 2012 afferent to codes 51 and 52 summed up must correspond with the balance accounts at the end of the reported period for August 2012 for code 49.

The form “The Centralized situation of arrears for the administrative-territorial unit general budget on the date of...” (Annex 30b.1 to the financial statements) must be completed only by the main credit controller of the local budgets, for the arrears of the administrative-territorial unit’s general budget reported in the form presented in Annex 30b “Overdue payments”, for code 40.”

The facts mentioned above highlight the necessity of combining both the reporting system based on the requirements of completing the financial statements and those regarding the monthly reporting system.

In the following section the information regarding the reporting of debts towards suppliers is illustrated through analytical models.

First of all, the subsectors’ analyzing method was attempted in order to automatically transfer the balance sheet data

into “Annex 40 (a, b, c) Public institutions’ assets and debts statement”, correlated with the information from “Annex 30(b) Residual payments” which was found out to be filled with errors.

Therefore, the following structure was attained in the first case:

The first degree synthetic account representing the suppliers was divided into current and non-current suppliers; these accounts were subsequently divided into subsectors’ accounts with regard to their inclusion or exclusion from the clearing due date of the current period.

Table 2. Suppliers (I)

Suppliers (I) from which		
Current suppliers from which		Non-current suppliers from which
Subsectors’ suppliers – each sector follows the subsequent structure		Subsectors’ suppliers
within clearing due date	within residuary due date	1. (S11) (S1311) (S1313) (S1314)
7, 30, 60, 90, 180 days	>< 30, 60, 90, 120, 365 days	2. (S123,S124,S125)
		3. (S21,S22)

Source: S.Briciu, G.G.Dragu, R. Ivan, 2010:478-483

The limitation of this model consists in the difficulty in providing highly accurate monthly data due to the usage complexity and thus not responding to the users’ needs. The second model was developed based on the criteria of clearing due dates and within each of them on activity subsectors:

Table 2. Suppliers (II)

Suppliers (II) from which		
Current suppliers from which		Non-current suppliers from which
within clearing and residual payments due date from which		Subsectors’ suppliers
within clearing due date	within residuary due date	1. (S11) (S1311) (S1313) (S1314)
7, 30, 60, 90, 180 days	>< 30, 60, 90, 120, 365 days	2. (S123,S124,S125)
		3. (S21,S22)
Each due date is established for each subsector;		

Source: S.Briciu, G.G.Dragu, R. Ivan, 2010:478-483

The calendar month was used for the clearing due date:

- from which past due debts period (less than 30 days, 30 to 60 days, 61 to 90 days new included category in addition to the

terms mentioned in Annex 30 “Past due debts” etc.) on subsectors for each of them.

Likewise, the 2nd degree synthetic account “Non-current suppliers” was divided into subsectors.

The solution for current period payment due date distribution was given by the calendar month clearing due date formula with the indication whether it is for the current or the following year. Therefore, the error rate was reduced in the case of classification according to clearing due dates so that invoices that had a 7, 30 or even 180 days due date could have matured within the same month.

Problems appear within sanitary sector where, according to payment regulations, suppliers have an up to 180 days due date, and starting with July these invoices must be included in the non-current debts even though they have less than a year deadline and could be paid until the end of year.

As a informatics solution to avoid data introduction errors, starting with the calendar month that follows the previous due date month, the accounts that were due in that month do no longer show a balance account and the fields can no longer be completed (the balance account of the subsectors due in January must be zero starting with February either as a consequence of payment or a transfer into the 30 days residual payment category).

In the following section we present the standard structure of the accounts highlighting the commercial nature with suppliers, for the grouping model focused on deadlines, as was previously mentioned, the way we envision the organization of the unique balance sheet at administrative-territorial unit level.

Characters registry regarding the structure of Suppliers group 40.

- 1) Characters 1-4 = 1st or 2nd degree accounting synthetic account
- 2) Character 5 = The type of current or non-current debts
- 3) Character 6 = The function of accounting account
- 4) Characters 7-8 = The financing source, a new solution in order to facilitate the centralizing activity at the level of administrative-territorial units
- 5) Characters 9-10 = pertaining to national programs (it is opted for the filter

character of these 2 necessary characters in the completion of columns 2, 2.1, of Annex 30b II “Synthesis of overdue payments and arrears at the date of...”)

- 6) Characters 10-11 = pertaining to post-adherence external funds (it is opted for the filter character of these 2 necessary characters in the completion of columns 3, 3.1, of Annex 30b II “Synthesis of overdue payments and arrears at the date of...”)
- 7) Characters 11-12 = pertaining to pre-adherence external funds (it is opted for the filter character of these 2 necessary characters in the completion of columns 4, 4.1, of Annex 30b II “Synthesis of overdue payments and arrears at the date of...”)
- 8) Characters 12-14 = Within due date (7, 30, 60, 90, 180 days)
- 9) Characters 15-16 = Overdue payments (30, 60, 90 days)
- 10) Characters 17-19 = Arrears (91, 120, 365 days)
- 11) Characters 20-21 = The sector or subsector according to the European System of Accounts ‘95 (ESA ‘95)
- 12) Characters 13-30 = Other information regarding the analytical account (fiscal identification code, supplier code or other analytical data elaborated by the credit coordinator depending on the entity’s needs).

We thus conclude that the hypothesis stating that it necessary to refine the standardized system of reporting to suppliers elaborated according to European System of accounts ESA 95 due to legislative changes is sustained by the current study.

Moreover, we acknowledge that occasionally these changes lead to inconveniences in the reporting system regarding the process as well as meeting deadlines, which constitutes a major risk factor in the present economic conditions in long term, paving the way for creative accounting.

3. Conclusions

Arrears represent overdue payments accumulated in time, as a result of not paying the liabilities towards suppliers, banks, budgets. Overdue payments in Romanian economy maintained after 2001 around 60

billion lei, reaching their highest point in 2003, when the overdue payments amounted to 63,5 billion lei and with a lowest point in 2006, coming to 53,1 billion lei. 2008 was characterized by a highest degree in the increase of arrears (increase of around 22% compared to 2007). Therefore, arrears reached 70,4 billion lei at the end of the year, compared to 57,8 billion lei at the end of 2003 [1].

One of the leading causes in maintaining a high level of arrears in economy is represented by the losses recorded by companies. Thus at the end of 2008 the losses of economic agents reached 42,9 billion lei, which represents 8,5% of GDP, compared to those recorded in 2007, when they represented 5,2% of GDP [2].

At European Union level it was taken the initiative of creating a system of prompt payment, which becomes relevant under the conditions of the present economic crisis, through adopting the legal dispositions of fighting the delayed payments for the transactions closed among economical agents or between them and public authorities.

According to the communitarian juridical order, a directive cannot be directly applied within the internal law of member states, requiring transposition national legislative acts, according to article 288 of the Treaty of the functioning of European Union.

Therefore, Directive 2011/7/EC regarding the fight against delayed payments within commercial transactions, due to its complexity and effects, creates a context that requires transposition measures in national legislation, respectively the modification/completion of existent normative acts or the elaboration of new ones depending on the case, concerning the mediation and alternative ways of solving litigations, elaborating an inventory of normative acts in force which include deadlines of more than 30 days and the possibility of their modification in the desired direction.

For example, for the health subsector, according to the law in force, the clearing terms for the invoices emitted by the suppliers of medicines and sanitary materials are as follows:

- 30 days for the validation of invoices for the medicine with or without personal contribution (starting with the date in which pharmacies submit the invoices to the health

insurance house) + 180 days in which the clearing can be made = 210 days (7 months)

- 30 days for the validation of invoices in the national health programs, to which another 90 days for clearing are added = 120 days (4 months); by the transposition of clearing terms directive for the consumption of medicine and sanitary materials used within the national health programs invoices should be cleared in maximum 60 days starting with their submission.

The preventive Accord closed with FMI/CE/BM took into consideration the transposition of Directive 2011/7/EC into Romanian legislation in due time, respectively 16 March 2013.

The issue of overdue payments poses a risk for the sustainability of public finances and thus represents a constant concern for the authorities, being carefully supervised within the agreements closed with international organisms, through quantitative and qualitative criteria (the extent of arrears for national economic agents and for local authorities).

At the level of public organizations there is a tendency to transfer the gained experience and to standardize organizational structures especially in the domain of local public administration. Standardization has a positive effect considering that it allows for making comparisons that are useful for control, but might also generate negative effects under the conditions of recording an excessive centralization tendency.

A paradox of the time we live in is that although hundreds of satellites monitor the planet's activity and the information technology is globally spread, enabling the collection, amassing, delivering and analysis of an impressive volume of data, the accuracy of economic-financial data remains tributary to the referential of reporting and manipulation of results [3].

Financial statements must convey a reliable image of the assets, debts, financial status (net assets / equity patrimony / equity capital), as well as financial and patrimony performance and patrimonial results. The application of accounting regulations regarding the accrual accounting entails the establishment of a set of **procedures** by the management of each public institution for all the undergone operations, starting with the elaboration of justificatory documents up to

the trimestral and annual financial statements.

As a direction for future research we are considering the following issues: the development of a new procedure for reporting the debts, the correlation between the analysis of the volume of overdue payments volume and arrears with the data provided by the special accrual accounts both to suppliers and other categories of partners – banks, employees, state budget at social and local level.

Abstract

Since 1970 there has been a tendency to increase taxation in the Member States, trend that persisted for three decades, given the extension of the public sector in the economy, and hence the growth of public spending.

In the late 90s, following the Treaty of Maastricht and then the Stability and Growth Pact, Member States were constrained to adopt measures to ensure fiscal consolidation (reducing annual budget deficits and public debt). Some have reduced spending, while others have instead focused on the increase of temporary taxes. There were, however, countries that, taking advantage of the boom period, proceeded to a reduction of the tax burden, especially on personal income taxation, taxation on companies and of social insurance contributions.

Keywords : tax burden, direct taxes, indirect taxes, social contributions, crisis.

J.E.L. Classification : H200, H300

1. The evolution of fiscal pressure in the EU

As specifies from the very beginning the last report of the European Commission regarding the taxation trends in the European Union, this remains an area with high taxes. In 2010, the average of fiscal pressure including social contributions in EU-27 amounted to 38.4% of GDP, exceeding by 40% the U.S. (24.8%) and Japan (26.9%). Similar facts are presented and compared with other non-European developed OECD

countries, where only Canada and New Zealand have fiscal pressure rates above 30% of GDP. This creates, of course, major competitiveness problems to firms within the European Union.

The data in Table 1 shows that at the EU-27 level, over the decade analyzed, there was a downward trend in the fiscal pressure (by 2 percentage points between the margins). It decreased slightly from 2000, but for a short period (two years), after which, under the pressure of reducing budget deficits, the tax burden resumed growth by 2007.

The first effects of the global economic crisis have already been felt on government revenues in 2008, although the economic growth turned negative in the EU only in following year, when the lowest level of mandatory tax levies to GDP (38.4%) was registered, level that has stabilized in 2010 in the context of a slight resumption of growth.

This trend is specific to most Member States, twenty of these recording a fiscal relaxation. The highest tax rate reductions were recorded in Slovakia (6 percentage points), Sweden (5.6 percentage points), Finland (5.1 pp), Bulgaria (4.2 pp), Greece (3.6 pp), Germany (3.2 pp). Seven other states have increased tax burden, Cyprus (5.8 pp), Malta (5.4 pp) and Estonia (3.2 pp) making themselves noticed. In the other states changes, in one way or another, were less significant, often under one percentage point.

In terms of future trends, the European Commission forecast in November 2011 an increase of the revenues in GDP by one percentage point. Concerning public expenditure, which during the period 2007-2010 has increased by five percentage points,

one can expect a decrease by two percentage points until 2013.

Table 1. Level and dynamics of tax burden (total taxes including social security contributions, as % of GDP) in EU Member States

Analyzing the level of taxation among Member States, what strikes are the large disparities between them. The range of variation in 2010 is over twenty percentage points of GDP between the country with the highest level of taxation - Denmark (47.6%) and the country with the lowest taxation - Lithuania (27.1%), i.e. a difference of 75%.

Above the European average, next to Denmark, stand Sweden (45.8%), Belgium (43.9%), France (42.5%), Italy (42.3%), Finland (42.1%), and Austria (42%). Below the European average, Lithuania is followed by Romania (27.2%), Latvia (27.3%), Bulgaria (27.4%), Slovakia (28.1%), and Ireland (28.2%).

These disparities can be explained in different ways and related to:

- the level of development of each country, developed countries, older EU member states practicing a higher level of

taxation than newer admitted into the European family, most former command economies (first nine positions as the level of taxation are occupied by EU-15 members. A connection should be made here with the taxpayer' contribution power (income and wealth) which provides a certain degree of supportability of the tax burden.

- the choices made by each state about the degree of involvement in the economic and social life especially and the delivery of public or private of social protection services (pensions, health insurance, unemployment), education, culture, etc.. Not incidentally the group of states with the highest taxation is dominated by Scandinavian countries.

- technical problems, some states giving economic and social assistance mainly through fiscal facilities (which reduce the tax burden), while others provide such assistance via direct government spending; at the same time in some states social transfers are exempt from taxes, while in others they are taxed, at least when they exceed a certain threshold, increasing the tax rate.

- finally, the phenomenon of tax evasion, by its magnitude, can affect the overall tax burden.

If between 2000 and 2007 some progress towards fiscal convergence desired at EU level can be determined, this process was interrupted by the crisis, centrifugal tendencies finding their explanation in the different intensity recession manifested in every state and various fiscal policy solutions that governments have used to counter the crisis.

2. The structure of fiscal pressure in the EU

The tax burden structure induced by the three main categories of compulsory levies (indirect taxes, direct taxes and social contributions) can be analyzed based on the data in Table 2.

A first observation that can be made is that at EU-27 level there is an almost equal distribution of fiscal pressure between the three main categories of compulsory levies, with an insignificant difference in favour of indirect taxes.

Contrary to these averages, among member countries the situation is highly differentiated, few states having a structure

similar to the levies of the European Union taken in its entirety (Italy, Spain, Netherlands, and Austria).

Table 2. The structure of fiscal pressure in the EU in 2010 (direct taxes)

Country	Overall compulsory levies % GDP	Direct taxes	
		% of GDP	% of overall compulsory levies
Belgium	43,9	16,3	37,2
Bulgaria	27,4	5,1	18,8
Czech	33,8	7,0	20,8
Denmark	47,6	29,9	62,7

Source: <http://ec.europa.eu/eurostat>

On principle, in developed countries members of the EU-15, direct taxes have major percentages, in seven of these (Denmark, UK, Sweden, Luxembourg, Finland, Belgium and Ireland) the share of direct taxes going beyond the indirect taxes. Interesting to note is that direct taxes, more "visible" for taxpayers, are higher in countries in which redistributive objectives are more pronounced, the group of seven being dominated by Scandinavian countries.

Instead, indirect taxes have a more important contribution in countries with lower development level, Bulgaria (55.4%), followed by Hungary (45.5%), Romania 45.2%, 43.8% Cyprus, and Poland 43.5% standing out. Among these, a notable exception is Malta, country where the participation of direct and indirect taxes to

the formation of public revenues is somewhat balanced.

Table 3. The structure of fiscal pressure in the EU in 2010 (indirect taxes)

Country	Overall compulsory levies % GDP	Indirect taxes	
		% of GDP	% of overall compulsory levies
Belgium	43,9	13,3	30,3
Bulgaria	27,4	15,2	55,4
Czech	33,8	11,5	34,0
Denmark	47,6	16,9	35,2
Germany	38,1	11,4	29,8
Estonia	34,2	14,2	41,6
Ireland	28,2	11,7	41,4
Greece	31,0	12,3	39,7
Spain	31,9	10,6	33,0
France	42,5	15,1	35,5
Italy	42,3	14,2	33,5
Cyprus	35,7	15,6	43,8
Latvia	27,3	11,5	42,2
Lithuania	27,1	12,1	44,7
Luxembourg	37,1	11,9	32,0
Hungary	37,7	17,2	45,5

Source: <http://ec.europa.eu/eurostat>

Important differences exist in terms of social contributions.

A particular case is represented by Denmark with an unbelievable level of social contributions (2.1%), in this country social protection (high, by the way) being ensured mainly due to taxes on personal income, which in 2010 accounted for over 80% of overall direct taxes. Lower social contributions are also found in the UK and Sweden, among the old member states Germany and France standing at the opposite.

Developing countries practice a high level of social contributions (the top hovering Czech Republic, Slovakia, Slovenia) in order to support social protection systems, which increases the tax burden on labour.

Table 4. The structure of fiscal pressure in the EU in 2010 (social contributions)

Country	Overall compulsory levies % GDP	Social contributions	
		% of GDP	% of overall compulsory levies
Belgium	43,9	14,2	32,4
Bulgaria	27,4	7,1	25,8
Czech	33,8	15,3	45,2
Denmark	47,6	1,0	2,1
Germany	38,1	15,5	40,8
Esthonia	34,2	13,1	38,5
Ireland	28,2	5,8	20,7
Greece	31,0	10,9	35,1
Spain	31,9	12,3	38,6
France	42,5	16,7	39,3

In Romania, the fiscal pressure issue became topical after 1989, with the first signs that the Romanian economy will become a market economy, while the tax system modernization was strongly recommended, a modernization which continues even after 22 years of transition.

Taxation level recorded in 2010 placed Romania on the 26th place among EU-27 countries, only Lithuania having a lower level of taxation (27.1%). This level is comparable with that tax in Latvia (27.3%) and Bulgaria (27.4%). Compared to the European arithmetic average (35.6%), the tax burden in Romania is lower by 8.4 percentage points and compared to the highest tax burden country (Denmark - 47.6%) the gap is 20.4 points percentage.

Under these circumstances, the fiscal structure has known significant changes within a 10 years outlook, by increasing the

share of indirect taxes in the overall tax levy to 45.2% in 2010 (compared to 40.4% in 2000), which places us on third place in the EU after Bulgaria (55.4%) and Hungary (45.5%) and well above the European average (38.6%). In parallel, the share of direct taxes and, especially, social security contributions decreased (from 23.2% to 22.6% and from 36.7% to 32.2%). Even with this level social contributions exceed the EU-27 average (31.1%), while direct taxes are well below the European average (30.4%).

The fact that our tax system has as main pillar consumption taxes is not a surprise, being a particularly of countries with less developed economies and with a lower individual income level, which makes direct taxes to lack a solid tax base. This goes particularly noticeable if we eliminate from the analysis the social contributions and we consider only pure tax levies. We find in this case that almost two thirds (66%) of tax revenues are obtained through indirect taxes and only 34% revenues from direct taxes.

3. Conclusions

The analysis of international practices and the trends in fiscal policy allow us to formulate some conclusions and perspectives on the complex issues of tax burden:

- from the analysis of the level and structure of taxation it results that its level varies according to the functions that assumed especially in terms of social protection;

- after the tax reforms developed in European countries in the 90s of last century a process of reduction of marginal tax rates in most countries began, observing that their high levels distort the economic activity and encourage tax evasion, even the conception of transition to the method of using taxes as economic and social levers gaining ground;

- as a consequence of the accession of new countries to the EU, there will be an alignment of the level of taxation and redistribution to the values recorded in countries with lower taxation;

- the Romanian fiscal system has reached that level of maturity as other tax systems in the EU, but there are some changes needed for harmonization with EU legislation and the removal of deficiencies;

- the tax burden and the level of taxation

in Romania are only apparently low, because, in fact, a low level of gross domestic product, an unequal distribution of taxation and the large number of taxes, for a large part of tax payers is burdensome;

- a fairer tax redistribution through a reconsideration of the relationship between direct and indirect taxes, an improved tax collection and the reduction of their level, as well as support to investment and economic development to increase income per capita and general welfare is needed;

- a reassessment of the level and forms of social protection in Romania, as well as labour taxation should be needed, because achieving a comprehensive social protection has a negative impact on the economic development.

Tax reform carried out in Romania should not stop at the achievements to date, a rearrangement of the domestic tax system to draw a new qualitative and quantitative structure following on.

Abstract

The non-normality of asset return distributions has been a stylized fact in the empirical finance literature. Fat-tailedness, in particular, can have significant impact on the accuracy in computing value at risk (VaR), which became popular from the mid – 1990s as a primary measure of market risks arising from the trading activities of banks.

The primary purpose of this study is to develop methodology VaR. At first VAR was only an educated estimate of the market risk, relative to a previously specified portfolio. VAR of a portfolio is a single figure, expressed in units of currency, summarizing within a specified holding period on a previously given confidence level..

All of these methods have different statistical assumptions and VAR results depend on the chosen method for a specified portfolio.

Key word: methodology VaR, Monte Carlo simulation, Stress Testing, Back-Testing, Risk Metrics

Classification J.E.L.: G11

1. Introduction

Investment and the portfolio theory have made a significant contribution to the theory of risk and return applied to securities. Indeed the Capital Asset Pricing Model (CAPM) has undoubtedly become one of investment.

Risk in this context can generally be related to the volatility of the return on a given security or a portfolio of securities. While this has obvious importance to investment or merchant banks, it must be

stressed that the activities of most modern banking groups do cross over to some extent due to the increased role of securities and derivatives in intermediation. Reducing risk through diversification has already been briefly mentions for virtually all areas of banking as it can be applied to any portfolio and can serve to reduce to exposure to all banking risks.

The new techniques appeared in the market risk management at first. In this area the necessary database was available, and relatively simple solutions offered a much better management of market related risks. With the passage of time in parallel with the increasing sophistication of trade financial instruments and increasing complexity of the market risk, models developed substantially to cope with the new challenges. A new style, better management of the market risk became necessary according to the changed circumstances. The new derivative product offered efficient risk management solutions, but in every derivative product there is a potential for big losses as a consequence of a very high leverage. The derivatives related problems further exacerbated with the difficulties related to a large portfolios. From the available solutions the Value-At-risk methodology almost became the standard for the industry. [8]

The original VaR numbers were only estimate assuming normal market conditions, and did not tell anything about adverse market situations when the market price volatility could be several times grater than under normal circumstances. Senior management and other users should keep in mind limitations of the VaR estimate as well.

VaR numbers are still very useful. Without stress testing procedures however the VaR numbers do not tell anything about

market crash situations and about the huge changes in the value of the specified portfolio. This stress testing is absolutely necessary because financial market tend to react increased price volatility to important events from time to time.

Although Var has limitations, its importance is much further reaching. It is a powerful management tool, which increase the transparency of market risks (especially derivative related risks) and measure them in very easily understandable financial terms. With help of VaR senior managers can avoid such risk management disasters as the Orange country case and the infamous Procter&Gamble case. In both cases seniors managers were not aware of the risk taken and could not control their employees' actions adequately. VaR can help to understand very sophisticated financial products, such as the hyper leverage, which was responsible for huge losses in the later case. [6]

Barings, Daiwa, Orange County and Long Term Capital Management...these are some of the banks that have lost billions of dollars in financial markets. These losses in many cases were the consequence of inadequate risk management systems in place and in many cases the result of poorly monitored market risk by the senior management. To address this problem some of the world's leading banks and financial institutions are turning to Value at risk (VAR); this is an understandable method of calculating and controlling market risks. [4]

Financial innovations such as derivatives have also made these banks and financial institutions take financial risk management seriously as many banks have lost huge amounts owing to trading in derivatives. In other words one can say that derivatives have started the revolutions of financial risk management that is now leading to every bank and financial institution using VAR.

2. Overview of VaR

It is the method of assessing risk that uses standard statistical techniques routinely used in other technical fields. It can be defined as follows:

“VAR measures the worst expected loss over a given time interval under normal

market conditions at a given confidence level”. [1]

It measures the volatility of the assets; the more volatile they are the greater is the risk of bankruptcy. If a portfolio manager holds a portfolio with a low volatility this means that the risk of making huge losses is very low. On the other hand, if an investment manager has invested in shares whose value fluctuates by large amounts, then apart from probability of making huge profits there is a greater risk of potential losses and this is what VAR measure. Apart from indicating losses VAR also indicates the time period over which these losses will occur.

These are many approaches to measuring VAR but so far the industry has not come to a consensus on the best method of calculating VAR. There are three main approaches to calculating VAR: the correlation method, historical simulation method and the Monte Carlo simulation method. A fourth method, the historical approach, is a simpler and less theoretical method than historical simulation. Each of these methods has its own sets of assumptions, so there is no consistent method for measuring risk. This is the reason why different VAR models give different VAR figures. Risk managers therefore have to seek to understand the limitations of each model and use the one or a combination of models that best fits their organizations. [5]

This is the simplest of all methods; it assumes that all the returns on the risk factors are normally distributed. Correlation's between the risk factors are constant and the delta (or price sensitivity to changes in a risk factor) of each portfolio constituent is constant. In this method the volatility of each risk factor is extracted from the historical observation period. The potential effect of each component of the portfolio on over all portfolios is then worked out from the component's delta and the risk factor's volatility. [10]

These effects are then aggregated across the whole portfolio using the correlations between the risk factors to give an overall volatility of the portfolio value. By scaling the volatility of risk factors, the desired confidence interval for VAR can be obtained.

Different methods are used to calculate relevant risk factor volatilities and correlations. The most straightforward method used is simple historic volatility; the

problem with such a method is that a single large market move can distort volatility over the required forecasting period.

The other method is weight unequally past observations, which is a more sophisticated approach. In this approach more weight is given to the recent observations, this is done so that the large jumps in volatility are not caused by past events that happened a long time ago. Generalized Autoregressive Conditional Heteroscedasticity, the Garch and exponentially weighted moving averages are the two popular methods used for unequal weighting. Garch volatilities capture more features of past changes in volatility. Both these models assume that future volatilities can be predicted from historic price movements. [9]

3. Historic-simulation method

The historic approach is simpler to understand than other methods. In this method the risk managers simply keep the historical record of daily profit and losses within the portfolio and then calculate the fifth percentile for 95 percent or 1 percent for 99 percent VAR. Apart from being simple, the historic approach is also more realistic. It is based on the actual results; therefore the historical system will pick up any major market events during the historic period. Another advantage of the historic method is that it does not require “mapping”.

Apart from being simple and realistic it has some weaknesses. For example, it is unsuitable if the weightings of the portfolio change. This is the reason why it is not suitable for scenario analysis. Hence, it may produce VAR, which does not reflect the current situation. Even if no positions are created or old positions eliminated from portfolio, the aging process can change a portfolio's risk profile significantly over time. One way of remedying such a problem is to use historic simulation. [3]

The historic-simulation method provides a straightforward implementation of full valuation. This method is relatively simple to implement if historical data have been collected for daily marking to market. In this method longer periods increase the accuracy of estimates but irrelevant data could be used, thereby missing important changes in the

underlying process. In this method returns are measured simply over intervals that correspond to the length of the horizon. Therefore one can say that it deals directly with the choice of horizon for measuring VAR. Since the method relies on actual prices, it allows nonlinearities and non-normal distributions. Therefore, full valuation is obtained from the historical data.

However, historic simulation is not free of criticism. For example, only one sample path is used; the assumption for this is that past represents the immediate future fairly. Historic simulation will therefore miss a situation with temporary elevated volatility. Secondly, VAR is a statistical estimation and therefore it can be subject to error if the sample size is too short or too large. [2]

Another criticism is that the method puts the same weight to all the observations even if they are old. Thus the measure of risk can drop significantly after an old observation is dropped from the window.

In practice users adopt simplifications, which increase the speed of computation. However, too many simplifications are carried out the benefits of full valuation can be lost.

4. Monte Carlo simulation (MCS)

Historic simulation takes only one path for market evolution whereas the Monte Carlo approach directs a computer to generate a series of share prices using a “random walk” approach.

The Monte Carlo simulation is more flexible than the above mentioned approaches; however, this approach also takes historical distributions for risk factor returns such as historic simulation rather than assuming normal returns. This approach is more computer intense than other approaches.

It covers a wide range of possible values in financial variables and fully accounts for correlations. The risk manager then specifies a stochastic process for financial variables as well as process parameters; these parameters such as risk and correlations are derived from the historic data. Each simulation will be different but in total all will aggregate to the chosen parameters. Once all the simulations are done then VAR can be found by listing all the outcomes in order of profit and loss

and cutting off at the required confidence level. This cutting off points represents the VAR. [7]

Unlike the historic simulation, in the Monte Carlo simulation, the evolution of market factors is to simulate through mathematical modeling rather than taking directly from the historic data.

Advantages of MCS:

As compared with other approaches, the Monte Carlo simulation has advantages. Some these advantages many are as:

- the MCS approach is more effective in capturing risk profiles of portfolio;
- this approach, because of its modeling precision, is best approach in quantifying large market movements;
- since it generates a large collection of sample paths, it can be used to test run a wide range of possibilities.

Disadvantages:

- the portfolio has to be revalued many times in order to generate a large sample of simulated paths;
- mathematical sophistication is needed;
- this approach is time consuming when running a risk analysis

All of the above-mentioned methods have their own advantages. Perhaps the best way is to check VAR measures with different methodologies and then analyze the sources of differences.

5. Stress Testing

Stress Testing, sometimes called scenario analysis, examines the effect of stimulated large movements in key financial variables on the portfolio.

The advantage of using such as a method is that it many cover situations completely absent from the historical data. This approach compels managers to consider events that they might otherwise ignore.

The Stress Testing method is completely subjective, so bad scenarios will lead to wrong measures of VaR. The choice of scenarios may also be affected by the choice of portfolios itself. For instance if in one moth the portfolio may be invested in national fixed income market, in this case the scenario will the focus on interest rate changes in the market. If the scenario

changes over time, the measure of risk will also change owing to this scenario.

This approach is criticized mainly because of poorly handling of the correlation, which is an important component of portfolio risk. This system is beneficial mainly for the cases where the portfolio depends primarily on sources of risk. Stress testing should be used as a complement rather than a main approach to calculate risk.

6. Back-Testing

Back-Testing is the method to verify the validity VaR; it is also recommended by the Basel Committee. This Method compares actual trading results with the model generated risk measures. If the differences are not close to each other then the model does not raise ay question about the validity of the model used to calculate the VaR, but if the differences are large enough then it raises alarms against the validity.

For financial institutions it raises some problems, for instance the difficulty of stripping out the effects of intra-day trading from the profit and loss figures, in order to makes them comparable to the VaR figures.

Secondly, the Back-Testing framework involves the use of risk measures calibrated to one-day holding period. These problems have been recognized by the Basel Committee, and it recommends that banks should develop the capability to perform Back-Tests by hypothetical valuations to the overnight VaR. However, this does not end the problem and therefore a lot of work needs to be done in this area.

7. Risk Metrics

The drive to launch a system for the management of credit risk continued from the fourth quarter of 1997. This was after JP Morgan introduced its own risk management system called credit metrics. It was launched in April 1997. Credit metrics evaluates the VaR resulting from credit exposure to a broad to a broad rage of individual cash and derivatives assets. This method assesses the credit quality result the changes in the credit ratings.

Credit quality is assessed by constructing the “transition” matrix giving the probability of change in credit ratings over a given

period of time. From this the expected change in the market value from the change in ratings is calculated. Finally the individual value distributions are aggregated with correlations taken into account between the credits. This gives a distribution of potential losses for the whole portfolio of assets. The credit metrics method not only allows wider credit quality but also calculates the likelihood that different types of loan will turn sour at the same time, producing a lower capital requirement for a well/diversified portfolio.

The credit metrics method also establishes a common benchmark for credit risk measurement. This makes it easier for pricing instruments such as credit derivatives. Advantages of this approach are these: since price and rate histories can be easily observed, this approach can therefore handle a large number of markets in a transparent fashion.

Secondly, since it uses the Delta Valuation method it is computationally efficient. Apart from advantages there are also some disadvantages. For example, the extrapolated volatilities and correlations used in this model are or necessarily the best estimates and may not reflect what is currently implied in the markets. Another disadvantage is that it uses the delta valuation method, which can only approximate the risks in non-linear positions.

Conclusions

From the above it can be concluded that risk management is fundamental to modern banking, and proper risk management processes should be seen as a vital and integral part of a bank's success. No matter how sophisticated, model banks use human judgment is still essential ingredient.

Therefore people at all levels in the hierarchy should have knowledge and understanding of risks management, and use the model to measure the risk management system present in the organization.

An Analysis of the Human Capital Management Effectiveness, as Key-factor of the Organization’s Performance

Drumea Cristina
University Transilvania of Brasov
cristinadrumea@yahoo.fr

Abstract

The paper aims to give a new perspective on the ways of analyzing and evaluate the human resource management factor in the grid o the company’s performance. It also stretches on new ways of measuring the work capability of personnel (individually and/or in strategic personnel units), perceived not only as a source of profit thru productivity, but as a key-factor in the organization’s competitiveness and success.

Key words: human capital analysis, performance appraisal, HRM Performance
JEL classification: M5, M12

1. Introduction

The quality of the human capital is crucial for any company, enabling it to maintain a competitive advantage in this knowledge economy era, away along with technology and innovation. These are the pillars of competitiveness in the sector.

However, the most competitive companies are often suffering from high turnover rates of qualified personnel thus find it hard to recruit the right talents at the right moments, while keeping straight the balance of costs.

In addition to conventional human resource management approaches, we find in practice that there is an urgent need to develop effective personnel selection mechanism to find the talents who are the most suitable to their own organizations.

We refer to all categories of personnel (direct productive and indirect productive ones, e.g. internal auditors, accountants - as an important role in regards to the human factor is played by „the quality of the professional accountant [...] as he holds a

significant role, ensuring the credibility of the accounting statements”[3]). It is why the recruitment process tends increasingly to be initiated „directly in the university environment, while we see more and more a professional environment submitted to many challenges and of a lack of highly qualified personnel”[2].

And recruiting the fit personnel is but the beginning of a process. We need to emphasize on the fact that after the recruitment process is completed, it is as well important to maintain a good process of continuous evaluation of the performance level of the human factor.

2. Human Resource Management (HRM) performance evaluation

Performing the various activities and tasks to produce the outputs in terms of the performance objectives (with its underlying performance measurements), must be within a responsibility framework. This will ensure proper linkages to accountability and clear communication of each team member’s assigned activity, against what the output will be measured to ensure the overall performance objectives of the unit are met. In short, this is meant to spot the necessary benchmarking points and indicators against what the employee’s results will be evaluated.

But evaluators need to be appraised as well, by means of specific techniques applicable to the processes and results of their work; this is the Human Resource Management policies and outcome.

Graham Andrewartha is one of the authors whose work is focused on the Human Resource evaluation techniques; a study called Andrewartha Correll Human Resources Evaluation (ACHR) and developed by the author in 1995 aims to

attain an abstract illustration of two controlling dimensions of human resources management, as in flexibility and strategic focus.

The ACHR is an organizational environment survey/employee behavior survey, used specifically in the human resources management practices, in order to support that part of the HR evaluation process that might lack in objectivity if done in-house.

The method allows as well adding other carefully designed issues relating to the organization at a certain moment in time.

The output is to obtain an organization average score on each dimension; averages can be calculated separately for each business unit, section or department. This facilitates significant comparison of the perception on Human Resources Management (HRM) techniques across different business units of the same organization.

It also enables a differential appraisal of perceived value or impact of the implementation of new HRM policies, such as team development, quality control, restructuring, personnel rotation between posts and/or duty stations, fixed-term appointments and similar initiatives.

The two mentioned dimensions have different value ranges, going from less to more, full extent on each element:

- For the element *Strategic Focus* the range goes from a focus on reactive, immediate, operational management issues through to an edge on long term, strategic issues.

- For the element *Flexibility* the range goes from a traditional, flat adherence to established practices and protocols through to a flexible response, taking each new situation on its intrinsic worth, allowing resourceful solutions and options.

The result of the combination of the two axes is a matrix (Fig. 1) that shows four types of Human Resources Management, framing a “free” zone, with emergent potential. The four resulting zones state the relevant types of Human Resources Management bridging the two concepts: flexibility and strategic focus.

The four resulting quadrants show virtually extreme situations, in practice concepts being more collided, as even though we find good matches especially in quadrants

Reactive, Planned and *Proactive*, we mainly see combinations of approaches in HRM typology.

Fig. 1 Matrix of Human Resources Management typology

In the *Restrictive quadrant*, Human Resources Management is accomplished with both low flexibility and a low strategy focus. It is the case of the organizations focused on preset, firmly established HR procedures, which are often applied in reaction to events. There is little forward planning activity in place and Human Resources Management practices are restricted. This would be the case of public organizations, which need less flexibility in reaction, as less confronted to adversative situations in the past. This I to be changed in our view, as nothing is surer than uncertainty especially in economic environments.

In the *Reactive quadrant*, Human Resources Management is put in place with high flexibility, but a low strategy focus. HR practices tend to be flexible and accessible but most of the activity arise post-event and mainly in response to external/internal situations. Human Resources Management is responsive but is still defined by historical background and traditions. There is a small amount of long term strategic Human Resources Management planning. This would apply to small and medium sized organizations, which either grew faster than they were able to adapt the management practices accordingly, or reside in a less challenging sector, with low-specialized personnel; this allows the organization to rely more on daily short-term decisions concerning personnel and maybe operational decisions in general.

In the *Planned quadrant* there is low flexibility, and high strategic focus. In this sector we find organizations that plan HR ahead efficiently, using strategic thinking and

anticipation. The application of HR practices, whilst planned, is nevertheless mostly bounded by rules and regulations. It goes especially for international (public) organizations that tend to plan ahead based on 2-3 years budgets for all (including personnel) expenditures. This lack of flexibility is due partly to respect of highly restrictive HR rules (regarding recruitment, appointment, separation, retirement), in order to ensure equal, full and free access to all categories of applicants and partly to lack of willingness to change what has been established and what was proven to be working. This kind of inflexibility acquires to the employee’s mentality as well, starting with HR people themselves, which creates rigid mindsets and future inadaptability.

In the *Proactive quadrant*, Human Resources Management is effected with both high flexibility and a high strategic focus. HR is extensively valued for its role as a strategic business partner, with key contribution to the leadership, to the business strategy formulation and change management. The approach promotes forward and flexible thinking within a considered and open structure, operating on learning organization philosophy. The HR entity is seen as a professional, strategic and tactical provider to the organizational direction and activity, and not as a processing component. It is and should be the case of majority of companies,

whether public or private, but is seen mostly on the private sector, especially with large organizations. Amongst other (previous mentioned advantages), it also ensures a good work climate, competitive yet professional, where employees may beneficiate from advancing professional pathways, having a securer long-term vision on their future careers.

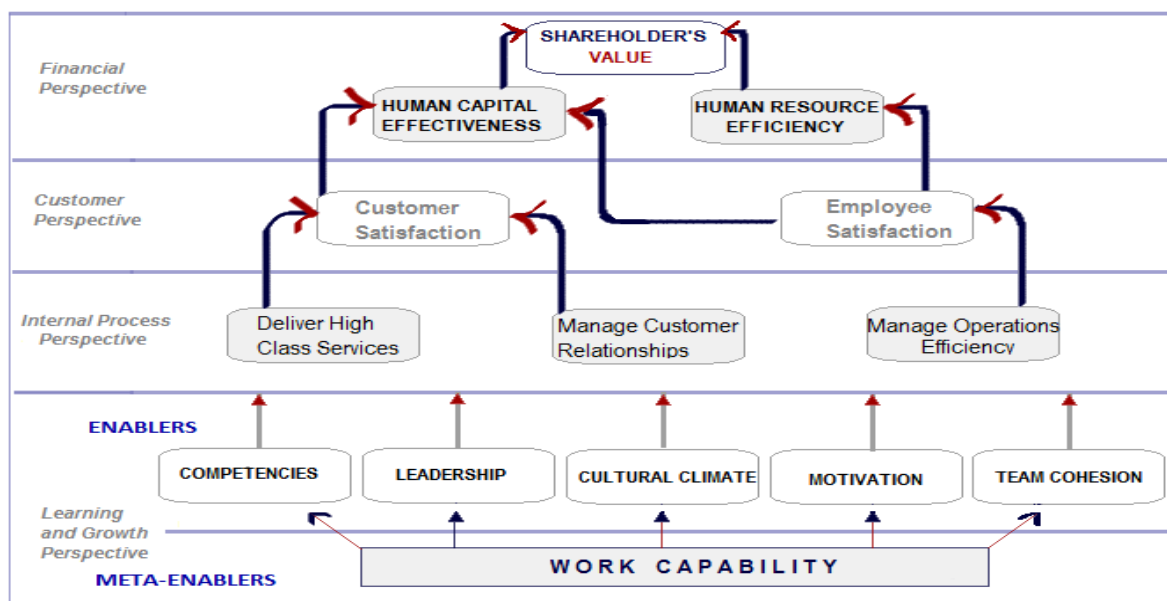

3. Work Capability Dimension

We shall not further refer to the work capability as a change or adaptation of an employee schedule, duties and responsibilities as consequence to an unexpected event (such as injury, temporary incapacity to work as per Job description requirements). This is the most common definition of terms, but we discuss mainly about the personnel’s ability to create value, thru a series of entrenched layers.

Thus, the structure of the business is mainly deployable on four different layers (Fig.2), as follows:

- financial layer
- customer relations layer
- internal business process layer
- human capital layer (or the learning and growth perspective)

Fig. 2 Dimensions of the Work Capability Strategy Map

Source: adapted from © Laske and Associates, LLC, 2002 [7]

The strategic objectives of the first three layers appear as what we could call “Human Resources receivables”. The human capital layer (or the learning and growth perspective) is set up in two sub-layers, that is:

- enablers, that help execute the designated strategic actions (it refers to competencies, team synergies, leadership, organizational culture) and
- capabilities (called meta-enablers) that trigger the enablers and measure the potential growth.

It is quite obvious that in order to improve the short and the long-term pragmatism of the organization personnel policy, there is needed to increase the number of Human Resources evaluation levels. By doing so, we take into account the organizational actual work capabilities which establish its level of current and future performance.

In order to analyze and quantify the work capability in sufficient perceptiveness means to open a timeframe through which we would be able to visualize the capability as it appears now, in the near future and in the far future.

The *current capability* is the level applicable to a person or strategic personnel unit at a given moment, for a specific job.

The *current potential capability* states for the maximal level of work a person or strategic personnel unit could carry out at any specified moment in time, in a preferred field of work and given environmental sustain.

The *future potential capability* states the predicted level of aptitude that a person or strategic personnel unit might possess at some specific time and for a precise set of tasks.

In the Human Resources analysis, the actual measurement of the three kinds of capabilities described above can be realized thru a capability grid or thru a capability metric system called Corporate Development Readiness and Effectiveness Measure (CDREM™). In CDREM, “variables together form an index; each index is specific to a particular enabler (as previously defined), such as leadership or team synergy and each enabler is measured in three different but interrelated time dimensions of capability: current applied, current potential, and future potential”[8].

When measuring team performance, we report results in a Capability Grid, while

group performance (15 to 50 people) is reported in the form of a Capability Metric.

In this way, it is possible to estimate not only the present performance, but the current and future potential performance two to five years ahead. The Capability Metric system is extrapolative. It gives insight into three aspects of capability: present performance, current potential (2 years ahead), and future potential (5 years ahead). The factors of the metric diverge according to whether we are looking at the present, or the near and far future. How can this measurement be done? It relays on criteria, which in liaison with significance coefficients gives an overall estimate for the three types of capability, as depicted previously.

Criteria for current performance are behavioral, while those for potential performance are developmental.

In summary, Capability Grid and Metrics are partly interview, partly questionnaire based instruments. Grid and Metric help the organization to make a step further than conservative performance management concept and evaluation, by detaching the input intangibles of the performance. Those two described dimensions, together with a third class of information - an analysis of the cultural environment in which performance takes place- it covers most of the aspects of an analytical human capital performance analysis.

Conclusions

The organization naturally seeks ways to become more competitive in its sector, exploiting all possible sources of competitive advantage, thus pursuing a progressively more proactive HR performance management.

Due particularly to new ERP solutions implemented in many structures of the company, it is now possible to obtain the predictive data on several aspects of its activity, including the Human Capital performance.

Once a year or in some cases even once every six months it takes place a staff performance assessment process, which creates firstly a traceable professional path for every staff that undergoes the evaluation, and secondly it traces down any underperformance, lack of motivation, or

even failure that employees may face. This helps both the organization and the employee to improve communication, to adjust expectations and to correct missteps when necessary. It is a good practice that is being implemented by more and more of medium and large organizations, not without reserves from the personnel that fears change.

It remains to be seen whether the management of the organization can adjust its present conservative approach and take the next step toward performance and increased competitiveness.

Corporate Governance Codes and their Implementation

Duca Florinița

The Academy of Economic Studies, Bucharest, Romania

University Artifex, Bucharest, România

Mihalache.andra@gmail.com

Abstract

As national economies become interconnected through global trade and communication, local standards of corporate governance have become increasingly important to investors. In this study we compare the thematic content of governance codes based on the nature of the issuer. We find that issuer identity plays an important role in deciding what themes will be emphasized within a code and helps to explain code evolution.

Key words: corporate governance, investors, corporate governance codes, global governance practices, comply and explain

J.E.L.: C10, G10, G30.

I. Introduction

The concept “corporate governance” has attracted various definitions.

Corporate governance is the system by which business corporations are directed and controlled. The corporate governance structure specifies the distribution of rights and responsibilities among different participants in the corporation, such as, the board, managers, shareholders and other stakeholders, and spells out the rules and procedures for making decisions on corporate affairs. By doing this, it also provides the structure through which the company objectives are set, and the means of attaining those objectives and monitoring performance [5].

Corporate governance is concerned with ways of bringing the interests of (investors and managers) into line and ensuring that firms are run for the benefit of investors[3].

Codes of corporate governance are a set of ‘best practice’ recommendations regarding the behavior and structure of the board of directors of a firm. Codes of corporate governance attempt to improve the firm’s corporate governance overall, especially when other mechanisms, such as takeover markets and the legal environment, fail to guarantee adequate protection of shareholders’ rights.

In such order, the European Commission’s communication for the Council and the European Parliament entitled “Modernising Company Law and Enhancing Corporate Governance in the European Union – A plan to move forward, 21 May 2003, COM (2003)” put the regulatory basis of the legal provision of institutionalization of the *Societas Privata Europaea*, unfortunately not yet entered into force, but of maximum interest from the point of view of the capital’s flexibility in terms of interest for investments. Such new supranational form of deployment of international affairs facilitates the spirit of competition, its advantages rising higher, when compared to lower costs of implementation of the investments on the Single Market, but also to the regulatory unification of the establishing rules [7].

The first code of good governance came into being in the USA in the late 1970s in the midst of great corporate ferment, with business, legal, academic, and political constituencies squaring off on what the role of the board of directors should be. The development of codes grew rapidly in the early 1990s, following the 1992 Cadbury Committee Report: Financial Aspects of Corporate Governance in the UK. The Cadbury Report became the flagship guideline that deliberately challenged the effectiveness of voluntary regulation and

British corporate democracy. The OECD Principles of Corporate Governance were endorsed by OECD Ministers in 1999 and have since become an international benchmark for policy makers, investors, corporations and other stakeholders worldwide. Thus, at the end of 2010, European Corporate Governance Institute report corporate governance codes for 86 countries.

II. Data Description

The sample used in this study consists of twenty-two members of the European Union selected on the basis of their adoption of a national corporate governance code. The first formal adoption of a national code of corporate governance for our sample countries occurs in 1995, while the most recent adopter in our sample is in 2012. The actual national corporate governance codes and related data concerning the dates of code adoption are obtained from the website of the European Corporate Governance Institute.

We describe our set of sample codes in Table 1 with a listing of their adoption dates and a history of their subsequent revision. We separate our sample of governance codes according to their legal regime as defined by LaPorta et al [2]. This allows us to compare groups of countries using a characteristic that has important implications for corporate governance and is widely established in the literature.

La Porta et al (2008) find that common-law countries have a stronger protection of legal protection investor rights than civil-law countries. Amongst the civil-law countries there is a difference between French-, German- and Scandinavian-civil-law-countries with those of German and Scandinavian having a stronger protection.

Table 1: Chronology of Code Adoption and Revision

Country*	Year of first adoption	Year of first revision	Number of revisions
Common Law			
United Kingdom	1992	2003	35
German Civil			
Austria	2002	2005	5
Germany	1998	2000	9
Switzerland	2002	2006	2

* The legal origin classification is from La Porta et al. (2008)

III. Code Variability and Country Clustering

We observe that the United Kingdom, the only common law country in our sample, is a relatively early adopter of corporate governance codes. Although France reports the first adoption in 1998, the U.K. issued a series of studies and public statements on the need for corporate governance and reform beginning in 1992 with the Cadbury Report. In 2000, the U.K. completed its internal debate over governance by formally adopting a national code of corporate governance.

The United Kingdom Corporate Governance Code has been instrumental in spreading best boardroom practice throughout the listed sector since it was first issued in 1992. It operates on the principle of 'comply or explain'. It sets out good practice covering issues such as board composition and effectiveness, the role of board committees, risk management, remuneration and relations with shareholders. The new edition of the Code was published in

September 2012 and applies to reporting periods beginning on or 1 October 2012.

Austria adopted a Code on Corporate Governance in 2002, updated 2005. It is a self-regulatory instrument, using “comply or explain” and is supported by the auditor, financial analysts and asset managers professions. Adherence is voluntary and results in a public declaration of commitment. The code was drawn up by a working party, composed of representatives of industry and academia; it also proceeds to an evaluation of the compliance with the code. The Austrian Code of Corporate Governance provides Austrian public limited companies with a regulatory framework for the management and monitoring of the company. It contains internationally accepted standards of sound corporate governance along with the rules of Austrian stock corporation law that are significant in this context.

The German Corporate Governance Code aims to promote the confidence of national and international investors, customers, employees and the public in the governance of exchange-listed German corporations. The Code brings together important statutory requirements, takes account of nationally and internationally recognized standards in the form of recommendations and provides suggestions for good and responsible corporate governance.

In Switzerland, the Swiss Exchange has issued in 2002 a Corporate Governance Directive, revised in 2006. The Swiss Code of Best Practice for Corporate Governance contains a recommendation for good governance inspired by international practice. It is a recommendation, and is essentially not binding.

The first committee chaired by Marc Viénot issued a Report in 1995 that was wholly aspirational in nature and emphasised that then-current French law and regulation was sufficient to support good governance practices by French companies. In December 2004 the Belgian corporate governance committee, active within the Belgian employers’ association, published a code applicable to Belgian listed companies. As in other states the code is essentially focusing on the functioning of the board and its relationship with management.

The French civil law countries exhibit the widest range in adoption dates of any of our legal regime sub-samples. As noted previously, France implemented the first formal national corporate governance code in 1995. Luxembourg is among the latest adopters, with its code being adopted only in 2006. The three earliest adopters among the French civil law countries have all revised their codes at least once since initial adoption. The adopters among the French civil law countries have all revised their codes at least once since initial adoption.

In 1999, the Hellenic Capital Markets Committee produced a White Paper titled “Principles on Corporate Governance in Greece – Recommendations for its Competitive Transformation”, also known as the “Blue Book”, which was closely modelled on the OECD Principles. SEV also developed a limited number of broad corporate governance principles in its “Principles of corporate governance by the Federation of Greek Industries” published in 2001.

In Italy, along with the significant changes in the company law, a Corporate Governance code or “Codice di Disciplina” has been adopted - in a renewed version in 2006 - by the Borsa Italiana with support from the Association of Companies Assonime.

In Portugal the Corporate Governance recommendations have already been issued by the CMVM, the securities regulator in 1999.

In Spain, a new corporate governance code has been in effect since 2005. It was drawn up by a special committee appointed by the government and composed of public officials, business representatives and experts. The purpose was to replace the previous Olivencia and Aldama reports .

In Finland Corporate Governance Recommendations for Listed Companies became effective in 2004. The work to establish a code started in the beginning of 2003 when a working group was formed by Helsinki Stock Exchange, the Central Chamber of Commerce of Finland, the Confederation of Finnish Industry and Employers.

The Norwegian Code of Practice for Corporate Governance was first presented in

2004 and a last revised version was issued in 2011.

The last subset of our sample countries are those that we refer to as former Socialist states.

The Czech republic Revised Corporate Governance Code was published in 2001. While it largely follows the OECD model, it also has links with the UK Combined Code. It is a voluntary code. As a country that uses the dual board model, the guidance proposes good practice for the supervisory and management boards. Updated 2004.

A voluntary corporate governance code was adopted in Estonia on 1 January 2006. Furthermore, some “Corporate Governance Recommendations” were developed by the Financial Supervisory Authority (FSA) in co-operation with the Tallinn Stock Exchange (TSE) and are intended to enhance corporate governance and transparency among listed companies.

In Romania, corporate governance has emerged in its regulatory and conceptual form in the early 2000s. The first corporate governance code was adopted in 2001. In 2009, it was replaced by a new corporate governance code, which is based on OECD principles. The new code is applied voluntarily by companies traded on a regulated market operated by the Bucharest Stock Exchange.

IV. Conclusion

Corporate governance refers mainly to the organisation of the relationship between the owners and managers of a corporation. The ways in which countries structure this relationship take different forms across the globe, reflecting different economic circumstances and national traditions. Corporate governance systems must be seen and understood in the context of the societies in which they function. Much conventional wisdom circulates on the characteristics of national systems, but it is not always supported by empirical evidence.

The convergence of national corporate governance codes is important to the EU from the specific perspective of completing the single market for financial services. Individual and communal interests are at stake that extend beyond safeguarding the interests of investors.

The General Risks Arising from the Faulty Application of the Accounting Principles

Ducu Corina Maria
„1 Decembrie 1918” University, Alba Iulia, Romania
corina_ducu@yahoo.com

Abstract

The identification of accounting risks is not always the easiest action undertaken by the entity because the changes occurring at all levels of aggregation of the economy cannot be entirely anticipated. Therefore, the problem of the risks that entities have to face has become an extremely serious one, requiring the establishment of measures and strategies in order to limit them.

Keywords: strategies, accounting risks, crisis, accounting principles, entity

JEL Code: M41, M10

1. Introduction:

Accounting quantifies, processes and transmits financial information about an entity, it makes the connection between the activities carried out and the decision-makers. Nevertheless, there is a series of risks arising from the activities carried out or the faulty application of the accounting regulations, a fact which generates a series of threats that affect the smooth running of the entity when the appropriate measures are not implemented in terms of minimising them. Thus, under the current conditions, it is necessary to identify the risks that the entity has to face and to propose strategies for their administration in order to survive in the context of the economic crisis.

2. The general risks arising from the faulty application of the accounting principles:

The loyal image is an objective aiming at the fair, real, objective presentation of the entity. The information presented in the financial statements reflects this aim of loyal image. However, the faulty application of the

accounting principles may overshadow this goal, generating a number of risks.

Thus, starting from the faulty application of the accounting principles a number of risks has been identified and presented, as follows:

1. The principle of activity continuity

It requires that an entity conducts its activity in the best conditions, without going into liquidation or reducing its activity. As a result, there is a number of accounting practices that generate a series of detailed risks as follows:

a. Delimitation of certain financial or accounting exercises throughout the entity's life, depending on which the following are established: financial position, financial performance and cash flows of an entity - the risk arising from the misunderstanding or misinterpretation of this principle can lead to the formation of a misleading image of the financial position, of the financial performance that can influence the economic decision of the financial statements' users.

b. The use of the historical cost and of the current (utility) value for assessing the assets, equity and debts, income and expenses – the assessment of the balance-related items using the historical cost and the current (utility) value generates an underrating risk of the assets and expenses and an overrating risk of the equity, debt and income related items.

c. The delimitation in time of the revenues and expenses - this type of activity creates the possibility of a false recognition of the above-mentioned elements in a period of time in which should not have been recognised, thus there is a risk of assessing and presenting the results of the entity that do not reflect a loyal image.

d. The impact of inflation on the accounting activities – the inflationist risk may influence the decrease of the purchasing power, which is reflected in the entity's purchase of goods and services.

2) The principle of accounting methods consistency and of assessment in accountancy

It consists of applying the rules and procedures related to the accounting and accurate assessment of the balance sheet items. By applying this principle a fair presentation of the financial position is ensured, as well as the comparability in time of the financial information. Non-compliance or misinterpretation of this principle generates an assessment risk, namely the situation in which the financial statements users are affected due to non-compliance with the comparability criterion which results in an assessment that affects their decisions.

3) The principle of prudence

It aims at the correct assessment of the assets, equity, debts, income and expenses in order to avoid overrating or underrating of the result. According to this principle, the overrating of the assets and income, respectively the underrating of the debts and expenses are not allowed by taking into account the devaluations, losses and possible risks generated by the activity of the current year or previous year. Thus, the risk of transfer of uncertainties in the future years will be avoided. The non-compliance with the principle or its circumvention leads to a distorted image of the financial position as well as to presenting an image of the entity's performance non-compliant with the reality.

4) The principle of the year independence

The principle implies that transactions and other events are taken into account only when they have occurred and not when payment or collection of funds is due. According to the regulations in Romania, this principle aims at delimiting in time the income and expenditure relating to the financial year for which the report is made, without taking into consideration the date of receipt of the payments. The consequence of applying this principle is that the income will be affected in the year in which they were incurred, respectively their registration upon acquisition, as well as registration of costs as they are being incurred.

The risk of not applying this principle is the presentation of a higher or lower performance in the annual financial statements depending on the registration or non-registration of income and expenses in

accounting. Tracking certain documents (invoices from suppliers, respectively invoices from customers) via certain non-accounting tools (cash flow) reduces the risk of non-payment.

5) The principle of separate assessment of assets and debts

According to this principle, it is necessary to assess separately the assets and the debts. Non-compliance with this principle generates the risk of an erroneous assessment of the financial statements components, which affects the entity's financial position and financial performance.

6) The principle of intangibility

It refers to the fact that the opening balance sheet for each financial year must correspond to the closing balance of the previous financial year. Non-compliance with this principle entails the loss of all qualitative characteristics of the information drawn from the financial statements. It also automatically leads to the non-compliance with the other accounting principles.

7) The principle of non-compensation

According to this principle, the compensation between the assets and debts or between items of income and expenses is not allowed. Therefore, all the claims and debts must be recorded separately in the accounts based on evidence. Nonetheless, any offset between claims and debts to the same entity can be registered only after accounting of the revenue and appropriate expenditures and by compliance with the regulations in force. Non-compliance with this principle leads to a wrong image of the entity's financial image and performance. In this case, the calculation of any performance indicators is questionable in terms of relevance of the results.

8) The principle of prevalence of the economic aspect over the legal aspect

It argues that the presentation of the values of the balance sheet and profit and loss account components is made by taking into account the economic substance of the transaction made, not only their legal form. The misinterpretation of this principle leads to an inaccurate presentation as compared to the economic reality of an entity's rights and obligations within the financial statements.

9) The principle of the significance threshold

It requires that the financial statements present all the information whose importance

may affect the external users' decisions. The risk of non-compliance with this principle may generate unnecessary costs, which also affects the entity's financial performance.

Risk management strategies resulting from the faulty application of the accounting principles:

- regular training of the staff from the financial-accounting department concerning the accounting principles provided for by law and any possible amendments;
- perfect compliance with the general accounting principles as they are stipulated and detailed by the legislation in force;
- their updating once with the modification of the law;
- the chief of the financial-accounting department must follow the compliance with the accounting principles in the financial-accounting activity and to intervene when deviations from it are noticed.

3. Conclusions:

The economic crisis creates a multitude of threats on the activities performed by an entity. In this context, it is necessary to identify the threats and to suggest measures to limit them so that the entity can perform a

culture that embraces risk and to perceive it at corporate level. The proper management of accounting risks aims at a true and fair image of the entity and the measures on the proper management contribute to rendering efficient the operations performed.

Abstract

In the context of globalization, the problem of the Foreign Direct Investments (FDI) and their influence upon modernizing the emergent economies had been some crucial concepts and facts within the major preoccupation of economists. FDI, through their core elements, assure economic development and prosperity, the necessity of tracking them and an efficient usage deriving from the need of integration and fulfillment of puzzling the national economies in the world wide economy. Regarding Romania, due to the high level of the FDI which had been accomplished by the foreign investors on the local market, the Romanian economy is much more exposed to the international financial market turbulences, because it is dependent vis – á – vis of western economies and influenced by the decision taken in the far side of the world.

Cuvinte cheie: foreign direct investments, trade balance, economic growth, inflation.

Clasificare J.E.L.: G12, F16, F21.

1. Introduction

Foreign Direct Investments (FDI) represents a way of development and not to consumption. However, FDI are often hijacked throughout engaging in balancing the payment balance affected by the imports increases in the situations in which the exports don't increase accordingly. This fact is resulting from the first years of transition in Hungary, or from the last years in Bulgaria

and Romania. Tracking FDI for facing the financial restrictions impose by the payment balance disequilibrium is not a strong argument in the condition in which tracking foreign capital can affect current account equilibrium.

FDI must constitute an instrument among others being at governments' disposal for attaining some concrete objectives, subordinated to the general objective, surviving and making functional the national economies in the frame of a European unique market.

On the other side of the economy, there is a very important and crucial factor that refers to the influx of FDI for the implementation and diffusion on the proper manner in order to organize the whole environment with the positive factors of growth and competitiveness in the emerging economies [1].

The trends remarked above have been reinforced by the liberalization of the new markets especially in the service sectors, the reduction of the capital movement restrains, and the creation of a friendly environment for FDI in a growing number of countries [2].

FDI is often seen as a major source of financing for emerging markets in recent years. It is certainly true that FDI provides very important financing for such countries, but the actual financing may be different from how it is portrayed [3].

As a consequence of globalization upon the relationships between territories, the territorial competition in terms of investments must not be ignored, because this fact is leading to a clearly image upon international investment market.

2. Assessing the Foreign Direct Investments and their importance

FDI, financial markets, banking system, and in general financial system are complementary elements in the implementation and dispersion process of gathering new technologies as a base for improving economic growth. The well functioning of the financial mechanism as a way of developing monetary and financial streams from the economy throughout objective interdependence with the real flows compete or inhibit the economy development process [4], [5].

The conclusion reached after several years of studies dealing with the relationship between FDI and economic development is that the effects of FDI are quite complex. From a macro perspective they are often regarded as generators of employment, high productivity, competitiveness and technology spillovers. Especially for the least developing countries FDI means higher exports, access to international markets and currencies, being an important source of financing, substituting bank loans [6], [7].

One of the advantages of integration is the increased openness of the economy to the outer world with beneficial effects on the flow received direct foreign investments, bilateral flows of workforce, productivity, etc. Within this context the Romanian economy draw higher inflows of foreign direct investments which will accelerate, by driving effects, the process of European integration [8].

FDI must be encouraged in countries with lack of natural resources or in the places in which the active offer being subject to privatization has been considerable diminished. Instead, it must be avoided the creation of an economy dominated by foreign enterprises, while national enterprises don't have the capacity of self financing the dynamical growth. For the increasing of the gross capital formation and being able to internalize transfers from the foreign investors, it must be imposed the development of the financial sector. The promotion policies of FDI must not be transformed in a substitute for developing of the internal investments potential.

3. Evidence of Foreign Direct Investments and their correlation upon the exterior commerce in Romania

Romania's position regarding the FDI was very lax in comparison with some other emerging countries and in comparison with expectations, being the second large country from Central and Eastern Europe after Poland. FDI had attained a maximum level of 9 % of GDP in the aftermath of the 2006, following Poland, Hungary and Czech Republic. Beyond the sharp decreasing of the FDI in the last three years (according to the figure no. 1), these have represented only 9% of GDP in 2006 (the biggest number until now); their impact upon economic growth must be considered limited, especially after the 2006s'.

Figure 1. Foreign Direct Investments in Romania in 2002 – 2011 period

Source: Author's elaboration based of IMF and UNECE databases

The reason for the Romania pitfall regarding attraction of the FDI are enriched in a several factor list [9], [10]. Certainly, within the most important factors were the lower privatization rhythms.

After we have shown previously [9], [11], the inflow of the FDI in Central and Eastern European Countries and especially in Romania was tied to the privatization

processes.

Romania has started the privatization measures in 1997, fulfilling only minor transactions until then. Consequently, FDI were beneath 2 % of GDP in the 1990 – 1996 periods.

Another threat for the Romanian economy is the damaging of the commercial balance and the *slow motion* exports in the context of the Euro Zone recession beginning. Amid to reducing the country rating and eventually necessity of adopting the restrictive fiscal policy, the evolution of the exchange rate will have to suffer. According to our opinion, the forecasts regarding the reduction until 40% of the current account deficits throughout FDI are true, than it appears the risk of diminishing the foreign reserves.

Amid to these appreciations, the projections from the banking system indicates that in the late December 2012 and in the early January 2013 the Euro – Ron will be over 4,6.

Figure 2. The correlation between exports and FDI in Romania in 2002 – 2011 period

Source: Author’s elaboration based of IMF and UNECE databases.

Analyzing the evolution on the inward FDI flows in Romania corresponding to the evolution of the last years export, we can observe some interesting sights. Similar to the previous views, we can’t observe a significant statistical relationship between the two time series (figure 2). FDI were almost triple in 2004 in comparison with the last three years, although exports don’t follow the ascending trend, being at first constant, and decreasing significantly in 2009 and being rebounded in 2011.

FDI had tripled in 2006 over 2002, but again, the exports don’t increased accordingly, being in line with precedent years. The growing rate on export has decreased significantly in 2009, in compliance with the decrease registered by the FDI.

These findings lead to the conclusion that from the statistical point of view the connection between exports and FDI cannot be sustained in the Romanian economy. This fact is true and if we consider that in general the percentage of the foreign associates in the manufacturing export was very low in comparison with Hungary and Poland (33,4% in 1999 in comparison with 88,8% in Hungary and 59,8% in Poland) [3].

Moreover, the influence of FDI regarding the Romanian export competitiveness can be founded in a quantitative manner. Many Romanian industrial sectors had been labeled as inefficient, with outdated technology, and a doomed quality per price product ratio. Regarding the companies, they had been a missing a know-how regarding international marketing. Therefore, FDI have become essential, because they have induced technology, management knowledge, increased productivity and the capability of accessing new markets due to the new logistical controls. Likewise, FDI had helped many enterprises in avoiding insolvency and continuing the ongoing exports.

The question raised by our findings is if the sectors which disposed the most FDI had strengthened in time the Romanian comparative advantage, because industry is dominating for the products and goods export.

According to some authors, the most important sectors (metallurgy, fuel and miner, alimentary and automobile one), sectors which that have encompass the vats

majority quantity of FDI and with the most foreign penetration explains the fact that the lowest presence of the FDI in wood, textile and footwear industry, (sectors privileged in Romania) is overrun by a large scale practices used by subcontracting intermediaries [12].

Figure 3 presents the correlation between FDI and export performances in Romania during the last ten years. As we can see, the export performances register a pitfall at the end of 2007 and a revival in the 2009. Starting from 2010 the evolution of these two indicators has been similarly.

Figure 3. The correlation between FDI and export performances in Romania in 2002 – 2011 period

Source: Author’s elaboration based of IMF and UNECE databases.

Some other clues regarding the relationship between FDI and exports are those offered by the ranking of the biggest companies in Romania and the exporting companies. Companies that are part of oil industry register a high increase lately due to the increasing oil prices. Some other major export actors are from the steel, automobile, electric and chemical industries.

In the process of investigating the nature of these companies we can observe that the most Romanian companies are owned by

foreigners. At first sight, we can track some delusive conclusions, namely that foreign owners had been playing a major role in supporting exports. Instead, a large part of Romanian biggest companies are oriented over the internal market, namely: Metro (German chain cash – and – carry), Romtelecom (phone operator, nowadays Greek property) and Orange (mobile phone operator, under the French control).

Even the biggest companies from Romania, Petrom oil company (soled in 2004 to OMW Austria) and steel company Sidex (bought in 2001 by the Ispat giant), and lately Mittal Steel which are in the top of the exports have failed in the hands of the foreign owners. These have been the first exporters even before the situation in which FDI have become attractive in Romania. A similar situation can be identified with the Petrom Refinery (the former Petromidia refinery) and other three companies being in the first exporters.

Figure 4. The correlation between FDI and Total trade in Romania in 2002 – 2011 period

Source: Author’s elaboration based of IMF and UNECE databases.

Beyond Solectum (American electronic industry company) and Draexlmaier (German company from the automobile industry) both companies started from the ground zero,

cases in which the companies don't existed before the appearance of FDI, an example in which FDI had played an important role for the export orientation of the Dacia Automobile.

The national automobile constructor bought in 1999 by Renault doesn't exported almost nothing before the privatization and starting form the Logan model of the Renault company al the end of 2004, export have increased rapidly.

Figure 4 presents the relationship between the inflow of the FDI and the total trade. As we can see, there is no significant correlation between these two variables, although they register some similar trends.

4. Conclusions

The efforts for tracking FDI must be oriented upon those investments which will encompass economic growth.

In the next period, Romania can consolidate its' role in strengthened a large variety of multinational companies which operate in the Romanian market, the regional pole position being conferred not only due to it's geopolitical size, but also due to the border position of the European Union with vast possibilities beyond Caucasus region, Central Asia, Balkans, Turkey.

I the 2008 – 2012 period, Romania still has a need in strengthened it's FDI, because their represent a safe source for the economic growth, and on the other hand, the device for the Know-how transfer: technologies, procedures and processes, structures and organizational cultures and some new mentalities. Consequently, FDI represents the main source for the clearing of the current account deficit.

Effectiveness of Various Types of Analysis in Investment Decisions on the Stock Market: Fundamental Analysis and Technical Analysis

crissgiovanni@yahoo.com

Abstract

The investor interested in efficient capital market investments should make an analysis of quoted shares to meet a series of questions: what to buy?, when to buy? and when to sell?. Such analysis can be done in two directions: technical and fundamental analysis. One of the elements to be considered in the fundamental analysis is the accounting information provided by the company's periodic reports (balance sheet, profit and loss account, etc.) and the evolution of the results and economic and financial indicators of the company. This article wants to determine whether technical or fundamental analysis is more efficient and what is the role and place of accounting information in making investment decisions.

Keywords: accounting information, technical analysis, fundamental analysis, accounting, capital market

JEL Classification: M41 Accounting

1. Introduction

Placing disposables on the stock market cannot be done „by ear” but must be based on a careful analysis of company's activity and market in general. The decision to purchase shares should not be taken at random.

Technical analysis is the process of studying the history of securities in an effort to determine the likely future courses. The specialists in technical analysis assume that the forces of supply and demand are reflected in traded securities prices and volumes. By examining these structures, they can make

predictions about the meaning and value of future evolutions of securities courses. In a more simplistic accept, technical analysis is:

- The study of quotes generated by the market, under a graphic form, in order to predict future price movements, based on indicators or graphic formats;
- The analysis of probability of the market movement (price) in a certain direction, using the previous values recorded of the price.

In the narrower sense of technical analysis, it is considered that the price fluctuations reflect forces and influences both rational and emotional. Price movements, whatever the factors causing them are, once published, will persist over another period of time and thus can be detected [1].

Technician's work is oriented in two directions: to identify the trend and to determine the end of it, moment when prices start to move in the opposite direction.

2. Technical analysis versus fundamental analysis

By using pressure indicators, specialists in technical analysis collect information about the evolution of the entire market by the following three types of signals [2]:

- indicators that show what kind of investors buy and sell shares;
- indicators that assess the market activity;
- indicators that reveal the psychology of individuals.

The second type of analysis, the fundamental one [3], is used by capital market players, who, in order to earn benefits, invest in medium and long term actions, at least one year. Fundamental

analysis consists in selection of potential securities to invest in, based on information about company's financial statements, field in which it operates and its position on the market [4].

At the same time, fundamental analysis seeks to determine a theoretical course of actions, namely to determine whether securities are overvalued, undervalued or fairly valued. Information necessary for the analysis are obtained from company's financial reports and based on them it may be developed forecasts on future income flows, dividends and market prices. Finally, the results are correlated with the influences that national and international political and economic environment have on the company.

Fundamental analysis serves to answer questions, such as:

- Is the company's revenue growing?
- Is it actually making a profit?
- Is it in a strong-enough position to beat out its competitors in the future?
- Is it able to repay its debts?
- Is management trying to “cook the books”?

It should be considered the following issues that through a combined use can make investment decision to be made effective [3]:

- latest news and information related to the issuing company can influence the course;
- company's shareholding;
- evolution of economic sector the issuing company is part of and the financial and economic environment as a whole. Macroeconomic indicators that may provide information about a country at a particular period are: gross domestic product, inflation, interest rate, exchange rate, fiscal policy, political environment;
- analysis of the company's periodic reports (balance sheet, profit and loss account, etc.) and evolution of the company's results and financial indicators.

Technical analysis and fundamental analysis are the two main schools of thought in the financial markets [6]. As we've mentioned, technical analysis looks at the price movement of a security and uses this data to predict its future price movements. Fundamental analysis, on the other hand, looks at economic factors, known as fundamentals.

During July-August 2010 were carried out researches on the capital market in Romania in order to determine whether technical or fundamental analysis is more efficient, and what is the role and place of accounting information in making investment decisions. The case study has resulted in the issuing and sending by e-mail questionnaires to complete by various capital market players in Romania. In this paper we will refer only to one of the questions that make up the questionnaire, question that is strictly related to the object of research in this paper.

According to the results of the research conducted, 68% of the respondents consider most appropriate the use of fundamental analysis to make investment decisions on the capital market to the detriment of technical analysis. In general, fundamental analysis is more used in making investment decisions on medium and long term.

3. Advantages and disadvantages of fundamental analysis

The greatest benefit derived from study of fundamental analysis is the ability to understand the causes that drive the market action. By understanding market dynamics, we can be confident in maintaining a position as long as the cause that triggered the trade exists [4]. A thorough grasp of fundamental analysis also ensures that we do not lose our composure in the face of market volatility. Those who employ fundamental studies in gauging the price action are confident that they are on the tracks of the greatest geniuses of forex trading [2]. All those who successfully made millions or billions in this business were users of fundamental analysis; and there is no reason to doubt that if we were to use the same methods we can achieve the similar, if not the same results with them. Other advantages are [6]:

- Allow identifying the factors that influence action price evolution;
- The relationship between factors and price can be established with mathematical and statistical methods;
- The analysis results are used by brokers and agents investors less confident in their abilities.

Among the disadvantages of fundamental analysis we can include:

- Requires a lot of work because the data must be representative;
- Indicates the general trend of stock prices because it takes into account data from issuers for long periods and the market change frequently;
- The results can be used for long term by investors having a significant capital.

4. Advantages and disadvantages of technical analysis

Technical analysis is simple and straightforward, with tools available to everyone from the seasoned hedge fund manager, to the novice retail trader. In addition, technical tools are easier to interpret than fundamental indicators, the understanding of which usually requires a period of diligent study [1]. Finally, since technical analysis focuses on the price action exclusively, the technical trader has only one needle in his compass: the price, on which any calculation about profits or losses must be based.

Technical studies have been refined and perfected over the years, and by using them we are making use of the heritage of thousands of experienced and knowledgeable traders who have contributed to the effort. By mastering the various aspects of technical trading, we can also minimize the role of guesswork and conjectures in analyzing the price action. While technical studies can give conflicting signals about the future, the error, if any, is on the part of the interpreter. By recognizing our flaws, we can better our analytical skills, and with better skills, wealth and success will be just a single blink away. Other advantages of technical analysis are:

- Share prices of the underlying graphs are easily obtained (in the press, the Internet);
- Indicators can be calculated using simple software;
- The methods and tools used for actions can be also applied to other types of securities;
- Allow the identification of the purchase or sale;
- Allow the identification of the future behavior of stock prices;
- The results are used by sophisticated investors and stockbrokers.

Among the disadvantages of technical analysis we can include:

- Requires constant observation of the market;
- Purchase or sales signals given by technicians may coincide with ones of the market and the analysis may not reach its goal.

5. Accounting Information as a main part of fundamental analysis

Specifically, fundamental analysis refers to the comparative study of some financial indicators of the issuing company. These economic and financial indicators are calculated based on information provided by financial and accounting statements of the company, balance sheet, profit and loss account etc. In addition, it should be taken into account in the calculation of some of these indicators also the market price of securities, reflecting investors' interest for that instrument, which is formed by confronting the demand and supply [7]. This way it is calculated a theoretical course of securities, being called accounting value that is comparable to the market value. From this comparison results if the securities are overvalued or undervalued, this being the first step for investors in adopting the correct decision

In Romania, concerning the analysis of periodic reports if the companies, since 2009, by Order no. 3055/2009 (art. 3, paragraph 1) [9] regarding the approval of accounting rules in accordance with European directives, legal entities which at the balance sheet date exceed the limit of two of the following three criteria, named forward size criteria:

- total assets: 3.65 million Euros;
- net turnover: 7.3 million Euros;
- average number of employees during the financial year: 50.

In these enterprises, accounting information are provided by the annual financial statements comprising [5]:

- balance sheet;
- profit and loss account;
- statement of changes in equity;
- cash flow statement;
- explanatory notes to the annual financial statements.

Article 6 of this Order mentions that companies whose securities are admitted on a regulated market, as defined by current legislation on capital markets, prepare annual financial statements with five components, as they are referred to in article 3 - paragraph (1), regardless of total assets, net turnover or number of employees [9].

The four principal qualitative characteristics of accounting information are intelligibility, relevance, reliability and comparability [9].

- *Intelligibility.* An essential quality of information provided by financial statements is that they should be easily understood by users. To this end, it is assumed that users have sufficient knowledge of business and economic activities, the accounting concepts and their desire to study the information with due attention. However, information on complex problems that should be included in financial statements because of their relevance in making economic decisions should not be excluded solely on the ground that might be too difficult to understand for some users.
- *Relevance.* To be useful, information must be relevant to decisions by users. Information is relevant when influence economic decisions of users, and helping them to evaluate past events, present or future, to confirm or correct their previous evaluations. Information relevance is influenced by nature and materiality. In some cases, the nature of the information is sufficient by itself to determine its relevance. In other cases, both the nature and materiality are important.
- *Reliability.* To be useful, information must also be credible. Information is credible when it does not contain significant errors, not biased, and users can be confident that what is right, and wanted to represent what is expected or reasonably to represent. To be credible, the information must represent faithfully the transactions and other events and it is proposed to represent them or are expected, reasonably, to represent them. For present credible information on events and transactions which aims to represent them, they need to be recorded and presented in accordance with their substance and economic reality, and not

just their legal form [10]. To be credible, the information in financial statements must be complete. An omission can cause information to be false or misleading and thus have no credible character and become deficient in terms of relevancy.

- *Comparability.* Users must be able to compare financial statements of an entity over time to identify trends in its financial position and performance. Users must be able to compare financial statements of different entities to evaluate their financial position and performance. Thus, measuring and presenting financial effect of the same transactions and events should be performed in a consistent manner within an entity and the time for that entity and in a consistent manner for different entities.

When we think to invest in an enterprise is necessary to make an overview of its situation, past performance and its future prospects [4]. This will depend, in large part, on the evolution of stock prices and/or on dividends related to the investors, the two basic sources of income expected from any action.

For this purpose, instead of carefully examine each balance sheet account balances, it can be use a set of indicators that transform the information arising from the financial statements of companies in order to facilitate their interpretation [10].

There is no limited set of indicators; they may be constructed depending on variables that need to be taken into account [8]. However, it is necessary to take certain precautions when carrying out such an analysis. First, not all indicators should be considered separately but on the contrary, it should be considered as a set of indicators for an overall assessment of each company situation.

Explanatory Note 9 for balance 12/31/2009 presents a group of indicators that can give information about the company as follows:

1. *Liquidity Ratios:*

- a) the current liquidity ratio

$$\frac{\text{Current assets}}{\text{Current liabilities}}$$

Current liabilities

- recommended acceptable value - at around 2;

- provides guarantee to cover current debt from current assets.

b) immediate liquidity indicator

$$\frac{\text{Current assets stock}}{\text{Current liabilities}}$$

2. Risk indicators

a) indebtedness indicator:

$$\frac{\text{borrowed capital}}{\text{equity}} \times 100$$

$$\frac{\text{borrowed capital}}{\text{employed capital}} \times 100$$

where:

borrowed capital=loans over a year

employed capital= borrowed capital+ equity

b) interest coverage indicator- determines how many times an entity may pay interest costs. The indicator value is lower, the entity is considered more risky position.

$$\frac{\text{profit before interest and tax payments}}{\text{interest expenses}}$$

3. Indicators of activity (management indicators) - provides information on:

- Speed entry and exit of cash flows of the entity;
- Entity's ability to control working capital and basic business activities of the entity;
- Rotational speed of stock (inventory turns) - approximate number of times the stock has been run throughout the year.

$$\frac{\text{sales cost}}{\text{average stock}}$$

- Number of storage days - indicate the number of days in which goods are stored in the unit

$$\frac{\text{average stock}}{\text{sales cost}} \times 365$$

- Rotational speed of flow – customers: calculate effectiveness entity in its debt collection; expresses the number of days until the date on which the debtors pay their debts to the entity. A rising value of the indicator may indicate problems with credit monitoring to customers and therefore more difficult receivable claims (bad customers payers) [8].

$$\frac{\text{average balance customers}}{\text{turnover}} \times 365$$

- Rotational speed of credit - provider: approximate number of days that the entity obtains credit from its suppliers. Ideally, should include only commercial lenders.

$$\frac{\text{average balance providers}}{\text{acquisition of goods (without service)}} \times 365$$

And to approximate purchases can be used cost of sales or turnover.

- Rotational speed of fixed assets [11]: assessing management effectiveness of fixed assets by examining the value of turnover generated by a certain amount of fixed assets.

$$\frac{\text{turnover}}{\text{assets}}$$

-rotation of the total assets:

$$\frac{\text{turnover}}{\text{total assets}}$$

4. Indicators of profitability

a) return on capital employed - means profits entity get from the money invested in the business:

$$\frac{\text{profit before interest and income tax payments}}{\text{employed capital}}$$

b) gross margin on sales:

$$\frac{\text{gross profit from sales}}{\text{turnover}}$$

The analysis of accounting information provided by the company's financial statements can be made by applying certain techniques or analysis tools. Internal users of accounting information have access to all company information, financial statements being analyzed under a more detailed and concise form. The analysis of accounting information pretends the following objectives [2]:

- knowledge of economical and financial situation of the enterprise;
- determining the causes which led to the current situation;
- determining the possible lines of action in case of a possible imbalance;
- forecast the future evolution of the company.

6. Conclusion

In fact, the optimal solution is to combine technical analysis with fundamental analysis

on short term. Although technical analysis and fundamental analysis are seen by many as polar opposites - the oil and water of investing - many market participants have experienced great success by combining the two. Nicholas Darvas in his book “How I Made \$2,000,000 In The Stock Market”, described how he selected winning stocks by combining technical analysis with the fundamental analysis of the companies. In conclusion, neither fundamental analysis nor technical analysis is more good for investments decision than the other. Both have their merits and should be used at the right times. If you are investing for a long-term, the fundamental analysis should play a more important role in determining the type of industry and company you choose. The technical analysis should play a more important role when deciding the entry and exit points of an investment. If you are a speculator, then all you are concerned with is the short-term, hence the technical charts.

As we have seen, 68% of the investors consider most appropriate the use of fundamental analysis to make investment decisions on the capital market to the detriment of technical analysis. When we talk about the fundamental analysis, performance of an investment is related to the quality of accounting and financial information reflects the reality of a transaction or transactions of securities. Current and potential investors are constantly evaluating publicly traded companies in order to make the best decisions that bring them benefits and to satisfy their present and future interests. Investment decision can be made on the following analysis of the capital market but also in terms of financial analysis based on accounting information [7]. Knowledge and use of accounting information relevant to the enterprise is the fundamental raw material in making all management decisions and investment in capital markets. Users of accounting information act, operate and make decisions constantly, using and understanding accounting information provided by financial statements. Account information may be the best friend of current and potential investor if is used and understood properly.

Social Protection Public Expenditures and Income Inequality

Enache Cosmin
West University of Timisoara
Faculty of Economics and Business Administration
cosmin.enache@feaa.uvt.ro

Abstract

For a sample of 29 European countries, the efficiency of social protection public expenditures in providing income support and diminishing income inequality is assessed in a panel framework. An increase in the size of the government intervention through social protection public expenditure is found to be associated with a decrease in income inequality. Also, we found evidence of the Kuznets effect. Not least, the results pointed out that a lower income inequality could be found in economies with high levels of employment, high tertiary education achievement, low levels of corruption and low levels of old age dependency ratio.

Keywords: Social Protection Public Expenditures, Income Inequality.

J.E.L. Codes: H53, D31, C33

1. Introduction

Income inequality is a major topic in economic research and a target of various policy measures. This widely shared interest come from both economic and social consequences of income inequality.

As pointed out first by Kuznets [17], it seems that between income inequality and economic growth there is an inverse U-shape relationship. The influential empirical works of Barro ([4], [5]) pointed out that increasing inequality is associated with lower growth rates in poor countries, while in rich countries is associated with higher growth rate.

Apart from its effects on macroeconomic performances, income inequality hinders prosperity, slows down the establishment of good quality institutions and limits the access to higher education [9].

Given these economic and social

consequences of income inequality, often government authorities assume the objective of flattening the distribution of income within the society through the implementation of various redistributive policies. For instance, the use of progressive taxation in combination with generous social security spending could contribute to reductions in income inequality.

This paper is concerned with the estimation of social security public expenditure impact on income inequality, taking into account various other economic, social and institutional determinants as well. The focus here is on size of the government intervention through social security spending, given the fact that at individual level what matters is the overall amount of social benefits received and not their type.

The rest of the paper is organized as follows. In the next section, a literature review on income inequality determinants is provided. Section 3 presents the data, the empirical model and the methodology used and also a brief discussion of the obtained results. Section 4 concludes.

2. Literature review

There is a vast literature on income inequality determinants, which include economic, social and institutional factors as well.

The seminal paper of Kuznets [17] highlighted a U-shape relation between the level of economic development and income inequality. At empirical level, this relation was confirmed in Barro ([4], [5]). However, this finding has been challenged on both theoretical and empirical grounds. For instance, Robinson [23] using a simple theoretical model pointed out that in a developing economy, without any targeted policies, the income inequality will remain stable or will increase in the long-run. Some

empirical analyses (see [3]) highlighted that the quadratic relationship between economic development and income inequality holds only when in the model are included some restrictions which are not supported by the empirical data.

Another strand of literature pointed out that labour market could play a role in explaining income inequality. The effects of unemployment on income inequality were usually studied in a framework of analysis provided in Blinder and Esaki [7]. For instance, Gustafsson and Palmer (see [12]) found that unemployment affects negatively the distribution of income. Decomposing unemployment in structural and cyclical components, Mocan (see [21]) found that only structural unemployment has a negative impact on income inequality. Labour demand orientation toward higher skill intensity could also affect income distribution [1]. Other characteristics of the labour market were found to be connected with income inequality as well, such as the percentage of the labour force in agriculture and union density [2] and labour market regulations [16].

The level of financial development seems to affect income inequality in a non-linear manner. Greenwood and Jovanovic (see [11]) suggested that in the first stages of economic development financial development will widen the income gap between the rich and the poor, and in the latter ones it will reduce income inequality. The beneficial impact of financial development on the income of the poor was also highlighted in Beck, Demirguc-Kunt and Levine (see [6]).

Education also plays a role in shaping the distribution of income. Knight and Sabot (see [15]) emphasized that the overall effect of education on income inequality will result after balancing two contrary effects, the “composition” effect and the “wage compression” effect. An increase in the group within the society with a higher education level will trigger on the one hand an initial increase and a later decrease in income inequality – the “composition” effect and on the other hand, an increase in the better skilled labour supply and a subsequent decrease in the education premium embodied in the wages which will reduce income inequality – the “wage compression” effect. At the empirical level, De Gregorio and Lee (see [8]) confirmed a significant but small

negative effect of education level on income inequality and also highlighted the distributional effects of education inequality.

Given that income redistribution is often an objective assumed and pursued by governments, one could expect that public intervention in this matter to have a significant impact on income inequality. In line with these theoretical assumptions, Milanovic (see [19]) found that the size of the public sector and the social security public expenditures are negatively related with income inequality. However, using a sample of African countries, Odedokun and Round (see [22]) found that only social security spending is reducing income inequality, while the overall size of the public sector has an opposite effect.

The impact of demography on the distribution of income was studied in various empirical works (see for instance [14] for the case of United Kingdom and [12] for the case of Sweden). However, the empirical results were inconclusive. Nonetheless, one would expect that increasing dependency rates to increase income inequality, given the fact that the income of the dependent persons tends to be lower than the income of working persons.

Not least, there are some social and political determinants of income inequality. Corruption was found to affect income distribution in an inverted U-shaped way and to provide a good explanation for a large proportion of the income inequality differential across a sample of 47 developing and industrial countries [18]. Also, increased corruption was found to be positively correlated with income inequality in a panel of 21 African countries [13]. Democratization was found to be a significant determinant of decreasing income inequality only in Judeo-Christian societies, while in Muslim and Confucian societies this effect is insignificant [20].

3. Data, Methodology and Results

The empirical sample consisted in 29 European countries (Belgium, Bulgaria, Czech Republic, Denmark, Germany, Estonia, Ireland, Greece, Spain, France, Italy, Cyprus, Latvia, Lithuania, Luxembourg, Hungary, Malta, Netherlands, Austria, Poland, Portugal, Romania, Slovenia,

Slovakia, Finland, Sweden, United Kingdom, Iceland and Norway). Data used for all the variables of the empirical model ranged from 2005 to 2010. The data source was Eurostat statistical database.

In our empirical model we used as a measure of income inequality the Gini Index (GINI). The index is scaled between 0 (perfect income equality) and 100 (maximum income inequality). Thus, an increase in the index value is reflecting an increase in the income inequality. Conversely, a decrease of the index points out to a reduction in income inequality.

Seeking to highlight the effect on income inequality of government intervention through social security system, we used as the independent variable of interest the social protection public expenditures (SPPE) expressed as a percentage of gross domestic product. Social protection public expenditure were defined according to European Commission (see [10]) as all benefits publicly provided to households or individuals in order to ease the burden of various risks and needs related to sickness/healthcare, disability, old age, survivors, family/children, unemployment, housing and social exclusion. We used in our empirical model the overall social protection public expenditures as independent variable, given the fact that for households or individuals is the total amount of social benefits that they value, and not the specific type of the respective social benefits.

A set of control variables derived from the appropriate literature was used as well. To account for economic factors which influence income distribution between individuals, we used as independent variables the gross domestic product per capita (GDPPC) expressed in euro per inhabitant (as a proxy for the level of development) and the employment rate (ER) (as a proxy for economic conditions in the labour market). In order to check for the Kuznets hypothesis a squared term of gross domestic product per capita was used in the empirical specification.

Also, some social determinants of income distribution highlighted in the literature were used as well. In this field, our choice was to use as control variables some measures of education and corruption. To proxy the education level, we used tertiary education

achievement (TEA), indicator defined as the share of the population aged 30-34 years who have successfully completed university or university-like education with an education level ISCED 1997 of 5-6. To proxy the corruption level within the society, we used the Corruption Perception Index (CPI) developed by Transparency International which ranges from 0 (high level of corruption) to 10 (low level of corruption).

Not least, given the fact that all the countries of the sample experience a demographic transition, we choose to use as control variables the children dependency rate (CDR) the old age dependency rate (OADR).

Given that all variables are percentages, in order to avoid scaling issues, the gross domestic product per capita variable was transformed in natural logarithms.

Descriptive statistics are given in Table 1.

Table 1. Descriptive Statistics

	GINI	SPPE	GDPPC	ER

A model with individual effects was our preferred empirical specification. The general form of the model was the following:

$$\text{GINI}_{it} = \alpha + \beta_1 \text{SPPE}_{it} + \beta_2 \ln \text{GDPPC}_{it} + \beta_3 (\ln \text{GDPPC}_{it})^2 + \beta_4 \text{ER}_{it} + \beta_5 \text{CPI}_{it} + \beta_6 \text{TEA}_{it} + \beta_7 \text{CDR}_{it} + \beta_8 \text{OADR}_{it} + \varepsilon_{it}$$

where:

GINI – Gini Index;

SPPE – social protection public expenditures;

GDPPC – gross domestic product per capita;

ER – employment rate;

CPI – Corruption Perception Index;

TEA – tertiary education achievement;

CDR – children dependency rate;

OADR – old age dependency rate;

$\varepsilon_{it} = \alpha_i + \lambda_t + u_{it}$, where α_i represent the cross section effects, λ_t represent the time effects and u_{it} represent an idiosyncratic error term.

The estimation strategy followed the traditional steps.

First, in order to validate the individual effects and to identify their respective type (fixed or random), a two-way fixed effects OLS estimation was carried out. The results of the estimation are given in column 1 of Table 2.

An F-test for the validity of cross-section fixed effects was employed. The null hypothesis that all $\alpha_i = 0$ could be rejected ($F(28,132)=18.18$, $p\text{-value}=0.0000$). Another F-test for the validity of time effects was used as well. The null hypothesis that all $\lambda_t = 0$ could not be rejected ($F(5,132)=0.76$, $p\text{-value}=0.58$). Given that only cross-section effects are valid we estimated the model without time effects.

Next, the model was estimated using cross-section random effects. The results of the estimation are given in column 2 of Table 2. In order to discriminate between fixed and random effects, a Hausman test was employed. The null hypothesis of the Hausman test is that both estimators are consistent, and the alternative hypothesis is that only the fixed effect estimator is consistent. The high value of the test ($\chi^2(6)=21.61$, $p\text{-value}=0.0057$) led to rejection of the null hypothesis. Thus, the fixed effects estimator should be used.

Finally, the problems of serial correlation and heteroskedasticity were addressed. Durbin-Watson statistic showed evidence of serial correlation in the residuals. In order to

correct these problems, we changed the method of estimation, using Feasible Generalized Least Squares instead of simple OLS. Also, we corrected for potential heteroskedasticity by computing White robust standard errors. The results of the estimation are given in column 3 of Table 2. The value of Durbin-Watson statistic highlighted the absence of serial correlation in the residuals. The low value of Jarque-Bera test could not reject the null hypothesis of residuals normality.

Table 2. Gini Index Estimation

Variable	[1] OLS Fixed Effects	[2] OLS Random Effects	[3] FGLS Fixed Effects
C	-271.6***	-165.6***	-116.6***

(***), (***) and (*) denotes statistical significance at the 1%, 5% and 10% levels, respectively.

^a DW – Durbin-Watson test for serial correlation.

^b JB – Jarque-Bera test for residuals normality.

An increase in the size of the government intervention through social protection public expenditures will lead to a decrease in the Gini Index value, thus lowering income inequality. This result points to the fact that in our sample of European Countries, income redistribution is still an objective pursued by governments through public social security systems.

Our results confirmed the Kuznets hypothesis regarding a U-shaped relation between gross domestic product per capita and income inequality. Thus, in the first and the late stages of economic development, further increases in the level of overall productivity will decrease income inequality. However, in the middle stages of economic

development, further increases in the level of gross domestic product per capital will increase income inequality.

The other economic factor taken into account, the employment rate was found to be negatively and significantly associated with the Gini Index. As expected, an increase in the employment level will lead to a reduction in income inequality.

Also, negative and statistically significant coefficients were estimated for the two social factors included in the empirical model. Increasing percentage of population with tertiary education appears to be an income inequality reduction factor. Also, an increase in the Corruption Perception Index (a decrease in the level of the corruption within the society) is associated with a decrease of the Gini Index (a reduction in income inequality).

Not least, the demographic dynamics were found to have an impact on income inequality. However, it seems that only an increase in the old age dependency rate will trigger an increase of the income inequality. The children dependency rate was found to have an insignificant impact on income inequality.

4. Conclusions

Using traditional panel techniques, our empirical investigation provided evidence regarding the impact of social protection public expenditures on income distribution, but also highlighted other potential determinants of income inequality.

First, social protection public expenditures were found to lower income inequality in our sample of European countries. This result points to the fact that governments are implementing efficient redistributive policies.

Second, our results confirmed the controversial Kuznets effect. In European countries, we found evidence of an inverse U-shaped relation between income level and income inequality.

Third, other significant determinants of income inequality were identified as well. These findings provide useful information for government authorities. Promoting policies aimed at increasing employment, reducing corruption or increasing education achievement will all contribute to significant

reductions in income inequality. Not least, a strong and positive effect on income inequality is given by increasing old age dependency ratio. Apart from putting a continuous pressure on pension systems, the increasing share of old age population has an additional negative effect, raising income inequality.

The Impact of Open Market Variables on FDI. Case of Romania

Ene Sebastian

dan_chilarez@yahoo.com

Abstract

This scientific approach intends to make an impact analysis which, using the quantitative methods, quantifies the effects generated by the elements that constitute open markets (trade freedom, investment freedom and financial freedom) on FDI. Knowing these effects allows to subsequently adopt the specific strategies and to develop multiple scenarios that can make the Romanian economy more attractive for foreign direct investment in terms of sustainability. To highlight the impact of the analyzed elements of FDI we have used specific quantitative analysis and statistical techniques that lead to the quantitative quantification as well as a number of causal explanations designed to better describe the phenomenon.

Keywords: foreign direct investment, determinants, multiple regression equation,
JEL : C53, E66, F21

1. Introduction

Financing the economic activities, the source of funds needed in finance, is an old problem, constant within each economy regardless of level of development, an aspect that is emphasized particularly in crisis situations. The relations and the influence factors regarding the implications of FDI on national economies have been studied since the early '50s, when the transfer of funds from the developed countries to the developing ones began to be accentuated, and transnational companies began to manifest themselves more and more intensely at worldwide level [1].

Many economists have analyzed the development stages of transnational

corporations [2], [3], [4], [5], or the motivations underlying the realization of FDI in a particular economy [5], [6]. They developed trends, theories and schools that define the main issues related to the finance of multinational companies and to the international finance. Presently, more than ever we deal with the problem of analyzing the effects that certain national policies and strategies have on foreign direct investment. It is known that FDI can produce positive or negative effects on the economy [7], the governmental policies, the negotiation of the way in which these financial flows enter or leave a country decisively influences all capital movements. There are countries that negotiate their access conditions, particularly regarding the resources, in a way that generates the maximization of positive effects, while in other countries entering or relocating FDI mostly creates negative effects.

From the analyses and the studies made at global level, an economy differs in attractiveness to another economy through a series of determinants [5], [6]. Numerous financial institutions or foundations analyze the factors which contribute to the attractiveness of an economy. The elements vary from one institution to another according to their importance. For investors, these analyses represent true landmarks in adopting the financial decision.

2. Model and empirical research

The determinants of FDI or the factors influencing these investments are analyzed by category or individually by various organizations. One of the most striking analysis is performed by the Heritage Foundation which calculates that annual index of economic freedom in a country [8]. The analysis uses ten variables that

contribute to the determination of the ranking by country: property rights, freedom from corruption, fiscal freedom, government spending, business freedom, labor freedom, monetary freedom, trade freedom, investment freedom and financial freedom). The last three indicators are part of the category of indicators that evidence the opening of the market in the respective country.

According to the Heritage Foundation, trade freedom expresses: *“trade freedom reflects an economy’s openness to the import of goods and services from around the world and the citizen’s ability to interact freely as buyer or seller in the international marketplace. Trade restrictions can manifest themselves in the form of tariffs, export taxes, trade quotas, or outright trade bans. However, trade restrictions also appear in more subtle ways, particularly in the form of regulatory barriers. The degree to which government hinders the free flow of foreign commerce has a direct bearing on the ability of individuals to pursue their economic goals and maximize their productivity and well-being”*[8].

In terms of investment freedom we must consider that: *“a free and open investment environment provides maximum entrepreneurial opportunities and incentives for expanded economic activity, greater productivity, and job creation. The benefits of such an environment flow not only to the individual companies that take the entrepreneurial risk in expectation of greater return, but also to society as a whole. An effective investment framework will be characterized by transparency and equity, supporting all types of firms rather than just large or strategically important companies, and will encourage rather than discourage innovation and competition”*[8].

Financial freedom implies *“a transparent and open financial system ensures fairness in access to financing and promotes entrepreneurship. An open banking environment encourages competition to provide the most efficient financial intermediation between households and firms and between investors and entrepreneurs”* [8].

Based on these considerations, we can quantify the impact that the open market (trade freedom, investment freedom and financial market) has on foreign direct

investment. In this sense the model is based on a multiple regression equation:

$$Y_t = a_0 + a_1X_{1t} + a_2X_{2t} + \dots + a_kX_{kt} + e_t, t = 1, 2, \dots, n \quad (1)$$

where: a_0 – is the constant value, a_1 - a_k are equation parameters, and x_{1t} - x_{kt} are variables of the function, e_t – standard error.

In this context, the equation becomes:

$$FDI = a_0 + a_1(TF) + a_2(IF) + a_3(FF) + e_t \quad (2)$$

where: TF represents trade freedom; IF – investment freedom, and FF – financial freedom.

The statistical data of these indicators are presented in Table no. 1

Table no.1: Values of the analyzed indicators

Observations	12	12	12	12

Source: data processed by the authors in the software Eviews 7

The statistical analysis outlines a relatively low standard deviation for FDI, their average value being 3.44 units. On the other hand, for the variables that characterize the phenomenon we can observe that the standard deviation is high, which highlights the major differences between the values of the statistical series of the variables. In the case of trade freedom, the deviation is 10.98 units, the variation of investment freedom is 16.71 units, and the variation of financial freedom is 7.78. It should be appreciated that in the last three years the values have increased for the first two variables while in the case of the third variable the values have remained stable. Regarding the analysis of the distribution of the data series we can observe that there is a difference of the deviation in relation to the symmetrical distribution around the average (skewness). So in the case of foreign direct investment and the variable of investment freedom there are positive values indicating a bias to the left with extreme values to the right, while the negative values recorded for trade freedom and financial freedom indicate an inclination to the right with extreme values to the left. The degree of flatness (kurtosis) indicates a platikurtic distribution for foreign direct investment, trade freedom and investment freedom, while for financial freedom the distribution is leptokurtic.

Table no.3. Matrix correlation

	FDI_LOG	TF	IF	FF
FDI_LOG	1.000000	-0.638014	-0.819204	0.246015
TF	-0.638014	1.000000	0.787262	0.126132
IF	-0.819204	0.787262	1.000000	0.151378
FF	0.246015	0.126132	0.151378	1.000000

Source: Source: data processed by the authors in the software Eviews 7

The analysis of the correlations existing between the analyzed phenomenon (FDI) and the variables that characterize it (TF, IF and FF) shows a strong link between FDI and IF, a link of medium intensity between FDI and TF and a weak connection between FDI and FF. In this context, we consider that the influence of the financial freedom variable on FDI is small, while the other two variables

have a greater influence highlighted also by the intensity of correlations.

The regression equation is highlighted below:

$$\text{FDI_LOG} = 0.0003515823731 * \text{TF} - 0.01817489147 * \text{IF} + 0.01668661854 * \text{FF} + 3.696651624 \quad (3)$$

The coefficients of the variables shows how the phenomenon is changed in the situation in which the value of the variables changes with one unit. It appears that for the variables of trade freedom and financial freedom the positive modification with one unit leads to a favorable modification of the phenomenon. It is not the same thing that happens in the case of investment freedom whose favorable change leads to an adverse change of the phenomenon.

R-squared has the value 0.81 (Appendix 1), while adjusted R-squared has the value 0.74, indicating that the variables explain the influence of the phenomenon in 81%, the difference being explained by other factors not included in the model. F-prob is below 5%, so the model is statistically valid.

3. Conclusions

As a result of the conducted research, we have found that FDI is influenced by the conditions generally named open market. The explanatory variables differently affect the phenomenon from a quantitative perspective. Although the correlation analysis shows that there is a correlation between the analyzed phenomenon and trade freedom, the coefficient attached to the variable produces a much smaller change than for financial freedom variable whose intensity of correlation is small but its influence is much greater. The investment freedom variable with which the phenomenon is most highly correlated, presents a negative influence whether the variable is positively changed.

Abstract

Romanian mutual funds industry managed to maintain an increasing trend despite of the dramatically consequences that the current financial crisis had on our weakened capital market..

Mutual funds’ managers have resorted to fundamental adjustments of portfolios’ structures considering the investors’ decreased risk tolerance. The negative evolution of the stock market and the investors’ reduced risk tolerance proved to be simulative factors for the proliferation of money market and bond funds.

The purpose of this paper is to analyze recent evolutions of Romanian mutual funds industry and to assess their risk-adjusted performance.

Key words: mutual funds, risk-adjusted performance, performance evaluation.

J.E.L Classification: G12, G20, G23.

1. Introduction

The current financial crisis deeply affected the Romanian capital market and determined a change in investors tolerance to risk. Yet, the negative evolution of the stock market and the investors’ reduced risk tolerance proved to be simulative factors for the proliferation of mutual funds and especially money market and bond funds. Money funds and bond funds are targeted mainly at prudent investors as an alternative to bank loans. Investors’ loyalty and the attraction of new investors (physical personalities), given that the interest on

fixed-term deposits exceed the profitability of these funds, are two very ambitious objectives.

The following tables present the main indicators of the Romanian Mutual Funds industry over the last four years.

Table 1. Main indicators of Romanian investment funds (2008-2009)

Indicators	2008	2009
Number of investors	90,694	164,446
Number of funds	52	51
Net asset (mil. Lei)	940.70	3,350.35
Net asset growth (%)	8	8
Net asset growth (%)	-1.42%	256.15%
Net assets/investor (Lei)	10,372	20,374

Source: AAF Reports at 31st December of each year

Table 2. Main indicators of Romanian investment funds (2010-2011)

Indicators	2010	2011
Number of investors	221,862	235,973
Number of funds	57	64
Net asset (mil. Lei)	5,488.071	8,000.259
Net asset growth (%)	63.81%	45.78%
Net assets/investor (Lei)	24,736	33,903

Source: AAF Reports at 31st December of each year

In 2008 the total net assets have decreased by almost 4 million Lei (from 954.261 in

2007). Yet in 2009 the increase in net assets is spectacular especially due to the investors' need to protect themselves from the consequences of the financial crisis by investing in money funds. 2010 and 2011 brought an amazing increase for the mutual fund industry.

If at the end of 2007 the proportion of bank deposits/certificates of deposits in the global portfolio equaled 23.61% in average, one year later it almost doubled to 41.28%.

Table 3. Total assets structure

Asset structure %	2008	2009
Cash	4.20%	2.70%
Treasury bills	15.21%	15.30%
Bank deposits/certificates of deposits	41.28%	45.04%
Bonds	24.71%	27.33%
Stocks listed	11.94%	6.70%
Derivatives	0.01%	0.04%
Other assets	2.66%	2.88%

Source: AAF Reports at 31st December of each year

In 2010 the level of stocks reached its minimum for this period of 4 years, with 5.06% in total assets, while treasury bills reached the maximum percentage of 18.97% in total assets.

In 2011 the percentage of bonds in total assets represented 52.61%, the investors becoming more and more interested in these safe securities with quite attractive yields. The percentage in total for the bank deposits decreased to 20.83%.

After a long period of decreasing trends in 2011, in the stocks listed category, it can be observed a small increase, from 5.06% in the previous year to 6.27%, in the current.

Table 4 presents the assets structure during 2010 and 2011.

Table 4. Total assets structure

Asset structure %	2010	2011
Cash	0.72%	1.93%
Treasury bills	.97%	14.68%
Bank deposits/certificates of deposits	27.63%	20.83%
Bonds	44.40%	52.61%
Stocks listed	5.06%	6.27%
Derivatives	0.02%	-0.13%
Other assets	3.20%	3.82%

2. Theoretical approach of risk-adjusted performance measures

The interest for mutual funds performance evaluation has increased during the last decades together with the role played by institutional investors on the financial markets.

Many recent studies have tried to answer the question whether active management adds value to the portfolio. For a „mean-variance” investor the question may be expressed differently: adding stocks to an actively managed mutual fund portfolio will affect the efficient frontier? If the answer is negative than the investor should rather prefer low commissions index funds.

The most elementary performance measure is a fund's return over a certain period. It is a simple and relevant measure for the investors but it fails in identifying the manager's stock-picking ability.

The expected return of a mutual fund is influenced by three factors:

- market performance and other risk factors;
- fund's exposure to risk factors;
- the stock-picking ability of the fund's manager.

In order to detect a mutual fund exposure to risk factors several risk-adjusted performance measures have been developed.

If the market model is an empirical one, the capital asset pricing model shows that at equilibrium the expected return on a financial asset equals the risk-free rate plus a risk premium proportional to the asset's systematic risk.

Portfolio managers try to obtain the highest possible return for a given level of risk. His contribution is evaluated in comparison to a passive investment strategy. Portfolio risk is either estimated by the systematic risk (portfolio's β) or by the total risk (portfolio's standard deviation).

Systematic risk-based portfolio performance measures are based on the CAPM and allow a comparison of portfolios with the same level of systematic risk.

Treynor's ratio (RT) is a return-volatility ratio computed by dividing portfolio return in excess over the risk-free rate to portfolio's

volatility. In a paper published in 1965, Treynor presented this portfolio measure which is based on the CAPM:

$$E(R_p) = R_f + \beta_p(E(R_m) - R_f)$$

where: R_p , portfolio's P return; R_m , market return; R_f , risk-free rate; β_p , portfolio's systematic risk.

$$\frac{\overline{R}_p - \overline{R}_f}{\beta_p} = \frac{\overline{R}_m - \overline{R}_f}{\beta_m}$$

At equilibrium the excess return of a well diversified portfolio per unit of systematic risk should equal the market excess return over the risk-free rate.

$$R_T = \frac{\overline{R}_p - \overline{R}_f}{\beta_p}$$

Sharpe's ratio is a similar performance index constructed in a risk-return approach. It is based on the existent relationship between the expected return of a well diversified portfolio and its risk.

$$E(R_p) = R_f + \frac{\sigma_p(E(R_m) - R_f)}{\sigma_m}$$

If effective return equals in average the expected return, the relation may be rewritten as follows:

$$\frac{\overline{R}_p - \overline{R}_f}{\sigma_p} = \frac{\overline{R}_m - \overline{R}_f}{\sigma_m}$$

It shows that in case of a well diversified portfolio, at equilibrium the risk premium per unit of total risk should equal the risk premium of the market portfolio per unit of systematic risk.

Sharpe's ratio corresponds to the right term of the above relation:

$$RS_p = \frac{\overline{R}_p - \overline{R}_f}{\sigma(R_p)}$$

Jensen's coefficient (J_p) measures the return unexplained by the CAPM. If managers expectations achieve in average the equation of the CAPM may be empirically estimated based on a regression model:

$$R_{p_t} - R_{f_t} = \beta_p(R_{m_t} - R_{f_t}) + \varepsilon_t$$

where all variables are ex-post data and ε_t is the residual variable.

It is possible to identify an inferior or a superior fund performance in comparison to the market portfolio by observing the value of the intercept in the following regression:

$$R_{p_t} - R_{f_t} = \alpha_p + \beta_p (R_{m_t} - R_{f_t}) + \varepsilon_t$$

If managers expectations are averagely achieved, the performance measure proposed by Jensen will verify the equation:

$$\alpha_p = (\bar{R}_p - R_f) - \beta_p (\bar{R}_m - R_f)$$

In order to rank portfolios Jensen’s alpha must be divided to the beta coefficient of each portfolio under comparison.

3. Empirical approach of risk-adjusted performance measures

The objective of mutual funds performance evaluation is to establish if funds managers are able to add value and to adopt the proper investment strategy. Portfolios managers justify their existence if in average they attain superior performance to passive investment strategy. The correct evaluation of mutual funds performance plays an essential part in the efficient functioning of these entities.

Our sample includes Romanian equity and balanced mutual funds which were observed between 2005-2011, mutual funds being long-term investment vehicles. The table below presents the results of traditional performance evaluation measures, the benchmark portfolio being the BET Index:

Table 7. Risk-adjusted performance measures

Mutal fund	RT _p	RS _p	J _p
Active Dinamic	-0.02	-0.11	-0.01
BT clasic	-0.001	-0.005	-0.0001

Source: Authors’ processing

Except for Intercapital and Napoca Romanian mutual funds don’t generate risk-adjusted performance and we wouldn’t expect them to considering the dramatically consequences of the financial crisis which led to negative real rates of return and a terrible bust of the capital market.

4. Conclusions

The Romanian mutual funds industry seems to continue a positive trend and in the same time the process of convergence to other European fund markets in terms of market indicators and market infrastructure. The Romanian market benefits from harmonized regulation to best standards and practices, which stimulate growth. Romanian mutual funds don’t generate risk-adjusted performance and we wouldn’t expect such a result taking into account recent evolutions of our financial market. Yet, Romanian investors’ trust in these investment vehicles is increasing and their perspectives remain promising. There still are sufficient aspects connected to the administration and functioning of these entities, which need to be revised. In the same time it is necessary to harmonize the regulation concerning the process of founding, administration and functioning of collective investment schemes with the European regulation, but without the automatic adoption of rules that don’t synchronize with the present features of the Romanian capital market.

The Influence of Conflicts of Interest on Firm Value

Georgescu Cristina Elena
Ovidius University of Constanta
cristina.georgescu95@gmail.com

Abstract

Agency theory was first developed by Jensen and Meckling. This theory has made substantial additions in financial theory because the corporation is not approached from unique perspective, that the shareholders and maximise their wealth, but try to offer solutions to harmonize the interests of stakeholders. In his business, company management must consider conflicts arising from bringing together a multitude of interests. If not recognized and properly regulated, these conflicts can jeopardize the effectiveness and may lead to reduced market value of the firm. Agency theory integrates the complexity of decision making within the firm, arguing the composition of the financial structure of the firm to maximize its value. Considering these circumstances, our paper examines application of the agency theory in Romania.

Keywords: Corporate governance; conflicts of interest; stakeholders.

JEL Classification: G32, D 23.

1. Introduction

Basically, the concept of corporate governance refers to the coordination of interests of various company stakeholders: shareholders, managers, employees, lenders, clients, suppliers, the state, et.al. Within every company an ensemble of particular relations develops, between natural or legal persons, with a stake in the business. In the progress of the entrepreneurial activity, the company's management or governance must take into account the subsistent conflicts, generated by the co-existence of various interests, within the corporation.

As case studies show, the company's performance and value are, concurrently and greatly, influenced, by corporate governance,

i.e. by the management and control systems and operations, implemented on a company level. Also, analyses done by numerous researchers in the field, indeed, show that, a company's financial structure holds an important role in the economy of productive companies. The Modigliani & Miller financial design endorses this statement, as it represents the base upon which the financial science and practice subsequently developed.

Further researches identified optimum capital structure patterns, which entice the maximization of the company's value. Thus, the design proposed by Jensen & Meckling shows that a financial structure may be obtained by making a favorable compromise between additional revenues and agency costs. The latter, predominantly, refer to, monitoring expenses held by the owners, justified by the existing discrepancies between the agent managers' interests and those of the principals. Agency costs can be lowered by debt, as the authors explain. This design nominates a theory for control within the company, which was later named the agency theory. According to this theory, the corporation consists of an ensemble of individuals, each with a specific utility function. If we are to look at this from a, completely opposite, view point, from that of the major principle of the corporate finances, we can assert that the affiliation of the capital is irrelevant, and may be chosen with the purpose of minimizing agency costs.

2. The agency theory, conflicts of interest and the value of the company

Formally speaking, the agency theory originated in the 1970's, but its fundamental concepts derive from a long and colorful history. Among its main influential factors, we list the ownership rights theories, organization management and economy, contractual law and political philosophy. By causing a new leap in the evolution of

finance, the agency theory signs up as a leading role model in financial-economical literature.

The agency theory was elaborated by Jensen & Meckling (1976), based on the bench/marks set by Fama & Miller (1972). This control theory integrates the complexity of the decision making process within the company, by motivating the make-up of the company's financial structure, in order to maximize its value. The managers' behavior influences the current results by each decision made, but their decisions have an, especially, powerful impact on the financing policy and strategy. Thus, the agency theory reflects the inefficiencies that arise from the conflict of interests between managers (directors) and shareholders (owners).

The agency theory states that the company may be regarded as an ensemble of contracts between the stakeholders. The general agent relation is formed in virtue of the contractual bond between the principal and the agent. The principal gives the agent decision making authority, for the fulfillments of certain tasks. The most remarkable agency relations present within companies are those between shareholders and managers and lenders and shareholders. These relations are not specifically harmonious, as the agency theory refers to the conflicts of interest between the principal and the agent.

The most important conflicts of interests, in regard to the impact on corporate value and performance, are those between the owners and the company managers. The agency theory shows that the manager is not preoccupied only by the maximization of the owners' assets, as he, himself, has a utility position to maximize. Thus, results the need to institute a proper and severe examination of the means by which the managers fulfill their contractual duties. Such a measure, however, may lead to a drop in efficiency for the agents, by creating a tense atmosphere at the workplace, unsuitable for gaining performance.

In order to solve conflicts between shareholders and lenders, most often, it resorts to ushering restrictive clauses in the loan agreements. These clauses are meant to reduce the moral hazard risk, induced by the shareholders' or managers' reprehensible behavior. Coerced by shareholders, managers

can involve the company in shady projects, but, the lenders will not realize the real risk level of the investment project until after granting the loan and the project's start. Lenders may include restrictions regarding the financing, dividend, investment policies, etc.

The board of directors represents the headstone of the corporate governance system and the interface between the shareholders and managers (Onofrei M., 2007). At the same time, it represents the link between the managers and the stakeholders involved in the company's activity. In order to achieve the target of maximizing the company's value, shareholders must ensure, through the board of directors, that they hold an agreeable amount of control over managers, with the purpose of (at least) preserving profitability.

The conflicts of interest have implications regarding corporate governance and business ethics. The agency costs are a certainty, subscribing expenses performed in order to support an efficient agency relation. To this extent we can also mention the expenses for the gratification of management performances (through bonuses). This way, managers are interested in acting in the shareholders' best interests.

In the agency theory pattern suggested by Jensen & Meckling, the company is considered to be a get-together of adversaries and partners, each with his own interests. The result is that managers are not exclusively interested in maximizing the owners' fortune, as they have their own utility position to maximize. Agency costs are generated by conflicts of interests. The authors identify a solution for reducing these costs: the call to debt (Jensen M. C., Meckling W. H., 1976).

One design of the optimum financial structure that integrates the two fundamental approaches, respectively the classical and that supported by the agency theory, is the one suggested by Leland in 1998. The design takes in the interaction between the financing decision and the administration strategy for the investment risk. According to the author, following the target of maximizing the shareholders' assets, after contracting additional debt, may lead to a series of conflicts between the agents, and agency costs: monitoring expenses made by the principal and warranty expenses made by the

agent. This article also examines the problem of risk management. Hedging allows for a higher debt burden. It is shown that the benefits of risk coverage are higher when agency costs are lowered.

Choosing the investment financing pattern and the relation with an optimum risk exposure, prove to be an essential factor of the economical performance of corporations. Scholarly financial literature is rich in analyses of the capital structure decision, qualitatively speaking. Be that as it may, it has yet to offer enough specialized benchmarks. The theoretical construction that approaches the capital structure remains imprecise, as opposed to the precision offered by the Black & Scholes (1973) design for option evaluation, with its add-ins.

One explanation for the companies' preference for loans is offered by Ross, in the signaling theory. To this extent, indebtedness represents a means of transmitting performance signals to the market, as well as signals referring to the risks characteristic to the activity (Ross S., 1977). It was suggested that an incentive system be created for managers, based on the fairness of the signals sent on the market.

The design starts from the hypotheses of the perfect financial markets (the absence of trading costs and tax effects, investor divisibility et.al.), but under conditions of informational asymmetry. The asymmetrically distributed information speaks of the company's performance, including its investment projects and its ability to handle risks. The financial structure becomes a means of identifying the various categories of companies activating on the market, by ensuring their classification based on their performance class (Stancu I., 2003).

The conflicts between managers and shareholders arise because the managers hold less than 100% of the residual interest. Thus, the agents will not intercept the entire earnings of their effective activity, but will be subject to a cost determined by their “abstinence” from the inefficient use of the controlled resources. Ultimately, managers will not hesitate to “take advantage”. The resulting inefficiency gets lower, the higher the capital share they own is (Harris M., Raviv A., 1991). By maintaining the managers' investment at a constant, in absolute values, the indebted will raise their

capital held percentage and reduce conflict generated costs.

Managers will maintain the company activating, even if investors would much rather have it liquidated. A higher indebtedness level supports the liquidation decision (bankruptcy becomes a probability), as it is associated with a high value of the company and a low probability of reorganization after declaring bankruptcy.

Numerous researches use the Fama-French methodology (1998), based on tax effects, in order to study the relation between financing decisions and the company's value, also considering other relevant factors: agency costs, asymmetrical information, etc. Generally, regression results show that non-tax effects advance on the tax effects of the financing (Wu X., Xu L., 2005). It turns out that this approach is useful in order to reveal information on the company's value, when non-tax effects are predominant.

In the Fama-French study, the authors made cross/sectional regressions in order to study the means by which the company's value is linked to dividends and debts. Basically, the main objective of the research is measuring tax effects, resulting from the evaluation of dividends and debts. Meanwhile, the influence of these effects on the company's value is also analyzed. It is shown that the value is positively correlated to dividends and negatively linked to debts. We deduce that dividends and debts send information on profitability (net expected cash-flows). This information, omitted by control variables, neatly advances on the fiscal effects of the financing decision.

3. The analysis of the agency theory in the case of Romania

In order to test the conformity with the principles of the agency theory on the Romanian market, Dragota (2006) used sample of companies listed on the BSE during 1997-2003. According to the methodology suggested by Rajan & Zingales (1995), banks and financial investment services companies were eliminated from the sample, as their debt level is strongly influenced by a series of exogenous factors.

Accounting and stock exchange information were obtained from several sources, respectively: web sites that supply

specialty information; the data base available through the Reuters press agency, including company enlistments; financial-accounting information from the Ministry of Economy and Finances. Although, officially, the information obtained from balance sheets and profit and loss accounts are made public, the actual elaboration of an empirical study is hindered by the lack of a public data base. To synthesize, the conclusions of this reference research are as follows:

- Romanian companies have a high indebtedting level, which is significantly explained by the balance of operation debts, that carry no interest;

- Profitable companies have less debt because they command enough private resources in order to finance investment projects;

- Private capital companies have started invoking, more often than none, long term resources, which constitutes a sign of recovery for the economical environment.

By using the information available in the balance sheets and resulting accounts of the companies listed on the BSE and RASDAQ, in the period 2001-2004, Robu (2005) analyzed the link between the stock price and the financial and accounting data, based on the following indicators in absolute capacity, share level wise: net profit, dividend, accounting value and sales. These indicators are relevant to investors, as they reflect the performances of the company under conditions of high irregularity of the ownership equity. For each individual indicator the following were calculated: arithmetic average, median, maximum and minimum limits. According to the results, the relations between the financial rates and the stock exchange performances of the companies in the sample, are generally frail in intensity and can be quantified only with the help of certain non-linear designs.

There are several theories regarding the contribution of the administration techniques to the creation of value for shareholders. Nonetheless, the imperfections of the capital market – agency costs, trading costs, taxes, and the growth of the external financing costs – reflect the means by which the value of the company may amplify.

A recent paper tackles the contribution of corporate governance policies to the risk management system, on a company level.

The research analyses the importance of management strategies from the perspective of the profitability and the financial leverage, as eloquent variables. The research steps are complex ones, integrating quantitative and qualitative information. The quantitative information represents financial indicators sampled from the accounting balance and the profit and loss account, while the qualitative perspective includes “dummy” variables, which reflect agency and monitoring costs.

Empirical results show a positive contribution of the dummy variables, in relation to the financial leverage. This way, even if the managers’ benefits are proportional to performances, which are susceptible to motivating them in order to ensure adequate management strategies and for being somewhat reserved towards indebtedting the company, this would not attract a lower financial leverage. This aspect might be interpreted as proof for the fact that the companies under analysis are receptive to external financing.

4. Conclusions

The agency theory tries to offer solutions for the harmonization of the stakeholders’ interests. Thus, in the course of its activity, the company management will have to consider conflicts arising from uniting a multitude of interests. Conflicts of interest might endanger efficiency and lead to a lower market value of the company if they are not identified and regulated accordingly. As a result, the means of financing is inseparably linked to the business organization method, the particular relations built between various persons directly or indirectly involved in the business, meaning the management or corporate governance.

In short, the company’s structure may be defined by a special complexity, in relation to objective agency conflicts and the effort to minimize agency costs. The fact that the company actors do not, all, have the sale objective, generally, leads to certain conflicts of interests, which in turn generate value loss. For this, the objective of the agency theory is that of creating an agency relation structure that will minimize agency costs and value losses.

The need to regulate the relation between stakeholders (shareholders, managers,

employees, creditors and other stakeholders), as well as that of resolving the conflicts between them, has become an issue of incentive for investors, as well as the general public.

Under these circumstances, the pioneering role of the OECD is commendable, seeing as how it managed to synthesize the basic tenets for applying corporate governance in 1999. These principles are meant to support the government efforts to perfect the legal framework and regulate corporate governance, on a national level.

Is the Options Market in Romania an Option for Investors?

Ghiță-Mitrescu Silvia

Ovidius University of Constanta, Faculty of Economic Sciences
mitrescu.silvia@gmail.com

Abstract

The second segment of the derivatives market in Romania, the options contracts has always been the "poor relative" of the futures market. This paper aims to analyze the main features of the options market in Romania in an attempt to determine the necessity and opportunity for its existence in the Romanian capital market landscape.

After analyzing the volume, value and the typology of the options contracts traded at Sibiu Stock Exchange in the last decade, we can conclude that we are facing a watershed moment for the options market, the dramatic decrease in the number of contracts traded putting into question the future existence of the market.

Although in terms of the types of contracts traded, investors have real alternatives for hedging and speculation, they seem to bypass the options segment and preferred the futures contracts. The explanation for this behavior consists, in our opinion, both in the illiquidity of the market and the lack of financial culture and experience of the investor.

Key words: options contracts, Sibex, volume of trades, market liquidity

J.E.L. classification: G23

1. Introduction

The Romanian options market has had a more hesitating evolution compared with the futures market. In their approximately 15 years of existence on the Romanian capital market, options have failed to arouse great interest from investors, who prefer futures contracts. Therefore, we consider justified the attempt to find a response to the question: is the options market in Romania an option for investors?

In order to give an answer to this question, we will try to identify the main

trends observed in the Romanian options market in the pre and post crisis period of time.

2. The Romanian options market evolution and trends

In terms of the range of products offered, the options market in Romania now has two categories of options: standard and binary. The underlying assets for the standard options are the futures contracts on shares of companies traded on the Bucharest Stock Exchange, currencies and gold. As of 2011 binary options were introduced to trading. They represent a type of exotic options that require payment of a fixed income if, at maturity, the price of the underlying asset reaches or passes a certain threshold.

The options traded at Sibex are American style, which gives investors greater flexibility, allowing them to require the sell (or the buy) to take place at any time up to the maturity date. Under these two aspects, Sibex can be included in the same category as most of the European stock exchanges, both in terms of the types of underlying assets as well as in terms of the options style.

2.1. The evolution of the volume of trades

If the volume of futures contracts traded included Sibiu Exchange in the top 10 European exchanges in 2008, the same can't be said about the options market, whose share in the Sibex transaction volume never exceeded two percent.

The number of option contracts concluded in the last 15 years at Sibex had an upward trend, from 133 contracts in 1998 (this value is not relevant as options transactions were introduced in November), reaching 52.079 contracts in 2009. The highest number of contracts traded was reached in 2002, when 67.300 options were closed. Then a period of

decline in the volume of transactions followed, due to the same reasons as the futures market slump, and, since 2005 a new upward trend that ended in 2009. That was followed in 2010 by a decrease in trading volume almost to the volume of 2005. 2011 brought a further decrease in the volume of transactions, but less than in 2010. In the second semester of 2011 the market gave the impression of a recovery, but it was short-lived, 2012 bringing the lowest trading volume in the history of the options market in Romania, letting aside the first year of trading.

Figure 1. The volume of options traded at Sibex between 1998 and 2012

Data source: Sibex annual reports

The post-crisis evolution of the options market was different from that of the futures market. If we compared turnovers in the 2007-2009 period we might be tempted to believe that the onset of the crisis was actually beneficial for the options market. In 2009 the total number of contracts increased by 30% over the previous year, the largest difference of 8.5 times, being recorded in November. Thus, 2009 was the second best year for options market since 2002. But the next three years have shown that lack of liquidity, a general characteristic of the capital market in Romania, has not spared even the options market.

In 2010 the volume of trading in options decreased from month to month so that in October reached a low of only 116 contracts. Compared to 2009, the total volume of options traded fell to 66.22%, the largest decline, in October, being of 98.22% while the only month that saw a higher volume over the last year was May with a 260,18% rise. The downward trend continued in 2011, when there were only traded a total of 13,105 contracts, with 26.13% less than in 2010.

After mid-2011, we can talk about a market rebound, trading volumes being higher compared to the same period of the previous year. September and October 2011 marked trading volumes of even 800% higher than the previous year, but this was not enough to offset losses in the first half.

Due to the loss of investors' interest in standard options, the Sibiu Exchange launched in April 2011 two exotic binary contracts, CALL options and RANGE options, with the exchange rate between the national currency and European currency and between Euro and U.S. dollar as underlying assets and weekly maturities.

Binary options are products designed especially for speculators giving the possibility of gain from estimating a certain trend in the underlying assets' price. In CALL binary options, the buyer relies on a price growth above a certain threshold; the seller is willing to pay a premium for a fixed amount negotiated if his predictions come true. If at maturity the price of the underlying asset exceeds the barrier, the seller pays a fixed amount, but if the price does not reach over the barrier, the seller retains the premium while and the purchaser gets nothing. In RANGE binary options, an interval of variation is established for the price of the underlying asset and if the due price is outside the barriers, the seller retains the premium and the purchaser gets nothing.

Although requested by investors binary options have not enjoyed the success expected, only 19 CALL RON/EUR contracts being traded during 2011, in the first two months from the introduction. The year 2012 brought with it a dramatic decrease in the volume of trading in options, the number of trading reaching only 8% of the previous year's amount. So, in our opinion, it is safe to say that 2012 marks the biggest market contraction since its launch in 1998.

By analyzing the volume of transactions with options carried out at Sibex during the financial crisis and afterwards we can conclude that investors do not have at their disposal a dynamic market, which is a first impediment for considering options a viable alternative for hedging or speculation.

2.2. The evolution of the value of trades

A second aspect which we will examine below is the evolution of the value of options transactions. In this context it should be noted, first, the positive dynamics of stock market volatility in Romania in the pre and post crisis [1].

If in terms of the volume of transactions the amount of 2009 exceeded that of 2008, the total value of contracts decreased to 94.5% from the previous year. The largest decrease of 80% was recorded in January, while the largest difference was recorded in November, when the turnover was 257% higher than the same month last year. The reason why the large number of transactions did not materialize in a large value is the small value of the underlying assets' prices. The same trend can be distinguished in regards to the futures market evolution during this period.

In 2010, the downward trend of option value set in the previous year continued, traded amounts registering a decrease of 66.53%, the largest negative difference being recorded in October of 95.49% while the single better month of 2010 compared to 2009, May, achieved an increase of 107.57%.

Figure 2. The correlation between the volume and the value of options transactions during 2009-2011

Data source: Sibex annual reports

For the years 2011 and 2012 the positive correlation between the volume and value of transactions remained, the months with the highest volume of contracts traded being the same months with the highest value of transactions. Overall, the transactions made in 2011 represented 69% of the previous year, while the volume in 2011 was 73.8% of

that of 2010. In 2012 compared to 2011, a volume of only 8.3% of the previous year led to a value of only 9%.

Figure 3. The monthly volume and value of options trades in 2012

Data source: Sibex annual reports

Therefore, a second setback for investors interested in option contracts can be stressed out: the lack of market liquidity.

2.3. The typology of option contracts traded at Sibex

A final tier of analysis that we will consider is that of the typology of option contracts traded on Sibex.

In terms of the type of wrights being achieved from buying the option contract, investors in Sibiu preferred to protect their short investments through call options. This demonstrates, in our view, the speculative nature of transactions conducted at Sibex.

Regarding the underlying assets, we can observe the same preference for the products of the financial sector as in the case of futures contracts. The most liquid options were those based on the futures contracts for SIF 5 shares (DESIF5), followed by options on futures contracts for the lei/euro exchange rate. Compared to other European markets, we notice both similarities and differences. A more comprehensive analysis of the similarities and differences between the Romanian options market and the European markets can be found in a 2010 paper by the same author [2].

The predominant preference of investors for the financial products (options based on share prices and currency exchange rates) can be explained by the high volatility of the financial sector, especially that of the exchange rate. Combining this feature with the prevalence of call type options we

conclude that the options market in Romania is a market mostly speculative.

3. Conclusions

Options on futures contracts traded in Sibiu offers real advantages for investors that can use them for both risk management and speculative operations. Call type options allow the purchase of the underlying asset at a predetermined price while put options allow protection against price erosion. Options' trading offers the opportunity to benefit from the price movements of the underlying asset without paying the full price. In addition, there is no obligation to purchase or sell the underlying futures contract and the actual risk is limited to the premium paid when purchasing the options.

In spite these obvious advantages, the capital market in Romania does not seem to be ready to use options to their full capacity at for at least two reasons: the low liquidity of the entire Romanian capital market and lack the experience and financial culture of the investors.

Given the evolution of the volume and value of transactions with options lately, its future existence is, in our opinion,

questionable. Although the Sibiu Exchange always tried to adapt to the requirements of investors in terms of the typology of contracts traded, they still have not responded as expected.

In our opinion, the coming years will be decisive in terms of the capacity of the capital market in Romania to trade options at a level comparable to other European markets.

The Analysis of the Correlation between the Banking System Profile and its Involvement in Transactions with Financial Derivatives

Ghiță-Mitrescu Silvia

Ovidius University of Constanta, Faculty of Economic Sciences

mitrescu.silvia@gmail.com

Abstract

The use of derivatives by commercial banks is a thorny problem lately, mainly because of the opinion of some experts that that activity led to the global financial crisis. This paper does not aim to analyze the effects that the use of derivatives by banks has on their performances, but to determine a profile of banks interested in using derivatives. To do this we will try to establish a statistical correlation between the volume of derivative transactions and two important components of the commercial banks' balance sheet: total value of assets and loans granted. The data used refers to the Czech banking system.

The conclusions drawn from the analysis revealed a direct correlation between the banks' size and the size of their intermediation activities, on one hand, and their involvement in derivative transactions, on the other hand.

Key words: financial derivatives, banking system, total assets, total loans, correlation

J.E.L. classification: G21

1. Introduction

The use of financial derivatives by credit institutions increased in importance during the recent decades. Studies on the increased role of derivatives in banking activities focused on two areas: the analysis of the motivations behind the use of derivatives by banks and the effects that this use has on bank risk [1].

Among the reasons why banks are interested in using derivatives we can include mainly hedging transactions generated by traditional intermediation activities and, to a lesser extent, in the opinion of some authors,

speculative operations [2]. Increased interest rate risk is another incentive to use derivatives according to experts [3] or [4]. There are also studies on the influence that the size of the banks [5] and ownership structure [6] have on the involvement of banks in transactions with derivatives.

In the second category of studies, many authors have tried to identify how the use of derivatives affects banking risks by reducing certain risk categories and generating other threats. From this perspective there are conflicting opinions among experts. A number of authors [7] consider that the use of derivatives reduces risks, while other specialists [8] and [9] consider that their use amplifies risks for banks.

In the following chapter we will try to test the existence of a link between the volume of transactions with derivatives and one component of commercial banks balance sheet: the total assets volume, first, and the value of customer loans, secondly, using data related to the Czech banking system.

2. The analysis of the correlation between the banking systems' value of total assets and total loans and the value of financial derivatives transactions

Derivatives transactions in the Czech banking system started in 1993. In comparison, in Romania the only available data to date covers the period between 2001 and 2002 when the value of transactions conducted by banks in this segment was, according to the National Bank, between \$ 82.5 and \$ 185.8 million, comparable to that achieved by the Czech market in 1995. The data that we use are denominated in the currency of the Czech Republic (Czech Koruna) and refers to the monthly evolution of the chosen indicators during 1993-2010, a period which we consider sufficiently large

in statistical terms to enable us to establish the existence and the meaning of the link between the indicators mentioned above.

The value of derivative transactions taken into consideration is the fair value of these contracts, as it is found in the aggregated balance sheet of the commercial banks in the Czech Republic, excluding the Central Bank. Loans refer to loans to nonbank institutions only, both in national currency and in foreign currency and do not include the governmental loans.

Figure 1. The value of transactions with financial derivatives performed by the Czech banking system between 1993-2010

Data source: Czech National Bank statistics

The analysis of the data series regarding the value of transactions with derivatives demonstrates heterogeneity, the coefficient of variation is over 100%, which leads to the conclusion that the arithmetic mean is not relevant to characterize the series:

Table 1. Statistical indicators of the evolution of derivatives transactions carried out by the Czech banking system

Arithmetic mean	49902.4
Series minimum (31.12.1999)	1067.0
Series maximum (31.01.2009)	235262.1
Variation range	234195.1
Maximum deviation	185359.7
Minimum deviation	-48835.4
Variance	2562698341
Standard deviation	50623.10
Variance coefficient	1.01

Next we go through the following steps for each of the relationships that we want to consider:

- the statistical analysis of data series through middle position and variation indicators;
- the graphical determination of the existence of a relationship between the

derivative transactions (independent variable) and the value of the indicators taken into account;

- the determination of the shape of the link function using linear regression;
- the determination of the strength of the link using the simple correlation coefficient.

We consider that the relationship between the two variables takes the form of a linear function of the type:

$$Y_{x_i} = a + b * x_i \tag{1}$$

where:

Y – the endogenous variable or dependent variable

x – the exogenous variable or independent variable

a – the error term (noise) – captures all other factors which influence the dependent variable y, other than x

b – the regression coefficient

The parameters of the regression function are estimated by the least squares method based on the following system of equations:

$$a = \frac{\sum y_i * \sum x_i^2 - \sum x_i * \sum x_i y_i}{n \sum x_i^2 - (\sum x_i)^2}$$

$$b = \frac{n \sum x_i y_i - \sum x_i * \sum y_i}{n \sum x_i^2 - (\sum x_i)^2} \tag{2}$$

In order to test the intensity of the relationship between the two variables we use the simple correlation coefficient (Bravais-Pearson):

$$r_{y/x} = \frac{n \sum x_i y_i - \sum x_i * \sum y_i}{\sqrt{[n \sum x_i^2 - (\sum x_i)^2] * [n \sum y_i^2 - (\sum y_i)^2]}} \tag{3}$$

The first correlation that we will try to determine is that between the volume of derivative transactions (independent variable) and total assets (dependent variable). The scatter plot chart reflects a relationship of interdependence between the two variables.

Figure 2. The correlation between the volume of derivative transactions and the total assets

Data source: Czech National Bank statistics

The statistical evolution of the total bank assets is characterized by the following indicators:

Table 2. Statistical indicators of the evolution of total assets of the Czech banking system

Arithmetic mean	2732390.2
Series minimum (31.03.1993)	1097835.0
Series maximum (31.08.2010)	4347267.9
Variation range	3249432.9
Maximum deviation	1614877.7
Minimum deviation	-1634555.2
Variance	748110324676.24
Standard deviation	864933.7111
Variance coefficient	0.316548383

As it can be noticed, the variance coefficient is much smaller in this case compared to than the value calculated for the derivative transactions, which implies that the arithmetic mean is relevant in this case.

After performing the necessary calculations, the following values are obtained for the regression parameters a and b:

$$a = 2022935,3$$

$$b = 14,21$$

The positive sign of the parameter b signifies a direct link between the value of bank assets and the value of derivative transactions.

Therefore the regression function is, by substituting the values obtained for the parameters a and b in formula (1):

$$Y = 2022935,3 + 14,21 x_i$$

The second correlation that we intend to analyze is between the value of derivatives transactions (independent variable) and the value of loans granted by banks to customers. Following the same steps as in the first analysis we found the results below:

Figure 3. The correlation between the value of derivatives transactions and the value of loans granted by banks

Data source: Czech National Bank statistics

Table 3. Statistical indicators of the evolution of loans granted by the Czech banking system

Arithmetic mean	1189729.66
Series minimum (31.01.1993)	570277.50
Series maximum (30.11.2010)	2175190.80
Variation range	1604913.30
Maximum deviation	985461.14
Minimum deviation	-619452.16
Variance	196806054139.86
Standard deviation	443628.28
Variance coefficient	0.37

By applying the calculation formulas we obtained the following values for the regression parameters and for the linear regression function:

$$a = 817228,1$$

$$b = 7,46$$

$$Y_{xi} = 817228,1 + 7,46 * x_i$$

As well as in the case of the first correlation, a direct relation is proved to exist between the two variables, a one unit increase of the variable x (the derivative transactions in our case) leading to an increased value for the variable y (value of loans).

To determine which of the two links previously analyzed is the most powerful we compared the simple linear correlation coefficients (Pearson) for the 2 pairs of data:

Table 4. The values of the Pearson coefficient for the two series

Correlation between the value of transactions with derivatives and:	Pearson coefficient
- the total assets value	0,832088
- the value of loans granted	0,851797

The results obtained show that the strongest influence on the value of their derivatives transactions is exerted by the value of loans granted. However the difference in value between the two analyzed data series is small, proving that the value of the total assets owned by the banking system is also a factor of influence for the value of transactions with financial derivatives carried out by banks.

3. Conclusions

We thus conclude that the value of derivatives transactions varies proportionally to the value of assets and loans, but is most strongly influenced by the amount of loans. This means, in our opinion, that there is a relationship between the volume of traditional operations performed by banks and their interest in the use of derivatives. The size of the banks, characterized by asset

value, also has a direct influence, the value of derivatives transactions increasing with increasing assets value.

Tax Evasion in the Context of Globalization

Grigorescu Gheorghe

“Constantin Brâncuși” University of Tg. Jiu
grig_g@yahoo.com

Abstract

Tax evasion is the logical result of flaws and inadequacies of an imperfect and erroneous assimilated legislation, of faulty methods of application, the scale reaching unimaginable quotes, increased during the economic crisis, aimed at circumvention and fraud the state in terms of fiscal by different methods. Tax evasion has consequences, primarily at a macroeconomic level, consisting of depriving the state of revenue due, thereby decreasing the room for maneuver in economic and social matters.

Keywords: evasion, taxation, globalization, taxes, state budget

J.E.L Classification: D20, F20, F60, G00, H30

1. Introduction

In any economy, the main purpose of a tax system is to provide a stable and consistent source of public revenue. In this process, a factor of particular importance is the reduction of tax evasion, given that it contributes to reducing the effectiveness of state institutions, as well as being a generator factor of corruption.

Tax evasion is the logical result of flaws and inadequacies of an imperfect and erroneous assimilated legislation, of faulty methods of application, and also of non-provision of the legislator, whose excessive taxation is as guilty as those that are provoked by this evasion.

Tax evasion has become a social danger affecting the economy of a state, along with social disorders. Tax evasion is thus, synthesizing, evading by any means in whole or in part from paying taxes, fees and other amounts owed to the state budget, local budgets, social security and special extra-budgetary funds by Romanian or foreign

individuals and legal entities. Depending on the place of manifestation, intensity, methods used, the antithesis of fiscal economic legislation, but also moral and tolerance society, fraud can take certain forms such as tax evasion, smuggling, fraud, and forms Unnoticed or speculative particular interpretations the legal provisions in order to evade or avoid tax (Boiță, M., 2009) [1]. Concerning this phenomenon, tax evasion is as ancient and ubiquitous in society as how old is the existence of the state and tax laws. The field of manifestation of the tax evasion is as large as it is wide and varied the scope of taxes.

2. Legal speculations of international and national fiscal policies

Legal tax evasion allows evading a portion of taxable matter, without this being considered misdemeanor or felony. Its frequency is higher in the periods in which are modified or are introduced new laws and when the state intentionally uses the tax to promote incentive economic policies to certain socio-professional categories or in certain areas of activity.

Legal tax evasion can take different forms:

- granting certain tax facilities (in the form of exonerations, partial exemptions, reductions, deductions) is a favorable frame for detouring from tax obligations payment by certain processes;

- granting exemptions defined in time, in the case of the establishment of new companies, from the payment of profit tax, is an example. In some countries, companies of persons have the right to choose that income be imposed either as capital firms, either for self-employed persons;

- when the state is facing more specific financial difficulties takes out of the scope of taxes income from bank deposits and from

investment in the form of securities issued state bonds.

- also, when the general expenses of companies are not regulated, there is a trend to overestimate them by unjustified economic increasing them. Overstatement of depreciation, by the legal establishment of a depreciation fund in an amount greater than the physical and moral depreciation of fixed assets is one way of reducing the tax base;

- income taxation of certain categories of individuals based on average income rules, creates conditions for taxpayers with incomes higher than average, for not paying tax on that difference;

- an additional possibility of producing legal tax evasion consists, as stressed earlier, the existence of tax havens, where are established and register their office address both individuals and legal entities to which are directing their profits obtained in other countries, eluding thus IRS. An offshore company is a financial instrument for planning and avoidance of taxes, raising the profitability of a business, coordination of productive activities in full freedom currency, but also in a comforting anonymity.

A tax haven is used generally to complicate and discourage attempts to document unreported income, to analyze the flow of funds and to demolish the arguments of defense by parrying sources of funds that are not taxable.

Moreover, tax havens are used to generate documents with appearance of legitimacy.

The main motivations for using fiscal "tax havens" can be grouped as follows:

- transactions that are motivated from this regard, but are consistent with the spirit and letter of the law, are considered "tax planning". Tax planning technique consists in directing profits from the real place of achieve them to the mother company with the headquarter in a tax havens, and can take various forms from service to the prices of import - export favorable distorted;

- transactions that benefit from some legal or administrative unintended slips are considered cases of "tax avoidance", which takes the form of captive insurance companies, investment companies, some forms of services and construction performed by entities such as the tax havens.

3. Reducing the taxable base by illegal speculation of national and international fiscal policies

Fraudulent evasion (illegal) requires deliberate circumvention of the fiscal law that is sanctioned by the law through pecuniary and imprisonment measures. As it is a social phenomenon with implications for financing public expenditure, fraudulent tax evasion consists in illegal concealment, in whole or in part, by taxpayers of taxable matter in order to reduce or eliminate tax obligations incumbent on them. Although there are a variety of methods to which taxpayers resort to illegal evades, we agree with the classification conforming to which illegal tax evasion takes the following forms [2]:

a) Traditional evasion that:

- consist in partial or whole evade from the payment of the tax obligations by completing and submitting incorrect documents, or by failure to produce documents required by law;

- includes the following main processes:

- drawing false fiscal statements or failure to produce them;

- intentional reduction of receivables with the purpose to reduce Value Added Tax (VAT) and taxable income through cash receivables without receipt and sales without invoice;

- deliberate increase of expenses to reduce taxable income;

- production and selling economic goods and services illegally;

- professional activities clandestinely rewarded (on the black);

- reducing the value of inheritances received and transactions with real estate.

- **b) Legal evasion** consists in hiding the true nature of an organism or a contract to avoid tax obligations (for example, when an Association contract is converted, in secret, in an employment contract for its beneficiary to obtain certain benefits from the quality of employee);

- **c) Accounting evasion**, difficult to identify in practice, consists in creating the impression of proper accounting records, using false documents in order to artificially increase costs, reducing revenue, reducing taxable income and therefore the tax liability owed to the State;

d) Evasion by evaluation consists in reducing the value of the stocks, overestimation of depreciation and provisions with the purpose of displacement of profit in time.

The lack of legal regulations, existing gaps in those in force, combined with the lack of cooperation of those responsible, with the establishment of commercial companies have been speculated by various creative individuals who have created a lot of companies apparently operating legally, but that cannot be identified at the legal office said. The establishment and operation of these "ghost companies", possibly through false identity documents, leases, isn't an end in itself, but to circumvent the law, often in tax matters. The experience so far shows that "great specialists" in ghost companies are mainly foreign citizens of Chinese origin and those from the Arab world. Also, a company that works correctly to a point, after which conflict with the law can become "business with ghost associates " by assigning (selling) it, along with the debts to suppliers and state, to people who cannot be identified, on the basis of false documents.

The consequences of the function of such "model of companies" are disastrous. These companies apparently legally established benefits from sales invoices, which immediately turn to supply bills drawn on at the "customer demand" at a purchase price almost equal to the sales one, fixed inputs, fictitious services, generating both unpaid taxes and fraudulent indirect tax recoveries.

4. Including an offshore company in the business relations of two companies. Case Study

When it takes place a commercial transaction or otherwise between two companies, goods or services depart from one direction and from the other one documents and money. The tax base would be represented by the difference between the price at which the goods were purchased, along with other expenses, and the price at which they are sold. An offshore company can be inserted into the middle of the transaction, with the profit obtained recorded in its books, instead of the original company. In this way, taxable profits are transferred from a high-tax jurisdiction to one with low

fees or no fees at all. The offshore company receives orders directly from the customer and commodities will continue to go from the manufacturer to the buyer. This interposition in the marketing chain is advantageous both for the vendor of goods and for the buyer as well. For example, a multinational company can be incorporated in an appropriate jurisdiction and used to finance subsidiaries located in countries with high taxes. The main advantages to be gained by the holder are:

- by using the double taxation avoidance Agreements (Double Tax Treaty) may be granted loans at attractive interest rates to subsidiaries;

- interest will be deductible by the subsidiary's profits and the tax that would normally be withheld on interest at source may be reduced or eliminated;

- also by using conventions (agreements) to avoid double taxation, taxes that would be levied on dividends paid by the subsidiary to the mother holding company may be reduced or eliminated;

- it may be possible to arrange a sale of subsidiary shares without applying tax for the capital gains at source or in the offshore company accounts;

- also it may be receive fees that will flow to the offshore company. The individual will then receive a salary for their services that will be chargeable wherever the employee is resident, but the difference between the fee and wage can be held offshore and reinvested without charge.

5. Conclusions

Analyzing the evasion phenomenon in depth, in the causes that produce it, extremely important is the repercussion state of taxes. Financial phenomenon of repercussion appeared when the taxpayers tried to reduce, as much as possible, the effects caused on their income by taxes levied by the state. Repercussion [3] means, summarizing, the transmission actions by tax payer's subjects, of their economic effects to other economic and social sectors, on other subjects, at other levels in other markets or other national or regional economies.

Repercussion manifested itself only when tax payers subjects (taxpayers legally) enter into economic relations with other subjects to

which they attempt to transfer their tax burden. On preventing and combating tax evasion it must be said that tax evasion, both in its legal form and in its fraudulent one, cannot be completely eradicated and this because perfect tax laws doesn't exist and taxpayer inventiveness has no limits and, more than that, however drastic the sanctions are there will always be taxpayers for which defrauding IRS gains will outweigh the risks to which they are exposed. Under these conditions, the fight against tax evasion considers limiting it and its adverse effects to the maximum possible, this being done on two levels, first in terms of prevention, and secondly in terms of the repression phenomenon.

Conceptual Framework Regarding the Account Consolidation Methods

Guni Claudia Nicoleta
“Spiru Haret” University, Constantza
borsanclaudia@yahoo.com

Abstract

The existence of several methods of account consolidation is due to the existence of several views on consolidation, depending on the type of information which was requested and on the persons interested in the information provided by the consolidated accounts. Once the applied methods have been established, we need to choose the consolidation procedure, depending on the group's complexity and on the type of links between the societies encompassed within the consolidation perimeter.

Keywords: global encompassing;
proportional encompassing; equity method.
J.E.L Classification: G3; G32; G34

1. Introduction

Account consolidation is an ensemble of techniques which allow for the drafting of the consolidated financial situations for a group of societies which is treated as a single entity. Theoretically, consolidation consists in substituting the value of equity securities owned by the consolidated company, with the part of the net situation of the consolidated society, which is from the outcome of the exercise corresponding to the equity securities owned. From a practical point of view, the accounts which are registered in the consolidated accounts must be drafted, on principle, at the same date as those of the consolidated company and must refer to the same reporting period. Should the date of closure of the business of a company included in the consolidation is more than three months prior to the date of closure for the consolidation, the consolidated accounts must be established on the basis of interim accounts.

2. General notions of consolidation methods

Account consolidation is a process which each society group organizes depending on its structure, on its information and transaction flow between its companies, on the professional reasoning exercised by the consolidated accounts drafters. Thus, the entire account consolidation process may be organised based on accounting methods or not.

Organisation based on accounting methods requires a consolidation log where, respecting the principle of the double party, we register all the operations requested for the completion of consolidated accounts, starting with blending restatements, account sums, and ending with eliminating reciprocal procedures and eliminating equity securities. For systematically building consolidation operations we can draft a register, Ledger, and the balances established therein can then be made into a consolidated trial balance, which will serve to prepare the balance sheet and the consolidated profit and loss account. The rigor of this type of organisation serves to large groups, with numerous branches, and which apply consolidation directly by the mother-company.

Organisation not based on accounting methods, as opposed to that based on accounting methods, requires drafting a consolidation panel which each group builds according to its own information needs. Regularly, this type of organisation is suitable for small company groups or for groups using level consolidation.

In practice there are three methods of account consolidation, depending on the control exercised by the consolidating company on the consolidated companies and according to the links that exist between societies; the method of global integration, the method of proportional integration and the equity method.

By control we understand the power of directing the financial and operational policies of a company in order to obtain advantages by undergoing a controlled company activity. Thus:

- if a company is under the exclusive control of the consolidating company, the substitution is made by entirely encompassing the balance sheet and the results account of the consolidated company into the balance sheet and the results account of the consolidating, dominating company;
- if a company is under the shared control of a small number of shareholders, thus being a multi-group company, the substitution is made by encompassing the balance sheet and the results account of the consolidated company, proportionally to the interests that the consolidating company has in it;
- if the consolidated company is under the notable influence of the consolidating company, the equity method will be used.

The 7th European Directive mostly presents global encompassing, but allows using the other two methods as well. Certain branches will be emphasised in particular cases when global encompassing would falsify the global group image and especially for:

- the branch having a completely different activity from that of the group;
- the foreign branch undergoing severe restrictions, compromising its being ruled by the mother-company;
- the branch whose encompassing proves to be impossible, as the information needed for establishing consolidated accounts cannot be obtained without exaggerated expenses or on normal terms.

3. Account consolidation by global encompassing

Global encompassing, used in order to consolidate companies exclusively controlled by the mother-company, consists of:

- encompassing within the accounts of the consolidating company elements of the balance sheet and of the loss and profit account of the consolidated company, after eventual restatements in order to harmonise them with the accounting principles of the group. The elements of the balance sheet and of the loss and profit account of the

consolidated company are aligned with those of the mother-company;

- eliminating reciprocal operations, as well as of the equities of the consolidated company, held by the group companies, correlated with the elimination of the share of own capital owned by the consolidated company;
- distributing own capitals and results between the consolidating company and minorities.

In the case of global encompassing, there are two specific columns for the consolidated accounts:

- consolidated reserves - represents the share of the mother-company of the accumulated reserves when the consolidated company was acquired or created;
- minority interests - correspond to the share of the own capitals out of the own capitals of the consolidated company which belong to the shareholders, other than the mother-company.

This method is characterised by the global encompassing of balance sheets and of results accounts of the branches at the level of the mother-company. It is the case of companies undergoing the exclusive control of the dominating company, which conducts their financial and operational policies. This exclusive control can be in law or in fact, which means that it can manifest the existence of an exclusive in fact control, even if from the legal point of view the condition of majority of the voting rights (50% plus 1) is not met, according to the shares held. In the situations when the owned branches control, in their turn, sub-branches, the consolidation procedure is a bit more complex, and in the case of mutual participations there are further aspects to be taken into consideration.

The method of global encompassing is a consolidation method stipulated in all accounting texts referring to consolidation. Historically, global encompassing is the first consolidation method. Global consolidation, which perfectly illustrates the principle of prevalence of economic reality over form or legal ownership, is considered the quintessential consolidation method. In the situation when a company is exclusively controlled by the dominating company, therefore its financial and operational policy is conducted by another company which thus

gains certain advantages, the method of global encompassing will be used. The exclusive control refers to owning, directly or indirectly, the majority of voting rights, i.e. more than 50%, but exclusive control can equally result from a contract or a statutory clause.

The stages of the consolidation process when applying global encompassing are:

1. Proper consolidation, consisting of:
 - account blending, taking into account the treatment imposed by adopting a unique method;
 - eliminating the fiscal influence from the accounts.
2. The proper consolidation, which requires:
 - aggregation of accounts in a consolidating support - consolidating panel or journal;
 - elimination of accounts and mutual operations;
 - elimination of group internal results;
 - sharing capitals belonging to branches.

The consolidated balance sheet, obtained by means of global encompassing, offers the most complete economic and financial image of power exercised by the group on the branches. The exclusive control determines considering the consolidated company's patrimony as being part of an ensemble of commercial and industrial means under the rule of a unitary decision. Therefore the consolidated balance sheet allows for the appreciation of the real structure of actives, of their financing means - the degree of debt and own capitals, while knowing the share of the own capitals which belong to the shareholders or to the associates considered a "minority" but who, completely aware, contribute to the general financing of the group. This method corresponds directly and perfectly to the economic view on consolidation regarding the entity.

By applying the global encompassing method, the consolidated profit and loss account will also comprise the result corresponding to the minority interests, (interest which do not control it), which reflect the share of the results of branches which belongs by right to the minority interests.

If the control that the dominant company has over a company within the group is shared with a limited number of associates or shareholders, who cannot make decisions regarding the activity of the controlled company except on the basis of a unanimous agreement, then we are talking about a concomitant control.

4. Account consolidation by proportional encompassing

Proportional encompassing is a lesser form of global encompassing because, as the name suggests, the encompassing of individual accounts of the consolidated company is reduced to the interest percentage owned by the consolidating company. This vision favours owners, as it is limited to the economic representation of their fortunes.

Proportional encompassing, used for consolidating companies controlled by the group, consists of:

- encompassing into the accounts of the consolidating company of a share corresponding to its participation out of the value of the elements of the balance sheet and of the profit and loss account of the consolidated company. A fraction thereof, represented by the voting rights owned in the own capitals of the consolidated company, is aligned to the elements of the balance sheet and of the profit and loss account of the consolidating company.
- eliminating, in a proportionate manner, of the encompassed share, of mutual operations, of internal results and of titles owned by the consolidating company;
- emphasizing the rights of the group within the reserves and the results of the consolidated company.

As a result of the compensation of the equity shares owned by the consolidating company with the corresponding fraction thereof out of the own capitals of the consolidated company, we have consolidated reserves. The proportional encompassing of the balance sheets of companies of common interest refers to calculating each active and passive role of the consolidated company, according to the degree of participation, represented by the owned equity securities, taking into account the fact that the operations between the consolidated companies have been eliminated. As far as

the result accounts proportional encompassing is concerned, this applies to each expense and income item of the consolidated company, based on the fraction that corresponds to the interest percentage of the equity securities owner company. This is how the emphasising of a business figure realised by the mother-company with third parties is possible, whether it was realised directly or by means of a common interest company, naturally after the elimination of mutual buying-selling operations has taken place.

Proportional encompassing is not provided under the accounting legislation of all countries. For example, American accounting texts do not mention proportional encompassing, the shares in entities controlled in group, where no single participant has majority of voting rights, being accounted by means of the equity method.

The proportional encompassing mechanism requires:

- cumulating the balance sheet elements of a consolidating company with the share of the elements of the balance sheet of the consolidated company, according to the interest percentage belonging to the consolidating company;
- eliminating mutual accounts between the two companies;
- determining consolidated reserves and consolidated results;
- eliminating equity securities in the consolidated company, which are owned by the consolidating company, by reducing the own consolidated capitals by the same amount;
- establishing the consolidated balance sheet.

Proportional encompassing requires the same working stages as for the global encompassing consolidation. Similarly to the case of global encompassing, internal loss is eliminated only when they do not represent a definite value loss, but are due to using transfer prices which are significantly different from the market values. Regarding the elimination of the associate participation in the entity under conjunctive control, the operation is simpler than in the case of global encompassing, because cumulating elements in financial reports is limited to the share of the associate in the actives and debts of

participation association and must therefore no longer outline minor interests.

5. Consolidation of accounts by means of the equity method

If a company is under the marked influence of another company in the group, being a company associated to the group, the consolidation will take place by means of equity, a method which consists of substituting, at the accounting value, the equity securities owned by the dominating company, with the corresponding value from the net situation of the consolidated company.

The marked influence over the management and financial policy of a company is when a company disposes, directly or indirectly, of a fraction at least equal to 20% of the voting rights of that company. Owning 20% of the voting rights constitutes only the presumption of marked influence; in order for it to actually exist, power must be effectively manifested by making decisions.

The equity method may be also applied when the structure of the accounts of companies under exclusive or common control makes it impossible for the global or proportional encompassing methods to be applied. The equity method used to consolidate accounts of companies where the consolidating company has a significant influence or owns strategic investments lies in substituting the cost of acquisition of equity owned by the consolidating company with the share of the own capitals of the consolidated company and in outlining the ownership by the group of the reserves and results registered by the consolidated company.

In the speciality literature, the equity method makes the object of two definitions, involving two separate ways of registration:

- the substitution method, by which one can substitute the equity securities in the balance sheets of the dominant company, at the level of the acquisition cost, with the share of the own capitals (comprising the result as well) of the issuing company, which belong to the dominant company. The difference between the share of the own capitals and the acquisition cost for the

equity securities is reflected in the reserves and in the consolidated results.

- the equilibration method, which consists in cumulating, at the value of equity securities reflected in the balance sheet of the dominant company at the acquisition cost, of the eventual share of the undistributed profit belonging to the dominant company or the diminishing of the value of equity shares with the eventual share of the loss belonging to the dominant company, as well as diminishing it by the part of the result which was distributed to the dominant company.

For both methods, the share of the result of the company's activity that the equity method is used on is mentioned on a different line of the result account. No matter the method used, the result, the re-estimated value of the equity securities belonging to the consolidated company, is the same. Unlike the previous consolidation methods, this does not require a sum of the balance sheets and of the profit and loss accounts.

The equity method refers to undergoing a smaller number of stages than in the case of global and proportional encompassing, assuming that the initial level of the cost for which the participation has been accepted be adjusted at the end of each financial activity, depending on the modifications suffered by the own capitals after the acquisition of the company.

As far as the balance sheet is concerned, the equity method consists in directly substituting the accounting value of the equity securities owned with the sum of the part with which they are equivalent in the own capitals of the issuing company. The equity method therefore consists of correcting the value of the equity securities in the balance sheets of the owning company, correction which takes into account the share of the latter in the own capitals of the associated company, at the date of acquisition and in the ulterior results.

In the balance sheet consolidated based on the equity method, the equity securities owned by the mother-company are re-evaluated based on the values which appear in the balance sheet of the consolidated company, the benefits accumulated by the mother-company in the consolidated company being shown separately. The main stages which take place in order to apply the equity method on the balance sheet are:

a) replacing, in the actives of the consolidating company, of the accounting value of the equity securities owned in the consolidated company, with the part which belongs to the consolidating company from the own capitals of the consolidated company by means of the equity method.

b) on the other side, the difference between the due part of the capital and the reserves of the company that are being equalled, reported to the accounting value of the titles, is transferred on the consolidated reserves, and the part of the consolidating company from the result of the company being equalled is reflected by means of the consolidated result.

By using this method, at the level of the consolidated balance sheet we outline the following particular items: equity securities, acquisition differences, consolidated reserves, consolidated result.

6. Conclusions

Unlike the global and proportional encompassing methods, in the case of the equity method actives, debts or own capitals, incomes or expenses are not taken over, as the substitution is made directly at the level of own capitals and of results. We must also mention that including the results of associated enterprises in the results of the investing company may often prove difficult, due to the limitation or impossibility of obtaining the needed financial information. The investor, without being in control, but merely having a notable influence, may not have access to the accounting records or mandatory or interim financial situations at a given date. IAS 28 requests that when applying the equity method the most recent available financial situations of an associated company be used. In the situation where the most recent available financial situations of the associated company are drafted at a different date than the date of closure of the financial activity of the group, interim financial situations for that date must be made. In practice however this may be impossible to do, in which case one must use the most recent financial situations of the associated company, under the condition that the difference between the reporting dates be consistent from an accounting period to the other.

Perimeter of Consolidation – Essential Element for Account Consolidation

Guni Claudia Nicoleta
“Spiru Haret” University, Constantza
borsanclaudia@yahoo.com

Abstract

The account consolidation starts with establishing the perimeter or consolidation, by means of which the group identifies and localizes itself in the national and/or international economic territory, which is established based on calculations on the control percentage of the mother-company on the entities which are to be consolidated. The processing of individual financial statements transmitted by the entities in the perimeter of consolidation is done in an organized manner, depending on the structure chosen by the group management, be it centralized or decentralized. Demarcating the accounting limits of a group or, in other words, determining the consolidating perimeter is the first step of the consolidation process. The consolidation perimeter encompasses all entities retained for drafting the consolidated financial statements.

Keywords: exclusive control, joint control, significant influence, interest percentage.

J.E.L Classification: G3; G32; G34

1. Introduction

Internationally there are many views regarding the consolidation perimeter, differentiated by the entities composing said perimeter.

Thus, in the USA the consolidation perimeter refers to the mother company and its subsidiaries. This restrictive vision regarding the contents of the consolidation perimeter is based on the principle according to which the consolidated financial statements need to only encompass the assets and liabilities controlled by the mother-company.

In the countries where proportional encompassing and the equity method are

used as consolidation means, the consolidation perimeter is composed of:

- the consolidating company which, in its turn, may be a mother company, an associate in an entity with joint control or an investor in an associated entity;
- the consolidated companies, that is the companies upon which the consolidating company exercises control, joint control or significant influence.

This more extended vision regarding the contents of the consolidation perimeter is to be found in the continental European countries.

2. Establishing the consolidating perimeter

The consolidating perimeter is formed by all the companies undergoing consolidation. The criteria which need to be taken into account when demarcating the consolidation perimeter are varied, but may fall under two notions:

- a restricted notion, according to which the consolidating perimeter shall only encompass those companies upon which the mother company exercises exclusive control. This notion is typical for the United States of America.
- a more extended notion which includes in the consolidation perimeter not only the exclusive control companies, but also those which undergo significant influence or joint control. This notion is typical for the European space.

International standards include in the consolidating perimeter both those entities with exclusive control, and those which undergo joint control by the mother-company together with other associates. The entities associated to the group are considered long-term investments, being recognized and evaluated as such within the consolidated financial statements.

The consolidation perimeter must not encompass those subsidiaries which were

bought exclusively for reselling within 12 months since their acquisition. This is the subsidiary non-consolidation exception currently stipulated under the revised version of IAS 27 "Consolidated and Separated Financial Statements".

The International Accounting Standards do not refer to insignificant elements, therefore taking into account the provisions of the General Framework regarding the drafting and presenting of financial statements and of the IAS 1 "Presentation of Financial Statements", the consolidation of subsidiaries should be done according to a significance threshold. Establishing this significance threshold may refer to criteria such as the turnover, the number of assets etc, and is a consequence of the optimization of the cost/benefits ratio as far as the financial-accounting information presented in the consolidated statements.

Applying the IAS 14, "Segment Reporting", makes it impossible to exclude a subsidiary from the consolidation perimeter just because its scope of activity is fundamentally different from that of the rest of the group. On the contrary, segment reporting of the financial statements can only result in better information of consumers.

Not including subsidiaries in the consolidation perimeter requires presenting some information within the explanatory notes attached to the consolidated accounts. This information refers to:

- the subsidiary which is not consolidated;
- synthetic financial data presented either individually or grouped for the non-consolidated subsidiaries, including the total value of the assets, liabilities, incomes and profits or losses.

The date of entry of an entity in the consolidation perimeter is the date upon which the investor buys the assets of said company, the date of taking over control or significant influence if the acquisition took place in several successive stages or the date stipulated under the takeover contract, if this is different from the date of assets transfer.

The date of exit of the consolidation perimeter is the date when the consolidating entity takes control or significant influence over the priority consolidated companies.

In the analysis of the consolidation perimeter we must take into account the following three dimensions:

- contents of the perimeter (legal and financial demarcation of the group);
- area of implication or influence of the group which is however excluded from the consolidation perimeter;
- the way in which the complex group thus constituted is ordered and organized.

The consolidation perimeter may suffer a series of internal modifications, respectively mergers of the consolidated entities or "subsidiarisation" of the activities. Acquisition or creation of new subsidiaries, cession and liquidation of the existing ones are the expression of the group strategy regarding the external growth, the extension of the geographic perimeter. They reflect the interest centres of the group or, on the contrary, the sectors they abandon or that they prefer to value at the right moment. The behaviour of the group is also reflected by the frequency and the importance of these operations, pursuing a series of factors such as localizing the movements in the centre or at the limits of the consolidation perimeter and influence analysis.

The variations of the consolidation perimeter reflect, on the other hand, the opportunism manifested by the group and its will to gain financial optimisation. Crossing some consolidation thresholds may have as effect:

- the onset of financial integration (where legislation allows it), with a possible effect tax reduction for the group (in the case where the group alleges losses of an entity);
- the inclusion in the consolidated accounts of a "bountiful" net treasury, or, rather, abandoning the consolidation plans for an entity with high external indebtedness.

The economic involvement perimeter includes all those entities in which the group has minority stakes, non-consolidation. By means of these participations, the group has proved its interest in it, amiably or with hostility. Frequently these minority participations represent the foundation of future agreements for developing joint subsidiaries, respectively for acquisitions which are to enlarge the group's perimeter.

The consistency of the consolidation perimeter is diversely structured, according

to the manner of organisation decided for the management of the group's internal diversity and wealth. The main options chosen by the groups of societies are prioritizing legal entities, making operational divisions and geographic divisions.

Operational divisions regroup subsidiaries which activate within the same sector. They may be grouped according to the market they act on, the clients they address and the technological flow. Organization of operational divisions is what therefore defines the specializations and main areas of activity of the group as well as the synergies that the group is pursuing in its different entities.

Choosing the internal organisation of the consolidation perimeter and prioritizing the functions within it reflects the strategic options of the group on the short run and on the long run. For establishing the consolidation perimeter we mainly refer to the control or influence exercised by the mother-company on its entities.

The control, as far as the International Accounting Standards are concerned, is the authority of managing the financial and operational policies of a company, in view of obtaining benefits from its activity.

3. Joint Control

Joint control represents the division of control, agreed upon by contract, over an economical activity, asset or entity, without one of the associates being able to make a decision when there is no mutual consent. The contract may stipulate that not every decision should be subject to mutual consent. For less important decisions, there is the possibility of a unilateral decision of the representative appointed by the investors to handle the partnership. Such a provision is meant to ensure the proper functioning of the joint venture.

IAS 31 "Interests in Joint Ventures" states that joint control exists only when:

- it is based on a contract;
- strategic financial and operating decisions relating to the activity require the unanimous consent of all the associates.

IAS 31 refers to three forms of joint venture:

- jointly controlled operations;

- jointly controlled assets;
- jointly controlled entities.

Because it involves setting up a new entity, the jointly controlled entity is the only one of the three types of joint ventures that falls within the scope of consolidation. Such an entity operates like any other company. Thus, the joint activity takes place within a legally independent entity, which controls its own assets, incurs expenses and secures income. Furthermore, it enters into contracts on its own behalf and provides the funding necessary to carry out its own work.

Several theories have been outlined regarding the holder of control within such an entity.

The first perspective is that of a "managerial company", according to which the main role in managing the entity belongs to the Board of Directors. As a result, those who have the right to elect the Board of Directors, to dismiss its members or to enforce decisions on it are those who have control over the entity. Exercising such control would require, theoretically, being the majority equity holder.

A second perspective is that of a "share-holding company", which prioritises existing investors and their role, based on the analysis of the results from a certain period, without the possibility for the shareholders to influence the decision making; this is achieved by appointing someone to work with the managers and continuously monitor them.

Managerial or share-holding based control must be judged in close relation with the Articles of Incorporation of the company, as well as the local laws, thus it is required to take into consideration the percentages of participation or the positions within the entity of each associate, the company management agreements, the cumulative voting system, the existence of shares with different characteristics, use of proxies, powers of attorney etc.

4. Exclusive Control

Exclusive control is divided into de jure exclusive control and de facto exclusive control. De jure exclusive control occurs when the mother company owns, directly or

indirectly, more than 50% of the voting rights of the subsidiary. De facto control is represented by situations in which, although the mother company owns half or less of the voting rights, in accordance with IAS 27 "Consolidated and Separate Financial Statements", it still has specific authority over the subsidiary.

These situations are:

- the mother company owns more than half of the voting rights based on agreements with other investors;
- a statute or contract provides the mother company power to govern financial and operating policies of the subsidiary;
- the mother company has the authority to appoint or replace a majority of the Board of Directors or of an equivalent body;
- the authority to gather the majority voting rights on the Board of Directors or another equivalent governing body.

5. Significant Influence

IAS 28 "Investments in Associates" defines the significant influence as the power to participate in decisions regarding the financial and operating policies of an entity which was subject to investing, but not to exercise control or joint control over those policies. This is manifested by the ability to:

- be present on the Board of Directors or another equivalent governing body;
- participate in the political decision-making process;
- make significant transactions with the entity in question;
- appoint the management personnel;
- provide essential technical information.

It is assumed that an investor has significant influence when he/she holds, directly or indirectly, at least 20% of the voting rights. This threshold is not indicative though, because the presence or absence of significant influence can be established independently of voting rights.

Establishing control and significant influence should not be limited to existing voting rights. IAS 27 "Consolidated and Separate Financial Statements" and IAS 28 "Investments in Associates" states that, in assessing control and significant influence,

we must take into account the potential voting rights that are currently exercisable or convertible. Potential voting rights, that are exercisable at a future date or whose exercise or conversion depends on a future event, should not be taken into account when assessing control.

Accounting regulations in our country do not specify an explicit definition of the scope of consolidation, but it relates to the mother company, the subsidiaries and the entities upon which the mother company and subsidiaries exercise joint control and significant influence.

Also, if an entity included in the consolidation manages another entity, together with one or more entities not included in the consolidation, the respective entity must be included in the annual consolidated financial statements, consolidation is therefore performed in proportion to its capital rights, held by the entity included in the consolidation.

In addition, if an entity included in the consolidation exercises significant influence over operating and financial policies of another entity, the participation interest thereof shall be present in the consolidated statements under "Equity Assets".

6. Conclusions

Accounting regulations in our country state that an entity may be excluded from consolidation when its inclusion does not add to the faithfulness of the view of the assets, liabilities, financial position and profit or losses of the entities included in these financial statements, considered as a whole. If two or more entities, considered as a whole, are significant in presenting an accurate view, they must, however, be included in the annual consolidated financial statements. The accounting regulations of our country, unlike international accounting standards, provide more opportunities for exclusion from the consolidation perimeter. In our opinion this situation gives mother companies more "grooming" opportunities for their consolidated financial statements, by excluding from the consolidation perimeter the entities that have losses under the pretence that they are insignificant, their

consolidation is expensive or their shares are held exclusively for sale.

Abstract

Romania was confronted in recent years with an unprecedented increase of indebtedness, be it private or public ones, leading to historical highs. Unfortunately, excessive leverage in recent years has multiple effects, some are present already other latent, but many of these will have manifestations in the near future or distant one.

Keywords: debt, debt service, currency reserves.

J.E.L. Classification: G21.

1. Introduction

One of the consequences of the financial and economic crisis, present in Western economies since 2007 and in Romania in the last months of 2008 was unprecedented increase of indebtedness be it private or public ones. Romania does not deviate from this scenario, both components of debt in recent years experienced historical heights. Unfortunately, excessive indebtedness in recent years has multiple effects, some present already other latent, but many of these will have events in the near future or distant one. This Communication aims to present the current situation of Romania's foreign debt in recent years and some of its consequences.

2. Developments in external debt

The first decade after 2000 meant for Romania in terms of overall economic expansion, economic and political

normalization, the accession to the EU, easy access to foreign markets and increasing capital flows entering the country.

Table No. 1. External debt balance (billion euro)

Year	Mid-term and long-term external debt	Direct public debt	Loans from the IMF (MFP)	Publicly secured debt	Publicly unsecured debt	Mid-term and long-term nonresident deposits	Loans from the IMF (NBR)	Short-term external debt	Total external debt
2007	38,5	8,2	0,0	2,0	25,1	3,2	0,0	20,2	58,7
2008	50,7	9,2	0,0	1,7	34,2	5,6	0,0	20,6	73,1
2009	65,7	12,0	0,0	1,5	39,3	7,2	5,7	15,4	81,2
2010	72,9	16,2	0,0	1,7	37,7	8,2	9,1	19,5	92,5
2011	75,6	19,5	2,3	1,5	35,9	8,5	10,2	23,0	98,6
2012 aug.	77,2	20,9	2,4	1,4	37,5	7,7	9,8	20,8	98,0

Source: NBR - Press Releases "Balance of payments and external debt" www.bnro.ro and author's calculations

The last years of this decade 2001-2010 have increased external indebtedness of Romania, in the context of the global financial crisis, when our country was forced to turn (in 2009) to a triple financial shield from the IMF, IBRD, EU contractually of about 20 billion euros, but factually of about 17 billion euros [1].

Here are some of the features of

Romania's foreign debt, as currently presented (Table 1):

- foreign debt reached nearly 100 billion in the past five years, almost doubling its volume;
- term structure improved significantly, especially in recent years, which means lower short-term risks. Thus, if at the end of 2007, the short-term debt represented about 40% of the total, at present, it has a 20% share;
- external public debt and quasi-public debt (foreign debt guaranteed by the state) has a low share in total of about 35%, but growth is worrying, it rose from 10 billion euro in 2007 to about 35 billion euros in August 2012 (including amounts from the IMF) [2];
- the most voluminous component of foreign debt has been and continues to be the private type. Thus, mid-term and long-term external debt, non-guaranteed by the state and medium and long term deposits of nonresidents were 28 billion euros in 2007 and in August 2012 had reached 45 billion euros, the share of these components in total external debt is relatively stable, slightly oscillating around 45%. It should be noted that to these values are also added most of the short-term external debt, which also originated in the private economy;
- from 2009, one of the components of external debt was the debt to the IMF, due to financial shield mentioned above. Debt to the IMF is currently of 12.2 billion euros and is found in the records of the NBR (about 10 billion euros) and the Ministry of Public Finance, MPF (2.4 billion euros).

3. Effects of external indebtedness

By its economic essence indebtedness means repayment of it, sooner or later, any debt must be paid. Using borrowed amounts in activities creative of economic value leads to the debtor being left with a income surplus resulting from the settlement of payments made on account of debt, including afferent interest, and operating expenses. The problem occurs when loans are used for activities that do not create economic value (of consumption financing). In the latter case, financing consumption by means of debt means higher consumption today, financed by debts and a much lower consumption in the future when revenue should be reduced

by the amount of the debts paid (refunded) and the related interest.

Table No. 2. External debt service by components (billion euros)

Year	Mid-term and long-term external debt	Direct public debt	Loans from IMF (MFP)	Publicly secured debt	Publicly unsecured debt	Mid-term and long-term nonresident deposits	Loans from IMF (BNR)	Short-term external debt	Total external debt
2008	12,1	2,1	0,0	0,4	8,2	1,4	0,0	30,2	42,3
2009	11,4	1,4	0,0	0,3	7,4	2,2	0,1	32,7	44,1
2010	14,0	2,0	0,0	0,2	10,0	1,6	0,2	23,8	37,8
2011	14,6	2,3	0,0	0,3	10,1	1,7	0,3	25,0	39,5
2012 aug.	10,3	2,2	0,0	0,1	4,6	2,5	0,9	23,0	33,3

Source: NBR - Press Releases "Balance of payments and external debt" www.bnro.ro and author's calculations

Obviously, increased volumes of Romania's foreign debt entailed increases in debt service (Table no. 2). Maximum of debt service was reached in 2009, with a value of 44 billion euros, a third of our country's GDP. In recent years, external debt service fell slightly under 40 billion euros, as a result of external debt consolidation, in terms of increasing medium and long term component and the contraction of the short-term one. In fact, external debt service resources means eliminating ventilation, austerity, unemployment, wage and revenue cuts and thus a decrease in consumption. Effects that, in recent years, more and more are beginning to feel and that the oldest of Romanian recall of 1985-1990, when they manifested more acutely.

Let's further see (Table no. 2) that about 60-70% of the external debt is the result of short-term external debt (meaning that of private economy) and if we add the medium and long term components of it, a volume of 37 billion euros is reached, over 90% of total service. Public component of foreign debt service has been reduced by about 3 billion in recent years, but will grow in recent years,

due to the fact that many public loans contracted in recent years reach maturity. However, 3 billion euros, of barely 40 billion euros, as are all revenues, means a consistent public effort.

Table No. 3. Current account balance by components (billion euros)

Year	a) Trade balance (goods)	- exports (FOB)	- imports (FOB)	b) Services, net	c) Incomes, net	d) Current transfers, net	Current count balance (a+b+c+d)
2007	-17,7	29,4	47,1	0,2	-4,4	4,9	-17,0
2008	-19,1	33,7	52,8	0,7	-3,7	6,0	-16,2
2009	-6,8	29,1	35,9	-0,4	-2,1	4,1	-5,2
2010	-7,6	37,4	45,0	0,4	-1,9	3,6	-5,5
2011	-7,5	45,0	52,6	0,4	-2,4	3,5	-6,0
2012 aug.	-4,8	29,7	34,5	0,5	-1,2	2,5	-3,1

Source: NBR - Press Releases "Balance of payments and external debt" www.bnro.ro and author's calculations

Because most of the external debt service holds private sources, the country's trade balance and current balance has to be examined, meaning the contribution of the private economy and private agents in the creation of external financial resources (Table no. 3). Romania's trade balance for goods witnessed a considerable improvement in the sense of a decrease of more than 3 times of the deficit from 18 to more than 5 billion euros, and this in the conditions of the positive trend for both exports and imports. Specifically, dynamic exports grew much larger than that of imports, meaning that Romanian products exported were becoming more competitive (aided also by the leu, increasingly weaker), but through imports the supply of Romanian economy continued with major products and with modern equipment for businesses. But the effect remains, negative balance (deficit) of the trade must be covered.

The services balance was in surplus (Table no. 3), reducing the deficit in the balance of goods, but the effect was minor (less than half a billion euros). Foreign

income balance has had and continues to have a negative impact, the deficit of foreign income paid and received by Romania (Table no. 3) was of about 4.5 billion euros in 2007, then decreased and stabilized in recent years at around 2 billion euros, but it is important that it be paid. Current transfers were permanent surplus component of the current account, and were used to pay (cover) other deficits, but, unfortunately, since 2008 and by 2012, they almost halved, decreasing from 6 billion euros to just over 3 billion euros. In fact, we know that many domestic workers abroad, due to growing unemployment and recession in the countries where they work, deliver less and less money home.

Finally, accumulating balances above, results the current account balance, which although much smaller, still remains poor, meaning still to be covered. Current account balance deficit, therefore of the financial effort of covering it being from 17 billion euros in 2007 to 5-6 billion euros in recent years (Table 3).

Cover of the current account deficit was made in recent years by foreign capital inflows: foreign investment and foreign debt component increases. In recent years, however, foreign investments in Romania decreased from about 10 billion euros in 2008 to about 1.5, at most 2 billion euros in recent years [3]. If foreign investments remain at this level, further increases in external debt will result, of about 3-4 billion euros per year, plus interest. Another possibility for payment of the balance of current account deficit, would be paying with the country's international reserves (if we can not attract new foreign investments and financing conditions in external markets will be more difficult and therefore contracting new debt would be very expensive).

In this context, the country's foreign reserves must be examined. From table no. 4 it is observed that in August 2012 international reserves stood at about 40 billion euros (plus a stock of currency of approximately 3-6 billion euros in MPF, but about which there is no official information, existing some managers' statements in this regard and an obligation imposed by the IMF, regarding the existence of a buffer of about 5 billion euros from MPF to pay external debt maturing from 2012).

Nearly 3 billion euros are in commercial

banks, so less than 10% and anyway this amount is not part of official foreign exchange reserves (but may be used for external payments). At NBR, (Table no. 4) Romania’s reserve manager, are found about 37 billion euros, of which slightly more than 4 billion euros in gold, increasing (by more than double), due to its growing quotations on profile markets. It is unlikely for Romania to sell gold to pay foreign obligations (especially that such action would be suicidal in the context of a fairly strong conservatism of the Romanians). Anyway, the size of this component is price given and in the future, it may fall.

Table no. 4. Reserve assets (foreign reserves and gold reserves) (billion euros)

Year	NBR – Monetary gold	NBR – Foreign reserves	NBR total	Commercial banks	General total
2007	1,9	25,3	27,2	2,5	29,7
2008	2,0	26,2	28,3	2,5	30,7
2009	2,6	28,3	30,9	3,6	34,5
2010	3,5	32,4	36,0	3,5	39,4
2011	4,1	33,2	37,3	3,3	40,6
2012 aug.	4,2	33,0	37,1	3,3	40,4

Source: NBR - Press Releases "International Reserves", www.bnro.ro and author's calculations

About 33 billion euros remain the currency reserve of Romania. We notice that (Table no. 4) since 2010 it has never changed, and since 2009 the IMF amounts joined it (more than 10 billion euros) and should be of 38 billion euros. Therefore Romania's foreign exchange reserves fell by almost 5 billion euros in recent years. In fact, the phenomenon of foreign exchange reserves’ decrease is visible in recent years also statistically, when there are practically no sources for growth. To be noted that a decreasing currency reserve means less potential to generate solvency and ability to pay.

4. Developments in external payments

A prediction of the evolution of Romania's payment obligations is quite risky. If trends of the past years will remain (although there are more pessimistic prediction) it is sure that:

- current account balance will remain negative;

- foreign investments levels will be modest, at least in the last two years;
- entries from European grant funds, which do not generate debt [4], but technically, may serve to settle prior maturities will remain modest despite the huge potential [3].

The only certainty for the next period is that of the maturity of payment obligations of the Ministry of Finance and central bank, resulting in financial protection package from the IMF, IBRD, EU, granted in 2009-2011, but also from other funding the state received (Table no. 5).

Table no. 5. The payment obligations of the Ministry of Public Finance and National Bank during 2012-2016 (billion euros)

Year	Ministry of public finance – IMF loan	Ministry of public finance - Eurobonds	Ministry of public finance – Bonds in euro in Romania	Total Ministry of public finance	NBR – MFI loan	General total
2012	0,1	0,7	0,8	1,6	1,5	3,1
2013	1,0	0,0	1,8	2,8	3,9	6,7
2014	1,0	0,0	0,9	1,9	3,7	5,6
2015	0,2	1,0	0,5	1,7	1,3	3,0
2016	0,0	1,5	0,0	1,5	0,1	1,6
Total	2,3	3,2	4,0	9,5	10,5	20,0

Source: Ionut Dumitru, Reassessment growth model in Romania - lessons and consequences of the crisis, the NBR conference "Financing the national economy", Bucharest, October 29, 2012, www.bnro.ro

Specifically, during 2012-2016, maturing loans, totaling 20 billion euros, spread relatively evenly between NBR and MPF (Table no. 5). Peaks are 2013 and 2014, the annual payment amounts are around 6 billion euros. Source of payment of which is:

- either stocks or currency reserves existing at the central bank or MPF, which means lower external debt, but decrease of financial resources in the economy;
- or refinance them by contracting new debts, which means maintaining external debt, perhaps increasing it with new interest, but maintaining funding resources in the country's economy.

5. Conclusions

As I previously said predictions are difficult to make because of numerous internal and external uncertainties.

However, we will try to estimate the effects of debt payments on Romania's international reserves that we previously talked about.

*Table no. 6. Effect of payment of the liabilities of the Ministry of Finance and the central bank on foreign reserves *) (billion euros)*

Year	NBR currency reserve at the beginning of the respective year	NBR currency reserve + gold at the beginning of the respective year	Repayments of loans - total	NBR currency reserve after repayment of loans	NBR currency reserve + gold after repayment of loans
2012	33,2	37,3	3,1	30,1	34,2
2013	30,1	34,2	6,7	23,4	27,5
2014	23,4	27,5	5,6	17,8	21,9
2015	17,8	21,9	3	14,8	18,9
2016	14,8	18,9	1,6	13,2	17,3

*) While there will be no entries in the foreign reserves from other sources.

Source: BNR data and author's calculations

In the first scenario, call it optimistic, we watched the effect of the payment of the obligations of the Ministry of Finance and the central bank on the foreign exchange reserves given that no entries will be made in the foreign reserves from other sources (on the premise that they will not be refinanced by new external debt). The consequence would be a decrease in foreign exchange reserves from 33 billion euros at present times to 13 billion euros after paying the obligations, meaning that we will retain only 40% of the current reserves (Table no. 6);

In the second scenario, call it pessimistic, we followed the cumulative effect of payment of the obligations of the Ministry of Finance and central bank and cover the current account balance in conditions where there will be no entries in the currency reserves from other sources, the current account balance will maintain at the value of

2012 and is not covered from other sources (on the premise that they will not be refinanced by new foreign debt). The consequence would be a decrease in foreign exchange reserves from 33 billion euros at present times to 7 billion euros after paying them, that means we will retain only 20% of the current reserves (Table no. 7);

*Table no. 7. Cumulative effect payment of the liabilities of the Ministry of Finance and central bank and current account balance coverage of foreign reserves *) (billion euros)*

Year	NBR currency reserve at the beginning of the respective year	NBR currency reserve + gold at the beginning of the respective year	Repayments of loans - total	Current account balance (estimation)	Total to cover	NBR currency reserve after repayment of loans	NBR currency reserve + gold after repayment of loans
2012	33,2	37,3	3,1	6,2	9,3	23,9	28
2013	23,9	28	6,7	6,2	12,9	17,2	21,3
2014	17,2	21,3	5,6	6,2	11,8	11,6	15,7
2015	11,6	15,7	3	6,2	9,2	8,6	12,7
2016	8,6	12,7	1,6	6,2	7,8	7	11,1

*) While there will be no entries in the foreign reserves from other sources, current account balance will remain at the 2012 value and is not covered from other sources.

Source: BNR data and author's calculations

Foreign exchange reserves decrease with volumes listed in the two scenarios is also a depreciation of the national currency, a lower capacity of access to foreign markets and, not least, a lower capacity to finance imports, restrictions of activity in enterprises, bankruptcies, unemployment etc.

From table no. 8 there is a pronounced sensitivity of the leu to movements in foreign exchange reserves. In fact, we find that the greatest depreciations occurred when foreign reserves showed the lowest relative growth. It is clear that under decrease of reserve depreciation will be more accentuated. For example, in the first months of 2012, in the conditions of reducing reserves by only 0.2 billion euros, the quotation lost 5% comparative to the previous year.

Table no. 8. Correlations between foreign reserves and currency depreciation between 2005 and 2011

Year	NBR Currency reserve (billion euros)	EUR - medium	EUR – end of period	Appreciation / Depreciation of medium quotation (%)	Appreciation / Depreciation of quotation at the end of the priod(%)	Currency reserve modification (%)
2005	16,8	3,62	3,68	-	-	-
2006	21,3	3,52	3,38	2,7	8,0	26,9
2007	25,3	3,34	3,61	5,3	-6,8	18,8
2008	26,2	3,68	3,99	-10,3	-10,4	3,6
2009	28,3	4,24	4,23	-15,1	-6,1	7,9
2010	32,4	4,21	4,28	0,6	-1,3	14,6
2011	33,2	4,24	4,32	-0,7	-0,8	2,3
2012 Aug.	33,0	-	4,53	-	-4,9	0,2

Source: NBR data and author's calculations

Also, there are a number of social effects associated with the decline in living standards imposed by the leu depreciation and are not excluded social and political movements.

Another solution is to fully refinance foreign debt on the international financial markets, which means an increase in external public debt by 20 billion euros. Thus, it would be reached the external public debt of 55 billion euros, which means an increase of the external public debt to 30% from GDP to 46% and strongly approaching the EU convergence barrier of 60% [5].

Perhaps the solution reached will be an intermediate one, between the two extremes considered, which is partial use of foreign reserves to pay a portion of foreign obligations due in the coming years, but also partial refinancing of these components of matured external debt. It remains to see the proportions of the two measures that authorities will opt for.

The Responsibility for Producing and Validating Financial-Accounting Information

Istrate Alina-Mariana

“Alexandru Ioan Cuza” University, Faculty of Economics and Business Administration,
Iasi

alina_mariana2004@yahoo.com

Abstract

The process of decision-making and carrying out of economic transactions is not possible in the lack of accounting information. In order to be useful, it has to be drafted according to the requirements of legal and ethical provisions. In this context, the role of accounting professionals is brought into play as far as the drafting, publication and validation of financial-accounting information are concerned.

This approach aims at a thorough study of the problematic of accounting truth and the true and fair view, following the approach of aspects related to the responsibility of accounting professionals with respect to the assurance of information quality.

We will have in view the production and communication of information, as well as its validation by means of auditing.

The results of research highlight the fact that the responsibility for producing faithful (real) financial-accounting information which is useful to the decision-making process pertains to the taking on of professional responsibility, the observance of legal framework and professional deontology norms, not to mention the disinterested application of professional experience and refinement.

Key words: accounting truth, true and fair view, audit, professional responsibility.

J.E.L. Classification: M41, M42.

1. Introduction

Accounting grasps and reflects economic phenomena, facts and activities, establishing a relation of reciprocal influence with the environment. It records events involving economic agents and provides images of their

economic situation. The information made available to the public has consequences on the actors of economic and social environment. Hence the *social function of accounting* which meets the need of informing users.

The behaviour of the accountant, accounting expert and auditor has to be a responsible and ethical one. The carrying out of tasks need not be influenced by interests and pressure exerted by customers. Moreover, accounting professionals have to be socially responsible as their work is important for society and may influence its well being.

Accounting economists are required to keep the history of an entity's economic activities in their records. The accuracy of their endeavour depends on their professional training, experience and moral values.

Auditors are the ones that come and check accounting truth, thus diminishing or even eliminating the degree of distrust and the risks undergone by the reality of financial-accounting information. Audit is the activity of examining accounting products for financial auditors to express a professional opinion on financial statements according to audit standards harmonized with international audit standards adopted by the Chamber of Financial Auditors of Romania.

Both the activity of auditors, experts and financial consultants and accountants needs to be carried out to a maximum extent of professional and social responsibility. In this sense, professional bodies responsible for the regulation and good conduct of accounting activities set and promoted strict technical, ethical and moral rules.

Taking on professional responsibility, both civil and legal and act on behalf of public interest is a distinct feature of the accounting profession [1]. Therefore, each auditor, accounting expert, financial

consultant, certified accountant and accountant in general is bound to respect *The National Ethical Code* of the profession. The totality of norms and ethical usages applicable to the exertion of a profession bears the name of *professional deontology*. In the case of the accounting profession, it mentions the optimal level of the professional's conduct that is responsible for producing and validating financial-accounting information.

Accounting information is, after all, the compromise between the users' expectancies and the possibilities of the accounting professional to reflect the economic activities of an entity. He has to analyze any threat for ethical values, foresee circumstances and relations that might endanger his principles and, when required, strongly refuse the violation of the profession's fundamentals. These are the *premises that contribute to the assurance of credible information*.

The purpose of this study is to research the way in which accounting information may be as close to economic reality and as relevant as possible for users. In this sense, we consider that the take on and respect of professional and moral responsibility by those entrusted with the task of producing and checking information is extremely significant. By means of qualitative analysis, we will approach a part of the factors that might contribute to the elimination of disloyal information risk.

Along with integrity, objectivity, professional competence and goodwill, confidentiality, professional behaviour, respect for technical and professional norms, independence is the fundamental with the highest importance in recording and reflecting economic truth in the financial statements of an organization.

2. Responsibility of producing financial-accounting information

Accounting records, classifies and regroups information on value movement based on the company's activities [2]. It follows economic aspects and records them in its own language. It issues economic information, influencing future economic events and transactions. In essence, it is an active participant, having an important role and a considerable influence on the social-

economic environment.

The task of organizing modern entities in documents pertains to the accountant. He is responsible for the faithful transposition of economic transactions in book records, using accounts as instruments. He is entrusted for guiding and harmonizing the numbers on the movement of means and resources in an enterprise. Ordered according to certain criteria and following a particular scheme, these figures show the situation of a company at a moment in time, irrespective of its complexity.

The reality of this representation may be sometimes influenced by the managers' personal interests, requirements which may need observing by accounting professionals, as well as legal omissions which allow the manifestation of “creative accounting”. However, quality, responsibility and ethical criteria do not have to be abandoned at all during accounting activities. They are mentioned in a clear manner and comprised in norms to guide and honour this profession with respect.

The accountant does not act in a world of his own, isolated by any possible influences. Clearly, the economic, political, legal and social aspects interfere with the accounting ones. Therefore, the professional has to take on responsibility, show professional deontology and render or aim at rendering a true and fair view without voluntarily omitting certain aspects and being influenced by various interests.

When the information produced proves to be inaccurate with the economic events that generated them, the result of decisions is far from the expected level. Solving this problem is one of the main concerns of the accounting profession nowadays.

The environment in which the accountant acts is susceptible to pressure which would influence evaluations, appreciations and, in the end, the image given. The one that needs to prevent the professional from giving information which favours or misleads some categories of users is *ethics*.

Irrespective of the situation, many people are tempted to avoid what is right by seeking immediate profits obtained with a minimum effort. Both accountants, people responsible for information production and entrepreneurs/managers that impose demands and make pressure on accountants to create

the image which ensures them the obtaining of competitive advantages, have to take into consideration the economic and social costs of the actions made, more than personal benefits.

A rigorous accounting is essential for the efficient drawing of capital and, implicitly, for the credibility that should be the basis of any business [3].

The accounting profession did not always live up to present standards. Unfortunately, some practitioners did not always prove integrity and responsibility towards the other actors of the economic environment.

For those that question, in this context, the role of accounting in economic life, let us try to picture a single day in which accounting was totally abandoned in the field of economy. Order would vanish and chaos, decline and bankruptcy were sanctions that natural laws of economy would apply. A single uninspired decision can take the company out from the profitable area into that of losses or even bankruptcy.

In spite of being an imperfect field, accounting lies at the basis of the decision-making process, by producing and disseminating information of economic use which may diminish or even anticipate risk.

3. Responsibility of validating financial-accounting information through audit

Even the less competent may notice that accounting information is nowadays present in almost all fields of activity, being a mandatory element in business, the decision-making process and progress.

Therefore, it is absolutely necessary for economic information to develop as area, content, efficiency, and, most important, credibility. This is in order to:

- faithfully reflect the patrimonial situation of the enterprise and the recorded results;
- provide the necessary elements to take correct decisions based on real facts and with considerable chances of success.

Information is an abstraction, a product of intelligent knowledge which depends on the level of knowledge and professional training of the one preparing it, as well as his honesty and morality. In order to check the qualitative features and test the goodwill of the one producing financial-accounting information, the *auditor* is brought into play.

After producing and communicating financial-accounting information on a market of information as response to the previously made demand, auditors are requested to certify its quality. They significantly contribute to the creation of a climate of trust between the various actors of the business world and give assurances meant to increase the credibility of information provided by accounting.

The various interests to obtain “the faithful representation of the enterprise” highlighted *the relativity of the true and fair view* and even discussed the usefulness of this concept. *True and fair view and accounting truth are relative as long as accounting norms are incomplete or can be manipulated.* They are incomplete when they do not give solutions for accounting treatment whose operations are not stipulated by accounting practices and policies, in which case the accountant has to use his imagination to face legal, economic or financial innovations for which not enough time is given so as to provide normalized or regulated accounting solutions. Another case is the one presenting insufficient information in norms.

Accounting truth is incomplete because accounting and financial information is generally expressed only numerically, and the appendixes to financial statements are treated superficially and contain too little descriptive information or even lack it.

The instances of “creative accounting” and fraud which may arise also suggest that accounting information is an instrument that can be manipulated by managers due to the alternatives in choosing certain accounting policies.

Most of the cases of this type were discovered as a result of external checks carried out by auditors. Thus, *in identifying accounting inadvertencies, the role of auditors needs to increase so that they are spotted in their initial stage before erroneous information is used.* The syntagm “it is easier to prevent than to cure” also operates in the plan of validating accounting information.

Identification, evaluation and prevention of the major risk in the life of enterprise by means of audit may avoid its bankruptcy and implicitly, the breach of the continuity principle [4]. Hence the responsibility of the auditor who is not only in charge with the

certification of accounting documents, but also with the contribution to assuring the continuation of activity.

More than the issuer of financial information, the auditor needs to make proof of *social responsibility* as he is the one that checks and testifies quality, and users request his services and rely on him.

Social responsibility ought to be regarded as a fundamental ethical principle which is in charge of expressing for “whom” and “what” an action, an expertise/ auditing report are responsible from the perspective of the ethical principle accepted and promoted at the level of society [5].

In matters of accounting profession, the proof of social responsibility lies in quality accounting information in accordance with ethical principles and norms.

4. Premises ensuring proofs of professional responsibility

The neglect of professional and social responsibility seriously damaged the economic environment. We have in view the great scandals that led to real calamities in the business world. *They triggered chain reactions, litigations and social convulsions, failed investment, including thousands of unemployed* [6]. As a result of their analysis, we consider that the main factor which lies at the basis of these events was the lack of professional responsibility of those that performed accounting and auditing missions. If they had carried out their activity in a responsible manner, they would have applied ethical and moral principles imposed by the standards in use and these disequilibria would not have been reached. Their non-application generated economic and financial problems worldwide.

In order to avoid the occurrence of similar events, it is very important to observe ethical principles and norms, as well as the take on of professional responsibility.

To ensure the necessary premises to professional responsibility and test its take on, the following aspects are required:

- Accounting professionals need to observe professional and technical norms issued by regulatory and control bodies in the field. They have the duty to respect the customer’s instructions with care and to the extent to which they are compatible

with the demands of integrity, objectivity and independence. Moreover, they have to show competence, impartiality, ethics and honesty in meeting professional obligations [7].

- In order to ensure high quality professional services for the public interest, expert accountants need to observe the provisions of *The National Programme of Continuing Professional Development* drafted by The Body of Expert and Licensed Accountants of Romania (CECAR) in accordance with *The Professional Standard no. 38* [8] established on the basis of *The International Standard of Education IES 7* issued by the International Federation of Accountants (IFAC).
- Besides seeing to the observance of ethical and professional norms, professional bodies need to improve the procedures of *quality control* applied to the activity of accounting practitioners and carry out actions of awareness to determine the take on of responsibility towards this profession and the field of work.
- Both accountants and auditors dispose of standards, accounting norms and procedures established by regulatory bodies guiding their activities. At the same time, legislation gives a particular role to professional reasoning. Despite its importance in the field of production and dissemination of information, it is essential in the carrying out of audit activities. *The way of use and principles that guide it are certainly a proof of professional responsibility shown by the accounting professional.*
- The provision of correct information is the result of a competent professional service.
- Social responsibility is a goal and an important premise of modern business. For the accounting profession, this is not only the fulfilment of obligations towards the demander of this service, *but also for all the actors involved in economic life.*

If professional responsibility first relates to competence and the respect of professional norms, professional deontology is centred on ethics which abides us by the observance of that norm’s spirit.

Conclusions

The ones entrusted with the production of financial-accounting information, as well as auditors responsible for the assurance of its quality and fidelity are in charge of contributing to the creation of a climate of trust between the various protagonists of the business world and to give assurances meant to increase trust in financial information.

Although they are active actors on a market – the information market, the purpose of accounting professionals is not to sell their product (namely financial-accounting information). Their aim is to make all the necessary efforts to grasp as faithful as possible and in an intelligible manner with the observance of the regulatory norms, the substance of economic transactions in a company. Only in this way users may be convinced that they dispose of all the right data when taking an economic decision. At the same time, it is also the way that ensures the greatest chances of success, a necessary premise in boosting business and economic development.

Regulatory bodies of the profession provide the legal framework necessary to ensure the true and fair view of the company's economic events. Where there are no such provisions, ethics and morality have to guide and ensure the correct and disinterested application of professional reasoning. For this purpose, we believe that the continuing training of professionals is necessary, as well as the supervision of their activities by especially appointed professional bodies.

We believe that “to be responsible for one's actions” is something learned and assumed through education. Although present in human beings, social responsibility comes into force when they see the implications of an action.

If we consider the social function exerted by the accounting profession, the accountants' responsibility for the way in which they carry out their activity and the consequences of their work on the other actors of the social and economic environment, has to be one of maximum commitment.

Both professional and ethical responsibility towards society forces business people and professionals in all fields,

respectively, to do what is right, correct and equitable, irrespective of the existence of a legal framework for the regulation of these actions.

The Financial-Accounting Communication and Affiliated Informational Risk

Istrate Alina-Mariana

“Alexandru Ioan Cuza” University, Faculty of Economics and Business Administration,
Iasi

alina_mariana2004@yahoo.com

Abstract

The requirements of the modern society called forth the material assets in favor of immaterial ones. We are especially making mention of information. These represent the basement of any decision, and consequently its success or its failing rests on the quality of the creation and communication process, as well as on the associated inevitable risks.

The horizon of the implications and of the profitableness that the financial-accounting information can draw in is vast. The elaboration process of the financial statements, bearing beneficial data, is not always a degage and an ethic one.

Although users are in need of and ask permanently for financial-accounting information, the confidence in the truthful reflection of the economical reality is quite diminished.

In this context, the present study sets itself to tackle the informational risk, an extremely important factor that has to be taken into consideration by the economic deciders.

Keywords: financial-accounting information, financial communication, true and fair view, informational risk, audit.

J.E.L. Classification: M41, M42.

1. Introduction

Expertise literature brings up the „social game” status of the accountancy. B. Collase calls accountancy „a social game, with actors and directors, with arbitrators represented by the resorts of normalization and settlement” [1]. In the opinion of Pesqueux [2], this brings new approaches related to equity on the market of information, as well as political, sociological and even philosophical suggestions.

The two quoted opinions hint to the usability of the accounting „products”, meaning of the financial-accounting information, for the users. By quality and fidelity, the information determines the success of a decision and consequently, the level of prosperity of the economical and social environment.

Along with its development, through usability, accountancy has become a social property, a critical instrument for being acquainted with the economic universe of the company, of its assets and of its modifications. At the same time, *it represents an intensifier habit of mind for the progress and the social well being* [3].

The facets of accountancy are more than obvious, being treated in the expertise literature. We shall also bear in mind an opinion that points out that *there is a necessity of accountability to redound to the social welfare and make of this world a better place* [4]. Therefore, the necessity for the generation and accounting communication is required, respecting the legal settlements, as well as the ethic and moral directions characteristic to the field. This represents, in our opinion, the first and the most important step of reducing the informational risks whereat users can be exposed.

We are signaling the fact that the status of „game/social property” of accountancy can also have negative connotations. We allude to the possibility of the managers to make use of accounting implements and legislative insufficiencies to manipulate the information and the economic reality according to their own aims. A simple example is the balance sheet, an instrument whereby the accounting truth can be shaped according to the interests of the customers. Hence, managers are able to apply for the elaboration of a balance for

the fiscal institutions, more pessimistic, one for the banks, more optimistic and one for the internal necessities, being also the closest to the economic reality.

If we regard those above mentioned and the fact that the true and fair view presented by the accountancy actually stands for „*a true and fair view of more possible*” [5], we will not be in the wrong if, when we speak about financial-accounting communication, we will also speak about the existence of an associated informational risk. In order to diminish and even eliminate it, we can appeal to auditing of the financial situations that certify the truth delivered through the synthesis documents and accounting reporting. When expressing its opinion, the auditor has to be convinced that the audit financial statements will not delude a cautious user, who is also interested in investing.

Thus, the user is assured that the accounting documents are drawn up respecting the regulatory framework and the professional praxis. This establishes a guarantee that the risks for the report to be inaccurate are minimal.

Research Methodology

The present study aims to be a qualitative one, offering the possibility to formulate some relevant conclusions for the accounting field. To that, we bear in mind the analytical and critical approach on the opinions already stated in the expertise literature and the issuing of some inherent opinions related to the talked about subject.

To carry through our aim that of studying the problematic of the financial-accounting communication and of the informational risk related to it, we are going to try on the assumption that *the current global crisis is not only a consequence of the economic crisis, but also one of a trust crisis*. Like we have shown in another study [6], discredit manifests as a phenomenon and affects the entire society and economy.

Although it is displayed in several forms and for all the human categories, for the present study we are going to have in consideration the discredit of holders in the accounting truth presented by the documents of accounting.

The approach of the stated problematic is going to be done by keeping on the following research directions:

- the informational risk in the generation process of financial-accounting information;
- the validation of information and the possibility of appearance of some inherent risks;
- the informational risk associated to the accounting communication;
- the risks associated to the phase of perception/comprehension of the information by the users.

2. The process of financial-accounting communication

Before going to the heart of the proposed matter, we consider necessary specifying some elements regarding the financial-accounting process of communication, in order to establish the importance of some significant aspects and emphasize them.

In the modern society, information has become inclusive. Progress and the development of science and technology have generated a huge amount of information.

Economic activity cannot be conceived without accounting information. *The existence, the dynamism and the mutation of the economic goods grew into information as a result of the data processing by the accountancy. Without their communication to the interested persons, this mutation process would not make sense. And without a correct informing, the success of a decision cannot be assured.* Therefore, it is preferred the absence of an incorrect information, than the holding and the foundation of a decision on its assumption.

In order to be reliable, the information needs to represent with precision the transactions and other events that this has proposed to represent, either it is expected in a reasonable way to represent.

As long as the users apply for independent assurances regarding the financial-accounting information and others indicators of the performances of a company, it means that they are aware of the risks of an inadequate informing. As a control solution, the financial audit represents an assurance service, in the sense that notifies and by this, protects the stockholding, the members of an association, the creditors, the managers and the employees, the authorities and the public.

3. The financial-accounting information and the informational risk

To take correct decisions, with a high probability of success, users need *real and useful* financial-accounting information. This task is for the professionals who produce, communicate and validate the accounting information, but also for the persons responsible with administration of a company.

Although all the regulatory bodies of the accounting field aim to issue norms, regulations and procedures able to fulfill the principle of *faithful representation of reality*, imperative for a correct report, its associated risks can not be entirely removed. It rather remains a goal of the profession. It is important for an interested user to have a good grasp of the risks that can arise from the moment of generation to that of communication and understanding of the information in order to take decisions and assume some risks learnedly.

3.1. The process of producing information

The information market represents the economic space where companies draw up and publish financial-accounting information to respond to the user's requests and needs.

Although regulations in the field provide a conceptual and operational support, *the factual content and the way of expressing the economic reality and the information are set a task before the economical entity and the accounting expert*. On that score, plus the legislative ambiguities, the alternate accounting treatments and the freedom granted to the professional judgment, we realize the large area of manifestation of the subjectivity factor in the process of generating information. *Subjectivity is associated, inferentially, to the rising of the risks of disloyal report*.

Financial reports represent „management's public declarations” [7] whereby the company communicates from a financial point of view with its environment, respectively with the information users. Are included here the present and potential investors, the hired employees, the creditors, the producers and others creditors, the clients and others debtors, the government and its institutions, as well as all the interested

public.

Elaborating financial statements involve from the management the definiteness of the principles and the use of the appropriate accounting methods, as well as the achievement of assessment and of correct reasoning in preparing the documents offered for publication. The managers of the company are let to choose between the obligation of presenting the results of the entity at their real scale (respecting the principle of the true and fair view) and the temptation to optimize them, so that they seem attractive for the investors. Mostly, the interests of the entity are most important and not those of the users.

A significant element in the phase of producing the accounting information is the estimation of *the materiality*. This is actually approached as a constraint (restriction) of recognition and an analysis of the elements presented by the documents of accounting report. In the eyes of the conceptual frame IASB, IAS 1 „*Presentation of Financial Statements*”, „*the information is significant if the omission or its mistaken description can influence the economic decisions of the users who underlie their decisional process on the strength of the financial statements*” [8].

We mention that the significance step acts for a limit of the information to be useful and relevant, limit that has to be established within the professional judgment.

The IASB frame asserts that it cannot determine the quantitative steps of the materiality and it cannot specify what could be significant in a certain situation, reason wherefore it solicits the professional reasoning.

We believe that the main risks that may appear in the generating process of the financial-accounting information are related to:

- the interests in administrating an entity, which can influence the mode of elaboration and presentation of financial situations;
- professional qualification and experts' ethics in charged with accounting the economic transactions;
- professional judgment that interferes when picking the account treatment and interpreting the law in force;
- the assessment manner of the significance of the elements that are going to be

included in the financial reports.

3.2. Validation of information

The knowledge process of the phenomena that points the whole activity of a company is carried out through theoretical and practical vehicles, appropriate for every activity department. They are based on *the comparison between effective reality and the norms, the programs and the decisions in terms*.

At the organization level, data are adapted by accountants, converted in information, and the information are validated by the audit and then communicated to the users.

In order to have the certainty of a faithful representation it is required that results of the accountancy to be validated by an expert who can give a *reasonable assurance* on compliance. Hereby, came into existence the practice and the theory of the audit.

The auditor is the one who, on the strength of *the findings and of the professional reasoning*, expresses his opinion on the quality of the company's activity, on the manner of which the funds are spent, on the development and exploitation of the cash flow and implicitly on the respect towards the business partners and the external environment, reflected by the quality of the transmitted information.

The audit report sustains the moral probity of the decision organs of the company while fulfilling their attributions and legal responsibilities and adopted acts, including those of informing and adequate communication. The auditor must examine the mains transactions, the accounting documents and those of economic inventory, as well as the structure and the performance of system of internal auditing. Bears in mind verifying the honesty and the equity of the accounting intercession reflected by the closing documents of the exercise, concluding on the content of the financial reports.

Through the audit report, this expresses its *responsible opinion* regarding the transparency and the reflection of the legal frame, offering in this way a reasonable assurance to the users of financial information.

Although a great range of the risks associated to the generation process of

information has been removed, there is a batch of factors which cannot be eliminated through the financial audit. These take the shape of some objective risks that can affect the quality of the report:

- the complexity of the economic transactions and the impossibility of an exhaustive checking;
- the restriction of expanding the audit's works, when the audit does not have the possibility to use the most adequate methods to obtain the probative elements;
- the supremacy of the professional judgment of the auditory while developing the audit, as well as the limits determined by the its implication, more or less objective;
- the inherent constraints of audit intercession.

The International Standards of Audit acknowledge and mention the existence of some audit risks - *the inherent risk, the control risk and the risk of being undetected* [9]. Thanks to them, the financial audit provides a *high assurance, but not categorical, that the information which is under examination is real, integrated and characterized by accuracy*.

The audit, means in the principal a value judgment, performed by a specialist, on the validity and implicitly, on the truth expressed by the company. At the same time, it integrates *the most useful and practical solution to reduce the informational risk and certify the accounting truth*.

The fact that the level of certification of the accounting truth/true and fair view is not absolute, is not necessarily the consequence of the profession's constraints, but more likely of some specific objective parameters, previously specified.

3.3. Communication of information

The aim of the periodic reports is to respond to the demands of the users, namely to provide information regarding the situation and the financial performance, the cash flows of the company and any other useful information for a wide class of users who aspire to adopt performing economical decisions.

The utility of the informational content of the annual financial statements for the decisive process results from the gratification

of two quality criteria: *relevance and credibility*.

Relevance alludes to the fact that information has the ability to generate a difference in the taken decisions by the decision factor [10].

Credibility represents the capacity of the information to express with extreme strictness the fundamental characteristics and the conditions of the facts on view [11].

Apart from these two characteristics, we indicate that the financial statements have to *comprise enough information* to make possible the foundation of a correct decision, with real chances of success. An important role in this sense falls on the notes that have to contain that additional information which can influence the decisional process.

Hence, the risks that related to the communication of the financial-accounting information apply, in the main, to:

- the delivery of some incomplete and insufficient information;
- the mistaken assessment of the materiality, so that to affect the relevance criterion;
- the communication of some embellished information, which changes the truthful characteristic.

Assuring some good relations, and implicitly, a good communication between the main players of the market information, respectively the producer and the user of the financial information, can be realized through the intervention of the accounting profession and of the national and international regulatory body of accounting. They monitor, settle, control, ameliorate and guarantee the quality of the communicated information [12].

3.4. Understanding the information by users

The informational risk is not related only to the generation, communication and validation of the financial-accounting information, but also to the users' capacity of perception.

In order to cut out the risks of misunderstanding or the wrong perception of the information, minimum specialized skills are required. When these do not exist, the easiest solution is to call for consultancy accounting services. In this manner, the agent of decision can make sure on the correct

understanding of the informational content of the accounting documents.

Conclusions

Financial-accounting communication is not by far riskless. The decisional agent has to take into consideration and analyze these potential dangers in the decisional process.

Regarding the informational risk, we have to bear in mind, first of all, that *the company is not only the subject of the report but also the emitter of the information*.

For this reason, the rational and dexterous user has taking into account for the subjectivity factor that can influence the way of producing the financial-accounting information. This aspect means, at bottom, an important source of risks of a disloyal communication.

Secondly, by financial reports, the companies' management sends forward information with priority to the company's owners. Therefore financial statements can be seen as a mirror of their performances and responsibilities. They represent the reasoning of the aspects related to the administration and management of the assigned resources, and also of the obtained results.

As the society becomes more complex, the agents of decision face a growing probability to receive inaccurate information. In the main, this fact is owned:

- to the bulk of data and to the complexity of the commercial transactions;
- to the personal interests that prevails to those of the users;
- the growing distance between information and users;
- to the development of „creative accounting” practices, in default of some definite legislative rules and to the manifestation of the professional judgment;
- to the decadence of the society from a moral and ethic point of view.

In order to regain this faith, we consider that the amendment of the financial-accounting communication, the identification of the affiliated risks and the relocation of certain solutions to limit/eliminate them are necessary.

We may also notice that, thanks the external users' need to trust financial situations, between the generators and the

users of the financial-accounting information, it is necessary the interference of the auditor, as pleader of accuracy and thoroughness of informing and communicating. Its role is that to blot out the doubt and the risk that the accounting reports to be framed with the non-observance of the settlements and the ethic principles.

Abstract

The analysis of the indicators that measure the economic and financial results is a very complex issue involving a number of theoretical and methodological aspects arising from the financial and economic activity of a company. The analysis of the indicator's system specific to the business performance analysis is aimed at measuring the outcomes on different levels of results.

The purpose of this paper is to present a summary of the indicators used in the analysis and measurement of the economic and financial results of a company. Their analysis should be guided depending on the results category we refer to, so that this construction to have concrete measures to raise the level of the results expressing the company's performance.

The article reflects a synthetic presentation of the indicators used to measure business performance, creating an overview of the outcome indicators: the workload, the profitability and the potential funding.

Key-words: performance, outcome indicators, workload, profitability, potential funding.

J.E.L. Classification: L2 Firm Objectives, Organization and Behavior

1. Introduction

The business performance is what contributes to improving the cost – value duo and not only what contributes to reduce costs or increase value. A company can create two types of values: an internal value and an external value: [4]

1. the external value assumes that the company has higher market value than the carrying amount of assets they hold. The difference between the market value of an asset and its carrying amount is given by the asset price increase on the market, growth that can not be influenced by internal decisions of the company, but by the specific conditions of the market.

2. the internal value assumes that the company creates economic value added, so a positive net value after the remuneration of all factors of production, including the cost of equity.

When we speak about the results of companies we have to consider three broad categories of indicators: indicators expressing the volume of activity, indicators expressing the company's profitability and indicators expressing the funding potential. On a comprehensive approach, each of these categories of indicators requires a thorough analysis which highlights issues like:

- the production and trading capacity analysis of a company by analyzing the indicators: production of goods manufactured, sold production, year production, turnover, value added;
- the analysis of the efficiency of the business activity by analyzing the indicators: the gross result of exploitation, the operational result, the current result, the extraordinary result, the net result;
- the highlight of the company's results on monetary plan using the following indicators: the ability to self-financing, self-financing and cash flow.

The comprehensive analysis of all indicators listed above highlights only the positive or negative results recorded by company. Positive results reflect the

performance of a company's activities, while the negative results reflect the mismanagement of the company's resources.

The performance concept is associated with three notions: **economy** (purchase resources at the lowest cost), **efficiency** (to maximize the results obtained from a given amount of resources, or to minimize the amount of resources for a predetermined outcome) and **efficacy** (results achieved are the expected results). [9]

$$\text{Performance} = \text{economy} + \text{efficiency} + \text{efficacy}$$

2. The overall assessment of the company's results on economic and financial indicators

The economic and financial indicators are an expression of the finality of the activities undertaken by a company. Economic and financial indicators are diverse and can be classified according to several criteria: [10]

- a) by their nature:
 - quantitative indicators (profitability, efficiency, labor productivity);
 - qualitative indicators (the extent to which customers are satisfied by the products, customer complaints and so on).
- b) by content: outcome indicators, indicators of efficiency, efficacy indicators.
- c) by frequency of use:
 - traditional indicators (turnover, gross operating surplus, profit, productivity, trading margin, rates of return and so on)
 - modern indicators, based on value creation (economic value added, value added in the form of cash flow etc.) and indicators of sustainable development.
- d) by their mode of expression, the traditional indicators are divided into: indicators in absolute and relative size.

Due to the complexity of the business undertaken by the enterprise and to the various informational values that the economic and financial indicators have, one can not use a composite indicator of overall assessment of the performance. In practice, several indicators can be used, depending on stakeholder interests and when the performance analysis of the companies is done.

A grouping of performance indicators can thus be performed depending on the financing

needs of the company and its growth rate, pursuing the four categories of indicators: [6]

FINANCING NEED	HIGH	D EBE ETE ETG CAF VAE	B EBE ETE ETG (CFD) CAF VACF
	LOW	A RR RI RF VAE VAP	C RR RF ETG VAE VAP
		GROWTH RATE	
		LOW	HIGH

Figure no. 1

The matrix of using performance indicators based on the growth rate and the need to finance company
Source: Niculescu Maria, *Diagnostic financiar, Ed. Economică, București, 2003, pag.63*

The companies from the four square is the following: [10]

➤ **Companies from A area** are companies that have reached maturity, with a low growth rate and low financing needs. The financial resources released by the current activity are sufficient to fund the activity and in order to measure the performance we have to use income based indicators (the economic rate of return (RE), the return on investment (ROI), the financial rate of return (RF)). For shareholders, it is also important the value surplus created by these companies, which is measured by the economic value added (VAE) and the market value added (VAP).

➤ **Companies of B type** have a high rate of growth of their activity and higher funding needs, which can not be achieved only through work. These businesses are booming and need external funding to finance their development. They should pay more attention to cash flow management in order to have the resources for the payment of due date obligations. The main risk of these enterprises is suffocation as a result of sudden growth, the growth exceeds the capacity of attracting financial resources and therefore the liquidity ratio decreases to a critical level.

For these companies, the most important indicators for performance measurement are those based on: the operating cash surplus (ETE), the overall cash surplus (ETG) or the available cash-flow (CFD), but also the gross

operating result (EBE), the capacity of self-financing (CAF) and the value added in the form of cash-flow of investments (VACF).

➤ **Companies from C area** present a high rate of growth, but they have sufficient resources for financing the activity, which places them in a privileged area. To assess performance we use indicators based on income (to quantify the effectiveness of own and borrowed funds) and on creating value, to point out earnings to shareholders.

➤ **Companies from D area** operate in a mature market with low growth rates, but they fail to provide full funding sources from their own work. The performance indicators used are those in B area (based on cash flows, showing the ability to pay installments due from banks), plus VAE.

The economic indicators for assessing performance are designed to support the decision making process within a company. But, as an indicator to be used in the decision-making process, it must be known its informational limits. Thus, an indicator measures one aspect of an economic activity, failing to capture its completeness and complexity, the conduct of the business, its influencing factors, the correlations with other aspects of the company. The more the analyst knows the informational limits of an indicator, the more it is able to eliminate some of them by making corrections or by using complementary indicators, which improves the process of adopting decisions.[10]

The formation of results is a highly complex process resulting from the company's lucrative activity, and the analysis and computation of outcome indicators is an operation following the process of forming the results.

Calculation of the outcome indicators is a technical operation, which is based on data provided by the accounting of the company and other additional information available to the analyst. The quality of the indicators calculation operation is determined for the accurate reflection of the results obtained objectively, as a result of carrying out the production process.

The computation of the outcome indicators has to be done according to the following principles: [11]

- to start from the objective mode of forming the results;

- the level of a result has to include only items of the same kind and which are evaluated on the same criteria.

The results expressing the workload can be structured in results expressing the production volume of the activity, results that express the volume of the trading activity and results which express the overall level of activity. Both results are formed simultaneously with the production and marketing process and can not take negative values, but can have up to a value of zero.

The results of the production activity are reflected in goods, works and services and are expressed in value by the cost of production, the price of registration, etc. The results of the production activity can be characterized by the following indicators:

- the physical production value - expresses in value the overall result of the productive activity irrespective of the destination of production achieved and its level of market capitalization;
- the production of manufactured goods - refers strictly to products for sale on the market;
- the production of assets is a non-profit economic result, aimed at meeting the internal needs of the company.

The trading activity is an activity which reflects the results of production. The main objective in the trading activity is the sale of products produced at a price higher than the cost of production.

The trading activity results form while achieving the market products, works or services offered for sale by a business, the value of these results depending both on the utility value of the goods and on the current market demand. Unlike the results of production, which are expressed mainly in physical form, those of the trading activity have from the start a value expression because they can be identified in the profit and loss account as revenues.[11]

The indicators that characterize the trading activity results are:

- revenues from goods sold - measure all revenues from wholesale or retail of their goods or those purchased from third parties;
- revenues from production sold - include revenues from sale of products, provision of services and execution of work, and

through this indicator it is confirmed the utility of goods sold and therefore of the productive activity of the enterprise;

- turnover - the most comprehensive indicator which measures the trading activity of a company; it is the sum of revenues from sale of goods, delivery of goods, execution of works and provision of services plus other operating revenues less rebates, discounts and other discounts to customers.

The overall result of the company is the result of combining the features of the other two business activities, namely the production and the trading one; it also combines the performance of production work with the performance of the trading activity.

The indicators characterizing this category of results:

- revenues from stored production - is an indicator that can have a dual effect on the overall result: an increase in the overall result when there is a storage situation, meaning when the production is greater than the products sold and a decrease in the overall result when there is a situation opposite to the storage one respectively when, in the analyzed period, production is lower than the goods trade.
- production of the year - the absolute level of the indicator includes the sales from the analyzed period, regardless of when the goods sold were produced, the production obtained but not marketed (in stock) and the production for domestic consumption;
- value added is the intermediate balance management expressing a value creation or an increase of value that the company brings to goods and services from third parties and allows the measurement of the economic strength of the company.

The structure of the results that express the activity volume is presented in the following figure:

Figure nr. 2

The structure of the outcome results that express the activity's volume

Source: Șteflea Petru, *Analiza rezultatelor întreprinderii*, Ed. Mirton, Timișoara, 2002, pag.40

The economic results that have relevance in terms of profitability are formed from a comparison of the global economic effects generated by an economic activity and the economic effort presumed by its development. This comparison may result in positive or negative values, depending on whether the business succeeds or fails to generate a higher volume of effects than the effort involved. The production activity generates effects in physical form (pieces, tons, kg, etc.) that are taken by the trading activity which makes them subject of the market trade. If after market trading we achieve a higher price per product than its cost of production, then that activity makes profit and we can say that it is effective activity, otherwise there is a loss and the continuation of the activity is not justified in terms of economic efficiency.

The main indicators characterizing the results expressing the profitability are:

- the operating gross result – reflects the ability of the activity to generate profit and can be found in two aspects, namely the gross operating surplus when it records a positive value and the gross operating deficit when it has a negative value;
- the operating result - as an intermediate management balance represents the result obtained from the operating, normal and current activity of the company. It is the first element that measures the economic rate of return, independent of the company's financial policy and the scope of the extraordinary items;
- the financial result – is formed as the difference between financial revenues

and financial expenses and its formation depends on two issues: the funding policy of the company and the financial investment activity;

- the current result consists of the operating result and the financial result and it represents the result of all current operations, allowing the assessment of the financial policy impact of the company on profitability
- the gross result is determined by summing the results for the three core business activities: operating, financial and extraordinary. This result allows comparing the performance of companies in the same industry.
- the net result is the most synthetic result with which to appreciate the overall profitability of a company. The net income approach can be made in three ways, as follows:[11]

a) from patrimonial point of view, the net result shows an increase in net assets as a result of running a profitable operation during the year;

b) from economic point of view, the net result is a „surplus” formed after covering all the company’s expenses from its total revenues;

c) from financial point of view, the net result represents the main self-financing source of the company.

The existence and carriage of cash flows of a company leads to results which express the potential financing of the company. The main indicators used in the characterization of potential funding are the self-financing capacity, the self-financing and the cash - flow.

These indicators highlight three key areas: the capacity growth of the company, the potential volume of owned financial resources which remains effective in the entity, as well as the determination at a time of the formation method of liquidity.

Briefly, the three indicators are:

- the self-financing capacity reflects the financial potential of economic growth of the company, respectively the financial source generated by the industrial and trading activity of the company after deducting all expenses paid at a particular time. The self-financing capacity (CAF) is revealed by the difference between the monetary income (receivable) and the

monetary expenses

- the self-financing has a synthetic character and expresses only the hypothetical amount of owned financial resources that remain effectively in the entity after the remuneration of all categories of participants in the activity. The self-financing or the net self-financing capacity is measured starting from the self-financing capacity and deducting the dividends paid during the year.
- the cash flow - this is of three types: operating, operational and total, the operating one reveals the cash flows arising from operating activities, the operational cash flow is characterized by cash flows generated from all activities of the company during a financial year and the total cash flow reflects all cash flows released at the enterprise level in a certain period of time.

3. Conclusions

The analysis of results is one of the main components of the economic and financial analysis, their analysis and evaluation settling the performance of a company. It can be seen from two points of view:

a) in terms of economic growth which analyzes the company's capacity to increase the volume of activity which is reflected by the results that express the workload; here we consider indicators such as: the physical production value, the value added, the turnover;

b) in terms of the profitability activity which examines the company's ability to effectively carry out economic activities.

In assessing and analyzing the results of a company the information provided by financial statements are required in order to issue a number of relevant considerations in determining the company’s level of performance.

In analyzing the results of a company we use a set of financial indicators aimed at providing information which reflects various aspects and conditions of the economic and financial activity, based on them the stakeholders can make beneficial decisions to improve the economic and financial performance of the company.

Showing the results achieved by the

company during the economic and financial activity lead to the characterization of the internal condition of the company. Thus, in determining their evolution are taken into consideration a number of issues such as: the assessment of the financial potential of the company, the changes in workload, the economic resources assessment, the analysis and quantification of indicators expressing the workload, its performance and potential funding etc.

Considerations regarding the Settlement of Inventory Differences

Lenghel Radu Dorin

„Dimitrie-Cantemir” Christian University, Faculty of Economic Sciences Cluj-Napoca
radulenghel@yahoo.com

Abstract

The determination of results of stock-taking is accomplished by comparing the quantities and values written in the stock-sheets with the quantities and values recorded in accounting. In fact, the differences acknowledged on the occasion of general inventory of patrimony are settled by the following approaches: direct recording of inventory pluses and minuses; the compensation of pluses with minuses of inventory; combined awarding of compensations and perishabilities; awarding perishabilities or acceptable drafts

Key words: inventory report, procedures of settlement of inventory differences, direct recording of inventory differences, compensation of inventory differences, awarding perishabilities.

JEL: M40, M41

1. Introduction

The determination of the stock-taking results is done directly in stock-sheets. These results are determined by the comparison of dimensions directly acknowledged by inventory with those recorded in accounting. If the quantities and values acknowledged in reality at a certain patrimonial element are higher than those from accounting, it results a plus of inventory, and in the reversed case, it results a minus of inventory.

The differences acknowledged on the occasion of the general inventory of patrimony are settled by the following approaches: direct recording of pluses and minuses of inventory; compensation of pluses with minuses of inventory; combined awarding of compensations and perishabilities; awarding perishabilities or acceptable drafts.

2. Determination of inventory differences

The determination of the results of inventory is done by the comparison of quantities and values written in the stock-sheets with the quantities and values recorded in accounting. The determination of factual stocks is done by counting, weighing, measuring or cubing, as applicable. The written balances are certified by the person who keeps the analytical records of the respective inventory and by the head of the financial accounting department.

From the abovementioned comparison, it can result pluses or minuses of inventory for which the inventory commission will ask for written explanations from the warehouse manager.

The results of inventory must be recorded both in the operational records and in accounting within maximum seven days from the date of approval of the inventory report by the administrators.

The determination of the results of inventory is done directly in the stock-sheets.

The results of stock-taking are written in an inventory report.

The proposals made in the report of the inventory commission are presented within seven days from the date of conclusion of stock-taking operations, to the administrator of the patrimonial unit.

The administrator of the patrimonial unit decides on the approach of resolution of the proposals made, with the observance of the legal provisions in force, with the approval of the financial accounting department and of the legal department.

Every year, the results of the general stock-taking of the patrimony are centralized in the inventory ledger, after the reflection in accounting and in the trial balance.

3. Methods of settlement of inventory differences

After the determination of pluses and minuses of inventory, we proceed to the settlement of differences. As a rule, the pluses are recorded as entries in the patrimony of the units, and the minuses are recorded on expenses or are deducted from the revenues relating to the variation of stocks, as applicable.

The determination of amounts imputable to the guilty persons is done at replacement value which represents the procurement cost of goods at the date of acknowledgment of the damage.

According to the legislation in force, the warehouse managers are fully liable to the economic agents for the damages (lacks in inventories) they caused in the inventory. When the warehouse manager has caused a damage in inventory at the workplace and this damage is not fully covered within a month, the economic agent will indemnify itself from the warranty in cash created.

For the purpose of correct resolution of lacks in inventory, the inventory commissions will take complete explanatory notes from the warehouse managers, from which should result the character of lacks, losses, depreciations acknowledged and the circumstances of their occurrence.

On the basis of the explanations received and of other documents and facts investigated, the inventory commissions formulate conclusions and propose concrete measures to the attention of management, which are to be adopted (compensations, perishabilities, imputations, deductions from inventory).

In reality, the differences acknowledged on the occasion of the general inventory of the patrimony are settled by the following approaches: direct recording of pluses and minuses of inventory; compensation of pluses with minuses of inventory; the combined awarding of compensations and perishabilities; the awarding of perishabilities or acceptable drafts.

These settlements influence the relationships between the management of the patrimonial unit and the subordinated staff (warehouse managers, cashiers, etc.).

a. Direct recording of inventory pluses and minuses

As a rule, for the stockable elements the pluses are recorded as entries in the patrimony of the units (class 3= class 6), and the minuses are recorded as expenses (class 6 = class 3), as applicable, minuses which are to be imputed, if need be (4282(461) =% (7588,4427).

b. Compensation of pluses with minuses acknowledged at stock-taking

At the determination of the value of the debit, in cases when the lacks in inventory are not considered infringements of the law, we take into consideration the possibility of compensation of lacks with pluses acknowledged.

The compensation of lacks with the pluses acknowledged at stock-taking allows the correction of errors of handling goods because of confusions between assortments.

The danger of confusions is determined by the resemblance between products, danger which appears following careless handling, when the labels from packaging disappear, as well as because of the carelessness of warehouse managers.

The competence of approval of compensations reverts in all the cases to the managers of patrimonial entities.

According to the norms regarding the organization and the stock-taking of the patrimony, the compensation of pluses with minuses of inventory operates only if the following **conditions** are fulfilled:

- the existence of the risk of confusion between the assortments of the same group of material goods because of their resemblance regarding the external appearance: colour, model, sizes, packaging and other elements;
- the pluses and minuses must refer to the same inventory period and the same inventories.

The lists with assortments of products, merchandises, packaging and other material values which meet the conditions of compensation are established every year by the administrators of economic units or budget managers.

We must also consider the following **rules** regarding compensation[1]:

- a) the quantitative equality between pluses and minuses is obtained by the elimination from calculation of quantities which exceed this equality (pluses or minuses, as applicable), starting with assortments, which have the lowest unit price, in the ascending

order of prices (warehouse managers are responsible for the smallest damage);

b) the differences of values, at equal quantities of pluses and minuses are determined between the total value of assortments acknowledged in addition and the total value of assortments acknowledged in minus, from the same group of material values;

c) following compensation, unfavourable differences cannot result for the company, and if they still exist, they are recovered from the guilty parties (following compensation, the patrimony of the entity cannot diminish).

c. Combined awarding of compensations and perishabilities

For the goods where drafts are accepted, in case of compensation of lacks with the pluses established at stock-taking, the drafts are calculated only in the situation when the missing quantities are larger than the quantities acknowledged in addition.

In case of material goods mistakable among one another, the quantitative perishabilities are given only if the sum of quantities acknowledged as missing is higher than the sum of quantities acknowledged in addition and only in the limit of these differences.

The drafts are given first of all for the assortments in which the lack was acknowledged, and if there are quantitative differences in minus, they can be given also for the other assortments in which pluses were recorded or there are no differences.

In each category, the order of giving perishabilities is the order used in the composition of goods in compensation (starting with the assortment which has the highest unit price).

The lacks of values, which can be covered as perishabilities are made of the value of missing quantities, which exceed the quantities acknowledged in addition, to which are added the negative differences of values resulted from the compensations of equal quantities.

d. Giving perishabilities or acceptable drafts

By perishabilities we understand the drafts that occur during transport, handling, storage and sale of merchandises, determined by natural processes such as: drying, evaporation, volatilization, pulverization, hydrolysis, cooling, freezing, melting,

oxydation, adherence to the walls of wagons or of vessels in which they are transported, decomposition, drainage, soaking, thickening, scattering, crumbling, breaking, including fermentation processes or other biophysical processes, in the process of sale in distribution network (wholesale warehouses, retail commercial units and public nutrition units in normal limits (legally approved) [3].

Because such phenomena cannot be avoided, it is natural that the objective losses suffered are acceptable within certain limits, without being attributed to carelessness or poor administration.

These normal quantitative losses are not the fault of the warehouse manager or of other persons, and as a consequence, they must be deducted from inventories as unimputable losses.

The competence of approval of quotas of drafts reverts in all the cases to the management of the company.

Therefore, the management will have to appreciate from one case to another, depending on concrete conditions, how much of the established quota is approved to each inventory.

The perishabilities can be given only after a factual check of the quantities of products that exist in inventory, established after weighing, counting, measuring and by other such procedures and after making compensations according to the legal provisions in force.

The maximum perishability limits allowed at storage and sale are established at the level of the whole activity of the legal person that pays profit tax, by the application of the coefficient established for the group of merchandises at the price of registration of incoming merchandises or at the delivery price for the merchandises sold during the period between two inventories. The same maximum perishability limits are also given for the merchandises from stock.

The perishability coefficients are established by the management of each entity, depending on the actual losses from the previous period and the new conditions created in the activity of transport, handling, storage or silage of the respective goods.

The losses or quantitative decreases which exceed the perishability norms established

are not deductible from the fiscal point of view.

From the fiscal point of view, the losses acknowledged at merchandises are deductible expenses in the calculation of profit tax within the limit of perishability quotas approved by government decisions.

The management of the companies can approve perishability quotas above the limits approved by the government or at other assortments of merchandises. These perishabilities reduce the patrimonial liability of warehouse managers. The perishabilities, whether they are established by the government or by the management of the company, cannot be given in anticipation, but only after the acknowledgement of a real lack by stock-taking or by the reception of procured goods.

4. Case studies regarding the settlement of inventory differences

a) the procedure of direct recording of inventory differences

The lacks in inventory must be recorded, knowing that after the stock-taking of a raw materials warehouse the following were acknowledged:

Table no.1 Settlement of inventory differences

No.	Causes of lacks	Lacks of values	Recording of differences
1	Carelessness in inventory	2.000	601 = 301 2.000 4282 = % 2.480 7588 2.000 4427 480
2	Theft, third parties	2.000	601 = 301 2.000 461 = % 2.480 7588 2.000 4427 480
3	Perishabilities	2.000	601 = 301 2.000
4	Natural disasters	2.000	671 = 301 2.000

Source: personal projection

b) the procedure of compensation of lacks and pluses of inventory

Following the stock-taking of a wholesale warehouse of wooden profiles inventory differences were acknowledged according to the table below. Make the compensation of inventory differences.

Table no.2 Situation at inventory

Assortment	Factual stock ~ m ² ~	Written stock ~ m ² ~	Procurement cost ~ lei ~
PM 1	600	300	10
PM 2	300	600	15
PM 3	500	200	20
PM 4	200	500	25

Source: personal projection

Solution: The compensation is made according to the table below:

Table no.3 Real compensation

Assortment	Procurement cost	Quantitative differences		Differences of values	
		+	-	+	-
PM 1	10	300		3.000	
PM 2	15		300		4.500
PM 3	20	300		6.000	
PM 4	25		300		7.500
Total inventory		600	600	9.000	12.000
Eliminated from compensation		-	-	-	-
Compensation		600	600	9.000	12.000
Result of compensation (9.000-12.000)		-	-	-	3.000

Source: personal projection

The main accounting entries following compensation are:

1. entrance of the lack of amount of 3.000 lei, resulted from the compensation of the four assortments of melamine fibreboard from the warehouse of wooden profiles:

$$607 = 371 \quad 3.000$$

2. imputation to warehouse manager:

$$4282 = \% \quad 3.720$$

$$7588 \quad 3.000$$

$$4427 \quad 720$$

3. retaining this prejudice from the warranty submitted initially by the warehouse manager:

$$4281 = 4282 \quad 3.720$$

c. the procedure of combined awarding of compensations and perishabilities

Following the stock-taking of a warehouse of salami and sausages, the following were acknowledged:

Table no.4 Situation at inventory

Assortment	Procurement cost	Quantitative differences (Kg)		Turnovers of entries (Kg)
		+	-	
S 1	1		10	1.000
S 2	2	10		2.000
S 3	3		10	3.000
S 4	4	10		4.000
S 5	5		5	5.000

Source: personal projection

Establish the situation at inventory, knowing that the perishabilities allowed during storage represent 0,05% of turnover, and S represents different assortments of salami.

Solution:

Compensation and awarding of perishabilities are made according to the table below:

Table no.5 Compensation and awarding of perishabilities

Assortment	Procurement cost	Quantitative differences		Differences of values	
		+	-	+	-
S 1	1		10		10
S 2	2	10		20	
S 3	3		10		30
S 4	4	10		40	
S 5	5		5		25
Total		20	25	60	65
Eliminations from compensation -S1			5		5
Compensation		20	20	60	60
Result of compensation		-	-	-	-
Perishabilities					
Calculated	Awarded	Value			
0,5	0,5	0,5			
1	-	-			
1,5	1,5	4,5			
2	0,5	2			
2,5	2,5	12,5			
7,5	5	19,5			

Source: personal projection

Because there is a minus of 5kg eliminated from compensation, we will award perishabilities starting with assortments with minus, which have the highest prices.

Calculation of perishabilities during storage:

$$PdS1 = 1.000 \times 0,05\% = 0,5 \text{ kg}$$

$$PdS2 = 2.000 \times 0,05\% = 1 \text{ kg}$$

$$PdS3 = 3.000 \times 0,05\% = 1,5 \text{ kg}$$

$$PdS4 = 4.000 \times 0,05\% = 2 \text{ kg}$$

$$PdS5 = 5.000 \times 0,05\% = 2,5 \text{ kg}$$

Even if from the calculation the losses allowed are higher than the real lacks (7,5 > 5), only perishabilities of 5 kg will be awarded.

The analysis of the procedure of compensation and awarding of perishabilities is:

1. uncompensated lack: 5 lei;
2. lack following compensation : 0 lei;
3. total lack: 5 lei;
4. perishabilities awarded during storage: 19,5 lei;
5. imputable lack: 0 lei.
6. accounting recording of total lack of 5 lei, which is fully covered by perishabilities:

$$607 = 307 \quad 5$$

d.the procedure of awarding perishabilities or legal drafts

Following the stock-taking we acknowledged the following:

- at assortment X, a minus of 5 kg flour with 6 lei/kg.
- the perishabilities allowed during storage were 2 kg.

Establish the situation at inventory.

1. recording of lack in amount of 30 lei:

$$607 = 371 \quad 30$$

2. imputation to warehouse manager 30kg:

$$4282 = \begin{matrix} \% & 22,3 \\ 7588 & 18 \\ 4427 & 4,3 \end{matrix}$$

3. retaining this prejudice from the warranty initially submitted by the warehouse manager:

$$4281 = 4282 \quad 22,3$$

5.Conclusions regarding the settlement of inventory differences

With regard to the settlement of inventory differences, the following conclusions can be drawn:

- The determination of the results of stock-taking is accomplished by the comparison of quantities and values written in the stock-sheets with the quantities and values recorded in accounting. The written balances are certified by the person who keeps the analytical records of the respective inventory and by the head of the financial accounting department. For all the pluses, lacks and depreciations acknowledged at goods, the

inventory commission requests written explanations from the persons who have the responsibility of management of goods. On the basis of the explanations received and the documents analyzed, the inventory commission establishes the nature of lacks, losses, damages and depreciations acknowledged as well as the nature of pluses, by proposing, according to the legal provisions in force, the method of settlement of differences between the accounting data and the factual data resulted after the inventory.

- In case of acknowledgment of imputable lacks in inventory, the administrators must impute to the guilty persons the missing goods at their replacement value.

- In case there are no presumptions of confusions between assortments and there are no drafts to give, the inventory commission will propose direct recording of pluses and minuses of inventory;

- In case there are presumptions of confusions, the inventory commission will propose the compensation of pluses and minuses of inventory;

- In case there are presumptions of confusions between assortments and there are drafts to give, the inventory commission will propose the compensation of pluses and minuses of inventory and the awarding of perishabilities;

- In case there are drafts to give, the inventory commission will propose the awarding of legal drafts;

- The proposals included in the report of the inventory commission are presented within seven days from the date of conclusion of stock-taking operations to the administrator of the patrimonial unit. The administrator of the patrimonial unit, with the approval of the head of the financial accounting department and the head of the legal department, decides on the approach of resolution of the proposals made (direct recording of inventory differences, compensation of inventory differences, awarding of compensations and perishabilities, awarding of perishabilities), with the observance of the legal provisions in force.

Particularities of Cost Calculation in Services

Lenghel Radu Dorin

„Dimitrie-Cantemir” Christian University, Faculty of Economic Sciences Cluj-Napoca
radulenghel@yahoo.com

Abstract

Management accounting in services is organized by the administrator of the legal person either by using specific accounts or by the development of accounts from financial accounting, or with the aid of his own technical operational records. The list of management accounts is adjusted depending on the purposes aimed at, which are: the highlighting of the cost flow, the determination of costs relating to services, the determination of revenues and of results depending on the activity which generates them, the performance of forecasts, etc.

Key words: cost calculation, actual cost of services, the management accounts system in services, on-balance sheet approach, off-balance sheet approach

JEL: M40, M41

1. Introduction

The use of balance accounts and their symbolization is performed so that the system of storage and access of information obtained should be flexible and allow a wide range of options. The list of management accounts is adjusted according to the purposes aimed at as follow: highlighting the cost flow, determination of costs relating to services, determination of revenues and results depending on the activity they generate, making forecasts, etc.

The inventory cost of a service provider comprises manual labour and other expenses with the staff directly engaged in the provision of services, including the staff in charge with supervision as well as the appropriate overheads[3].

2. Organization of cost calculation in services

The reason for the application of management accounting in the services sector consists in the need for determination of the price of fees for the services provided. The manager has to know both the value of gross margin relating to the service provided and the value level of expenses that have to be covered by gross margin, with a view to determining the profit of the company.

As for the approaches of organization of services management accounting, only the Minister of Public Finance Order no. 1826/2003 makes statements, among which we recall: management accounting is organized by the administrator of the legal person, either by using specific accounts or by the development of accounts from financial accounting or with the aid of its own technical and operational (off-balance sheet) records [3].

The use of accounts from the new class is not compulsory, as the calculation of costs can be performed off-balance sheet, with the aid of tables in Excel.

In Minister of Public Finance Order no. 3055/2009, only the management accounts from the new class are presented, and not the approach of operation of accounts.

We shall approach hereinafter only the accounting approach by adjusting the accounts from the new class to the particularity of services.

3. Case study regarding the calculation of costs in services through the accounting approach

We shall present hereinafter a hypothetical case regarding the approach of development of management accounting at SC Student SA. SC Student SA, which has as object of activity the provision of car training services, carries out the following activities:

car training – analytical account 01; road legislation – analytical account 02; psychological examination – analytical account 03; transport of persons – analytical account 04; rents and other revenues – analytical account 05. During a period of management the company makes the following operations:

Table no.1.Situation of revenues and expenses -lei -

1. Revenues from car training	91.895
2. Revenues from road legislation	7.535
3. Revenues from psychological examination	4.501
4. Revenues from transport of persons	20.071
5. Revenues from rents and such other revenues	18.126
6. Expenses with fuel relating to car training activity	13.273
7. Expenses with fuel relating to the activity of transport of persons	4.500
8. Expenses with fuel relating to administration	3.000
9. Consumption of energy and water relating to the activity of rental	1.264
10. Consumption of energy and water – administrative building	5.613
11. Expenses with other services regarding the training activity	46.147
12. Expenses with other services regarding the activity of transport of persons	975
13. Expenses with other services regarding administration	511
14. Expenses with local taxes and duties	410
15. Expenses with insurance premiums for car training activity	1.186
16. Protocol expenses	172
17. Expenses regarding other consumables relating to road legislation	458
18. Expenses regarding other consumables relating to the transport of persons	62
19. Expenses regarding other consumables relating to the training activity	1.340
20. Expenses regarding other consumables relating to administrative costs	1.710
21. Expenses regarding unstored materials	13
22. Expenses with communication	734
23. Expenses with banking commissions	427
24. Wages for car training activity	10.593

25. Contribution of the unit to social insurances – car training	2.103
26. Contribution of the unit to the unemployment fund – car training	50
27. Contribution of employer to healthcare – car training	551
28. Contribution of employer for health care benefits – car training, 0,85%	90
29. Other social duties – car training	103
30. Special funds, payments guarantee fund – car training	26
31. Wages relating to road legislation activity	1.340
32. Contribution of the unit to social insurances – road legislation	270
33. Contribution of the unit to the unemployment fund – road legislation	7
34. Contribution of employer to healthcare – road legislation	69
35. Contribution of employer to health benefits, road legislation - 0,85%	10
36. Other social duties – road legislation	12
37. Special funds – payment guarantee fund – road legislation	3
38. Wages relating to the activity of psychological examination	1.340
39. Contribution of the unit to social insurances – psychological examination	270
40. Contribution of the unit to unemployment fund – psychological examination	7
41. Contribution of employer to health care insurance – psychological examination	69
42. Contribution of employer to health benefits – psychological examination - 0,85%	11
43. Other social duties – psychological examination	12
44. Special funds, payments’ guarantee fund – psychological examination	3
45. Wages relating to the activity of transport of persons	2.015
46. Contribution of the unit to social insurances – activity of transport of persons	407
47. Contribution of the unit to unemployment fund – activity of transport of persons	10
48. Contribution of employer to healthcare – activity of transport of persons	102
49. Contribution of employer to health benefits – activity of transport of persons, 0,85%	16
50. Other social duties – activity of	19

transport of persons	
51. Special funds – payments guarantee fund – activity of transport of persons	4
52. Indirect wages relating to the five activities	2.077
53. Contribution of the unit to social insurances, indirect wages	420
54. Contribution of the unit to unemployment fund, indirect wages	10
55. Contribution of employer to health, indirect wages	105
56. Contribution of employer to health benefits, indirect wages	16
57. Other social duties, indirect wages	20
58. Special funds –guarantee fund of payments for indirect wages	5
59. Administration wages	9.360
60. Contribution of the unit to social insurances - administration wages	1.870
61. Contribution of the unit to unemployment fund – administration wages	46
62. Contribution of employer to health insurance – administration wages	486
63. Contribution of employer to health benefits – administration wages	79
64. Other social duties – administration wages	91
65. Special funds, guarantee fund of payments – administration wages	23
66. Depreciation of vehicles relating to car training activity	4.426
67. Depreciation of overhead projector relating to road legislation activity	81
68. Depreciation of vehicles relating to the activity of transport of persons	3.017
69. Depreciation of car washing machine, car training and transport of persons	26
70. Depreciation of computers, printers, administration building	2.897
71. Penalties of invoice paid later	20
72. Expenses with profit tax	2.730

Source: personal projection

We shall determine the actual cost by activities and the result by the five activities.

a) The recording of operations in management accounting will be carried out according to the table below:

Table no.2 Ledger

ENTRANCE OF REVENUES	MANAGEMENT ACCOUNTING		
1. revenues – car training	931.01	=	902.01 91.895
2. revenues – road legislation	931.02	=	902.02 7.535

3.revenues psychological examination	–	931.03	=	902.03	4.501
4. obtaining revenues –transport of persons		931.04	=	902.04	20.071
5. obtaining revenues – rents, other		931.05	=	902.05	18.126
DIRECT EXPENSES					
1. fuel, car training		921.01	=	901	13.273
2. other consumables – car training		921.01	=	901	1.340
3.insurance premiums		921.01	=	901	1.186
4. wages – car training		921.01	=	901	10.593
5. health insurance 20,8%		921.01	=	901	2.103

b) In view of establishing the actual cost by activities, you will go through the following stages:

b.1. distribution of indirect expenses by each activity at the end of the month, depending on the revenues of the five activities:

$$KCI = \frac{CI}{V01 + V02 + V03 + V04 + V05}$$

$$KCI = \frac{2692}{91.895+7.535+4.501+20.071+18.126} =$$

$$91.895+7.535+4.501+20.071+18.126$$

$$\frac{2.692}{14.2128} = 0,0189$$

RD 923:2.692 lei

b.2. Actual distribution of indirect expenses by activities:

$$CIR01 = KCI \times V01 = 0,0189 \times 91.895 = 1.739$$

$$CIR02 = KCI \times V02 = 0,0189 \times 7.535 = 143$$

$$CIR03 = KCI \times V03 = 0,0189 \times 4.501 = 86$$

$$CIR04 = KCI \times V04 = 0,0189 \times 20.071 = 381$$

$$CIR05 = KCI \times V05 = 0,0189 \times 18.126 = 343$$

$$\% = 923 \frac{2.692}{14.2128}$$

$$921.01 \quad 1.739$$

$$921.02 \quad 143$$

$$921.03 \quad 86$$

$$921.04 \quad 381$$

$$921.05 \quad 343$$

b.3. The actual cost by each activity will be obtained from the records of the account 921: SFD 921.01:81.627; SFD 921.02: 2.393;

SFD 921.03: 1.798; SFD 921.04: 11.508;
SFD 921.05: 1.607.

c) In view of establishing the full cost, you will go through the following stages:

c.1. distribution of administration expenses by activities, depending on the revenues of the five activities:

$$KADM = \frac{CADM}{V01 + V02 + V03 + V04 + V05}$$

$$KADM = \frac{30179}{142.128}$$

$$\frac{91.895+7.535+4.501+20.071+18.126}{142.128} = 0,2123$$

RD 924:30.179 lei

c.2. The accounting formula of actual distribution of administration expenses is:

$$CADM01=KADM01 \times V01=0,2123 \times 91.895=19.511$$

$$CADM02=KADM02 \times V02=0,2123 \times 7.535=1.600$$

$$CADM03=KADM03 \times V03=0,2123 \times 4.501=957$$

$$CADM04=KADM04 \times V04=0,2123 \times 20.071=4.262$$

$$CADM05=KADM05 \times V05=0,2123 \times 18.126=3.849$$

%	=	924	<u>30.179</u>
921.01			19.511
921.02			1.600
921.03			957
921.04			4.262
921.05			3.849

c.3. The accounting formula of registration of full cost by activities is:

$$\begin{array}{l} 902.01 = \% \quad \underline{101.138} \\ 921.01 \quad 81.627 \\ 924 \quad 19.511 \end{array}$$

$$\begin{array}{l} 902.02 = \% \quad \underline{3.993} \\ 921.02 \quad 2.393 \\ 924 \quad 1.600 \end{array}$$

$$\begin{array}{l} 902.03 = \% \quad \underline{2.755} \\ 921.03 \quad 1.798 \\ 924 \quad 957 \end{array}$$

$$\begin{array}{l} 902.04 = \% \quad \underline{15.770} \\ 921.04 \quad 11.508 \\ 924 \quad 4.262 \end{array}$$

$$\begin{array}{l} 902.05 = \% \quad \underline{5.456} \\ 921.05 \quad 1.607 \\ 924 \quad 3.849 \end{array}$$

d) In view of establishing the profit or loss by activities, the profit and loss accounts will be opened:

D	902.01	C	D	902.02	C
101.138		91.895	3.993		7.535
	9.243				3.542
	SFD:				SFC:
	loss				profit
			D	902.03	C
			2.755		4.501
					1.746
					SFC: profit
			D	902.04	C
			15.770		20.071
					4.301
					SFC:
					profit
			D	902.05	C
			5.456		18.126
					12.670
					SFC:
					profit

4. Conclusions

As for the organization of calculation of costs in services, the following conclusions can be drawn:

– As for the methods of organization of management accounting in services, only the Order of the Minister for Public Finances no. 1826/2003 makes clear statements, among which we recall: management accounting is organized by the administrator of the legal person, either by using specific accounts or by the development of accounts from financial accounting or with the aid of its own technical and operational (off-balance sheet) records.

– However the medium and small service providers can easily use the off-balance sheet approach, which is based on a table in which are found the components of the actual cost and of the result.

– But for the large service providers at which direct and indirect costs are localized at the level of several activities of service provision, it is imposed the rational use of accounts from the new class, with the aid of softwares, in view of facilitating the work.

– In all accounting regulations, the calculation methods are not detailed, they are only enumerated (standard cost approach, order approach, stage approach, global approach, direct costing approach or other approaches adopted by the legal person, depending on the method of organization of the activities of service provision, the particularity of the activity, the particularities of the activities and one's own needs).

– The use of accounts from the new class is not compulsory, the calculation of costs for the companies which have few activities of service provision can be performed off balance sheet with the aid of tables (centralizing lists of expenses and revenues).
–As for the case study, from the analysis of records of accounts 921, we acknowledge that the car training activity is in loss with the amount of 9,243 lei, and all in all we acknowledge a profit of 13,016 lei (the other activities are profitable), from which it results the need for a better sizing of expenses for the car training activity;
–Regardless of the method of organization of management accounting in services, the on-balance sheet approach or off-balance sheet approach, the manager has to select the most appropriate approach of calculation and system of organization, depending on: the type of activities, the purpose followed by management, the seasonality of activity, the object of activity, etc.

–The lack of a rigorous system of calculation of the cost of services, regardless of the method of organization of this system, leads to the wrong fixing of prices of fees for services, with a direct influence on the return on the activities of service provision.

Department, Romania,
oana.lobont@feaa.uvt.ro and crisina.nicolescu@feaa.uvt.ro*

Abstract

To establish the public sector performance requires a difficult undertaking, related to the definition of performance, practical way to obtain performance and finding the most appropriate indicators true which performance is quantified.

Starting from the idea that, in most cases, the production of performance of goods and services is at odds with strict regulations and bureaucratic procedures in this field, managers seeing these barriers to high performance, so, identifying economic size to quantify performance seems impossible.

The set of indicators used in this paper consists of descriptive variables of effectiveness/quality of governance, as operational variable that refers to the empirically measurable characteristics of public institutions or programs developed by them.

Keywords: public management, governance, performance measurement indicators

J.E.L. Classification: C82, E02, H11

1. Introduction

In order to perform an analysis of performance indicators in the public domain, first we must perform a content analysis on public management and public administration. It is necessary and appropriate, for beginning, explaining the basic concepts as they are presented in specialized dictionaries because, although linguistically between management and administration words there is a semantic association, the two concepts are very different in content.

The importance of addressing public

organizations from the managerial perspective has increased greatly under the impact of the success achieved by private companies, developing, in recent years, a public management model found in the literature as new public management, managerialism, market-oriented public administration paradigm post-bureaucratic, entrepreneurial government or governance.

2. Theoretical background

Management characteristics of the public organization are related to the level and nature of the restrictions imposed on its operation, especially since public organization should harmonize different interests and more complex needs of a large number of people. Therefore the distinction between administrative and managerial approach of public sector comes to mark the transition from "welfare state" to "entrepreneurial governance model."

The first significant content difference between the two concepts comes from Latin where the notion of government comes from "minor" and "ministrare", meaning to serve, to govern, while management comes from "manus" meaning to lead and control directly.

In modern Romanian language dictionary [1] administration is explained as "all administrative bodies of a State" and management is "the art of business to lead and organize".

A managerial approach lies in its center and the market competition, representing a radical version of public institutions and governments, where public servants in leadership positions are viewed and addressed as active agents of development policy of public organizations, not only as persons appointed by the State to carry out

predetermined objectives.

Therefore, in this paper we intend to identify and analyze possible indicators to measure public sector performance, based on the implementation of the performance measurement indicators from the private sector.

Sizing the state of knowledge in governance efficiency approach involves a diverse literature, showing less consistent results due to the heterogeneity of public sector. We are aware that a proper analysis would involve providing critical analysis of the concept of governance by making terminological boundaries between the notions: government, governance, administration, bureaucracy, public leadership and public management or to make a comparative analysis enter the corporate governance and institutional governance or identifying legislative factors, economic and social factors which influence governance structures, but the purpose of this paper is simply to understand the controversy generated by the difficulty of measuring institutional performance.

According to Department of Economic and Social Affairs (2007:2-3) [2], there is three main types of governance, *political or public governance*, whose authority is the State, government or public sector and guaranties the order and the cohesion of a society, *economic governance*, whose authority is the private sector and provides a material foundation and third, *social governance*, whose authority is the civil society, including citizens and non-for-profit organizations and provides a moral foundation.

It is imposible to summarize the most recent related literature, for the major empirical studies in the field of measuring good governance, because, considering the main levels drawn from these studies stands approaches from the perspective of Efficiency, Transparency and Participation as Good Governance.

But underlying all these different interpretations, there are definitions of government efficiency, achieved by *United Nations Development Programme (UNDP)*, where governance is defined as the exercise of economic, political and administrative authority to manage a country's affairs at all levels, *World Bank*, where governance is viewed as the manner in which power is

exercised in the management of a country's economic and social resources, *Organisation for Economic Co-operation and Development (OECD)* where governance designates the use of political authority and exercise of control in a society in relation to the management of its resources for social and economic development or *The Department for International Development (DFID)* who links good governance to particular policy outputs (provision of basic services) policy outcomes (macroeconomic stability), institutional processes (opportunities for people to influence policy) and institutional outputs (personal security).

The general consensus on measuring the effectiveness of public ruling, found in all these studies highlight the characteristics of the data set used in the sense of integrating all significant attributes of quality, but these attributes are passing the notion of quality and are committed to notions such as appropriateness, relevance, credibility, consistency and accessibility [3].

3. Methodology, data and results

Measuring the quality/effectiveness of governance is important from several perspectives, or when it must assess the impact of policies in order to determine future development projects, or to estimate the investment climate.

In this regard, a number of international organizations seeking to build and adapt a series of *indicators* to measure public sector performance, understood in every sense that is given. However, it is important to understand in the indicators approach, the clear distinction between them from the *standard* notion because this is the acceptable performance level in terms of a specific numerical criteria. In addition, there are several types of indicators: *economy indicators*, *efficiency indicators* and *effectiveness indicators*.

Also, the literature distinguishes between *context indicators* related to the specific environment in which it operates some public institution, *input indicators* related to logistical resources, human and financial resources of a public institution, *process indicators* which refers to how resources are used in a public institution, the management inputs, the functioning of the organization,

output indicators referring to achievements or products of public institution, *outcome indicators*, which refers to the impact and incidence.

This study attempts to address the issue of ways to build a set of indicators to assess overall performance. The construction of these indicators can be considered either a *single input or outcome indicator*, usually use for comparisons between inflows and outflows of public resources, or various possibilities of *combination and aggregation of these indicators*. [4]

Thus, it can provide *robust data sets*, leading to quality analysis, in this respect the integrity and independence of international organizations playing a crucial role in ensuring objectivity in data collection from standards, codes, treaties, and various administrative documents (UNDP, Eurostat) [5]. But equally, it can be use data based on *subjective perceptions* of individuals, collected through a complex processes, such as surveys, interviews, discussion groups, surveys conducted by national or international experts. [6]

Moreover, international organizations such as World Bank, United Nations Development Programme, The Department for International Development and The International Monetary Fund [7], plays a sensitive role in translating academic research into practice, often ambiguous in terms of government effectiveness, particularly in relation to economic development, with all the problems and ambiguities level measurement or causal relationships.

Of individual indicators to measure the effectiveness of governance we consider indicators accounts by World Bank, namely The Index Investment Climate Survey (ICS) and the World Business Environment Survey (WBES), which were concentrated on cross-section data and oriented towards investment climate issues such as physical infrastructure, the structure of factor and product markets, interactions within different businesses, industrial regulation, law and order, or tax and customs administration.

However, it is generally recommended to use aggregate indicator that offers a number of advantages among which the construction of a set of data for a large number of countries, providing more accurate measures

or testing cross-country differences [8], [9].

Various studies published in the literature considers government effectiveness from multiple perspectives, in this respect are built metrics by different organizations such as *private entities* such is the Economist Intelligence Unit, Euromoney and PricewaterhouseCoopers, considering different investment climate aspects, or on *sectors* like IHS Energy for country rankings of petroleum exploration attractiveness.

In an attempt to identify which aim to analyze, we need to scale characteristics and dimensions of governance in terms of:

- *competitiveness*, in this respect being able to use World Economic Forum's Global Competitiveness Report, International Institute for Management Development's World Competitiveness Yearbook, and International Finance Corporation's Business Competitiveness - Ease of Doing Business Report [10];
- *governance*, with instruments such as The World Bank's Governance Indicators [11], Country Policy and Institutional Assessment, Database of Political Institutions, Ibrahim Index of African Governance, Afrobarometer, Latinobarometro [12];
- *legal and economic issues* - the European Bank for Reconstruction and Development's Legal Indicator Survey, Public Expenditure and Fiscal Accountability, Open Budget Index, Polity IV, Political Risk Services;
- *development*, using Human Development Index;
- *environment*, holding data with the reach of the World Economic Forum's Environmental Sustainability Index;
- *transparency*, based on information provided by Transparency International Index, Reporters Without Borders, Global Integrity Index [13].

Or, we can consider the possibility of measuring performance at different levels of manifestation, in this regard, building the tool to assist cities in improving local governance using The Urban Governance Index, developed by The United Nations Human Settlements Programme, UN-HABITAT.

A balanced approach involves two major types of performance indicators "*objective indicators*", which refers to aspects of

performance, which should always be concerned about and the “warning indicators” that tell us whether or not we should be mulling over some certain aspects.

Although it is considered that a panacea of “good governance” does not exist, that does not mean that real situations are not perfect, so, on this optimistic idea is basing this paper, with the hope that we can highlight the quality/effectiveness of governance by monitoring the quality of all elements because identification of defining institutional architecture is essential.

4. Conclusions

After a careful comparison, both conceptually and empirically, we find that the World Bank defines the right indicators to measure the quality/effectiveness of governance true The World Governance Indicators providing the best tools for making meaningful comparisons in the EU area or at national level. [14]

Therefore, in this context, the success of public institutions depends of how governments will find motivation and appropriate control mechanisms in the production of goods and services without rigid procedures implemented at the level of each public entity.

It is necessary to outline a new dimension of performance or even improving performance in the public sector, from many valences that were given in the literature to performance concept, placed in the current economic environment, in order to better reflect the results consistent with stakeholder requirements.

Some Ways of Thinking Romanian Political System and Their Relevance for Development

Lobonț Oana-Ramona

*West University of Timișoara, Faculty of Economics and Business Administration,
Finance Department, Romania,
oana.lobont@feaa.uvt.ro or lobont_oana@yahoo.com*

Abstract

The approach proposed in this paper takes the conceptual foundation of neo institutional theory, which seeks to understand the relationship between institutions, behavior and results, proposing at the same time, to highlight the customizations needed in case of emerging economies, in terms of government effectiveness, explained by clear and predictable distribution of powers between the fundamental institutions of the state, through the involvement of citizens in the political system, by equity and fairness in the legal system construction and implementation of public policies and not least, the responsibility, prudence and transparency in public decisions.

The core dataset used in this paper is composed of variables related to the political system and electoral rules, choosing to highlight for Romania only descriptive variables of the composition of the Government, changes in government and governance type (minority/majority coalition/single party) ie, elections period and population turnout.

Keywords: political system, elections, political context, Romania.

J.E.L. Classification: E61, H11

1. Introduction

The theoretical assumption from which this paper pictures itself is that, the public decisional mechanism, in the institutional context, cannot work but in accordance to the continuous, opened and transparent performance of the institution and always “in the letter of the law”, in order to consolidate, reinforce the democratic image of a political

power with implicit consequences.

The factors and the institutional practice represent reflections, answers to rules and conventions which have their convergent point in the concern for economic, social and political stability, with a series of factual determinations. The institutional context, the legal system, the electoral system explain, from different perspectives and depending on the paradigmatic within they are studied (the classical economy institutionalism or the neo-institutionalism), the differences between states, in regard to the level of development.

Conceptual foundation of the proposed approach assumes the neo-institutional theory, which pursuits to understand the connection between institutions, behavior and results, aiming in the same time, to emphasize the necessary features in the case of an emergent economy, as to what concerns the efficiency of governance, explained through the clear and predictable allocation of power among the fundamental institutions of the state, through the degree of involvement of the citizens in the political system, through equity and correctness in the construction of the legal system and in implementing the public policies and not lastly, through decisional responsibility, caution and transparency.

2. Theoretical background

The political phenomenon, far from being an utopia in a democratic society presents a series of dependencies and connections with other sciences, including the science of public administration, explanatory for the importance of bureaucracy in governance [1] or for the recognition and legitimating of electoral processes [2], the economic sciences explanatory for the substantiation of reforms in the public sector, of public decisions and of economic policies [3], or

sociology which, through the organisational theory, explains the interference between the institutional system and society [4].

As a subsystem of the global social system, the political system includes political relations, political institutions and political concepts and the understanding, balancing, clarifying and exploring of these components cannot be achieved but in the context of interdisciplinarity. Such approaches facilitate the exploration of the political system and, the theoretical available tools emphasize a research from the political, sociological, administrative, systemic and even philosophical perspectives.

Leicht and Jenkins (2010) [5] propose a systematisation of the field of political science according to its matter of study: *institutional theory, theories of the state, theories of democracy, the study of political elites, theories of conflict, class analysis, etc.* Another similar, conventional and widespread fragmentation is that of Goodin and Klingemann (2005) [6], which identifies the main elements thus: political institutions, political behaviour, comparative politics, political theory, international relations, public policies and political economy and political methodology.

Analyzing the role of institutions in society, North (1991:3-4) [7] believed that the institutional factors represent “the rules of the game in the context of a society or, more formally, the human constraints which shape/mould the interactions between individuals”, also pointing out the fact that “institutions are meant to reduce uncertainty through creating an appropriate structure for day to day life”.

Therefore, from the political perspective, institutions define and limit the set of opportunities and constraints, that are formal (constitutional, property rights) and informal (norms), and which organise the political area, and by matter of consequence the community, to which the political decisional factors must relate and towards which they must become more responsible in manifestation.

According to Diermeier and Krehbiel (2001: 7) [8], the institutional theory “states and sustains fixed behavioural postulates for the political actors, in the collective choice framework” and, also according to the aforementioned authors it is more appropriate

to speak of neo-institutionalism as a method because “there is no such thing as a neo-institutional theory of rational choice”

Therefore, a rich potential development of this conceptual framework can be open, joined with the approaches of neo-institutional provenance, the social systems in transition theory, the limited rationality theory, and also with elements of political science, sociology and decision theory, improving the simplifying approaches based on the rational agent model, the median voter model or on the search of an optimality understood in a restricted Paretian acceptance. (Keating and Dela Porta, 2010) [9].

3. Methodology, data and results

The analysis of the political system, in an integrative manner, as a system located at the interaction of the social system and the judicial, economic, cultural and other systems that are present in the social life, situate in the center of its preoccupation, the study of its effects. The starting point in the approach we are taking represents the way in which the elements of the political system are interconnected, as it represents an especially important issue in analyzing and predicting its behavior, the identification of relationships between elements, between these and their assembly, as well as between these and the environment, being an especially difficult operation most of the times. But the verity of the relationships depends on the instruments and the techniques used, on the temporary horizon of the observation, on the spirit and ability of observation, analysis and synthesis, as explaining that, sometimes, the identified causal relations have some degree of subjectivity, especially in the social systems, as the political system is, and in the use of these relations rests a greater or lesser degree of uncertainty.

For the same reasons mentioned above, in the analysis of the political system, we can even discuss of a *multiple perception*, which implies both the formulation of the various demands, converting these requirements through legislation, decision making, execution by administrative means, as well as the support elements and the means of support recovery, permanently determining

status changes, characteristics and traits changes, emphasizing its dynamic character.

Although the political system is an institutional system, the determining function which distinguishes the political system from other similar systems is *to assign values through public authorities, in a society, through the decisions adopted and public policies implemented*. Therefore, addressing the political system in its size, ca not disregard its construction as a set of political communities, institutions and organizations (political parties, political formations, alliances and interest groups), the relationships they develop, the institutional arrangements on which they function (the electoral law, the Constitution, the political attitude and behavior), as well as their members (politicians, unions, lobby groups) and the values to which they relate.

The Romanian democratic system succeeds in functioning through a modern democratic political system, based on multi-party system and free elections. Table no. 1 highlights the Romanian electorate voting preferences, which seem to change over time, in the condition of concerning vote turnout. The legislative power had mandates of four years, except for the first legislative power, which lasted only two years, being invested for both Houses of Parliament, directly through similar electoral mechanisms. The ideological and political preferences of the parties, formed by the Romanian governments, in a cohesion of a set of ideas, values which to substantiate government programs, have been of center-left in 1990-1992, 1992 - 1996 and 2000-2004, when the opposition was represented by center-right parties (except for the period 1994-1996, when the nationalist parties supported the government) and of center-right in 1996-2000 and 2004-2008, when the opposition was formed from center-left and nationalist parties (2000: PSD ran as PDSR as Social Democratic Pole Alliance with PSDR; 2001: PDSR merged with PSDR into PSD; 1992: PD-L ran as PD-FSN; 1996: PD-L ran as part of Social Democratic Union (USD); 2000: PD-L ran as PD, 2004: PD-L as part of Justice and Truth Alliance (DA (PNL-PD)); 2000: PUNR ran as part of National Alliance Party (PAR (PUNR-PNR)); 2004: PNGCD ran as PNG, 1996: PNL ran as part of Democratic Convention of Romania (CDR); 2004: PNL ran as part of Justice and Truth Alliance (DA (PNL-PD)).

Table no. 1 Parliamentary Election in Romania over the period 1992-2008 (%)

Party	PSD/PC	PDL	UDMR	PRM	PNL	Vote turnout
1992	0.00	10.19	7.46	3.90	2.63	76.3
1996	21.52	12.93	6.64	4.46	0.00	76.0
2000	36.61	7.03	6.80	19.48	6.89	65.3
2004	36.61	31.33	6.17	12.92	0.00	0.00
2008	33.10	32.36	6.17	3.16	18.57	18.57

Data source: European Election database for parliamentary elections and from the International Macro Data Resource - Comparative Political Data Set III 1990-2009 compiled by researchers at the University of Berne (Armingeon et al. 2011) for voter turnout

The Romanian political context fits within the lines pictured in the table below (Table no. 2), where the utopia left-right political collaboration is a constant for Romania, confirming a process of refusal of participatory democracy, in society, and of ideological and behavioral homogenization of politicians. The core of the data set consists of variables related to the political system and electoral rules, choosing to highlight for Romania only the descriptive variables of the composition of the Government, changes in government and governance type (minority/majority, coalition/single party), and the dates when elections are organized and turnout population, with a series of methodological notes (*Methodological Note (1) - right and center hegemony is represented by the value 1; right and center domination, value 2; balance of power between left and center / right, value 3; dominance of social democracy and other left parties, value 4; and the social democratic parties and other left parties hegemony, value 5; Methodological Note (2) - 1) a single party government majority; 2) minimal winning coalition; 3) the excess of coalition; 4) minority one-party rule; 5) minority, more parties in government; 6) interim government or technocratic; 7) others; Methodological Note (3) - Number of changes in government per year, due to 1) election 2) resignation of the prime minister, 3) divisions of the government, 4) lack of parliamentary support, or 5) the head of state intervention; Methodological Note (4) - as a percentage of parliamentary seats, weighted by the number of days of government in function, in a given year*)

Table no. 2. Overview of Romanian political context

Period of analysis	Cabinet composition (1)	Type of Government (2)	Number of changes in government (3)	Cabinet composition: Right-parties (4)	Cabinet composition: Center parties (4)	Cabinet composition: Left parties (4)
1990	-	-	-	-	-	-
1991	4	1	1	1.94	0.00	98.04
1992	4	3	1	8.00	0.00	91.97
1993	4	4	0	0.00	0.00	100.00
1994	4	5	1	16.79	0.00	83.19
1995	4	5	0	20.36	0.00	79.62
1996	4	5	2	17.02	0.68	82.29
1997	2	3	0	60.95	12.50	26.54
1998	2	5	2	81.56	16.71	1.96
1999	2	5	2	82.37	16.88	0.72
2000	2	3	1	60.29	12.36	27.34
2001	5	4	0	0.00	0.00	100.00
2002	5	4	0	0.00	0.00	100.00
2003	5	4	0	0.00	0.00	100.00
2004	4	4	2	0.61	0.22	99.18
2005	2	5	0	41.74	26.74	31.52
2006	2	5	0	41.74	26.74	31.52
2007	2	5	1	64.14	27.74	8.12
2008	2	5	1	71.35	27.32	1.34
2009	3	2	2	63.04	0.40	36.56

Data source: *The MacroDataGuide, Comparative Political Data Set III, 1990-2009* [10], [11].

Thus, the quality of political representation, caught in a binary political cleavage, depends on a number of technical issues such as the electoral system, the party system and government formation, in order to ensure durability for the democratic construction. In this context, the functioning of a democratic regime depends, not only on the institutions through which the division of responsibilities between the executive and the legislature is carried out, but also on a number of formal and informal procedures through which political actors influence the system operating life.

Therefore, only a stable institutional structure, favorable for the demonstration of freedom and rights, in all their forms of manifestation, is able to provide the fundamental premises of durable development, especially in the reality of the new interconditionality, within the economical-social-environmental triad, which raises new concerns for grounding this

type of development.

4. Conclusions

Keeping in mind the controversies in the field, with the openings and their limits, in theory, the political system must be considered in all the senses that are given to it, including both the political consciousness, in its psychological and ideological components, as well as the political relations, action relations powered by alliance relations between groups, the categories, social classes or intermediate relations between these and the political institutions and organizations that have the mediating role of transposing the political ideology of social communities in practical political actions for conquest, consolidation, control, maintenance and defense of their political power.

Abstract

Enterprise financial performance is measured by the difference between revenues and the expenses incurred to achieve the revenues. Revenue recognition and evaluation take place according to applicable accounting regulations.

The present paper envisages the way to recognize revenues in compliance with IAS 18 “Revenue” and OMFP 3055/2009 regarding the approval of accounting regulations compliant with European Directives.

Key words: revenues, recognition, IFRS, accounting policies

J.E.L classification.: G21

1. Introduction

In the current international context, the transparency of company-related information is needed more than ever before. The main users of accounting information, namely investors, need clear, credible, financial and non-financial information, comparable at international level according to which they must substantiate their decision making. In order that accounting information users should be certain about such information, it should be the outcome of accountancy performing in accordance with various accounting norms and rules.

2. Content

In the present international context, company information’s transparency is increasingly required. The main users of

accounting information, namely investors, need financial and non-financial information which must be clear, reliable and comparable at international level according to which they can make their decisions. In order for accounting information users to have the certainty of receiving such information, it should be the outcome of accountancy following certain accounting norms and rules.

Internationally, the accounting convergence/harmonisation effort involves the development of accounting principles and standards applicable, entirely or partially, to a set of countries, entities or by a group of experts in the accounting profession[1].

The term “convergence” is a generally accepted desideratum at world level as the goal is to reach the same point or the same result in the field of accounting norms. Convergence equally concerns professional bodies, normalizers and users of accounting financial information.

The application scope of financial accountancy is represented by business entities (enterprises) whose goal is to make profit.

Enterprise financial performance is measured by the difference between revenues and the expenses incurred for the revenues. The main goal of an enterprise is to maximize profits and minimize costs. In this respect, enterprises lay down accounting policies taking account of the particular nature of their activities.

”Accounting policies are detailed methods for evaluation, measurement and recognition an enterprise has chosen from among those accepted by the law, from among accounting standards or accounting practices [2].

The present paper aims at comparatively analyzing the accounting policies related to revenue definition, classification and recognition.

Revenue definition shown in the IASB general accounting framework is in compliance with both national and international accounting norms. Revenues are ”increases of economic benefits during the accounting period in the form of inflows or enhancements of assets or decreases of liabilities that result in increases in equity, other than those relating to contributions from equity participants”. The definition of revenues includes both the income arising from ordinary activities and the gains from other sources [3].

- The income arising in the course of ordinary activities is referred to by a variety of different names including sales, fees, interest, dividends and royalties.

- The gains are elements corresponding to revenue definition and may occur as the outcome of ordinary activities.

Since gains are increases in economic benefits, their nature is not different from the nature of ordinary activity income and therefore the general framework does not include them as a distinct structure.

Revenue definition also includes unachieved profits such as those ensuing from the revaluation of securities, or the increase in fixed assets’ book values. If the profits are recognized in the loss and profit account, they are shown separately since their presence is very important in the decision-making process.

Defined from the perspective of inventory exchange ratios [4], revenues are ratios of inventory exchanges in relation with the gains achieved from performance and ownership. In other words, they indicate resources/outcomes accomplished, being made up of the consideration received or receivable in a counterparty with the sale of goods, works and services, or of holdings.

According to the definition of revenues which rely on the international conceptual framework, there is a condition to recognize revenues as compared to assets and debts’ structures. It is noticed that revenue recognition is subject to the recognition of assets and debts. A revenue is recognized at the same time with the recognition of an increase in an asset and/or a decrease in a liability.

The applicable pattern is the following [4]:

- What is an asset?
- What is a debt?
- Has an asset or a debt changed its value?
- Increase or decrease?
- To what extent?
- Where has value change ensued from?
- Relationships with equity holders?
- What is the outcome?
- Is it an income, an expense, a profit or a loss?

Table 1. Revenue recognition during recognition of asset increase or debt decrease

<p>Assets → Controlled resources resulted from past events with potential future economic benefits</p>	<p>Increase: - cash - receivables - goods and services received in exchange of goods and services rendered</p>	<p>Recognition: → REVENUES</p>
<p>Debts → Current liabilities arising from past events and whose discount is expected to produce resource outflow which incorporates economic benefits</p>	<p>Decrease: - cash - debts - rendering goods and services to a creditor in order to meet their duty of loan payment</p>	

In the context of IFRS application, the general criteria shown in the conceptual framework are:

- the inflow of future economic benefits associated with transactions;
- costs or values can be measured reliably enough.

The regulations in our country by means of OMFP 3055/2009 use the general criteria for assets’ and debts’ recognition but not those regarding revenues and expenses.

Revenue recognition starts from an enterprise’s activities which generate other activities consuming resources and producing outcomes.

In compliance with tax year independence, the transactions generating expenses and revenues are taken into account at the time they are generated or committed. In order to raise revenues, there are four major stages[4]:

manufacturing, invoicing or credit sales; money collection; incorporation;

- manufacturing is the stage of generating a product as the outcome of resource consuming activities (for example, manufacturing process and end products);

- invoicing or credit sales mean the transfer of ownership from seller to buyer;

- money collection is the stage when the outcome sale generates money;

- incorporation is the strict accounting stage when incomes are included into outcomes in order to absorb associated costs.

Revenue entries at the time of their occurrence is the result of commitment accountancy which forbids revenue recognition while collecting money.

According to international regulations by the IAS 18 referring to “Revenues”, the criteria for revenue recognition are usually applied for each separate transaction, event or circumstance, thus being able to reflect economic reality. The transactions and events approached by IAS 18 “Revenue” are sales of goods; service rendering; use of enterprise assets by third parties. IAS 18 provides additional specific recognition criteria in compliance with the revenue category.

Sales of goods: they refer to the products manufactured by an enterprise in order to be sold, goods purchased for resale, goods purchased in retail trade, lands and real estate for sale.

The criteria for the recognition of goods sale revenues are shown in the table below:

Table 1 Revenue recognition criteria

IAS 18	OMFP 3055/2009
- the entity has transferred to the buyer the significant risks and rewards of ownership of the goods;	- the entity has transferred to the buyer the significant risks and benefits associated with ownership of the goods;
- the entity retains neither continuing managerial involvement to the degree usually associated with ownership nor effective control over the goods sold;	- the entity retains neither continuing managerial involvement to the degree usually associated with ownership nor effective control over the goods sold;
- the amount of revenue can be measured reliably;	- the amount of revenue can be measured reliably;
- it is probable that the economic benefits	- the entity is likely to get future economic

associated with the transaction will flow to the entity;	benefits associated with the sale of goods;
- the costs incurred or to be incurred in respect of the transaction can be measured reliably;	- the costs incurred in respect of the transaction can be measured reliably.

The table above shows full compliance between the provisions of IAS 18 and those in OMFP 3055/2009.

However, if one considers the order stipulation, namely “Revenues arising from sales of goods are booked at the time of goods’ being handed over to the buyer, at the time of goods delivery against invoice or in other conditions stipulated in the contract which authorise the transfer of goods ownership to the buyer” and the control-based recognition principles, there might be troubles while recognizing and measuring revenues.

Example[5]: An entity invoices goods for a buyer on a certain date and the delivery is to take place on a subsequent date. At the time of invoicing, the entity does not hold the respective goods.

A question arises about the “ownership” criterion: Is the revenue recognized? In the invoicing context, the buyer is the owner of goods and here comes the “control” criterion: How probable are the delivery and the actual control transfer if the seller does not hold the goods yet?

If an entity retains the significant risks and benefits associated with goods ownership, the transaction is not a sale, so no revenue is recognized.

Here are some examples of situations in this respect[5]:

- when the goods are shipped subject to installation and the installation is a significant part of the contract which has not yet been completed by the entity;

- when the buyer has the right to rescind the purchase for a reason specified in the sales contract and the entity is uncertain about the probability of return;

- when the entity retains an obligation for unsatisfactory performance not covered by normal warranty provisions;

- when the receipt of the revenue from a particular sale is contingent on the

derivation of revenue by the buyer from its sale of the goods.

IAS 18 states that when an entity is uncertain about collecting receivables recorded previously, the estimated part to be received is recognized as an expense. When the uncertainty is removed, the amount is received, and the entity shall recognize it as a revenue.

According to OMFP 3055/2009, in the event of uncertain receivables, there are impairment adjustments for the expenses that can be cancelled on behalf of revenues.

Still according to IAS 18, revenues include only the economic benefits received or receivable by the entity on its own behalf. The amounts collected on behalf of third parties (VAT, sale fees, excises) must be excluded from the revenue category as they are not benefits the entity is likely to receive on its own behalf.

In the practices of some entities in our country (especially those who are not obliged to undertake financial statement audits), there are true hardships that make the accounting information producers infringe the criteria for revenue recognition from sale of goods. This is mainly due to fiscal incidences, especially to value-added tax and tax control procedures which have not adjusted to the evolution of accounting regulations. A transaction should not normally be subject to taxes until the criteria for revenue recognition from goods sale have been met.

Rendering of services refers to constructions, installations, repairing, technical assistance and service, brokerage etc.

In compliance with IAS 18, revenue recognition associated with the rendering of services depends on the reliable estimation of the transaction outcome. An entity recognizes revenue from the rendering of services by reference to the stage of completion of the transaction when at the end of the reporting period, it can reliably estimate outcomes. The outcome of a transaction can be estimated reliably when all the following conditions are satisfied:

- the stage of completion of the transaction at the end of the reporting period can be measured reliably;

- the amount of revenue can be measured reliably;

- it is probable that the economic benefits associated with the transaction will flow to the entity; and

- the costs incurred for the rendering of services and the costs to complete the services can be measured reliably.

The advance payments received by an entity must not be used to find out the stage of completion because they do not reflect the services performed.

As far as the rendering of services is concerned, OMFP 3055/2009 states that recognition of revenues from rendering of services occurs according to the percentage of completion. Rendering of services also includes works executions and any other transactions that cannot be referred to as goods deliveries;

- the stage of work completion is determined by work statements accompanying invoices, acceptance certificates, or other documents testifying the accomplishment and acceptance of services rendered;

- as to construction works, the revenue recognition arises from the acceptance protocol signed by the beneficiary.

IAS 18 related to “Revenue” refers to the revenues ensuing from service rendering whose approach is similar to the approach of construction contracts compliant with IAS 11 “Construction contracts”. OMFP 3055/2009 does not make clear the differences between a services contract and a construction contract. In order to understand the differences, the provisions laid down in IAS 11 “Construction contracts”, IAS 18 “Revenue” and IFRIC 15 “Agreements for the construction of real estate” can be useful.

Revenue arising from the use by others of entity assets refers to the revenues arising from interest, royalties and dividends. They are recognized when it is probable that the economic benefits associated with the transaction will flow to the entity and the amount of the revenue can be measured reliably.

IAS 18 “Revenue” states that revenue shall be recognized on the following bases:

- interest shall be recognized using the effective interest method as set out in IAS 39 “Financial instruments: recognition and evaluation” which sets the depreciated cost of a financial asset or of a financial liability, and

allocates interest- or expense-related profits during the corresponding period;

- dividends shall be recognized when the shareholder's right to receive payment is established;

- royalties shall be recognized on an accrual basis in accordance with the substance of the relevant agreement.

3. Conclusion: It can be ascertained that from the perspective of IAS 18 "Revenue", the recognition criteria are general and also customized depending on the transactions and events falling under IAS 18.

Still according to IAS 18, revenues include only the economic benefits received or receivable by the entity on its own behalf. The amounts collected on behalf of third parties (VAT, sale fees, excises) must be excluded from the revenue category as they are not benefits the entity is likely to receive on its own behalf.

In the practices of some entities in our country (especially those who are not obliged to undertake financial statement audits), there are true hardships that make the accounting information producers infringe the criteria for revenue recognition from sale of goods. This is mainly due to fiscal incidences, especially to value-added tax and tax control procedures which have not adjusted to the evolution of accounting regulations. A transaction should not normally be subject to taxes until the criteria for revenue recognition from goods sale have been met.

OMFP 3055/2009 neither provides nor forbids a breakdown, clustering or grouping of transactions in order to recognize revenues.

Decisions shall be made in the context of applying the principle of business prevalence over laws.

IAS 18 states that when an entity is uncertain about collecting receivables recorded previously, the estimated part to be received is recognized as an expense. When the uncertainty is removed, the amount is received, and the entity shall recognize it as a revenue.

According to OMFP 3055/2009, in the event of uncertain receivables, there are impairment adjustments for the expenses that can be cancelled on behalf of revenues.

Abstract

In order to take a decision on investments, and entire process of identification, evaluation and selection of projects is assumed, so as to bring major benefits to an organization. The decision on strategic investments demands a series of challenges and involves the most experienced managers of the company within the field of investments; this happens since, on one hand, a wrong decision might be taken, and on the other hand, the company might lose an opportunity that cannot be capitalized anymore in the future. Like this, a company might lose extremely precious resources, as regards its future development or growth. Such a decision, taken in the view of carrying out a strategic investment, emphasizes all the elements of a classical cost – benefit analysis.

Keywords: traditional investments, green investments, strategic investments, Public-Private Partnership.

J.E.L. Classification:Q01, E22, O52, P28, R42.

1. Introduction

The strategic [13] investment has been represented by an investment carried out by a corporation or affiliated company to a young company, which brings it an added value or a profit. The aim consists in earning access to particular products or to the technology that the beginner company wishes to develop, but does not benefit from funds. Such investors have started to be different as comparing to the traditional investors or those financial, which mainly aim on achieving profits on very short term.

A strategic investment is represented by a transaction tightly connected to mixed companies. As concerns the strategic investments, a company can carry out an investment towards another company. Such agreements are conceived in order to serve to the common business aims. The strategic investments have involved a great variety of transactions. The planners of such transactions have taken decisions as regards the strategic investments when they believe that the investment is not only directed towards the financial objectives, but towards larger business or strategic objectives, also. The effective details of business agreements have varied from business to business. A strategic investment has been differentiated from an investment of “capitalist venture” type, whose aim consists in generating a huge profit in a very short time. The strategic investments have started with the identification and evaluation of various projects, as well as making a selection able to stimulate the competitive advantage of a company. Within a strategic investment, the investor will generally achieve common or preferential actions within the targeted company. More than that, the two companies will be able to conclude contracts of supply and provision, agreements of sharing technology or of research and development.

1.1 Advantages and disadvantages of the strategic investment and partnerships

The benefits of the strategic investments are connected to the access to company's resources, where investments are done at a relatively low price. The risks related to the strategic investment are in connection with the identification and evaluation process of various strategic options of investments,

which might be quite complex, time consumers and expensive.

Notwithstanding, the sense of a strategic investment might prove certain valences. The first way refers to the moment when an individual or a company will invest, in the view of generating secure and steady efficiencies, and usually in accordance to a consultancy company advices, able to keep up to the market tendencies; these might address to the customer's needs. In the second stage, one might talk about the investments to another company, a lower one, usually in the moment of its start, with a longer term strategy, and also by achieving a profit on long term. The strategic investment might also determine the feature of a public environment, as an investment into national objectives, of significance related to the common objectives of a society, of the transport infrastructure and of producing energy; in generally, it is about those fields that are related to the state's security. The reasons for which such investments take place are various, but among the most important, one might mention the following:

- the investment is carried out because a smaller unit accomplishes similar products;
- a small company can become in time a client of the investor company;
- The “adopted” company becomes a source of technologies and innovating ideas.

The experts have argued that such investments have been really benefic, since they allowed companies to maintain themselves autonomous, thus encouraging new investors to involve. The strategic investment has been also generated from the social responsibility of the high companies that can encourage them and are able to make dynamic the business environment, by means of “the adoption” of small companies, on their first stages; this is obviously done in order to achieve some benefits. In this way, a micro-environment has been created, more active or more dynamic and efficient for a company.

The strategic investments have started by the identification and evaluation of various projects, as well as by making a selection able to stimulate the competitive advantage of the company. As regards a strategic investment, the investor is in generally

achieving common or preferential actions within the targeted company. More than that, the two companies might adopt contracts of supplying and provisioning, on sharing technology or research and development agreements. A strategic investment is usually influencing what the company is carrying out (this refers to products or services that are offered, as well as to processes and practices applied). As result, a series of advantages and disadvantages can be emphasized [14].

Some of the benefits of the strategic investments are represented by the following:

- The strategic investments offer access to the investments companies' resources, to a relatively low price. On one hand, the investor company might have as goal the access to technology, and on the other hand, the other company has access to the financial resources. In this way, the costs related to research for the investor company will be reduced.
- As regards the investor company, a strategic investment is carried out for a part of the control over the company, which beneficiates of investment. Such thing will allow to the company to protect the investment, as well as on modeling the business direction of the lower company, and also the products and services lines.

Among the disadvantages, one might mention:

- The process of identification and evaluation of various strategic options of investments, which might be significantly complex, time consumers and expensive;
- The higher company can express the willing of taking over the smaller company, to a certain moment in the future, once the smaller company has proven to be viable and productive.
- In the situation when a smaller company is not able to accomplish the agreement, for any reasons, there will be always the risk on taking it out of the market, from the investments process.

1.2 The comparative analysis of the traditional and strategic investments

Professor Shark J. brought in foreground a series of stages necessary to accomplish strategic investments [8]. Firstly, it is about

identifying the expenditures proposals, the quantitative analysis of the cash flows, the evaluation of qualitative order issues, as well as performing the best decisions, by taking into account the points already mentioned above. Professor Shark J. mentioned that many times a logical and under argumentation construction will bring towards a really strategic investment. In the same time, one might admit that the specialty literature will emphasize only some of these stages, ignoring the others. This point is added to the other reasons, for which the managers are frequently accused on bad decision taking on investments, and which do not have a strategic succession. Hayes and Abernathy [3] and Hayes and Garvin [4] mentioned long time ago the company's mistake and especially the mistakes of people taking decisions, on focusing on only quantitative matters and cash flows type issues, since such decisions will unavoidably take towards negative strategic involvements. Within a strategic analysis, there are points significant to be taken into account, and which we find in the larger sense on classifications carried out by professor Shark.

If we refer to the traditional approaches on making investments that include the recovering, the efficiency of investments, the accountancy profitableness, the residual income, as well as the cash flow updated, they have been criticized on a series of principles, basing upon various reasons. Among the main critics, one might mention “the short vision” and the exclusion of the non-financial type working, achieving benefits on short term, wrong assumptions over the status-quo, the inconsequent handling of the inflation, as well as promoting a non-valuable behavior on practices within the investments field.

The investments proposals are in generally taken exclusively by the investment department. A strategic investment takes into account all the benefits that might have over the company, of all its compartments, of the employees, of the partners and over the state. As result, the effects are capitalized outside the investments department, as well. The approach of a strategic investment introduces the computer assisted designing, as well as using objective systems and algorithms on input and output.

The second issue related to the traditional investments and their evaluation consists in their inability on taking into account the non-financial benefits, idea that is mentioned within the evaluation of the strategic investments. Such non-financial order type issues refer to the manufacturing flexibility, to the information flows, on designing the evaluation system, on developing the databases or the already used software.

The third issue refers to time. A traditional investment follows a short focalization time on achieving the profit. The strategic investments are carried out on a longer term, and the profit is achieved on long term, thus quantifying economic, social and technological type factors.

The fourth issues is dedicated to the status-quo of an enterprise, which by its angle of traditional investments, it is not reached in case of failure; the competitive position of the company remains unchanged. Such proposal is not true. Professor Parks [7] carried out an analysis in this way, proving that elements related to cost, quality and solid partnership will remain unchanged, and the company's image towards repeated investments failures will be affected not only inside, but especially within the current or potential partners group. The same opinion was underlined by Drucker, which added that “the accountancy cost will give information about what a person is doing for a company, but not related to what a person is not doing for a company”.

The fifth issue regarding the traditional investments, comparing to those strategic, has as first point of attraction the value. Many times, the managers that present the investments proposals have carried out imaginative calculations. Being aware of the very high standards, which the senior managers own, the authors of the investments projects have aimed on taking the issues to extreme, to pass beyond the rational limit, or even more far away, by issuing unreal hypothesis and results.

There are also a series of viciousness of the traditional investment, but if we look more pronounced, the issue signifies more and more an improvement of the method, and less and less a conceptual mutation. One might call them “seeming viciousness”, but it greatly depends upon the angle where the analysis is performed. In this way, in order to

evaluate the strategic investments, two types of means [1] can be applied. The first approach involves a change within the analysis frame of the traditional investments, aspects that take into account the flexibility, the quality, information and the actuality. The second approach assumes to have recourse to a series of analytical frames, which are based on significant misalignments from the traditional approach, as concerns the costs management, the multi-attributions decision taking, the value analysis, the hierarchical analytical method, the research and development methods, as well as the uncertainty method.

2. The Public - Private Partnership, a strategic partnership

The public – private partnership (abbreviated by PPP) signifies a governmental or private service, a business, which is financed and exploited by means of a partnership between the Government and one or more companies from the private sector. Such systems are denoted sometimes as PPP or P3. PPP involves a contract between an authority of the public sector and a private company, where the private part provides a part or an entire public service, and assumes its substantial financial, technical and operational risk within the project. For some types of PPP, the cost of using the service is supported exclusively by the services users, and not by the contributors. There is no unique definition of the Public-Private Partnership. PPP refers in generally to time, long time partnerships, concluded between the public and private sectors agencies, especially aimed towards financing, designing, implementation and operation, as well as facilities of services infrastructure; these have been traditionally provided by the public sector. Within a PPP, each partner, by a compulsory contract or other type of mechanism, is usually agreeing to share the responsibilities related to submit and apply a project. Such type of collaboration or partnership is built on the experience of each partner that fulfils an adequate allocation of the resources, as well as a management of risks and responsibilities. The Public-Private Partnership also assumes a project based on concession, between the Government or an

legal entity on one hand, and a company of the private sector, on the other hand, in order to deliver an infrastructure service, and then imposing some taxes on using [15].

In other situations, the capital investments have been done towards the private sector, where the costs on services providing were supported totally or partially by the government. In the situation of projects that aim on creating public goods or of infrastructure for a certain sector, the government might offer a subvention of capital, so that it will be able to increase the attractiveness for the private investors. In other cases, the government can support the project by offering subventions or exemptions from taxes. Normally, the governments have looked to encourage the private environment in order to accomplish investments into the infrastructure, and especially in the fields not endowed with a material or logistical basis, in order to carry out actions. As regards the 21st century, the public-private type partnerships have offered an unique perspective over the aspects of cooperation in the network of public management. They are a consequence of the New Public Management of the 20th century, and occurred under the pressures of the globalization.

As regards the theoretical or ideological basis, the PPP is carried out on both the principles of the capitalist market economies, but also on the social principles, on corporatist type. The supporters of the liberalism have taken into consideration the part of the state as minimal management, especially with part on orientation and regulation. In this way, the main part of the state consists in defining the general frame, on supporting it favorable, in accordance to the economy's functioning on a capitalist market. From this point of view and assuming ideologically, the state should not intervene not even within the infrastructure achievement, or of other public interest fields. Nevertheless, taking into account the world reality, where the state manages certain sectors, the cooperation with the state, as regards the capitals, is welcomed. Those that prefer a social, corporatist economy assume the idea of certain centralization on some fields, in the power of the state. The people should be helped on developing his or her business; the people cannot help by

themselves. It will remain in analysis if the centralization of funds and their directing by the state represent a form of help, or the distribution of the financial flows towards the private sector where part of people are working within signifies a form of help.

One might mention the idea of Paul Ligniere as regards the Public Private Partnership, since it has a dual vision over it, thus offering a larger image and more complete over the concept and its practice [6]. Largely, the author mentions that PPP refers to all the collaboration forms between the public authorities and the private companies. The state supports and encourages the enterprises, by various forms of support, as well as initiatives, without intervening in their activity. In a restricted way, the author also mentions that PPP refers to the collaboration on certain projects, among the same parts, by acting depending upon the contractual type. The author agrees that the PPP should offer benefits for both partners – even if the objectives are different, they might be reached by the same activity. Complementary, the two parts involved will promote the economic development.

3. Conclusions - Solutions [16]

The public-private partnerships can contribute on the economic recovery, as well on a long lasting development of the European Union. Regarded as a combination between the public ability and that private, this has become essential in the context of the economic crisis. Nevertheless, the European Committee has been faced with obstacles in the way of financing the PPP, as well as of the means on encouraging them. Regarded from the European Union point of view, the public-private partnership types represent innovating solutions on financing, promoted by the European Union, and which are able to contribute towards [12]:

- Projects on public interest facilitations, especially on the infrastructures and of public cross-border services;
- Sharing the financial risks and reducing the infrastructure costs, where these are normally financed integrally by the public sector;
- Supporting a long lasting development, the innovation, research and development, by a strong competition

and commitments of the private enterprises.

Financing the European Union can be used for the co-financing of the Public-Private Partnerships. In this way, the interested national, public and private parts might beneficiate of:

- The structural funds, associated to the PPP, as well as the JASPERS, JESSICA and JEREMIE funds;
- The funds of the European Bank on Investments and of the European Investments Fund;
- The financial instruments of the trans-European transport network (abbreviated as RTE-T), which encourages the private financing contribution, the risk capital and offering of bank credits;
- The Frame Program 7 on research and development, as well as technological common initiatives.

The European Union also recommends the use of instruments on innovation, meaning:

- The facility on financing, with sharing of risks (abbreviated under FFIR), established by the European Committee and BEI, in the view of facilitating the access to credits;
- The competitiveness and innovation frame instruments (abbreviated as CIP), which might support the PPP in the fields of research, technological development and innovation.

A series of obstacles have occurred in the same time, in the way of creating the PPP. The economic crisis has determined the growth of credit cost, a reduction in the banking dates of payment in order to reduce the credit duration, and a lack of financing for the process on public acquisitions. This is the reason, for which the European Committee presented a temporary community's frame for the state assistance, on supporting the access to financing during the periods on economic crisis, being aware of the fact that creating the PPP will many times involve significant financial resources, an expertise and specific preparation in the public sector, complex financial agreements, as well as long term commitments from the authorities. The European Committee will also encourage the PPP in the field of

technological innovation, by many programs that are essential on the European Union competitiveness. One should understand the idea according to which the risks and responsibilities are shared between the public and private under interest. In such conditions, the Committee will ensure the access to financing by means of the subventions, public acquisitions or investments.

The economic crisis had a negative impact over the public finances, as well as over the projects that need long term investments. In this way, in 2012, as part of the economic recovery plan, the Commission initiated a series of specific action on promoting the PPP creation, meaning [16]:

- Creating a group of dialogue and exchange between the parts under interest and involved within a PPP;
- Growth of the financial available resources, by means of the European instruments, already existing, and by developing specific instruments;
- Ensuring that the public and private bodies of management should be treated equally as regards the European funds;
- Proposal to a new judicial instrument, as regards the concessions on public services attributed to the private sector;
- Extension of the field on applying the European financial instruments;
- Finalization of the impact evaluation, as regards the initiative related to assigning contracts on services concession;
- Improving the accountancy practices;
- Dissemination of the specialty knowledge and of the know-how;
- Promoting the information, communication and innovation technologies.

The Recovery Term’s Contribution to the Identification of Value Losses from the Use of Fixed Assets. Opportunities and Limitations in the Implementation of the Mathematical Model within the European Area, A Parallel with the Reality Encountered within the Romanian Area.

Manea Marinela – Daniela
„Valahia” University of Targoviste
m_manea7@yahoo.com

Abstract

This paper sets out to further pursue a previous research which focused on testing the mathematical model regarding the recovery term’s contribution to the identification of the value losses from using the fixed assets in the Romanian accounting area. We will treat here the realities encountered in the implementation of the mathematical model recovery term of the economic asset within the European area. There have also been covered the existent differences between the techniques and tools employed in the two areas, the Romanian and the European one, with regard to the testing of the suggested mathematical model.

Key words: updated estimated recovery term, economic asset, estimated cash-flow, discount rate.

J.E.L. classification: M41.

1. Introduction

Currently, within the European accounting practice, creativity holds a very important role, outrunning the traditional things in accounting [1]. In our attempt to identify models and working tools available for the Romanian professional accountants for implementing the International Financial Reporting Standards and European Directives, we initiated a mathematical model in a previous paper that tests the recoverability of an entity’s economic asset. For the model’s validation we considered it necessary its testing within the practice of the groups in the European and the Romanian area. In a previous paper we presented the specific traits encountered in the Romanian area regarding the limitations in the

application to the mathematical model proposed. Likewise, we proceeded to carry out a comparison between the two realities – the European one and the Romanian one, concerning the set of annual financial situations and the availability of the information provided to the users, necessary for the testing of the suggested mathematical model.

2. Specialized literature

Our action was initiated starting from the updated estimated recovery term of recovering the investment from finances; according to the specialized literature, the recovery term [2] of the sum allotted for investment expresses the number of recovery years through the updated annual medium cash flows ($CF_{act/an}$) of the invested capital (I_0) and it is determined according to the following relation:

$$T_r = \frac{I_0}{CF_{act/an}}$$

This indicator ensures a choice of the investment variants according to the speed of recovering the invested capital. Therefore, those investments that recover the invested capital in a larger period of time will be penalized because the risk of not recovering it grows proportionally with this period of time. This was the starting point of our research and subsequently the recovery term indicator for the investment underwent modeling and restatements.

3. Methodology

3.1. The method

In a previous study we proposed to realize a mathematical model – recovery term through which we could identify a sub-assessment index for the entity’s assets, through the formula [3]:

$$T_r = A_e / CF, \text{ where}$$

T_r = recovery tem;

A_e = medium economic asset;

CF = updated expected medium cash flows.

The recovery term obtained expresses in “cash flow” years the period of time the entity needs to recover the capitals invested in the economic asset. Validating the mathematical model imposes its testing in practice and for this it was selected a representative sample of groups of societies within the Romanian and the European area where the proposed mathematical model’s development will be observed.

In our action to establish, through calculating the recovery term, a depreciation indicator for an entity’s economic asset, we resorted to an artifice, by changing the terms of the updated estimated recovery term, as it follows [4]:

✓ the initial investment was reconsidered and substituted by the economic asset seen from the point of view of the invested capital, in a net sum –absolved of amortizations and value adjustments– both for the one itself and the attracted one;

✓ regarding the sum of the updated medium cash flows, we resorted to replacing them with updated expected cash flows for an interval of maximum 5 year. Projections for the cash flow have been carried out, according to the DCF method, subsequently updated to an appropriate rate identified on the market.

In the action we initiated to test the recovery capacity of the economic asset of a society through the updated annual medium cash flows, after going through the theoretical steps [5], we proceeded to selecting the groups of societies within the European and Romanian area where the testing of the suggested mathematical model was utterly necessary. Within the European area the selection of the groups of societies did not raise any problems, since the information provided by the set of annual financial situations was sufficient and pertinent for the initiated problem. On the other hand, within the Romanian area, the

testing of the mathematical model encountered difficulties regarding the dimensioning of the representative sample.

In the following chart we will present the list of the groups of societies selected from the Romanian space, as well as the analysis of the three representativeness criteria previously identified and each society’s reaction:

[6], (Manea M., ICBE 2012)

- (1) Percentage of fixed assets within the economic asset;
 - (2) Drawing the “Cash flow situation” according to the direct/ indirect method;
 - (3) The discount rate – market identification, average capital cost;
- DM – the direct method;
IM – the indirect method;
ACC – average capital cost;
ME – modeled by the evaluators.

3.2. The sample

In a previous paper we presented the specific traits encountered in the Romanian area regarding the limitations particular to an economy that is in transition, where the market information is insufficient, not all the instruments are known and the working

procedures formalized for reflecting the respective information in the set of annual financial situations, the Romanian accounting system, respectively the professional within the domain have at their disposal a reduced capacity for implementing the creative accounting. Under these circumstances, in order to implement the suggested mathematical model, for modeling the representative sample of societies, there has initially been chosen a number of 81 groups of societies. After applying the three representativeness criteria, out of the 81 societies, as a consequence of the limitations encountered in the Romanian accounting practice, only 37 societies were left. Subsequent to the sample’s modeling, there have been outlined directions of action applicable to the entities within the Romanian area, such as:

- ✓ the necessity to formalize the working techniques and tools used to render the information regarding the fixed assets within the set of annual financial situations published by the societies;
- ✓ a better selection of information concerning the fixed assets provided by the market, respectively a special attention for the markets, even insufficiently developed within the Romanian space;
- ✓ an increased availability coming from the professional accountants concerning the understanding of the practices and techniques specific to the creative accounting, respectively their implementation within the Romanian area;
- ✓ the continuous improvement of the Romanian professional accountants in the initiative of the regulatory autochthonous bodies to closely examine and implement within the accounting practice the techniques and instruments of the creative accounting.

If in the Romanian space there were identified a series of difficulties and limitations in the modeling of the selected and analyzed society sample, clearly caused by the specific conditions of the autochthonous economy, in the European area the issue was much more clear, since the financial situations loyally expressed the reality from the accounts as well as the one of the estimations specific to the creative accounting. Therefore, starting from the same three representativeness criteria employed in the Romanian area, after leaving aside those

societies that did not simultaneously fulfill the proposed criteria, in the group’s structure we find 54 societies, as it follows:

4. Results interpretation

The differences registered at the level of the three representativeness criteria within the European area, compared to the Romanian one, previously presented, are significant and visible at the simplest analysis. The following can be concluded:

✓ the percentage of the fixed assets in total economic asset did not register values as big as in the case of the Romanian societies – 27 out of the analyzed societies have fixed assets in percentages of up to 30%. Other 8 groups of societies have a share of fixed assets in total economic asset between 30%-50%, the rest of 19 societies have a share of over 50%. The lower share, as it is the case for 50% of the analyzed societies, can be explained through the capacity of the foreign societies to implement the principle of the prevalence of the economic over the juridical, which presupposes that a society does not necessarily have fixed assets in patrimony, but it can earn them in leasing. Therefore, the first representativeness criterion in selecting the sample of societies within the European space can be considered fulfilled;

✓ concerning the method of compiling “The cash flows’ situation”, it has been noticed from the study of the set of annual financial situations of the 54 societies the use of the indirect method, useful for our initiative, which renders the second representativeness criterion fulfilled; without drawing a conclusion, we see as necessary the extension of the practice of the groups of European societies regarding the use of the indirect method in compiling the cash flows’ situation within the Romanian area;

✓ likewise, the discount rate used in measuring the updated estimated cash flows was identified through the composition of the set of annual financial situations published by the groups of societies; this varied between 6% and 14%, all the 54 groups of societies treated this variable with real interest within the set of financial situations regarding the annual reporting, which denotes an important

preoccupation of the professional practitioners and of the managers as well for reflecting the exactness and reality of the accounts;

✓ from the analysis of the set of annual financial situations of the groups of societies within the European area, there can be observed the seriousness of the action of compiling annual financial reporting, the high degree of formality of the accounting information, respectively the managers' and professional accountant's availability to convey the accounting information – both sufficient and pertinent.

5. Comparisons with the reality from the Romanian space

By going through the parallel between the Romanian reality and the European one, having as an objective the modeling of the society sample where the mathematical model can be tested regarding the contribution of the recovery term to the identification of the value losses from the use of fixed assets, there were delineated on one hand the seriousness and the good practices used in the European space within the annual financial reporting carried out, and on the other hand the lack of interest and vision of the Romanian practitioners that do not handle the specific available instruments and techniques. We note the following identified elements – conclusions:

✓ within the European area the final sample is formed of 54 groups of societies where the suggested mathematical model will be tested. From the set of annual financial situation published by the entities, the external analyst gradually went through and identified those representativeness criteria such as the share of the fixed assets in economic total asset, the way of compiling “The cash flows' situation”, respectively the measurement of the discount rate used in modeling the updated estimated cash flows. There must be noted the observation according to which, within the set of published annual financial situations, the external analyst effortlessly detected the necessary information, without resorting to estimations and modeling or to the professional assessors' help in modeling some of the variables. This is why we consider that the further study of the European practices of compiling the annual

financial situations and the formalization at the Romanian entities' level of the working procedures used at an European level are utterly necessary.

✓ within the Romanian area, the external analyst encountered a series of difficulties in modeling the representative sample of societies. Therefore, although there was initially identified a number of 81 societies from the domain of transportation, logistics and transportation assistance, as a consequence of the lack of necessary information from the set of annual financial situations, the number was cut back to only 37 societies. Following the method of presenting the information from the annual financial situations published by the Romanian societies, we consider that a widening of the information spectrum covered here is necessary. If we only cover the fixed assets, in Note 1 – Fixed assets, the Romanian societies present insufficient information concerning their assets, such as: a) gross values of the fixed assets (information about the existent balance at the beginning of the financial year, elements regarding increases, concessions, transfers and other reductions such as the balance at the end of the financial year), b) value adjustment elements under the form of amortization respectively adjustment for depreciation, without presenting detailed information concerning the estimations for implementing the creative accounting, like the future cash flows from the use of fixed assets, the discount rate, etc.

6. Conclusions

Implementing the suggested mathematical model in the European area and subsequently in the Romanian area, has pursued its validation regarding its implementation as an indicator for the possible future value losses attached to the fixed assets. Through its calculus, the management and the professional accountants within the entities have at their disposal a working tool that is easy enough to model, based upon the already available information as well as using restatements and estimations specific to the creative accounting. First and foremost, we are talking about the measuring and evaluation of the updated medium annual cash flows for an interval of 5 years which

necessitate forecast and update knowledge. Furthermore, the identification of the discount rate specific to the modeled cash flows can raise difficulties for the professional accountants, but resorting to the information on the market, respectively the one owned by the specialist assessors, this structure can be outlined without any special hindrances. By analyzing the way of measuring the discount rate of the future cash flows from the use of fixed assets at the level of the two areas, the following conclusions can be drawn: a) within the European space each society is concerned with the adequate measurement of the discount rate in a specific element of reporting, more precisely we are talking about a special annex within the set of the published annual financial situations, therefore the external analyst is capable to easily identify values between 6.14% and 14% - note in the current study the last column in Chart nr.2 “The analysis of the representativeness criteria in the societies selected from the European area”; b) within the practice of the Romanian societies, the external analyst found himself unable to identify within the set of annual financial situations the variable of discount rate of the cash flows from the use of fixed assets, resorting, therefore, to the help of assessors practitioners who fixed a discount rate for the societies that belong to the same working field. This fact constitutes in a limitation of the Romanian accounting system which failed to formalize all the techniques, instruments and working procedures necessary for transposing in the annual financial situations published by the societies the data necessary for the information users. Under these limitative circumstances the external analyst is coaxed to resort to the professional assessors for modeling the discount rate necessary for updating the estimated cash flows.

Therefore, we consider it necessary that the Romanian accounting practice adopts a set of practices and instruments for widening the spectrum of information included in the set of annexes to the annual financial situations published by the societies, as a necessity for the future reporting of the Romanian entities.

Health Insurance and Implementation of Private System

Mangra Mădălina Giorgiana

University of Craiova, Faculty of Economics and Business Administration
madamangra@yahoo.com

Abstract

This paper shows that social security, as the main health care system, is based on principles aimed at the compulsory coverage of all citizens, who are allowed accessibility to a certain package of services. The financial balance between the amount of contributions received and expenditures must be respected in order to perform the medical services. The independence of health insurance organisms in administration of funds, which are collected and used in the alternative, is ensured. The importance of private health insurance is emphasized, as well as the option for the private health care system that allows access to a wide variety of services within primary and secondary treatment, and makes many social groups to prefer private health care sector and to join complementary, additional or substitute private health insurance.

Keywords: insured persons, public and private health system, social health insurance, principles of insurance, bill.

J.E.L. Classification: I 13, I 15.

Introduction:

Failing to adopt rules to permit the functioning of the legislation, private health insurance know an upgrade as a result of the opportunities offered to those customers in comparison with that of the state system, namely: the coupler system introduced in the different offices and hospitals in a differentiated manner and family vouchers for low income people.

Insurers can also propose various other services. Traditional health insurance clearly involve measuring a person's risk of disease,

depending on age, sex, area of work or medical history, the access to medical services and treatment being guaranteed by the health insurance contract.

On the other hand, there are abroad travel medical insurance either for tourism, work, study, covering illnesses and accidents happening outside Romania [1].

Health insurances

Being a complex social and biological phenomenon, the health of population has always been in the attention of governments, and many physicians [2] such as: Constantin Caracaș, Ștefan Stâncă, Victor Babeș, Ioan Cantacuzino, concerned with achieving healthcare reforms, have contributed over time to the scientific organization of Romanian medical system, proposed health regulations or founded hospitals.

In retrospect, the regulation of healthcare organization, from a legal perspective, is reflected since 1874 when the first Health Law is enacted, followed by the 1910 Health Law, the Health and Social Care Law in 1930, and the contributory health care system, type Bismarck, governed by the Code of Social Security and Social Insurance Law issued in 1938.

Between years 1948-1990, the organization of health care in Romania was centralized and planned, being governed by the principles of the Soviet model, type Semașko.

Since 1989, the healthcare reform was approached in several stages, governments trying to develop structures and policies. Primary health care system is represented by the social security, based on the following principles [3]:

- mandatory coverage of all Romanian citizens residing in the country or temporarily abroad, and foreign citizens and stateless persons residing in Romania;

- solidarity among all social categories;
- subsidiarity in the collection and use of funds;
- accessibility of the insured at a package of health services;
- compliance with the financial balance between the amount of contributions received and expenses incurred for performing medical services;
- independence of health insurance organisms (Health Insurance National House, Health Insurance County Houses) in managing their funds;
- possibility for insured to make a free choice of a family doctor, specialized physician and health units.

Other categories of persons covered by the social insurance system, without contribution payments, are children and young people up to 26 years if they are students, apprentices or have no income from employment, as well as disabled people who do not realize income from employment or are in their family care.

Both employees and those who are not employees but pay their contribution have the quality of insured.

Health insurance funds [4] are intended for payment of drugs and medical services provided formation of a reserve and redistribution fund, and funds' management expenses. The risk of death is assured.

For different occupations and different sexes, insurance premiums are diverse, covering costs [5] relating to: hospitalization, convalescence, home treatment after discharge, allowances for maternity, family doctor consultations, other consultations, diagnoses, surgery.

The insured sums paid are inclusive, equal to a daily allowance in case of hospitalization or surgery, or as compensation.

In case of permanent health insurance, the insured shall get a preliminary investigation, whereas by paying it he wants to protect himself against incapacity for work due to accident or illness. Insurance premiums are fixed and the insured will receive regular compensation when incapacity for work occurs.

The insurance represents a primary coverage or additional clause in the case of terminal illness, the sum assured being paid from the moment of disease diagnosis and

having the aim to offset the costs of medical treatment.

New healthcare bill brings up some modifications [6]:

-cheap medical services will be deleted from the basic healthcare package;

-doctors are no longer employees of the state and their salary will be negotiated with the hospital manager;

-hospitals will be autonomous financially and managerially and will raise funds from any activities (programs and projects), provided that these do not affect the quality of medical services and the hospital's good functioning.

-citizens will be able to enroll in a public or private insurer, dismantling the CNAS monopoly and insurance houses will reorganize in the mutual type insurance companies, after the Belgian model;

-emergency medicine remains guaranteed by the state.

Lack of expertise and quality of the services offered by the national health system has determined a number of people to go into the private health sector, although lower costs for patients (insured) in public hospitals convince many individuals to stick to the health services of public sector.

Development of the society and increasing health incidents on individuals determine the development of private medical sector which offers a variety of services, both in the primary and secondary line of treatment

According to Law no. 212/2001, the types of private insurance for payment of medical services are:

-Complementary, private insurance supporting entirely or partially the payment of services that are partially excluded by social health insurance from the basic package, including co-payments;

-Additional, private insurance supporting entirely or partially the payment for services which exceed the basic package of social health insurance system by providing a high level of comfort, easy access to special health care at home or abroad;

-Substitutive, private insurance cover totally or partially the payment for any service.

Economical-financial operation, the insurance is prefigured by law and is

represented through a contract in which the insured commits himself to pay an insurance in exchange of which the insurance company guarantees and commits itself to pay compensatory finances or insured amounts in the case of production of an event with consequences over the insured.

Both the insurances and reinsurances represent a complex system which contains beside personal insurances, goods insurances, third-party liability insurances, foreign insurances and reinsurances in currency and other insurances like those regarding welfare, health, and lay-off.

The way in which an insurance company is organized and managed is strongly related to the requests of the national and international insurances and reinsurances market.

Besides the factors which are common for all activity domains, in insurances interfere specific factors which determine the way of organization and management of the insurance activity.

The relations between the insured and the insurer, their rights and obligations are established by private health insurance contract. The insured agrees to pay a private health insurance premium to the insurer, the insured being an individual or the employer.

Conclusions:

In conclusion, we can say that prove to be extremely useful the following measures: reorganization of municipal insurance houses into mutual type societies, creation of a system of private health insurance in competition with the public insurance system, review of the basic package of health services, but also that costs made on private health insurance, incurred by the individual or the employer, are tax deductible and the choice of health care providers by the insured and the insurer is free.

Corruption in the Public Sector of the Emerging Economies Inside the European Union Perimeter. Causes and Scores of the Phenomenon.

Mardiros Daniela-Neonila
Universitatea “Alexandru Ioan Cuza” Iași
Facultatea de Economie și Administrarea Afacerilor
mardirosdaniela@yahoo.com

Abstract

This article is presenting his debut as a corruption-related concepts such as those involving its definition, the corruption importance, the institutional causes of corruption in the public sector and the attempts to quantify it by Transparency Internațional, world leader in the fight against corruption. Looking the definition of corruption, this proves a quite difficult element due to the lack of an unanimous opinion about what this phenomenon means. Regarding the causes or the roots of corruption, the opinion according to that at the corruption basis exists the poverty is invalidated by the fact that the phenomenon is captured also inside the developed economies. In the end of the paper we have tried a presentation of corruption scores calculated by the international organism previous mentioned, with examples for the European Union emerging economies.

Keywords: corruption, cause, effect, emerging, economy.

J.E.L Classification.: M, M4, M48.

1. Introduction

Motto: Well for that is creating this huge LEVIATHAN named COMMON Good or STATE (in latin, CIVITAS), which is only an artificial man, even of a greater stature and strength than the natural, for whose protection and defense exists; and in which the sovereignty is an artificial soul, giving life and movement to the whole body; magistrates and other legal officials..., artificial joints; (...) property and wealth of all private members are the force; people's health (its security) is their firm; (...) equity and laws, an artificial and voluntary

reason...(T. Hobbes, Leviathan). The characterization of a society requires the surprise of the two levels that its existence is going on and which are taking the form of two distinct sectors, public and respectively, privat. Providing essential public services for society members, the public sector is characterized by a particular form of monopoly. At the opposite pole, the private sector is the manifestation of competition due to the existence of alternative in terms of goods and services provided to the consumer. And while private sector leads on principles of efficiency, exist the same concern for the public sector [1].

2. The public sector and the corruption associated with it

The public sector can not be effective while it is governed by corruption, in greater or less measure. Generally speaking, the evaluation of the mode in which a country is lead use, for most of the cases the GDP/capita value, even if the welfare of a nation depends bu a serie of factors not related to the GDP calculus (the unequal distribution of income, the qualitz of environment, the leisure modality etc.) [2]. As consequence, the welfare of a nation can not be reduce only at GDP and productivity because the citizens are confronted with various dimensions of political, social and cultural type. As a logical consequence, a good governance must assure an environmenta characterized by the existence of efficient policies and institutions [3]. Regardless of the economy that characterizes a state (developing, emerging or developed) it suffers, in greater or less measure, state intervention embodied in the objectives that government aims to achieve. The greater or less measure in which this thing is is materialized or more precisely is quantified

by means of certain indicators associated to the government power and channeled on the following directions: ▪ *information* (of the various interested parts, including public, about the state of public finances and the performance of governmental activity); ▪ *help* (for the public - members of society - for it to choose for one or other action knowingly and, finally, to understand the impact of his/their actions on public money); *the ability of public to judge the performance of a government and its institutions*. The accumulation of these three areas will result, finally, in the society guiding for the evaluating and possibly redefine, of the tasks to be performed by the public sector and its specific institutions. Excessive government regulations are not necessarily the way because on the one hand have the effect of increasing workload in the informal sector On the other hand, allows regulators to be corrupt.

2.1. The definition and the importance of corruption in the public sector

One difficulty in fighting corruption is the one of its defining because the lack of unanimity opinion about what is corruption put under question or make non-operational the anti-corruption strategies. In many cases, corruption and illicit are seen as similar terms (Bardhan, 1997), fact which could lead us to conclude that a corrupt behavior is in violation of legality [5]. However, we have to be careful on this absolutization given that not all illegal behavior shows corruption as not all the corrupt conduct is illegal. Talking about corruption is preferred the approach of the two levels of corruption (state sector versus private sector) because, not infrequently, they are interrelated. Related to corruption in the public sector, Typically this may occur when to certain taxpayers which can roughly be regarded as sources of revenue for the public budgets, through the taxes they pay, are providing poor quality public services, when some are served preferential for a bonus or when they are asked for bribes by public officials. The other side of the coin represented by the private sector "benefits" also by the existence of corruption in the form of decisions made by company managers in their favor and thus detrimental to the company or shareholders

[7]. In both types of corruption exist a contradiction between what a person, represented in first case by the public official and in the second case by the company manager, should do and what it actually is doing. Any definition of corruption includes its political side expressed by the existence of an central or local executive, „for sale”. The idea is circumscribed to the definition which the World Bank associates to the corruption seen as public power exercised in exchange for a gain, with small and large values, of it which may reach, finally, to the state capture by private interests. Summarizing, it can say that the more restrictive definition of corruption is the abuse of government power related to its monopoly on public services. All previous definitions have in common that they bring to the forefront the „corruption's actors” and not the action itself [6]. Related to the public sector, all cases of corruption supposes the combination of civil servants, of individuals, firms or industries and of public officials, reason why we can not exclude private persons and companies from the definition of corruption in the public sector.

2.2. Types of corruption and their characteristics

Transparency International (TI), world leader in the fight against corruption, defines it as abuse of invested power to private gain that affects everyone whose life, livelihood or happiness depends on the integrity of the persons invested with authority [4]. This makes us look more closely for the abuse of power than to those who show a corrupt. Sharon Eicher in “Corruption in international business: the challenge of cultural and legal diversity” defines corruption as any act by which a person, who should protect the interests of another person, acting detrimental to the latter. An overview of the classification of corruption is presented in Table 1. The basis idea is the one that, for the last two types of corruption classified by TI we talk about a serie of corruptio acts as part of a certain management strategy directed either to increase profit or to acquire power or welfare [8]. On the point of view of Banfield but with reference to the TI classification, official corruption can be appreciated as functional and the personal corruption as

dysfunctional.

Table 1. Types of corruption and its characteristics

Classification's promoters	Types of corruption	Characteristics
Transparency International	In accordance with the law	Act committed to obtain money quickly (small corruption).
	Against the law	Act committed to circumvent the legal regulations.
	Functional	Corrupt behavior for the firm benefit.
	Dysfunctional	Corrupt behavior against the firm.
Banfield	Personal	Person who does not fulfill its obligations to serve their own interests.
	Official	The illegal acts for a purpose (bribes someone to obtain benefits for their company).
OECD	Active	The one who accept to give bribe.
	Passive	Made by an public official in return for payment.

Corruption matters because, although apparently not make victims, these: inhibit or reduce the rate of economic growth, may affect national security by distorting markets and competition; spread cynicism among citizens; undermines the rule of law, damage the legitimacy of government and corrode the integrity of private sector; reduce the investments; reduce infant mortality and decrease literacy; affect how countries formulate their economic policies; is related to economies with more restrictive regulatory environment; influence governments on how to spend the money altering the composition of government spending detrimental to the future economic growth. Is lower in developed economies, in the traditional liberal democracies, in those with a higher share of women in government and in economies with open trade history. Another dimension of the corruption's importance is

how deep is rooted in the culture of a country because as long as they benefit from corrupt behavior, leaders will not punish not honest subordinates but nor will appreciate and promote the honest one.

2.3. Knowing the causes of corruption, a step in the phenomenon's control process

According to many opinions, the most obvious cause of corruption is considered to be poverty, adding to this others because if we just stop here would mean that the rich countries could theoretically not be affected by corruption. Not true because the corruption scandals not only affect poor countries (Germany – the case of Siemens, the Bavarian power and communications giant embroiled in the largest bribery case in the history of the Federal Republic; France - the Bettencourt affair involves illegal payments by the business woman Liliane Bettencourt to members of the French government associated with Nicolas Sarkozy in 2010, etc., all great economic powers in EU). So we can say that the corruption phenomenon is not only due to poverty but also to welfare. The plundering of national wealth and the spending of public money for personal interest have negatively impact on economic and social development. Therefore, the effect is of boomerang: corruption generates poverty and poverty leads to corruption. Corruption occurs as a result of the existence of weak institutions of state, both in terms of their development and human infrastructure. When state institutions are weak, rules can be ambiguous, leaders are not held responsible for their actions and bribe, nepotism or other unpleasant behaviors related/unrelated to corruption are emerging. Corruption is, in the same time, a drain of a nation's productive effort which is more concerned with finding ways of cheating the system, often without realizing that it is in fact the system. Since corruption in the public sector can be equated with the state intervention in economy, policies such as those aimed at liberalizing, stabilization, deregulation and privatization can significantly reduce the possibilities of developing corruption. Where state regulations are ubiquitous but yet public officials have reserves looking their application, individuals are often tempted to

pay them bribe in order to circumvent laws and, although it would not be so, officials are tempted to accept bribes. Controlling corruption in public sector make necessary to identify the causes giving rise to its such as: Political practices (being the mechanisms by which economic and political relations are maintained, the existence of weak rules of conduct whose violation is not punished has as effect the exacerbation of the economical and political corruption). Economic incentives (motivates people to break the rules and money amounts stimulates unethical behavior). Trade restrictions - if importing a certain good is subject to quantitative restrictions, the license to import that became very precious and the importers, to obtain it, will consider the variant to bribe the officials who has the necessary competence in the domain. Generally speaking, the protection of certain domestic industries (car making for example) by the foreign competition through the prices (can be imported a limited number of foreign cars on year) lead to a semi-monopoly for the local industry. Local producers are lobbying to establish and maintain such prices and some of them will wants even to bribe influential politicians just to keep the monopoly. This protection is equivalent to reducing the openness degree of that country's trade and has the effect of increasing corruption because a high degree of the trade openness is associated, quite strongly, with a reduced corruption. In other words, countries tend to be less corrupt when their trade is relatively free according to the government restrictions from which the corrupt officials can abuse. Price control - purpose is to bring down the price of goods below their market value (most times of political or social reasons); price controls create incentives for some individuals or groups to bribes the officials to maintain the flow of such goods. State legitimacy (those who respect their officials, because they see them as moral leaders, are less tempted to engage in corrupt behaviour and such cheating). The assessment of the degree of openness and the public trust in the honesty of politicians are presented in Table 3. Government subsidies – can be a source of corruption and the latter flourishing for the case of certain industrial policies allowing poorly targeted subsidies to be acquired by

firms who are not targeted. The more such subsidies exist in industry, with both the corruption index will be higher. The values of the subsidies and other expenses for the governments of the emerging economies from EU was, as percent from the government expenses, inside the 2007-2009 period of time, the following one: Bulgaria – 58-64%; Hungary - 61-63%; Latvia - 65-70%; Lithuania - 62-68%; Poland - 69-71%; Romania - 50-60%. The low salaries of civil servants in comparison with the one from the private sector represents a source of small corruption. When civil service pay is too low, civil servants can be forced to use their position to take bribes especially for the case when the expected cost of their caught is small (reprimand or even less) because in the economies in transition the existence costs exceeds the monthly salary. Occurs in this way an increase in prices in the administrative system (taxpayer must submit of bribery and the civil servant is not brave enough to have a high degree of morality because it asks himself, naturally, why should he be the moral when others are not). Endowment of natural resources (oil, gold, gas, etc.) is an example of corruption cause as long as they can be sold at a price much higher than their extraction and the sale itself is subject to strict government regulations that corrupt officials can not see with intention. Resource-rich economies are often subject to corruption than the poorest. Sociological factors– an index of ethno-linguistic fractionation (division of society based on ethnicity and language) was identified as being correlated with corruption because public officials are more inclined to favor those related to them, in societies where family ties are very strong (the number of ethnic groups in the analyzed countries are: Bulgaria - 13; Hungary - 10; Latvia – over 10; Lithuania - 4; Poland – 17; Romania - 19). On the other hand, cultural orientation, moral and ethical value vary according to the fundamentals of each country, indicating its influence on individual behavior in society. Government effectiveness (the state's most powerful tool in influencing the economic activity is, no doubt, exercising its enforcement and regulatory power; but public decisions are taken by determined individuals who not always use rational criteria; state may set price controls, limits

wage growth, regulate monopolies, protect consumer controlling advertising and products quality, can set limits on contaminants emissions etc. and, especially, may reserve for itself production of certain goods and services; deal directly with the production of goods and services of strategic economic or military interest or of public goods which are used even by those who do not pay and which may not be available in sufficient quantity by private initiative (national defence, education, health etc.). The question is how well does this? In all the world countries, governments are accused of lack of efficacy in the management of public enterprises, many of them suffering losses for years and years, fact explained by the principle of subsidiarity, meaning the state's concern for unprofitable productions. State decisions are taken by politicians in power, general perception being that consumers and entrepreneurs take decisions according to their own interests but still, politicians decide/should decide according to the common good, which unfortunately does not happen in reality; without reference to the corrupt politicians who use power for personal enrichment, all over the world politicians take decisions according to their interests; in a democratic country where there is freedom of the press, politicians' interests coincide with those of most people). Anti-corruption programs of countries express the desire to improve the rule of law in spirit of society's honesty and integrity growth. Government efforts to fight corruption are seen as not effective but the role of governments and media are crucial in stopping corruption. An image for the appreciation of government actions against corruption in the emerging economies of EU is presented in Table 2. Rule of law (in countries where the rule of law is weak, people tend to behave capriciously). Capital (family, neighbors, community are factors that influence human behavior).

Table 2. Perception of the public about the governments actions in their fight against corruption in the emerging economies of EU

GCB 2008	VI	I	U
Bulgaria	1%	8%	13%
Hungary	41%	29%	16%

Lithuania	0%	3%	12%
Poland	20%	34%	28%
Romania	4%	13%	10%
GCB 2008	E	VE	DK/DA
Bulgaria	32%	36%	11%
Hungary	9%	2%	3%
Lithuania	39%	40%	6%
Poland	13%	0%	5%
Romania	25%	34%	15%

Source: Own adaptation after the data from source [13]; Legend: VI-very ineffective; I-ineffective; U-unexistent; E-efficient; VE-very efficient; DK/DA-do not know/do not answer.

So, we can say that Corruption in the emerging economies of the EU seems to have increased compared to the last 3 years. This can not be a good sign because in a corrupt environment, resources will be directed to unproductive sectors (police, army etc.) detrimental to the elite who will have to identify ways to protect their position and social welfare, the brain drain being one of these. Inside the economies take into discussion looking the corruption, the most affected parts of the public sector are political parties. The actions of governments from the analyzed economies, in their fight against corruption, are seen, in most cases, as ineffective. Among the possible causes of this situation we might mention: the legacy of corrupt government; desire for change manifested only on the lowest levels of power; too ambitious promises of politicians which can not be honored and that, so, erodes the confidence of the people that they represent; the introduction and application of state reform is seen as applicable only for ordinary citizens and not for those with high positions in state (these personalities or do not "need" for reform, or are hostile to anyone who would try to achieve it); institutional mechanisms are generally constructed that are unable to sustain progress after its promoters have left the scene.

3. Scores for corruption in the public sector of the emerging economies inside the European Union

We tackle the corruption assessment using the instrument represented by the composite index of perception of corruption (IPC) provided by Transparency International (TI), international body qualified to fight corruption (Table 3). We must say that, according to the TI methodology, corruption is even higher, as the value of the score associated to the phenomenon is smaller.

Table 3. Scores of corruption in the public sector of the emerging economies of European Union

Country	2007	2008	2009	Score
Bulgaria	4,1	3,6	3,8	The value „0” of the score shows a very corrupted economy.
Hungary	5,3	5,1	5,1	
Latvia	4,8	5,0	4,5	
Lithuania	4,8	4,6	4,9	
Poland	4,2	4,6	5,0	
Romania	3,7	3,8	3,8	
Country	2010	2011	The value „0” of the score shows a very clear economy from the corruption point of view.	
Bulgaria	3,6	3,3		
Hungary	4,7	4,6		
Latvia	4,3	4,2		
Lithuania	5,0	4,8		
Poland	5,3	5,5		
Romania	3,7	3,6		
Average score for emerging economies				4,41
Average score for developed economies				6,91

Source: own processing using the data from reference [12]

4. Conclusions

After the analysis of the data from Table 3 we can say that, for the emerging economies inside the EU exist a high level of corruption in the public sector (the average value associated to the phenomenon is), in comparison with the value for the corruption in the public sector of the developed economies (6,91). Inside the group of the emerging economies exist differences between countries looking the corruption indicator value, the order of ranking on corruption in the public sector being as follows: Bulgaria, Romania, Latvia,

Lithuania, Poland and Hungary. For the case of Romania exist a high level of corruption in the public sector, the romanian economy being situated on the second place inside the group of emerging countries, after Bulgaria.

Budgetary Incomes and Expenses, Expression of the Public Sector's Dimension of the Emerging Economies Inside the European Union Area

Mardiros Daniela-Neonila
Universitatea “Alexandru Ioan Cuza” Iași
Facultatea de Economie și Administrarea Afacerilor
mardirosdaniela@yahoo.com

Abstract

The issues discussed inside this article refers to the identification of certain budgetary indicators which, by their level, characterize the public sector of the emergent economies inside the European Union. Due to the fact that those indicators have different connotations, we will proceed to their particular description, as image of the public sector dimension of the mentioned economies. We propose, therefore, to address the situation of the emerging economies from the European Union area taking into discussion the public sector dimension evaluated through the prism of the total budgetary expenses, total budgetary incomes, health expenses in the public system and through the expenses which are corresponding to the social benefits.

Key words: public sector, expenses, budgetary incomes.

J.E.L. classification: M, M4, M41.

1. Introduction

Not infrequently we hear the phrase „public sector versus business environment”. As a consequence, we ask the logical question: *Are the two sectors totally independent or not?* Let's suppose, by reductio ad absurdum and according to the mathematical theory, that the answer would be affirmative [1]. The hypothesis of any connection lack is, first of all, contested by the fact that the activity of private sector is governed by a legislative framework whose promoters are the state's institutions (Parliament, Government, ministries) [2]. Another connection of the public sector with the private one can be addressed through the employees, most of them being graduates of

public education. And the examples in the dismantling of the initial hypothesis may continue. Once we had established the connection between the two levels of the economic life deployment, we are putting the problem of the public sector characterization through its dimension. Expression of the domains in which we have the state's intervention inside the economy, the dimension of public sector could be interpreted as a dependent variable by the political ideology of the government in duty. Along with the dimension of public sector, it's intensity could be translated through the amplitude of the state actions in different domains of the economic life. The proportion between the number of public education institutions and the private ones or the one registered between the number of public hospitals and the private ones are just a few examples of the public sector's intensity in domains such as the one of education or health. We can say that the higher this ratio is greater, with both the intensity of public sector in such activity areas is bigger.

2. The dimension of the public sector under the impact of the influence factors

Considered to be unproductive in comparison with the business environment (private sector), the public sector has been and is subject, especially in recent years, to a series of pressure looking its dimension reduction, the last one action turning, in the current global economic situation, into a permanent concern [3]. As an alternative, we can say that to avoid this situation in which the public sector reducing will generates economic and social costs, for the public sector is more appropriate the alternative of the appropriate management of the factors with influence the dimension of the public sector such as: the impact of modernization over the public sector (it can be translated by

imposing new requirements to the public sector such the ones bounded to investments in infrastructure and to the process of generating higher skilled workforce, whose finality can be translated through changes of the existent structure and whose effects could be found in the unemployment increasing, as a consequence of the occurrence of ultra skilled trades; in the same time, the dimension of public sector depends by the improving of the material conditions and also by a stronger concern for the health insurance, actions which have as effect the life expectancy increasing and, implicitly, the increasing of the funds allocated for the social programs, retraining of the unemployed, public health and pension systems, fact which put pressure on the public sector dimension, through the increasing of the expenses on such destinations); the redistribution of incomes between the social segments under the impact of democracy [(is related to the desire of politicians to get majority of votes and can influence them to take a number of regulations with fiscal nature by which to achieve a transfer of income from the rich one (fewer) to the poor one (more numerous); thus, the state revenues obtained through the taxation of the wealthier social strata (property taxes, incomes taxes etc.), will return to the poor, through the social assistance programs, or through the programs of subsidizing various activities that they had benefit (road and rail public transport, education and public health systems etc.); the result of these measures could be reflected by the increasing of the public expenses on certain destinations and by the changing of their structure, with final impact over the public sector dimension, in the sense of its increasing]; the economic internationalization; the mobility of the production factors (work and capital) increased significantly in the context of globalization, fact which impose restrictions for the governments looking taxation and public money spending (that, because if it assumes that the economic increasing depends on investments, and the last ones depends by profit, the governments are interested to maximize the investors profits through a low taxation, so as to attract investors and to avoid the capital export; on the other hand, the existence of small taxes do not represent a certainty in terms of

attracting investors; if, instead, at a low level of taxation we add the maintenance of the wages at a low level, the investors interest can be stimulated; in other order of ideas, taking account by the fact that the gains which correspond to the invested capital depends, the utmost by the production factors productivity, the investors will prefer a country with a high level of taxation and very high productivity to a country in which both, taxation and productivity, are very low [8]. Reported to the last option of the capital suppliers [6] we can talk about an increasement of the budgetary incomes, with directly and proportional implications over the public sector dimension.

2.1. Total budgetary expenses-expression of the public sector dimension

As general tendence, the expenditures of the public sector are situated, for all the analised emerging economies, under the level of the resources which are necessary to be allocated on the respective destinations (Table 1).

Table 1. Total budgetary expenses in the public sector of the emerging economies inside the European Union area

Country	I % GDP	2007	2008	2009
Bulgaria	TBE	34,935	35,167	36,174
Hungary	TBE	50,641	49,205	51,380
Latvia	TBE	35,701	43,149	44,073
Lithuania	TBE	34,809	37,282	43,941
Poland	TBE	42,187	43,194	44,510
Romania	TBE	35,724	36,994	38,469
Country	I % GDP	2010	2011	2012
Bulgaria	TBE	36,639	34,566	34,893
Hungary	TBE	45,163	52,402	45,839
Latvia	TBE	43,379	39,337	38,496
Lithuania	TBE	42,058	39,320	38,577
Poland	TBE	45,366	44,472	44,013
Romania	TBE	38,705	35,503	34,047
Average of the total budgetary expenditures for the emerging				40,92

economies	
Average of the total budgetary expenditures for the developed economies	47,12

Source: own processing using the data from source [9]; Legend: I-indicator; TBE-total budgetary expenditures.

The analysis of the data from Table 1, looking the dimension of the public sector, through the prism of the approach regarding at the budgetary expenditures, shows a first feature for the emerging economies, namely the one to be situated, from the point of view of the public sector dimension, to a level describe by an average value of 40,92% from GDP (under the average value registered by the developed economies of the same area which is about 47,12% from GDP). And then, questions naturally arise: Why all the concern for reducing the size of the public sector in emerging economies?; It's so bad to have a large dimension for the public sector? and Why the developed economies allocate a bigger percent of GDP to the public expenditures, increasing in that way the dimension of their public sector, in comparison with the emerging economies? The answer for the first question could be the one that, unlike the developed economies, the emerging one are confronted, on one hand, with the existence of insufficient resources to cover the expenditures and, on the other hand, with the inefficiency of the public money spending [4]. Bounded to the second question, the answer is negatively in the sense that not the existence of a public sector of big dimension represents a problem, but to can ensure the resources which are necessary to fulfill efficient the public sector functions. For the last question, the answer could be the one that, for the developed economies, on one hand, the budgetary incomes are well dimensioned and, on the other hand, the stage of economic development allows allocation of larger sums of public money on primary destinations such as those related to education, health and social protection. On the other side, the developed economies affords an overbidding public expenditures in relation to the incomes (budgetary deficit), superior of the one of the emerging economies, because the stage of economic development and the stable political climate can constitute guarantees for budgetary

deficit correction [5]. At the opposite pole, the emerging economies, which not yet reached their level of desired development, are tempted to primary use the public money for economic actions, allocating much smaller amounts on other destinations. For the particular case of Romania, the average value of the indicator of total budgetary expenses represents 36,51% from GDP, fact which makes Romania to occupy the penultimate place in the top of the emerging economies looking the dimension of the public sector, under the aspect of the total budgetary expenses.

2.2. Expenditure on social benefits, expression of the public sector's dimension

The overall picture of the public sector dimension through the prism of the total budgetary expenses and incomes is completed by the expenses on social benefits. Any economy, no matter how gifted as the natural resources point of view or through the advantages appeared as a consequence of it's geographical location, could not progress if, in addition to those two fundamental factors (nature and capital) did not also exists the work factor. This is because in both, private sector but especially public sector, the performance largely depends by the employees occupational training, seriousness and conscientiousness. The normal remuneration of their labor is represented by the salary but, when from certain motives they can no longer perform their work capacity, the state, at whose revenues contributed, is required to provide them help through social benefits. The latter are represented by the public sector expenses materialized in the amounts that it pays (through the government) toward citizens, and whose destination is the one to help people in a difficult situation from financial point of view, due to one of the following circumstances: sickness, disability, accidents, because of age, following the loss of the breadwinner, maternity leave, iparental allowance etc. Due to the fact that emergent economies are characterized by the existence of a population with a modest standard of living, it is interesting to quantify the dimension of the public sector through the public social benefits (in other words we are

talking about the amounts allocated on that type of destinations). The data for the above theoretical aspects are presented in Table 2.

Table 2. Expenses with social benefits in the public sector of the economies inside the European Union area

Country	I % GDP	2007	2008	2009
Bulgaria	ESB	9,6	10,1	12,1
Hungary	ESB	15,5	15,9	16,5
Latvia	ESB	7,1	8,1	12,6
Lithuania	ESB	9,1	10,9	15,2
Poland	ESB	14,2	14,0	14,7
Romania	ESB	9,2	10,4	12,7
Country	I % GDP	2010	2011	2012
Bulgaria	ESB	12,6	11,9	NAD
Hungary	ESB	15,9	15,3	NAD
Latvia	ESB	12,5	10,8	NAD
Lithuania	ESB	13,0	11,2	NAD
Poland	ESB	14,8	14,1	NAD
Romania	ESB	13,0	11,5	NAD
Average of the expenditures for the emerging economies				12,48
Average of the expenditures for the developed economies				15,30

Source: own processing using the data from source [9]; Legend: I-indicator; ESB-budgetary expenses with social benefits; NAD-not available data.

Interpreting the data in Table 2 reveals a new feature for the emerging economies in comparison with the developed one, namely a much smaller size of the public sector, translated in terms of sums allocated for social benefits. The present statement is substantiated on the average values of the indicator looking social benefits which, for the emerging countries group is by 12,48% of GDP, and for the developed one, by 15,30% of GDP. For the particular case of Romania, the average value of the indicator is by 11,36% from GDP, fact which ensures to the country the third place in the bottom of the table prepared on this occasion, after Latvia and Bulgaria. As consequence, for the emerging economies, the social needs arising from

events by the type of the one previously mentioned will be done in a much less measure than for the case of the developed economies.

2.3. The dimension of the public sector for the emerging economies inside the European union through the prism of public health expenses

In general, to meet economic and social needs of citizens, with a limited level of resources, appears the temptation of governments to reduce the size of the public sector (considered unproductive), through the expenses diminution. Nothing more inappropriate because the effect is one of vicious circle: the diminution of personal expenses for example, that for Romania's case fell from 9,2% from GDP in 2009 to 8,4% in 2010, 7,0% in 2011 and 3,2% in 2012 (at the level of January-May period of time), had as effect the diminution of the contributions (social and health one), the impoverishment of state social insurance budget, respectively of the single national health insurance fund budget and, finally, the reducing of the life quality of those who depended on those amounts. And the examples could go on (goods and services - impediments to the activity of state institutions, education, health and so on). A conclusion can be drawn from this: the public sector downsizing, by budgetary expenses reducing, must be done very carefully and focused to identify those categories of expenditures, whose decreasing variation produces a minimal negative impact particularly on citizens, generally on the economy [7]. That, because a nation who is doing badly can not have a high labor productivity, may give rise to social conflicts, political and economical instability, is not relevant to investors, stagnating or even falling into recession. A number of other elements which are characterizing the status of emerging economies in comparison with the one of the developed economies is the small size of certain components of the public sector such as the expenses in the public health system (Table 3).

Table 3. Health expenses in public sector of the economies inside the European Union

Country	I % GDP	2007	2008	2009
Bulgaria	HE	3,95	4,09	3,98
Hungary	HE	5,34	5,18	5,29
Latvia	HE	4,24	4,12	4,06
Lithuania	HE	4,52	4,77	5,50
Poland	HE	4,53	5,05	5,35
Romania	HE	4,26	4,42	4,42
Country	I % GDP	2010	2011	2012
Bulgaria	HE	3,76	NAD	NAD
Hungary	HE	5,06	NAD	NAD
Latvia	HE	4,09	NAD	NAD
Lithuania	HE	5,14	NAD	NAD
Poland	HE	5,44	NAD	NAD
Romania	HE	4,37	NAD	NAD
Average of the expenditures for the emerging economies				4,70
Average of the expenditures for the developed economies				6,80

Source: own processing using the data from source [9]; Legend: I-indicator; HE-health expenses in public sector; NAD-not available data.

Thus, according to the data from Table 3, the poor allocation of public funds for health is given by spending on this destination which are about only at the level of 4,70% from GDP, in comparison with the developed countries which have in view, for that destination, a value of about 1.5 times higher (6,80% from GDP). As we also observed in the previous examples, there are differences in this indicator including between the emerging economies, Romania being on the third place at the end of the ranking, before Latvia and Bulgaria, but well below the developed economies average. From the priorities point of view some similarities occurs in sense that for both, developed and emerging economies, the resource allocation policy is social welfare and health (we took into consideration in rank only the analyzed expenses).

2.4. Total budgetary incomes-expression of the public sector dimension

The approach of the public sector dimension from the total budgetary incomes point of view (Table 4) put into evidence one new feature for the emerging economies case namely that, reported to the GDP, the level of the incomes mobilized to the budget is significantly lower than the one of the developed economies group (only 37,27% from GDP for the first category of countries in comparison with 43,38% from GDP for the developed economies).

Table 4. Total budgetary incomes of the economies inside the European Union

Country	I % GDP	2007	2008	2009
Bulgaria	TBI	38,191	38,037	35,256
Hungary	TBI	45,563	45,528	46,892
Latvia	TBI	36,344	35,606	36,224
Lithuania	TBI	33,800	34,013	34,733
Poland	TBI	40,306	39,514	37,162
Romania	TBI	32,253	32,164	31,203
Country	I % GDP	2010	2011	2012
Bulgaria	TBI	32,694	32,466	33,009
Hungary	TBI	45,163	52,402	45,839
Latvia	TBI	36,165	35,925	37,310
Lithuania	TBI	34,972	34,084	35,702
Poland	TBI	37,523	39,241	40,782
Romania	TBI	32,271	31,383	32,183
Budgetary incomes average of the emerging economies inside the European Union				37,27
Budgetary incomes average of the developed economies inside the European Union				43,38

Source: own processing using the data from source [9]; Legend: I-indicator; TBI-total budgetary incomes.

For the particular case of Romania, according to the Table 4 data, the reporting to this indicator allows it, unfortunately, the occupying of the last place in the top of the emerging economies takes into discussion,

with an average dimension of the public sector, from the total budgetary incomes point of view, of 31,909 % from GDP. Generally speaking, taking into consideration all the indicators previously mentioned we present, in Figure 1, the dimension of the public sector of the emerging economies inside the European Union, in comparison with the developed economies which belongs to the same area, in terms of total budgetary expenses, social benefits expenses, public health expenses and total budgetary incomes.

Figure 1. Average of total budgetary expenses, social benefits expenses, public health expenses and total budgetary incomes for the emerging economies of the European Union in comparison with the same categories of expenses for the developed economies inside the same area.

Source of data: tables 1-4; Legend: A- Average of total budgetary expense; B- Average of social benefits expenses; C- Average of public health expenses; D- Average of total budgetary incomes.

Further on, taking into discussion the last indicator as total budgetary incomes, the dimension of the public sector in the emerging economies is subordinated, as value, to the one of the developed countries inside the same area. A new question arises: The economy of the emerging countries can not emit more resources or there are impediments to mobilizing it to the budget? The answer is a middle one in sense that the income's release is bounded to the amounts affected to certain public sector expenses (salaries—subsequently generating direct taxes, VAT – indirect tax (through the final cost supported by the final consumers), contributions – part of the current budgetary incomes; goods and services – bounded to the good functioning of the state's institutions

etc.) and as long as they are subject of a diminution process, to reduce the size of the public sector purpose, automatically, the effect is the one of the budgetary incomes decreasing. On the other side, the budgetary incomes will be better and in bigger proportion collected to the budget and certainly more plentiful if the emerging economies will not „benefit” of a high level for the tax evasion.

3. Conclusions

In the end we can conclude that the keeping under control of the public sector dimension, to avoid its oversize (which requires, later, legal regulations for dimension's reduction) suppose, in fact, a permanent supervision of the budgetary incomes, budgetary expenses and other public expenses, as a means for quantifying the public sector size.

The Analysis of Financial Structure Rates at Private Pension Funds Managing Companies

Matei Gheorghe

Militaru Nicolae Daniel

University of Craiova, Faculty of Economics and Business Administration

ghematei@yahoo.com

militarunicolaedaniel@yahoo.com

Abstract

The pension reform in Romania has pursued the following main directions: the changes in the retirement age which is set to increase gradually, the decline of early retirement in the system, benefit reduction of certain professional categories and the development of the private pension system. The main direction of activity is the development of private pension markets: Pillar II and III in order to ensure adequate incomes in retirement. The study focuses its attention on public pensions market privately managed, pillar II, aiming to analyze the private pension funds and the financial structure rates of Private Pension Funds Managing Companies.

Keywords: private pension pillar II pension fund, financial structure, liquidity.

J.E.L. Classification: C60, H5.

1. Introduction

Pension funds are currently a source of capital which needs to be maximized by consistent fiscal measures in order to ensure a balance between investments and benefits. The financial security of retirees can be achieved only through diversification of pension sources:

-public pension system based on the principle of solidarity between generations;

-private pension system based on capitalization and highlighting participants' contributions in individual accounts.

The second pillar on which we will focus it is a public pension system privately managed, which has a defined contribution scheme, ensuring taxpayers a minimum benefit resulting from the contributions paid

less the legal fees and any other transfer penalties. The participation in the system is mandatory only for new entrants of age under 35 years.

In 2007 (the year when it was completed the implementation of Pillar II in Romania) on the mandatory private pension market acted no less than 18 pension funds remaining at present only 9 pension funds with a value of net assets of 8762.59 million lei as shown in the table 1. [3]

Table 1. Net assets (million. RON)

Source: table accomplished by authors based on data provided by PPSSC

It is noted that ING PPFMC has a market share based on net assets of 37.89% and a market share of 30.34% according to participants, maintaining the top position in participants' option since 2007 when it had a market share of 33.21%.

2. Analysis of the financial structure rates

Financial structure ratios are parameters for the orientation of company management regarding the cost of funding sources and its on influence the effectiveness [1]. To reach this goal we calculate and interpret several installments of financial structure. The Private Pension Funds Managing Companies (P.P.F.M.C.) following structure simplified balance sheet at 31.12.2011:

Table 3. Simplified financial structure

Crt. No.	Assets	Balance Sheet (lei)

Source: table accomplished by authors based on data provided by PPSSC

2.1 Patrimonial solvency (P.s.)

$$P.s. = \frac{\text{Equity capital}}{\text{Total liabilities}} \cdot 100 \quad (1)$$

Patrimonial solvency reflects the degree to which the company meet payment obligations.

Table 4. Patrimonial solvency

Nr. Crt.	S.A.F.P.A.P	P.s.(%)
1	ALLIANZ ŢIRIAC	93,04
2	GENERALI	99,93
3	BRD	99,93
4	BCR	99,66
5	AVIVA	99,95
6	EUREKO	99,94
7	ALICO	87,00
8	AEGON	99,84
9	ING	99,95

Source: table accomplished by authors based on data provided by PPSSC

We think that patrimonial solvency is good, because it exceeds 30%.

Patrimonial solvency of the 9 Private Pension Funds Managing Company is considered good and is due to the high value they have their sources in liability company.

2.2 The financial autonomy ratio (F.a.r.)

$$F.a.r. = \frac{\text{Equity capital}}{\text{Permanent capital}} \quad (2)$$

This report expresses the independence of the company to creditors. The value of this ratio must be greater than or equal to 0.5.

Table 5. The financial autonomy ratio

Crt. No.	P.P.F.M.C.	F.a.r.
1	ALLIANZ ŢIRIAC	1
2	GENERALI	1
3	BRD	1
4	BCR	1
5	AVIVA	1
6	EUREKO	1
7	ALICO	1
8	AEGON	1
9	ING	1

Source: table accomplished by authors based on data provided by PPSSC

The higher this ratio is greater than 0,5 with the degree of financial independence is higher societies. In our case analyzed companies' financial autonomy ratio is 1, which means that they are independent from creditors.

2.3 The rate of indebtedness in term (R.i.t.)

$$R.i.t. = \frac{\text{Medium and long term obligations}}{\text{Permanent capital}}$$

The company can benefit from a medium and long-term debt, if the rate is less than 0,5.

Table 6. The rate of indebtedness in term

Crt.No.	P.P.F.M.C.	R.d.f.
1	ALLIANZ ŢIRIAC	0
2	GENERALI	0
3	BRD	0
4	BCR	0
5	AVIVA	0
6	EUREKO	0
7	ALICO	0
8	AEGON	0
9	ING	0

Source: table accomplished by authors based on data provided by PPSSC

All companies can benefit considered medium-term debt.

2.4 The rate of debts (R.d.)

$$R.d. = \frac{\text{Total debts}}{\text{Total of assets}} \quad (4)$$

Table 7. The rate of debts

Crt. No.	P.P.F.M.C.	R.d.
1	ALLIANZ ŢIRIAC	0,0069
2	GENERALI	0,0061
3	BRD	0,0064
4	BCR	0,0033
5	AVIVA	0,0049
6	EUREKO	0,0056
7	ALICO	0,1299
8	AEGON	0,0015
9	ING	0,0049

Source: table accomplished by authors based on data provided by PPSSC

Values resulting from debt rate analysis shows that the analyzed companies are financially stable, mainly due to the low level of debt.

2.5 The rate of equity capital to fixed assets (R.E.c./F.A.)

$$R.E.c./F.A. = \frac{\text{Equity capital}}{\text{Fixed assets}} \quad (5)$$

This ratio expresses the conditions for financing all fixed of capital assets of the company.

Table 8. The rate of equity capital to fixed assets

Crt. No.	P.P.F.M.C.	R.E.c./F.A.
1	ALLIANZ ŢIRIAC	1,116
2	GENERALI	1,648
3	BRD	0,000
4	BCR	1,125
5	AVIVA	1,337
6	EUREKO	0,000
7	ALICO	1,529
8	AEGON	1,344
9	ING	1,122

Source: table accomplished by authors based on data provided by PPSSC

A value higher than one, means that all assets are financed by equity. If our two BRD company Eureka recorded a nil value which means that all equity is not sufficient to finance all fixed.

2.6 he rate of permanent capital to fixed assets (R.P.c/F.A.)

$$R.P.c./F.A. = \frac{\text{Permanent capital}}{\text{Fixed assets}} \quad (6)$$

The over-unit value of this ratio means that all assets are financed from permanent capital as natural.

Table 9. The rate of permanent capital to fixed assets

Crt. No.	P.P.F.M.C.	R.P.c/F.A.
1	ALLIANZ ŢIRIAC	1,116
2	GENERALI	1,648
3	BRD	0,000
4	BCR	1,125
5	AVIVA	1,337
6	EUREKO	0,000
7	ALICO	1,529
8	AEGON	1,344
9	ING	1,122

Source: table accomplished by authors based on data provided by PPSSC

Two of the companies analyzed (BRD EUREKO) have a value of nil rate permanent capital to fixed assets which means that not all fixed assets are financed by equity capital standing like normal.

2.7 General liquidity (G.I.)

$$G.I. = \frac{\text{Current assets}}{\text{Current liabilities}} \quad (7)$$

This rate reflects the economic components to turn into a short-term liquidity. In our case the resulting value exceeds the permissible limits, this is a feature encountered in investment funds.

Table 10. General liquidity

Crt. No.	P.P.F.M.C.	G.I.
1	ALLIANZ ŢIRIAC	2,39
2	GENERALI	640,74
3	BRD	1556,56
4	BCR	34,40
5	AVIVA	506,54
6	EUREKO	1781,71
7	ALICO	3,31
8	AEGON	170,95
9	ING	219,88

Source: table accomplished by authors based on data provided by PPSSC

All companies analyzed show a general solvency higher than one, more than 2.5, which means that they are available to shelter cash shortages caused by debt repayment.

2.8 Immediate liquidity (I.L.)

$$I.L. = \frac{\text{Current assets-stocks}}{\text{Current liabilities}} \quad (8)$$

This indicator should be between 0,8 and 1. In our case, all Private Pension Funds Managing Company have the ability to meet short-term debts of receivables and cash. The high value of this indicator is due high assets compared to liabilities.

Table 11. Immediate liquidity

Crt. No.	P.P.F.M.C.	I.L.
1	ALLIANZ ŢIRIAC	2,39
2	GENERALI	640,74
3	BRD	1556,56
4	BCR	34,40

5	AVIVA	506,54
6	EUREKO	1781,71
7	ALICO	3,31
8	AEGON	170,95
9	ING	219,88

Source: table accomplished by authors based on data provided by PPSSC

A special feature of immediate liquidity value we find for BRD and Eureka, a value which is due to low level of company debt.

2.9 Overall solvency ratio (O.s.r.)

$$O.s.r. = \frac{\text{Total assets}}{\text{Current debts}} \quad (9)$$

The high value of this ratio reflects a situation where creditors of the company enjoys good security on its part.

Table 12. Overall solvency ratio

Crt. No.	P.P.F.M.C.	O.s.r.
1	ALLIANZ ŢIRIAC	14,38
2	GENERALI	1626,60
3	BRD	1556,56
4	BCR	300,22
5	AVIVA	2005,40

4	BCR	0,334
5	AVIVA	0,049
6	EUREKO	0,056
7	ALICO	14,93
8	AEGON	0,150

Source: table accomplished by authors based on data provided by PPSSC

3. Conclusions

Considering the value resulting from the analyzed financial structure rates we can say that ING is a stable and efficient pension fund, confirming leadership status private pillar. Not only ING but the eight other pension funds showed good results, being among the first in Europe due to prudent investment due to, exposure to low stock and high exposure to government securities, managing overall performance to overcome in some places not only inflation but also interest on bank deposits, gaining profit.

To ensure an adequate and sustainable income to pensioners, pension funds should record higher rates of return as the accumulation phase and in the payment of pensions

The weighted average rate of return of private pension funds for the last 24 months is 6.1856%. Overall the value of pension funds confirming his leadership status on the private pension pillar II market has grown steadily since 2007, reflecting a mature market of mandatory private pensions.

Possibilities to Increase the Funding of the Healthcare System in Romania

Miculescu Marius-Nicolae

Christian University „Dimitrie Cantemir”, Faculty of Management in Tourism and Commerce, Timișoara
marius.miculescu@yahoo.com

Abstract

Many studies about the healthcare system in Romania highlights the funded under the European average and the money is allocate often not well spent. To increase the quality of healthcare the state must develop a series of reforms that will lead to increased revenues and reduce the costs of healthcare services. This paper aims the evolution of the healthcare system in Romania in the last decade and presents some opportunities that deserves used to increase funding in this area.

Keywords: *healthcare system, financial increase, general income, value added tax on productive activities*

Classification J.E.L.: M40

1. Introduction

Performing health systems are characterized by a high capacity to prevent disease through an efficient management of chronic disease development through an appropriate response to patient needs and in a fair and efficient and effective allocation of existing resources. These desiderates can be made through a series of mechanisms for generating and allocating funds in the healthcare system. Health care systems in European Union countries are very complex and vary from country to country.

In all European Union, governments are involved in financing health care. Most Member States are using a combination between social insurance contributions and direct government funding of health. Finance a system at national level can be achieved only by involving the state to purchase resources, directing them in accordance with the aims pursued and levers to influence

economic, social and cultural development. [1].

The main objective of financial mechanisms is to create sufficient financial resources for pay the services and spread financial risk in terms of ensuring a fair health care.

Strictly from the perspective of public funding, the **general income model** tends to bring a progress in financing the healthcare services in comparison with individual payroll taxes or individual insurance. In a certain manner, adapted to the Romanian fiscal and financial system, a tax "for health" in fixed rate could be applied to the total income obtained by economic entity which uses employed staff.

2. Short analysis of the health system in Romania

In essence, the healthcare services in Romania was, and is an organized and financed by the state, and it is made from a network of state-owned hospitals, managed into a centralized structure with have on top the Ministry of Health.

Financing the health care system is based on social health insurance is the main system economic and social relations health care, are compulsory and works decentralized on the principle of social solidarity and subsidiarity in the collection and use of the Funds, and the right of patient to choice free the physician, hospital and the health insurance entities. Social insurance for health funds are composed by contributions of insured persons, contribution of entities that employ employee, subsidies from the state budget and local budgets and other sources.

The system was developed on the equity principles, ensuring access to health care services for all people. Access to services was not influenced by the patient's payment

capacity.

At present, financing public healthcare budget is: the state budget, the budget of National Fund of Health Insurance (FNUAS), local budgets, revenues, external credit external grants, donations and sponsorships. In total financing sources, the share is held by National Fund of Health Insurance (FNUAS) with 75%. FNUAS is currently funded by employee contributions (5.5% of their income) and employers' contributions (5.5% of salary fund).

So financing healthcare system in Romania is made by allocated from the state budget a percentage of GDP, which in 2008 was 4.1% and 3.9% in 2009, amounts to arrive in system through the Ministry of Health and subordinated organizations.

In time the contributions to FNUAS decreased progressively from a total percentage of 14% in 2001 to 11% in 2008. At the same time, it should be noted that the number of direct tax payers has declined significantly in the same period by about 4 million people in 2007 compared to 2000. In this moment 5 million people contribute to financing the system that should benefit equally 22 million citizens. This was due to the exclusion of payment of the different categories of population, without allocate equivalent funds to compensate the exemption of payments.

Since 2006 the government has tried to find new sources of financing the health budget by introducing the **vice tax** imposed on tobacco products and alcohol and contribution on sick leave. This contribution rate of 0.75% was applied on salary fund, and in 2007 the percentage was changed to 0.85%. Of this contribution it will be paid employees whose sick more than 5 days.

Financing the health care units and ambulatory units privatized, is performed through contracts with health insurance funds that reimbursed medical services. Reimbursement the medical services is written on Framework Contract, which is approved annually by government decision.

In the Romanian healthcare financing system have appeared the private insurance, they are a supplement rather than a substitute for financing the primary healthcare system.

3. Increase the health financing system in Romania.

Health systems consume large resources in all countries, in the last 30 years recorded a continuous increase in the level of resources needed, increase due mainly: aging population; discovery more efficient medicinal products and more advanced technology, but also more expensive, increasing number of people which receiving healthcare.

Increased financing of healthcare system in Romania has been a priority of the government focused lately, so Presidential Commission produced a report which shows that "areas where authorities must intervene are financing and organization primary care system services, medicinal product policy and human resources". [2] Following this report written in 2008 there were a series of debates on the subject that ultimately focused on the issue of increased costs in the system. Increase total spending on health has aroused much controversy both nationally and intentional being considered as a future investment that creates benefits but also increase costs in the current economy.

As can be seen from the following figure in Romania total expenditure on health percentage of GDP is the lowest in the EU, which shows lack of interest of the government to invest in the future population health and unable to ensure continuity of production.

Figure no. 1. Total expenditure on health as percentage of GDP in EU countries

Source: WHO Department of Health Statistics and Informatics (May 13, 2011). "World Health Statistics 2011". http://www.who.int/whosis/whostat/EN_WHS2011_Full.pdf

Romanian health system is faced with a very delicate issue, namely National Fund of Health Insurance (FNUASS) insufficient and does not cover expenses incurred for the care and treatment of patients - people at a certain quality level. (Figure 2 .). With this problem faced other EU countries. For example Italy which seems passed over this situation, it following the example of the UK health system by introducing **value added tax on productive activities**, which employers have to pay. Employer activities without a healthy person cannot give expected benefit.

Solving the problem involves creating a financing system consists of general and specific taxes, private insurance, consumer spending and other direct payments to distribute the risk equitably as possible across the population, according to the existing political and institutional realities.

As a solution to resize the National Fund of Health Insurance would be the introduce a percentage rate to be applied to the value added production activities and the elimination rate of 5.5% paid by the employer and currently applied on salary fund, and reducing the rate of 5.2% to 2% retained by the insured persons. In this way we can speak of an increase of net salary of the employee with the opportunity to invest or save money and contribute to future growth.

Figure no.2. National Fund for Health Insurance - billion

Source: <http://www.cnas.ro/informatii-publice/bugetul-fnuass/evolutia-fnuass>

Creating a pluralistic financing system of health activities, choosing the financing of the German health system, composed of public and private resources (with a total of 52 houses private health insurance), could lead to the creation of a competitive

environment and thus increasing the quality of care.

Creating a pluralistic financing system of health activities, choosing the financing model of the German health system, which is composed of public and private resources (with a total of 52 houses of private health insurance), could lead to create a competitive environment and thus increasing the quality of healthcare.

The system will provide equal opportunity to access the medical services and will ensure an equitable payment services. Payment arrangements will be made known to the entire population. Financing the health system will make by insurance funds and patients payments. The state budget will fund national health programs and investments in hospitals, high performance buildings and equipment. Health insurance funds will finance health services (primary, outpatient, hospital, emergency, dental, rehabilitation, pharmaceuticals offset). The patient will pay just a part of medical services and other health services it must be paid without discounts.

Ministry of Health should elaborate a contract model by establishing a series of protective clauses in public acquisition undertaken by public health entities that cannot make some investments in various equipment that are inefficient and would increase total costs unnecessarily. [3].

The National House of Health Insurance, the provider of funds for primary health services must clearly define the package of minimum health services for the population, to establish the rights of patients, to improve quality of care by imposing quality standards, streamline medical services, to support decentralization in central and local growth management act.

Quick and easy access to European funds could be one of the alternatives for financing healthcare entities with funds. Ministry of Health should promote and support these actions. 2013 is the year in which the Romanian Government should prepare the entities to make projects for the year 2014 to access the European funds.

4. Conclusions

Romania must choose a new kind of health policy, to make citizens more

responsible to not abuse with the medical services and local authorities to be more attentive to health care costs.

Once with redefinition the minimum package of services and introduction of co-payment, the patient has control over healthcare services, which has access for free. Also the patient must know the cost of medical services and medications received and that it must pay because they are not covered by private health insurance.

Licit Tax Evasion And Its Implications

Moisescu Florentina
University “Dunarea de Jos” Galati, Romania
Faculty of Economics and Business Administration
fmoisescu@ugal.ro

Abstract

Tax evasion represents, undoubtedly, the central vector of underground economy, which, in interaction and interdependency with the other specific components of economic-financial criminality, gives the true amplitude to the informal side of economy. Tax evasion is one of the complex, extremely important, economic-social phenomena which countries nowadays are faced with and its undesired consequences are sought to be diminished, eradication being, practically, impossible. The effects of tax evasion are reflected directly on tax levels, they lead to distortions of the market mechanism and may contribute to social inequities due to the taxpayer’s different “access” and “inclination” to tax evasion.

The actions carried out by the organised crime structures in the field of business, favoured by the legislative ambiguity and normative volatility, and, especially, by the weaknesses of the tax administration and coercion, lead to the disequilibrium of the supply and demand on markets, by means of the system of markets and parallel prices. Consequently, a reduction of the volume of public financial recourses occurs, “manipulating” (negatively) even the budget deficit.

Key words: tax evasion, licit tax evasion, illicit tax evasion, evasion ways

JEL classification: M41

1. Introduction

Being a social phenomenon with financial implications, tax evasion consists in *taxpayer’s totally or partially evading taxes, by any means, benefitting from the legislative gaps and resorting to*

ingenious manoeuvres for wholly or partly hiding the taxable matter.

The use of the phrase “by any means” does not mean that both legal and illegal means have been considered because, by making use of exclusively legal means, one cannot break the law. Thus, all the means referred to above are illegal.

Similarly, in the French specialty literature, there were opinions according to which “in tax, we cannot speak of permitted and forbidden fraud. There is a licit ability and an open or hidden violation of the law”.

Consequently, tax evasion consists in *taxpayer’s evading the total or partial payment of financial-budgetary obligations, by any means banned by the law.* [1]

Criminal liability in terms of non-patrimonial tax obligations is regulated by Law 241/2005 which sanctions tax evasion and related crimes.

In terms of the manner of perpetration, there are two types of tax evasion:

- Licit tax evasion (carried under the cover of law)
- Illicit tax evasion (fraudulent)

Licit tax evasion occurs when part of the income of assets of a person or of a social category is saved from taxation by resorting to a combination unconditioned by the law and thus “tolerated”, overlooked. Therefore, this is the result of the ability to choose a path to follow.

Illicit tax evasion consists in the dissimulation of the taxable item, in the undervaluation of the taxable matter or in using other ways for eluding the payment of the due tax, all by trespassing legal provisions.

The avoidance of the tax laws and, implicitly, the avoidance of paying financial obligations, are achieved by three main ways:

- creation by the law of favourable tax regimes;

- taxpayer's refraining from performing heavily taxed activities;
- simply breaching the tax law.

In the present paper, we will analyse in detail the phenomenon of licit tax evasion, in accordance with existing legal regulations, based on a practical application.

2. Licit tax evasion – application

Tax evasion, as strange as it may seem, is not just a deed worthy of the public contempt. There is the so-called “legal tax evasion”, under the cover of creative accounting and characterised by the taxpayer ducking the law, resorting to a combination which is not provided by the law and, therefore, tolerated. Essentially, creative accounting is a set of accounting techniques or methods (recording, synthesis, consolidation and communication to stakeholders) which aims at maximizing company results from the perspective of the managers' interest.

It is not hard to notice that, in the case of creative accounting, we are speaking of the performance of licit tax evasion. Consequently, creative accounting only exploits certain inaccuracies, gaps or inconsistencies of the tax legislations, in order to minimise the impact of taxation on the final results of the organisation. Or, this is precisely the description of legal (licit) tax evasion. As long as creative accounting is “correct”, meaning that it only exploits the deficiencies and inaccuracies of the tax laws, we cannot speak of tax fraud. When tax laws are breached, of course, we are faced with tax fraud. Therefore, things are just like in “orthodox” accounting: as long as tax laws are not violated, we cannot speak of tax fraud. [2]

Exploiting the insufficiency of legislation, taxpayers pay only what they cannot avoid. Examples are plenty: from the classical system, regarding the creation of amortization or reserve funds, in a larger amount than it would have been appropriate from an economic standpoint (shrinking thus the taxable income) and up to the transfer of salary costs to the company-individual or self employed person, the range of the used means arouses both admiration and concern.

“Licit” tax evasion is not conceptually defined by our legislation, although the term

is accepted by tax practice, based on intra legem operational procedures which elude the provisions of a sanctioning regime. Licit tax evasion is built on the basis of legislative paradoxes which do not allow an unequivocal confirmation or information of certain controversial and interpretable legislative aspects. Licit tax evasion represents the underestimation of the taxable matter by promoting certain tax exonerations or facilities (generically named favourable tax systems) which allow the “run from taxation” without breaking the law directly, these practices being somewhat tolerated by the permissiveness of tax regulations. We can say that the tolerated tax evasion is the natural consequence of legal inadvertencies, sometimes imperfectly assimilated in practice; the basis for its existence is the equivocalness of law and the principles of the tax law according to which the institution and levy of taxes and dues cannot be interpreted by their extension.

“Tolerated” tax evasion is based on the full exploitation of any possible legislative gaps in the field of taxation and appears under a range of manifestation forms, know also as “apparent” tax deductions. Apart from the tax deductions explicitly regulated by the applicable law, there is also a series of tax deductions which are not expressly specified, but which are not forbidden either. Practice has proven the existence of these “hidden” tax deductions, assimilated with the forms of “tolerated” tax evasion and favoured by the relativity of the legal - illegal delineation. [3]

The economy, still inappropriately adjusted in point of structure, the existence of sources of bureaucratic circuits, as well as the diversification of contradictions and redundancies which facilitate the interpretative instability of the law texts favoured the ascending trend of licit tax evasion.

“Hidden” tax evasion focus on promoting a tax system favourable for the taxpayers, sometimes even to the detriment of economic performances. Taxpayers attempt to place themselves on a favourable position in relation to the tax burden they are subject to, in order to benefit as much as possible from the advantages implied by the applicable tax regulations.

A concrete example is the one of micro-enterprises which can pay either tax on profit

(16% afferent to the profit) or on income. The question is simple: when is it more “profitable” to pay income tax and when profit tax? The answer is mathematical in nature: it is more profitable to pay income tax when 3% of the income is below 16% of the estimated profit (seen as difference between income and costs). The inequality leads to the conclusion that for the 3% income tax to be more profitable, the estimated costs must be below 81.25% from the total estimated income. [4]

S.C. EURO MONTAJ GETA S.R.L. Galați produces commodities in value of 30.000 Euro/month (360.000 Euro/year), the gross profit being of 10% (36.000 Euro/year). As it has exceeded the turnover of 100.000 Euro/year, the following year the profit tax will be of 16% of the gross profit:

profit tax = 16%*36.000 = 5.760 Euro
 Shall be accounted:

	691	=	441		5.760
<i>Income tax expense</i>			<i>Income tax</i>		

Net profit 36.000 Euro - 5760 Euro = 30.240 Euro

Dividend tax = 30.240*16% = 4.838 Euro
 Shall be accounted:

	457	=	446		4.838
<i>Divident payment</i>			<i>Other taxes</i>		

Total tax 5,760 Euro + 4,838 Euro = 10,598 Euro

Shall be accounted:

	%	=	5121		<u>10.598</u>
441	<i>Income tax</i>		<i>Current bank</i>		5.760
446	<i>Other taxes</i>		<i>accounts</i>		4.838

It remains effectively with the entrepreneur 36.000 – 10.598 = 25.402 Euro

What can he do be left with more money? In other words, how can he use the legal provisions in his interest, thus entering the so called “legal tax evasion”?

Usually, Romanian entrepreneurs do not organise PR, marketing, advertising, database analysis, customer analysis, etc. departments, although these activities are vital to the proper development of the business and should be given a great deal of attention. But, if in another company, the entrepreneurs externalised these services they fulfil now among many other things? These services would be: advertising, market research, transport, but other as well: databases

processing, handling-storing, even lease of goods (the hall in which the production company operates can be transferred to the micro-enterprise, and the latter can lease it to the production company), lease of equipment, etc. This company would have the status of a micro-enterprise provided that one employee (two at most) is enough for dealing with finding customers, maintaining customers and consecrated suppliers, competition research, organisation of meetings between the management of the first company with business people, processing partnership and credit files, elaboration of personnel policies, etc. Of course, its scope of business could be business and management consultancy but the income obtained from this source cannot exceed 50% of the total income.

Going further with the example, we assume that this second company, S.C. Star Consulting SRL Galați perceives a 2% fee of the turnover of the larger company for consultancy services and 8% of the turnover for the found partners, for market research, management of exportation contracts (marketing services), etc.

Therefore, the turnover of the second company is of 36.000 Euros and the profit of the first company is 0 or near 0, therefore the first company does not owe profit tax. We assume that in the case of the micro-enterprise costs (salaries, prospecting, organisation, etc.) are of 1.200 Euros per year (presuming that the same employees are used as for the producing company, with moonlighting, one hour per day, as allowed by the Labour Code, and the employees have self-employed persons licences and contributions are lower than in the case of employees).

The income tax of the second company, which is a micro-enterprise, because consultancy incomes are below 50% of the total incomes:

Income tax = 3%*36.000 = 1.080 Euro
 Shall be accounted:

	698	=	441		1.080
<i>Other expenses</i>			<i>Income tax</i>		
			<i>with taxes</i>		

Dividend tax = 16%* (36.000 – 1.080 – 1.200) = 5.395 Euro

Shall be accounted:

457 = 446 5.395
Divident payment Other taxes

total due taxes in the case of the micro-enterprise

1,080 + 5,395 = 6,475 Euro

Shall be accounted:

	%			
	=	5121		<u>6.475</u>
441 <i>Income tax</i>			<i>Current bank</i>	1.080
446 <i>Other taxes</i>			<i>accounts</i>	5.395

The entrepreneur is left with 36.000 – 6.475 – 1.200 = 28.325 Euros

It results that through a more structural activity, the difference between the taxes paid in the first situation 10,598 Euros and the costs with the micro-enterprise (6.475 + 1.200 = 6.675) is of almost 3.000 Euros! And this for a turnover of 30.000 Euros per month.

3. Ways of licit tax evasion

We will present below some of the ways available to taxpayers for carrying out such evasion activities, under the cover of law, as the used procedures are extremely diverse and vary with the type of tax. Among the main forms of licit evasion used at present in various countries of the world are:

- advantages in kind (work cars, more than generous compensations constituting professional costs, etc.) granted by the company owners to the best paid employees in order to elude higher rates of income taxation;
- reductions of income tax for the profit reinvested for the purpose of developing profitable activities;
- the possibility to deduct from income (profit) certain costs regarding amortization and reserve funds in a larger amount than economically justifiable;
- residences abroad, in tax paradises (financial centres which offer more favourable taxation conditions) for natural persons and commercial companies.

Japan offers an entire range of tax-free incomes (the interest recorded for the current bank deposits, the interest for governmental debentures which do not surpass 3,5 millions of yens, incomes from interests for smaller

deposits, etc.) which allows full resort to licit tax evasion.

Regarding the “doors” opened in 1990 by the Romanian tax law, there was the massive possibility of evasion by the creation of new commercial companies by the entrepreneur of a company which approached the period of profit tax exemption.

An example of tax evasion under the cover of law is the taxation of the income obtained by certain categories of natural persons on the basis of average income norms, taxation which creates conditions for the taxpayers obtaining incomes above the average to avoid paying tax for the difference in question.

Another example of legal evasion which allows for a part of the income to escape from taxation is represented by the tax facilities granted to the economic agents from certain branches of the economy, upon the establishment or during the development of the activity, such as VAT exemptions on importation or exportation, excise duties, etc. or reductions of the profit tax.

Accelerated amortization, when permitted by the law for certain categories of fixed funds, leads to the diminution of the taxable profit in favour of creating an amortization fund larger than the one imposed by the value of wear and obsolescence, recorded by fixtures during the concerned period.

Table 2.1 Structure of tax evasion on income sources, between 2007 and 2010

	2007	2008	2009	2010
VAT	28,1	37,8	58,9	56,2
Profit tax	19,6	25,4	24,8	22,6
Excise duties	4,8	1,6	4,8	5,98
Payroll tax	2,1	2,3	1,0	2,3
Other taxes	45,4	32,9	1,5	13,0

Source: D.A.P. Florescu [5]

The analysis on sources of origin of tax evasion reveals that between 2007 and 2010, the largest part is located in the VAT where the total share of evasion is placed between 28,1 and 58,9%, followed by profit tax (19,6 – 25,4%), other taxes and dues (10,5 – 32,9%), excise duties (1,6 and 5,9%) and payroll tax (1,0 – 2,3%)

4. Conclusions

As an economic-social phenomenon with most ingenious forms of manifestation, tax evasion remains a “poisoned” presence in the Romanian society (and not only), its negative effects being generalised at the level of the entire functional circuit of the economy. According to the (undesired) span of the phenomenon, it generates distortions and even blockages (even if only partial) in the proper operation of the mechanisms specific to the competitive market economy.

The competitive advantage conferred by tax evasion to its “adepts” is not one to be neglected; thus, while, the people resorting to evasion thrive by eluding tax obligation, fair companies are sometimes forced to shut down due to the unequal competition they are exposed to.

The authorities which should tackle the issue of licit tax evasion are the political (parties and the parliament) and administrative (government) bodies. Tax evasion under the cover of law can be avoided by correcting, improving and optimizing the legal framework which allowed it in the first place.

The concept of tax evasion existed, exists and will exist as long as the state and the tax will continue to exist. Tax evasion is the result of the permissiveness of an imperfect and erroneously assimilated legislation, with faulty and cumbersome applicability, with structures full of tidewaiters and unprofessional individuals, concerned by personal gains - all these are as many nuanced and significant elements in the study, analysis and identification of solutions for fighting this phenomenon which breaks one of the essential principles of the constitution of any country: “before the law, all citizens are equal”.

Offshore Jurisdictions And Tax Evasion In Romania

Moisescu Florentina
University "Dunarea de Jos" Galati, Romania
Faculty of Economics and Business Administration
fmoisescu@ugal.ro

Abstract

Tax is the price of civilization. Tax havens are the price of globalization. By using tax havens, we demonstrate how to avoid payment of taxes through legal methods of tax evasion.

The most important advantage gained by offshore companies is an attractive tax due - "low tax" or "no tax". There are other arguments in favor of offshore companies - confidentiality guaranteed for the final beneficiaries - owners, flexibility in the management, readiness with which such companies can be established.

This will lead to increase social inequitable social as well as deepening economic-financial crisis.

Key words: tax evasion, jurisdiction offshore, tax paradise.

JEL classification: M48

1. Introduction

Do you think that taxes and fees that you paid are too big and starting a business effective becomes today a lens very hard to reach? The solutions for this problem, presented in this paper are classical tax evasion and set up a company in a country considered as tax paradise (the method to be used very often by the big companies).

Thus, tax evasion is a mass phenomenon, a real plague of the economy, although it has been carefully studied and analyzed by the practitioners and theoreticians it is vaguely defined and dominated by contradictory views.

In the second part of the work we support the idea that it is a high level of tax evasion in our country, without the risk that it may be a merely political statement because only subtraction of sum from debts by tax

payers, it may be the key to the survival of 60% of the population of Romania in view of the fact that their income shall be placed below the poverty.

On the other hand, the level of investigation is unnatural for the persons associated with different companies which have recorded losses in each year.

In the third part of work we have presented methods for tax evasion through offshore jurisdiction and advantages that it offers companies registered in these countries.

In the end of work we have presented concrete cases of tax evasion and the conclusions that we reached from the study of this topic.

2. Tax evasion in Romania

Tax evasion is a very complex social economical phenomenon facing all countries in the world, fight against it being practically impossible.

There are views according to the which tendency towards tax evasion has in the report inversely proportional to the level of income tax and directly proportion to the rate tax. Excessive taxation by the state is a cause which leads to an essential tax evasion.

From the point of view legislative, a taxation exaggerated is understood through the prism large number of tax to which it is forced cart Romanian taxpayer, but also of instability in time of founded legislation of duties and taxes.

Romania is on the second place in the world by number of payments of taxes to be paid annually by firms-133- on the first place being Ucraina-with 135 payments of taxes, regarding the "Doing Business 2011", report by World Bank.

Romania is on the 151 place from 183 world economies (in world are 194 states recognized), by the ease with which a

company may satisfy its obligations to the state.

A business in Romania lose 222 hours per year for the 113 pay taxes and total tax rates is 44,9%. For comparison in Sweden taxes companies pay twice a year, and in Hong Kong,three times.

Regarding “Doing Business 2011”, Romania is on 56 place (55 in Doing Business 2010), in a ranking of 183 economies analyzed the situation of the world. So in the “Where it’s easier to do business” , Romania is itself in the document cited after Bulgaria (place 51), Botswana (52), St. Lucia(53), Azerbaidjan (54), so that in 2012, Romania is on 72 place, after Bulgaria(59),Hungary (51),Slovakia (48).

According to a report by the U.S. State Department, the financial fraud in Romania could increase about \$ 1.5 billion. According to this report illegalities about the value added tax(VAT) is 10% of all financial fraud down from previous years when they represented 45%.

As tax evasion is so far only by approximate methods. According to a report by the Ministry of Finance, tax evasion in Romania was estimated at a level of 17-18 % from GDP (gross domestic product) between 2009-2010.

Our country is the only state affected by the crisis who tightened taxation in all its components.

Areas that is very prone to evasion are: alcohol and tobacco which expects an explosion on the black market.

Table 1: Summary of tax rates and administrative burden in Romania 2011

Tax or mandatory contribution	Payments (number)	Statutory tax rate	Tax base
Social security contributions	12	20.8%	gross salaries
Corporate income tax	4	16.0%	taxable profits
Health insurance contributions	12	5.2%	gross salaries
Fuel tax	1	included in fuel price	
Building tax	2	1.0%	building value
Medical leave	12	0.9%	gross salaries
Unemployment	12	0.5%	gross

contribution			salaries
Accident risk fund	12	0.15-0.85%	gross salaries
Labor inspectorate commission	12	0.25%-0.75%	gross salaries
Guarantee fund	12	0.3%	gross salaries
Vehicle tax	2	fixed fee	
Land tax	2	RON 0.3 per square meter	land area
Firm tax	4	A fixed amount per square meter of lighting panel	the surface of the lighting panel
Environmental taxes	1	RON 1 per kilo of packaging	weight of packaging
Stamp duty on contracts	0	various rates	type of contract
Total	113	222	

Source: Doing Business database

Tax evasion profile fits that of employees who are overworked. Such offenses are committed by officials (or private entrepreneurs) with training in economic and financial, bearing the name of “white collar”.

Occidentale surveys, reveal that people that commit fraud are:

- a rate of 30% women;
- with a stable family situation;
- in general married people;
- less likely to be true but they are educated;
- less likely to have criminal record;
- is unlikely to abuse of alcohol;
- also more optimistic;
- more motivated and more self esteem than others.

Tax fraudsters are between 25-54 years and they have a profession that involves swelling of expenditure or the omission of income.

3. Offshore Jurisdiction

Tax Haven,get a resonance today increasingly deeper into the world so big giant and across the world living standards well below the poverty line and multilying them simultaneously and complex number of advantages offered to foreign investors.

OECD (2001 - Organization for Economic and Cooperation and Development), identifies key factors in the definition of the paradise fiscal must meet three criteria:

- no tax or only nominal taxes, these jurisdictions offering a place to escape oppressive taxation of non-residents out of the way the country of residence;
- lack of effective exchange of information (strictly confidential);
- lack of transparency in legislative and administrative provisions.

There are other types of benefits that can be found in offshore areas:

- elimination of exchange controls - usually, offshore companies can conduct their financial transactions and retain their financial reserves in any currency without special permission
- accounting lack the obligatory young - many offshore tax havens do not require companies to keep accounting records, which result in saving substantial savings, and related considerations of prestige.

Factors that determine the choice of tax haven include: discriminatory treatment of foreign investment, encouraging foreign investment, reduced taxation, banking secrecy, resident or resident individuals and influence their changes and operating costs.

Under the current economic crisis, more and more Romanian companies have set for “everyone is concerned with expenditure reducing”. Assessments of market actors talk about an increase of 30% of the market from the beginning of the crisis and estimate that over half of its Romanian business people have a profit accumulation company.

Specifically, to establish a company you can call a law firm or accounting and presenting the activity of the company I wish to establish and specify the budget that I have then expect a personalized offer from agent then go directly to such jurisdiction and appeal to local lawyers.

Establishment as it cost me?

And to jurisdictions establishment costs range from:

- 1000 euro in Panama, Belize, Bahamas, or British Virgin Islands where is not required the existence of accounting.

- 2.00-2.500 euros in Malta, Seychelles or Dominica;
- 3000-3.500 euros in Gibraltar, Isle of Man, Hong Kong or Singapore;
- 4000 euros in Cipru;
- 6000-15.000 euros in Switzerland, Luxembourg, Liechtenstein;

Administration cost me as?

- any money if I just want company and so and I will personally take care of all acts;
- from 700 euros yearly rated worst jurisdictions to 2000 euros monthly in Switzerland and get specialized consulting services.

Results obtained for money

A company whose establishment costs 4000 euros, get tax cuts but the shareholders are in sight and can be identified by anyone check register in that country.

Paying the maximum charge of 13.000-15.000 euros, company has nominal shareholders and directors. But they are legal and if anyone wants to check it, you find that have headquarters in other tax havens where other shareholders, the Russian doll system, benefiting the entire insurance management, juridical and accounting but has a virtual office with fax, e-mail, phone, where a secretary answers 24 hours of 24.

In offshore you can pay one kind of tax, income tax, ranging from 0 to 10%. There are several countries or regions in the world known as tax havens but the most prestigious are Switzerland, Luxembourg, Liechtenstein. How long establishment?

- Between 3 days and 1 month.

How abolish?

- Telephone within 24 hours

4. Tax evasion through offshore jurisdiction

4.1 Transfer price manipulation

It is estimated that 60% made by the trade occurs within multinational group.

Internal transfer prices established for these are not checked and are not governed by market principles.

This is the greatest irony of free market economy : a significant proportion of world trade (which occurs within multinationals) is not regulated by the prices set by the market.

Term transfer pricing is used for transactions between related parties, those transactions are not subject to free market rules and can be influenced by subjective factors such as policy group companies in terms of minimising cost group. Overall effect on the parent company could be an increase in the profits valuation.

Practically, companies operating in higher tax regiments are likely to transfer products and services below market prices to ensure that lower income and profits are reported by reducing their tax obligations. On the contrary, companies that receive goods and work in lower tax regimes are likely to report higher profits, because tax rates are lower.

An important aspect of rising the problem of transfer prices are transfers of intellectual property rights and intangible assets.

If a patent is developed in the USA and sold at a low price to a an affiliated company in a country with low taxation, income will be moved if any royalty or other payment is less than real value of the license.

Intangible assets such as: new medications or inventions tend to not have comparison and therefore is very hard to known copyright which should be paid in accordance with principle: *arms-length price*. Intangible assets therefore represents a special case in terms of control of transfer prices.

Together with the existence of tax havens, these intra-group transactions offer a facade of legality for the passage to a new jurisdiction from another jurisdiction with very low levels of duties as a normal course of business.

Decisions establishing transfer prices have an impact on accounting, managerial efficiency, profitability investments, as well on products and prices.

In USA ,82 of the biggest companies have realized gains over 1,1 trillion dollars in the period 2001-2003 without charges by State to pay.

According to studies the USA lose each year over 170 billion dollars in uncollecting taxes, so that the share of taxes in GDP is just 1,3 %.

It is estimated that annually are lost between 25 to 85 billion pounds because of

tax evasion in tax level in Great Britain.GDP is less than 2,5 %.

Examples of large companies that use offshore areas to increase their international competitiveness: Boeing, Caterpillar, Chevron, Daimler-Chrysler, Easteman-Kodak, Exxon, General Motors, Microsoft,etc.

4.2 Carousel fraud type

Form of fraud on the VAT with a the most serious consequences through the taxes diverted away from pay and very difficult to detect is the known as the “carousel “fraud,

This fraud avoidance systems involve the payment of VAT.

Thus, there are established enterprises which claim that they are doing international trade, but they not pay the VAT indebted, to permit the other links in the chain of fraud to make the deduction of notional payment of taxes and to obtain a refund or reduction of VAT indebted.

In reality, societies concerned have no real activity and their headquarters is often the address of a postal boxes.

Ussualy after a few months of existence these companies disappear without declare and pay tax on what makes them difficult to detect by tax authorities.

This type of fraud is based on a relatively simple mechanism at least in apparent : the operator in the country of origin without VAT invoice (because of an intra-community delivery that come into the category of transaction exempted from VAT deductible) and operator in the country of destination will apply the reverse (VAT) charge for this operation (because it makes a purchase with intra-community counting and intra-community VAT cost associated with registering of the rate of taxation of his country, both the VAT deductible and VAT collected, but without effectively payment the acquisition)

Subsequently intra-community acquisition, the operator in case disappers without registering (for accounting terms), to declare (in terms of tax), and pay the VAT collected for subsequent deliveries made on its internal market (so-called “bottle filled” company, collectors of tax liabilities relating to VAT but which will never be paid).

Parties involved in this type of fraud are:

Firm ghost or missing trade is the star of this fraud and the company 's rule without real activity managed by people of the facade.

The company ghost can buy goods without paying VAT in the EU to its suppliers, and to sell the same goods with VAT without to pay VAT collected.

Company pad or buffer may have activity real or not, her role is to buy and sell large amounts of goods no added value.

Conduit company is an international firm pad, and has the same activity as buffer, only that it is a table in another state than the client and stimulates fraud in their clients' State.

This companies do not commit fraud in countries of origin.

5. Examples of legal tax evasion

Band U2

The band is Irish origin ,and his members have tax residence in Ireland. Till 2006, Ireland does not tax income artists and singers ,but starting from 2007 annual revenue of artists that have become taxable exceeded 500.000 euros (individual income tax cca 43%).

They could keep the Irish tax residency and receive fees through an Irish company paying Irish tax on profits (12,5%).

However the band chose to incorporate a company in the Netherlands where the tax regime applicable to artists (tax on royalties) is the only 5%.

Although the band U2 adopted optimization method is perfect legal, it does not correspond with ethical and moral model that group members have won it over the years.

On the other hand this model makes us reflect on the natural urge tax payers to lessen any legal (and sometimes illegal) tax burden.

Google

Google has cut its worldwide tax bill by about \$1 billion a year using strategies like “Double Irish” and “Dutch Sandwich”, which move profits through units in Ireland, the Netherlands and Bermuda (where there is no corporate income tax).

In 2006, Google signed off on a 2003 intracompany transaction that moved foreign

rights to its search technology to an Irish subsidiary managed in Bermuda called Google Ireland Holdings, so a subsequent profit overseas based on those copyrights has been attributed to foreign subsidiaries rather than to Google in the U.S. where the technology was developed.

Following that transaction (known as a “buy in”) Google made several acquisitions, spending \$1.65 billion for online-video site YouTube in 2006; \$ 625 million for e-mail security service Postini in 2007; and \$3.2 billion for web-advertising company DoubleClick Inc. in 2008 and the prices paid by the foreign subsidiaries for the rights to software and other intangibles moved offshore that formerly belonged to those three companies.

Conclusions

Tax havens contributed to the financial crisis in several other ways: by fostering dangerous complexity, secrecy and mistrust; by serving as offshore booking centres massively boosting financial liquidity, and by helping create tax incentives that led firms to load up on debt

Tax havens offers the possibility to avoid taxes, financial regulations and criminal laws.

Both wealthy people and large companies tax havens offer a way to escape the domestic constraints, risks and tasks remains valid for the population.

Image according to which offshore jurisdictions are exotic lands, islands with palms joined by Switzerland and Monaco are false.

The largest tax havens are rich countries. A revealing example is the U.S. that although leading a fierce campaign against tax evasion it offers facilities for corporate secrecy that is so difficult to “break” such as Swiss banks. Not many people know that the state of Delaware (USA) is a tax haven, and more than half of U.S. companies have a subsidiary in this state.

It takes a strong fight against tax havens development promoted especially by developed countries, but as long as the State's needs will be growing, the fiscal pressure will move in same direction. It is expected that the 21st century will be offshore

domiciles century due to rapid development of this sector

Abstract

Innovation is a means to success for the beer companies in the years to come. Even during the recent economic crisis it is noticeable an increase of profitability by leveraging the impact of the innovation.

Key word: innovation, profitability, business excellence, success.

J.E.L Clasification: E 32

Introduction

In 2007 the Romanian beer market was estimated at one billion Euros gross turnover.

With the arrival of the crisis, in 2008, the non-food market, one of the Fast Moving Consumer Goods (FMCG) segments, was fully affected, with a powerful impact on the beer market.

Consequently, from a total volume of 19.3 million hectoliters sold in 2007, reported by INSS, in 2008 the growth rate of the beer market decreased from 9%, annual growth in 2007, to 6% in 2008, however the greatest blow to the beer market happened in 2009, when it took a fall of 14%, compared to 2008, in absolute amount a contraction of about 2.9 million hectoliters.

Graph 1. Romanian Beer market evolution 2007-2011

Source: Nielsen RA

Analysis

The descending trend of the beer market can be noticed also in 2010 with an annual decrease of 4%. Only from 2011 we can talk about market stabilization. This translates into a small growth of 1% compared to 2010. Even through the figures look positive, the total volume sold in 2011 was around 17.1 millions hectoliters, below 2006 volumes.

During the crisis period consumer preference tends to migrate to cheaper brands segment, especially to the value segment of the beer market. If in 2011, the value segment of beer market represented about 42% of total retail market, in 2012, on year to date August figures, value segment grew to about 51% of total market, main winning brands being Bucegi (Heineken), Ciucas (SAB), Noroc (Bergembier) and other value brands.

The economic crisis had an impact not only on the total volumes sold but also from a profitability point of view, the competing brewers seeing the same effect. The final consumer became more susceptible to price offers which led the brewers to act highly promotional from the price perspective so as to make the product more appealing to the consumer.

Looking at the main competitors from the beer market, top three remained SAB (South African Breweries), Heineken and Bergembier SA with a cumulated market share of about 75%. However, the brewer that succeeded to come on top is Heineken, which now has a market share above 35%, by leveraging a divers portfolio with multiple value brands such as Bucegi, Neumarkt, Hategana and Harghita.

Another characteristic of the crisis period is the cautious behavior of the final consumer which was tempted less to try new products or new entry segments such as strong beers, with higher ABV, Ursus Strong, Noroc Tare, or flavored beers such as Redds, where the cumulated share in the beer market remained under 1%.

In 2011, the year that we can say the beer market decline stopped, Bergenbier SA tried to come with a new proposal for the consumer, also trying to revitalize a niche segment, the flavored beers, with the launch of a new product – Bergenbier Lemon. Despite the efforts behind this launch, the end result was not as hoped for.

As from 2012, we can talk about the reversal of the trend for the beer market. Looking at the beer volumes from 2011 and 2012 on a year to date August basis, 2012 shows a growth of 8% in terms of shipments, reported by INSS, and 10% if we consider retail market, as confirmed by Nielsen RA.

In May 2012, Heineken, by leveraging the awareness and brand health of Ciuc, one of the brands in their portfolio, launched Ciuc Radler, a lemon flavored beer. To support the launch of this product, Heineken invested massively in all media channels: Radio, Tv, Outdoor etc, the total amount spent is estimated at around 1 million euro.

The considerable effort put behind Ciuc Radler, a beer from the flavored beer segment, led also to the growth of the segment as a whole. On year to date July figures, the flavor category had a share in the beer market of 1.6%.

Graph 2. Flavored Beer segment: Volumes and Market Share evolution

Source: Nielsen RA

Ciuc Radler’s launch strategy proved to be a successful one, Heineken gaining in just

four months 34% market share from the flavor beer segment.

The momentum of the flavor beer segment, created by the launch of Ciuc Radler, helped also the other competitors to capitalize on the opportunity. Redds from Ursus and Bergenbier Lemon grew in volumes with the segment. If Redds lost some market share in the segment, Bergenbier Fresh Lemon went from 1% share in 2011 to 6% market share on year to date July 2012 figures.

Graph 3. Flavored Brands 2011-2012 market share change

Source: Nielsen RA

Looking at different types of innovation in the beer market, it is clear that the Romanian brew manufacturers tried to come with various ways of becoming more appealing to the consumer. From a packaging point of view, the aluminum can offer went from the traditional six pack to eight pack and even twelve pack, to increase the drop, but also to four pack, a more attractive offer if we talk about out of pocket.

Nevertheless, the undisputed winner in pack types remains the PET, especially 2.5 liter and also 3 liter PET.

We can observe that the 2.5 liter PET is slowly becoming standard packaging in the beer value segment but also in the CSD (Carbonated Soft Drinks) market, as part of the non-food category, with the main competitors Coca-Cola and Pepsi.

Prior to 2011, the Romanian brewers showed little interest in developing new products, in offering innovations, but focused more on the existing offers trying to maximize on absolute volumes sold.

Conclusions

Only from 2011 there is a visible change in the way the big beer producers tackle the beer market. And starting with 2012 the result started to come as well: higher volumes and also higher profitability, as the line extensions have a greater margin contribution than the mother brand, with positive impact in the P&L.

Only as from 2011 we can notice a totally different approach of the market, and starting with 2012 the result was visible: increase in volumes and profitability, because of the good impact of the innovations in the company's P&L.

If it were to compare the beer markets from Central and Eastern Europe during 2011 and 2012 we can see that the focus is to offer to the consumer more and more choices by increasing the portfolio of flavored beers. Looking at the actual trend, it is fair to assume that this approach will continue over the next few years as well.

Romania, as part of this region, can also expect an increase of the innovative activity in the beer market, especially in the flavored beer segment, as seen in 2012. However this activity cannot be limited at the liquid itself but also packaging wise (reintroduction of the thermo sensitive labels, other keg sizes etc.).

Creative Accounting between the Risk of Disloyal Information and the Assurance of Fidelity in Information

Munteanu Petrică

*Faculty of Economics and Business Administration, „Alexandru Ioan Cuza” University,
Iasi*
mp05_ro@yahoo.com

Abstract

The complexity of economic transactions, their dynamic and the peculiarity of the activities carried out by each enterprise does not afford the coverage of the entire economic universe by accounting norms and regulations.

National and international organisms acknowledge the legal limitations owing to the previously mentioned objective reasons. Therefore, they acknowledge and give freedom to professional reasoning which should be a completion of norms and a supporting factor of the true and fair view.

By means of a critical approach and a qualitative method, we will analyze aspects pertaining to creative accounting. A controversial subject in the literature of the field for which we will highlight both the negative connotations (the ones encountered most often) and the positive ones.

The study emphasizes the fact that creative accounting techniques may be both a source of disloyal information and the way in which the principle of true and fair view is ensured.

Key words: creative accounting, true and fair view, financial-accounting information, informational risk.

J.E.L. Classification: M41, M42.

1. Introduction

The globalization of business is a permanent challenge for accountants. They are facing new manifest forms of identity of companies in incessant competition on a too greatly amplified market where the need for information is immense and diverse, becoming sometimes a marketing and advertising instrument. In this context, the accountant needs to find quick solutions to

adjust to the new informational demands without waiting for normalization. Thus, *the need for creativity* is imposed so as to find solutions and treatments meant to favour the companies' image and help them acquire certain advantages without breaking the law.

As many economic and accounting uncertainties rule the environment in which the company carries out its activity, many of the elements of financial statements cannot be precisely measured, but simply assessed. *The option of enterprise management for one of the multiple treatments and accounting policies implicitly creates the possibility of intended choice for the one that answers its interests.* They do not always converge to a true and fair view, but rather to a convenient one.

Thus, a distortion of the quality of accounting information occurs, generating uncertainties with respect to the consistency and compatibility of information destined to users.

In this case, we are dealing with an intention accounting, or, in other words, we are entering the sphere of creative accounting.

Originally creativity, as a term associated with human activity, has a positive connotation. Its valences impose the idea of innovation, development and improvement through creation.

In the field of accounting, due to several disloyal practices, creativity is associated with the process making use of the gaps in present norms, through accounting, engineering in view of manipulating the information provided for users.

In what follows, we will approach both the positive and the negative side of creative accounting. We will insist on the latter as it is the most encountered one and became a problem in the accounting profession.

2. Considerations on the concept of creative accounting

Although it subscribes to the list of controversial subjects and is frequently approached in the literature of the field, there is no common viewpoint in professional and academic viewpoints as far as the definition of the concept of creative accounting is concerned.

Creative accounting was first mentioned almost half a century ago by the father of accounting, Luca Paciolo. In his reputed treaty, *Summa de arithmetica, geometria, proportioni et proportionalita*, he presented several creative accounting techniques. One of them pertains to Venice where, in the context of a well-developed external commerce, the relations between traders were recorded based on the principles of double entry accounting and written in ink in primary and secondary book records. When discrepancies occurred, the bottle of ink was often spilt on the records. It was not by mere chance that the record became undecipherable every time.

Meanwhile, the concept preserved its essence, yet the implications of practicing creative accounting rose and managed to affect companies that act globally, and in this way, influence the life of people. The alignment of the accounting profession to commercial interests to the detriment of ethics was deeply criticized, being associated to the impairment of the status of accounting, its rigour and correctness.

According to various definitions, creativity in accounting is a process in which accounting professionals make use of their knowledge in the field to manipulate the figures of a business [1]. This becomes possible by exploiting legal gaps.

The responsibility of drafting financial statements to reflect the performance of the activity carried out by a company and its financial position at a certain date belongs to the company managers [2].

In principle, the leaders' conjectures and intentions have to respect the limits set by normalization. *When objectivity becomes impossible and norms uncertain, ethics comes in.* This is undoubtedly the significance of the British notion of *true and fair view* rendered in Romanian as “*imagine fidelă*”.

Despite being true, the view on the enterprise provided by accounting needs to be fair. For this purpose, ethics is asked for help in attenuating the likely shortcomings of the technique. Without ethics from the ones producing it, there is the risk for the accounting model to become a “*simulacrum*” of the enterprise used for communicative purposes [3].

Creative accounting is represented by “an overall of procedures that aim at changing the result level for the purpose of increasing or decreasing it, or the presentation of financial statements without the mutual exclusion of these objectives” [4].

Also called *aggressive accounting*, *imaginative accounting* or *intention accounting*, creative accounting is the manipulation of accounting figures most often in the spirit of the law, exploiting its gaps. Despite all these, it contravenes to good practices as it does not render a faithful image of the company whose accounts are affected.

The notion was first coined in literature, in 1973 by the British researcher J. Argenti who established a *direct relation between creative accounting practices, the managers' incompetency and business decline, mentioning that the use of creative accounting is a clue for an upcoming crisis* [5].

The expression made quite an impression in Great Britain when in the 1980s, the country made obscure “*business*”. Further on, in Anglo-Saxon literature, *the concept was mentioned several times in works referring to the bankruptcy of enterprises.*

Bernard Colasse mentions that “*it would be wrong to believe that regulations and norms render the accounting image of an enterprise objectively. They describe, in an explicit manner, only the way in which this image was “depicted”. But on the other hand, they leave a manoeuvre margin which is both indispensable and irreducible to those that draft financial statements, a margin they can use in agreement with the financial or communication policy of the enterprise*” [6].

He considers creative accounting to be an overall of accounting practices at the limit of the law used by some economic agents for the purpose of improving the image of their financial position and their economic-financial performances. Furthermore, he

mentions that *these practices occur as a result of the existence of gaps in accounting norms and because human creativity is limitless.*

Almost similarly, Trotman defines creative accounting as *a communication technique which has in view the amelioration of information provided for investors* [7]. Thus, the economic agent shows financial statements to present to potential investors which were subjected to techniques meant to generate not only a favourable image on the market, but also *the illusion of results which seem more attractive than they actually are.*

Another definition which is more precise reads as follows: “creative accounting is the procedure that allows management to take advantage of the irregularities in accounting norms so as to present a distorted image of financial performance. *It observes the letter, but not the spirit of the law*” [8]. If we take this assertion into consideration, we claim that the ethics of accounting professionals is the only one compelling the respect of the law.

The list of definitions given to the concept of creative accounting is a long one. Last but not least, we mention a definition which we believe to be the most complex one. It belongs to K. Naser [9] who asserts that creative accounting is:

- *the process that, due to the existence of breaches in rules, manipulates accounting figures and, taking advantage of flexibility, measurement and disclosure practices that allow the turning of synthesis documents from what they are into what managers want them to be;*
- *the process through which transactions are structured so as to allow the „manufacturing” of the desired accounting product”.*

3. Creative accounting and the risk of disloyal information

Researchers’ definitions and opinions in the field mostly reflect the negative connotations and implications that practice attributes to the concept of creative accounting.

We may say that it *encompasses techniques which contravene business ethics, often found at the limit of the law, but which do not cross the barrier between licit and*

illicit, or we simply cannot establish whether they crossed it or not and which can be qualified as crimes and risk the intervention of the Courts of Law. By analyzing this definition, we understand that it is difficult to distinguish between a merely “creative” and non-criminal practice and a “normal” one.

Lainez and Callo claim that creative accounting is the use of possibilities – the existence of options, freedom of professional reasoning, subjectivity and gaps in norms provided by accounting legislation to present financial statements able to reflect *an intended image of reality, and not an objective one* [10].

As a journalist, Griffiths noticed that most economic agents hide their profits. He asserts that financial statements are drafted based on “embellished” records, the figures resulting having been modified. He renders creative accounting as legal fraud [11].

Most part of the specialty works present the negative significance of creative accounting and its usefulness in misleading external users of synthesis documents. This is because the creativity of the accounting professional was and is still used for more or less illicit purposes. Most often it serves the interests of the company or manipulates various categories of users. Therefore the notion of creative accounting is associated with the increased risk of disloyal information.

The negative side of creative accounting which pertains to the risk of incorrect information, manipulation and misleading of users is one of the main motivations for which decisional factors more and more often require professional services of financial auditing meant to check and certify the quality of process of production and dissemination of financial-accounting information. Audit is the easiest solution for decision-makers in economy to eliminate a great part of the informational risks they are subjected to and ensure the chances of success for the decisions taken.

4. Creative accounting, solution to ensure the fidelity of financial-accounting information

Creativity, according to the Romanian Explanatory Dictionary, has a positive connotation and involves the development of

positive skills for innovation or change. Accountants, in the accomplishment of their mission, respect strict rules and record figures but, at the same time, *the diversity of norms, regulations, treatments and existing accounting policies gives the possibility of a legal and favourable exploitation of the flexibility provided by accounting* [12].

Although second in line, *accounting creativity is shown in the provision of accounting solutions in relation to a certain management situation which is not stipulated by the norms.* In fact, this is the direction pointed by accounting provisions which give freedom and recommend professional reasoning when provisions are insufficient or absent.

Professional reasoning is one of the ways to exert accounting creativity both negatively and positively. It is consecrated by *accounting norms which require that when their application is not enough for a faithful reflection of reality, derogation from them should be made.* Although professional judgment should serve the purpose of “the true and fair view”, through the freedom given to the accounting professional, room for creativity is left with the particular amount of subjectivity involved and the implied risks.

Still related to the positive connotations of creative accounting, we consider that *exploiting the legal flaws without detouring from the law in the context of serious economic difficulties, in view of ensuring the principle to continue activity, is creative.* Only when laws are broken intentionally, we can speak of inequality and fraud.

Considering the term as such, *creative accounting is not a crime as long as it is kept within legislative boundaries, irrespective of its flaws being exploited.* Once the border of legality is crossed, the area of crimes is reached and we are no longer speaking of creativity, but of fraud.

However, the positive connotations of creativity are lost. In most situations involving creative accounting, the valences vary from minor manipulations within the limits of the law, to crime and fraud. Moreover, negative advertising related to the accountants’ role is associated to financial scandals and fraud, as shown in the case of financial scandals. This fact cannot be contested, having in view that accounting

professionals drafted the annual financial statements and validated them through audit.

Conclusions

Generally speaking, accounting regulations are a subject for interpretation, and company managers tend to make a profit from this aspect. Legal flaws, accounting options, norms ambiguity lay the foundation for the display of creativity in accounting professionals.

Accounting creativity can be applied in several ways which are more or less accepted by the law. It can have a well intended accounting support – the observance of accounting rules and the assurance of economic fidelity shown in accounting records, but most often it overcomes the border of correctness, taking the shape of disloyal accounting.

The concept of creative accounting is usually employed to describe the process that allows accounting professionals to contribute their experience and knowledge for the purpose of manipulating the figures included in annual financial statements.

Only in a secondary plan does creativity support the development of regulations, yet this acceptance is nowadays outdated.

While the concept of social responsibility is developing more and more, and society seeks responsible directions for sustainable business practices, the accounting profession became guilty of deprioritizing public interest. In spite of social order, the increase in importance of synthesis documents, the intensification of the activity carried out by normalizing bodies, accounting information manages only in part to meet its objective of rendering an image as real as possible of the profit and business of an entity.

In most cases, creative accounting practices support personal interests, and not the aim of a true and fair view. Taking this aspect into consideration, and recalling the essence of the term of “creativity” which is a positive one, “intention accounting” “disloyal accounting” or an equivalent term to design these embellishment techniques could be more proper.

Even if creative accounting techniques are most often a speculation of the lack, ambiguity and flexibility of norms, they are also the solution for adapting accounting

practices to the peculiarities of the company and the evolution of its activity. In many cases, it can represent, along with professional reasoning, a way to reflect the substance of economic events and observance of the accounting principle of faithful representation. When serving the aforementioned objective, professional freedom contributes to the assurance of accounting information fidelity. Contrarily, it becomes a considerable source of informational risks undergone by users.

Initial Recognition of Tangible Assets

Nistor Ion

Valahia University of Targoviste
smaranda_gabrielescu@yahoo.com

Abstract

Using in an appropriate way the professional judgment for the correct application of recognition criteria is a compulsory requirement for the entity. The professional judgment in delimitation and recovery the value of the assets individual or on groups has an important role for the entity because the wrong classification of the assets may have future implications on how to recover their value.

Key words: recognition, credibility, judgment, cost, tangible assets

J.E.L. Classification: M41

1. Introduction

The real assets of an economic entity is the "engine" of that entity and for the attention which the administration and management exercise in managing and capitalizing them, it was more need of their recognizing and of a correct information about the way in which they are recognized in the financial statements.

Recognition the assets is highlighted by the specific conceptual approach of the general framework. The recognition criteria are different from the ones that are specific for the patrimonial approach. Thus, the General Framework provides criteria – recognizing pairs that represent the result from the tandem: utility (get / reduce future benefits) and money quantification (cost or value determined reliably). If an item of a tangible asset is important and relevant, but these two conditions are not met for its recognition it should still presented in the explanatory notes [2].

The U.S. rules state that the recognition process includes both initial recognition and also subsequent amendments, including the elimination from the financial statements that

respectively item (the derecognition process) and any decision on recognition must meet some basic criteria.

An item of tangible asset which is recognized as an asset must be measured initially at its cost. For tangible asset recognition it is applied the general rule that assets which generate future economic benefits and that are held for more than one year are valued at cost of acquisition or production cost [4].

In order to determine whether an item satisfies the first criterion for recognition, an enterprise should determine the degree of certainty of future economic benefits flow based on the evidence available at the time of initial recognition. The existence of sufficient certainty that future economic benefits will be generate toward the entity requires to receive benefits related to the asset and bear risks. This insurance is usually available only when the entity has assumed risks and rewards of the asset, before this situation to occur, the transaction to acquire the asset can usually be canceled without significant penalty, so as in this case the asset is not recognized [1].

The second criterion for recognition is usually satisfied because through the exchange transaction which highlighted the purchase of the asset identifies with its cost. The initial recognition of a tangible asset is conditioned by a reliable assessment of the cost.

The first condition for recognition is satisfied only if the entity proves that can get future economic benefits attachable to the asset, directly or indirectly, and that it takes risks, too. The future economic benefit is the potential to contribute, directly or indirectly, to the cash flow of cash or equivalents to the entity. The potential may be a productive one as part of the operating activities of the entity.

Contribution of the assets to the cash flow is explained by the fact that the entity uses to

produce goods or provide services to customers, who are willing to pay, cash or equivalents in order to get them. Also, the assets can contribute to cash flow through their ability of reducing cash outflows by minimizing costs (eg a new technology) [3].

As regards the condition of credibility, it usually doesn't raise particular problems, as if the acquisition of tangible assets, credibility is proved by documentary evidence of purchase, and in case of assets production, cost credibility is performed on transactions concluded by entity with third parties for supplies and consumption of raw materials, staff and the use of hired labor and ensuring these factors, that by using generate costs.

As follows the reality frequently encountered in practice, namely that the structure of a tangible asset may cover tangible assets with different life, each of these must be registered by a separate manner, in accordance with the recognition principle, the cost comprises both the purchase price and the costs attributable to start-up [5].

A component of a tangible asset, whose life is shorter than the fixed combination which is part of and which will be replaced before the retirement of all, is identified and recognized as a separate component and amortized over its specific lifetime. At the end of their useful life it is recognized and replaced with a new component, the latter being recognized itself as a separate component of all fixed.

It's the case, for example of a building equipped with heating that must be recognized as a tangible asset that depreciates separately, since its lifetime is much smaller than that of the building.

Another significant example is the cost of future inspections and maintenance that are listed separately in the asset structure, as a discrete component. Since the recognition of expense for maintenance, inspection um Y for x years of life is achieved at the end of x years when the next inspection occurs, the origin of Y component um is recognized, and that bill that includes new inspection expense will be capitalized and amortized over the life.

Also important spare parts and safety equipment are considered tangible assets when the entity expects to use them over

more than one year, although usually they are recognized as inventory and carried at cost, during using them. Similarly, spare parts and safety equipments are recognized as assets when they are necessary for the operation of a tangible asset.

Daily maintenance costs of an item of tangible asset are expenses of the period, which is represented by the costs of labor and consumables, their purpose, is to repair and maintain the item of tangible asset.

In Romanian accounting regulations, tangible assets that are used in lots or sets or make a single body, lot or set are recognized at the value of the entire group, body or set only if they have the same useful life [4].

However, if the useful life of the components that enter into a tangible asset structure differs from the resulted asset then each component is recognized separately.

Using in an appropriate way the professional judgment for the correct application of recognition criteria is a compulsory requirement for the entity. The professional judgment in delimitation and recovery the value of the assets individual or on groups has an important role for the entity because the wrong classification of the assets may have future implications on how to recover their value.

According to IAS 16 Tangible assets, there are not included in the accounting treatment of tangible assets, the tangible assets classified as held for sale, biological assets, operating and evaluation assets concessions and mineral reserves. Provisions of IAS 16 "Tangible" are applied instead for the development or maintenance of tangible assets listed above, except for tangible assets classified as held for sale, their rule making it applicable provisions of IFRS 5 "Non-current Assets Held for Sale and discontinued Operations".

In accordance with IFRS 5 "Non-current Assets Held for Sale and Discontinued Operations", an entity shall classify a tangible asset (or disposal group) as held for sale if its carrying amount will be recovered principally through a sale transaction rather than through continuing use. According to the principle of entity assets not classified as an asset held for sale assets (or disposal group) to be scrapped.

This follows from the fact that its carrying amount will be recovered principally through

continuing use. For an entity to classify a non-current asset (or disposal group) as held for sale must meet the following criteria:

- management (or a senior person in the company who can approve action) establish a sales plan;
- asset (or disposal group) is available for immediate sale in its present condition only under terms that are usual and ordinary in the sale of such assets (or disposal group); initiated a program to identify the buyer and all other actions necessary to implement the plan to sell the asset (disposal group's);
- sale is highly probable and qualify for recognition as a complete sale, within one year from the date of classification as held for sale assets (with some exceptions, listed in Annex B of the standard);
- asset (or disposal group to) be traded at a price that is reasonable in relation to its current fair value;
- necessary to achieve the plan indicate that it is unlikely that significant changes to the plan and that that plan will be withdrawn.

Are possible situations that are due to events or circumstances beyond the control of the entity, which may be extended for one year of completing the sale of assets held for sale. Thus, the standard IFRS 5 "Non-current Assets Held for Sale and Discontinued Operations", set out in Annex B situations where an asset will continue to be classified as held for sale by prolonging the period necessary for the sale [2]:

- the date the entity commits to a plan to sell a non-current asset (or disposal group), it is expected that third parties, but no buyer, impose certain conditions on the transfer of the asset (or disposal group) that will lead to the extension of the sale;
- Actions necessary to meet these conditions cannot be initiated until we obtain a firm commitment to purchase;
- Purchase commitment has a high probability within a year.
- Entity obtains a firm purchase and the buyer or third party shall (will) impose conditions on the transfer of asset (or disposal group) previously

classified as held for sale, which conditions will extend the period for completion of the sale;

- have taken timely action to meet these conditions;
- Expect a favorable resolution of the delaying factors.
- During the initial period a year previously considered unlikely circumstances arise and consequently asset (or disposal group) previously classified held for sale is not sold by the end of the period, and: Within one year of the initial entity has taken measures necessary to the changes in circumstances; Current asset (or disposal group) is actively promoted on the market at a reasonable price, given the changed circumstances, and
- Above criteria are met.

In accordance with standard IAS 40 "Investment Property" accounting treatment of land and buildings is different depending on the destination. These properties differ real estate or real estate investments are in properties occupied property [2].

Investment property is property (land or a building - was a part of a building - or both) held rather to earn rentals or for capital appreciation or both, rather than for: to be used for the production or supply of goods or services or for administrative purposes, or to be sold in the ordinary course of business.

Property occupied property is property held for use in the production or supply of goods or services or for administrative purposes.

In principle, an investment property is held to obtain rental income as independent from other assets held by the entity or to increase the capital or both. Only those real estate investment properties as owner used to be covered by standard IAS 16 Property, Plant.

Investment property is sometimes called passive investment, to differentiate it from actively managed property, for property, plant, whose use is integrated into the rest of the entity's operations.

An appropriate method for understanding the definition of investment property is offered these examples of IAS 40 Investment Property in paragraph 8. According to the

standard, the following examples are real estate investment [2]:

- owned land rather for capital appreciation in the long term to short sale, in the ordinary course of business;
- land held for a currently undetermined future use;
- building owned by the entity (or held under a finance lease) and leased out under one or more operating leases;
- vacant building held to earn rentals under one or more operating leases;
- property that is being constructed or developed for future use as investment property.

A suitable method for understanding the definition of investment property is offered these examples of IAS 40 Investment Property in paragraph 8. According to the standard, the following examples are real estate investment [2]:

- owned land rather for capital appreciation in the long term to short sale, in the ordinary course of business;
- land held for a currently undetermined future use;
- building owned by the entity (or held under a finance lease) and leased out under one or more operating leases;
- vacant building held to earn rentals under one or more operating leases;
- property that is being constructed or developed for future use as investment property.

2. Conclusion

Romanian accounting regulations do not deal differently tangible assets classified as investment property and assets held for sale. They are recognized in the category of land or construction or real estate investments are treated as part of inventories, if fixed assets held for sale.

To identify what constitutes an individual item within tangible assets requires the application of reasoning for applying the criteria to define the circumstances or different types of entities

Can be grouped insignificant individual items, such as molds, tools and dies, and then apply those criteria to the total value of these items. Spare parts and equipment, interest

may be considered to tangible when the entity expects to use them for several periods.

Similarly, if the spare parts and servicing equipment can be used only in connection with an asset and their use is expected to be irregular, they are accounted for as tangible assets and are amortized over a period not exceeding useful life of that asset.

Separate parts and servicing equipment are usually recorded as inventory and recognized in profit or loss as consumed..

However, separate and permanent equipment are considered tangible assets when an entity expects to use more than one period. Similarly, if the separate parts and servicing equipment can be used only in connection with an item of property, they are accounted for as tangible assets.

Abstract

To illustrate the social prestige or the degree of “science” that operates a profession or a scientific discipline begins with its history. Therefore, an incursion of accounting history helps us to better understand its actual statute, both as scientific knowledge and as social practice.

Accounting history, like the history of any other science, aims research, document-based, of origins and development stages, from the first accounting notes till accounts today.

Key words: accounting, history, development, institutionalization

J.E.L. Classification: M41

1. Introduction

Professor Dr. B. Pendorf, in his paper *Geschichte der Buchhaltung im Deutschland*, writes the follows: “Who want to become master in an art, must study its history”, and he further stated: “without history basement all possibilities remain with no result and the appreciation of present phenomenon uncertainly and with lack of maturity”.

The beginnings of accounting faced with the first economic activities of human. As man become an economic creature (*homo oeconomicus*), appeared also the need to measure and record its economic activity on individual or community. The necessity of accounting was present both on a corporate with power holders (princes, priests, kings, etc.) and those who practiced trade changes, to measure, memorize, communicate and authenticate different economic “acts” or, generally, social reports. Methods of

measurement and accounting record were very different like the material support where were made, and they started with bone and stone inlay, with notes on burned clay or papyrus tablets and then keeping paper books until the contemporary era, characterized by dematerialization of accounting records, by using electronic handling of information [1].

2. Historical landmarks in the evolution of general accounting

Accounting evolution, as social practice, is related to human becoming economic creature. The origins of accounting go back with thousands of years when people were “something” of their reality, through bone inlay or even writes on clay or papyrus tablets. Although there are opinions according to which are accounts from the period when people know about numbers, all these events are only forms of rudimentary accounting [5].

As a result of archeologically discoveries, we can support today the existence of some primitive elements of accounting from thousands of years before our era, such as the 55 numbering traces of slots, divided in two series in a radius of wolf. This is probably the oldest numbering car: each animal killed was a notch in the bone. Counting was also made by vertical grooves on the walls of prehistoric caves using pebbles. Greeks and Persians used them to count strings.

Over times, clay objects took the place of stones. In Mesopotamia, Sumerians used rectangular clay tablets where inlaid drawings and drying turned into genuine documents [2]. Signs used like this slowly gave birth to cuneiform and hieroglyphic writing so that the first accounting systems have linked the fate of the writing in general.

In antiquity, the first author of accounting is considered Hammurabi (2002 - 1960 BC) the king of Babylon, who ordered engraving on a block of diorite of the oldest commercial and social law code known, which imposes a legal obligation recording certain transactions in the form of calculations.

The first accounting centers in ancient Greece were temples, under their protection was carried out all public and private life. Here took place exchange, here appeared the first deposits bank comprising all the elements of modern financial techniques. First bankers kept a logbook or "ephemeris" where they detailed the daily operations writing the revenue and the expenditure chronologically, one under the others, allowing operations of addition and subtraction [6]. Registers were probative value.

To the Romans accounting books were known as calendar. Roman bankers, precise and meticulous perfected the accounting technique by opening accounts for others. Separating the receipts from payments is due to them by using two columns in the cash book called *acceptum* (credit) and *expensum* (debit). In Rome the obligation to keep records was for the head of the family. This requirement generally moral, may become legal in certain circumstances. Cicerone (106-43 BC) is the one who specifies regarding the accounting registers on Romans. The main accounting document was a journal of income and expenses (*Codex accepti et expensi*). The registry that keeps the track of all transactions, without spaces or erasures, a sort of Big Book today, was *Codex rationum* [9].

In its today understanding, accounting started its history from Middle Aged, with the development of monetary economy and appearance of germs capitalism. The Renaissance Spirit and especially development of business in big cities of Northern Italy (Florence, Venice and Geneva) have made possible the continuing "refine" of accounting practices, so in the fifteenth century is used accounting "after Venetian method".

In Middle Aged, is a discontinuity in the evolution of roman civilization so there took place a stagnation of accounting, probably generated also by restricting trade area and feudal development of economy.

In this era accounting registers are named: "memorials" and they record assets and liabilities chronologically. These documents were kept, especially by the monks from abbeys [4].

During the Crusades took place a development of accounting and forming international economic and financial powers as military-religious orders (as that of Templar). These kept a strict evidence of revenues, expenditures and clients, transforming the monasteries into fortress where they kept safe values. Records were kept a real account that had in debit the amounts owned by customers, in credit the payments made by him, the balance representing the debt.

The memorial has evolved into simply entry accounting with the diversification of production and services units, and also with the increasing of transaction complexity. Thus, appear accounts as coherent assemblies that are attached to a type of operation or exploring entity. These accounts are kept at the beginning on a single column then evolve into a Venetian appearance (two adjacent columns) [6].

Economic necessities determine the appearance of some private accounts such as the account "Capital" (used by companies for their partners) or the account "Profit and loss" that keeps the evidence of business result.

The end of Middle Aged, characterized by development of commercial links, extension of credit, making operations in distant towns and manipulation of increasingly important capitals, determine the adaptation and improvement of accounting in order to face with the new requires [4].

From the end of the thirteenth century the record is kept in one account for the customer and another for the supplier. Each operation determines two records: one in the customers or supplier account and one in the home account. This requires keeping different registers.

Thus appear the accounting in double entry, long before first treaty of accounting that presents it. This is thanks to a Franciscan monk, Luca Paciolo, who published in 1494 in Venice an encyclopedia named "*Summa di arithmetica, geometrica, proportioni et proportionnalitá*" that includes thirty six capitols regarding recording accounts.

Paciolo refers to three registers: memorial, journal and big register. He demonstrates the technique of double entry and consistency of equality between debit and credit amounts. In his accounting literature work *Tractatus de computis et scriptis*, that is the Treaty of double-entry accounting, is presented for the first time the describe of double-entry, the most characteristic element of accounting, in the technical report. We owe to Luca Paciolo the promotion and popularization of double-entry accounting, that didn't suffer major changes until today [10].

Generating double-entry accounting in European countries is accelerating with the discovery of printing (XV century). Gradually, between XVI-XVII centuries, the new method of accounting- double-entry accounting, starts to have generally applicability, especially in Western Europe and emerging and accounting literature.

The current appearance of accounting is due to France where in 1673, by order of Colbert, traders are obliged to keep accounting registers and the journal receives the legal evidential quality. Thus, accounting becomes a control instrument of the state such as it is in the present, by its fiscal role.

The development of accounting to provide date (determining patrimonial results and situation), is linked to the appearance of anonymous societies and legislation regarding these (middle XIX century in Germany and 1867 in France) [9].

The way of analytical accounting that will be named management accounting is open by the development of modern industry from the second half of XIX century, with the necessity to know the products' costs.

Multiplication of joint stock companies, which separates the management of companies by their owners, industrial revolution and appearance of competition, with the second half of XIX century, will do to outline the content of management accounting, to the managers and that is undisclosed, which delimits from general accounting and produces the balance sheet and profit and loss account, for the shareholders [8].

With the first decades of XX century, business accounting becomes a nominated social practice. Nominated processes of accounting, at national level, but regional or global too, have brought a new grade to the

accounting language: this becomes also a nominated language, which is standardized. So, the existence of a standardized accounting language ensures some advantages: allows a greater transparency on organization's activity, facilitates the dialogue between actors who operate on accounting data market, facilitates the decisional and control process [5].

The current technical progresses concretized in omnipotence and omnipresence of computer change the accounting work and determine new theoretical discussions about methodology and principles of accounting.

3. Conclusion

From studying accounting in different levels of human society development, it appears that in slavery ordination existed accounting notes, presented as primitive form, especially in old nations with advanced civilization and economy (Babylonians, Egyptians, etc.).

Following the evolution of feudal ordination of accounting, it appears that in this ordination begin to systematize these notes, to outline a more advanced accounting technique as a result of improving the procedures taken from slavery ordination and introducing others, even trying to elaborate some accounting theories. In many Italian cities were used, since XII century, simple-entry accounting, and in others, even double-entry accounting.

Towards the end of feudal ordination and early capitalism that needed a better performed accounting, appeared an advanced accounting technique. By generalization of companies' practice experience, appeared a theory regarding base problems of accounting as science.

In XIX century will appear the first major attempts to normalize accounting. From one country to another, this “institutionalization” of accounting will be made in different rhythms and ways.

In conclusion, we can say that doctrinal and practice development of accounting is closely related with cultural environment where it evolves, seen in all its components: economic, social, judicial, fiscal, politic and even religious.

From entire accounting past, it appears that in all social ordination was felling the need of using accounting with the help of which they could organize, analyze and interpret the phenomenon linked to business activity of human society.

Therefore, a number of philosophers and economists, familiar with principles and role of accounting, concluded that this discipline is one of the most sublime discoveries of the human spirit and each householder must use it, as a mirror of past and guide of future.

An Approach for Convergence Regarding the Fair Value Concept versus Fair Market Value

Oncioiu Ionica

Abstract

The goal of a methodical business valuation process is to arrive at a clear and supportable estimate of “fair market value”. On the other hand, determining the “fair market value” of a business is important not only when the owner is putting up a “for sale” sign; it also can affect long-range planning. In the same time, the challenge in recent decades is related to the identification of methods and indicators able to measure the effects that fair value accounting and fair market value produce in the new economy. Because fair value is a very similar concept to fair market value occurred over time many divergences related to the use of these concepts. The present paper aims to capture the efforts made so far to assess and clarify need for convergence of these two revolutionary concepts in the context of new economy.

Keywords: fair value, convergence, market

J.E.L. classification: M41

1. Introduction

An examination of the definition of fair value also helps clarify whether or not other amounts used in IFRS financial statements are fair values. For example, as most (but not all) business transactions are arm’s length transactions between knowledgeable willing parties, most historical costs approximate fair values at the transaction date. At subsequent dates, historical cost and historical cost-based amounts are not fair values (other than by coincidence). Therefore, cost less depreciation, cost less amortization and amortized cost, as well as amounts determined using the equity method or

proportionate consolidation and the net book value of an entity, are not fair values and are often significantly different from fair values.

Fair market value generally means the highest price, expressed in dollars, that a property would bring in an open and unrestricted market between a willing buyer and a willing seller who are knowledgeable, informed, and prudent, and who are acting independently of each other. Market value is also distinct from fair value in that fair value depends on the parties involved, while market value does not. For example, IVS currently notes fair value “requires the assessment of the price that is fair between two specific parties taking into account the respective advantages or disadvantages that each will gain from the transaction. Although market value may meet these criteria, this is not necessarily always the case”[1]. Fair value is frequently used when undertaking due diligence in corporate transactions, where particular synergies between the two parties may mean that the price that is fair between them is higher than the price that might be obtainable in the wider market. In other words “special value” may be generated market value requires this element of “special value” to be disregarded, but it forms part of the assessment of fair value [2].

The goal of fair value accounting is to estimate as best as possible the prices at which positions held would change hands in orderly transactions based on current information and conditions.

The contemporary accounting phenomenon has features based on the need or harmonization, convergence, compatibility and unity in book-keeping, seen also as general objectives of this field, which could be realized only by its normalization. The accounting convergence regarding the concept of fair value is the process of

elaboration of accounting norms in a manner able to lead to a similar fact or goal, by stressing the similarity between national – regional – international levels.

The convergence regarding fair value is realized on two plans [3].:

(1) the convergence between the national and international standards;

(2) international convergence IAS/IFRS – US GAAP

The competition between the American reference and the international one results in the improvement of the accounting norms, namely that they become more and more comparable, compatible but also more and more convergent.

A first dimension of convergence in accounting it is represented by the convergence between the USA ACCOUNTING STANDARDS (USGAAP) an INTERANTIONAL STANDARDS OF ACCOUNTING (IAS/IFRS). Even if there were major differences between the two accounting referential regarding this concept, IASB and FASB agreed to identify all the points of disagreement in order to insure in a reasonable period the necessary convergence.

A second reason leading to the convergence of accounting systems are the desire for unity among conditions of competition in various countries. A synthesis of phenomena and aspects which could be considered as causes leading to the need for international accounting harmonization /convergence regarding fair value includes[4]:

(1) the economies encountering an accelerated process of globalization;

(2) the requests from financial accounts users (a factor determined from the first one). Thus, we shall aim towards a unity of economic language and accounting as an instrument of communicating information;

(3) the extension process of the European Union;

(4) the phenomenon of capital markets globalization.

In this context, the national and international intercessions have as a target realizing a convergence between national and international norms for a unique value (fair value). The appliance of this concept impose the outlining of it’s utility, the knowledge of attaining techniques, assures much better than the historical cost the qualitative

accountancy information and gives a plus to the user’s certainty, because these one will be able to avoid the negative aspects, referring to the interest-evaluations and reliability of a patrimonial entity.

With the FASB having decided, in Statement of Financial Accounting Standards 157 Fair Value Measurement, that fair value is an exit price notion; the IASB is left to decide whether or not it agrees. Preliminary indications are that while the IASB may largely agree with the FASB’s articulation of exit price, it may also see the need to articulate an entry price notion, because of the perceived use of that notion under the banner of fair value in some IASB standards. More specifically, some may make the case for the use of entry price on initial recognition of an asset or liability with a switch to exit price for subsequent measurement [5].

The fair value option is a step in the direction of making US GAAP more harmonized with international GAAP, but it is a very small step. The main point in this module is that fair value adjustment of all financial and non-financial items on the balance sheet will not necessarily bring the balance sheet significantly closer to the fair value of the firm as a whole. The problem is that the value of the firm is most likely highly impacted by unbooked items that are not on the balance sheet and cannot be adjusted for fair value. Debate should therefore center on the measurement attribute to be used in assessing an asset’s recoverability; fair value, or the higher of value in use and fair value less costs to sell.

2. Fair Value Concept and Fair Market Value: antagonistic relationship

The analytical and empirical research methods and techniques used in this paper. The majority of the data were extracted from two sources: International Accounting Standard Board (IASB) and IASC.

Before considering further the use of fair values in IFRS versus fair market value, some clarification of its meaning may be useful [6]. The first point to recognize is that, as with some national standards. IFRS use the term ‘fair value’ as a generic term that may be applied to all assets, liabilities and equity instruments irrespective of whether

they are quoted or traded on active markets. In other words, IFRS use market value as a subset of fair value - it is fair value as determined in an active market. This approach allows for the fact that fair value must be determined in some circumstances in which the asset, liability or equity instrument is not traded in an active market. This is the case when, for example, tangible or intangible assets are exchanged or unquoted equity or debt securities are used as the purchase consideration in a business combination.

Edwards and Bell (1961) [5] invite us to consider a semi-finished asset to enumerate the various dimensions through which we can describe the asset, and thus to calculate and define all the possible permutations arising from this multidimensional consideration.

Three dimensions are suggested:

1. the form (and place) of the thing being valued;
2. the date of price used in valuation;
3. the market from which the price is obtained.

They choose a subset of the alternatives in Table 1. for their own detailed theoretical development and appraisal.

Table 1. An array of value concepts

<i>Value date, market</i>	<i>Initial inputs</i>	<i>Present form</i>	<i>Ultimate form-disposal</i>	<i>Ultimate form-use</i>
Past, entry	Historical costs	Discarded alternatives	Irrelevant	Irrelevant
Past, exit	Discarded alternatives	Discarded alternatives	Irrelevant	Irrelevant
Current, entry Current, exit	Current costs Irrelevant	Present costs Opportunity	Irrelevant Current market values	Irrelevant Current economic values
Future, entry	Possible replacement costs	Possible replacement costs	Irrelevant	Irrelevant

Source: Edwards and Bell (1961) [5]; last column author

In the absence of quoted prices in active markets, the IASB requires the use, when possible, of market information and favors widely used and accepted valuation techniques. Therefore, for assets, liabilities or equity instruments that are not traded in active markets or for which current quotes from such markets are unavailable, the entity must estimate fair value using market information (e.g. market rates of interest when determining the fair value of a debt

instrument). This reflects the fact that any rational, knowledgeable and willing party would take into account market information when exchanging such an asset or equity instrument or, in settling such a liability, the estimate of fair value takes into account market prices. This principle is reflected in IFRS 2, IFRS 3, IFRS 7, IAS 16, IAS 39, IAS 40 and IAS 41. Since the advent of the IASB in 2000, the onward march of the fair value concept has continued apace[7]. The concept is included in the definitions section of IFRS 2, IFRS 3, IFRS 4 and IFRS 5. IFRS 7 cross - references the reader to the IAS 39 definition, and IFRS 6 allows the use of the revaluation model in IAS 16[8]. The new single statement of financial performance towards which IASB, FASB and others are working is clearly designed to facilitate reporting under a fair value world. It is not yet officially in the public domain, even in draft, but see Barker (2004) [9]. Notwithstanding these anticipated developments, the emanation of the fair value concept seems to have occurred more or less spontaneously, and certainly more or less haphazardly, over the past couple of decades, with no clear theoretical foundations (Warrell, 2002) [10].

The IASB is also unlikely to change this principle but it is likely to issue further guidance on its application.

For assets, liabilities or equity instruments that are not traded in active markets and for which market information is not available, the estimation of fair value is likely to be difficult and, possibly, unreliable. IFRS allow greater flexibility for the use of less reliable fair values for the initial measurement of an asset or liability or when accounting for compound transaction (otherwise the asset, liability or transaction or its components would be excluded from the financial statements). They also still require the use of fair value in impairment testing (otherwise the carrying amount of the asset might be overstated).

Fair value less costs to sell (IAS 36 and IFRS 5) and fair value less point-of-sale costs (IAS 41) are, by definition, based on fair value but are lower than fair value. Net realizable value (IAS 2) probably approximates the fair value of inventories held for resale but exceeds the fair value of work in progress and raw materials as it does

not allow for any profits on the completion of inventories.

When fair values are used for the subsequent measurement of assets and liabilities, it is less clear whether they should be entry prices or exit prices. The IASB appears to be moving towards the use of exit prices (see, for example, the requirement in IAS 39 to use bid prices for financial assets and the proposals in IASB (2007)), which could result in the recognition of a loss for the difference between entry price and exit price on the initial recognition of an asset.

It is not surprising that there appears to be some consistency between the recent IASB statements discussed above and recent FASB comments. On 23 June 2004, FASB issued an Exposure Draft of a proposed Statement, ‘Fair Value Measurements’ [5]. This proposes a definition of fair value as ‘the price at which an asset or liability could be exchanged in a current transaction between knowledgeable, unrelated willing parties’, which definition seems at pains to preserve semantic differences between FASB and IASB, rather than to seek convergence.

Fair value accounting – also referred to as “mark-to-market” accounting – has played an important role in U.S. generally accepted accounting principles (GAAP) for more than 50 years[1].

Beginning in 1979, SFAS 33 required large corporations to provide a supplementary schedule of condensed balance sheets and income statements comparing annual outcomes under three valuation bases: Unadjusted historical cost, Price-level adjusted (PLA) historical cost, and Current cost entry value (adjusted for depreciation and amortization). Companies complained heavily that user did not obtain value that justified the cost of implementing SFAS 33. Analysts complained that the FASB allowed such crude estimates that the SFAS 33 schedules were virtually useless, especially the current cost estimates. The FASB rescinded SFAS 33 when it issued SFAS 89 in 1986.

In 1993, FASB expanded the fair value recognition requirements by issuing a standard that required debt and equity securities that were held for trading or held for sale to be carried at fair value in the balance sheet and required changes in fair value to be recognized in the income

statement or in a category of equity referred to as other comprehensive income. This was augmented in 1998, when FASB standards were adopted that required derivatives to be measured at fair value.

At the joint meeting of the IASB and the FASB in October 2005, the boards established explicit long-term objectives for improving financial reporting for financial instruments, to help the boards evaluate and prioritize future projects on financial instruments. In addition, the boards agreed to work towards those long-term objectives while retaining the ability to work either jointly or separately (if necessary) on shorter term objectives that are consistent with the long-term objectives.

The IASB has subsequently issued a discussion paper Measurement Bases for Financial Accounting — Measurement on Initial Recognition which proposes that all assets and liabilities should be measured on initial recognition at their fair values even when these amounts differ from cost. Remarkably, the discussion paper does not justify this change other than by arguing that fair value is more relevant than historical cost. While that claim may be true and may lead to subsequent measurement at fair value, it does not justify recording, say, the acquisition of an asset on acquisition date at an amount different from what was paid for it.

As explained earlier’ the new approach gives rise to day gains and losses when the fair value of an asset or liability differs from the fair value of the consideration given or assumed. It also places an immense burden of financial statements that will have to determine the fair value of every transaction in order to consider whether it should be recorded at fair value instead of cost. The approach is absurd in those cases in which an entity is required or allowed to measure the assets or liabilities at subsequent balance sheet dates at historical cost or historical cost-based amounts.

In 2006, FASB issued a new standard, FAS No. 157, Fair Value Measurements, which provided a single, consistent definition of fair value, established a common framework for developing fair value estimates, and required expanded disclosures about those estimates. FAS 157 establishes a hierarchy of valuation techniques that varies

based on the availability of observable market information[5]:

- Level 1 inputs are “observable market data” – such as the quoted price for an identical stock or bond in an active market;

- Level 2 inputs are “other observable market data” – such as quoted prices for similar assets or liabilities in active markets; quoted prices for identical or similar assets or liabilities in inactive markets; interest rate, yield curve and similar data that are observable at commonly quoted intervals; and other data that may be corroborated by market data (mark-to-market measurements); and

- Level 3 inputs are “unobservable firm supplied estimates,” including the reporting entity’s own analysis of the underlying economic data that market participants would factor into the pricing of the asset or liability (mark-to-model valuations).

Some of the advantages of fair value valuations, as mentioned in specialized literature, (Penman S. H., 2007) are as follows[12]:

- investors are interested in value, rather than costs, so that’s why information must be reported using fair value;

- in time, historical cost becomes irrelevant for establishing the company’s financial situation.

Prices provide an updating of the information regarding the value of the assets;

- the accounting system based on fair values reports an economic result;

- the fair value determined based on market prices is not affected by factors that are specific to certain companies.

Convergence regarding fair value does not mean however the failure of accounting harmonization, but an obvious intercession aimed towards using an appropriate communication in a globalizing context, with the goal of having a common reference, International Financial Reporting Statements, while the short term goal of convergence is to eliminate the individual differences between US GAAP and the current IAS IFRS. Within this short term project, FASB analyses various issues and either suggests alterations in the American norms, in order to eliminate the differences found, or it communicates to IASB the reason for which it decided not to alter the provisions of US GAAP, while at the same time IASB is carrying on a process

of revising IFRS, taking, as the case may be, the same measures as FASB.

Regarding fair market value irrespective of whether fair value is an entry price or an exit price, it is worth remembering that the range of possible estimates for the fair value of any asset or liability often significantly outweighs the difference between entry price and exit price. Recently, Mocciaro Li Destri, Picone & Minà (2012) [11] have underscored the subtle but important difference between the firms’ capacity to create value through correct operational choices and valid strategies, on the one hand, and the epiphenomenal manifestation of variations in stockholder value on the financial markets (notably on stock markets). In this perspective, they suggest to implement new methodologies able to bring strategy back into financial performance measures.

On the other hand, IFRS are placing much more emphasis on the use of fair values to record transactions and to allocate the initial amount of transactions among its constituent parts. This process began almost twenty-five years ago and reflects the practice in many national standards. The growth in such requirements also reflects the increasing complexity of many business transactions as well as the IASB’s desire (and that of business entities and their auditors) to ensure that IFRS deal with a large proportion of these transactions. Fair value accounting or fair market value, or some other estimates of value, must be used; otherwise non-cash transactions will be omitted from the financial statements and compound transactions will not be disaggregated. If the use of fair values in such circumstances is new, the previous financial statements lacked relevant information.

It is true to say that IFRS are placing much more emphasis on the use of fair values to record transactions and to allocate the initial amount of transactions among its constituent parts. This process began almost twenty-five years ago and reflects the practice in many national standards. The growth in such requirements also reflects the increasing complexity of many business transactions as well as the IASB’s desire (and that of business entities and their auditors) to ensure that IFRS deal with a large proportion of these transactions. Fair value accounting

or fair market value, or some other estimates of value, must be used; otherwise non-cash transactions will be omitted from the financial statements and compound transactions will not be disaggregated. Furthermore, if it is seen as something new, it brings into question the way entities and their auditors were applying national standards and the apparent emphasis that some have placed in the past (and continue to place) on such notions as prudence. If the use of up-to-date estimates increases the amount of such liabilities, the previous financial statements lacked prudence.

3. Conclusions

One obvious conclusion that may be drawn is that, apart from the replacement of 'buyer'/'seller' by 'parties' and the extension to cover liabilities and equity instruments granted, the definition of fair value in IFRS has remained unchanged for almost twenty-five years. It is therefore surprising that there is some uncertainty about its meaning and some confusion about what amounts are, and what are not, fair values.

Moving from theory to practice, the question perhaps becomes: What would be gained by creating a new fair value standard? Would any of those potential differences be eliminated? This takes us back to the academically traditional debates on the pros and cons of the various theories of income measurement and asset valuation. Many academics, including the present author, have strongly held views on these issues. But since the fair value notion seems not to alter these debates, we leave our views until another occasion.

In essence, therefore, this concept in context of new economy gives a significant push towards current values in general and towards fair value in particular, but also strongly insists that fair value, as such must be genuinely based on *market* expectations, i.e. again, not entity-specific.

In conclusion is strongly supportive of current values and regards fair value as a valid contender for an appropriate current value, but, like EFRAG, is not at all convinced by the apparent determination to avoid entity-specific measurements.

Convergence especially regarding fair

value is not an easy thing! Even the president of FASB declared that the greatest challenge of the convergence process was to persuade the national business communities about the necessity for an international accounting language. Perhaps people don't like change in general, preferring rather to keep their status quo. However, it is absolutely clear that the subprime crisis that gave rise to the credit crunch was primarily caused by firms, investors, and households making bad operating, investing, and financing decisions, managing risks poorly, and in some instances committing fraud, not by accounting.

Opportunities to Improve the Romanian Capital Market by Means of Pension Funds

Abstract

Any state is concerned with the development of its capital market which allows it to attract important investors that can ensure economic growth and resource accessibility at lower costs. In this respect, the use of funds attracted by the private (stakeholder) pension funds can be a solution.

Key words: public pensions, privately managed pensions, capital market

J.E.L. classification: J26, J32

Introduction

Every state is concerned with the development of its best financial system which can allow for the **provision of liquidity needed in practice development with fewer and fewer gaps. In this respect, capital market in its capacity as the device to attract and invest available money** is interesting to all categories of investors, either individuals or businesses, either small or large investors. The economic financial crisis which started in 2008 has shown that capital markets can be the engine of an economy or, on the contrary, can prevent economic growth.

Speaking about the prospects of capital market development nowadays in the context of many and diverse political, social and economic events involves the attempt to find out about the solutions to increase the interest in the market.

It is known that the presence of a capital market provides the economic system where it grows the opportunity to access financing resources more quickly and sometimes at

lower costs and also the chance to invest with the purpose of better outcomes.

In this respect, economic history proves the higher concern for the identification and market presentation of appropriate financial instruments designed to satisfy the most diverse requirements of investors.

The governments of countries where there are capital markets are interested in attracting as many offerors as possible to support market growth.

Whereas private businesses have the ability to access the financial system provided by the capital market by issuing stocks and bonds, the public system represented by central and local governments can intervene by means of bond issuance. As a representative of the demand, a capital market also brings forth mutual funds and pension funds.

It is believed that a solution for increasing the interest in the Romanian capital market performance is supplied by the investment which can be achieved by pension funds.

1. Romania’s pension scheme

Countries all over the world have reformed or are reforming their public pension schemes, suggesting new private saving systems for retirement because of the same reason almost all the time: the pressure upon the public system and the state’s less ability to manage it properly because the population is growing older, the retired live longer, the number of national insurance contributors is decreasing which make public pensions no longer able to ensure the reasonable replacement rate for revenues during active periods.

In this context, the interest in settling this matter is quite old. In 1979 at the World

Bank’s suggestion, Chile promoted the first multi-segment system for the organization of the pension scheme. The system has been followed by the countries in Eastern Europe since the 1990’s.

The first country in Central and Eastern Europe which has reformed its public pension scheme is Hungary. In 1994, it commenced Segment 3 – Optional Stakeholder Schemes and in 1998, Segment 2 – Compulsory Stakeholder Pensions. Poland subsequently followed the example and started to use the multi-segment system in 1999. The detailed description of the time the multi-segment system started to work in the region’s countries is shown in Table no.1.

Table no. 1: Multi-segment system in Central and Eastern Europe

Country	Segment 2	Segment 3
Hungary	1998	1994
Poland	1999	1999
Czech Republic	n.a	1994
Slovenia	2000	2000
Latvia	2001	1998
Bulgaria	2002	1994
Estonia	2002	1998
Croatia	2002	2002
Lithuania	2004	2004
Slovakia	2005	1997
Romania	2007	2007

Source: CSSPP

Romania began the reform of its pension scheme in 2007 by the introduction of Segment 2 and Segment 3. Law 263/2010 regarding the unified superannuation scheme including further amendments and additions sets out in Article 6 the people holding compulsory insurance in the public pension scheme according to the law.

Segment 2 is definitely designed to the people contributing in the public pension scheme and aged up to 35 years old, being optional to those who are between 35 and 45 years of age. The system of privately managed pensions is regulated in Romania by Law no.411/2004. At present, every employee pays social insurance contributions (Ro. CAS) associated with the public pension scheme, being equal to **10.5% of the gross wages** of every contributor.

The contributions in private pension plans are not additional financial obligations to participants, but an amount of the individual

contributions in the public pension scheme. At the moment, the transferred share is **3.5% (2012) and is to reach 6% in 2016.**

Choosing a stakeholder pension means that some of the amount shall be sent to the individual account of every participant in their selected stakeholder pension funds.

Segment 3 is available to everybody as there is no age limit. Therefore, anybody can contribute in the scheme by up to 15% of their monthly gross incomes. In order to benefit from an optional pension, the legislation in the field requires that every participant should have at least 90 monthly (not necessarily consecutive) contributions in the fund, be at least 60 years old and hold a minimum accumulated amount. As far as Segment 3 is concerned, there is one more fiscal element, therefore there is fiscal deductibility of 400 Euros/year to every employee and 400 Euros/year to every employer.

The main features of the pension scheme organization in Romania are shown in Table no.2.

Table no.2: Features of Romania’s pension scheme

Segment	Features
Segment 1	Superannuation scheme
	Based on generations’ solidarity, namely ”you pay and go”.
	Well-defined benefits
Segment 2	Private management
	Compulsory for people up to 35 years of age
	Optional for people aged 35-45
	Clear contributions
Segment 3	Private management
	Clear contributions
	Voluntary participation
	Individual accounts

2. Pension funds and capital markets in Romania

In Romania, pension funds are made up as civil entities whose operations are managed by a management company set up as a joint stock company, with a primary capital of at least 4 million Euros with respect to the fund of privately managed pensions, respectively

1.5 million Euros in terms of the companies managing the funds of optional pensions.

In Romania during October 2012, there were nine pension funds managed privately which ran activities for 5,706,913 participants and their total managed assets amounted to 9,054,273,844 Lei. As to the funds for optional pensions, the number of participants was 285,614 and their managed asset was 571,362,673.

In order to provide fund contributors with pension rates to allow for their decent living, the legislation makes it possible for pension fund managers to invest in various money market and capital market instruments.

Thus, the law sets out an investment structure that can be accomplished by pension funds in order to ensure on one hand the proper outputs of such money placements and on the other hand, the best coverage of hazards the investment in risky financial instruments might face. The Supervising Commission for Stakeholder Pension Funds states that the privately managed pension funds may have the following investment structure (Article 25, Indent 1, Law 411/2004 regarding privately managed pension funds and Article 87, Indent 1, Law 204/2006 regarding optional funds):

- money market instruments including Lei accounts and deposits in a bank, Romanian business, or branch of a foreign credit institution authorized to operate on the Romanian territory, which is not subject to special monitoring or special management, or has valid operating permit, and these instruments should not exceed 20% of the total value of the pension fund assets;
- government securities issued by the Romanian Ministry of Public Finance, issued by European Union member states, or belonging to the European Economic Area, amounting to maximum 70% of the total value of the pension fund assets;
- bonds and other securities issued by the authorities of public local governments in Romania or in European Union member states, or in countries belonging to the European Economic Area, amounting to maximum 30% of the total value of the pension fund assets;
- securities traded on regulated, controlled markets in Romania, in

European Union member states or in countries belonging to the European Economic Area, amounting to maximum 50% of the total value of the pension fund assets;

- government securities and other securities issued by third countries, amounting to maximum 15% of the total value of the pension fund assets;
- bonds and other securities traded on regulated, controlled markets, issued by the authorities of public local governments in third countries, amounting to maximum 10% of the total value of the pension fund assets;
- bonds and other securities of foreign non-governmental bodies, if the instruments are listed on authorized stock exchanges and if they meet rating requirements, of up to 5% of the total value of the pension fund assets;
- equity securities issued by certain bodies undertaking collective investment in transferable securities in Romania or in other countries, amounting to maximum 5% of the total value of the pension fund assets;
- other investment set out in the Commission's norms.

Consequently, the law allows the access of pension funds to the capital market.

The analysis of the investment structure ensuing from pension funds (Table 3) highlights the following:

- orienting the pension funds mainly to government securities – explained by the fact that such instruments yield good outcomes in relation to investment-associated risks;
- more concern for stocks, which are some financial instruments providing better outcomes with corresponding related risks, than the concern for bank deposit investment;
- lower concern for municipal bonds (1.11% in terms of optional pension funds);
- the pension funds have not used the financial instruments provided by other bodies undertaking collective investment (0%)

Table no. 3: Structure of pension fund investment (%)

Investment structure	Segment 2– 5,708,610 participants	Segment 3– 283,118 participants
Bank securities	9.19%	8.06%
Government securities	72.87%	67.12%
Municipal bonds	0.47%	1.11%
Other securities – traded corporate bonds	4.32%	4.84%
Bonds and other securities of foreign non-governmental bodies	0.93%	2.14%
Stocks	10.97%	14.26%
OPCVM equity securities	1.32%	1.24%
Other collective investment bodies	0.00%	0.00%

Source:***CSSPP Newsletter, September 2012

The analysis undertaken allows for the conclusion that the amounts engaged by pension funds may as well enliven the capital market in Romania.

Whereas with respect to pension funds that are managed privately things may be changed only as far as the people aged at least 35 are concerned and the other people have compulsory superannuations, in terms of optional pension funds, things may be different. Therefore, positive effects upon the capital market might be brought about by the awareness of employees who will be retired in the future and thus they can understand what the Romanian public pension scheme and not only will mean within the next 10-20 years and even further on.

Pension funds may be associated with mutual funds if one considers the aspects related to the legal organization (civil entities), to how contributions are collected (by participants' submissions), to the presence of investment structure. The main difference lies in risk degree and risk assumption.

While in mutual funds the degree of risks may be different from the investment structure as the state only lays down investment limits and risks are entirely assumed by investors, in pension funds apart

from investment limitation there is also a reduction of bankruptcy risks, with the Supervising Commission for Stakeholder Pension Funds ensuring the ongoing supervision of the pension scheme.

The Supervising Commission for Stakeholder Pension Funds – the autonomous government authority for prudential regulation and monitoring subject to parliamentary controls, providing the public, transparent, effective control of stakeholder pension scheme management seeks to adopt a norm which will help restrict the investment from private pension funds. In a new formula, some investment that can take place at present might be removed, such as:

- bonds of issuers that do not hold an investment grade;
- securities issued by companies mainly operating in the real estate field;
- equity interests issued by other bodies of collective investment (Ro. AOPC).

In the draft for the amendment of CSSPP norm, “investment grade” is described as a performance indicator granted to a financial instrument issuance, to an issuer, or if necessary, to the issuer’s parent company. Approving the amendment could generate an increase in issuing costs by up to some hundred thousand Euros depending on the issuance value.

As to the investment in equity securities issued by other bodies of collective investment, the decisions shall not influence the capital market negatively as pension funds have not recorded any investment in this type of assets.

Conclusions

Therefore, pension funds may ensure higher attractiveness of the capital market if:

- the number of participants in optional pension funds is rising;
- they remove the proposal that municipal bonds should hold an “investment grade”;
- the participants in the fund are informed, namely they are guided towards choosing the funds that can achieve high outcome investment.
- the fiscally deductible contribution rises;

- private companies initiate reward plans that include the submission to optional pensions.

The analysis undertaken herein also proves that the capital market has true growth chances on reliable bases which do not considerably affect participants' pension amounts if employees are aware of what it means to wait for public pensions and not secure their future themselves.

Cost Information – an Objective Necessity in Optimizing Decision Making

Petre Mihaela – Cosmina

Petroianu Grazia - Oana

oana_petroianu@yahoo.com

Abstract

An overall growth can be registered at macro and micro level without achieving a development and this only under conditions of continuous improvement methods and techniques of organization and management within the unit. Cost and cost information play an important role being considered and recognized as useful and effective tools to reach any leader. They have features such as multiple facets to facilitate continuous improvement towards business unit.

Cost awareness represents a decisive factor in decision – making or in planning further activities. The analysis and registration of data regarding past activities costs are only a facet of cost accountancy. Managers are also concerned with the future of costs, their level lying on supply and production decisions, as well as on some price policy.

Key words: decision, cost, efficiency, information

J.E.L. Clasification: M4, M40, M41, M49

1. Introduction

Considering that in the modern management thinking of a unit, its results are followed and estimated on working places, either functional or productive, it is imperative that the decision factors have, at any moment, the necessary data regarding cost level and improvement. The settling of this problem only partially answers the decisional process within the unit, the main problem being the application of some calculations to really and effectively evaluate the use of material values and physical work

generated by the production process. At present, more than ever, the leader of all the working places must intensify his activity in order to know and reduce the cost product per unit, a general appreciation factor of the business unit activity, considering the quantity of production as a second aspect. This can also be explained by the fact that the achievement of physical production does not require special efforts, as long as the production process is mechanized and automatized and the production graphics are observed.

The special importance to be paid to production cost derives from the continuous exchange of goods on the outer market, when competitive are only those products with high parameters and low costs.

Under these conditions any leader must have useful information about production costs, information which characterizes the way of organizing the production process of the whole aggregate of the unit. Eventually, the cost is the indicator which lays out the production structure, in the way that it directs the production process to the manufacture of products demanded on the market, resulting that the cost information as part of economic informational subsystem of the business unit covers a complex area of the business unit activity, enhancing a series of economic and technical factors to achieve the economic value of a product, a value which contains: the usage value, the esthetic value, the exchange value and cost which alongside with other elements is an essential factor in the efficiency of the activity.

Through its complex and etheregenous content, the cost is an indicator which sums up the value consumption and physical work in the production process, as well as their transformation and incorporation in the end

product. Under these conditions any leader of the unit, beginning with the foreman and ending with the firm manager, has to be informed about the cost level and development in order to make efficient solutions. As the costs level is equally influenced by the contribution of technical and economic staff of the unit, it is imperative a fruitful cooperation of these two professional categories, a cooperation which can be achieved by making mixed working teams within technical departments, as well as in the production, research and design ones. Data and information resulting from these analyses are useful decision factors for:

- cost control and analysis on technological operations for each cost generating product and place;
- unit operational management by fixing responsibilities and by controlling the task fulfilment;
- settlement of final financial results;
- estimation of task fulfilment by the unit departments;
- decision making for normalization and optimization of economic process.

Considering that decision-making presupposes the existence of more information, it results that the selection of an optimum decision depends on the number of information, and its value is proportional to a certain point with the heterogeneous degree of information. Therefore in this case, it is conclusive the correlation between the quality of a decision, the complexity of activities within a unit and the quality of information furnished, a decision being made optimum when there is a significant volume of information.

At the decisional level of management, there are quite often discussions regarding the causes generating the increase of information volume, they sometimes being pretty high, without and analysts' explanation of the interaction between the volume of information and inner and outer environment.

In order to put to practice the cost operational control it is necessary to modify the unit departments point of view which have cost attributions, in the way of their being more concerned with the current analysis of cost planning fulfilment, in the detriment of the effective calculation.

At present the information furnished

regarding cost production can be largely used only in making strategic decisions, in the idea that at the data when the information is presented to the unit management the production process to which the information refers is already finished, and the interventions which take place are too late, the situation being generated to a certain extent by the traditional procedures within most units.

2. The efficiency of cost informational system

In order to increase the role of cost information and to raise efficiency, the specialized departments must concentrate their attention and give more time to fixing in a fundamental way, the cost planning at the level of costs centres, and by an operational follow up to inform the decision – making factors about the deviations from the quantitative and value norms, so that they may take proper measures.

As long as this cost information does not offer these data in due time and structured on causes and responsibilities, it does not tally with the major interests of the unit, it cannot fulfill, in good conditions, the role of useful tool for unit management.

In this context, for a cost information to really become a competitive and efficient support in fundamenting and optimization of decisions, it is imperative to improve the cost calculating methods, in the way of assuring decisional factors, at all organizational levels with operational information regarding the cost level, the deviations and causative factors. Only in this way the cost can become a useful instrument in firm management and organization, to enable to clearly see the way the activity develops and the unit results, the cost information proving one of its useful principles visible in furnishing information necessary to know and direct the activity.

Being aware of the special importance of cost level in activity profitability, when the economic efficiency is important in internal and external competition, it is imposing that each leader, no matter the position he holds in the hierarchy, think economically, through the perspective of costs at which the object of activity is achieved, because not any speciality problem can be settled only by thinking in the respective domain, without

examining it as regards the costs.

Under these conditions not any action can be done, not any measure, activity or an economic process, without following up or analysing the costs in advance, a reason for which it is necessary to pay the whole attention to cost calculation, which have to be considered as a basic problem for all departments, services, firm management.

A factor which is not negligible is the efficiency of cost informational system. Therefore, if information offered by this is not useful in making decisions, or in control or planning, then which might be its value? In order not to confront ourselves with such situations, the system has to satisfy the following requirements:

- is the system adequate for the organization from the point of view of goods production and/or rendered services?
- do reports, situations, answers to questions, analyses, which are considered as outings of the system, contain relevant information to the proposed aim?
- do these outings appear at regular and small intervals so that to have an assured efficiency?
- are these reports, situations, analyses, answers to questions, addressed to persons responsible for decision – making?
- is the presented information relevant, enough detailed and exact for the pursuit aim?

Looking through these requirements it results that each cost informational system will be unique, as it will have to answer the requirements of a certain organization.

3. Decision – making optimization

The essential feature of management process, decision, represents the act of passing from thinking to action.

Specific to decision in the field of production costs is the fact that at the basis of its endorsement lie costs and costs information, the decision being the expression of a rational, coherent act taken on the basis of judicious interpretation of some data and information which are collected and worked out, so that a solution can be found to minimize the production costs.

The act of management, in all the fields of activity and at all levels, begins with the statement of the pursued aim and ends within this process with the decision taken, all the other management functions being conditioned by the objectives made through the adopted measures.

From the analysis made on several decisional processes, having in view the complex interaction within any process, there have resulted the following characteristic elements of any decisional process in the production cost:

- the decision – maker, who is to select one of the existing alternatives, considered the most efficient;
- the decision maker objectives, respectively the proposed consequences to be achieved, for the decision criteria;
- formulation the decision maker gives to the decision problem met;
- the multitude of the possible variants, which characterises a decisional situation;
- the multitude of decision criteria of the decision – maker, that is the points of view he takes into consideration in the selection of a variant;
- the multitude of states, each state represents the complex of conditions which makes that to one given alternative corresponds a certain consequence out of many possible.

The decisional process is an action which takes place at all organizational levels, covering both the short – term perspective and the long – term one. The plans are activated by decisions, and for a significant number of decisions it is necessary the contribution of a financial analysis or of a quantitative one, according to the situation, so that rational conclusions can be taken. That is why the practice of managerial accountancy is profoundly implied in the decisional process.

An important contribution to the alternatives evaluation during a decisional process is that referring to risk evaluation and uncertainty. Uncertainty is always present, the same its consequences, because the whole decisional process refers to future.

Decisions under uncertainty conditions represent a factor of capital importance in management.

A good manager has to know to promptly act and also to the point under uncertainty conditions, and for this he needs a decisional model. Practically such a model constitutes a formal model of decision – making support, often based on quantitative techniques. The decisional model includes the following elements:

- a selection criteria (objective function), which is the objective which can be quantified; usually this objective is represented by cost minimization;
- a set of alternative decisions as a result of which the objective can be achieved;
- a set of relevant decisions which can affect the results; these events, taken together, must have an exhaustive character (to cover all the possible situations); taken separately, they must be disjunctive;
- a set of probabilities, that is of possibilities of appearance of some relevant events;
- a set of possible results, which measure, in the terms of objective function the estimated consequences of different possible combinations of actions and events; every such result depends on a certain event and on a specific action.

4. Conclusions

The growth of economy complexity imposes the continuous improvement of informational, decisional system, its organization in a unitary form, efficient and modern in the same time.

In the concept of efficient management of the new business society, the economic informational system, and especially, the cost information, must assure the data necessary for the multilateral knowledge of the economic process, of reality by organizing a rational evidence, based on unitary principles to offer the necessary data for making decisions at all organizational levels, by creating informational material supports, to be able to offer an objective characterisation of phenomena and economic processes and to assure the furnishing of the necessary elements to give evidence to long – term processes regarding the economic growth and

economic efficiency, in investigating the new management tendencies.

The importance of providing information regarding production costs results in the role which this subsystem has in the establishment and follow up of the provided objectives, in sensing the negative phenomena and in furnishing the necessary data for an effective adoption of operational solutions in the development of the unit activity.

Starting from the idea that an essential point in improving the activities in all the economic domains is the establishment of an effective informational system, in many business units there have been made and implemented improving programmes for the informational system especially by providing them with advanced technology.

The personal measures initiated to improve the economic informational system impose the intensification of preoccupations and efforts in order to apply the new advanced methods able to assure an efficient follow of production costs and to raise on a superior level the calculation role as main informational source in the decisional process, by a permanent relation of cost information, between the suppliers of information and the decisional factors.

Accounting Considerations of Companies Distressed. Specific Theory and Practices

Petrescu (Neacșu) Claudia-Maria
Valahia University of Targoviste
claudia77neacsu@yahoo.com

Abstract

At some point in their history, most successful companies suffer a decline or stagnation of their performance. This causes anxiety at the organizational level, through continuous development of new companies in an environment with limited resources implies a slower growth or even stagnation and disappearance of the old company. Especially, must not overlook the fact that Romania's economy has been for over 20 years in a stage of continuous adaptation, determined to replace the centralized economy to market economy mechanisms. If until modern times the aim of bankruptcy procedure was to pay debtor's liabilities due to the liquidation of available assets, at present, in Europe, legislation is no longer limited to measures to regulate the treatment of insolvency, but establishes procedures applicable to the debtor not insolvent yet.

Key words: Companies in difficulty, Insolvency, Judicial reorganization, Reorganization strategies, Liquidation.

J.E.L. Classification: M41

1. Introduction

It is undeniable that any economic activity takes place within the existing legal framework at a moment, in a certain country. Therefore, the economist must adjust the judicial norms, reason for which the real economy is conditioned largely by judicial regulations.

But equally, the right must be appropriate to economic and social realities existing at a certain period of time, as the characteristics of population for which were enacted the laws.

Insolvency law is not used any more to define it as “cessation of payments” because,

even if they describe the same phenomenon, surprise different perspectives. If insolvency, defined as lack of funds to pay eligible debts, refers to debtor's subjective characterization of its economic status, cessation of payments is the objective expression of insolvency, being at the same time the external manifestation of preexisting inability of payment [3].

According to the Law no.85/2006 as it was modified by the Law no.169/2010, insolvency may appear in two forms: insolvency presumed as valid: -“when the debtor after 95 days of maturity, didn't pay the debt to the creditor” and impending insolvency – when proves that debtor can not pay at maturity “outstanding liabilities incurred, with available cash funds”.

Also insolvency differs from insolvability that is characterized by superiority of passive elements of the debtor to those of its assets. Along with the appearance of the Law no.381/2009 regarding introduction of arrangement and ad hoc mandate came a new conception of “difficulty status” which must be different from “insolvency status”. Difficulty status is different from insolvency status by the fact that the owner of the company in difficulty is able to face with outstanding liabilities. From the explanation of this concept offered by European Community Law on state help, appears that the difficulty status is mainly characterized by losses, decreasing turnover, excessive inventory or overproduction, high debt and decreasing net asset. Moreover, according to the law regarding state help, the company in difficulty must be unable to recover with its own resources or funds provided by owners/shareholders and short or medium term being in danger of getting out from economic cycle [5]. This extra condition is not available in our law, the owner of the company is encouraged to call the procedure as soon as possible after he realize and accept

the existence of difficulties because it is possible that the source of problems to be the poor management. Insolvency balanced on one hand available cash funds and reliable, liquid and outstanding debts on the other hand.

If by modern era the goal of bankruptcy was to pay debt's liabilities as a result of liquidation of available assets, at present, at European level, the law is no longer limited to regulate treatment measures of insolvency, but establishes procedures applicable to the debtor that is not insolvent yet. Due to anticipation of insolvency, debtor may benefit from early intervention of justice that will prevent its appearance. The company's possibility to have justice protection before being in cessation of payments is taken from U.S. Law and can be a real instrument of economic recovery [2].

Saving enterprises depends largely on early recognizing and accepting the existence of difficulties. Enterprises' difficulties are not necessary financial, although regardless of origin, finally they acquire a financial expression. Usually, performances decreasing partial arises from financial problems, it is the translation of some economic, technical, commercial or human imbalances within the organization or of the tightening of economic, judicial, social, competitive conditions in the environment where it evolves. All these factors reflect the normal continuing of enterprise's activity.

Examining the literature devoted to the decline of enterprises, but also from real economy data, identifies a series of causal factors which frequently have a negative impact on enterprises' performances. Generally, the causes of enterprises' difficulties may come from certain characteristics of environment where it act or from certain errors and internal and organizational difficulties [4].

Enterprises operate in an environment with quickly and complex evolution that influences its possibilities of existence and action. So, the nature and changes of an environment where operates the society require an increased flexibility, a permanent adaptation but they can have a negative influence on its performances. In the actual context, the environment is usually changing thanks to a combination of factors, including technical progress, so it is vital to correctly

identify the magnitude and rhythm of response from the organization. In literature was underlining correctly that the majority of companies ignore the crisis and changes appeared suddenly, unexpectedly, in the external environment of company, because they see its as being temporary, with low intensity and with no relevance to its performances, tended to focus more on internal aspects. For this reason, the company doesn't respond adequately and quickly enough to environmental changes, which can lead to difficulties.

Difficulties generating causes for enterprises can take many forms,, especially reducing the demand for products and services and increased competition, law changes, technological development that makes actual products and services to become old, or reducing availabilities and accessibility of environmental resources. Competitiveness intensification, both the level of prices and products, is viewed as a common cause of company's difficulties. Thus, competitors may manufacture at lower prices, benefiting from scale economy effects, or they can launch new products and services that better satisfied needs and preferences of clients. Competitors' actions endanger the competitive position of organization which, to maintain a competitive advantage, must respond with counteract actions. Also, a strong competitiveness of prices proved to be a common cause that generates difficulties for many Western European companies [3].

Changing legislation and enforcement by the stat of technical, social, consumer protection or environment constrains may have a negative impact on companies' performances, being another external cause that generates difficulties. Certain enterprises may be in disadvantage due to tightening legislation or due to adaptation of certain governmental policies such as: subsidies, differentiated taxes, environment protection, and social policies.

Given the rhythm of changes that occurred in the last years, it is clear that technology plays an important role in crating some durable competitive advantages. Equally, technological development may be also a negative factor on enterprise's performances, given that it cannot be protected from technical and technological

advance of competitors. Low accessibility of resources is another causal factor for enterprises' difficulties. This may be due to some negative movements in raw materials prices, a natural reduction of resources level or due to the fact that property or control of raw materials are held by competitors.

Companies internal difficulties generally come from failures or errors on organizational level which, if are correctly identified, may suggest good solutions to facilitate recovery. Personal characteristics and key leaders' behavior play a major role in company's difficulties, without just incompetence [1]. Managers may become very tied to the strategies that they created and practiced, so that the organization applies very rigid and conservative strategies based more on tradition and concepts, sometimes outdated, and not on a rational analysis, that causes a decrease of enterprise's performances. Managers' indecision and too long terms for making important strategically decisions also lead to a decrease of performances and difficulties because opportunities are changing quickly and the company will be in a disadvantageous position compared with competitors [3].

High specialized companies, that are concentrated only on a product, are very dependent on fluctuations in demand regarding clients' needs, changing their preferences, buying possibility, so that they become very vulnerable.

An inadequate financial structure contribute to increased vulnerability of company and its dependence toward those who borrow funds, generally banks, if this do not have enough proper resources to finance the activity. A high debt rate will result, sooner or later, into a decreasing of performances, because a company with moderate debt rate is considerate more prepared to respond opportunities. High debt rate and insufficient resources lead to decreasing financial autonomy, making it very sensible to a series of another conjuncture factors such as not paying bills on time by clients, bankruptcy of an important client or its activity's fluctuations. Also, a conservatory financial policy, characterized by lack of reinvestment of profit, a high rate of dividends paid to shareholders and an increased liquidity, to the detriment of some investment programs

to obtain long-term profitability will inevitably lead to difficulties and even to company's bankruptcy.

Companies that have a costs structure significantly higher than the main competitors, usually suffer an important competitive disadvantage. High costs can be determined by many factors, such as: insufficient focuses on efficient production increasing in order to benefit from the scale economies' effects; unreasonably high expenses on labor; excessive dependence on a few number of suppliers; unfavorable location towards suppliers and clients; operational inefficiency, which is usually the result of a poor management, etc. [4].

Maintaining business continuity and recovery requires an efficient supervision, especially at management level, in order to avoid premature founding of difficulties which threaten the functionality of the company. Thus, it is necessary that legal regulation offer the adequate mechanisms in order to detect and prevent both company's difficulties and their amplification up to a level where the survival of the company is questionable (bankruptcy, goods liquidation). Especially because the company's disappear involve consequences extremely serious on economic and social level, resulting among others, in a propagation of difficulties towards other organizations, due to the impossibility of asset recovery, suppression of some jobs or the loss of certain fiscal revenues. As such, the question is protecting not only some private interests, and especially of the company that faced with difficulties, but also some general interests, especially of society as a whole, reason for which detecting, preventing and treatment mechanisms of companies' difficulties must exceed the scope of managerial and organizational actions, needing the intervention of legislature [2].

French legislation contains a legal coherent rule to prevent and treat the companies' difficulties before cessation of payments and which has been greatly improved by adaptation of Law no. 2005-845 of 26th July 2005 regarding saving companies. It's several steps, as follows:

- Order companies exceeding certain size to hold provisional accountancy, preparing a series of documents (the situation of achievable and available

assets and liabilities, provisional outturn account, provisional financing plan), that must be presented to the Commissioner of Accounts (the equivalent of internal auditor in Romanian law) and to the works council [2]. Unlike the normal accounting documents that allow the knowing of passed situation of company, provisional documents identify means that will be available for it in the future, in order to adapt them to the established objectives.

- Establish an alert procedure in case of circumstances which will affect the economic situation of company and continuity of its activity [3]. The procedure may start at the initiative of the Commissioner of Accounts, works council, shareholders, or, in certain conditions, even the chairman of the trade, and the alert addressed to company's leaders or the General Assembly. This procedure is aimed to prevent the leaders of the company regarding the appearance of difficulties and inciting them to make adequate recovery measures.
- The possibility of debtor that faced with difficulties, not being in cessation of payments, to request the court to appoint a professional ad hoc representative to assist the leaders of the company in negotiations regarding conclude an accord with their mainly creditors and partners, in order to obtain grace period to pay claims, a rescheduling of them, remitted their debt, new funds, etc.
- Establish a conciliation procedure that can be open at the request of debtor, even if he is in cession of payments, with the condition that this situation did not exceed 45 days. The conciliation procedure ban take up to 5 months, in order to facilitate with the help of a professional conciliator, concluding an amicable accord between debtor and his mainly creditors and partners, or even with new partners, to finish the difficulties of the company and to ensure his survival, continuing the activity and maintaining jobs. The accord

between debtor and creditors is approved by the court.

2. Conclusion

Avoid at all insolvency and postpone final outcome are not really ends. If the difficulties that debtor faced with are severe, the debtor should asks for opening the insolvency procedure. To the extent that the company is unviable, quickly liquidation is necessary before any attempt to recovery. The debtor should know that the survival of the company is not always desirable. In certain circumstances, company's liquidation is the best option, because nothing justify sacrificing creditor's rights, if the debtor cannot be solved. Continuing a ruinous business may engage even penal responsibility of those who are guilty for the appearance of insolvency or for deliberately deteriorated. Such an attitude can cause chain insolvency of counterparts' partners of debtor or the whole group of debtor, and such a result must be avoided.

Financial and Monetary Research Center „Victor Slăvescu”, Bucharest, Romania
gabriela_piciu@yahoo.com

Abstract

The article presents a study which aims to analyze the role of Basel regulatory in the context of changing the behaviour of financial markets actors.

The main focus of the Basel Committee is regulatory relating to the activities of international banks. As discussed of the industry and almost all major banking organisations are own international enterprises.

Key word: Basle Capital Accord, risk management, credit risk, banking industry

Classification J.E.L.: G21, G28

1. Introduction

More than a decade since the collapse of the Bretton Woods, fall that caused severe disruptions in international financial markets, the Basel Committee on Banking Supervision introduced the so called Basel Accords a mixed approach containing institutional and practical issues of hedging and banking risk management, in the context of changing the behaviour of financial markets actors.

In this framework, the first step was the Agreement known as the Basel I, introduced in 1988 fully implemented in 1993, recognized in more than 100 countries, including the CEE-10 countries, implementing it in national banking systems.

Based on the assumptions focus on aggregate capital of financial institutions, vital in reducing the risk of default and potential cost of potential bankruptcy compensations and losing the depositor trust, the Basel Committee stressed on the effective collaboration need with supervisors to properly implement the principles set out in the Agreement.

The second step was the Basel II, initially published in June 2004 and finally implemented in 2006, intended to create an international standard for banking regulators to control how much capital banks need to fight against the types of financial and operational banking risks a negative externality to the whole economy.

2. Basel II

One focus was to maintain sufficient consistency of regulations so that this does not become a source of competitive inequality amongst internationally active banks.

Advocates of Basel II believed that such an international standard could help protect the international financial system from the types of problems that might arise should a major bank or a series of banks collapse.

The main objectives of the Agreement, reached in fact, were:

1. Increase the total volume of international capital in the banking system at a favourable economic growth;
2. Directing financial institutions to business areas compatible with its own size as well as the need more flexibility and risk sensitivity reasoning behind the drafting of a new agreement.

Comparisons between Basel I and Basel II:

Currently Agreement:

- a) It focuses on one single way to measure risk.
- b) Presents an unique dimensional approach based on a general structure ensemble

New agreement proposal:

- a) Emphasizes the role of internal ratings of financial institutions, monitoring reports and market discipline.

b) It is a flexible, multidimensional approach which stimulates the improving of risk management and a greater sensitivity to risk.

Proposals for new Agreement call for more flexibility and less correction.

The new framework intends to increase the safety and robustness of the financial system by applying detailed recommendations in the three pillars that form the structure of Agreement

1. Minimum capital risk management
2. The supervisory process
3. Market discipline and total transparency.

On one hand, pillar I sets capital requirements for credit financial, and operational risk.

On the other Basel II deals with a larger portfolios of credit risk providing a wide range of options for calculating capital requirements according to specific vulnerabilities exposure.

In this framework, there are three methods used for this purpose: standard approach, the basic approach and advanced approach using IRB.

The standard approach is closest to this risk management framework (Basel I), establishing fixed risk weights depending on the type portfolios (authorities and central banks, credit institutions, companies, and so on).

Differentiating elements are:

-promoting a greater sensitivity to risk (by refining these categories)

-the use of external ratings, the supervisory authority is responsible for recognizing the external rating agencies on the basis of qualitative

-broadening accepted tools and operations in order credit risk mitigation.

Approaches based on IRB are the largest element of novelty, based on theories of asset valuation.

Capital requirements are calculated according to the following risk parameters:

-Probability of default (PD) - the loss in case of default (loss given default LGD)

-Exposure to the debtor (exposure at default EAD) and exposure-maturity (maturity-M).

Capital requirements are determined by subtracting from the bank's risk exposures (determined for a confidence interval of

99.9% and a 1-year horizon), the expected loss associated (ELA)

The latter is compared with the provisions level and, depending on the outcome are influenced own funds.

Expected loss is determined according to the formula: $EL = PD \times LGD \times EAD$

In the basic approach of internal models, credit institutions determine PD, and supervisory authority sets remaining risk parameters. In the advanced approach, credit institutions calculating their own parameters to determine capital requirements. In the latter case, the difference between economic capital and the governed is minimal.

Capital requirements for operational risk appeared for the first time as distinct.

Risk is defined as the possibility of incurring losses due to inadequate internal processes, human error, cloud systems or external events.

For calculating capital requirements credit institutions may choose one of the following:

-Basic Indicator Method: requires possession of capital equal to 15% of average gross income for the last three years of activity.

-Standardized Method: decompose the bank's operations in eight categories of activities and the capital requirement is determined by multiplying the net revenue for each category of activity with a percentage between 12% and 18%.

-Advanced method: Enables use of internal models for measuring capital requirements for operational risk.

Market risk experienced no substantive changes to the additions to the provisions of Basel I in 1996.

Pillar II addresses qualitative prudential requirements through monitoring process. The supervisory authority receives greater powers to assess banks' internal procedures regarding capital adequacy based on risk profile.

In turn, credit institutions must be able to identify, measure, and report all hazards to which they are exposed and allocate capital accordingly. Risks are not only those captured in Pillar I, but also the liquidity risk, interest rate for the exposures which are not included in the transactions portfolios, risk, residual risk as well as the concentration, reputation and strategic risks.

The supervisory authority may require additional capital if it considers that these risks are covered and/or bank has not implemented appropriate control systems. Finally, the need to build the premises for EADS intervention mechanisms to prevent banks the capital minimum threshold.

Pillar III encourages market discipline by developing a set of detailed reporting requirements to the supervisory authority and to the public. Increasing transparency lowers information asymmetry and risks could be better evaluated. Reporting requirements are both qualitative (e.g. the consolidation level, ownership structure, the bank's strategy for certain exposures etc.) and quantitative (e.g. value capital components, capital requirements for all risks and so on).

3. Impact of international regulations on Romania

Basel II was implemented in the European Union by reconfiguring the specific surveillance directives.

Those regulations incorporate a number of differences to the provisions of the Basel Committee, the result of negotiations between Member States taking into account the national specific conditions.

The first difference was the fact that European settlement in principle has been applied on a consolidated and individual level to all credit institutions and investment services companies, regardless of the complexity of their work, while Basel II was designed especially to international active banks.

Secondly, it gives greater role cooperation between supervisory authorities, promoting the growth of financial integration in the EU. European approach intent to provide uniform conditions of work for all credit institutions.

In the case of Romania, the implementation of Basel II involved a series of challenges for both institutions (adjusting risk management and information systems, staff training, and procurement databases and so on) and National Bank of Romania (adaptation of surveillance, developing new regulatory framework, staff training, etc.).

The central bank has established a four-step strategy for implementation of Basel II in Romania:

Step 1: Initiate dialogue and exchange of information with both national (Romanian Banking Association, Ministry of Finance, National Securities Commission) and international entities (other supervisory authorities) involved in Basel II.

Step 2: Development of banking tools mechanisms for achieving the standards imposed by Basel II, in particular by:

-transposition into national law of Directives and adapting prudential reporting system;

-develop guidelines for the validation of internal models;

-Performance assessment tasks of implementing the Basel II at the credit institutions.

Step 3: Validation of internal models of credit rating regarding the credit institutions

Step 4: Checking applying the provisions of Basel II credit institutions.

The regulatory framework will be substantially reconfigured. Laws on banking, credit cooperatives, savings banks and mortgage banks, the popular savings industry all will be reviewed. In turn, secondary legislation will be amended to meet the requirements under the three pillars of Basel II.

For the implementation of the European Directive at the Steering Committee was adopted the framework of national options

These options are circumscribed particularly to the issues of credit, operational and market risks, as well as to individual and consolidated supervision on banking assets. In formulating the position against national options was adopted a prudential policy.

Table 1 shows the main changes in risk weights resulting from the exercise of national options for the standard approach. The biggest impact will be located to the retail exposures (people and SMEs treated as retailers) and at the exposures secured by residential properties.

A simplified estimate indicates a 16% reduction of risk-weighted balance sheet exposures for corporate loans and retail segments, which will further increase the solvency of credit institutions.

The last but not the least, regional and local government lending could become more expensive since the estimate that the

financing needs of these entities will increase considerably in the context of integration.

The impact of transposing the Basel II regulatory on credit institutions and financing economy needs a complex hardly estimation. Difficult reported by banks to restructure databases on exposure classes specified in Basel II, was the main problem encountered.

Table 1. Specific credit risk weights in the standardized approach of Basel II compared with Basel I.

Type of exposure	Risk exposure Basel II	Risk exposure Basel I
Governments and central banks, financial institutions similar (for exposures other than those denominated and funded in domestic currency)	0	50
Credit institutions (exposures longer than 3 months)	20	50
Regional and local governments	20	100
Retail exposures (including households and SMEs treated as retail)	10	75
Exposures secured by residential property owners	50	35
High-risk exposures	100	150

Source: NBR, *Financial Stability Report 2006*

Since 2007, few banks in Romania have adopted the internal models based approach for the following reasons:

- Capital of banks is significantly higher than the regulatory minimum (12%) and thus has no incentive to conserve their funds by using advanced methodologies;

- Romanian banking market could be considered too small to justify the costs of implementing the advanced approaches of Basel II, banks are currently facing the propensity to increase market share;

- Quality of statistical data for interesting patterns could be unsatisfactory;

- Some banks have not internalized the Basel II project in the spirit of modern risk management; most banks choose

standardized approach for credit risk and basic indicator for operational risk.

Table 2. The approach stated by credit institutions in Romania in 2007 used to calculate capital requirements for credit risk and operational

Approach	Number of credit institutions.		
	07/2005	11/2005	05/2006
Credit risk			
The standard approach (standard or simplified)	13	30	31*
IRB - based approach	3	2	2
IRB - Advanced approach	1	0	0
Credit institutions undecided	17	2	0
Operational Risk			
Basic indicator	11	17	20
The standard approach	10	13	13
Advanced internal models	4	2	0
Credit institutions undecided	9	2	0

*included and banks said they would use Basel I approach in 2007

Source: NBR, *Financial Stability Report 2006*

Validation of internal models by the supervisory authority is the basis for a credit institution to use other approach than the standard one in determining capital requirements.

That is the reason for BNR to develop guidelines for validation for each type of risk under Pillar I (risk, credit risk, market risk and operational risk).

Principles that will underpin the validation process are:

- Primary responsibility belongs in the validation process of credit institutions, the supervisory authority only assessing how the bank has made itself validation;

- Validation represents briefly, the predictive assessment capacity of a bank's risk and;

- Validation is an iterative process, based on both quantitative factors and qualitative.

Implementation of Romanian banking validation sector could be more difficult, both in terms of the rating process and rating of the related system.

Three important aspects to consider the validation.

Firstly, even if the model is built by the parent bank and validated by the supervisory authority of the country of origin, national local management must be able to demonstrate that the model used capture adequately the Romanian banking market risks characteristics.

The model could be very performing, at the first sight but can not capture some minor risks at the aggregate level, but important for Romania.

Secondly, we believe that national local management should not be a simple manipulated actor to use internal models as black boxes, but must have a satisfactory knowledge management of using the specific models.

In fact, the top managers must be fully awarded to the exposure risks that affect the financial and banking entity.

Finally, feeding patterns database is a challenge. Currently there is a long history for statistical databases that must be used to quantify capital requirements. Importing such bases must demonstrate that they can capture the structure and dynamics of the banking market in Romania risks.

4. Proposal for Basel III

Announcing the revised proposal for Basel III, contains much important information's that, as far as it would seem, remained so far unnoticed. At first glance, the document containing only rules that in general became less strict. Obviously, this provides a very optimistic perspective of banks, particularly those in Australia and

Japan, but in short term it could be expected a Revision of this behaviour. There are also other issues not clear in the document, which are very interesting.

Especially during direct allocation on 8 years - less likely chosen based on a random factor, but rather considering the massive action to repair the banking balance sheets. And with the new set of rules that are only marginally stricter than Basel II regulations, this clearly shows that central bankers are worried - both on the global economy and financial system of situations.

Since last year, some European nations like France and Germany lobbied the proposed Basel III regulations to be less severe and the BCBS (Basel Committee on Banking Supervision) responded by reducing the number of exclusions and establishing a satisfactory transition period. [4]

New consultative document is based on an analysis of the results of the Quantitative Impact Study (QIS) and serve as a draft for discussion that will be conducted CHOS meeting.

5. Main changes:

Tier capital ratio less severe exclusion rules. Two points were removed from the list of mandatory exclusions from this core capital ratio announced in December last year. Intangible assets (software largely in terms of value) and deferred tax assets (net DTA). Other points are now partially returned to core capital ratio after initially were removed: Deferred tax assets (net) and investments in common stocks of financial institutions be allowed, however, for both, the limit set is 10 % of the component of the bank's common shares. [1]

- Definition leverage ratio. Minimum leverage (core capital/Assets) is 3%. After the effects of leverage will be tracked over the four years starting in January 2013, a final proposal will be announced in July 2017, new regulations will be implemented in January 2018.

- Liquidity coverage ratio (liquidity coverage ratio) reduced. Overall, the requirements were reduced. Regarding the liquidity coverage ratio, the rate of run-off levels were low, while in terms of loan rates on longer maturities (Net Stable Funding Ratio), the available maturity term was

extended for financing. The proposal also includes a response to country risk that market worried lately is included a reduction of 15% in certain bonds. [6]

-Gradual introduction period - about 8 years Application of new rules on liquidity coverage and leverage ratio will begin in January 2018. Period of gradual introduction of new regulations on the capital adequacy of capital is not clearly specified, but it is anticipated that a reasonable period of gradual introduction will be allowed.

And long relaxation "phase-in" should cause a concern. Beyond the obvious, namely that financial institutions will trade above as a result of this relaxation - their earnings will be revised upwards simply because, in fact, they will have to save less capital reserves - and long relaxation "phase-in" should cause concern. That relaxation is more significant compared to the original version of December 2009 document, should generate long-term concern in the financial sector, particularly in Europe and the U.S. [3] Currently, a repair action unfolds balance in these regions, but this process can be revived simply by considering a higher level of risk, and, given the regime of very low interest rates would be really tempting. In the short term, this will obviously have a major effect on the unique institution both in terms of earnings, and in the balance sheets „clearing”. In the long run, it entails serious risks for a new crisis in the financial sector caused by excessive risk taking and, unlike the first crisis, European governments and the U.S. is so indebted that it will be extremely difficult to help everyone else. [2]

6. Conclusions

Revised proposal provides that new regulations on leverage and liquidity coverage ratio will come into force in January 2018. This transition period (longer than the approximately six years stipulated in Basel II) appears to be caused by:

-lack of evidence of a real recovery in the global economy;

-the current situation in various countries. While during the "phase-in" for new regulations on the capital adequacy of capital (Capital Adequacy Ratio) was not specified, we anticipate that it will be allowed a reasonable transition period.

From our point of view, this should generate a different concern, namely that the financial sector is less solvent and likely will remain so for many years, despite the recent stress test results. If this hypothesis is true, a further slowdown in global recovery curve could put the financial sector in the U.S. and Europe under huge pressure.

Romania must make a concerted effort to improve the sovereign country rating, getting a good rating as required by the entry into force of the Basel III treaty because Romanian banks will take into account in the lending activities the country rating.

In addition to higher interest rates and higher costs because interest will be imposed depending on the quality (the rating) the borrower, a significant impact on banks will have the Basel III regulations for capital requirements. [5]

Fiscal Management between Fiscality and Accounting

Pintea Mirela-Oana

mirela.pintea@econ.ubbcluj.ro

Abstract

The existence and functioning of economic entities take place in an environment where the state through its fiscal institutions, makes its presence felt strongly and continuously through a number of laws, decrees, regulations, orders, circulars issued, published, repealed wholly or partially, republished, added, revised, refined or suspended. So, we can say with certainty that taxes influence economic decisions taken on every day base. Therefore in the management of a company has its defined place the fiscal management, that involves managing the fiscal side of the activities within the entity.

Through this study we try to present the concept of fiscal management, concept insufficiently discussed in the literature, concept that is at the convergence between fiscality and accounting.

Key words: fiscality, accounting, business management, fiscal management.

J.E.L. classification: H20, H32.

1. Introduction

The existence and functioning of economic entities take place in an environment where the state through its fiscal institutions, makes its presence felt strongly and continuously through a number of laws, decrees, regulations, orders, circulars issued, published, repealed wholly or partially, republished, added, revised, refined or suspended. Fiscal and accounting regulations come to directly or indirectly influence the activity of an economic entity which acts as a taxpayer.

Since in Romania both fiscality and accounting rules are developed by the Ministry of Finance, the interdependence between accounting and taxation is very

tight, which causes the tax influences on accounting to seem even more obvious. Between accounting and fiscality is a complex relationship because accounting is a prime source of information for tax authorities and most tax liabilities are based on accounting data.

However in the relationship between accounting and taxation there is an important issue that refers to the fact that principles, rules, laws and regulations of both components are not similar in all cases. In a regulated accounting, accounting information consists of its principles and rules. Instead, tax information serves as a basis for taxation according to taxation principles, rules and standards defined by tax law.

2. The interdependence between fiscality and accounting

Regarding fiscality and accounting there is an attempt to clarify the influence of one over the other. We can identify among the different stands of Romanian and foreign authors, the following possibilities [5]:

- accounting is influenced by fiscality;
- accounting depends on fiscality;
- accounting influences fiscality.

In the literature we find a generally accepted opinion that is about the existence of interdependencies between fiscality and accounting. Moreover, the two disciplines are often dependent of each other because we can define companies or state institutions as a set of accounting and tax documents to be analyzed as a whole and not independently of each other.

Accounting responds from an informational and decisional point of view to the issue of separate economic values management. Economic entities were and are the space for accounting representation and action. Accounting should provide information for all information users such as

equity investors, taxation as state representative, bankers, customers, suppliers - as business partners of companies, government institutions and employees.

One of the informational interests to which accounting must respond, considered by some authors to be the main one, is the fiscal interest. Accounting has always had issues regarding its reconciliation with fiscality. The cause for such situation was generated by the fact that not in all cases accounting principles for evaluation and economic calculations converged with the fiscal ones, which does not subordinate the presentation of a true image of operations taking place in the economic entity as fiscal principles aim the stimulation or inhibition of some activities.

Also, the fiscal regulations aim to directly or indirectly influence the activity of an entity that acts as a taxpayer. So, we can say that the objectives of taxation consist in calculating, charging, placing, tracking payment of taxes and contributions owed by economic units to state. Therefore the foundation and motivation of fiscality are represented by taxes. The taxes system must fulfill the following functions [11]:

- a) to finance public spending, pursuing the objective of budgetary performance;
- b) income redistribution according to equity principle;
- c) to stabilize business or imbalances for economic efficiency.

In a market economy fiscality has a double face for any company. On the one hand, it is reflected in the state compulsory levies, influencing the company treasury. This gives content to the notion of tax burden. On the other hand, the company may use for its interest the fiscal principles and methods. Thus, the operating or investment activities of the company can use methods and techniques whose tax incidence gives advantages that result in a positive treasury [10].

In Romania, the links between accounting and taxation are characterized by the fact that the taxation authority borrows many rules from accounting. Accounting influence on tax law is explained by the fact that, for measuring taxable matter, the taxation authority had to find rules for evaluation, time separation, depreciation and so on. It would have been unnecessary to create their

own rules, while the accounting had already consecrated procedures [10].

Since in Romania both tax and accounting rules are developed by the Ministry of Finance, the interdependence between accounting and taxation is very tight, making the tax influences on accounting seem even more obvious. Between fiscality and accounting appears a divergence that can be explained by the difference of purpose between the two disciplines [12]: while accounting has as an objective to determine the bases for taxes, taxation task is to establish rules than can adapt as better as possible to accounting functions.

The objectives of the tax system in the national economy are materialized by providing the necessary resources to carry out state functions and tasks through tax levies, as well as providing the necessary means to exercise the public authority intervention in the economy, to correct market failures, to limit the effects of the economic crises or to prevent them. In the market economy conditions, the state can't make an intervention in the private sector through administrative methods but can use leverages provided by the tax system to achieve certain directions of the economic and social policy [4].

Any operation at the microeconomic level is subject to tax regulations in force, so we can safely assume that the activity at the micro level is influenced both by direct taxation and indirect taxation as well. In this sense fiscal influences on economic entities are divided into the following categories:

- taxation influences acting on all economic entities, regardless of how they treat taxation in business management (are influences that occur due to changes that arise from time to time in the tax law). The purpose to quantify these influences is to analyze and predict business performance scenarios depending on changing tax legislation.
- taxation influences acting only on companies which use taxation as an active tool in managing the company. In this context it appears the notion of fiscal management.

Fiscality is a reality of the everyday economic life, being a very important factor in the management of a company's revenues and expenses where it appearing under the

form of taxes, fees and contributions paid by a company to public budgets. In this context all owners and managers are interested in managing their tax flows and tax accounting so that the costs required thereby are minimal and tax law is not violated. Also, fiscality represents a major decision factor for investment because it represents an important cost for every business transaction, as it is showed by a study conducted in 2005 by the World's Bank. This study reveals 14 main worries of the business community when taking investment related decisions. Among them, the tax level comes in third, and the tax regulation and administration comes in seventh.

Regarding Romania there is a study published in 2009 and conducted by the financial consulting firm Deloitte, entitled "Romanian fiscality – The radiography of an incomplete reform", that reveals that there is a need of the Romanian business environment for authorities to pursue a medium and long term financial strategy and to focus their efforts to reduce the frequency of legislative changes. So, according to the study, 34% of the surveyed persons considered that the premise for a financial environment proper for business development is the stability of law and 22% of them expressed their desire for the introduction of clear procedures in the tax administration [13].

The relationship fiscality - accounting is a subject that can be analyzed in the context of optimizing company's fiscal management. According to some authors we must not let the fiscal policies influence us when choosing the accounting policies even though this would mean less work [2].

3. What is fiscal management?

At the level of an entity it is delimited and operates under effectiveness conditions the so called fiscal management at the same time with commercial or financial management. "The existence of the enterprise fiscality generates the need for an information system to manage the numerous fiscal rules on the subject of taxation, base of taxation, tax rate, term of payment, facilities and fiscal penalties. Such a system must have a preventive and assuring character regarding

the fiscal rights, obligations and penalties for irregularities "[7].

Through the Fourth Directive of C.E.E. it was established the interactivity between the accounting law and tax law. This is achieved by a company's fiscal management. The fiscal management is the art and science of applying methods, techniques and procedures in order to substantiate programs, to organize and coordinate the processes of collecting the fiscal incomes, in order to use efficiently the public money and to satisfy the society's needs.

The subject of study of fiscal management is the analysis of distortions or deviations by incompatibility between the fiscal and accounting rules, convergences between them and determining, based on their analysis, the strategy, fiscal risk and fiscal efficiency of an entity. [7]

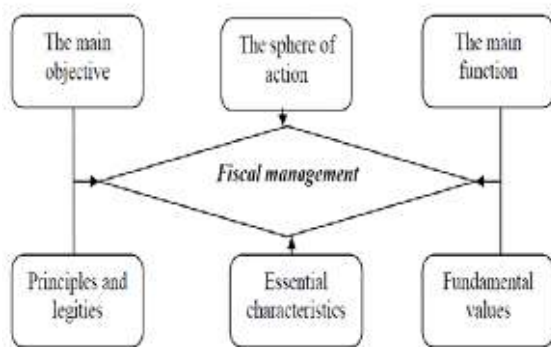

If we talk about fiscal management first we must explain the concepts of fiscal security and fiscal efficiency, two essential components which define fiscal management. Fiscal security must constantly be among the current objectives of each economic entity because it represents one of the classical aspects that describe the relationship between the company and fiscality. Any economic entity must comply with the basic rules and deadlines imposed by tax law because it is always at risk of fiscal control, control likely to reveal irregularities. So, in view of these mentioned, the economic entity can thus minimize fiscal risk, promoting efficient management of financial resources and avoiding losses due to penalties or sanctions.

To manage in an efficient way the company's financial and economic resources means taking into account the fiscal size of the business. Based on the financial analysis of synthesis documents from accounting it can be establish past performance and it can be estimated the fiscal risk and efficiency. The last mentioned is the second essential component that defines fiscal management. The company has to define an autonomous fiscal policy, detached from the rest of the company, with a single and independent objective: research of the less taxable legal ways. When we refer to a company's efficiency we mean the extent to which it succeeds to achieve its objectives. So, fiscal management as well as commercial management and production management is

integrated in business management and therefore it should be defined in terms of the objectives of general policy of the company or in relation to the strategy adopted.

The existence of fiscal management determines the delimitation of the essential coordinates of it [3]:

Figure no 1. The essential coordinates of fiscal management

Source: Comanicu, 2007:4.

The fundamental objective of fiscal management is represented by the understanding and enhancing of the role of the taxes in the social economical life of a nation, considering to determine a real partnership between the state and tax payers in order to form and use the public financial resources.

Fiscal management objectives take into consideration to ensure fiscal security and efficiency through research of form and substance prescriptions, delays, deferrals, exemptions imposed by tax law. In this way the entity is avoiding tax penalties and proceeds to a better allocation of its financial resources. Entities need to optimize their relationship with fiscality on a financial and economic plan.

The action sphere of fiscal management must take into consideration the processes and management relations identified both at national and international organism's level with attributions in the fiscal domain and also at tax payer's level.

According to Comanicu the process of management were first identified by Henry Fayol, who identified the main functions of management on the basis of an analysis, namely: prevision, organizing, command, coordination and control. Also many other famous specialists such H.Koontz,

C.O'Donnel, W.J.Duncan, H.Churg, H.B. Maynard, proposed the following management functions: prevision, planning, evidence, operating, executing, control, etc.[8].

Starting from here we can identify the main functions of fiscal management as beeing the prevision function, the organizing function, the coordination function, training function and the control and evaluation function.

The fundamental values which must be taken into consideration in determining the processes and the relations of fiscal management have on the basis [3]:

- assuring a coherent functionality of the managerial process and the structures of the entities with attributions in the fiscal field;
- the analyses of the endogenous and exogenous factors which influence the relations of the fiscal institutions with the economical, social and political medium;
- identifying the best modalities of using the resources in the sense of maximizing the fundamental objective of the fiscal management;
- elaborating a realistic fiscal politics based on efficiency and efficacy.

According to authors like Androniceanu the fundamental values are structures according to their belonging (internal and external values), being recognized values as ethics, moral and democracy [1].

The identification of fiscal management characteristics has on the basis: the specificity of fiscal obligations; the general principles of taxation; the specific of fiscal and budgetary activities; the tasks and functions which belong to taxes, the rights and obligations of tax payer's individual and juridical persons [3]. So, the fiscal management is a type of management oriented to the participative dimension, being based on a coherent system of performance indicators.

Regarding the general principles of fiscal management we take into consideration the following: the principle of defining and applying the unitary management according to the influence of the medium; the principle of legality; the principle of motivating all the factors involved in the fiscal activity and the principle of efficiency.

Even if the law is the same for everybody, not everybody understands the idea the same way, and this leads to a situation in which not all companies may benefit of certain facilities provided by law because facilities aren't always easily noticeable or, in connection with other economic and financial aspects of a company, facilities may result in different effects.

Even though, theoretically, the tax system acts upon all companies, so that the influence on economic and financial performances is obvious in all companies, latter doesn't operate identically in the decisions regarding the performance of economic activity, which is why differences may arise in the actions of taxes on a company's expenses [6]. It should be also noted that managing taxes and fees, for the purposes of optimizing their level, it doesn't mean breaking the law.

4. Conclusions

Fiscal management addresses all economic entities aimed at obtaining profit. This determines the need to respect the main mechanisms of fiscality, without the deviation of the professional accountant from the fundamental objective of accounting namely to obtain a clear, complete and real image of the entity's patrimony, financial position and results.

Fiscal management is at the intersection of accounting with fiscality but also should take into account the macroeconomic evolutions and economic context in which that entity operates. There for, in the context of the current global economic and financial crisis, where the need to capitalize is increasing, the need of fiscal costs' optimization is stringent. Fiscality imposes certain rules and procedures but also provides the potentiality to choose among several variants, so the economic entities can use this option system according to the goals they have at certain moment in time because it is the legitimate right of taxpayers to optimize their fiscal costs always in accordance with fiscal laws.

Optimizing fiscal management involves managing the fiscal aspects of economic entities in such a way as to ensure compliance with the relevant legal provisions, to minimize fiscal risk and to ensure in the same time the lowest level of tax burden.

General Aspects Regarding the Influence of Fiscal Reglementation on the Performance of a Company

Pintea Mirela-Oana

Universitatea Babeş-Bolyai Cluj-Napoca, Facultatea de Ştiinţe Economice şi Gestiunea Afacerilor

mirela.pintea@econ.ubbcluj.ro

Abstract

Taxation, by its nature, is closely linked to the economy and economic system. Everyday the economic entities experience the influences of fiscality and state over the course of their current activities through fiscal regulations because they can not ignore their role of contributor to the society in which they operate. This is precisely why businesses should conduct an analysis of the fiscal parameter that influence on their activity. Thus, a sound and efficient fiscal management is a critical variable in the economic entity's financial strategy.

Any operation conducted at the microeconomic level is subject to tax regulations in force, so we can safely assume that the activity at the microeconomic level is influenced both by direct taxation and indirect taxation as well. In this study, we tried to highlight how fiscal rules affect the functioning of economic entities and also their profitability.

Key words: fiscalty, fiscal reglementation, fiscal system, fiscal management.

J.E.L. classification: H20, H32.

1. Introduction

Fiscality is a reality of the everyday economic life, being a very important factor in the management of a company's revenues and expenses where it appearing under the form of taxes, fees and contributions paid by a company to public budgets.

Any operation conducted at the microeconomic level is subject to tax regulations in force, so we can safely assume that the activity at the microeconomic level is influenced both by direct taxation and indirect taxation as well. In this sense we can

divid the influences of fiscalty on economic entities into the following categories:

- taxation influences acting on all economic entities, regardless of how they treat taxation in business management (are influences that occur due to changes that arise from time to time in the tax law). The purpose to quantify these influences is to analyze and predict business performance scenarios depending on changing tax legislation.
- taxation influences acting only on companies which use taxation as an active tool in managing the company. In this context it appears the notion of fiscal management.

The objectives of the tax system in the national economy are materialized by providing the necessary resources to carry out state functions and tasks through tax levies, as well as providing the necessary means to exercise the public authority intervention in the economy, to correct market failures, to limit the effects of the economic crises or to prevent them. In the market economy conditions, the state can't make an intervention in the private sector through administrative methods but can use leverages provided by the tax system to achieve certain directions of the economic and social policy [5].

2. Aspects regarding fiscalty

So far there are at least two approaches to the concept of fiscalty, namely:

- a) Taxation is seen as all taxes and fees in a state.
- b) The second approach focuses on defining elements of the tax system in general and it defines it in terms of relations between the elements that form the system.

The first approach enjoys brevity and expressiveness, allowing an easier and more

efficient pragmatic analysis of the way in which fiscality is built and it is working within a country. So, according to this approach fiscality represents all taxes collected from individuals and businesses that supply public budgets [3].

By entering the second line approach, some authors believe that the tax system "comprises a set of concepts, principles, methods, processes on a lot of elements (like taxable matter, tax subjects) between which manifests relations arising from design, regulation, settlement and collection of taxes and that are managed under tax law in order to reach the system objectives" [13].

The tax system represents all taxes achieved through a mechanism based on the techniques, methods and tools specific for tracking and control the economic activity. The basic law of the state confirms the obligation of all citizens to contribute through taxes to public expenditure [9].

The approach regarding fiscality on international level has seen two major directions [1]:

- European continental approach, according to which the tax levies consist of taxes and contributions and there are conceptual differences in terms of content;
- Anglo-Saxon approach, according to which levies shall comprise all elements of a fiscal nature called "taxes" and their role is to provide the majority of the public revenue. There is no conceptual difference in the content.

The fiscal systems represent a key factor to influence the efficiency of the economy [6]. Gradually, with the development of society, the state diversified its role, reaching now to be a major player in the economic and social life. An increasing role of the state in economic life it is manifested through the following [12]:

- state intervention in economic life, either through regular behavior of an economic entity or by exercising its attributes of market regulator. In the first case the state can be the producer, consumer or intermediate and, in the second case, acts as the authority on monetary, financial and fiscal domains.
- state involvement in the economy at both the microeconomic and macroeconomic level. State involvement at the microeconomic level involves establishing

measures such as setting minimum or maximum prices, setting minimum wage limits etc. Involvement at macroeconomic level seeks to eliminate imbalances in the economy (inflation, unemployment and so on). This state involvement is achieved through monetary and fiscal policy.

Regardless of the approach, in all countries the taxes and social contributions have a major importance. According to the Romanian Constitution, Article 56 "All citizens have the obligation to contribute to public expenditure through taxes". Extrapolating this statement not only individuals but also economic entities are required to contribute with taxes to the income of the state. Thus, a "tax is a form of sampling a portion of the income and / or wealth of individuals and companies available to cover the costs of state government. This sampling is mandatory, grant and without a direct compensation of the state " [11].

3. Fiscal policies

Tax law was created and is corresponding to texts of different origin. For reasons of legitimacy and consent to tax, the law has long been privileged by creating the tax law, strengthening the rule of law in regulating sources.

The main sources of tax law are [9]:

- a) legal sources;
 - b) conventional sources;
 - c) regulatory sources;
 - d) jurisprudential sources.
- a) legislative sources are the main source of tax law. The law represents the act which has the main authority in fiscal matters. Certain tax provisions may be made by government ordinances, if the Parliament empowers the government to issue them.
- b) conventional sources are established through agreements, treaties and conventions. It stands out: the international conventions and the community provisions.
- c) regulatory sources are the administrative doctrine by which laws are filled to their implementation through decrees and ministerial orders at lower hierarchical level to laws. This regulatory power execution of tax laws is autonomous. Rules, instructions and circulars regarding enforcement rest with the Ministry of Finance.

d) jurisprudential sources are reasonings of fiscal nature by jurisdictions disputes and they often refer to taxpayers' appeals regarding interpretation of laws by the fiscal authorities (rules, instructions and circulars of the Ministry of Finance). Jurisprudence comes to correctly interpret the law and its implementing rules and to complete notions that the law has not defined precisely.

However taking into account the aspects mentioned above, any economic entity must define its fiscal policies. Fiscal policies represent a set of decisions, choices and actions at company level with the objective to achieve an optimal fiscal cost to match the company's aspirations or in other words they represent the concrete manner in which specific instruments and techniques are used to achieve the objectives of fiscal management.

Practically, fiscal policies have the following objectives [2]:

- “to ensure the fiscal security of the company, namely the compliance with the fiscal regulation of its field of activity;
- fiscal efficiency, namely paying and discounting of some taxable amounts as small in relation to the freedom of manoeuvre provided by fiscal regulations;
- to organize a fiscal management based on minimizing fiscal costs made according to the following structure:
 - the management cost for developing the information system and its operation for fiscal interest;
 - the actual financial cost consisting of the sum of fiscal expenditure regarding taxes, including income tax expenses;
 - the liquidity costs determined by the taxes settlement, costs of tax debts and costs on certain fixed terms of payment of taxes”.

At the level of an entity it is delimited and operates under effectiveness conditions a so called fiscal management at the same time with a commercial or financial management. "The existence of the enterprise fiscality generates the need for an information system to manage the numerous fiscal rules on the subject of taxation, base of taxation, tax rate, term of payment, facilities and fiscal penalties. Such a system must have a preventive and assuring character regarding

the fiscal rights, obligations and penalties for irregularities "[8].

The fiscal management is the art and science of applying methods, techniques and procedures in order to substantiate programs, to organize and coordinate the processes of collecting the fiscal incomes, in order to use efficiently the public money and to satisfy the society's needs.

The company has to define an autonomous fiscal policy, detached from the rest of the company, with a single and independent objective: research of the less taxable legal ways. When we refer to a company's efficiency we mean the extent to which it succeeds to achieve its objectives. So, fiscal management as well as commercial management and production management is integrated in business management and therefore it should be defined in terms of the objectives of general policy of the company or in relation to the strategy adopted.

4. The influences of the fiscal regulations on the performances of a company

Through taxes, the state wants to collect financial resources for the public budget. When it comes to businesses, taxes, representing a sampling of their available financial resources available to the state, have the effect of reducing economic and financial performance achieved [10]. And yet one wonders whether the state can use taxes as a determining factor in increasing the performance of an economic entity? The answer to this question is found studying the regulations that have been adopted over time in Romania, namely the use of tax as economic and financial leverage which aimed to influence in a positive manner different sides of the economic activity of firms.

The discounts or exemptions from income taxes have followed a double benefit for both state and businesses, so [10]:

- granting tax exemption for a certain period of time since the establishment of an entity (starting from 1991 until the year 2006) desired, from the state's point of view, the development of the private sector that could develop its business. The tax would be recovered indirectly as a result of taxation of higher future profits.

The benefit to the companies was that they remained with all profits, thus providing additional funding without cost.

- 50% reduction in profit amounts spent to finance investments aimed at making investments in the development and modernization of production technologies or to protect the environment (during 1995-2001) aimed to positively influence the investment behavior of economic entities and the realization by them of investment in environmental protection. The result aimed was to increase competitiveness of economic entities, to increase national investments and to protect the environment.
- income tax reduction for businesses that created jobs for the disabled, represented for the state an economic and financial measure that aimed the integration into the working environment for persons with disabilities (with benefits in terms of reducing the state costs with social protection for them). Following these jobs, businesses benefited from an additional source of funding, and, by reducing income tax to be payed, they obtained an increase in business profitability.
- charging a lower tax rate for profits obtained following the receipt of revenues in foreign currency represented an economic and financial leverage through which the state aimed an increase in the level of exports and the introduction of the foreign currency in the country. Traders who made exports could benefit from this facility through additional funding sources to benefit (difference between regular tax rate and reduced tax rate) or through the possibility of setting lower delivery prices.
- providing tax relief for businesses that invest significant savings aimed at increasing the capital invested in Romania, especially from external sources. The tax would be recovered indirectly from taxes on wages for jobs newly created, the future taxation of developed business, etc.
- providing a reduced tax for agriculture aimed to develop the agricultural sector in Romania, to increase investment in this area so that businesses could benefit from a tax reduction.

Analyzing these tax regulations one can find a common aspect, namely their influence in increasing the capacity of self-financing of economic entities which may cause an increase in their profitability by reducing income taxes payable to the state.

The tax system works on all businesses, therefore, its influence the economic and financial performance is manifested in all economic entities. State intervention through taxes on economic and financial performance of the companies has manifested as a consequence of the adoption of administrative measures. Among administrative measures with incidence on the company's fiscality who acted or acts in Romania can be remembered [10]:

- financial control and sanction tax evasion;
- application of valuation methods established by the state for fixed assets;
- establishing a system of depreciation of fixed assets without taking into account the specific the economic agents;
- granting exemptions, reductions, delays, deferrals of tax payments for certain economic entities;
- subsidies (negative taxes) etc.

The efficiency of the fiscal and financial control causes the creation of a competitive environment in terms of tax, being able to get higher financial – fiscal performances due to evasion removal.

Regarding granting tax exemptions, reductions, rescheduling, postponing for payment of taxes or subsidies only to certain economic entities, such measures have effects on economic entities and adversely affect the business environment.

Starting from the above, we may say that the reduction of the tax cost represents one of the main concerns of any company. This decrease may be done through good information on tax regulations in force, but, especially, by using tax mechanisms, for increasing a company's rate of return [7]. All this because fiscal management objectives take into consideration to ensure fiscal security and efficiency through research of form and substance prescriptions, delays, deferrals, exemptions imposed by tax law. In this way the entity is avoiding tax penalties and proceeds to a better allocation of its financial resources.

In market economy, the state can not make an intervention in the private sector

only through administrative methods but can use leverages provided by the tax system to achieve certain directions regarding the economic and social policy [5].

5. Conclusions

The organization, design and operation of fiscality lead to changes in social, economic and political environment. Therefore, fiscality must be assessed not only from a static perspective, but also from a dynamic one. Through its use as an instrument of political decisions, taxation is both generator and fruit of fiscal policy. This means that fiscality determines the operation of different sampling techniques and mechanisms for taxes for political, economic and / or social purposes.

Taking into consideration the fiscality is important and necessary because, from the way it is built and operates, conclusions can be drawn on the tax burden, fiscal policy and efficiency of the public authority involvement in economic and social life of a society. Taxation pursues the objectives of economic and social policy of the state.

Fiscal policy is developed not only at the macroeconomic level. Businesses, according to the strategy addressed, use tools and techniques that allow them to obtain tax advantages. In this respect, it is required to action towards reducing the tax burden both in absolute and in relative size (by reference to turnover) as well as cost and fiscal risk.

Testing for Sibex Market's Long-Term Memory

Pochea Maria-Miruna

„Babeş-Bolyai” University, Faculty of Economics and Business Administration
miruna.pochea@econ.ubbcluj.ro

Abstract

Long-term memory or long-term dependencies of financial time series' returns allows testing the efficiency of capital markets. This paper investigates the long-term memory in Sibex market by both static and dynamic approaches. Identifying the long-term memory in futures market can be useful for detecting arbitrage opportunities in this market and thus for managing portfolios of financial assets. For measuring the long-term dependencies we used the Generalized Hurst Exponent because it has the smallest estimation error compared to other methods. The implementation of GHE test on rolling windows allows for robust results concerning the degree of markets' informational efficiency in time.

Keywords: long-term dependencies, futures contracts, Generalized Hurst Exponent, informational efficiency, Sibex.

JEL Classification: G11, G13, G14,

1. Introduction

The crisis that started in 2007 in the U.S. and then spread to almost all regions of the world will have a major impact on economic sciences. Although history has given us many examples of financial crises which would have allowed for a view on the evolution of the current crisis, policy makers suffered from the syndrome "this time is different". Reinhart & Rogoff (2012) define the syndrome "this time is different" very simple: the principle on which is based is the belief that a financial crisis is something that happens to other people, other countries and other times; the crisis can't happen here and now. We make things better, we are smarter, we have learned

from the past mistakes. The old rules of valuation no longer apply. Based on the long history of financial crises of about eight hundred years, Reinhart and Rogoff demonstrate in their book that history tends to repeat and future governments and investors should contemplate before stating "this time is different" as it will almost never be. In this context we aim to identify the long-term memory in the most important futures market in Romania - Sibex. Mandelbrot and Wallis (1968) have called this feature of time series the "Joseph effect" referring to the biblical seven years of plenty that would be followed by seven years of dearth. The long-term memory of financial time series must be analyzed in the context of informational efficiency hypothesis.

The concept of efficiency is discussed in modern financial theory, as Bachelier (1900) intuited in his doctoral thesis by the early twentieth century. He recognizes that the "past, present and even the discounted future events are reflected in market price, but often it doesn't show an apparent connection with price changes." This identification of informational market efficiency determined Bachelier to continue: "if the market fails to predict its fluctuations, we consider it to be more or less likely, and this probability can be calculated mathematically." Bachelier's work was the driving force not only for Albert Einstein's concerns on Einstein-Wiener process of Brownian motion, but also for numerous discoveries in the financial world of the second half of the last century.

Unfortunately, Bachelier's contribution was overlooked for half a century until Samuelson (1965) has focused his research on informational efficiency and demonstrated in his paper "Proof that properly anticipated prices fluctuate randomly" that the prices in

the financial markets evolve randomly and are not connected. In essence, this means that prices follow a random walk process, which means that prices cannot be predicted. Subsequently, based on microeconomic approach of Samuelson, Fama developed the concept of informational efficiency. Fama, who is recognized as the father of efficient market hypothesis considers that the market is efficient in terms of information if the *prices always fully reflect all available information*, under the supposition that transaction costs and taxation are ignored and the information quickly penetrate the market and is freely available to all market participants.

Fama's definition (1965) of an efficient market is: “*An efficient market is defined as a market where there are large numbers of rational, profit-maximizers actively competing, with each trying to predict future market values of individual securities, and where important current information is almost freely available to all participants. In an efficient market, competition among the many intelligent participants leads to a situation where, at any point in time, actual prices of individual securities already reflect the effects of information based both on events that have already occurred and on events which, as of now, the market expects to take place in the future. In other words, in an efficient market at any point in time the actual price of a security will be a good estimate of its intrinsic value.*”

On an efficient market, prices fluctuate randomly and investors may not obtain consistent gains to compensate for the risk they have assumed. In such a market, the trading price reflects the *true theoretical value* of that title. If we could determine this real value, we will probably be able to obtain a higher profit by buying the asset when the price is too low and selling it when the price is too high.

2. Long-term dependencies

The main criticism of classical studies on informational efficiency is that statistical tests are focused on the analysis of the absolute informational efficiency. In other words, the results of these tests lead to the conclusion that the market is or is not weak-form efficient, but

provide no information on the degree of efficiency or inefficiency. This inconvenience has not allowed researchers to observe if there have been improvements in market efficiency over time or to make a quantitative comparison of the degree of efficiency between different markets. Yet, modern financial literature tries to identify possible factors (financial liberalization, market capitalization, market liquidity, setting price limits, institutional and technical changes, the impact of financial crises) that could determine a market to be efficient or inefficient.

In a study which critically approaches the traditional statistical tools used for testing the validity of the weak-form efficiency hypothesis, Saadi *et al.* (2006) recommend the use of empirical tests which are able to identify both linear and nonlinear financial time series dependencies.

In a similar study Lim *et al.* (2006) present relevant arguments in favor of nonlinear dependencies identified between international markets with different operating mechanisms. As the presence of nonlinearity contradicts the weak-form efficiency hypothesis, the empirical results concluded that all markets under analysis were inefficient.

There is no doubt that the concept of perfect efficiency is utopian, but it would be unfair to classify all markets as inefficient, regardless of their development stage. In this context it is expected that developed markets have higher efficiency degree than the emergent ones. This could be explained by the fact that a more detailed analysis realized by traders on higher liquidity markets should ensure a rapid elimination of arbitrage opportunities generated by either linear or nonlinear dependencies. That's why the new concept of *relative efficiency* referring to markets ranking according to their efficiency degree has been introduced in financial literature.

Campbell *et al.* (1997) noted that the market cannot be absolutely informational efficient because this is a benchmark intangible in practice. Campbell introduces the concept of *relative efficiency* which involves the establishment of the market efficiency degree rather than analyzing absolute efficiency which

ultimately reduces to choosing between efficiency and inefficiency.

In the financial literature, most studies are based on the idea that any deviation from a random walk process is a deviation from the hypothesis of informational efficiency. These deviations are caused by the presence of short and long memory. Even if most time series satisfy the stationarity assumptions they could present long-term dependencies which may be low in intensity but worthy of consideration.

Long-term memory or long-term dependencies can be tested using Hurst exponent. There are several methods for estimating the Hurst exponent: analysis of R/S Hurst proposed in 1951 and introduced in economics by Mandelbrot and Wallis in 1969, Geweke & Porter-Hudake method (1983), analysis of modified or generalized R/S (Lo A.W., 1991), fluctuations' analysis after removing trend (Peng *et al.*, 1994), the moving average method after eliminating trend (Alessio *et al.*, 2002), fluctuations' analysis after eliminating multifractal trend (Kantelhardt *et al.*, 2002) and generalized Hurst exponent (Di Matteo *et al.*, 2005). All these methods have both advantages and disadvantages, but for more accurate results we will use GHE test because it has the smallest estimation error compared to other methods. The implementation of GHE test on rolling windows allows for robust results concerning the markets' degree of informational efficiency over time.

3. Generalized Hurst Exponent

Generalized Hurst exponent was first proposed by Barabasi & Vicsek (1991) and resumed by Di Matteo *et al.* (2005) for financial time series. The Hurst exponent, which we simply denote H , is used as a measure of long-term memory of time series and his values can range between 0 and 1. Depending on the values taken by the Hurst exponent, financial time series are:

- *independent time series* if $H = 0,5$ or close to 0,5, the series follows a random walk process. In other words, the present has no impact on the future.

- *anti-persistent time series* if $0 < H < 0,5$, *i.e.* events are negatively correlated over time. Thus, if the price increased / decreased in the past, most likely it will decrease / increase in the future. Anti-persistent behavior depends on the intensity of H near 0;
- *persistent time series* if $0,5 < H < 1$. In a persistent time series an increase in value will most likely be followed by another increase while a decrease in value will most likely be followed by another decrease. Persistent behavior depends on the intensity of H near 1.

In a weak form informational efficient market, it will be impossible for an investor to predict the market price and gain systematic profits because the best prediction based on the historical data is the actual price and price variations are independent and identically distributed (i.i.d.). This implies the absence of serial correlation or in other words the absence of memory in stock prices, no information at time t or before this time being able to improve forecasting prices and returns. Consequently, a weak form informational efficient market is in a restrictive approach, a random walk process with a Hurst exponent equal to 0.5. If $H \in (0, 0,5)$ or $(0,5, 1)$, the market is not efficient because the time series' prices are strongly autocorrelated on long term, they contain useful information for determining the series future prices and they permit modeling the different lengths cycles in order for long term predictions to be relevant, as such allowing investors to "beat" the market.

Suppose that $X(t)$ is the logarithmic price of a futures contract at time t , where $t = \nu, 2\nu, \dots, k\nu, \dots, T$ with the observed period T and the fraction of time ν .

The detection of long-term dependencies and generalized Hurst exponent's estimation is based on the q order moment of the process's increases $X(t)$, $X(t) \equiv \ln(C_t)$:

$$K_q(\tau) = \left\langle |X(t+\tau) - X(t)|^q \right\rangle / \left\langle |X(t)|^q \right\rangle$$

following the law $K_q(\tau) \approx (\tau/\nu)^{qH(q)}$ where the time τ can vary between $\nu = 1$ day and τ_{\max} days. For $q=2$, $K_q(\tau)$ is proportional to the autocorrelation function $a(\tau) = \langle X(t+\tau)X(t) \rangle$. Following the model proposed by Di Matteo *et al.* (2005) we established $\tau_{\max} = 19$ and $q = 1$ for valuing $K_q(\tau)$. $H(1)$ describes the scale behavior of the absolute values of increases and it is expected for its value to be very close to the classic Hurst exponent. After obtaining several values of $K_1(\tau)$ for different τ , $H(1)$ can be estimated by running the following regression by the method of ordinary least squares: $\ln[K_1(\tau)] = a + H(1) \cdot \ln(\tau/\nu) + \eta$ where a is a constant, and η is a stochastic component.

Wald statistic, which follows a Chi-square law with one degree of freedom, is used to test the null hypothesis $H(1) = 0,5$ (the absence of long memory). The statistic is calculated according to the formula $W = \frac{(H(1) - 0,5)^2}{(SE)^2}$, SE is the standard error of the generalized Hurst exponent.

4. Data and empirical results

In our study, for empirically testing the efficiency of futures market we have used futures contracts on SIF5 as underlying asset (common stocks issued by SIF Oltenia S.A.), these being the most liquid futures contracts on Sibex. We have grouped the DESIF5 futures by maturity into four categories: 3 months, 6 months, 9 months and 12 months. The period under analyses is January 2005 - August 2011, resulting in a volume of 1541 observations for the futures contract with a maturity of 3 months, 1331 observations for the contract with a maturity of 6 months, 1,057 observations for the contract with a maturity of 9 months and 798 observations for the futures contract with a maturity of 12 months.

For testing the long range dependencies on DESIF5 futures market, we applied GHE test

both static and dynamic on rolling windows of 512 observations each, in order to observe the evolution over time of the prices' long term memory and implicitly the evolution of the weak-form futures market' efficiency degree. The results of GHE test are presented in the next table.

Table 1. Results of static GHE test

		H(1)	SE	W
DESIF5	3	0,563	0,0193	10,92765**
DESIF5	6	0,598	0,0121	65,59661**
DESIF5	9	0,58	0,0111	51,94384**
DESIF5	12	0,623	0,0184	44,68632**

Source: Authors' processing

Note: *** denotes significance at 1% level

** denotes significance at 5% level

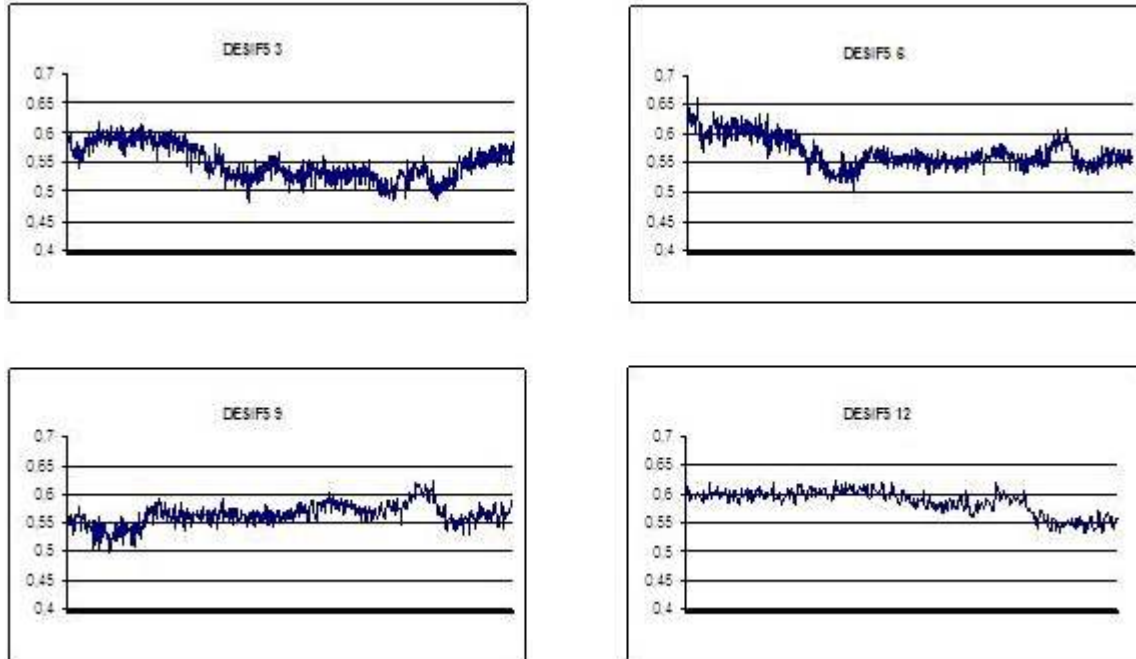

It is noted that for all four contracts reviewed, the market has a persistent behavior, long-term dependencies being indentified. The null hypothesis of the Wald test is being rejected at a significance level of 1% in all cases (Wald test critical values are: 6.6 (1%) and 3.8 (5%)). Generalized Hurst exponent takes values between 0.5638 for DESIF5 contract with a maturity of 3 months and 0.623 for the one with a maturity of 12 months. The values of Hurst exponent indicate an increase of efficiency for DESIF5 futures contract with a maturity of 3months and a decrease of efficiency for the contract with a maturity of 12 months. The explanation could be that the liquidity of the contract with a maturity of 3 months is much higher than the one of the contract with a maturity of 12 month.

The implementation of GHE test on rolling windows allows for robust results concerning the degree of markets' informational efficiency in time. The length of a window is 512 observations because this is the number of observations established by the financial literature. The values of Generalized Hurst exponent were initially estimated using the first 512 observations and then removed the first one and added the following maintaining the window's length unchanged. The procedure

was repeated until the last observation was used. The values obtained are represented in figure 1. It is noted that long memory is present in all DESIF5 contracts, *i.e.* temporal variation

of the generalized Hurst exponent shows a stable behavior reflected by episodes of persistence.

Figure 1. The time evolution of $H(1)$ of GHE test on rolling windows

Source: Authors' processing

The GHE test' results applied over the entire period, as well as over rolling windows, reflect the acceptance of long memory hypothesis for all four contracts over all the analyzed period. The results of this study show that the efficiency of the market is not a static concept and that its intensity can vary over time.

5. Conclusions

The investors on futures market may be interested in determining the degree of market efficiency because it can provide useful information in order to adopt hedging or arbitrage strategies, to minimize their risk and to maximize their gain.

After applying the GHE test both static and dynamic for testing the Sibex market's long-term memory, we found that the market presents a persistent behavior, so it has a long memory for all four groups of contracts.

The identification of long-term dependencies in the Sibex market's series of futures prices reflects the fact that this market has a certain degree of predictability which investors could exploit.

Futures market in Romania has grown considerably in recent years offering investment opportunities, portfolio diversification and hedging for investors that operate both nationally and globally and we hope to continue on the same line in the future.

Abstract

The problem regarding the financial performance of the companies is related not only with the critical examination of them, but also with the evaluation realized by the audit team regarding company’s financial statements. As a fact, the lower the financial performance is, more importance to audit practices is conferred. This study is going to evaluate the performance of companies by calculating the Z score using the Anghel Function. The sample is used by evaluating the companies from the BSE (Bucharest Stock Exchange). As the model is pointing out the companies that obtained higher or lower performance, the financial audit is also important to the present context.

Key words: key words financial audit, financial performance, accounting principles, discriminant analysis, z score

JEL Classification: M40

1. Introduction

Companies' performance is very important as it can influence both the decisions taken by the managers and the decisions taken by the investors. Moreover, the reason for choosing to evaluate the financial performance of the companies is essential if the macroeconomic environment is considered. From the practical point of view, quantifying financial performance of the companies can be influence by the decision given by financial auditors. As a

fact, there is a strong correlation between the financial performance obtained by companies and the audit as the last one has to realize more valuation models if the performance is getting worst. Not only could the auditors be responsible for unreliable information, but also the managers who can modify the financial elements in order to obtain higher benefits besides their normal remuneration.

Taking these elements into consideration, we considered that the performance of the companies can be both influence by the way the financial data are audited and moreover, the way that each element from the balance sheet and the profit and loss account is reported during a financial period.

2. Literature review

The problem regarding the financial performance evaluation is considered to be one of the main activities through the economic environment. The anticipation regarding the changes that can appear in the economic environment is difficult to establish, and that is way a proper evaluation of the performance obtained by companies is necessary. As there are several problems regarding the definition of financial performance, the decisions taken by the audit are essential as they definitely influence the behaviour of each stakeholder.

The main literature is focusing on point out that the performance is best measured by supervised pattern recognition technique. FitzPatrick, P. J. (1932) [1] is considered to be the first who realised that financial ratio presented important changes with 3 years

before the bankruptcy of the company. Winakor, A. și Smith, R.F. (1935) [2] obtained same conclusion, as financial ratio decrease, in a 10 year, period while the performance got worst. However, Beaver, W. H. (1967) [3] is considered to be the proposer of discriminant analysis technique as he try to identify a way through which could be explain why the company cannot pay its debts and why this fact is followed by bankruptcy. The risk analysed was introduced by measuring the proportion of each financial indicator realized.

An important changed happed in 1968, when Altman, E. I. (1968) [4] emphasis the difference between one varied and multiple varied models of discriminant analysis he is the first one who applies the pattern recognition technique and moreover the person who introduce the scoring method in order to realize a separation between healthy companies and companies that have important problems. After that, several studies had been realized in order to improve the Altman Model or that pointed out other way of calculating the probability of bankruptcy of the companies like Altman, E, Handelman, R, Narayanan, P (1977) [5], Deakin, E.B (1972) [6], Edminster, R.O (1972) [7], Taffler, R.J (1982) [8] , Conan, J, Holder, M (1979) [9].

Not only the foreign literature is emphases the importance of establishing some ratios with which the low performance evolution of the company could be identified. As a fact, the Romanian literature also points out the importance of supervised pattern recognition. Dinu E,Curea S.C (2009) [10] releaed that the classical fundamental analysis and the Technical one perform poorly upon the assessment of the company's performance that the technique made by discriminant analysis as the last one can reflect specific factors that are related with the economic crisis.

One of the most relevant models to Romanian economy was realised by Anghel, I. (2002) [11] who used 276 enterprises from 12 sectors of national economy. The study has one particular situation, as it includes not only the companies that were deployed for bankruptcy, but also firms in default, companies with a critical limit of payments or institutions which have consecutive losses. Moreover, regarding the supervised pattern

recognition, other models have been realised upon the Romanian market, like Manecuta, C, Nicolae, M (1996) model [12], Ivoniciu (1998) [13] , Bailesteanu , G (1998) [14], Statev I. V (2006) [15], Sajin, P (2010) [16].

As the current paper is focusing also on the connection between audit and financial performance, we considered that is it important to illustrate some researches in the field. As a fact, Chin-Fook Yap , B, Gun-Fie Yong, D, Poon, W. C (2010) [17] identified that financial indicators often appear in the auditor reports and moreover, that the ratio analysis and the bankruptcy prediction models are useful for financial auditors as they are required to approve if a company has the ability to continue its existence or not.

Eldridge, S and all (2012)[18] emphasis that the changes in auditor activity can increase financial distress variables as these changes can be percept a way of decreasing the performance of companies' main indicators. Mironciuc, Robu& Robu (2012) [19] point out that financial auditor is important in order to detect financial fraud which could be obtained by manipulating financial indicators that the company report in order to prove that it has realized a better financial performance than that obtain in the previous financial reporting period.

Moreover, Spathis et all. (2007) [20] used the discriminant analysis in order to predict the auditors opinion, while Höglund, H (2007) [21] considers that there are insufficient qualified auditors opinion in order to perform a discriminant analysis for predicting the auditors opinion, while the connection between it and financial performance could not be denied. Several studies have also strengthened the connection between financial performance and auditors reaction, like Dang, L (2004) [22], Al- jabali, MA Abdalmanam, O, Ziadat, K. N (2011) [23].

3. Methodology

As the connection between the performance measured through financial indicators and the auditors cannot be omitted, an analysis was realise in these research upon this problem on the Romanian Market. Due to it, the companies listed on the Bucharest Stock Exchange were analysed by calculating the Z score established by Anghel. The

discriminant function calculated by Anghel was realized in 2002. As several financial problems have been observed through the last years due to the economic crisis, we wanted to point out how the performance quantified using a 10 years performance function is still valid when the Romanian Economic background is considered.

The data used is from the Bucharest Stock of exchange and moreover from the site of each company listed, as some information in order to determine the Z Anghel score could not be identified on sites that provide financial information.

The Anghel Z score is calculated using the formula that is trying to identify the performance of the companies using for financial indicators. As a fact, these indicators are as follow: the ratio between net profit and total revenues as a measure of income profitability rate, the ratio between cash flow and total assets as a measure of covering the company's debt with cash flow, the ratio between total debts and total assets as a measure of debt-asset ratio and the ratio between debts and turnover of the company multiply by 360 as a measure of rate that quantifies the payment of liabilities that the company has. The importance of cash flow is also pointed out by Oancea-Negescu, M.D. and Cismanu, I.D. (2009) [25] as it can offer proper information about the performance that companies on the Romanian market can obtaine.

The Anghel function can be summarize in the following form

$$Z=5,676+6,371*X1+5,393*X2-5,1427*X3-0,0105X4$$

Where the elements X1 to X4 reflect the indicators mention above.

Moreover, as the performance was quantify by using this function, a correlation with the audit standards was realised as there are some important elements that have to be taken into consideration.

The idea of research is based on the fact that there are some accounting principles that have to be analysed and to considere how the company is going to perform its future activity.

The data analyse do not include the companies that are financial institution as their reporting form of financial statement is

different from the companies perspective, as the elements that are considered assets for companies are considered liabilities for bank and also the assets that could be identified in the financial statements of financial institution could be liabilities for companies. Nonetheless, the investment societies were not considered as their financial results are somehow under-evaluated by the market so not a proper evaluation of their performance could be realised.

4. Results obtained and the connection with the auditors' activity

Results obtained are really important as a connection with the auditor activity should be definitely realised. First of all, the international audit standard 570 point out that the principle for the persistent and continuous activity is essential in order to give a proper evaluation of the company's activity. As a fact, all factors that asses the degree of uncertainty associated with the financial results- depending on the event that occur and influence them should be evaluated. As a fact, the auditor has to obtain adequate evidence regarding the efficient use of this principle by the managers when the financial statements are realized. They should obtain conclusion of the existence of a significant uncertainly that may affect the ability of the company to continue its own activity. As a fact, the Z score can be a relevant measure of the performance obtained by the company. The explication that the Anghel Score was used is based on the fact that the analysis of the cash flow obtained by the company is essential in order to give proper information about its performance.

The idea of research was to illustrate the performance for listed companies on the Bucharest stock of Exchange. Actually, from the total number only 54 companies were analysed, as 12 companies do not provide all the financial data needed for calculating the Z score, the investment societies were excluded and also the banks.

Taking these elements into consideration, we considered that a descriptive statistic of the indicators use and of the Z score calculation should be provided in order to illustrate the evolution of the market.

Table no 1. Descriptive statistic for the elements used and for the Z score

Variable	X1	X2	X3	X4	Z
Minimum	-3,587728	-0,554205	0,000012	0,000092	-22,906314
Maximum	0,880134	0,180497	1,251659	7,773837	10,987060
Average	-0,089439	-0,001435	0,394322	1,006631	3,059995

Source: Own calculation

As it can be seen the table presents the lowest and highest values obtained for the ratio analysed and also for the final variable which is the Z score. In order to reveal who obtained these values, we consider necessary to realize another table.

Table no. 2. The highest and lowest values for the indicator analysed and the companies that obtained them

Variable	Highest value	Company	Lowest value	Company
X1	0,880134171	FP	-3,587727687	CGC
X2	0,180496535	VNC	-0,554205093	BVB
X3	1,251659173	MJM	1,18719E-05	BCM
X4	7,773836667	IMP	9,15347E-05	BCM
Z	10,98705991	FP	-22,90631437	CGC

Source: Own calculation

Moreover, in order to evaluate the performance of the company, by calculating the Z score established by Anghel (2002), the results were presented also in a table as it is considered to be the easiest way of reporting.

Table no. 3. Number of companies that have high/low performance

Indicator	High performance	Indecision	Low performance
Number	41	4	9

Source: Own calculation

As it can be seen, the companies listed on the Bucharest Stock of Exchange are generally characterized by high financial performance, while some are dealing with several financial problems as their Z score is under the critical value 0. The companies that are in the indecision area could improve of decrease their financial performance, the

final result depending not only by the decisions taken by their managers, but also by the way they decide to report their financial statements.

Regarding the audit and the performance size of our study, there is another element that has to be taken into consideration. Considering the international audit standard 560, the auditor is not responsible for elements that appear after the auditor’s report and he it is not mandatory for him to reevaluate the financial situation of the companies audited. If the indicator that affects the financial situation of the company manifest its influence before the audit report is published, than the audit should discuss the situation with the managers and director of the company, regarding the way the indicator affects the financial situations and moreover if a there is a need of a necessary modification. When the indicator manifest its influence upon the audit report has been published, similar analyse should be realized in order to point out how the new element influence the total performance obtained by the company.

Moreover, in order to give a reliable opinion by the audit team, they have to analyse the credibility of the previous audit and financial situation reports taking into account the accounting policies that were applied, without eliminating the contingencies and commitments existent.

5. Discussion about the result obtained

The problem regarding the Anghel model is that even it has a 95 % probability of identifying the default and the bankruptcy problems is that is not offering a descriptive statistic of discriminant function values and it does not specify the weight of sample tested that is in the area of uncertainty so no comparison with the results obtained by its author could be realised. Other problems regarding this model are related to the fact that only the financial element of the companies were analysed, without considering the other element like social aspects, corporate governance ones could influence the performance of the companies. Moreover, the model does not consider the differences that can appear between different sectors.

Another problem is related with the fact, that even though there are general principles that guide the auditors behaviour, their practical activity still has some ambiguous information as not a truly detailed report about the company's financial performance is presented to the shareholders of the company.

Other problems that appeared and influence the results obtained are the way companies do not report their primary financial data even though they are listed on the Bucharest Stock of exchange, so the level of transparency is lower than it should be. Moreover, there is not a proper way of reporting and the consequence is that the way of collecting the financial data is difficult.

As a fact, further reached is going to be established by realising a discriminant function for the companies listed using both the financial and social elements for the companies, by considering if the influence of industry affects the performance of the companies and moreover, by validating the result with sample from other industries and also with the evolution of the stock price evolution.

5. Conclusions

In the main literature, there is no acceptance referring to the way “performance” can be defined as there could be used not only classical indicators, but also modern concepts that include value added and market valuation. It is however considered that the patterned recognition method offers better evaluation of company's performance as it can surprise the influence of factors during a financial crisis.

The researched made tried to point out how the performance is measured using the Anghel Z Score for the companies that are listed on the Bucharest Stock of Exchange. The conclusion of the performance analysed was that approximately 76% from the companies listed are considered having no problems when the performance concept is evaluated, 7,4% are in the indecision area, while 16.6% from the companies analysed are considered having important financial problems as their performance level is under the critical value. Moreover, the research tried to establish a connection between the performance obtained and the audit practices

and we have concluded that the auditors should evaluate the performance taking the credibility of financial data into account and nonetheless that it could be not their fault if unreliable financial information is provided by the managers of the company [26] As a fact, as long as the auditors applied the international audit standards, the way they evaluate the performance and the credibility of data provided by the company could not be questioned.

The Financial Action Task Force and Combating Financing of the Terrorism in Romania

Popa George Dorel
Ovidius University from Constanța
Faculty of Law, Public Administration and Sociology
popageorgedrd@yahoo.com

Abstract

After the tragic events of September 11, 2001, at international level, have been taken important decisions to combat terrorist financing. Today, the phenomenon of terrorism has become a global threat due to factors such as globalization of national economies, multinational companies, bank trusts existence, development of information technology and "shorter" distances between different countries. Terrorism tends to have a planetary character given by the highly developed international relations and economic interdependence between countries of the world. To those factors, appeared the ethnic and religious tensions in some parts of the world.

Keywords: combating financing, terrorism, financial action, globalization, economy

J.E.L. Classification: Law and Economics General; K 30

(FATF) is an inter-governmental body established in 1989. The Objectives of the FATF is to set standards and promote effective implementation of legal, regulatory and operational measures for combating money laundering, terrorist financing and other related threats to the integrity of the international financial system. Money laundering, terrorist financing and the financing of the proliferation of weapons of mass destruction is serious threats to security and the integrity of the financial system [2]. The FATF Special Recommendations are adopted periodically on protection of the integrity of the global financial system. The FATF standards have been periodically revised to strengthen global further safeguards and protect the integrity of the financial system. FATF provide governments with tools to take action against financial crimes. At the same time, these standards set priority areas such as corruption and tax crimes [3].

Introduction

As member of NATO and European Union, Romania has a number of obligations in the area of security in the Black Sea region, and thus has taken important steps to ensure the safety of external borders and took a series of legislative measures to counter terrorism and other additional crimes.

The Financial Action Task Force and terrorism.

In this international context, different countries of the world started to block terrorists' financial resources and limited access to financial systems[1]. In this are an important actor isThe Financial Action Task Force. The Financial Action Task Force

Romania and the fight against financing of terrorism

Following the FATF recommendations Romania established in the last 10-11 years law regulations in this domain. According to the law 535/2004 acts of terrorism can take the form of several offenses covered by the the Romanian Penal Code and other special acts.Romanian law details the specific procedural steps in order to gather information on terrorist acts, and the responsibilities for different law enforcement bodies. The adopted acts also prohibits financial and banking operations in order to finance terrorism on Romanian territories. In Romania, the tools to combat terrorist financing are similar to those used for money laundering: standard methods to "scan"customer, continuous monitoring of

specific transactions (e.g. rapid transfer of money transfers having “unknown” destination) and transfers of money from individuals located in countries with a high risk of terrorism. Under these circumstances, it is necessary that banks and other financial intermediaries to pay special attention on nonprofits and charities organizations or operations related to this organizations. Under the provisions of Law no. 656/2002 on preventing and combating money laundering, the National Office for Preventing and Combating Money Laundering received data and information continuously on persons suspected of financing terrorism. Furthermore, the Office has received from Financial Crimes Enforcement Network - United States, several requests for information on people who are being investigated by the FBI and are suspected to be related to the terrorist attacks on the U.S. in 2001. That list has been sent to the Romanian authorities and competent institutions in fighting and preventing recycling of funds. Office searches in its own database and other database and established that people on the list of Federal Bureau of Investigation have no track on financial activities, or other activities in Romania. Office responded also to different questions coming from other European Union partner about persons suspected on financing terrorist organizations. Investigations undertaken by the Office concluded the lack evidences about criminal financial activities undertaken by terrorists through the Romanian banking system. At the same time, the Office has received reports of suspicious transactions submitted by banks on various strangers on the transfer of funds without commercial justification. Their intention was to transfer funds from countries with high terrorist risk using Canada, U.S. and Romania. After checking performed by the Romanian authorities, the initial issues were not confirmed. After the events from September 11, 2001, when attacking civilian targets in the United States caused thousands of civilian casualties, the conflict approach by the allies in NATO fundamentally changed. Because terrorist organizations are actually armed groups that have a specific organization, weapons and other military equipment, they cannot function without the financial and material resources. Hence, one

of the most effective ways to prevent and combat terrorist threat is to eliminate their financial sources [4].

Security Council of the United Nations after September 11, 2001, drew up a list of 372 individuals and companies suspected of funding some action or terrorist groups. After the United Nations called on Member States, all countries blocked the accounts of these people and also forbidden any financial transaction of these persons and companies.

Romania has issued Law 159/2001 on preventing and combating banking sphere system for financing acts of terrorism, law covered all the recommendations of the United Nation Security Council.

Therefore, a person who collects funds directly or indirectly, knowing that these funds will be used for acts of terrorism, will be punished with imprisonment from 5 to 20 years. In the same way is sanctioned the person who performs acts of terrorism financing funds. Romanian law forbids any operations banking sphere persons mentioned in the United Nation list. The list is periodically renews based on information received from United Nation and other Romanian or foreign institutions involved in combating terrorism.

Conclusions

Romania as a member of the international community has a duty to combat the scourge of terrorism. From this point of view, Romania will always cooperate with other countries but also with international organizations with interests in this area. Cooperation will take place in multiple areas. Perhaps the most important area is to harmonize the future Romanian legislation with the international recommendations and to implement the best practices regarding the financing of terrorism.

Abstract

The present paper aims to highlight the main aspects of tax evasion and the causes of economic and financial crime. The main theme is of interest by its actuality. It seems that the economic and financial crime is "fashionable" as demonstrates the upward trend in various fields in which now is manifested, making difficult to limit the scams and the frauds

Keywords: economic, financial, crime, banking, tax evasion

J.E.L.Classification: K 30

Introduction

Various studies and analyzes made over the time demonstrates that these phenomena exist from the contemporary era, but in Romania occurred preponderant since 1989. Economic and financial crimes, aimed the fields such as construction, petroleum products trading, and trading in tobacco and alcohol, leading even to tourism, so the volume of tax evasion has grown exponentially from that period. For example, a study by the former National Agency for Control shows that in 2004, tax evasion reached a volume of approximately two billion.

Thus the problem of tax evasion gets a major interest in Romania, primarily due to the existence of the economies severe lack of capital, which led to the creation of legal tax avoidance, or rather to tolerate it.

A concrete example in this regard is imposing the income of certain categories of individuals on the basis of average normal

income tax, that creates conditions for taxpayers with incomes higher than the average, not to pay the tax difference.

Another example is the businesses in certain sectors of the economy, the establishment or during the development activities, in the form of exemptions from VAT for the activities of export tax, excise, etc. or tax cuts.

Regarding illegal tax evasion, among the most frequent cases are falsifying the balance sheet as a means to defraud the IRS, which requires an agreement between the owner and chief accountant. Therefore they are held jointly and severally liable for the offense committed. Reduce taxable matter results of reducing turnover by registering in unit costs of personal expenses of the employers. Another example of illegal tax evasion is recording the common outstanding expenses, or execution of a double register of real and one dummy copy, or even shift in personal accounts of parts of the benefit, the composition of false accounting register, and so on.

It should be noted that although the theoretical approaches tax evasion is linked to money laundering process, the two are distinct phenomena: tax evasion involves stealing by any means, in whole or in part by the payment of taxes and other amounts owed to the state budget, local budgets and state social insurance budget and extra-budgetary special funds, by natural and legal persons, Romanian or foreign, instead that the money laundering is an financial economic process which ranks opposite position, namely profit obtained illegally, apparently wants to receive legal income. Therefore, from this perspective, individuals involved in tax evasion offenses reveals

much higher incomes in accounting than they actually achieved, while operators involved in economic financial activity such as money laundering, reports regularly returns much higher than the real ones.

The current system analysis highlighted, that widespread manifestation of tax offenses is determined and made by a number of factors, among which we have: size of the tax levy, tax sanctions policy, and the preparation and organization of the fiscal. Regarding the size of a tax levy, this is about taxes whose rates are too high in relation to the taxes. For these reasons taxpayers, people are required to pay these taxes State are tempted to not honor its payments to the state budget, to the social security budget and health assurance In terms of sanctions, they are in the form of fines and penalties. The State raises income levels of the budget by collecting fines and penalties, the raised number and the high level of penalties and fines may result in a financial jam and finally to the closure of several economic units. The preparation and organization of the fiscal system also influences specifically the manifestation of these criminal phenomena.

As a specific and new phenomenon, with the multiplication of bank units and the demand for services from people to these institutions we have a picture of the financial banking crimes. The particular interest to this kind of crime is aroused by the fact that this sector should be the greatest transparency, but the reality is totally opposite. To better analyze this type of crime, it will be analyzed in terms of legal criminal issues. In December 1989, the 58th Interpol General Assembly session was centered on the analysis of the illegal international financial transaction systems. Such "underground" banking systems dates back a long time, probably before the advent of banking systems in current acceptance and apparently originated in the Orient.

Underground banking system involves transferring without traces, in various banking areas, large sums of money bypassing legal procedures, especially in those countries that have no regulations on foreign exchange control. The reasons for using this system are different from sending small amounts of money to relatives in poor countries, tax evasion and financing major crime - political or religious terrorism, arms

and drug trafficking. Name under which it is known this system varies from one area to another: "chop shop" in Chinese, "Hund" or "Hawalli" the Indian sub-continent and "stash house" in Latin America. The term "chop" is the name given to a document so important that could replace the receipt and "Hawalli" is one word in dialect "Urdu" which means "reference recommendation" and not least "hund" which means "trust" in Hindi.

We can say that by the organization and operation statutes each banking company sets their own ways of working in the field, but you must follow certain mandatory rules which generally apply to all companies with this profile. From this perspective, we will keep under review the compliance of the main legal norms governing banking business and the banking companies in Romania - Law no. 58/1989 [1].Legislature has not provided for in the Law on banking activity, excepting the banking discipline violations, distinct crimes may be committed in this area, which can occur in practice due to the large amounts they operate, especially as forgery and use of forgery as well as deception.

A widespread phenomenon faced by banking companies is the issue, to limit the amount of checks without cover, by some economic agents. In January 1992 the General Accounting Directorate and statements of the National Bank issued a regulation on interbank settlements, completed in June 1992 and the end of 1993. The current regulation is provided by the interbank rules settlement no. 1 from 24 January 2000 [2] on the procedure for the declaration of interbank operations of banks in special settlement regime. This Regulation provides for deadlines and concrete ways in which banks can settle units, regulating the financial relations between economic agents.

Another interesting aspect to note is that the actual national legislation [3], regulating financial activities that can be undertaken by banks, some of these activities as well as some accepting deposits from the public funds, loans, transfers of accounts payments and reimbursements, and even their own transactions on behalf of clients or negotiable monetary instruments, checks, promissory notes, certificates of deposit [4] etc. This poor bank management encourages corruption among officials of the

departments of verification, forecast and control [5]. Also faulty management of bank assets has led to the possibility of laundering large sums of money [6].

In connection with the prevention and sanctioning of money laundering activities, they came under Law no. 21/1991, repealed by Act No. 656/2002 published M. Oh. No. 904 of 12 December 2002. With this law was founded National Office for Prevention and Control of Money Laundering.

Rules provided by Law no. 21/1991 are supplemented with the Law No 78/2000 on preventing, discovering and sanctioning corruption. According to Law no.21/1991 the meaning of money laundering is mentioned in art. 23 - some of these provisions are: concealment or disguise of the true nature of origin, location, disposition, movement or ownership or rights over their property, knowing that the goods come from committing crimes or other acts described in this article is the acquisition, possession or use of property, knowing that they come from committing crimes - or by legal or natural persons referred to in Article 8, including: real estate agents, casinos, credit institutions and branches of credit institutions in Romania foreign private pension fund managers, individuals involved in the privatization process, other natural or legal persons trading in goods and / or services [7].

Knowing all legal requirements is essential, even more as the business world is constantly pursuing delinquent act closer to the edge of the law, to cover his actions as much as possible, through a pseudo-legality to inspire confidence and research evade judicial bodies.

Conclusions

The economic and financial crime can be avoided only by perfecting and improving the content of the law that made it possible [8]. In the absence of an appropriate legislative framework to the socio-economic reality, these crimes will continue. The main factors that led to the enhancing of the phenomena should be close observed and permanently taken the legal, administrative and financial measures.

Features of Budget Execution in Public Institutions’ Budgets Entirely Funded by Public and Local Budgets; Case Study in an Educational Institution

Popa Ionela

”Constatin Brâncoveanu” University of Pitești
popaionela80@yahoo.com

Abstract

Budgeting, a set of steps taken by state competent bodies in order to materialize the financial policy applied by governmental authority, takes place in the following stages: setting out the budget statement, approving the budget, budget execution, budget execution completion, controlling and approving budget execution completion.

Budget execution is described in specialized literature especially as a stage in the budgeting process in the components of the national public budget (public budget, social insurance budget, budgets of territorial administrative units).

The present paper aims at highlighting several features of how budget execution takes place in the budgets of public institutions which are entirely funded by the public budget and local budgets.

Key words: budget, budgeting process, budget execution, revenues, expenses.

J.E.L. classification: H61, I22

1. Introduction

Law 500/2002 of Public Finance defines the **general consolidated budget** as all budgets that are part of the budget system, aggregate and consolidated to make up a whole”. The components of the public budget are also highlighted by the law: public budget; state social insurance budget; special fund budgets; state treasury budget; budgets of public autonomous institutions; budgets of public institutions funded totally or partially by the public budget; public institutions’ budgets entirely funded by own revenues; fund budget from foreign loans contracted or guaranteed by the state, and whose refunding, interests and other costs are provided by

public funds; budget of non-reimbursable foreign funds.

The totality of consecutive stages for the preparation, approval, execution, control and reporting of the budget ending with the approval of the general budget execution account is called a budgeting process.

The present paper seeks to emphasize several features of the budget execution stage in one of the budget components mentioned above: public institutions’ budgets totally or partially funded by the public budget, state social insurance budget and special fund budgets.

2. Features of the budget execution in educational institutions

The budgeting process, namely all the steps taken by the state’s competent bodies in order to implement the financial policy of the governmental authority, takes place in the stages below: preparing the budget statement, approving the budget, budget execution, budget execution completion, controlling and approving the completion of budget execution.

Budget execution is that stage of the budgeting process including the collection of budget revenues and the payment for the expenses approved by the budget.

In educational institutions that act as legal entities, the budget execution has several features.

A. Execution of budget revenues

As far as the revenues of educational institutions acting as legal entities are concerned, Law 1/2011 of National Education sets out that the financing of preuniversity educational institutions comprises basic financing, complementary financing and additional financing.

Basic financing comes from the public

budget, more precisely from amounts broken down from VAT and other public budget revenues based on an indicator, the standard cost per pupil/preschooler, calculated in compliance with the methodology laid down by the Ministry of Education, Research, Youth, and Sports and ensures the good development of education practices. Basic financing covers the running expenses of educational establishments.

Complementary financing provides capital expenditure, social expenses and others related to public preuniversity education practices. The law of education states this type of financing comes from the local budgets of territorial and administrative divisions the preuniversity educational institutions belong to, and from amounts broken down from the VAT. As to these aspects, the author believes that ensuring the necessary funds for capital expenditure (investment, major repairing etc.), for social expenses (teachers' commuting costs, social aids, pupils' transportation, pupils' assessment etc.) and for other types of costs related to educational practices is difficult enough. On one hand, one considers the current development of budget indicators in Romania with a significant difference between revenues and expenses which limits the value of public budget transfers, and on the other hand, one takes account of the lack of legal provisions designed to force the budgets of territorial and administrative divisions to be part of educational establishments' funds. Specifically, the public budget over the last years has only ensured the financing of running expenses in educational institutions whereas local budgets do not have the legal but the moral duty to help finance the educational establishments within the town/village jurisdiction.

The third type, additional financing, is provided as a fixed lump sum of money by the budget of the Ministry of Education, Research, Youth, and Sports meant to reward public preuniversity educational establishments which have had the best outcomes in terms of mainstreaming or school performance.

B. Execution of budget expenditure

The expenses incurred from the budgets

of preuniversity education institutions in Romania have lately envisaged the following destinations: personnel expenses, material expenses, scholarship expenses, and capital expenditure.

Each expense category involves the observation of specific stages set out by operational procedures prepared by authorized people in the educational institutions.

Thus, personnel expenses are funded by the public budget by means of local budgets and they are calculated based on certain softwares for education personnel's salaries. At present, the function is performed by Edusal Programme conceived for the computer-assisted records of education institution personnel as it includes all the necessary features to calculate personnel salaries.

Material expenses are funded by the public budget from shares broken down from the VAT by means of the local budget (basic financing) and also from the revenues of territorial and administrative divisions.

The main classes of material expenses are shown in the table below:

*Table 1:
Classes of expenses in the budgets of
educational institutions having legal
liabilities*

Number	Indicator code*	Indicator
1	2001	Goods and services
2	200101	Office furniture/equipment
3	200102	Cleaning materials
4	200103	Central heating, lighting, movement
5	200104	Water and sanitation
6	200108	Postage, telecommunications, radio,TV, Internet
7	2002	Current repair works
8	2005	Goods in the form of small inventory
9	2006	Movements, relocations, transfers
10	2011	Books, papers, documentary materials
11	2014	Employee safety
	2030	Other expenses

Source: Made by the author

* - Indicator codes are detailed in accordance with the Classification of Public Finance in force for the year 2012, approved by Order no.1954/16.12.2005 including subsequent amendments and additions.

The expenses incurred in public institutions are subject to specific procedures according to the way they have been contracted. Thus, for expenses related to utilities, the contract concluded between the parties (contracting authority and goods supplier/service provider) and the invoice are the legal basis of the operations associated with expenses (commitment, liquidation, payment instruction and payment). The other classes of expenses must be carried out by acquisition procedures set out in Emergency Ordinance 34/2006 regarding the allocation of public acquisition contracts: public auction, restricted auction, negotiation, competitive interaction, inquiry, offer contest, direct acquisition. Irrespective of the procedure underlying public acquisitions, it must be justified by special documents: purchase requisition, purchase explanatory note, order note, receipt and difference finding note, consumption voucher, individual delivery-receipt protocol etc.

The payment of bills for the purchased goods, rendered services or works is made by public institutions during the 24th-the31st day of each month. In compliance with the provisions in Order of the Ministry of Public Finance no.2281/ 2009, liability for the payment of bills representing goods purchased, services rendered or works performed outside the previously stated period is held by the budget manager.

3. Conclusions

The actions taken to finance preuniversity public education have been oriented towards the preparation of a unified, coherent system for making up financing sources and transparently allocating the funds needed in every educational establishment, in order to ensure the proper conditions for the high quality of the entire educational process.

Based on the principle of decentralization, the reforms in school management and education financing have resulted in a new method for preuniversity education financing.

The financing of preuniversity public

education has been regarded in a reticent manner by the people involved (especially teachers). Their main fears were that the funds originally allocated to their salaries might have had other directions, that mayors would roughly interfere with school activities and personnel policies, and that local budgets would not be able to ensure resources for schools' material and development expenses.

Fortunately, their fears have not become reality: salary funds have retained their legal direction and school managers who used to have few rights and obligations as school financial managers and directors have become concerned with their own development and have attended educational management classes paid for by themselves.

Financial Accounting Management and the Financing of Health Systems

Popa Marius Florentin

Facultatea de Medicina, Universitatea “Ovidius” Constanța

Abstract

In recent years there is a growing trend of increasing costs in the healthcare system. Funding is thus a key factor for the management health system. There are multiple modalities of financing, namely either by budget or by different types of insurance. Also in fundraising there are involved various situational factors. There is the problem of informal payments which lies outside official channels of payment, and that disadvantage low-income people.

Key words: financial accounting, budget, fundraising, insurance

JEL Classification:

Introduction

Health care represents all that is necessary to make possible the definition given to medical services, by OMS: «Health is a complete welfare state from the physical, psychological and social point of view, and not only the lack of disease or invalidity».

Health system has a share of only 10 % among the determining factors of health state, but it consumes up to 90 % of the budget assigned for health. The occurrence of the modern concept of health care, assumes the development of medical sciences, with impact on health care, but industrialization underlines the need of better work conditions and a more performant health care.

Thereby health insurance systems start to develop: for example, Bismarck was the first who initiated in 1884 the introduction of compulsory accident and disease insurance (disease funds), then mining and other isolated projects in the industrial field brought new solutions: for example, health maintenance organizations (HMO) were initially developed in such situations (a supplier was paid by a proprietor to offer care services to all his employees), and mass

medicine has a primordial role in the exposure to epidemics and in organized nursing.

The occurrence of the modern concept of health care assumes the generalization of health insurance and compulsory cover, which started at the end of the 19th century, and especially after World War I in most of western countries. Two main patterns are pointed out: the «Beveridgian» pattern (after Lord Beveridge, who established the national health system in GB - NHS), this being a state system financed through charges (GB, Denmark, Sweden) and the «Bismarckian» one: (after Bismarck, the German chancellor), provided through disease funds (Germany, Switzerland, France, etc) financed through contributions as a percentage from the salaries (employee/employer), excepting Switzerland (taxation per capita).

After World War II a spectacular development in the medical world is observed se by the emergence of diagnostic instruments: Rx, scanners, RMN, etc, by technological processes in surgery: gastroscopy, assisted respiration devices, or by progress in medical sciences and pharmacy, thus developing a new medical branch called alternative medicine (acupuncture, homeopathy, etc).

The increase of costs takes place due to: new expectations (consumers society) and new challenges (AIDS, etc), the discovery of better, yet more expensive treatments, rate of population's aging, which leads to the increase of care needs, or new discoveries in technology along with the occurrence of new expensive medicines, etc.

The reduction of the share of state-allotted resources, due to the recession of the '90s in Western Europe and to the changes in Eastern Europe generates a pressure for privatization, liberalization and introduction of market mechanisms in public services, a pressure for quality from the consumers, and the decrease of costs and information led to

major efforts for restructuring health care services.

The trends regarding health care know new approaches, namely a competition appears between insurers and suppliers, contracting between payers and suppliers is realized, financing of activities, not of the institutions is introduced and needs are harmonized (care required) to the supplied services (care offered).

Care management supposes case management, cost management, integration of care; also an important role is played by risk management and quality management.

Market mechanisms that lead to the improvement of performance are developed and thus the competition among suppliers undertakes that insurers sign contracts with suppliers optionally, the contracts containing a number of conditions for both parties (Examples: discounts in common interest: rebate for immediate direct payments, quality criteria: the supplier agrees to participate in quality assessment programs, educational criteria: the supplier agrees to participate in training programs, cost criteria: the supplier agrees to prescribe generic medicines, criteria regarding data: the insurers will provide data for the assessment).

Unlike the financing of institutions (hospitals paid by monthly stipulated budget or fixed rates per day without considering the acuteness of the cases treated), financing of activities means that the hospital is paid for what it does for the patient.

Activities are obtained from the encoded medical information about each patient, which describe what illness he/she had (diagnostic) and what was done (procedures). A classification program (software) assigns codes to various groups, which are clinically significant and with similar costs. Financing needs periodical adjustments, because it is never sufficient in the USA: financing problems (14% of PIB, 5000\$/person/per year) or Switzerland: financing problems (12% of PIB, 3600\$/person/per year), or never satisfactory in Germany '97: unadjusted financing maintained the hospitalization duration of 5 days for meniscetomy. Financing is a key factor for health system management, thus the promotion of alternative services being fulfilled prom in Bulgaria: 85% of the Insurance Fund finances the doctors in

primary care sector, and in Switzerland: the pressures imposed by the budget on hospitalization led to the increase of ambulatory care sector and the support of consumers' satisfaction, insurances pay for balneal treatments.

The objectives of health systems are the universal access for all the citizens, rendition of high-quality services, which respond to patients' care needs, the efficient use of resources, and the functions are in relation to the financing of health services, collection of funds; the pooling of collected funds (fund pooling), allotment of incomes; use of funds – purchase of services and supply of health services.

The financing modalities have multiple possibilities: financing from the state budget, financing by health social insurances, financing by private (voluntary) health insurances, financing by direct payments, financing by savings accounts for medical services, or community financing. Situational (transition) factors intervene in the collection of funds, factors that are represented by revolutions, change of the governing parties, structural factors - economic increase rate; dimension of informal sector; stability of political institutions; the ability of national/local administrative structures; levels of corruption, etc., demographic factors - proportion of elderly population; dependence ratio: population ≥ 65 years + population ≤ 14 years population 15 – 64 years, the structure of husbandries and cultural factors - trust in the government; status of professionals; population's preferences; perception upon informal payments and “presents”, etc.

The financing from the state budget is realized by general taxes and charges (collected to the state budget and then allotted to health and other sectors), by special charges (taxes or charges with special destination for health), indirect charges (on income/profit/property), indirect progressive charges (on transactions/merchandise: charges on sales, VAT, excise taxes, import/export charges), local national regressive charges or territorial inequities and by external loans/donations/grants, the burden on the next generations who are often submitted to the creditor's strict conditions and options.

The National Health Systems (Beveridge pattern), implemented in Great Britain, Ireland, Scandinavian Countries, Spain, Portugal, Italy, Poland, Latvia, Albania are characterized by the fact that the main financing source are the taxes, they have a general coverage of the population, represent the most progressive type of health system, have reduced administrative costs and present control of funds.

The financing by social health insurances is realized by compulsory contributions of the employees and employers, where freelancers, agricultural workers can be considered eligible, particular situations also existing: unemployed, pensioners, persons with handicap or groups with reduced incomes financed by national/local budget.

The contributions of eligible persons are collected by independent agencies, thus ASS unique funds being created in Croatia, Estonia, Hungary, Slovakia, local funds (houses), branches of the National House in Romania, a unique social insurance fund in Belgium, more independent funds in France, multiple individual funds defined on occupational/geographic criteria in Austria, Germany, Czech Republic, Lithuania, or an association of insurance funds in Luxemburg.

Social Health Insurance Systems (Bismarck pattern) appear initially in Germany in the 19th century, under the denomination of fellowships. Examples: Western Europe being consolidated systems adapted through a long period of time: Germany, Austria, France, Holland, Belgium, Luxemburg, or in Central and Eastern Europe where they see a fast transition, with imported patterns: Croatia, Czech Republic, Hungary, Slovakia, Estonia, Lithuania, Slovenia, Romania.

Private (voluntary) health insurance has several types, namely:

Substitutive health insurance replaces other cover forms and addresses to the persons who are not eligible for ASS or who have the liberty of leaving ASS (Germany, Holland).

Additional health insurance which functions in parallel with other cover forms, allows a faster access to services or better conditions to obtain them, offer a greater freedom of choice of the supplier, is often met in the countries with National Health Systems.

Complementary health insurance includes services that are not offered (or are only partially offered) by the other cover forms.

The financing by direct payments are the payments effectuated directly between the consumer and the supplier of health services, without the intervention of a financial agent and is differentiated on several types:

- Co-payment → payment of a fixed amount for each service
- co-insurance → payment of a percent from the service cost
- deductible → payment of the first “x” lei from the service cost, the third paying party covering the overrun of this amount
- full payment of the service.

Community financing is applicable to rural communities and is based on the contributions of the members for obtaining a package of medical services, having as basic principles the cooperation among all the members of the community, trust among the members, government that offer support by legislative initiatives, technical and financial assistance.

Informal payments – “Payments to individual suppliers or institutions, in kind or in money, which are situated outside the official ways of payment, or which are destined for buying services that are normally offered for free by the health system” (Maureen Lewis, 2002)

These payments comprise the payments “in envelope”, “contributions” to hospitals, and also the counter value of certain medicines and sanitary materials acquired by patients, creating a context in which health expenses decrease in transition countries against a maintenance of an overbid in the sanitary sector, having as a result the establishment of very low salary levels, create an informal market for health services inside the public system, the funds go to individuals and not to the system, being illegal and outside the financial control, informal payments restrict the access of those with reduced incomes and may be considered a “present” received after offering nursing as an informal payment.

Conclusions

Primary management style is most commonly found in administrative units with political responsibilities being indicative characterized by detailed allocation of tasks, monitoring each stage and suitable to a team in the training process.

There is a relatively short operation period of the system of healthcare insurance in Romania, the healthcare units have not individualized, the funding, although it is based on an solved case, not uses another tariff per weighted case resulted from the analysis of the hospital activity. The National Commission for Accreditation of Hospitals has not yet been established and, the hospitals reform is not very advanced either, the general trend is to continue operating all units, regardless of performance achieved and the needs of the population. In this context, it is understandable that management adopts a similar attitude, which we can name it "survival."

As a general conclusion, we can say that healthcare organizations managers are using indicative or participatory management styles, characterized by detailed allocation of tasks and under development or less experienced teams. They are flexible but situational adaptability is reduced, which results either in a very rapid situational dynamics nor the severity or novelty of the faced problems.

It is necessary to optimize the healthcare managers, regarding first the flexibility and situational adaptability, values that would increase the efficiency of organization in which are working the mentioned managers.

Impact of XBRL on Financial Reporting in Romania

Radu Florin

Valahia University of Târgoviște

florinuniv@yahoo.com

Abstract

In many fields, the transition to digital support for documents or information in a wider sense, involved only the simple replacing the old paper documents with text files. Normally, this thing allowed a significant economy of paper, storage and distribution of those documents and, somewhat, facilitated even search data. However a number of other benefits of digitization information remained unexplored. So, unlike a specific search where would have exactly indicated the search criteria, all available documents must be fully read when the search is only for those documents that interest at a time. This happen because data of these files, although are “digitized” are not enough “marked” to be handled by processing tools, human intervention remains, under the circumstances, inevitable.

Key words: XBRL, XML, IFRS, financial reporting, accounting.

J.E.L. classification: M41

1. Introduction

The main obstacle in external reporting of financial information falls within the owner of each document which displays these information. For financial reporting to be intelligible, necessary data for describing reporting elements depend on these documents to understand the international context [1]. Publication of financial-accounting information to interested partners should not be limited to simply using of documents which describe the situation of the entity. The necessity to analyze financial statements by fiscal authorities, credit institutions, auditing institutions, investors

and other partners interested by the financial statement of the entity, is manifested with an increased intensity. In the context of automatic processing and analysis of financial information by all stakeholders, manifested, more acute, the need for standardization of accounting data transfer errors-free, safe and in an uniform and intelligible format.

Automated external financial reporting and analysis is accompanied by a series of technical challenges [2]:

- regional and even international differences of reporting financial statements formats;
- geographically dispersed systems or divisions of the same organization, means similar financial data, but not necessarily same format;
- any new solution adopted for financial reporting requires extra effort regarding the training of employees involved in the activity;
- financial information requires a permanently monitoring of the correct electronic transfer;
- the history of reporting should be stored in data warehouses which requires extraction, transformation and easy uploading with each reporting performed.

A solution which successfully respond to all these challenges is the language for business reporting XBRL (eXtensible Business Reporting Language), seen as a standard to define and swap information about financial performance of the company.

XBRL is an international standard for publishing, sharing and financial analysis of reporting data, which simplifies the preparation and publication of financial documents. The main idea is to collect data once and to convert them into more formats through automatic processing.

XBRL is a world business environment, which represented the protocol TCP/IP for Internet [3]. Perhaps this acronym, XBRL, will become as known as HTML or IFRS. We consider that another comparison, founded in our research, worth mentioning here: XBRL represent for EDI which Internet represented for Minitel.

Financial information published on the Internet usually has the form of an electronic file. This electronic file format takes many forms: generally, pdf format, and also HTML, rtf, text, sheets. In this form, financial information becomes easier to distribute than the “traditional” version-paper. Not everyone who uses financial information is our of business; inside it are situation when the information must be “reformatted” to be transmitted from one subsidiary to another or even between operational entities. For information to be automatically exploited, it must be explained. Each element of it must be accompanied in the same time by the definition and the way of using. Such a label could take, for example, the following form: “*this number is the net result of the company ... for financial exercise ... and it is expressed in ...* “. Experts speak about the “context” of information or meta-information (information about information). The context is the one which allows the understanding of information. If it can be coded, it will allow to computer to make certain automatic processing [4].

Under these conditions the problem of processing information is the labeling of this. Or, this is a task that information is particularly adopted. All automatic data sharing (EDI – Electronic Data Interchanges) is based on this principle. The problem is developing a convention at the same time be flexible enough to adapt to many circumstances, without recovering labeling but fairly accurate for automatic processing.

XBRL (eXtensible Business Reporting Language) proposes this convention.

2. XBRL impact on financial reporting

Financial markets know many years of turbulences of whose origin are very often linked to precarious information shared by companies regarding their activity. Enron,

Tyco or Worldcom are painful examples of lack transparency in accounts.

To take full advantage of digitization the efforts must be concentrated on rigor of format and standardization information. Financial information was delayed in this area since the appearance of XBRL which, thanks to its structure inherited from XML, requires an organization that facilitates collection and processing information. This project is just one of the aspects that disturbed accounting in the last years.

In many areas, the shift to digital support for documents or information in a wider sense, involved only the simple replacing the paper documents with text files. Of course that this allowed economy of paper, easier storage and distribution of those documents and, somewhat, even search data. However, a number of other possibilities offered by digitization information remained unexplored yet. So, all available documents must be always fully read when the search is only for those documents that interest. This happen because data of these files, although are digitized are not properly “marked” to be handled by processing tools, human intervention remains inevitable. Digitization gain from this point of view is minimal.

One of the consequences of this environment change is an increasing requirement regarding financial reporting, both qualitatively and quantitatively. Companies should publish more important, richer, more frequently and more diversified comments. Where often the company was satisfied in presenting few numbers of its activity, for the future, it will have to give textual justification and specify concise choices it made and why the management believes these choices are the best regarding accounting rules. It is normal to recommend companies with their transition to IFRS to publish its financial statements in XBRL [5].

At the present financial reporting passes through three major changes [2]:

- market imposes new needs to regulate financial information, and transparency in the reporting process is greatly enhanced;
- the Internet created an omnipresent infrastructure for global, local, intra and inter-companies connectivity;
- new standard of data exchange already appeared and allows that relevant

information to be made in an agreed format and shared across organizational and geographical boundaries.

These three changes require changing the way in which the producers and consumers of financial-economic information create, disseminate, share, analyze and use business data. The essence of this change is to focus on improving standards concerning economic and financial reporting model, data connectivity infrastructure and their change format.

Next, we will present how can XBRL to answer the diverse challenges of financial reporting [6]:

- *Developing and publishing information:* use of a common language drastically reduces the needed time compilation the information from heterogeneous sources, thus avoiding many restatements. This also limitates introducing errors that otherwise would multiplicates with each stage, requiring rework every time. So, establishing consolidated accounts may be done quasi-automatic.
- *Division and comparability of financial information:* a common language allows facilitating the information understanding by those who didn't participate to its development. A “marked” language allows, if marking are correctly adjusted and expressed, restitution of the context in which information was extracted and which is not necessarily visible in only one part of information analysis. A very simple example of this situation is: a table containing amounts of money but doesn't specify the currency is not exploited in this way. Or, XBRL has from XML the possibility to associate attributes to each element. These attributes can reconstruct the context. Information comparability is one of the main criteris in accounting.
- *Verify financial information:* a marking language favors verify information. Indeed, we know in advance where to find a data, it is not necessary to be searched or reconstructed. A verifiable information inspires more confidence and offers more gain in transparency.
- *Analysis of financial information:* currently it is estimated that financial analysts spend more than a third from their time to reprocessing information, so a very important part of their work is not to

analyze information. An information directly usable allows gain time, a reducing of introducing error risks, the possibility of handling a substantial volume of information and analysis of better quality.

To analyze the impact of the transition of XBRL to IFRS, first must be understand how it works. To transfer from a computer to another the information of a annual report was first developed a “syntax”, a computer grammar know as “specification”. This syntax allows expressing basic parameters common to all financial statements be it currency, period or/and other elements.

This syntax is associated with a series of dictionaries called “taxonomies” which are specific to each accounting rule. (IFRS, US GAAP, UK GAAP). These taxonomies represent a translation in informatic language of accounting rules. Its contain elements required to establish financial statements as are defined in accounting rules (tangible assets, turnover) maintaining the link between elements and rules. Taxonomies can be adapted by companies to take account of the specific needs both by internal and external reporting and can be managing in many languages. IFRS taxonomy brings together around 3000 individual terms with links between rules and available in many languages.

XBRL has four main advantages that facilitate transition to IFRS [7]:

- *Use taxonomy for defining reporting.* It is much easier starting from a taxonomy to make the link with rules and translate them as financial statements than start from text itself to build the balance sheet, income statements, cash flow and all related marks. This will simplify and reduce difficulties and investments required to translate IFRS rules as annual accounts and then define an adjusted accounting plan.
- *Parameter and development of interfaces with accounting systems.* Once defined reports must be produced and then consolidated needed information to establish the accounts. Today, certain ERP systems already accept XBRL, and taxonomy can be accepted by the system to collect information following the required scheme and to make financial statements in XBRL format. Always there

is the possibility to transform a taxonomy into a Excel file or to traduce data from an accounting XBRL format using appropriate software. XBRL allows collecting structured information from heterogeneuos financial systems that coexist in companies without developing specific interfaces adapted each time the system which transmit or receive information is modified.

- *Transparency and financial communication.* Today, the accounts that are available to entrepreneurs, are returned, simplified and too high cost for analysts to trasform its. With XBRL exchange and extraction financial data published on web will be automated and enhanced sectoral benchmarking. For example, readers and users of financial statements may have only bt few clicks a table with wished information, such as rate “gross margin/turnover” for all companies in a particular sector using the same referential, without having to reintroduce information.
- *Maintain all accounting procedures when rules are changed.* It will help with taxonomy (of course, starting from changes propused by the IASB) to transmit these changes to branches before proceeding to accounts consolidation.

3. Conclusion

In the context of streamlining the financial reporting process, XBRL has major implications in relevant information dissemination, required to express the enterprise’s health and business performance. Therefore, the regular publication of financial statements to different partners or financial and regulatory authorities or the standard accounting information collection for internal reporting needs is becoming unavoidable.

The economical-financial communication of the companies continues to be characterized by an unsatisfying level of content standardization or by a significant quantity written on paper, which leads to a real discomfort for the economical operators and the national system as an assembly.

Abstract

The reliance of the investment funds market to the capital market development, to the liquidity of the traded shares, to the evolution of the funded companies and by the investors changing behavior against a changing environment has generated unforeseen fluctuations in the global economy and in the activity of investment funds internationally, nevertheless.

The current paper aim is to stake out the economic significance of the investments made by the investment funds, and intends to mark their role in boosting the economic activity, i.e. to support the economic growth and to identify the main factors that have been stimulating or inhibiting the investment funds dynamics during the last period of time.

Key words: mutual funds, crisis, investors, economic growth, stock market liquidity

J.E.L. Code: E22, G10, F40, O16

1. Introduction

As collective investment schemes, the intermediary activities provided by the investment funds have offered new possibilities for fructifying the resources held by the individual and institutional investors, whereas encouraging the development of the capital market and boosting the entire economy. Specifically, it outlines the role of the intermediaries by conducting the fund investment activity and stimulating the interdependency between savings and investments towards transforming the former in investment. Based on this interdependency, we can emphasize the dual role of the investment funds business. First,

there is the household savings fructification in terms of risk - return and, on the other hand, is about supporting and strengthening the capital market and the real economy. Related to these action lines and the main operations carried out, i.e. attracting and funding capital, the investment funds act as intermediaries between holders with a surplus of capital (investors) and companies in need of funding. In the strengthening of this statement, Boudemagh M., De Nouel Ph. define the undertakings for collective investment as “tools that allow for financing an economy by channeling the savings to the capital market”[3, p.15].

According to this definition, we identify the dual role of the investment funds, both at the level of saving and throughout the national economy.

As a component of the financial system, the investment funds can assign the following influences on the process of the economic growth [1, p.13]:

- a more efficient allocation of the capital;
- increasing the speed of turning savings into investments;
- risk diversification;
- improving the corporate governing;
- enhancing savings.

Although the priority interest of the capital holders is set on maximizing the gain that comes down according a certain risk set out in the prospectus, it becomes particularly important the role and the impact of the investment funds to boost the overall economic activity. Also, this is based through the multiplier and accelerator principles, as long as the investments produce effects on shaping the economy and on supporting the correlation between incomes, savings, consumption, production, etc.

Due to the complexity, the timeliness and the continuous growth of investment funds area, this paper complements the existing literature, becoming a first step in assessing the determinants of the Romanian investment fund market development.

2. Literature review

The prolonged debating on the topics that involve “the financial system is developing the economy” or “the economy promotes the financial development” has extensively been studied. Given the complexity, the dynamism and their interrelationships, various economic theorists and practitioners have encountered difficulties on rigorously establishing all the elements related to the content and the investment mechanism.

In this regard, the first studies were assigned to the macroeconomic analysis of the investments, as are the studies of Kahn's (1931) – which has developed the theory of the investment multiplier (further discussed by J.M. Keynes in his book, *The General Theory of Employment, Interest and Money*, published in 1936) and the accelerator principle of the economic growth by increasing the aggregate demand as a result of making additional investments attributed to Aftalion A. and subsequently taken by J.M. Keynes, S. Kuznets, R.F. Harrod and Samuelson P. In addition to these two principles, there are other models that address the correlation as a model through the impact of investment on the economic growth, such as are the models of R.F. Harrod, E. Domar, IB Clark and R. Solow [8]. In the mid of 80s, a new theory arises on the relation of the capital accumulation and the economic growth, attributed to Romer P. and Lucas R. Their theory assumes that the capital accumulation is associated with the accumulation of knowledge, whereas in time is not maintained under the same conditions, but require the use of new goods and technologies for which are needed new inflows of capital.

Classical economists and later the neoclassical ones found that "the supply creates its own demand", while self-regulating economic processes on a long term economy always finds its equilibrium position. Consequently, the economic balance is based and provided by [6, p.56]:

- investments have opposite forms throughout the economy. Saving equals the withdrawal of purchasing power. The effect is felt in decreasing the aggregate demand. Also, occurs a contraction of the whole economy, a phenomenon commonly called recession;

- investments play an expansionary role for the economy. To invest is to buy goods and services, maintaining and expanding other economic activity and all these have an effect reflected in increasing the total economic output, ie GDP;

- because there is a shorter or longer time between the investment initialization and when its effects are felt, it might occur additional demands that have not yet counterpart in goods and services;

- since the economy is always struggling to get steady, on a long-term the savings will be fully compensated by the money invested. Instead, on the short term, there may be inconsistencies. Amounts saved can sometimes exceed the amount invested and vice versa. Increasing amounts saved will increase the supply of spot and term deposits. Consequently, the interest rate will be reduced, encouraging the investments and discouraging the deposits. Eventually equilibrium will be restored [10]. Alike, the increasing investments over the existing economy will increase the demand for loans. The interest rate will see an upward trend, discouraging the investment and encouraging the deposits.

Thus, we find that, the classical model is centered on the primary element that determines the level of investment activity in the economy and affects mainly the saving – investment, that is the interest rate.

Over time the studies on investing were oriented towards the stock market investments, but most of them were inclined to study the performance and the risk, also towards improving the investment return and investment portfolios.

Strictly on the theme of the investment funds, although was dated historical since the early nineteenth century (the first U.S. fund - 1824 - Massachusetts Hospital Life Insurance Company [7, p.5]), the early studies appear around 1950 after the establishment of the Investment Company Institute (ICI abr.).

The interest for investment funds comes from the fact that in these collective administrations of capital investment is a

"comprehensive process which relates to the availability resulting from the process of saving and the demand for financial resources in the economy of a country" [3, p.9]. Also, the investment funds are considered themselves "a savings product" [3, p.19], and is directly related to the evolution of the saving process.

As a fact, since 1990, the investment funds industry has proven to be one of the components with the highest rate of growth of the financial sector in the European countries [3], becoming an important way of saving which has earned a significant weight of the population savings in almost all the European countries. The gradual migration of household savings from classic deposits was largely directed to the investment funds, which registered a growing rate of collected total assets. This situation is likely to be explained mainly by the lower interest rates on bank deposits, increasing incomes, increasing financial education, capital market development, the assessment of benefits (diversification, risk reduction, cost savings, professional management, etc.) and the appreciation of the return on investment funds. All these conditions have caused a reduction in the growth rate of savings in traditional instruments, such as bank deposits.

3. Creating economic growth through mutual funds investing

„Does the investments sustain the economic growth and the economy?” and „Does the economy supports the

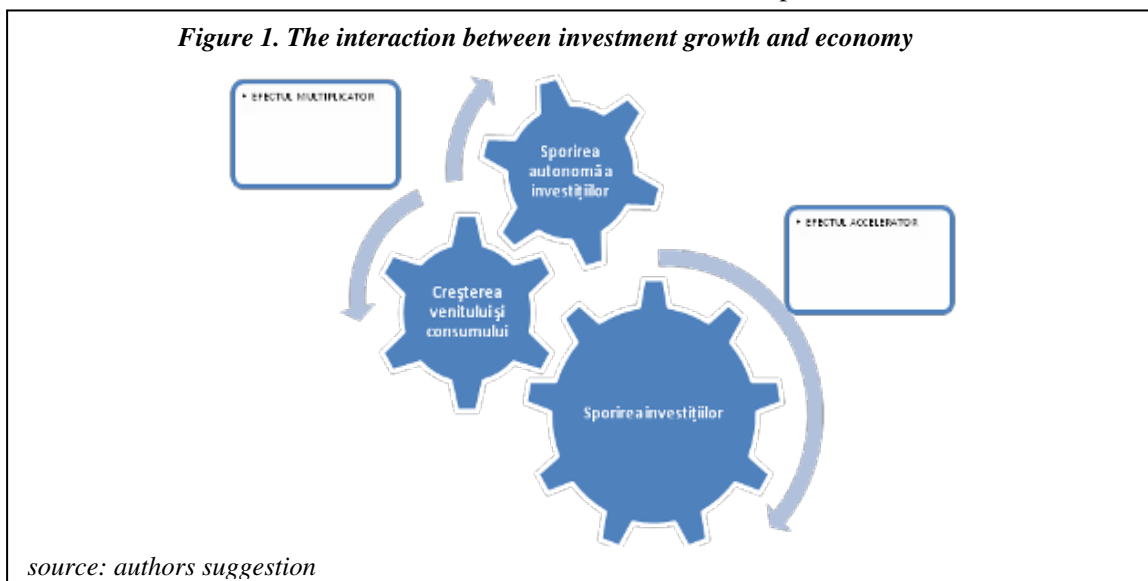

investments?” are two controversial debates among economists. From this contradiction, we propose to identify the causal linkage between the investment funds and economy. In this respect, is necessary to mention the assertion of Prof. Anghelache G. (2000): "Capital is the sap that feeds the economy, and if its channels (e.g. investment funds) are insufficient, missing or wrong cut, the economic progress can be questioned"[2].

Since Keynes's theories this topic was exciting for economists. For example, Harrod R., the supporter and follower of the Keynesian theory developed the first theory on economic growth due to the link between the capital and the incomes achieved in the economy. He has demonstrated that "the current capital gain will increase the revenue in next year, which in turn will create a new growth in capital" [9].

Subsequently, the multiplier and accelerator principles drew the investments' role thorough the interaction made between the growth of the income and investment, showing the increasing trend on income by growing the investments, which produces training effects (i.e. acceleration) to the economy due to the production of goods and thus on supporting the revenue growth and consumption.

Figure 1 presents the following effects driven from the multiplier and the accelerator principles:

- an increase of the investments leads directly to increasing the demand for consumption and disposable income –for which companies are incited to increase

production;

- to increase production, it is necessary to increase investments;

- the induced increase of investments depend on the changing of the national income and the allocated rate of the national income to investments;

- since at a relatively small increase in consumption and income, the investment rate grows greater – reason why it is used the term accelerator of consumption and income over investments [9, p.248];

- the initial increase of the consumer demand will result in higher growth of the investment demand. As the consumer demand growth begins to decline, the investment demand will decrease and may even reach zero;

- as a consequence, when national income changes positively from the previous period, the investments may increase, may stay the same or decrease.

For underlying the contribution of the investment funds on the economic growth, we appreciate that it's important to identify the relationship between total assets managed by investment funds and the size of the gross domestic product. This comparison was promoted by Khorana et al. (2005) on determining the size of the investment funds industry.

In relation to the GDP volume, the European investment funds registered an annual average growth rate of approximately 12.90% over the period 2003-2009 [5, p.25]. A significant increase of the rate of investment funds in the GDP was registered by Romania, with more than 25 times bigger rate in 2009 compared to 2003, when it accounted only a rate of 0.02% of the GDP. Although during the year 2009, the rate of investment fund assets to GDP was less than 1% and only 0.45% of GDP, the increasing economic significance of investment funds was spectacular compared to other European countries that have experienced even contractions from the financial crisis in the years 2006-2009, as it is the case of Greece (-80%), Portugal (-54%), Italy (-51.73%), the Netherlands (-32.88%), Spain(-28%), Turkey(-26%), Austria (-20.4%) and Germany (-10.68%).

The spectacular growing rate of the investments in mutual funds as percentage in GDP for Romania's case is mainly due to the

attraction and the growth of the amount of total assets allocated to investment funds, up from 29 million in 2003 to 1134 million dollars in 2009, i.e. up to 39.1 times (3910%) than the situation in 2003. Moreover, this increase was higher than the GDP growing rate of only 53% during 2003-2009.

As a result, this changing of the growing rates of the fund investments as a percentage in GDP indicates the increasing trend of the investment funds markets in Europe and more accurate in the Eastern Europe countries. However, this proves a certain extent and strategic reorientation of the funds investments into new areas of the EU countries that could provide investors with new opportunities and better chances to improve the performance of funds.

But, in these circumstances, all the investments made didn't ignore the extent of capital market development. In fact, investors and other players on the investment funds market (depositors, banks, etc.) are attracted to the stock market progress, and in particular of the extent of its volatility.

4. Mutual funds dynamics on driving liquidity to the Stock Market

Mutual funds are important players in the capital market of Romania, even if in their short history have passed two major crises (in 1994 and 2000 by the collapse of FMOA and respective FNI), and yet to the recent financial crisis. Moreover, in the past years there has been a steady increase in the total net asset value allocated and managed by the Romanian investment funds; and in contrary to general market situation it has been registered an increase in the number of investors and the number of funds established.

The total increasing of the net assets across the industry of investment funds amounted in 2010 about 1,713 million as ICI Factbook states (almost 5622 million EUR), being almost 50 times greater than the assets managed by the 21 existing funds in 2003. Also, even if Romania had to face the global recession in 2008, the activity of the investment funds has decreased by only 10% of the total net assets. However, the number of the investment funds increased 2.27 times at the expense of making additional subscriptions, with 36% higher than in 2007.

Hence, we find a contrary situation to that observed globally. The period beyond 2009 until today proves to be a favorable one for the Romanian investment funds and for the foreign investments in Romanian assets.

Thus, since 2008, have been established at least 11 new open-end funds and other 5 close-end funds, which had attract new investors gradually, reaching in 2010 a total of 303,441 investors in the 67 Romanian investment funds [5] and another 55 foreign investment funds that are active on the Romanian financial market.

The turnover of the capital raised and managed by these funds, assumes a special attention on the growth of the stock market liquidity through the significant share of the total assets managed in the capitalization value of the domestic stock market.

We find that, while the share of total net assets managed by the investment funds in the amount of market capitalization increased significantly, today it is encompassing 11.27% of market capitalization. This is encouraging, since it is proving that these alternative investments are basic pieces of the capital market development and in increasing its liquidity.

During 2011, the stock market has drawback again following a stagnating year (2010) and a partial recovery in 2009, as it could be seen in Table 1 [11].

Unlike the development of the stock market, the investment funds have attracted additional capital, amounting to manage 2388 million (approximately EUR 1.6 billion), i.e. up 39.4% over the volume of total assets in 2010, in a double volume compared to 2009 and almost seven times of the total net assets managed at the end of 2008 (the only year of contraction of the investment funds in Romania).

The decrease of the market capitalization in 2011 led to lower indices. For example, the Romanian BET Index (based on the ten most important stocks listed on the regulated market of Bucharest Primary Stock Market) ended the year 2011 with a decrease of 17.7%. This is the third full year of decline in its history (by -50.2% in 1998 and -70.5% in 2008). Alike, BET-FI index, the investment quoted companies index, lost 12% due to significant fluctuations recorded in the latter part of 2011 on the account of the maximum holding limit by an investor in the capital of a SIF, from 1%, up to 5%.

In terms of market liquidity, it increased in 2011. The amount of the transactions with shares was rising by 76.78% in 2011 compared to the situation in 2010, reaching 9.9 billion lei (2.3 billion EUR) vs 5.6 billion in 2010, rising to 94, 11% compared to 2009 when the turnover was 5.1 billion lei and an increase of over 41% compared to the year

Table 1 The evolution of the stock market capitalization in GDP and the rate of the total net assets of the Romanian mutual funds in the market capitalization between 2003/2011

Years	Rate of market capitalisation in GDP (Ci/PIB)	Annual growth of the rate Ci/PIB	Rate of the Total Net Assets of Mutual funds in the volume of the market capitalisation AT/Ci	Annual growth of the rate AT/Ci
2003	9,38%	-	0,52%	-
2004	15,61%	66,37%	0,61%	17,64%
2005	20,81%	33,31%	0,53%	-13,33%
2006	26,73%	28,43%	0,75%	42,30%
2007	26,54%	-0,72%	0,87%	15,22%
2008	9,96%	-62,48%	1,64%	88,66%
2009	18,82%	89,02%	3,74%	128,33%
2010	20,04%	6,45%	5,29%	41,45%
2011	11,79%	-41,16%	11,27%	112,99%

source: authors own calculations using BNR and CNVM statistics

The above table shows that the growth rate of the capitalisation share as a percentage in GDP is significantly reduced by 41.16% in 2011 compared to 2010.

2008 (7 billion lei) [11]. Mostly, this increase was based on the transactions made with the Property Fund unit funds, whose liquidity was at 52% of the total shares transactions in

2011. Moreover, if we could neglect the transactions made on FP unit funds, then the total liquidity of the regulated market of the Bucharest Primary Stock Market (BVB) would have been only at 4.8 billion lei, below the values from the past years.

Closely related to the stock market dynamics and the various sources of financing investments, another important determinant of the investment impulse is the performance index of the foreign direct investment (i.e. Inward Performance Index engl.) which expresses the share that a state has in the world's total foreign direct investment made during the year and the share that holds in the global GDP [4]. If the index has a value above 1, then the respective countries attract an investment volume above the expected level, given the favorable economic regime, namely an attractive business environment and favorable macroeconomic conditions. By default, the financial and portfolio investments in mutual funds can track this index as long as it proves the attractiveness of a market.

5. Conclusions

Overall, investments have a multiplying effect over the economic activity of a country, involving and developing the economic recovery, enhancing the investors' attractiveness to the respective market. However the multiplier effect of investments doesn't follow the development of the investment funds market, on the contrary it is ensued by an aggregate contribution of the entire economy (stock market, banking sector, money market, business environment, etc.). Furthermore, we found that the development of the investment funds is supported by the economic growth, and hence, investment funds are depending on their position on the capital market, the volume of the managed assets and even of the transactions made, factors that could be also a driver for the economic growth.

Abstract

In an attempt to identify the main determinants of attraction or inhibitive factors for investments, the current paper evaluates the Romanian mutual fund market development. Using a regression analysis on quarterly data during 2004Q3 – 2012Q2, the study explores the impact of current financial crisis on mutual funds.

The paper is organized as it follows. Part 2 presents a brief literature review and extracts the studies that appreciate best the determinants of the mutual funds dynamics. Next section is set on defining the Romanian investing climate and its importance for sustaining the economy through mutual fund investing. Then, section 4 concludes.

Key words: mutual funds, financial crisis, stimulating factors and inhibitors, economic stability

J.E.L. Code: E22, E32, G10, G20, F40, O16

1. Introduction

The investment environment stability is essential for all investors, as long as, any time of instability can attract significant variations in the amount of the capital invested, or severe outputs which could cause a massive stock prices fall, and by default, restricting the capital market.

As part of the capital market, the collective administration of funds was developed by the cyclical developments of the economy [9]. This is certified by the fact that during the periods of economic

expansion, the collective investment grows and matures, and in periods of instability are arising measures to ensure the investor protection and are the range of actions on the money market are getting diversified towards ensuring the security and the preservation of the capital.

By default, we can admit that the investment fluctuations for different activities (not only for the investments made in mutual funds) show that the cyclical economic situation and the economic policies do not have an uniform effect on all investments, instead, they act differently, sometimes in the conversely direction, from one category to another. This structural dynamics between different types of investment funds is due to the investment flows fluctuations caused by a variety of factors, circumstances, which reflect the cyclical changes in the economy. In general, the macroeconomic changing evolutions are seen as key factors that significantly influence the future developments in the financial markets, and at the same time, and in turn are considered to be strongly influenced by the dynamics of the market [25, p.119].

Nevertheless, investors are interested in the structure of the GDP and in the extent of contributions for understanding the components of the growth factors [3, p.18], as long as, the GDP defines the relationship between the vitality of the economy and the capital market [3, p.19].

Another factor that may determine the impulse for investments is the regional economic situation and / or the global economic status, which may significantly

change the investments made in an open economy. For example, the strong financial turmoil generated by the effects of the latest international crisis led to the impairment of the investment fund industry, while affecting the entire economy in terms of the national economy's dependence on the external financing [18, p.60].

Undoubtedly, the incitement and the appetite for investing are driven by many other factors that depend on the changing phases of the economic cycle. It is known that in the boom phases of the business cycle, the increasing consumption is a result of the revenues increased and as a condition of the production and services development and their diversification through the multiplier effects [28, p.247]. By contrast, in a recession, due to a slightly lower income and consumption, a reduction in investment might happen, which could be stronger than the weaker economic activity [28, p.248]. To this end, an economically declined economy needs first to stop this negative trend and then to start pushing the impetus factors for investing [28, p.251].

Thus, to ensure an attractive investment climate in terms of the status of the national economy, it is necessary to track all the economic factors and more, all fully maintaining the stability of the national economy for ensuring its growth.

Therefore, in substantiating the exciting factors in attracting capital and placing (funding) them into the economy through the investment funds and other intermediaries, it is necessary to know the main determinants of the investments.

2. Literature review

Given the complexity and the dynamism of the investment funds market, various

economic theorists and practitioners have encountered difficulties on rigorously establishing all the elements related to the content and the mutual funds investment mechanism.

With a history since the early nineteenth century (1824 – date of founding Massachusetts Hospital Life Insurance Company), the mutual fund industry has encouraged researchers on finding its main determinants starting with J. Clouse's first scientific study in 1952 (as stated by Seth C.A. and Parvaez A., 2005 [22, p.16]).

Among the first studies, the Allderice F.B., Farrar D.E. model (1967) distinguishes by its innovative analysis based on a matrix of explicative variables for the investment fund flows variation during 3 years (1963-1965), in the case of the 45% of the total active funds in 1966 in US (i.e. 169 mutual funds).

The Allderice F.B and Farrar D.E. model represents a basic framework on presenting the relation between a dependent variable and its determinants. It was constructed as a linear equation, where Y, the dependent variable, is defined by the volume of the investment flows in mutual funds, X – the determinants matrix (independent variables), b – the vector of the structural parameters that explain the relationship between Y and X, and u – the vector of stochastic errors [1; 22]:

$$Y = X * b + u \quad (1)$$

Later, the studies have been constructed on index based models, such is the one of Groh A.P., von Liechtenstein H. and Lieser K. (2008), but most of them, rely on a regression analysis and the component analysis.

From the comprehensive literature, we extract several aspects defining for the appropriate models and their main results, as could be seen in Table 1 below.

Table 1. Short review of the related literature

<i>Related studies on the determinants of the mutual fund industry</i>	<i>Observations</i>
Allderice F.B., Farrar D.E. (1967) [1]	The model aims to identify the factors that affect the volume of capital inflows into investment funds. Starting from the simple correlation of several explanatory variables, the authors select five categories of factors considered to be statistically significant: (1) <i>the economic conditions</i> - against which is believed to affect uniformly all the participants of the industry; this category is subdivided in sub factors such as: growth of gross domestic production growth, securities price evolution, the increasing of the disposable income and factors that may vary and differ depending on the type and the size of the investment funds industry; (2) <i>the effort of placing (selling) unit funds</i> ; (3) <i>the fund performance</i> , (4) <i>the fund</i>

	<p><i>size</i>; and (5) <i>the fund objectives</i>. In total, 12 explicative variables were driven following the successive transversal analysis of the three years.</p> <p><i>Results</i>: The investors' behavior and their attitude towards the mutual funds depends mostly on the performance of the investment funds, the selling effort and less on the economic conditions, the funds objectives and the size of funds.</p>
La Porta et al. (1997, 1998)	<p>La Porta et al. model highlights for the first time how the legal environment is influencing the size, the dynamics of the capital market and the company's ability to finance itself using this alternative of investing.</p> <p><i>Results</i>: A positive relationship between the legal environment and the investor protection was identified. The countries with poor investor protection are significant influencing the stock market and the equity funds dynamics.</p>
Massa M., Goetzmann W., Rouwenhorst K. (1999), [17]	<p>They take into account and emphasize the causality between the inputs and outputs of the capital flows and vice versa. By forming a matrix of correlations between daily net flows during a year and a half for the main categories of assets (stocks and bonds), the model has the novelty of adding the principal components analysis built on a) the weight gain to a dollar invested, b) the fair share of flows and c) the share of funds on different objective categories, on defining the size of the mutual fund industry.</p>
Fernando D., Klapper L.F., Sulla V. & Vittas D. (2003), [12]	<p>The novelty of this study is given by the inclusion in the analysis of some variables that define the efficiency, the liquidity and the market integrity. In this respect, the model includes several elements of the capital market development, the transaction costs, the level of security for transactions and the investor protection.</p>
Khorana A., Servaes H., Tufano P. (1999, 2004, 2005) [14], [15], [16]	<p>The authors continue their studies started in 1999 [10-12] by re-shaping their sample on 55 states (2004 research papers), respective 56 states (in 2005) and by analyzing four main characteristics: the legal and regulatory environment, the demand determinants (i.e. the characteristics of potential investors), the supply determinants (which are linked to the structure of the financial sector) and the financial market.</p> <p><i>Results</i>: The main findings are focused on observing the significant increased allocations in the investment funds industry in some countries due to the existence of the economic conditions that favored the increase, while in other countries, the investment funds industry remained underdeveloped or become "nonexistent" due to lack of certain conditions. Specifically, it was identified that there is a close linkage between the improvement of the legal environment and the investment fund industry, meaning that the market is higher in the countries where the investors' rights are better assured. In addition to the general conclusions, the study demonstrates that the investment funds industry is estimated to be higher in developed countries, where the population has a high level of education, but also where is a consistent history of this industry. Equivalently, the study confirms the existence of a small investment fund industry in those countries where exist barriers to entry and starting a business are high.</p>
Covrig V., Ng. L.K., Chan K. (2004) [5]	<p>The authors have attempted to explain the international allocation in equity funds by determining the slope and the attitude of investors in choosing international funds or funds domiciled in the country of residence. The panel of data used was grouped into <i>six categories of criteria</i>: a) economic, b) capital control, c) the capital market development, d) indicators of familiarity, e) the protection of investors and f) other potential explanatory variables.</p>
Antunes A.G. (2007) [2]	<p>Proceeding a variable selection, Antunes A.G. structures them in two categories: <i>fund-level variables and country-level variables</i>. In the first category are included: the main category of assets held by the fund, the investment area, the geographic allocation, the strategies adopted, the fund age, the level of fees (annual fees, initial subscription fees, redemption fees) and the fund performance. On the other hand, the countries characteristics take into account other four sub-categories of potential explanatory variables: the legal features, the supply characteristics, the demand characteristics and features of trading - noting that this category largely retains the structure proposed in 2003 by Khorana A. et al. However, the study integrates a series of dummy variables to identify the class or type of assets, the strategies type, the compliance with UCITS regulations, the geographical orientation, etc.. Antunes A. demonstrates that for 2002-2004 period, the funds contained in his study experienced a negative performance with an average about 5%, trend explained due to the economic recession that has affected the financial markets globally.</p>
Groh A.P., von Liechtenstein H, Lieser K. (2008) [10]	<p>The model is constructed for identifying an index of venture capital funds market attraction. By using six main characteristics that are influencing the investors attraction for a certain market, such are: (1) the economic development, (2) the size and the liquidity of the capital market, (3) the taxation level, (4) the investor protection and corporate governance, (5) the socio-human criteria and (6) the entrepreneurial opportunities, the model proceeds on constructing a comparison scale to the average level of the index, which is associated with 100 points and correspondent to the EU development.</p> <p><i>Results</i>: Romania is included in the category of countries with "weaknesses in attraction of investors in the domiciled investment funds" on behalf of a score of 77 points to the average of EU 100 points and below the average of countries EEC of 85 points. Also comparable results below the CEE countries have registered: Spain (82p), Italy (81p), Bulgaria (79p),</p>

	Slovakia (76P) and Greece (69P).
Ferreira M., Keswani A.M., Antonio F. and Ramos S.B (2011) [13]	Using a 16.316 equity open-end funds sample from 27 states during 1997-2007 and 10 explicative variables derived from: a) the economic development indicators; b) the capital market development indicators; c) the indicators of investor protection and the quality of the legal framework c) the indicators of investment fund industry development and concentration. <i>Results:</i> In terms of the national markets of investment funds, the variables on the capital market liquidity, the investor protection indicators, the indicators for the implementation of the legal requirements and the indicators of concentration had a positive effect on fund performance, while the relative economic conditions have not identified any significant influence. Also, in countries with high income per capita and better education, investors know better the market opportunities and are investing in mutual funds. There is no evidence from modifying the GDP per capita and the fund performance, while the intensity of using the Internet services has a significant influence on the investment funds activity, especially while it is coupled with better information and investors' education. There is a positive relationship between trading volume and the fund performance, but a negative relationship with the transaction costs.
Salgarnik G. (2012) [21]	On a ten year sample 1999-2009, Salgarnik G. evaluates the mutual funds dynamics using two types of indicators: performance indicators and non-performance indicators. The linear regression between the performance indicators (i.e. gross earnings of the fund, the share of fund performance against the average performance of funds category, the subscription time, the earnings adjusted at risk, the tracking error) and the non-performance ones (i.e. the linearized value of the total net assets, the net inflows expected to increase by a dollar of the total net assets, the normalized inflows of the fund, the market share of the fund, the costs and the age of funds scaled in months) expresses a significant difference between the two categories of investors, reporting that the individual investors are dominated by the unsophisticated ones, who do not change appreciably the results in relation to investment funds performance, while the majority of the institutional investors can be categorized sophisticated, adjusting their behavior to the performance measures.

Source: authors own structuring

3. Potential determinants of Romanian mutual funds dynamics

3.1. Methodology

In order to investigate the impact of global financial crisis on the value of total net assets, we estimate the following regression:

$$TNA = c_1 + c_2 * BET + c_3 * DEP + c_4 * LEN + c_5 * EUR + c_6 * UNE + c_7 * GDP + c_8 * SAV + c_9 * FDI + c_{10} * FIS + c_{11} * IFM + c_{12} * NMF + c_{13} * DUM + \varepsilon_t \quad (2)$$

where:

TNA represents the total net assets;
BET is the Romanian stock exchange index;
DEP is the deposit rate;
LEN shows the lending rate;
EUR represents the exchange rate EUR/RON;
UNE is the unemployment rate;
GDP represents the gross domestic capital;
SAV shows the value of savings as a percentage of gross domestic product;
FDI are the foreign direct investment;
FIS shows the fiscal pressure;

IFM is the index of mutual funds;
NMF represents the number of mutual funds;
DUM is the variable dummy, which takes the value of zero for the period before financial crisis, respectively the value of one for the period after the implementation of current crisis.
 ε_t - is the error term

The dependent variable and the independent variables: the number of mutual funds, the index of mutual funds are taken from ICI Factbook. The source of the Romanian stock index is the database bursanoastra.ro. The other independent variables are taken from Eurostat database.

3.2. Empirical results

$$TNA = 2.155 + (-0.091) * BET + (-0.047) * DEP + 0.024 * LEN + (-6.44) * EUR + (-0.11) * UNE + (-0.956) * GDP + (-0.016) * SAV + 0.221 * FDI + (-0.037) * FIS + 3.93 * IFM + 0.464 * NMF + 0.289 * DUM + \varepsilon_t \quad (2)$$

The financial crisis affected all the sectors of economy worldwide [17, p.289]. The

results of our analysis show that this impact is not significant (table 2). Also, we must not forget the fact that EU accession coincided with providing a point of confidence in the stability of the national economy and the experience of other countries such as Czech Republic, Hungary and Poland show that European integration had a significant impact on stock market capitalization, which grew by an annual average rate of 48% and the turnover by 77% after accession [4, p.283]. But the evolution of Romanian stock index

value of total net assets. It is surprising the negative and significant impact of exchange rate of EUR/RON (5%), while the foreign direct investments have a positive impact on the values of mutual funds (1%).

The annual growth of gross domestic product has a negative impact (10%). This result is due to the current crisis. The other independent variables proved to be insignificant in explaining the dynamic of total net assets of mutual funds.

has a negative and insignificant impact on the

Notes: White t-statistics are in parentheses. *, **, *** indicate statistical significance at 10%, 5% and 1% levels.

4. Concluding remarks

Despite the expectations of an imminent collapse of the worldwide economies and the international financial systems, the Romanian mutual fund market is witnessing the confidence of its investors. In addition, the paper emphasizes the main determinants with significant impact to the Romanian investment market which has been defined only by a slightly fragility.

Towards ensuring a certain level of development for the mutual fund industry, we are conscious that the investment impulse

depends on many other key elements which will encourage further research.

The Impact of Innovation Activity on the Romanian Economy. Comparative Analysis

Rus Mircea-Iosif

Babeş-Bolyai University

The Faculty of Economics and Business Administration

mircearus2004@yahoo.com

Abstract

This article presents the innovation activity in Romania through a comparative study conducted between 2002-2010. Moreover it treats also the implications of innovation on developing regions. These regions are in the view of the European Union underlying the development of the innovation activity, as well as the financing of this work by the EU programs, especially through the two most large-scale grant programs of innovations, called Europe 2020 and Horizon 2020.

Key words: *innovation, financing, regionalization, turnover*

JEL Code: *G28, G29, O30, O31*

1. Introduction

The world is in a profound, permanent and increasingly rapid change. Complex phenomena that occur in Romania suggest the medium and long term consequences which could hardly been forecast in a scenario, given that we are in a changing world. A world of complex and contradictory trends is born before our eyes. The time for spontaneous actions, for a message widely understood, for passivity is gone. Continuing such an attitude, under the false and dangerous soothing sentence of "pragmatism", means to prove lack of capacity and inability to contribute to sketching the defining structures of this world, that we want so much to be modern and dynamic, and inside which the value should be the unique criterion of social victory.

In Romania, the importance given to science has decreased, being regarded as a mere consumer of scarce resources. The lack of coherence between different states structures

manifests itself in a weak relationship between economic policy and political science.

The reformist statements in recent years have always given a wave of hope in increasing the role of science, but practical reality oppose our hopes incompetence, poor management, old style nomenclature. In the context of EU accession, Romania should take into account that the West is operating on a normally bases in which competition naturally eliminates the weak. [1]

2. Innovation in Romanian enterprises

Innovation activity is present in Romanian companies, especially in the small, medium and large ones.

The period analyzed in the study is between 2002 and 2010, period which was divided into four other periods: 2002-2004, 2004-2006, 2006-2008 and 2008-2010.

The machinery, equipment and software purchasing was the main activity in which the companies were involved to carry out innovative activities.

Innovative enterprises are classified in two categories: technological innovators, more exactly enterprises that have introduced new products or processes or significantly improved, and non-technological innovators who have implemented new ways of organizing or new marketing methods.

In carrying out the innovation activity, businesses have precise objectives, in order to achieve better results, increase productivity and the number of employees. Thus, the main objectives of innovation are:

- ❖ Workers health and safety improvement;
- ❖ Reducing environmental impact;
- ❖ Reducing material and energy costs per unit of production;
- ❖ Reducing labor costs per unit of production;

- ❖ Increasing the capacity of producing goods and services;
- ❖ Improving the flexibility of the production of goods and services;
- ❖ Improving the quality of goods and services;
- ❖ Entering new markets or increase market share;
- ❖ Replace obsolete products or processes;
- ❖ Expanding the range of goods and services. [2]

During the analyzed period the percentage of innovative enterprises grew steadily until the period 2006-2008; then between 2008-2010, due to the emergence of the economic crisis, this percentage has declined, as can be seen from Table. 1:

Table 1. Situation of innovative and non-innovative companies in the period 2002-2010

Nr.	Period	Innovative Companies	Procentage (%)	Non-innovative companies	Percentage (%)
1.	2002 – 2004	5.171.	19,9	20.853	80,1
2.	2004 – 2006	6.013.	21,1	22.475	78,9
3.	2006 – 2008	9.986	33,3	19.993	66,7
4.	2008 – 2010	8.116	30,8	18.214	69,2

(Source: Author’s processing of data published on www.insse.ro)

It should be noted that the number of innovative enterprises followed an upward trend, the same trend as the allocation of funds for R & D and innovation, reaching "peak" in 2008, when it recorded the highest economic growth after the year 1990.

The total value of innovation expenses followed the trend shown in the previous table:

Table 2. The total value of innovation expenses in the period 2002-2010

(millions lei)		
Nr.	Year	Expenses value
1.	2004	4.589,1
2.	2006	6.421,7
3.	2008	10.264,4
4.	2010	3.771,6

(Source: Author’ processing of data published on www.insse.ro)

Innovation expenditures are made for the following activities:

- *research – internal development* – includes systematic creative activities undertaken within the company in order to increase the volume of knowledge and their use for the realization of products (goods or services) and new and improved processes including software development;
- *research – development* – including research activities – development made by other companies or research institutes;
- *purchase of equipment and software* – includes the purchase of advanced machinery, equipment, hardware and software for the production and / or new or significantly improved processes;
- *acquisition of other external knowledge* – including the purchase of licenses for patents and unpatented inventions, know – how and knowledge from other businesses or organizations.

The percentage of these expenses in the period 2002-2010, is shown in the following figures:

(Source: Author’s processing of data published on www.insse.ro)

(Source: Author’s processing of data published on www.insse.ro)

(Source: Author’s processing of data published on www.insse.ro)

(Source: Author’s processing of data published on www.insse.ro)

Innovation intensity is present, especially, in business sector than in the service industry, especially for companies that produce and promote new products for other companies, which are in a larger number than companies promoting products for the market. The turnover of these companies is shown in the tables below:

(Source: Author’s processing of data published on www.insse.ro)

(Source: Author’s processing of data published on www.insse.ro)

(Source: Author’s processing of data published on www.insse.ro)

It is easy to notice that before the advent of the economic crisis there was a diversification of product innovation activity, while after 2008 these companies have been oriented in the greatest extent, to products remained unchanged.

3. Innovation and regional development

European integration as a political process but also as a specific form of globalization, a process interpreted in a common sense as leading in the direction of a more emphasized integration into the functional structures of the European Union, led, among other things, to an institutional revalorization (taking as a valorized starting point the European regional archetypal model – before the nineteenth – century) of the regional territorial level. The growing importance of regions as administrative units of business management let also to an increased competition level between them and the national level, or simply each other.

The premise from which we start to analyze the role of innovation in regional territorial horizon is that according to which the growth and development are consequences of the reunification of factors necessary and sufficient for an algorithm capable of generating the best results (outputs) as result of the work of at least two different types of productive factors (inputs) whose elasticity of substitution is constant. [3]

Determinable consequences of growth always involve negative territory: pollution, depletion of renewable resources, inefficient allocation of factors on branches or sub-branches factors etc. We can also say that these determinable consequences do not involve a negative territory, no more than the statement „exception strengthens the rule”; we can have a large sectorial development to mono-industrialize a region or a country, but with unpredictable consequences. Getting technology able to propel a region in another comparative category of production is so important that any side effects fade, in a significant measure.

But we can also add that the development has a much more pronounced territorial character than the growth, which can only be recorded in growth poles that will not reverberate economically and socially on the region of origin. The change of industrialism

perspectives in the late twentieth century and the beginning of the twenty – first century means adding to the classical logic of factors, technological and infrastructural resources and markets, the minimal mode regarding institutions, leadership and organizational culture. [3]

European initiative in this area to spend at least 3% of the aggregate European GDP does not represent an output of the system, inasmuch as relative dissemination obsession of clusters development in a manner more or less uniform throughout the whole Union does not appear to be a relevant solution. But it seems that the real discrepancy (setback) comes mainly from the inability to assimilate innovation’s own culture, a situation that can be put in light, for the European context, quite evident both in – a comparative basis East – Asian, not only North – American. That is because, many Asian countries, regardless of the social – political background (military dictatorships, communist countries, liberal democracies), have registered such significant progress that it transform them into models with specific relevance to any country engaged in the contemporary global economy mechanism. [3]

Precisely to eliminate these gaps at the EU level, two programs were initiated, two programs meant for funding innovation, Europe 2020 and Horizon 2020 more exactly, the latter being an ambitious funding program worth over 80 billion euros in period 2014-2020. Also the 7th Framework Programme for financing research – development – innovation earmarked for 2012, through two financing programs, the amount of 654 million euros, of which the amount of 108 million euro to stimulate innovation in small and medium – sized companies (SMEs).

In Romania, unfortunately, the regional distribution of innovative companies is uneven and has depended very much on the modalities of financing of these companies. Surprisingly, during 2008-2010 on the first place are the North-East, South-East and South-Muntenia regions situated ahead of more developed regions, is right from other points of view. I believe that this discrepancy is due to the fact that some enterprises in the 'leading' regions were set up either in disadvantaged areas and benefited from certain tax incentives; either it were established during start-ups and spin-offs programs. The percentage of these innovative

companies, by development regions is presented below:

(Source: Author`s processing of data published on www.insse.ro)

4. Conclusions

If innovation was imposed in Romania, becoming an essential part of the continuing development or at least of maintaining it within a competitive economy from now on; now it remains as years pass and the assessment of the economy to edify more and better. One thing is certain: Romania should not deviate from this path of at least two reasons: first, the trend is moving towards the European Union countries and, secondly, Romania should keep this trend in order to receive funding from the European Union. Funds for the innovation activity are high and so Governments who will succeed to the leadership of Romania will have to allocate amounts for this activity from the budget, so as in 2020, to be allocated 2% of GDP for research-development and innovation activities.

adriana.fp@gmail.com

Dobre Florin

flndobre@yahoo.com

The Bucharest University of Economic Studies

Abstract

The presence of options in accounting raises the problem of the criteria adopted for choosing one policy or another. The freedom to choose the accounting policies, controlled by the management of the company in its intention to achieve the planned objective, leads to a selective choice for reducing the result or for increasing it. The study presented below intends to prove that the disclosed result doesn't show real, reliable information; therefore it is recommended not to be used in the financial analysis by its self. That is how the continuous attempts of finding other more reliable financial – accounting information are explained.

Key words: accounting policy, simulated options, subjectivity, financial statements, accounting result

JEL Classification: M40

1. Introduction

Great importance is given to accounting information due to its mandatory character to express truth, fairness, clarity and precision. Information must be as close to reality as possible, as a result of the fundamental purpose of accounting to effectively manage the company's economic and financial resources for future decisions to be taken. Therefore, rules, norms, computation and assessment methods, accounting rules must be respected and applied.

The accounting policy is part of a dual logic of optimizing choices and of financial communication of the company with its environment. The choice is made in a framework set by many sources of

accounting law and of fiscal rules, as well, applicable especially regarding the financial statements. Within these, Casta (1989) [1] illustrates policies such as:

- Setting or modifying the assessment methods;
- Selecting or changing methods of financial statements disclosure;
- Setting the model and aggregation degree of information published in the financial statements, in general, and in the disclosures, in particular;
- Selecting the information disclosed in the annual report;
- Determining the date of financial information communication;
- Voluntary publication of optional synthesis documents, such as the Financial Board;
- Choosing or changing the auditor;
- Total or partial alignment to an recognized international accounting referential;
- Abandonment of certain accounting principles.

Accounting policies are ways of solving a problem. The existence of multiple variants that can be used in providing solutions to various situations leads to accounting options. The referential used for elaboration of accounting policies allows alternatives for registration and assessment in accounting, that is various methods of estimating the entity's financial position, financial performance, or cash flows

This paper adds to the literature the perspective on how the existence of options and choice of methods, leading to principles, concepts, conventions, rules and specific practices used in accounting and in financial reporting, is mandatory for development of accounting policies.

The paper is organised as follows. In the next subsection we review the existing literature on the role of accounting policies and options, as well as on the possibility of choice granted to the business in the intention to achieve planned objectives. Furthermore, we will present our testing case through which it is shown how different choices lead to different results. This would be the case when a company is free to choose between two accounting policies following a certain goal. We conclude the section by drawing a conclusion on the possible effects of options on the business' financial information, in general, and on its accounting result, in particular.

2. Relation to Prior Research

According to the definition adopted by both international boards IASB and FASB [2], the accounting policies are the specific principles, bases, conventions, rules and practices applied by an entity in preparing and presenting financial statements. Continuing to search in the literature, we find the opinion of Nobes (1998) [3], who defines accounting policies as assessment, measurement and recognition methods, applied by the company, based on those generally accepted by law, accounting standards and business practices. As defined by Casta (1989) [1], the accounting policy represents the assembly of choices made by management on the accounting variables, leading to the arrangement of the content and form of financial statements in compliance to applicable regulatory requirements. Accounting policies defines both theory and method underlying the preparation and presentation of financial statements (Ristea, 2003) [4]. Reports on annual accounts management, periodic reports and additional disclosures are also included however, within their scope.

Watts and Zimmerman (1990) [5] lauded the positive accounting theory, as a mean of explaining the companies' behaviour in terms of accounting policy, considering that decisions taken answer to the result maximization objective. In addition, Gietzmann and Trombetta (2001) [6] discuss effects of firms' specific choices of accounting policies. The choice of historic accounting policy, for instance, can be used

to communicate private information about the firm because the choice interacts with the optimal firm strategy for voluntary disclosure. They underpin the fact that the choice of an accounting policy is either not directly considered or it is embedded in the disclosure decision, considering that the disclosure decision is effectively one that establishes the precision of an accounting report. According to Hope (2002) [7], accounting policy disclosures reduce uncertainty about forecasted earnings. Nevertheless, if investors and analysts are not sure about the accounting policies used in measuring income, they face more uncertainty in forecasting future earnings numbers, this leading to a less importance given to financial statement information.

Knowledge about the applied accounting policies can be most easily obtained from firm-specific disclosures. This information can be easily obtained indirectly by analyzing the time series of earnings and by having firm and industry-specific expertise, in terms of stability of a firm's operations and industry structure. Tarca (2002) [8] identifies national law, stock exchange rules and competitive market pressures as factors that impact on the selection of accounting policies to be used in the preparation of the firm's financial statements. In addition, the firm's attributes and the preferences of its managers are known to influence choice of accounting policies.

3. Research design

We built our research on the belief that the manufacturer of accounting information can manifest bias on a certain purpose by allowing the existence of options, namely the possibility to choose between different accepted methods and accounting treatments, subject to national and international provisions in force. Nevertheless, such policies have to be permanently used and need to be published.

It is, for instance, the case of the fungible inventories output. Among the policies possible to be adopted we mention for example FIFO method (first in, first out), the weighted average cost method and the LIFO method (last in, first out). The accounting

option refers to choosing one of the three versions.

The option for a method or another is determined, according to the fundamental objective of accounting, by the need for truth, for obtaining a fair view. Therefore, through accounting, real and fair information is ensured, credible for all users, including for taxation. Moreover, the company' organizational model, as an object of accounting evidence and taxation, must be also considered. In these terms, a series of principles, rules, and conventions can sustain options for a method or another. The consistency principle itself offers the possibility of changing the methods to be used, with effects on the content and value of information. In reality, we discuss about a coordinated action, through which alternatives of action are elaborated, in the attempt of exploiting weak points of regulations, which can influence the content of the financial statements, the way of understanding and usage of accounting information obtained by various users.

Our research is based on a case study, through which, by the help of figures, we test some simulated options and their impact on the accounting result, in order to choose the most suitable to the company' interest.

Our research hypothesis is based on considering that three such interests can be followed:

- The stability of the result during the period;
- High results in the first years;
- Low results in the first year.

We chose three from the most common accounting policies – those referring to depreciation methods, expenses and revenues recognition in the case of a construction contract and inventories output assessment.

As referred to the **depreciation policy**, we tested two of the methods – straight line method and the double decline method, on the case of a non current tangible asset, having a useful life of four years.

In terms of considering the revenues and other expenses to be constant from one year to another, we determined the influence on the result in the two cases.

Table no. 1. Influence of depreciation methods on result

Income statement	1st Year	2nd Year	3rd Year	4th Year	Total
Expenses with straight line depreciati on method	30.000	30.000	30.000	30.000	120.000
Expenses with degressive depreciati on method	45.000	28.133	23.433	23.434	120.000

According to the consistency principle, the result can be influenced by the depreciation policy only in the year of investment. This means that the straight line method once choosed as shown above, the company must comply with this choice in the next three years, even if in the in the second year it realizes that another method would rather be used. In reality, companys can change the depreciation methods, the period or the residual value when the initial estimates don't correspond to the actual situation. These changes of estimates can significantly affect the current result and that of future financial years.

In order to reflect the case of recognition of expenses and revenues in a construction contract we based our testing on the case of a construction contract of a storage space, on a period that lasts from 1st of January, 1st Year till 10th of January 4th Year. The estimates amount to 400.000 m.u., while the estimated cost of works in the contract was of 300,000 m.u., distributes as follows: 64.600 m.u. in the 1st Year, 98.800 m.u. in the 2nd Year 8, 66.600 m.u. in the 3rd Year și 70.000 m.u. in the 4th Year.

The company can choose to recognize expenses and revenues based on either the completed – contract method or the percentage-of-completion method. We must underpin though that according to the national accounting regulations and IFRS referential, revenues from service contracts is recognized in the period during which the service is rendered, generally under the percentage-of-completion method.

1. In case of using the completed – contract method, the information extracted from income statements is as follows:

Table no. 2. Influence of the completed – contract method on result

Income statement	1 st Year	2 nd Year	3 rd Year	4 th Year
Revenues from services	64.60	98.800	66.600	170.00
Cost of services	0	98.800	66.600	70.00
Impact on current result	0	0	0	10.00

Source: Own computation

2. In case of using the percentage-of-completion method, the information extracted from income statements is as follows:

Table no. 3. Influence of the percentage-of-completion method on result

Income statement	1 st Year	2 nd Year	3 rd Year	4 th Year
Revenues from services	86.13	131.7	88.80	93.33
Cost of services	3 ¹	33 ²	0 ³	4 ³
Cost of services	64.600	98.800	66.600	70.000
Impact on current result	21.533	32.933	22.200	23.334

Source: Own computation

¹ 400.000 * 64.600 / 300.000 = 86.133 m.u.

² 400.000 * 98.800 / 300.000 = 131.733 m.u.

³ 400.000 * 66.600 / 300.000 = 88.800 m.u.

⁴ 400.000 * 70.000 / 300.000 = 93.334 m.u.

It is found that the two methods have the same impact on the recognized total result of 100,000 m.u. They differ, however, in terms of periodically outcome measurement and reporting during construction works.

In order to assess the output inventories, we chose as cost computation variants FIFO method (first in, first out) and the weighted average cost method based on the consideration that both methods are allowed by Romanian legislation, as well as by IFRS referential. We set the final figures based on hypothetical quantities of merchandise

purchased and consumed during the year, in terms of prices increase, and we only took for analysis the total cost of exits. The impact of the two assesment metods on the result during the four years of simulation is presented in the table bellow.

Table no. 4. Impact of the two assesment metods on the result

Income statement	1 st Year	2 nd Year	3 rd Year	4 th Year
Cost of goods sold – FIFO method	16.000	48.800	72.800	40.000
Cost of goods sold – Weighted-average cost method	20.000	51.600	69.500	38.648

Source: Own computation

We present the following table summarizing the influences of policies adopted on the result:

Table no. 5. Influences of policies adopted on the result

Items	1 st Year	2 nd Year	3 rd Year	4 th Year
Depreciation expenses				
- straight line method	30.00	30.00	30.00	30.00
- degressive depreciation method	0	0	0	0
- straight line method	45.00	28.13	23.43	23.43
- degressive depreciation method	0	3	3	4
Result from construction services				
- the completed contract method	0	0	0	100.00
- the percentage-of-completion method	21.533	32.933	22.200	23.334
- the weighted-average cost method	3	3	0	4
Expenses with inventories				
- FIFO method	16.00	48.80	72.80	40.00
- Weighted-average cost method	0	0	0	0

- Weighted-average cost method	20.00	51.60	69.50	38.64
	0	0	0	8

In making correlations and calculations we assumed that annual result before including depreciation expenses, the result from construction works and expenditure on inventories is constant and amounts to 1,000,000 m.u.

In the attempt to determine the best choice, we narrowed the scope of possible combinations, keeping for each of the four years, the options that lead to obtaining the highest, respectively lowest result in the analysed year, so that, annually, the difference between the two options is maximal.

Table no. 6. Possible combinations of methods

Option	Chosen methods	Effect
1	- degressive depreciation method - the completed – contract method - Weighted-average cost method	Lowest result in the 1 st Year
2	- straight line method - the percentage-of-completion method - FIFO method	Highest result in the 1 st Year
3	- straight line method - the completed – contract method - Weighted-average cost method	Lowest result in the 2 nd Year
4	- degressive depreciation method - the percentage-of-completion method - FIFO method	Highest result in the 2 nd Year
5	- straight line method - the completed – contract method - FIFO method	Lowest result in the 3 rd Year
6	- degressive depreciation method - the percentage-of-completion method - C Weighted-average cost method	Highest result in the 3 rd Year

7	- degressive depreciation method - the percentage-of-completion method - Weighted-average cost method	Lowest result in the 4 th Year
8	- straight line method - the completed – contract method - FIFO method	Highest result in the 4 th Year

Table no. 7. Results obtained

Explanations	1 st Year	2 nd Year	3 rd Year	4 th Year
Result from Option no. 1	935.000	920.267	907.067	1.037.918
Result from Option no. 2	975.533	954.133	919.400	953.334
Result from Option no. 3	950.000	918.400	900.500	1.031.352
Result from Option no. 4	960.533	956.000	925.967	959.900
Result from Option no. 5	954.000	921.200	897.200	1.030.000
Result from Option no. 6	956.533	953.200	929.267	961.252
Result from Option no. 7	956.533	953.200	929.267	953.334
Result from Option no. 8	935.000	920.267	907.067	1.037.918

The annual result showed above is the one before including depreciation expenses, result from construction works and expenses with inventories.

4. Discussions and implications

When choosing a policy or another, the company management may pursue objectives other than the relevancy and credibility, such as:

- Reducing announced losses;
 - Minimizing taxable profits;
 - Increase or decrease the current result;
 - Increase or decrease of distributable profits;
 - Temporary smoothing of accounting results in order to reduce the risk presented in the financial environment.
 - "arrangement" of balance sheet (window dressing), which, through its structures, trying to better satisfy prudential rules, contract clauses or the other criteria required by the market
- We analyze the

results obtained by choosing each of the eight options presented, depending on business objectives.

If the company pursues **long-term stability of the result**, option no. 7 is what best serves this goal. This involves combining the following: degressive depreciation method, percentage-of-completion method and weighted-average cost method.

In order to fulfill the goal of obtaining **great results in the first years**, option no. 2 is to be chosen, decision which involves combining the following methods: straight line depreciation method, the percentage-of-completion method and FIFO method.

Based on the analysis of data from the above presented table, the third possible goal – **lower results in the first years**, can be achieved by applying option no. 8, that assumes the adoption of the following methods: straight line depreciation method, completed – contract method and FIFO method. In this case, the method chosen for expenses and revenue from construction contracts that lead to fully recognition of income in the last year has the highest influence. The testing outcomes show that business results can be brought to a desired image by the action of accounting professionals and "forbearance" of accounting rules.

5. Conclusions

Result often depends on the size of the accounting methods adopted, because the results obtained by their implementation may be different in most cases. In circumstances where company uses liberal methods, the yield may be increased in the short term, but of mediocre quality. Furthermore, the same effect would be achieved if the company has great benefits as a result of unusual facts, occurring over a short period of time.

After analyzing the hypotheses presented, we can conclude that the result is a subjective indicator, depending on the stakeholders, on the economic and political system, as well as on the leadership and management of the company.

To support this statement, we subscribe to the opinion of Capron (1994) [9], according to which "the product provided by accounting can only be the result of a

compromise between expectations and multiple demands."

Abstract

In our work we start from the discrepancy between the views of practitioners and theorists accountants. This discrepancy increased once the abstract theoretical research, which resulted in a lack of intelligibility for practitioners. The latter believes that specialists in educational establishments were removed interest accounting practice, while researchers argue that the interest of the practice is defined by a very narrow horizon. Our opinion is that a theory of practice removing and vice versa will only lead to a limitation of satisfying the need for financial and accounting information users. Since, therefore, we believe, accounting research should be directed towards theoretical research linking information with the information provided by the reality of the economic environment in which the activities but also the evolutionary behavior of users and we considered it useful in analyzing the assessment and recognition of debt an enterprise.

Keywords: debts, recognition, evaluation

J.E.L. Classification: M40, M41

1. Introduction

IASB Framework states that "directly related balance sheet structures assessment of financial position are assets, liabilities and equity. "Thus, if debt can retain the following definitions:

- IASB General Framework: Debts Is a present obligation of the entity arising from past events and settlement is expected to result in an outflow of resources embodying economic benefits;

- British General Framework: Reductions

are probable future economic benefits arising from present obligations of an entity to transfer assets or provide services to other entity that result Tall past transactions or events;

- American General Framework: Are present obligations of an entity to transfer economic benefits as a result of past events and transactions;

In conclusions, the three definitions include the same elements: present obligation of the entity arising from past events that is likely to cause an outflow of economic benefits from the entity.

Recognition is incorporated into the balance sheet or income statement an item that meets the recognition criteria. This process involves the description in words of that element and assigning a certain amount, and include that amount in the total balance sheet or profit and loss account. Items that satisfy the recognition criteria should be presented in the balance sheet or income statement.

Non-recognition of these items can not be corrected either by disclosure policies accounting policies used or by notes or information suplimentare. Un item that meets the definition of a structure financial situation must be recognized if:

(a) it is probable that any future economic benefit associated with the item to enter or leave in or the entity, and

(b) the item has a cost or value that can be measured (a) reliably.

Probability of future economic benefits. The concept of probability is used in terms of recognition criteria have a reference to the uncertainty that future economic benefits associated with an item or they will go out of body. This concept is imposed by the uncertainty that characterizes the environment in which they operate any entity. Evaluation of uncertainty related to

future economic benefits take into account information available when the financial statements.

Evaluation's Credibility. The second condition that an element must satisfy to be recognized is that they have a cost or value that can be measured (a) reliably. In many cases, cost or value must be estimated (a) the use of reasonable estimates is part essential in preparing financial statements and does not influence their credibility. Where however, can not be made a reasonable estimate, the item will not be recognized in the balance sheet or profit or loss.

An item that, at some point, no longer meets the criteria for recognition can be recognized later as a result of circumstances or events ulterioare. Informatii on an element that has the essential characteristics of a structure of the financial statements, but does not meet the criteria for recognition may nonetheless be disclosed in the notes, explanatory material or supplementary tables. This procedure is recommended if knowledge of these elements is considered relevant for the assessment of the entity's financial position, financial performance or financial position changed by users of financial statements.

A liability is recognized when it is probable that an outflow of resources embodying economic benefits will result from the settlement of a present obligation and the amount at which the settlement will take place can be measured reliably. In practice, obligations under contracts whose total or partial non-performance is balanced by both sides (for example, liabilities for inventory ordered but not received yet) are not generally recognized as liabilities in the financial statements. An essential characteristic of a liability is that the entity has a present obligation. An obligation is a commitment and a responsibility to act in a certain way. The law may require the entity to meet its obligations as a result of a contract or legal requirements.

Explanatory Dictionary of Romanian language defines obligation as a civil relationship whereby one or more persons are entitled to claim other people, we are indebted to give or to do something. In most cases, the obligation is reflected by generating transactions of goods and services involving the existence of primary and

amounts to be paid. Thus, every transaction is recognized, there is certainty the future transfer of benefits from the entity.

2. Recognition Debts

The IASB Framework required to distinguish between current and future commitment obligation. Management of an entity's decision to acquire assets in the future or guaranteeing a loan made to an associated enterprise is not a present obligation but a future commitment. In this case, since there documents that provide certainty leaving future benefits, we can not talk about a debt level of balance.

Only when the entity has a binding agreement to purchase the assets or insolvency reliable information about the associate, there are economic consequences output ensures certainty of economic benefits.

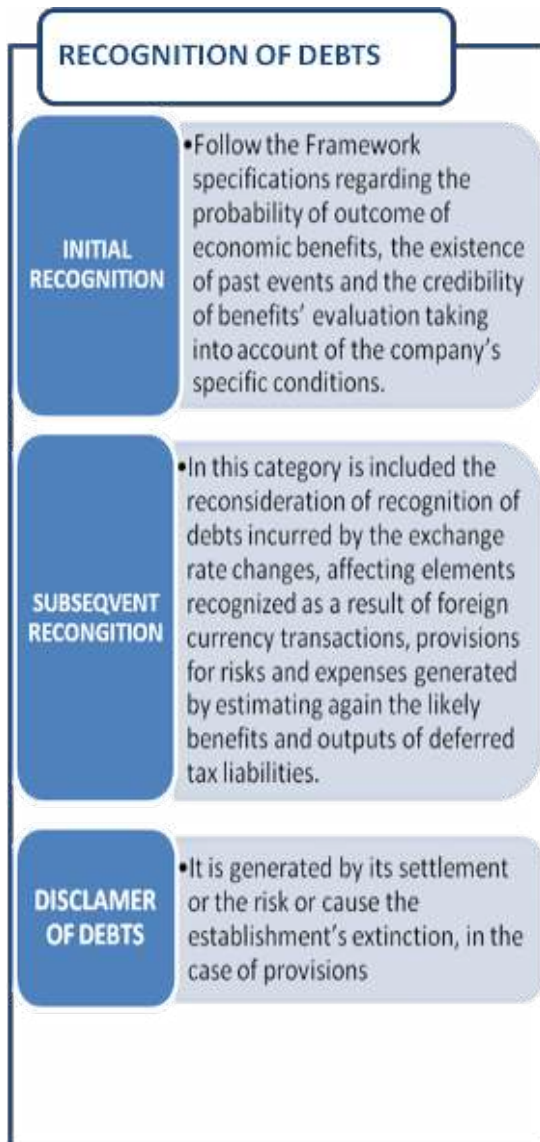

Settle a present obligation usually involves, giving entity to certain resources embodying economic benefits in order to meet the demands of the other party. Extinction of a present obligation can be done in several ways, for example:

- (a) cash;
- (b) transfer of other assets;
- (c) provision of services;
- (d) replacement of that obligation with another obligation, or
- (e) the conversion obligation in equity.

Credibility evaluation criterion does not pose serious problems for debt, since the events generating the transaction are based on documents clearly intended to regulate the value of debt. We believe, however, that an argument must be attached to this statement. We start from the fact that the transaction that generates the document can be used in measuring the liability event and to recognize the asset resulting from the transaction. However, the evaluation for that asset needs to take into account other elements, and, in most cases, the amount recognized for the asset in the financial statements of the buyer does not overlap the value of the item recognized in the financial statements of the seller. Instead, the debt value recognized by the buyer must correspond precisely to the amount of the claim known by the seller.

We can talk even about the moments of debts (liabilities) recognition:

Figure 1. Moments of Debts' Recognition

(Source: projection of the authors)

Regarding the evaluation of debts, we must remember the following points considered to be most important:

- At the moment of their recognition, liabilities are valued at nominal value, represented by the value of equivalents obtained in exchange for the obligation or the amount expected to be paid in cash or cash equivalents for the settlement of debt;
- Foreign trade operations are valued at the exchange rate in effect on the date of actual transaction;

- The balance sheet liabilities in foreign currencies should be assessed and reported using the exchange rate in effect on that date, and exchange rate differences are recorded as financial income or expenses.

Some liabilities can be evaluated only by using a high degree of estimation. Some entities regard these liabilities as provisions because they are defined "*debts with chargeability and doubtful value.*" Recognition of provisions is done when the entity has a present obligation generated by past events, so it is likely that an outflow of resources will be required to meet the obligation and also a reliable estimation to be made of the amount of the obligation.

Provisions can be distinguished from other liabilities due to the uncertainty factor related to the chargeability or value of future debts required for extinguishment of the expense.

Starting from the definition attributed to evaluation by the IASB Framework, "Evaluation is the process of determining the monetary amounts at which financial statements' structures will be recognized in the balance sheet and profit and loss account. Assuming the choice of some evaluation bases, we present an analysis of debts in terms of the measurement basis.

Evaluation of debts in the light of measurement basis

Tabel no 1

BASIS OF MEASUREMENT	OBSERVATION
HISTORICAL COST	<i>Debts</i> are evaluated at initial recognition. (According to IFRS)
CURRENT COST	<i>Debts</i> will be measured at the undiscounted amount of cash or cash equivalents that would be required today to pay the liability.
REALIZABLE VALUE	<i>Debts</i> are presented at the level of settlement value, i.e. the undiscounted amount of cash that would be paid for debts in the normal course of operation
PRESENT VALUE	<i>Debts</i> are presented at the present value of outflows from future net fund that are expected to result in payment obligations in the normal course of operation.

(Source: projection of the author)

3. Conclusion

In conclusion, the definitions of debts presented above identify their essential features, but their usefulness for decision, in other words, the reason for their presentation in the financial statements, however, is achieved by applying the recognition criteria. Both definitions of the elements and probability criteria require the delimitation of future economic benefits. Note that by maintaining the actual cost (specific in the evaluation of the balance sheet), a basic certainty grounded in the past is replaced by with another currently offered, which however will become pretty quickly past. If we appreciate everything from the perspective of past, the choice of this convention is fully justified, but in terms of the perspective of future, the question is whether other basis would be more appropriate.

Abstract

The role of accounting information in the decision making is essential, especially thanks to its dual, the circuit processes information in a financial accounting and management accounting cycle. In this way, management uses the information to determine business strategy on the one hand, and to provide operational management on the other. Accounting area is not isolated but is covered by a complex system of links inside (productive and functional segments, their makers), and the outside (customers, banks, shareholders). By its action, accounting even lead to optimization of the decision, the corresponding allocation of resources. Destination information system of an economic entity is providing support and exploitation of the decision, setting the relationship between these two sides. Subsystems can be found in its composition dedicated to activities and information purposes aimed ultimately lead productive process, having as a common basis, the accounting information.

Key words: decision making process, information system, financial accounting, management accounting, information system of inventories.

J.E.L. classification: M41, M40.

1. Introduction

One of the essential components of a company's information system is the accounting-financial segment.

When the main aim is to implement a managerial information system, the

organization's accounting must become the most active element, with the greatest influence. There are at least two approaches: first, it is a financial-accounting activity that meets management requirements at different levels, and secondly, it represents the administration and management of their resources as an urgent necessity.

Analyzing the role of accounting-financial information system in the decision making process, the first factor to be emphasized is the fact that the report accounting- financial information – decision, in terms of accounting in double circuit, implies certain nuances, even restrictions. Thus, we may point out there is information of financial accounting and information of management accounting.

In these circumstances there are many questions about the justification of this classification, the boundary between them, the differences between the two categories and the data that may be highlighted as crucial information.

2. Financial accounting and management accounting - business information system components

There have been published many works in accounting literature that attempt to answer these questions. We have chosen a few opinions that we consider justified: the two "sides" of accounting have different privileged users (financial accounting for external ones, management accounting for the internal) but in both cases "balanced information products", between simplicity and sophistication, must be provided. A too large set of evaluation criteria for assessing the quality of information is required,

different for the two situations. As far as management accounting is concerned, relevance is the one that prevails, while in the other case, reliability (objectivity) is considered first.

In general, internal accounting is closer to the decision-making, especially in terms of operational management.

In the long run, however, the company's strategy is directly (by decision makers who conceive) or indirectly (through third party beneficiaries) influenced by financial accounting information.

A second point to note is the fact that, with the implementation of new information and communication technologies, the "border" between the two types of accounting is not as marked as it used to be.

Differentiation must give its place to correlation, in order to achieve, in both cases, the improvement of decision making process. While internal accounting is closer to the structure and activity of the firm, the general accountancy links it with the overall exterior.

As part of the two types of accounting already mentioned, the stocks accounting is relevant in terms of the dual relationship reflecting the two circuits, because they operate with information accompanying the entire course of material flows and can be encountered in transactions with the exterior and in the specific conversion of production process.

The quality of leadership has both a side strictly related to the internal environment of the economic entity and one that concerns the ability of decision makers to integrate business in a competitive environment. The external environment "is talking" to the company, based on financial-accounting information. The fundamental objective remains "to provide a true and fair view of the entity's economic situation and results".

Accounting-financial segment should not only have a role of execution (processing), not only look to the past, but also to get involved in the management of the company's forecasting process (strategic management). At the same time, it will be redefined by the means of new instruments which are available to them: information resources and managerial methods (procedures). Accounting normalization and harmonization processes should not be neglected in this context.

A particular attention should be paid to measuring and analyzing the effects of decisions made, based on financial information. It must be kept in mind, in this connection, that the accounting is not isolated but is part of a complex system of links both with the interior (productive and functional segments, their decision makers), and the exterior (customers, banks, shareholders). It is not about permitting to make the decision but, by its action, accounting even leads to optimization of this process and to the corresponding allocation of resources.

We believe that information regarding current material resources provided by the accounting information system, is reflected in an autonomous circuit forming the information system of inventories (stocks), perfectly overlapped on the scheme of an economic entity's information systems. Its complexity, due to involvement in keeping the evidence of costs, expenses, revenue from sales and the change in value of material goods existing in the property of firm, allows a meaningful analysis of its structure as a system.

The essence, and also destination of information systems, is to provide support for exploitation and the decision, setting the relationship between these two sides. In a structural model, the information systems are presented so:

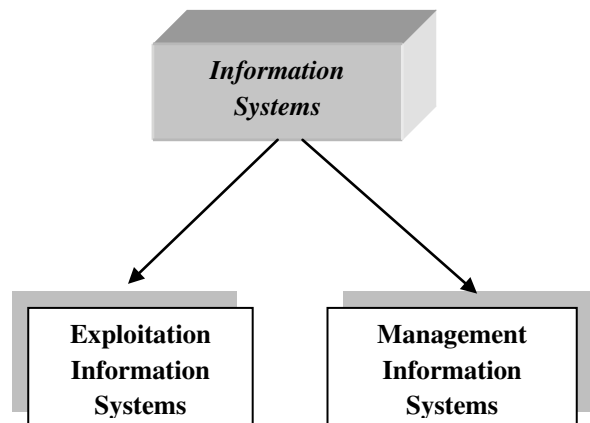

Fig. 1 Information system components

Within each system structures are found on objective information, presented as follows:

3. Characterization the systems from the perspective of information

Information systems for exploitation, considered *operational* as well, are focused on the representation and coordination of execution systems' activities. The large volume of primary data, including those on stocks, is stored and reflects transactions, flows or status of business. Some of the information on stocks is intended for the operational system, and we can identify them in transaction processing systems (purchasing, sales), control of production and systems aimed at processing in accounting the management of stocks. If used in the management system, they mainly concern short-term decisions.

Possible and useful applications at this level refers, for example, to sales transformation into physical quantities, to checking the budget allocate for various operations during the storage, by calculating periodically the real values corresponding to the quantities determined by budget.

The information obtained may allow, in our opinion, warnings if the current situation deviates from what was planned.

While providing a wide variety of data, information systems for exploitation are not oriented towards important information, necessary for management, and are formulated respecting precise and repetitive rules. Their goal is the efficient processing of commercial transactions, production process control by monitoring material consumption according to the parameters set (possibly through automated processes), update of the database on stocks and increase of the efficiency of insurance activities for the material resources and finished products according to contracts.

The main features of these systems in terms of data and information are:

- repetition - the data used in processing and foreground are repetitive, falling within certain time intervals;
- strong detailing, required by the need for insurance of control regarding the property values and the way in which material resources are consumed and used;
- strongly structured form for both input and output data, due to the possibility of predefining them and the necessity of mixing them;

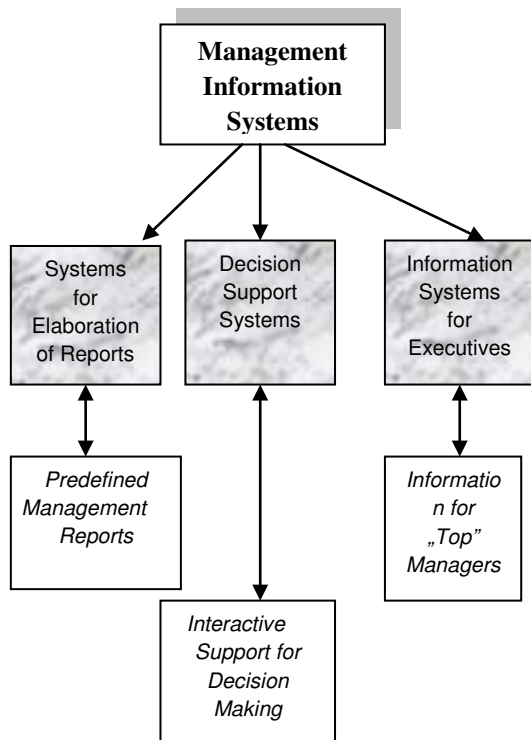

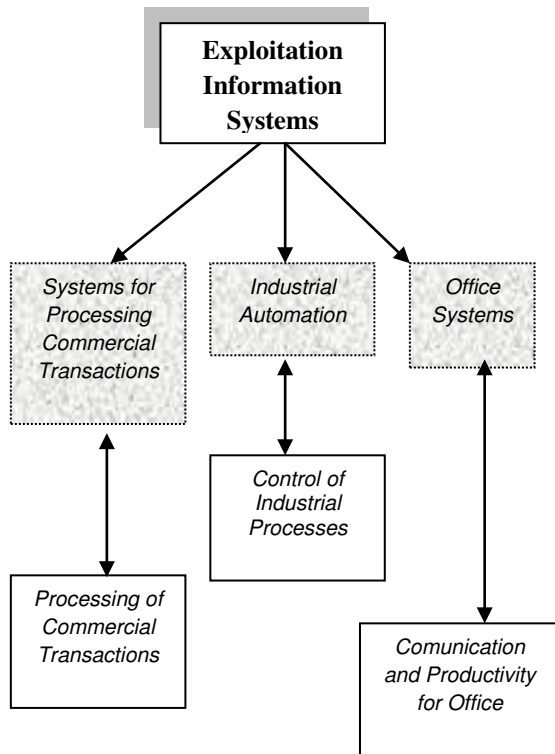

Fig. 2 Classification of information systems depending on their objectives

- increased accuracy, due to the accurate, strict formulation of information requirements and multiple checks to what data are subjected to before being processed (checking and correlation of data with stocks accounting).

Thus, most of the decisions at the operational level are programmable in the conditions of automation of operations regarding stocks.

Management information systems are designed to assist managers in making decisions based on information regarding the management, supervision and control of enterprise's resources and hence of its stocks.

Structuring on various levels of management (operational, tactical, strategic), generates a corresponding tie of information systems and their role in business management.

Information systems designed as report generation systems are processing data coming from transactions and production so that any primary information entered into the system triggers a cycle of processing in several steps, as follows:

- a. data collection - at supply, the number, date, supplier, purchased goods, quantity, price and so on are registered;
- b. operations processing - by charging management with the respective goods;
- c. updating files and databases in synthetic and analytical stocks accounting;
- d. obtaining documents and reports necessary to the management of a certain compartment (for operational decisions).

Depending on when they are provided, the reports offered can be divided into:

- periodic reports, with a default format providing to managers the information on the weekly situation of stocks of raw materials or finished product, and sales and purchases of goods
- reports about exceptional situations, for example, decrease of stock under the level of safety or increase above the maximum rate, lower sales than planned, demand of a product over the existing stock;
- reports upon request, responding to a specific requirement, in a query language, that allow such analysis comparing stocks of two groups of sales or goods or from two different management periods.

Information systems to assist decision are supporting the user (manager or analyst) in

poorly structured decision-making processes, with a tactical and strategic dimension on the environmental in which it is applied. Starting from a basis ensured by the operational information systems, the contribution of this system resides in the *learning process* that it induces to the decision maker and *amplification of his reasoning*, having an objective perspective on the scenarios presented to him.

The mode is interactive, and the information is timely, with reference to a particular aspect of a product or process. Thus, it allows the analytical modeling, data mining and graphical representation of information and managers can explore different possibilities and obtain provisional results to formulated assumptions.

Delimitation of the information system on stocks from the information systems regarding other activities is not possible or rational anymore, the analysis resulted at the level of information systems meant to assist decisions involving multiple data regarding overall business activity.

We believe that the analytical modeling allowed in this context may refer to:

- ✓ analysis of initial data variants, by observing the repercussions of some variables' change on other variables. An example would be the evolution of finished goods inventory when monthly sales would increase by 15%;
- ✓ sensitivity analysis by observing the consequences of repeated (successive) change of one variable on other variables. Increasing the stock of material resources value with 100,000 lei compared with the turnover estimated to determine the change in the daily speed of stocks' rotation;
- ✓ analysis to determine the purpose, by changing several variables repeatedly until the variable-objective reaches the "target" value. One can try to obtain the total cost of supply to the value determined in the budget by combining successively the values of storage costs with those of launch, in different conditions;
- ✓ optimization analysis, by finding values for certain variables subject to specific restrictions, for example: determining the optimal interval between supply and their cadence or the optimal lot of supplies stocked in case of a minimum and maximum stock permitted and the average daily consumption.

The nature of decisions at this level of management is partially structured, since it involves subjective judgments and interventions that can be correlated with certain data and formalized models.

Strategic information systems are interactive and meant to support decision and „top” managers. They can be information systems that "bring" strategic advantage, defined as information systems of strategic importance (which allow the computerization of activities to achieve a sustainable competitive advantage), and information systems to support strategy (for strategic information, providing tight coupling between the information system, the decisional one, the modeling-designing system, and especially with the purpose one).

Information systems for strategic management are designed as a combination of all the other systems in order to present a summary of the current situation and future trends of factors designated by management as key factors for success, indispensable for achieving the strategic objectives. The rapidity of access to information and their relevance, as well as the analytical modeling options and presentation of managers' requirements characterize this system.

Decisions have a non-programmable character, due to different data sources and the information that are analyzed and can change in real time, which requires great flexibility of the system.

To provide information necessary for the decision making process, an information system for strategic management will include complex processing processes, some oriented towards the financial-accounting field, and other using quantitative techniques of analysis.

In this way, by processing the databases of exploitation and management, an optimal combination of products at sale for a maximal turnover can be achieved. Sourcing from a supplier with raw materials needed for production in different quantities, for a period of time that ensures stability, can lead to a low cost of this activity.

4. Conclusions

Therefore, an economic activity is managed properly when the decision's formulation, implementation and control of

its execution are related to accurate and complete intelligence, provided by accounting. Business success is undoubtedly linked to the interdependence *information-decision-action-results* or *accounting-management-accounting*.

Clear and accurate reflection of reality with the help of accounting information system allows the evaluation of the company's effectiveness based on management criteria, and by forecasting data enables the connection of future objectives with the dominant economic developments.

Abstract

“Integrity may be seen as the quality of having a sense of honesty and truthfulness in regard to the motivations for one’s actions”; There is no information as accessible to internal and external financial analysts and decision makers as financial statements. This type of information is widely accepted as the basis for a whole range of different financial management decisions, both of tactical as well as strategic nature. There have been created a lot of financial statement based analytical instruments to be used in different circumstances regarding return, risk, asset turnover, liquidity, solvency – to name but a few. But to believe that all these instruments are perfectly efficient for any decision requires a big leap of faith. This is due to the wide known aspects regarding financial statements “window dressing” techniques that distort financial information to match some undercover needs of certain company officials. Everybody in the financial management world knows how financial statements could be made to look better, if such a need is to arise. From a management globalization point of view, is this a widely spread practice or it represents just some isolated cases? Do decision makers and investors blindly believe in financial statement information integrity, or they question any piece of information and verify its relevance? Does financial management of global era is that better-off using these unethical practices or it’s just a “matter of perspective”?

Keywords financial statements, information, relevance, integrity

JEL Classification Code: G11

1. Introduction

Aim of this paper is to develop a methodology to verify the relationship between the quality of accounting disclosure and company’s perception on the financial market.

We studied four possible methods to reach this goal:

- the empowerment of some accounting regulations governing the quality of accounting information;
- the analysis of environment and reasons that underlie the manipulation of accounting information;
- the analysis of the relationship between corporate governance and accounting disclosure;
- analysis of the relationship between ROI and EPS.

Any of the four approaches will require an empirical analysis. Out of these four alternatives, the one chosen in the paper is to assess the possible dependence that exists between exchange rate return and financial return rate for a publicly traded company. The approach is difficult in many ways because the two measures of performance have different calculation basis and reflect completely different economic dimensions. We will try to clarify these issues in the paper. Obviously, an approach of economic profitability rate does not change the essence of the problem, but in the context of our approach, due to the nature of evidence, only

the rate of return that can be considered is the financial one.

Return on equity, known in international theory as "return on equity", allows assessing the efficiency of capital investments of shareholders and their continued appropriateness, calculating the ratio between net income and equity of the financial year. Accordingly this rate reflects supply and demand report results at a time or a short-term basis. From a purely economic view, it highlights if what the company produced meets market demand when analyzed.

Return stock has a different interpretation, being evidently the result of a completely different method of calculation. What is characteristic of this rate is the element of perspective - what future interest represents that society in the view of potential investors. Therefore, stock market prices, allowing the calculation of the return on the stock, apparently have nothing in common with the current performance of the company, so the way it responds to current market demand, but with potential performance, i.e to those that relate to in the near and distant future. Therefore we can say the following, with reference to the two rates.

Return on equity can be an indicator in assessing the market position of the company traded but obviously one cannot establish a relationship of dependency, theoretically understandable. Examples and counter examples exist obvious enough. We further examine a few examples, nevertheless highly relevant. The fact that a particular company is currently profitable cannot ensure a good stock market quotation. There are now companies with huge profits, so the return rates extremely financially high, but still know a regression of stock. Obviously this can be explained by the potential investors' fear of the lack of insight into this company. Equally there are companies that are struggling to the limit of profitability, but to which the meaning of stock prices is only rising. This phenomenon also is simple to explain. The future looks bright for these companies. Therefore the potential interest is growing.

Yet a total indifference relationship between the two rates can exist, at least in the long run. This is the motivation to the present attempt. Our attempt is based on this observation empirically tested and verified

for longer periods of time. Consequently, our belief is that it can identify a relationship of dependency between the two rates of return. It is important how it looks like this dependence and what allows us to say that it exists in reality. In this respect, nothing can be more useful than a mathematical model that can be tested econometric. This is the essential purpose of this paper. In the next section we present the theoretical model and then we justify its correctness by econometric means.

2. Literature review

There is a rich theoretical background covering the issue of earnings quality and firm valuation in a global environment.

First type of effects we consider are related to empowerment of some accounting regulations regarding the quality of information.

Thus Elbanan [2010] proves a positive connection between the adoption of IFRS and the quality of earnings and the integrity of accounting information in the emerging economies due to the adoption of IFRS. The main reason – IFRS reduces the set of allowable accounting treatments.

Furthermore, Kim and Shi [2012] investigates whether and how a firm's voluntary adoption of IFRS influences the extent to which firm-specific information is capitalized into stock prices.

This and other studies show that the enhanced flow of firm-specific information into the market increases firm-specific return variation, which in turn lowers stock price synchronicity (Durnev et al. [2003], Piotroski and Roulstone [2004], Fernandes and Ferreira [2008])

Another approach to the issue regards motives that underlie the manipulation of accounting information.

Beaver, Correia and McNichols [2012] have examined the presence of discretion in financial reporting extensively in respect to financial ratio model for predicting bankruptcy.

Prior literature documents a number of settings in which management aims to obscure the underlying financial condition of the firm opportunistically (Watts and Zimmerman [1990], McNichols [2000], and Beaver [2002]).

Another approach used to test the information integrity is to analyze the relationship between corporate governance and disclosure according to a broader view that encompasses a stakeholders' perspective rather than only the shareholders' one [Michelon and Parbonetti, 2010].

Beasley [1996] argues that poorly governed firms with powerful insiders and CEOs, are more likely to be associated with higher levels of financial statement fraud.

3. Method and result

The empowerment of some accounting regulations governing the quality of accounting information. Many of the world's countries have already applied or will soon start to apply IFRS or other sets of regulations to insure the quality of accounting disclosure.

In order to establish a relationship between the application of IFRS and integrity of accounting information, within the sample, there could only be used countries that provide statistical data related to situation before and after the empowerment of IFRS.

Thus the cross-country sample being limited, the global nature of the research will have been impaired.

The analysis of environment and motives that underlie the manipulation of accounting information. The motives of managers to manipulate accounting information differ widely in a cross-country comparison or in a comparison between listed and non-listed companies.

Thus manager of a listed company bend the reality using accounting information in order to boost share prices, this meaning that usually the effect of such practices aim at reporting larger-than-real amounts of earnings

Non-listed companies aim mainly to reduce their tax exposure.

Nevertheless, the concrete methods to window-dress financial statements vary widely between companies and economies

Thus there are great difficulties inherent to devising a statistical model of the effects of accounting manipulation techniques on relevance and integrity of disclosed information on a global scale.

The analysis of the relationship between corporate governance and accounting

disclosure. The issue of corporate governance practices' effects on the relevance of accounting information imposes certain difficulties related to the normalization of these practices' effects in different countries.

Corporate governance comprises a wide array of actions and practices that differ greatly in nature and results across countries.

Companies from developed economies widely accept to apply such practices in order to boost shareholders and other stakeholders confidence in the quality of management and hence – the quality of disclosure information.

In developing countries such practices are used on a much smaller scale.

The last method that could be used to test the relevance and integrity of accounting information is the relationship between return on investment (ROI) and earnings per share (EPS). This is the most accessible approach in terms of constructing an econometrical model due to the availability of statistical information.

As well this information could be normalized to allow a cross country analysis.

Unfortunately, the only type of companies that could enter such an empirical analysis would be the listed companies.

Therefore, this is the approach we would choose.

As mentioned in the introductory section, we suggest building a mathematical model able to emphasize the dependence on the return exchange rate towards the financial return. Thus the fundamental assumption that justifies such an approach is that, on the long term, the dynamics of the financial growth rate may influence the exchange rate dynamics. Financial rate variation effects can be instantaneous, but may also manifest as a delayed effect process. Usually, potential investors on the stock market observe its tendency and then decide whether or not to proceed with the purchase or sale of shares. Just this phenomenon is the one establishing the purpose of exchange rate quotations, and thus, ultimately, the size of the return and exchange rate.

Thus we introduce the following notations:

r_t represents financial profitability at the time t .

R_t represents the stock exchange profitability at the time t .

According to the hypothesis mentioned above, we suggest the dynamics of the two variables to be described as follows:

$$R_t = a_0 + a_1 r_t + a_2 r_{t-1} + \varepsilon_t \quad (1)$$

The two variables R_t and r_t are obviously random processes characterized by the averages and $r = E(R_t)$. Consequently

$$E(R_t) = a_0 + a_1 E(r_t) + a_2 E(r_{t-1}) + \varepsilon_t \quad (2)$$

$$R = a_0 + a_1 r + a_2 r = a_0 + (a_1 + a_2)r \quad (3)$$

The significance of the three constants is as follows. a_0 represents the autonomous component given by the medium reaction of the stock exchange market, independently by the paths of the financial profitability rate. This component is given by the average of the potential investors' interest effect. The constant a_1 quantifies the instant effect of the financial profitability rate variation, and the constant a_2 quantifies the delayed effect of the financial profitability rate variation. We can still draw some appreciations upon the significance of the two coefficients a_1 and a_2 . The numeric dimension plays an important role in this case. Obviously, the dominant effect belongs to the component that is characterized by the greater coefficient absolute value. As expected, it should be a_2 because the reaction of the stock exchange market is delayed. If mathematically speaking the model suggested can be theoretically justified, and by doing that we have in mind purely the economic theory, it is not enough. An econometric approach is absolutely necessary. The hypotheses of the econometric analysis are the following ones:

- the residual variable ε_t is stationary, normally distributed, zero average and constant variable.
- It is independent from the financial profitability rate.
- It is non-autocorellated.
- The random variables R_t and r_t are stationary and have constant averages and variants.

Under these circumstances, we can obviously state:

$$Var(R_t) = (a_1^2 + a_2^2) \cdot Var(r_t) + \sigma_\varepsilon^2 \quad (4)$$

All these hypotheses referring to the two variables R_t and r_t as well as the residual variable, they are essential in order to ensure the relevancy of the model suggested. Econometrically speaking, they can be checked by the help of statistic tests, as well

as by the Durbin-Watson or Ljung and Box tests.

It is highly important that the residual variable to be non-autocorellated, because we can thus introduce the hypothesis according to which unpredictable perturbations may lead to delayed effects in time. If this aspect is verified statistically, then only the a_0 coefficient will be modified, the rest of the coefficients remaining constants.

Regarding the last hypothesis, this one can be verified by an ARCH model type, or by a GARCH model type.

$$\sigma_\varepsilon^2 = \alpha_0 + \alpha_1 \varepsilon_{t-1}^2 \quad \text{Model ARCH} \quad (5)$$

$$\sigma_\varepsilon^2 = \gamma + \alpha \varepsilon_{t-1}^2 + \beta \sigma_{t-1}^2 \quad \text{Model GARCH}$$

(6)

where σ_ε^2 is the variant of the residual component. If the hypothesis is correct, the values of the coefficients α_1 , α or β and should be null, according to the model in use.

These hypotheses are obviously extremely necessary in order to ensure the relevancy of the model. It is very important to state at this point that all these may be verified starting from a data base regarding the dynamics of the two variables.

4. Conclusion

There are a number of approaches to be used in developing a model to test the relevance and integrity of accounting information.

Out of the four presented techniques we would chose the correlation between return on investment and earnings per share.

The availability of statistical data makes our choice to be the easiest one, but, as well, it offers data that is comparable across the countries from the sample.

The presented statistical model can also be enhanced to include some elements of the three other techniques presented above, like some tests regarding large scale use of IFRS regulations, or some corporate governance policies applied by sample companies.

Any suggestions on how to improve and to enhance the relevance of the model would be very welcome.

Budget – Sustainable Development Tool and Instrument in the Fight of Economic Entities Against Economic Crisis

Tănase Gabriela Lidia
ASE, București
gabrielatanase26@yahoo.com

Abstract

In the current economy, where all countries are affected to some extent by the economic crisis and more companies stop their activity, an increasing importance is given to available resources, their use, savings, efficiency, effectiveness, cost reduction, elimination of waste, and a careful and detailed planning of the activity. So we begin to turn our attention to sustainable development involving, among other elements, efficient use of resources that can lead to economic growth, may prevent or attenuate the economic crisis and of course we focus on budgeting process in economic entities which, through the efficient control of resources and a detailed planning of their use and others characteristics, they contribute not only to the implementation of sustainable development, but also to supporting entities in an uncertain environment.

Key words: *economic growth, resources, sustainable development, performance, budget*

J.E.L classification: G31, M41

Introduction

The premise of this research was to identify the extent to which sustainable development can lead to economic prosperity for economic entities or reduce the effects that economic crisis has on them and also to study the role that budgets play in sustainable development of companies and thus in maintaining them on the floating line in an environment dominated by uncertainty. Therefore, in this paper we will bring to your attention sustainable development, that can teach us to take care of our resources so we can ensure our existence and future survival,

but also an old, but still current instrument to support the management of economic entities in achieving efficient resource management, reduce costs and increase performance: budget. We will discuss about the way that budget planning can help an economic entity to survive in the existing economic environment and contributes to its sustainable development.

Research methodology

The research aims to highlight the importance of budgeting as a tool both to protect and support the economic entity during crisis or in an unstable economic environment and as a tool for sustainable development, which in turn helps to reduce the effects of the economic crisis and improves the economic environment. This research is a synthesis of the ideas published on sustainability and budgets. To achieve our goal, we used a basic research methodology, but also deductive and inductive research mechanisms.

1. Conceptual assertions regarding budgets in economic entities

Budget, as defined by the explanatory dictionary of the Romanian language [4], is a balance of income and expenditure presented for a determined period. In research papers, budgets are seen as support for managers in the decision making process and includes an estimate of revenue and expenditure for a future period clearly defined, based on goals set by the entity for the forecast period. So, not only budgets aim to support the economic entity's management in achieving their objectives, but they also involve careful management of resources (estimated revenues) and shows their distribution or use (costs estimated to be incurred). The research papers abound in presenting the benefits of

budgets preparation and use in economic entities. Hansen and Van der Stede (2004) [5] see budgets as tools for operational planning of activity, performance evaluation, objectives communication and strategy implementation. Heindenberger et al. (2003) [6] show the true essence of budgets, linking their importance to the financial stability of the entity and its competitiveness. They argue the importance of keeping expenditure under control for financial stability which will be affected if they spend too much. If the amount allocated in the budget is too small, the risk of affecting the company competitiveness will appear. Braga (2006) [1] assigned budgets the role of maintaining financial balance between income and expenditure, efficient resource allocation and the role of sustaining the managers for effective management of the business. Braga (2006) also believes that budgets contribute to activities planning, control and coordination, help establish authority and responsibility, offering advantages such as: motivation, activity supervision and coordination, control and communication. Budgets are believed to increase performances if the budgeting technique adopted by the economic entity takes into account the company's size, structure, strategy and its perception of environmental uncertainty (King et al., 2010) [8] or if the economic entity adopts a participatory budgeting process, by involving employees in the decision-making process and motivating their lack of impact on budget, if that is the case (Libby, 1999) [9]. Participatory budgeting has an impact on the employee's performance through the ambiguity of the employee's role, job satisfaction and the employee's dedication (Chong et al., 2006) [3].

The main characteristic of budgets prepared by economic entities is the fact that they focus on the balance between available resources and the needs of the entity, helping the managers to assign resources in an efficient manner that leads not only to the achievement of the objectives set by the entity, but also to performance. Analyzing what the research papers has to say on the budget process in economic entities, we synthesized the main positive aspects of budget preparation in table No. 1, as follows:

Table 1 Advantages of the budgeting process in economic entities

Advantages of budgeting
Estimates position and future performance of the economic entity
Contributes to activity planning and coordination
Puts into balance resources with the way that they are use
Correlates resources with the economic entity objectives
Leads to goal achievement
Ensures an efficient management of resources
Ensures a financial balance
Contributes to increased performance for efficiency, effectiveness and savings increases
Ensures activity control
Offers information regarding cost
Supports decisions and corrective measures to improve activity and performance
Helps maintain competitiveness
Helps establish authority and responsibility
Supports sustainable development
Provides safety for economic entities in an uncertain economic environment

Source: own sources

Unfortunately, in the actual context of economic crisis, an increasing number of economic entities stop their activity as a result of inability to adapt to the economic environment and due to the fact that the resources available are insufficient. From our perspective, one of the many causes that lead to such a result is the poor management of economic entities resources. For an economic entity, its resources are the most valuable asset in today's crisis and their use should be planned so that they can get maximum results with minimum effort. An efficient allocation of resources, a permanent control exercised over them, a detailed analysis and planning of costs and the adoption of relevant measures to reduce them, represent, from our point of view, basic measures for the survival of any entity especially in the conditions of economic uncertainty. That is why the management of economic entities must put emphasis on proper planning activities that

allows them forecast future periods. This would ensure some security and stability. The budget is therefore an indispensable tool for business efficiency and performance and of course for resource and consumption. So, this management tool helps, although maybe not in an obvious way, overcome the instability of the economic environment and adopt sustainable development.

2. Theoretical approaches on sustainable development

Sustainable development represents a concept that has gained more and more importance in recent years, as people began to realize the impact of economic, technological and social development over the natural environment. One of the most comprehensive definitions of sustainable development is formulated by the World Commission on Environment and Development, presented in the Brundtland Report also called "Our Common Future". In their opinion, *sustainable development* or *sustainability* is actually "meeting the needs of present without compromising the ability of future generations to meet their own needs" (Budică et al., 2009) [2]. Sustainable development involves initially the preservation of ecosystems and sustainable use of and natural resources (Tudorescu et al., 2008) [13]. Although the concept was originally designed to protect the natural environment and its resources, it has been extended, and includes now both the economic and social environment. Irimia (2009) [7] sees sustainable development as the adoption of an economy with low emissions, energy saving, efficient technologies in terms of reducing resource consumption, sustainable consumption behavior and sustainable transport, which involves strengthening ties between climate change, energy, financial and social sustainability. Budică et al. (2009) [2] considers sustainable development to be a set of forms and methods aimed to increase socio-economic development and designed to maintain a balance between natural potential and socio-economic systems. It also brings into question the essence of sustainable development, namely the emphasis on the welfare of future generations. Sustainable development aims to increase the quality of

life for the present generation, but also for future ones.

The seven strategies for sustainable development adopted by the European Union include: climate changes, sustainable transport, sustainable consumption and production, conservation and management of natural resources, public health, social inclusion, migration and global poverty (Irimia, 2009) [7]. Among the key objectives of sustainable development are: environmental protection considering the negative impact of economic developments, social equity that promotes equality and non-discrimination, fundamental rights, economic prosperity that relates to development, knowledge and innovation and is designed to contribute to the quality of life, create new jobs, etc.. (Budică et al, 2009) [2]. Tudorescu et al. (2008) [13] as well as Stoica (2005) [11], believe that sustainable development involves a balance between needs and resources or between objectives and means to achieve them. Tabăra et al. (2007) [12] talks about the optimal level of consumption so that the impact on the environment and the welfare of future generations can be reduced, attributing to sustainable development the role of balancing economic and social development without affecting the natural balance.

The main features of sustainability, in our vision, are presented in Table 2.

Table 2 Characteristics of sustainable development

Characteristics of sustainable development.
Reduces consumption
Resource Protection
Protection of economic and social environment
Sustainable consumer behavior
Socio-economic development
Ensures the balance of economic, social and natural environment
Rational satisfaction of human needs
Allows needs satisfaction for future generations
Increased quality of life now and for future generations
Man- central element of sustainable development

Focuses on improving business processes: efficiency, effectiveness, productivity, waste reduction, efficient use of resources, etc.
Maximizes welfare with available resources
Helps creating new jobs
Promotes Public Health
Concern for the future
Social Engagement: people, public institutions, economic entities, regulatory bodies, global organizations, international commissions, etc.
Reduces the environmental impact of economic growth
Social equity
Promotes development, knowledge, innovation and economic prosperity
Maintains a balance between development and the impact on the environment (economic, social, natural)

Source: own sources

3. Correlations between Budgets- Sustainable development- Economic environment

From our perspective, budgets, sustainable development and economic environment are interconnected, influencing each other.

Sustainable development is a tool to improve quality of life by protecting the natural, the social and the economic environment. It thus contributes to economic growth and alleviates economic crisis, waste of resources, etc. Tudorescu et al. (2008) [13] brings into question the link between environment and economy. Stoica (2005) [11] shows the interdependence between environment and economy, saying that economic growth stagnates because of limited natural resources and that we must resort to a development that maintains economic growth, but also environmental conservation. Popescu et al. (2005) find that savings, efficient use of resources, use of renewable resources and, why not, technologies that do not harm the environment, lead to economic growth.

Budgets are tools for implementing or adopting sustainable development. Budgeting, by its nature, involves effective management of resources, resource

protection, reduce consumption, waste, increase economy, efficiency, involving concern for the future of the entity, for the future survival of the company, for performance and development, and may also involve costs for reducing the impact on the environment, its recovery, etc.. The development of the entity through an effective budgeting process means new jobs, the increase of the quality of life and a positive economic impact. In other words, budgets not only contribute to the implementation of sustainable development policies, but also help restore and sustain the economic environment. As economic entities get richer, work more efficiently and are more developed, they generate benefit for the state, economy and social environment. Economic entities' wealth means higher taxes, more jobs, more commercial relationships, higher contributions for the state budget and the increase of the quality of life. Higher incomes of the state budget mean an increase in the quality of public services, the quality of medical services, education, salary increases poverty alleviation etc. Thus, an effective budget activity can have a positive impact on the economy of a country, either directly or through sustainable development.

The relations between budgets, sustainable development and economic environment are presented schematically through Figure No. 1.

Figure 1. Correlations between Budgets- Sustainable development- Economic environment

Source: own sources

Conclusions

This research highlights the importance of budgets within economic entities. Budgets can be considered tools of sustainable development, but also tools that contribute to economic growth and development. Sustainable development is a way out of the crisis, but its implementation must be supported by policies of sustainable development and by economic entities. It is necessary to encourage economic entities to understand and apply sustainable consumption and production [14]. From our point of view, sustainability begins and ends with economic entities. Economic entities are considered to be primarily responsible for the environmental “depreciation”, for the consumption of resources and pollution. Also, if we want sustainable development to become a reality, entities must be the ones that embrace, understand and implement sustainability. In other words, sustainable development starts with the entities. Thus, given the current economic uncertainty all over the world, in different shapes and forms, budget becomes very important and the role of an efficient budgeting process within economic entities should not be ignored.

State of Knowledge in Insurance Economics: Uncertainly Levels and Response to Uncertainty

Tănăsescu Paul
A.S.E.Bucharest
cristina_gradea@yahoo.com

Abstract

“While analyzing the current economic crisis, which we can consider the first ever global crisis that started with banking problems, we are asking if this crisis was strictly a financial one or a crisis due to the phenomenon called globalization. What caused the global financial crisis was the lack of information” as is sayed Phd Cristina Gradea in the article Effects of globalization on companies.(1)

Uncertainty is doubt about the ability to predict future results. Uncertainty arises when an individual perceives risk. Today, the concept of risk seems to synonymous with the one of activity. Although ubiquitous in business, and not only, risk is often relatively difficult to detect or predict.(2)

Key words: crisis, globalization, uncertainly, insurance, risk.

Clasification J.E.L.: G22

1. Introduction

“We note that the notion of globalization is very common, especially in recent decades. There were amplified various aspects and connections of this concept, which continues to develop at a particularly fast pace. The idea of globalization is present everywhere: in science, communication, technology, military area, in the environment, etc.”, as is sayed Phd Cristina Gradea in the article-Effects of globalization on companies.(1)

2. Levels of uncertainty

Uncertainty is a subjective concept and can not be measured directly Since uncertainty is a state of fact of the individual,

it varies from one subject to another In complex activities, such as participation in a risky business, some people are very cautious, while others take more aggressive positions.

Although risk aversion explains some of the unavailability to participate in the business, the level of risk perceived by the individual also plays a key role.

This level depends on the information that an individual has available to assess the likelihood of future results and the individual's ability to process information. (3)The level and type of information about the nature of risky activities have a significant effect on uncertainty. This type of uncertainty is not found in the previous examples of, the two bets in which the possible outcomes and their associated probabilities were know with certainty. Uncertainty can be divided into levels or degrees;the degrees of uncertainty are shown in Table I.

When uncertainty is not present, we are confident about our predictions, certainty arises when we can predict future outcomes with total confidence. Some examples of certainty include expectations of the laws of physics, like the law of gravity or the laws of motion.(4)

At level 1, the lowest level of uncertainty, possible outcomes were identified and we also know their associated probabilities of occurrence. Level 1 can be described as objective uncertainty. Many games of chance, such as card games, dice and roulette are examples of level 1 of uncertainty. In these games, the results are based on the bet made by the participants in the game, and the probabilities can be calculated.

The previous example of the two bets in different amounts also fall in Level 1 of uncertainty.

*Tabel I. Williams, Arthur C. ; Smith, Michael L.
Risk management and insurance*

At level 2, the probabilities are not known

Level of uncertainty	Features	Examples
Zero. Certain	future results may be accurately anticipated	laws of physics, natural sciences
Level 1 (objective uncertainty)	future results are identified, but the probabilities are known	card games, dice
Level 2 (subjective uncertainty)	future results are identified, but the probabilities are unknown	fire, automobile accident
Level 3	future results are not fully identified and probabilities are unknown	space exploration, genetic research

exactly, but possible future outcomes were identified. Uncertainty of level 2 could be present at a game where you have to guess the color of a ball drawn from an urn containing 100 balls of different colors, but the proportion of colors in the 100 balls is unknown.

Level 2 - Subjective uncertainty - characterized more risky business, investment projects and risks insured. For example, the owner of a car that could be damaged in an accident can identify the following possible future situations: vehicle may or may not be involved in an accident.

If the accident occurs, the damage can be mild or important even cause total loss. Most car owners do not know the precise estimates on the likelihood that they will be involved in an accident and even less potential damage estimates.

These estimates, if they can be determined, will depend on factors such as road quality, duration of use how the owner uses his car and how the traffic participants drive their car, the car's maintenance etc.

At level 3, the nature of future results is uncertain, they are not fully identified. Examples of uncertainties in this category are the first attempts to explore the cosmos or attempts to use atomic energy for peace. In these projects, and other types of scientific research, the nature of possible results is not fully identified prior to the project (or experiment).(5)

History has proven that human nature, the human desire to extend the boundaries of knowledge and obtain serious economic gains from exploiting new technologies are important incentives for undertaking activities at level 3 uncertainty.

3. Response to uncertainty

Uncertainty can have powerful effects on human behavior. In extreme cases, uncertainty can lead to paralysis of action, more often, however, uncertainty affects compensation levels necessary for engaging in such risky activities.

Also, uncertainty can lead individuals to protect themselves from future situations identified as particularly unpleasant.

For example, a research lab could refuse a vaccine against diseases if no government promise to cover any damage resulting from vaccines side effects reported by the vaccinated people.

Clearly, the answer to uncertainty is partly influenced by the level of uncertainty.

Risk management that can be associated with level 1, approaches the statute of science.(6)

Casinos can predict the profitability of their business as a whole despite the fact that they can not predict the outcome of gambling separately.

Mortality (risk of loss of life) within large groups of people is another example of the uncertainty of level 1. Unfortunately, the most important risks faced by organizations involve uncertainty of level 2 or 3.

The organization must therefore rely on less scientific methods for assessing and controlling risks at these levels(7)

“The economic crisis we are in and that humanity itself has created, is also a consequence of insufficient supervision on bank loans based on quantity and not quality. What is needed on the market today, is a new economic and financial world order”, as is

sayed Phd Cristina Gradea in the article Effects of globalization on companies.

Each country should have an anti-crisis economic program set appropriately to each nation economic parameters, program meant to increase public confidence and to produce immediate visible effect.

Level of uncertainty caused by a certain type of risk may depend on the entity that bears the risk, for example, an insurer or a governmental entity can consider earthquake risk as level 2, while an individual may consider it of the level 3.

This difference in perspective can be a consequence of the ability to estimate the consequences of possible future situations.

An insurer or government entity has the resources needed to study the phenomenon of earthquake.

If the insurer wants to issue insurance against earthquakes, it will have an economic incentive to form solid estimates, and these estimates are often inaccessible to the individual, he will be unable (and often in no need) to base them on.(8)

An entity confronted with risk can take measures which decrease the level of uncertainty. Contractual limits for damages established by an insurer for an insured may decrease the uncertainty level from 3 to 2.

4. Conclusions

”Globalization, by its proportions, and perspective changed the economic life as a fundamental change in human history. By its major implications it determined redefining our possibilities and limits of local action. Globalization is a system where the objective function aims the whole in order to eliminate adversity and competition, to generate creative destruction” as is said Phd Cristina Gradea in the article Effects of globalization on companies.

In general, individuals with risk aversion prefer lower levels of uncertainty in that they are willing to pay for information or other means that reduce uncertainty to a lower level. Insurance is an obvious example, a driver who perceives automobile accident risk at level 2 is willing to pay a premium that exceeds the expected damage accident for a policy to cover any damage.

Due to the insurer experience in assessing this risk, uncertainty of the insurer's

perspective is at level 1, while the individual one is at level 2 or 3.

In conclusion, any complex economic process has a degree of uncertainty that can not be removed. In the modern concept the uncertainty is a broader concept that can not be confused with risk.

Applying IFRS in Romanian Banking System - Limitations and Challenge

Tofănică Ramona-Ionela
Horomnea Emil

„Alexandru Ioan-Cuza” University of Iași
ramona_tofanica@yahoo.com
ehoromnea@yahoo.com

Abstract

This paper makes an overview of the literature regarding IFRS application, both globally and in our country, expressing some personal considerations on key financial and accounting domains, which present the biggest challenges in terms of impact on the banks financial situation.

Key words: IFRS, banking system, challenges, Romania

J.E.L. classification: M41, G21

1. Introduction

Due to the global economy and global capital markets, accounting rules were standardized at international level. To get-together in accounting, the convergence involves removing individual differences between national and international accounting standards. Thus, there will be a single set of global accounting standards of high quality, which requires clear information, similar in common use.

Romanian banks are now fully engaged in the process of converting to IFRS and starting from 1 January 2012, IFRS replace accounting principles generally accepted in Romania.

2. Literature review

According to Jermakowicz & Gornik-Tomaszewski (2006), implementation of IFRS in Europe, must lead to comparability and transparency of financial reporting, to monitor managers' actions, and thus to decrease information asymmetry and to diminish capital costs [1].

However, studies done on the effects of

IFRS application in Europe have reached different conclusions. Li (2010) [2] found that IFRS application resulted in a reduction of capital costs, while Daskal (2006) [3] and Gornik-Tomaszewski & Jermakowicz (2006) [1] have not found a significant reduction of them. Armstrong et al. (2010) [4] and Lenormand & Touchais (2009) [5] found an improvement in the quality of accounting information published after the mandatory IFRS application, while Paananen & Lin (2009) [6], on the contrary found a decrease in quality.

IFRS application in the EU-27 countries led also to the following observations: high volatility of reported results (Hoogendorn (2006) [7]) which makes it difficult to assess the performance of companies (Gornik-Tomaszewski & Jermakowicz, 2006 [1], KPMG, 2007 [8]); Barth et al. (2008) [9] found that, after applying IFRS there is less evidence of earnings management, while Paananen & Lin (2009) [6] found an increase in revenues in management after applying IFRS in Germany.

Regarding the IFRS application in the banking system, we can draw some conclusions. Studies have shown how these standards are applied in different countries (Delvaile et al, 2005 [10]) and obstacles, difficulties in applying IFRS (Larson & Street, 2004 [11]; Jermakowicz & Gornik-Tomaszewski, 2006 [1]). Bushman & Landsman (2010) [12] analyzed the negative effects on regulatory requirements for Spanish banks. Dunne et al. (2008) [13] have studied the IFRS application in the United Kingdom, Ireland and Italy, and concluded that a major problem identified in all three countries was related to staff training and adaptation to rapid change.

For banks, major changes were required in informational systems, various processes

and operating models being introduced. Banks reported that they had to do many operational changes to implement the new reporting rules. One of the main problems was related with the implementation of certain standards that are completely irrelevant once implemented (such as loans using the effective interest method).

Some empirical and qualitative studies examined various aspects of IFRS implementation in Romania. Ionaşcu et al. (2011) [14] investigated the perception of listed Romanian companies on the effects of implementing IFRS and institutional factors that might influence them, while Albu et al. (2011) [15] explored the views of key stakeholders in financial reporting (users, accountants, auditors and standard setter) on the application of IFRS. Bunea et al. (2011) [16] investigated the opinions of certified accountants in Romania concerning the possible IFRS application for SMEs. Other studies have analyzed the influence of IFRS application on the capital costs (Ionaşcu et al, 2010) [14], Munteanu et al, 2011[17]). Several studies conducted by KPMG Romania (2010 and 2011) [18] focused on IFRS application in the banking sector. They analyzed differences in national accounting requirements applicable to credit institutions and the International Financial Reporting Standards and measured their impact on banks' capital and income.

Furthermore, in the IFRS use as accounting basis from 1 January 2012, Stefan & Musat (2011) [19] analyzed the regulations issued by the National Bank, Grecu (2011) [20] analyzed the challenges of implementing IFRS Romanian banks from the managers and auditors perspective, while Răducănescu & Dima (2011) [21] analyzed the impact of IFRS implementation on prudential regulations.

3. Application IFRS in Romania

The adoption and application of IAS / IFRS standards in Romania is based on EU legislation relating to the IFRS implementation in the Community area, namely the requirements of European Regulation 1606 and of Council on the application of International Accounting Standards. Hence, the Ministry of Finance has set the following steps on the

implementation of IFRS in Romania:

- IFRS application in 2006 - according to OMFP no. 907/2005, operators that were public interest entities as defined by law, drafted a separate optional set of financial statements in conformity with IFRS, for their own users information needs, other than state institutions, according to their choice and adequate implementation capacity [22];
- IFRS application in 2007 - according to OMFP no. 1121/2006, companies whose securities at the balance sheet date have been admitted to trading on a regulated market and consolidated financial statements were required to apply IFRS in these situations; these companies were allowed to establish a separate set of annual financial statements obtained by applying the IFRS for users information, other than state institutions; the other public interest entities as defined by law, could apply IFRS to individual or consolidated financial statements for their own information needs [23];
- IFRS application in 2008 - for companies whose securities at the balance sheet date have been admitted to trading on a regulated market, IFRS implementation strategy was that provided by the CNVM. For them, as for other entities, Ministry of Finance provided the preparation of annual financial statements obtained by applying the accounting regulations harmonized with EU directives, approved by OMFP no. 1752/2005, which is the basis for determining taxes, and in addition [24], firms and national companies were required to prepare a separate set of individual annual financial statements and consolidated financial statements, obtained by applying IFRS for their own users information needs, other than state institutions; legal persons belonging to a group of companies and are included mother-society consolidation by a parent applying IFRS must prepare a separate set of individual annual financial statements, obtained applying IFRS for their own users information needs, other than state institutions; other public entities that receive grants or loans guaranteed by the state whose value exceeds the amount of 500,000 Euros had

to prepare a separate set of annual individual and consolidated financial statements, obtained by applying IFRS for their own users information needs, other than state institutions;

- IFRS application in 2010 - continued IFRS application for the preparation of a separate set of financial statements, financial statements set considered in determining the tax burden being prepared under accounting regulations with European Directives approved by OMFP no. 3055/2009 [25]. As a result of recommendations from the World Bank, the International Monetary Fund and banks requirements, the Romania National Bank issued Order no. 9/2010 which provides that the IFRS application will be applied to the individual financial statements of the credit institutions for recording transactions from 2012 [26]. In order to inform regulators authorities during the transition period, credit institutions were required to prepare a second set of financial statements for 2009, 2010 and 2011 under IFRS approved. Stephen and Musat (2011) [19] explains that this compromise was necessary because of the heterogeneity of training credit institutions apply IFRS immediately (some banks have experienced several years reporting in accordance with IFRS, while other banks had to apply IFRS for the first time);
- After 1 January 2012, certain regulatory changes were needed to clarify the impact of changes on the prudential indicators and calculating tax profit. National Bank issued Order no. 27/2010, which contains accounting rules in accordance with IFRS. It also includes rules for approval, auditing and completion of financial statements, chart of accounts, prescriptions related to primary documents and records used and the additional information, but does not prescribe a standard format for financial statements or other recognition, measurement and classification of different rules those under IFRSs.

Prudential aspects affected by IFRS were those related to provisions (such provisions are accounted in accordance with IFRS measurements), solvency, currency and equity positions. New prudential filters have

been introduced to avoid the impact of IFRS implementation on Romanian banks solvency. IFRS use as the basis of accounting involves applying IFRSs when each transaction is recognized.

4. Limitations and challenges of applying IFRS from 2012 in Romania

In detailing financial and accounting issues involved in converting to IFRS, we select six areas that will have a major impact on the financial statements or whose implementation will require increased resources. Further, we proceed to approach these issues in the synthesis. [20]

- Impairment of financial assets (IAS 39) is an area in which accounting requirements for supervision and risk management intersect; it is the area with the greatest impact accounting, but also the most exposed value judgments and, as such, the most controversial. Beyond the difficulty of adopting "loss events" model of new parameters and concepts such as probability of loss and collective provisioning, all challenges in it, the challenge starts from the foundations of this methodology. IFRS approach focuses on professional judgment, which is crucial in estimating the number of factors used in calculating the provision, leading to a high subjectivity. Banks must develop not only methodologies in line with the general principles stipulated by IFRS, but also systems validation provisions (back testing, stress testing, etc.), therefore to reduce or correct the subjectivity element. Romanian banks used with the matrix method of calculating provided by Romanian statutory regulations must also understand that IFRS methodology is a living methodology, constantly changing: new information may become available indicating impairment of portfolio part or the need for further segmentation of its; parameters must continually be updated and at the same time, banks must assess whether the historical reality matches the present and always check if there is need to adjust the parameters obtained based on historical data to reflect more closely the recent developments.
- Recognition and measurement of

financial instruments (IAS 39); Financial instruments constitute the largest part of the assets and liabilities of banks and IFRS are prescriptive, which often leads to major implementation problems. IFRS requires that all financial instruments are recognized initially at fair value, which often, but not always, is the price/cost of the transaction. After initial recognition, they are measured at fair value (assets held for sale and assets held at fair value through profit and loss), amortized cost or cost (loans and receivables portfolios and assets held to maturity). The challenge comes from the need to determine the fair value, but also from the cost amortization requirement. For example, in the case of a loans portfolios acquisition, the purchased portfolio will not be recognized at the value it was purchased, but as the fair value represented by the present value of estimated future cash flows and the difference between the present value and the amount paid will be a gain or a loss, which will be amortized over the life of the portfolio purchased. In addition, the need to determine the fair value is not just at initial recognition. Although some instruments are measured at cost or amortized cost, even for this IFRS requires that the fair value to be disclosed in the notes to the financial statements. Thus, banks will have to determine the fair value during the period of detention for all financial instruments held by them.

- Accounting treatment of investment securities (IAS 39), declining financial markets are particularly problematic in accounting for investment securities. The statutory accounting framework does not provides recording for pluses value for titles securities and hence their reflection in reserve accounts / profit and loss accounts, less valuable instruments classified as investment securities are recorded in the income statement in the statutory accounting. Following the transition to IFRS as accounting basis, both pluses and minuses of value are recorded in own capital - in reserve accounts. The challenge will not come from the recognition for pluses value, unforeseen in the statutory accounts, but from the development of methodologies

by which to determine the moment when the value decreases recorded in reserves should be recognized in profit or loss, or the moment in which decreases in value meet the criteria for "significant" and "prolonged" under IFRS, to recognize a provision in the income and loss account.

- Revenue recognition (IAS 18, IAS 39) – depreciation charges for the loans using the effective interest rate method. The effective interest method is a method of calculating the amortized cost of a financial asset and allocation of profit from interest in the relevant period. The effective interest rate is the rate that exactly discounts estimated future cash flows received during the expected life of the financial instrument or, where appropriate, a shorter period to the net carrying amount of the financial asset. When calculating the effective interest rate, an entity shall estimate cash flows considering all contractual terms of the financial instrument (e.g. prepayment), but will not consider future credit losses.
- Deferred tax; (IAS 12) The conversion to IFRS, Romanian banks will record significant revenue from the release of provisions, their taxation and related tax regime could have a major impact on the balance sheet either through tax deferred account or the account of profit statement, or on both.
- Consolidation of special purpose entities (IAS 27, IAS 12); The main challenges of consolidating special purpose entities refers to the control concept, defined in IAS 27 "Consolidated and Separate Financial Statements" as the power to govern the financial and operating policies of an entity to obtain benefits from its activities. IFRS contains specific instructions on applying the concept of control for special purpose entities, since many of them have predetermined objectives and is thus difficult to determine who controls them. A special purpose entity is defined as an entity designed to meet a specific, well defined. In practice, it often requires an individual analysis to determine whether an entity can be seen as a special purpose entity. The problem raised by such entities is that often complex judgments needed to

determine whether the criteria for consolidation of special purpose entities.

5. Conclusions

Until now conversion to IFRS is one of the most important missions that Romanian banking system has experienced.

IFRS is not prescriptive as to the format of the income statement, the balance sheet and other components of the financial statements, but brings disclosure requirements in the additional statutory requirements notes.

IAS 1 "Presentation of Financial Statements" includes minimum requirements for presentation of financial statements, including the content and information on their structure. Thus, presentation of financial statements may differ significantly from one bank to another. Romanian banks have been confronted with the problem of choosing formats presentation, and the challenge will be for financial statements users in understanding of different formats. In this respect, the notes will need to be very detailed and IFRS provides very comprehensive / elaborate / detailed presentation requirements in many areas. Additional IFRS requirements include the presentation of explanations and descriptions of the value judgments of management and sensitivity analysis.

IFRS changes require constant attention not only from the accounting department, but also from the leadership of Romanian banks.

At present, a large part of IFRS are subject to review by the IASB, which has already issued several exposure draft for concerned amendments and announced clear intentions in replacing certain standards. Many of the IFRSs permit early adoption and, therefore, bank management should have sufficient time to consider whether early adoption could benefit, like processes simplification involved in reporting and a more accurate reflection of the financial statements, or

otherwise, if the new standards may pose new challenges and costs that will need to be planned in advance.

Accounting Risks Impact on Accurate Image

Abstract

The economic activities are influenced by uncertainty and risk. The current economic crisis has underlined that the non-compliance with the ethical rules leads to the spreading of the negative effects worldwide. Their spread was done according to the degree of dependence of the countries with the world economy. This manifestation, clearly normal in a market economy, highlights the risks any economic activity has to face regardless of the aggregation level where they occur.

Keywords: accounting risks, economic crisis, strategies, entity.

JEL Code: M41

1. Introduction:

The new economy offers the possibility of using time and space with greater speed employing computer science and communication technologies so that information must determine the most appropriate choice, but especially to lead to decisions that may eliminate or reduce a great deal of the risks specific to any economic activity.

Risk identification is not always the easiest action undertaken by the entity because the changes occurring at all levels of aggregation of the economy cannot be entirely anticipated. Therefore, the problem of risks that entities have to face has become an extremely serious one, requiring the establishment of measures and strategies for limiting them. Increasing the entity's interest in the implementation of certain services to help reduce threats on the entity's performance has now become a key concern.

2. Accounting risks impact on accurate image

The aim of the financial statements is to provide information about the financial position, financial performance and changes in the financial position of an entity.

“The information on the reporting entity's financial performance helps users understand the profitability generated by the entity for its economic resources. The information on the overall profitability generated by the entity provides clues about how well the management has fulfilled its responsibilities for the efficient and effective use of the reporting entity's resources. The information on variability and the components of this profitability are also important especially for assessing the uncertainty of the future cash flows. The information on the previous financial performance of the reporting entity and on how the management has fulfilled its responsibilities is generally useful for predicting the future returns obtained by the entity for its economic resources [1].”

“The financial information, in order to be useful, must be relevant and it must represent exactly what it aims to represent. The usefulness of the financial information is enhanced if it is comparable, verifiable, timely and comprehensible [2].”

In case the information does not fulfil these qualitative features, there is a risk of losing the relevance and even the usefulness.

The national and international specialized regulations directly relate to the concept of faithful image through the recommendations made concerning the annual financial statements, on the financial position and on the financial results. The risk of not applying the provisions related to the faithful image

generates an erroneous and distorted image of the overall entity. Thus, “the maker” of the financial statements must provide further information in order to underline this fact. Even if there are contrary provisions related to the faithful image, an exception must be made for the financial statements to be presented fairly, and the derogation must be mentioned in the annexes together with an explanation and the effects of the derogation.

The international specialized regulations [3] indirectly refer to this concept, being a condition for the accounting information to be credible. According to the International Financial Reporting Standards, faithful representation means that transactions and events are presented reasonably. An example is represented by the transactions and other events that are reflected in the assets, debts or equity to meet the recognition criteria and to be presented in a credible way. Thus, there is also the risk of less credible representation, not necessarily because of bias, but due to: the inherent difficulties in identifying the transactions and events to be assessed; the inherent difficulties in the design and implementation of the assessment and presentation techniques.

The faithful image is also subject to other accounting risks such as:

- a) misapplication of the accounting principles;
- b) wrong classification of the balance sheet items;
- c) inaccurate recording of the economic-financial operations in the accounting records;
- d) inadequate classification of the economic-financial operations in the correspondent accounts;
- e) failure to chronologically and systematically record the accounting data;
- f) improper filing of the financial-accounting documents;
- g) misuse of the software on the acquisition of the accounting information and their recording in the explanatory documents;

The strategies to fight accounting risks are delineated as follows:

- regular training of the personnel from the financial-accounting department concerning the accounting principles stipulated by law and any changes occurred;

- compliance with the general accounting principles as they are stipulated and detailed by the legislation in force;
- updating them once with the changing of the legislation;
- the chief of the financial-accounting department must comply with the accounting principles in the financial accounting activity and intervene when he/she notices deviations from it;
- regular training of the personnel from the financial-accounting department on ways of assessing and recognising the elements of the balance sheet related structures and of the profit and loss account;
- setting an accounting policy regarding the assessment of the balance sheet items and the profit and loss account, setting its application, as well as communicating the policy to the staff responsible for its implementation;
- checking the compliance with the accounting policy set by the entity’s management by the chief of the financial-accounting department;
- any deviations or changes in the accounting policy are made only with the consent of the Board of Directors;
- regular training of the personnel from the financial-accounting department on the mandatory accounting entries stipulated by the laws in force as well as the method of filling them in and archiving them;
- all the accounting entries shall be made based on the primary documents and filled in and drawn up in accordance with the legal provisions in force, only after the prior approval of the respective operations by authorised persons;
- checking and correcting, if necessary, the correctness of entries in the accounting books by the chief accountant of the accounting department;
- the establishment and training of the persons responsible for filing in accordance with the law;
- identification and use of an adequate space for archiving the documents;
- permanently keeping informed on the laws related to archiving documents;
- regular training of the personnel from the financial-accounting department

concerning the use of the specific software;

- providing specialised care by a specialist in the IT field;
- creating an implementation team to contribute to implementing the software.

The development of strategies is a sure way for the smooth functioning of the entity. Choosing the appropriate strategy for the field in which it is intended to be implemented, as well as all the analysis of all the elements leading to its implementation contributes to identifying a favourable direction for the entity.

3. Conclusions:

The need to identify risks, to manage them properly, and to continuously monitor them is becoming a major goal that endorses the survival of the entity. The current economic conditions have brought to the fore the risks generated as a result of carrying out financial-accounting activities and their adverse effects, effects which create turbulence within the entity. The elaboration of a series of strategies in terms of reducing the accounting risks contributes to presenting a faithful image and to providing clear and accurate financial information to the internal and external users.

Abstract

Experts believe that is being wasted so many resources, allocating budgetary policy that does not provide a sufficiently clearly identifiable European added value. In addition, the Community budget has often been criticized for lack of transparency. The General rules concerning the distribution of resources and financial contributions from Member States are often altered by ad hoc derogations which causes a high degree of complexity. To counter these deficiencies, in 2005 within the framework of the European Council of December in Brussels, it was decided to launch the process of the reform of public finances at the EU level, exercise is also known as the budgetary review process. At the same time, the review of the budget was part of the compromise achieved on the new financial perspective 2007-2013.

Keywords: EU budget, incomes, expenses, GNI resource

J.E.L.: H60, H61, H62

1. Introduction

The European Commission tried to have a dialogue based on the principles of monetary considerations separate. If the discussion on the budget reform would wear at the same time outlining the financial terms of the future financial perspectives, the dialogue on the reforms it would be extremely difficult.

The European Commission, the EU budget has proved to be effective in achieving the European aspirations in key

areas, such as economic growth, solidarity, security, but stiff when it was put in the face of unforeseen situations (food crises, natural disasters).

Moreover, the budgetary system currently focuses too much on the contributions rather than on results. The Commission points out that the annual negotiations are guided to a great extent in terms of net balance – how do you get, versus how much to contribute.

There are already more analysis that identifies the weaknesses of the construction budget at european level and advancing proposals for reform, which will be useful to them.

2. Analysis of the current community budget

The main weaknesses of the EU budget:

On the expenditure side:

- the budget: perceived as far too low and stiff capped in relation to the Union's ambitions. The proposed solution is obvious: the appropriate resources and "flexibility," which involves giving up the global ceiling rigid foresaw 1.23% of GNI and the adoption of an approach that starts from the policies and priorities ("policies" first "approach");

- the structure of facts brought forward: three quarters of the Community budget was and is represented by the support for farmers and poor regions. Advanced solutions: reforming the CAP (agricultural expenditure reduction). Other lifelong privileges that support solutions for agriculture, parallel to the allocation of resources ' appropriate ' competitiveness, which would generate a reduction in the share of agriculture in the

budget (the process would be similar to the reduction in the share of the agricultural budget in relation to structural actions: support for farmers has increased, but at a rate lower than the increase in the structural funds). Besides competitiveness, there are a number of other preferences (United Kingdom, for example, favors a reorientation of expenditure by transforming the EU into a "global" to intervene, humanitarian etc. in various hot spots around the globe). More general level, the EU budget is criticised for its emphasis on redistribution ("juste-long-distance moves"). Many experts argue that would have required a shift to Community expenditure to the provision of public goods at European level, including macroeconomic stabilization.

The income:

- too much complexity to the system of own resources;
- the absence of a genuine "own resources" of the Union, in accordance with the provisions of the Treaty, other than receipts from customs duties;
- the privileged treatment accorded to non-Member States (United Kingdom, Netherlands, Sweden, Austria, Germany), the beneficiary of some corrections. All at sea is the current institutional framework, say a decision in the matter of the budget focus too much on the net balances. Member States perceive the payments from the Community budget as participation fees at a club, what makes the ultimate objective in negotiations to maximize profits or minimize net contribution.

Among the advanced solutions include:

- exclusive funding the Community budget of the GNI resource (this proposal is supported, among others, Alain Lamassoure, an European parliamentary);
- the correction of national contributions;
- the introduction of a European tax.

Strengths of the Current Arrangement

Throughout the discussion on EU budget almost no voice to defend the strengths and achievements of the current budgetary framework. Often, the mere fact that the EU budget:

- is about 1% of Community GNI (in terms of the share of public expenditure in the Union is 47%);

- has maintained this decent weight for a long period (the share of public expenditure in the Member States has seen a rising trend);
- did not allow the development of tools such as the public debt (dropped out of control in a number of Member States);
- financing did not put in jeopardy the fiscal competition between Member States.

These are notable achievements, which must be maintained by keeping the factors that have made them possible, beyond the redistribution of funds between the various chapters and policy priorities.

3. An assessment of the proposals for reform

Incomes (own resources)

- Summary of financing based on the GNI resource:

The most interesting reform proposals have been advanced on the income of the Community budget. In particular, the solution of Alain Lamassoure advanced – financing the Community budget of the GNI resource-offers the possibility of a number of controversial elements of the construction budget. The new system is clearly transparent and simple, easy-to-press and defended. Furthermore, it is a flexible system, you can easily remove the complexity of corrections.

The best politically solution is that of combining funding resource GNI-based own resource traditional (mainly customs duties), which represents about 15% of the budget. This last is a "resource of its own", in the sense described in the Treaty.

- The introduction of a Community tax:

The proposal to introduce a tax of a community is nothing other than the return to the old discussion concerning harmonisation/EU tax consolidation. This initiative will have as a result:

- the possibility of the supranational Community principle to impose other fees-in the long term, the community will become the dominant way;
- the control of the Member States of the Community budget will be lower, and in the long term will disappear; uncertainty in tax revenues will complement logic development of a type of European public debt equivalent to attract huge resources in the public sector, the possibility of using tax release for

attracting investments and generate economic performance will disappear. This lever is essential especially for the least-developed States (EU-12), who can't compete than very hard in terms of celelelate conditions for attracting capital to the old Member States (internal bureaucracy, infrastructure, monetary stability, etc.);

- elimination of tax competition and the disappearance of a significant incentive to apply responsible economic policies (the regulatory regimes are more numerous, the most productive citizens he can refocus more easily zones activities and resources to the more "friendly". This shift, associated, among other things, with a loss of tax revenue, means a more intense pressure on policy-making than classic speech concerning the effects of taxes. Continuous pressure of Comsiei and of some Member States of Switzerland are graitoare relative to the meaning of the current european discourse on the "harmonisation").

Expenses

- Addressing the policies first:

The fundamental reason for which this approach should be rejected is that it weakens one of the two pillars of the budgetary stability: the rule limiting expenditure% of GNI foresaw 1.23 community website. It is an open invitation for all lobbyists to imagine a utopian policy, put in place by the side of the community.

Alain Lamassoure lists and he foresaw 1.23% ceiling keeping between the principles that govern the discussions on the revision of the budget.

- Macro stabilization/public goods:

Macro stabilization at european level requires a different size of the budget and other principles of operation (acceptance of deficits and public debt). It is an idea even more fanciful than the tax.

In terms of public goods, the Union is already committed to projects such as the trans-European transport networks (TENs), research and development, protection of the environment (with a significant component from the spring European Council – Global heating). Your continued use of the speech concerning the provision of public goods at european level will not result in excessive centralization than in Europe, the result of

new production and new public goods by supranational side(all the arguments against the collection also apply in this case. Mention that private solutions for the provision of certain public goods are more neglected in Europe compared with the US). Any budgetary implications will not be negligible, given that the old policies (support for agriculture, structural funds) will not be abandoned, even their Treaty.

- Agriculture and structural funds:

Reformation of main pillars of community support frameworks and in particular of the agricultural sector-is a long time on the agenda of the EU. For the purposes of discussion in this context, we consider that the following details are required:

- the renationalization of the PAC is practically impossible as long as the legal basis for this policy is the Treaty;

- there is a strong group of Member States which consider that agriculture must be modernized, not renationalization;

- the Member States who support an increase are generally developed States, with research structures fine-tuned and that will be the main beneficiaries of this diversion of resources;

- the idea of introduction of national co-financing as a solution to increasing the CAP budget without increasing the resources allocated to the Community budget is not very advantageous for countries with a large agricultural sector and an economy which is at the lower end of the top performance, as Romania or Poland. Co-financing would introduce additional pressures on the national budget, increasing the risk of exceeding the threshold of 3% set by the stability and Growth Pact and would frustrate the agricultural resources that can be used for the declared priorities: infrastructure, health, education;

- on the cohesion policy, the European Commission's vision centered on addressing macroeconomic, sectoral, having no connection with the approach of territorial cohesion policy. This is surprising considering that the entry into force of the Treaty of Lisbon increase and references to territorial cohesion. There is a risk that the cohesion policy should become a policy of charity and not one addressed to territorial development.

4. Conclusions

The fundamental strategic option that a Union has to be done now and in the future is between a budget with a decent budget constraints, countries – of the kind that you currently have, and a budget constraint lax, who will end up sooner or later in the enormous expenses.

Mention among the arguments in favor of a tolerable budget than the fact that there is a strong correlation between connection/the level of public spending and economic performance (view the levels of public spending and the relative performance of the US and the EU, but also the good performance of "codășelor" in the taxation (e.g. Ireland). This type of argument for keeping under control of public expenditure has been rediscovered recently and used repeatedly by representatives of the ECB) and that fiscal consolidation will weaken causal link between taxation and performance and will generate public costs still high and weaker performance.

Budgetary reform put fundamental level the problem of choice between two paths:

- one, the development by keeping public spending under control at Community level, private initiative, the rejection of protectionism, improve the business environment to encourage domestic capital formation and his attraction. In some form, this is the solution (the community side) focused on rules and not on money;

- the other, to maximise community public expenditure growth by giving up budgetary constraints countries currently available and enhance the collection.

The first way counts on productive citizen and on the creation of wealth, the second-on being able to come out winners in the massive redistribution will accompany the process. Times, this hope is one of the theoretical; redistribution is a political process, controlled, in one form or another, for those who bring their resources.

Accounting Integration in Corporate Governance System – Factor to Attract Investments

Ungureanu Mihaela
„Alexandru Ioan Cuza” University of Iasi,
Faculty of Economics and Business Administration
myhaella5@gmail.com

Abstract

Without international harmonization of accounting practices, conflicts and incompatibility financial information from different countries could not be resolved. In addition, the expansion of global markets makes it more difficult to transparent disclosures about contingent liabilities and off-balance sheet items. A proper accounting require dissemination of information, both voluntary and mandatory, to create competitive advantages in the market.

Thus, a company can receive a rating assessment of certain market intermediaries, improving trust, credibility and reputation of the company.

Keywords: accounting, corporate governance information, investments.

Jel Classification: G11, G37, M41, O16

Introduction

Definition and nature of accounting have changed over time. From the traditional perspective, in a simpler form, this implies a relationship by which some people are required by others to provide explanations and responsibility for their actions. Later, its meaning has changed, being found in its scope both the report, keeping accounts and application of judgment or punishment, taking into account the needs of citizens.

Shareholders access to information should be improved through modern means of communication, used both by businesses and authorities. Companies comply with legal requirements and provide information required by regulatory bodies, but often shareholders access remains limited, especially to outsiders (outside shareholders). In recent years, the situation has improved

due to development of electronic communication environment, by which all stakeholders can access the desired information.

Transparency of financial reporting is closely associated with disclosure, nature of presentation and public access. Some authors distinguish between the disclosure or the scope of information dissemination and their communication. They argue that transparency can not be achieved when are not comply reporting conditions – especially the ethical – set in accounting standards. So the broadcasts should be be accessible to the interested public by reporting tools to ensure transparency: using a simple language, standardization, electronic access, consultation and appeal rights. On the other side, commercial confidentiality militates against public access to information about private funding and considers necessary government involvement in developing an effective framework of transparency, allowing confidentiality for sufficient time to limit access information for hostile parties (competitors), but also ensuring a proper accounting.

1. Modernizing the regulatory framework of governance and accounting

Corporate governance approach of political economy perspective emphasizes the importance of legal regulations in grounding managerial strategies and decisions. These norms determine the extent to which countries differ according to the degree of investors protection, the impact of capital markets size, firm value, distribution policies, ownership structure and financial options. In case of an acquisition/fusion, strong protection of shareholders and accounting standards from acquirer country, may result in payment of higher premiums.

Since the 1990s there was a wave of reports in the private sector that recommended monitoring of procedures and structures, seeking to obtain two major results. Firstly, improving the reporting quality by increasing the efficiency of internal control systems and the independence of external auditors. Secondly, some changes are pursued in the Board of Directors' activities. According to some authoritative sources – CIPFA – as in the private sector, public sector governance assumed the two objectives above. Regarding the last objective the reports in the private sector include:

- emphasizing the need to control corporate policy content;
- achieving internal control mechanisms closely related to the decision of the Council;
- encouraging ownership activities and Council independence.

To achieve these objectives, the regulatory authorities in the private sector focus on the structure of the Board, highlighting the role of independent directors, whose growing number was one of the most visible elements of corporate governance reform at the international level. Also have been recommended creating and strengthening the role of committees subordinated to the Council, such as audit, nomination and remuneration.

Transparency has become, over time, an important indicator of quality of corporate governance system in an economy. Years 1993 and 1994 were for Japan, the first real attempt to improve the transparency and accounting. In this respect, SEHK (Hong Kong Stock Exchange) and HKSA (Hong Kong Society of Accountants) have established a working group in Corporate Governance (Corporate Governance Working Group - CGWG), which developed a series of best practices, as would be:

- separation between the chairman of Board of Directors and the CEO;
- the existence of at least two non-executive directors (independent);
- members of the same family can form the board up to 50%;
- the existence of two committees made up exclusively of non-executive

directors (audit committee and remuneration).

The second requirement listed became effective once 1995 and the formation of an audit committee remained a voluntary initiative. The Code of best practices revised in 1998 by SEHK, introduced obligation for listed companies to present, from the next financial year, on the quarterly and annual reports, the reasons why were or were not established audit committees.

In 2001-2002, financial reporting scandals have prompted regulators to react. Thus, in the U.S. Sarbanes-Oxley Act has emerged, which took effect on July 30, 2002. In the United Kingdom was published in January 2003 the Higgs Report concerning non-executive independent directors, in response to corporate failures and governance deficiencies that contributed to the fall of markets. The Combined Code, first published in 1998, was updated in the 2003, based on Smith and Higgs reports, underlining the importance of Board role and structure.

The wide financial scandals have led the European Union to develop a new corporate governance code according to which increase investors demands on quality of information required, on which investment decisions are based. At present, there is a set of principles and rules in this regard, which takes into account the independence of non executive directors, but also the obligation of listed companies to publish statements of compliance or noncompliance on corporate governance. Framework of Union in the this area has as main regulations:

- Directive 2003/6/EC concerning market abuse;
- Directive 2004/25/EC is considering the takeover bids;
- Directive 2004/109/EC concerning transparency of listed companies;
- Directive 2006/43/EC on the audit;
- Directive 2007/36/EC governing shareholders' rights.

Quality of accounting standards is also an important factor in determining the degree of shareholders protection. On mergers, the standards applied to the resulting new company are those of the purchasing company country. There are situations when merging entities can choose the rules of a third country or international standards, the most common choices being between U.S.

GAAP and IFRS. Similarly to business relations, regulatory environment can prevent institutional investors to exercise fully their right of expression. The existence of certain regulatory barriers may constrain the ability of institutions to exercise influence within corporations. The current financial crisis showed that the governance system used was not efficient enough, concluded that in the future, is required a high quality management. Starting with July of 2011, the European Commission initiated a public consultation program on how to improve the governance of companies, the main topics for discussion being: solutions for a better functioning of the Board and increasing its members' diversity, monitorization and implementation of national codes of governance, but also a more sustained involvement of shareholders.

2. Accounting information in business leading

The key concept when talking about corporate governance is transparency, which requires a permanent information. Providing prompt, in the request moment, of correct information, is the basis of principles concerning the functioning of capital markets. If this assumption is not met, investors are deprived of a real image on the company, so that they can not take knowingly decisions. Lack of trust forms a barrier to investment, leading to a high cost of capital and reducing the efficiency of resource allocation. Information and transparency provide to all stakeholders the optimal framework for economic and managerial performance assessment, analysis results decisively influencing the future behavior. An effective information system helps the public to enter the “secrets” of the business environment, examining its performance through the activities and policies at entity level. The new economy exploits more and more the best practices concerning ethical standards governing the relationship between various business partners. Equal access to information (simultaneously access at the same information), ensures fair treatment for all shareholders.

New technologies, through modern communication possibilities offered, provide

effective, fair and transparent information. Because it is the responsibility of managers, such as corporate governance is developing as a solution to their delimitation of the company's owners, since the interests of both sides are often different. Shareholders seek high profits and dividends as a rigorous control over the decisions of managers, while the latter want more power of decision and negotiation, remuneration and other financial benefits, for example, shareholdings in firm.

Accounting pursues many objectives that can be achieved in various ways, but the basic objective is to provide complete and accurate information to all interested parties, where an essential role has the financial reporting, so that we can talk again about the importance of transparency. Over time has increased the awareness of accounting role for the present and future of an enterprise and business environment as a whole. Regulatory authorities in the field claim that a high quality of information, especially financial ones, allows for the stakeholders better investment decisions and informed choices.

Some authors have demonstrated, making an assessment of the national corporate governance, the existence of a positive relationship between governance transparency and accuracy of financial analysts' forecasts. Rating agency Standard & Poor's uses in assessing companies, the rating score in this regard, called Transparency & Disclosure Ranking Score, based on the amount of information on corporate governance from annual reports. The more this quantity is, the less costly acquisition of information is, benefiting analysis services, enhancing the quality of results obtained by specialists. This situation is also associated with a low market risk, a higher price of shares and a lower cost of capital. It can be observed so that the acquisition and dissemination of information by financial analysts is a mechanism for reducing the risk of corporate governance and positive effect on the capital market. An equally great relevance for investors and analysts have and non-financial information, their content is directly related to reducing leakage and increasing the accuracy of financial forecasts.

From the perspective of investors, the concept of transparency includes aspects of: accuracy, consistency, adequacy,

completeness, clarity, convenience and timeliness. Worth noting the relatively low level of attention that many entities attach to explain the accounting policies of restatement of incorrect information. Executives often avoid a dialogue on such issues, leaving them into the responsible financial account. There are situations when the market may request details of the accounting issues involved, to prove whether and to what extent, the executive has intervened in handling information.

Regulations on financial reporting have been decisively influenced by the globalization and internationalization processes. Tendencies come from the European Union which means acquisitions and competition, and from the IASB (International Accounting Standards Board) and IPSASB (International Public Sector Accounting Standards Board) on the reporting process. IASB standards affect, directly, the reports of the end of the year, but they are also indirectly intervening during the period (for example, contracts are developed in the spirit of compliance with accounting requirements, especially regarding risk transfer).

Accounting depends on the flow of information used by each entity in part in preparing its annual accounts and a critical evaluation of accounting policies requires a transfer of information between organizations. Voluntary information are reliable if it moving towards efficiency goals such as improving the liquidity of capital markets firms, reducing its costs and can be used by financial analysts. Managers develop opportunistic behavior when there is no disclosure control regarding the company. If the credibility of a reporting is questionable, investors will require a gradual return to compensate the information risk.

Responsibility accounting improves governance system, not only by efficient market functions, but also by reducing monitoring costs. When the executive respects the principles of a proper, accountable and transparent accounting, are offered premises for introducing and applying the best strategic decisions in the interest of the parties involved. In a developed company, responsibility accounting, but also global governance are dispersed at subunits. Entity as a whole can

not be responsible if its subunits are not. Thus, improving overall responsibility requires that in each subunit to exist transparent decision making and financial reporting processes,, independent audit and internal control. Also a responsible accounting promotes the exchange of information and communication throughout the company. We can not talk about good corporate governance in the absence of effective information and communication systems. Information is key in making profit forecasts, designed to meet market expectations for company performance. If the corporate governance systems provide valuable and relevant information that analysts can include on their predictions, then it will be observed an improvement in forecast quality and reduced dispersion.

Ideally, corporate governance should provide an early warning system for the organization back on track, anticipating problems that may lead to a crisis. Thus, if a company has effective mechanisms of governance it must be able to identify a problem before the proper production, which involves the ability to collect, process and evaluate information. Therefore, institutional investors should seek creating systems of control for all companies in the portfolio, in order to facilitate the initiation of changes necessary to correct any deviations found in strategic actions. In this respect, are necessary information processing systems by which being evaluated the existing strategy and the set actions long-term desired.

3. Accounting and capital investment

Numerous studies of the domain have shown how the quality of a company's accounting is reflected on the efficiency of capital investment as a determinant of economic productivity. Also, accounting affects the functioning characteristics of financial markets. Accounting opacity is associated to higher costs of publicly traded capital. So, unwanted situations can occur, for example a rationalization of capital, as a result of information asymmetry between managers and investors. When managers can manipulate private information to issue overvalued securities, rational investors would withdraw their capital. Another example can be illustrated by the willingness

of managers to increase the established consumption and expanding the business to the detriment of investors remuneration for their capital.

Accounting transparency should reduce both adverse selection (tendency to issue securities at a steep price) and moral hazard (excessive risk taking, because the costs are supported by the party). Transparency involves preparation, auditing and disclosure of information using high quality accounting, financial and non-financial. In addition, an independent annual audit can provide external and objective assurance about the accuracy and reliability of financial statements. Considering that few companies will voluntarily provide transparency, this concept should be mandatory. Legal requirements in this respect are essential to give all shareholders information as real as possible about business value and to protect minority rights against domestic abuse.

A higher quality of enterprise accounting system helps to improve the efficiency of investments made by reducing possible frictions. The role of accounting is also essential to the country level, especially in economies where stock markets are the main sources of capital, since investment decisions are strongly influenced by accounting information. In economies where creditors have a dominant role, banks may obtain information from private sources, to directly monitor managers' work once the capital has been invested.

There is an analogy between investment decisions and behavior of individual investors. Thus, they show an aversion to risk if they expected safe gains and are willing to take risks when facing losses. When company's performance constitutes a reference point, is normally that the decision to invest to oscillate between risk aversion and its assumption. When management is suspected to take irrational decisions on capital investment in order to increase firm value, this behavior could be mitigated through good corporate governance. Moreover, such an attitude may be limited by availability of resources, for example, financial constraints, such as cash flow, dividends, capital and investments density.

In terms of a transparent financial reporting, capital providers can evaluate the investment risks in three ways: removing the

need for regulatory and forcing managers to pay more attention to the reports; allowing public access to information, to comment on financial data; promoting a continuous discipline, by means other than those of control over managers.

Ability to attract fresh capital is a fundamental factor of competitiveness. Better information will help investors to make choices based on real situations, being attracted by companies with open structures, with well-established practice of financial information and with possibilities to appeal management decisions. Investors will prefer those firms allowing them an assessment of inherent risks in their holdings.

(Instead of) Conclusions

Accounting profession considers corporate governance a search for management rules to prevent and correct the fraudulent practices of the company and granting unfair privileges. Financial reporting is, above all, an external control device that may require more or various forms of financial and non-financial information, other than those commonly used in private sector companies to meet corporate governance rules. Financial and accounting information constitute input of the implemented control mechanisms.

The importance of accounting in the governance system is highlighted by international studies, considering the role of financial information to attract new investors and maintain already existing relationships. Although it must be noted the contribution of other responsible persons, the professional accountant is the essential factor in preparing the information for internal and external users. He represents a complex entity that simultaneously requires ethical, accounting, economic, legal and even informatics skills. In the current context of globalization, professional accountant should be in line with international trends and not restricted only to the national regulations.

Relevance to investors of information relating to quality and efficiency in governance and administration of listed companies shows that improving corporate governance can be a strategy to increase their overall performance, namely to increase the stock price of their shares in the capital market and hence to increase business value.

Information Assurance Due to IFRS Adoption

Abstract

Currently, cross-border business operations are current currency and capital markets know no territorial limits. Standardization and harmonization have imposed an uniformity of accounting terms in national and international regulations. In this context, it makes direct reference to the accounting rules comply with the European Directives and International Financial Reporting Standards (IAS/IFRS), which are submitted to the first two fundamental concepts: performance and financial position, and on the other hand, investor, the main user of accounting information about their evolution.

This article aims to evoke the current diversity of accounting systems and consequences of IFRS adoption might have to obtain understandable, reliable, relevant and comparable accounting information. This follows if IFRS has positive or negative effects, if represents a solution or an impediment for financial reporting.

Keywords: IASB, IFRS, accounting normalization, accounting system.

JEL Classification: F23, M16, M41.

Introduction

The term “international accounting” means while the accounting problems raised by the internationalization of business (accounting operations in foreign currencies, financial information by geographical area, etc..) and those related to the diversity of accounting practices worldwide.

Accounting harmonization and standardization processes started by adopting international accounting rules known as International Accounting Standards (IAS) issued by the International Accounting

Standards Committee (IASC), an organization founded in 1973 in London. Currently are used International Financial Reporting Standards (IFRS), developed and published by the International Accounting Standards Board (IASB), which replaced the IASC since 2001. IASC former rules retains the title and remain in force as long as they are not superseded by the IASB standards.

In terms of global application of the accounting rules, can be distinguished two categories of countries. Firstly the ones that apply and require the application of IFRS by enterprises, among which the most important are Australia, China, Russia. Then there are those seeking convergence of national standards with the international ones, without excluding the possibility of the latter adoption. Among the most important countries are Brazil, Canada, USA, India. United States is a special case where the IASB would have a considerable success if they would give up their own rules, those of the FASB, to adopt IFRS.

1. Diversity of practices and accounting systems

The early 1970s was the period of major advances in international accounting, particularly under European Union (Fourth and Seventh Directives) and International Accounting Standards Board (IASB). These efforts led, in particular, to the gradual reduction of the differences between the two main global accounting referential that American standards (U.S. GAAP) and the IASB (IFRS). In the EU, the process culminated with an obligation for all listed companies to use IFRS since 2005. European example was followed by several major countries such as China and Australia. Canada also decided to adopt IFRS in the future, as Russia and Japan.

Even if these advances are remarkable and true, it would be wrong to believe that now, worldwide, accounting is computerized. Many countries are indeed for the time off the process of harmonization, particularly Africa and South America. In the United States, even if they work together for many years with the IASB, the rules always show significant differences from IFRS. In conclusion, it should be noted that harmonization has opened large companies, especially in the consolidated accounts. In Europe, the obligation to apply IFRS is only for listed companies. Also in the U.S. where only listed companies are required to apply FASB rules. International accounting harmonization was therefore a process with two speeds: fast, large listed companies, but much slower for the others. Analysis of the accounts of different nationality remains therefore always tricky, especially when it comes to small and medium enterprises.

Many authors have tried to summarize these differences by proposing a classification of national accounting systems. The most common typology is that which speaks of Anglo-Saxon accounting system and continental, each specific to a group of countries that adopt specific accounting principles and practices. The following table (Table no. 1) summarizes this classification, given the country representative of each system.

Table no. 1 – Types of accounting systems

Anglo-saxon system		Continental system	
American influence	British influence	Fiscal basis	Legal basis
United States	United Kingdom	Italy	Germany
Canada	Australia	France	Sweden
	New Zealand	Belgium	
		Spain	

Explanation of differences between accounting systems have explored the diversity of economic, legal and political differences between countries. Some experts estimate however that this approach is insufficient and national accounting characteristics are reflected fundamental cultural factors.

A. Economical, legal and political factors

Differences between accounting systems are also explained by several factors: the

legal system, mainly the financing of enterprises, taxation, political and economic ties between countries.

The influence of these factors explains the differences in accounting normalization concepts that exist in the Anglo-Saxon and continental European countries. In the first, the responsibility is left to professional organizations setting standards (GASB in the United States, the AUC in the United Kingdom) while in the second group, the main accounting rules are included in the law (in French Commercial Code, Handelsgesebuch in Germany...).

It is traditional to oppose to Anglo-Saxon capitalism the “rhéna” capitalism. The first is marked by strong stock markets, which provide the essence of funding large companies. In such a system, accounting promotes the investments, from which publication of large amounts of information that are considered most closely as possible the enterprise. In the countries belonging to model “rhéna” are rather financial institutions (banks and other financial establishments) that provides to companies the essence of their resources. The main focus is therefore the protection of creditors from which the importance attached to the principle of prudence which is often more important than the objective of fair presentation.

Fiscality strong influence the accounting practices in continental Europe because in these countries, only the actual expenditure accounted for are tax deductible. Enterprises have therefore a tendency to align their accounting to the more favorable tax rules, even if it leads, for example, the finding of depreciation or non-economic provisions justified. In the Anglo-Saxon countries instead is calculated the fiscal result almost with a few exceptions, regardless of the sheet result. Fiscality has therefore much less impact on accounting practices than in continental Europe.

In the the economic and political links, it is obvious. Colonial countries have exported their general accounting system or area of influence. It is not by chance that most of the states relates to the British Commonwealth and Francophone African countries to French model. Share of economic relations is also reflected in the similarity of American and

Canadian accounting systems or German and Swiss.

B. Cultural factors

Without denying the importance of the economic dimension, it may be that cultural factors play a role in the development of accounting systems. Literature holds four dimensions that characterized every culture: individualism, power distance, uncertainty aversion, masculinity.

Some authors have sought to establish a correlation between these variables and certain features of national accounting systems, in particular the type of regulatory (or legal professional) degree of consistency, prudence and transparency. Have been proposed also some assumptions on the relationship between three characteristics of the accounting system (professionalism, care, confidentiality) and two cultural dimensions (individualism and aversion to uncertainty).

Also, there was the initiative of developing a general model accounting systems which strives to combine environmental, cultural and institutional factors. They tested this model correlating observed the accounting practices in 50 countries with a number of variables representative of various explanatory factors. Significant relationships emerged for each series of variables, which tends to show that national accounting systems are the result of interactions between all factors.

2. Informational efficiency in the context of international accounting diversity

Numerous studies have tried to assess the economic consequences of diversity accounting practices of "quality" earnings also stock market relevance of accounting numbers.

Several authors have hypothesized that the quality of the result sheet, defined as the ability to reflect true economic performance depends on the legal system of the country. The default idea is that countries as regulated accounting is subject to considerable political pressure (which establish and impose accounting rules), unions and banks. In these countries, accounting result should be considered first and foremost as a wealth divided among various interested parties (stakeholders) of the enterprise in the form of dividends (shareholders), taxes (state) and

raw (employees and managers). Each of them, seeking to ensure consistency remuneration, preference went to the stable results over time, from which accounting rules give managers a wide latitude on when to record the result, no gain or weight. In the common law countries, however, the objective of accounting is to serve the needs of investors. They are first of all interested in the ability to reflect accurately the outcome of real economic performance of the enterprise, with a preference for the manipulated outcome, incorporating good and bad news immediately.

Have been studied two constitutive dimensions of quality results "punctuality" (timeliness) and "prudence" (conservatism). Punctuality is the measure by the degree of association between the accounting and stock return action (more correlation is strong accounting result is considered high point). Prudence is defined as the ability to incorporate outcome information quickly so evil and the good. As expected, the results of enterprises located in common law countries (United States, Canada, United-Kingdom and Australia) are more punctual and conservative than those of companies domiciled in countries as regulated (France, Germany, Japan).

In the same vein, was observed and the correlation between the average return on assets (ROA) and country businesses deemed variable measures the country's economic performance (growth rate of gross domestic product). It was found that the degree of association is stronger in the United States and in the United Kingdom than in France and Germany and, in this sense, accounting better reflects the real economic performance in common law countries are characterized by a strong protection of shareholders, a market-oriented financial and accounting independence from taxation.

Careful analysis of the results was correlated with the various legal and judicial system, the degree of caution to ascertain that the result is higher in countries that enjoy a high quality judiciary (i.e. impartial) also giving considerable protection to shareholders. Prudence is also inversely proportional to the degree of state involvement in the economy.

Previous studies based on the assumption that managers of law companies located in

countries governed, has a latitude greater freedom to delay accounting for losses than their Anglo-Saxon counterparts. Handling results (earnings management) should be more frequent in these countries than in common law. However more research came to results contrary to this hypothesis.

Previous works developed in the United States showed a discontinuity in the distribution of differences between published and the expected outcome analyzes, a sign that managers tend to avoid announcing results below forecasts. Given the possibility of handling large results as regulated countries, we can expect that the phenomenon is more pronounced in these countries than in the United States. Survey evidence suggests that it means nothing because American companies that appear most in the tendency to manipulate the results to avoid dangerous announce a surprise to the market. If the practice of hidden reserves and smoothing results found in German countries (Germany, Switzerland, Austria) give credit hypothesis that manipulation of results is much stronger in countries as regulated than in common law countries, the research cited above shows that U.S. companies do not hesitate to possession also result to avoid disappointing the market.

For the Anglo-Saxon, accounting purpose is to provide useful information to investors. Accounting ability to get a result and an amount of equity correlated with profitability and market capitalization, ie the relevance of stock (value relevance) quantifying the accounting is therefore ultimo criterion to compare the quality of different accounting systems. Considering the market orientation of Anglo-Saxon accounting, we expect this stock to be irrelevant as higher in these countries than in others.

However, majority of researches does not confirm the superiority of Anglo-American accounting model over that of continental Europe. Based on this researches, it seems difficult to conclude that Anglo-American accounting system is superior to its counterpart in mainland Europe in terms of relevance stock. It seems, rather, that investors accommodate with the operating system almost all of equal importance is given accounting figures, regardless how they are determined.

3. IFRS generalization and informational consequences

For a long time, only firms in less regulated countries such as Switzerland were able to apply IAS/IFRS because, compared with most other countries, these rules were not fully compatible with national rules. Things have changed in the early 2000s by the decision of some countries, especially those that have recently passed to a market economy (China, Eastern Europe) to adopt IFRS. But it is especially the European Union option to make IFRS mandatory for all listed companies which gave considerable importance to these rules. The European rally to IFRS convinced the Americans to work with the IASB to develop common rules and, in 2007, to cease to require foreign companies listed in the United States to recalculate them the result and equity under U.S. GAAP.

IFRS are generally more stringent than the rules they replace. They allow fewer accounting options and required to publish more information. We can expect that their application to reduce information asymmetry in the market.

A tool for testing this hypothesis is to measure the difference between the offered and requested (bid-ask spread) of the considered enterprises' actions. Indeed, if information was perfect the course of action would be unique and this difference would be zero. Applying IFRS should therefore be accompanied by a reduction in this difference. Wondering about the real extent of application of IAS/IFRS before they become mandatory, some authors have found that reducing the price scissors would not only apply to companies applying “rigorous” IAS. The authors, whose compliance with international norms was only partial, saw that their price difference is significantly reduced. It was also found that the effect on prices is lower cutter with company size and number of analysts who monitors it, which tends to show that the adoption of IAS / IFRS firms which often have little information is available.

Information asymmetry can also be measured by the analysts forecasts and through the errors of the expected results. If IFRS can reduce information asymmetry, the dispersion and the errors should be much

lower than before the adoption of these rules. However, the forecasts are more dispersed for companies applying IFRS or U.S. GAAP than those using local rules. It can be appreciated that this result is due to the fact that international and U.S. standards have reduced the possibilities for smoothing latter results are more difficult to predict the adoption of these rules than before. Given the forecast errors, there is an inverse relationship between forecast errors and the degree of compliance of financial statements with IFRS. For the countries of Continental Europe, analysts forecast errors were lower for companies applying IFRS or U.S. GAAP than for others.

Most studies on companies that have adopted IFRS during the last 15 years have shown that changing accounting rules was accompanied by a decrease in behavior management results and a tendency to defer accounting for losses. The effect was however limited to voluntary application of international rules not found any significant difference for companies that are expected to become mandatory IFRS. These observations relative importance of accounting rules, showing that mandatory enforcement is not sufficient to ensure the quality of accounting figures, which are also the characteristics of the institutional environment is evolving enterprise (legal system, the protection of investors, and so on).

Once IFRS were oriented information needs of investors could expect that their adoption resulted in an increase of the relevance stock (value relevance) accounting figures in continental European countries. Empirical researches are far from unanimous on the subject. If, as expected, and increases adoption of IFRS accounting information quality by reducing information asymmetry and limiting the possibilities for manipulation of results that investors should take into account in setting the conditions for financing the cost of companies' capital will be reduced.

(Instead of) Conclusions

Recent years researches has shown that it is still difficult to determine what lasting consequences will have the application of IFRS in Europe, these studies are relatively few and partly contradictory. Most are also

based on observation of companies that deliberately applied the international standards and is not therefore certain that their results can be generalized to all listed companies. Several informational studies suggest that the results are highly dependent on local institutional and legal context, applying the same rules is not sufficient for the homogeneity of accounting practices. Therefore, further researches are needed to elaborate a first evaluation of the generalization IFRS.

Harmonization achieved in the listed companies do not in any way forget that other companies remain subject to national rules covering economic, social and cultural specialties. Even though it also seems to show a uniform movement under the IASB and its draft regulation on SME accounting, changes should be much slower at this level, as legal, fiscal and cultural barriers will be compensated by the pressure of financial markets.

Abstract

Even if during crisis the internal saving process should be low as far as investment needs are concerned, in Romania this has been contradicted.

The evolution of the banking saving process of both the population and the legal persons has become positive again lately after the 2009-2010 contraction. This positive evolution was firstly possible due to the attractive level of the interest rates offered by the banks for the deposits in the national currency and secondly due to the relative amelioration of the dynamics of the labor income.

The economic policy should encourage both the public and the private internal saving process including the system of tax-deductibility as well. This is especially necessary under the circumstances of the following period when the financial capital will be more and more expensive due to the financial crisis generated by overindebtedness and demography.

Keywords: deposit, ceiling, guarantee fund, deponent

J.E.L Classification: G21

1. Introduction

The balance of the crisis years show an alarming situation in almost all aspects, but there is at least one domain in which the Romanians have made amazing progress and that is the saving process of the population.

2. The Evolution of the Bank Deposits between 2008 - 2009

According to the statistics provided by the National Bank of Romania (NBR) and the Guarantee Fund of The Bank Deposits (GFBD) the bank deposits of the population have increased from 68.6 billion lei in February 2008 to 115 billion lei in December 2011 (the sum includes the value in lei of the foreign currency deposits too).

In other words, the deposits of the population have almost doubled in the past four years even if the real increase is smaller if we take into consideration factors such as the evolution of the inflation and the devaluation of the euro. For example, according to the NBR data the single currency had an average value of 3.68 lei in 2008 whereas at the moment its value exceeds 4.5 lei.

Even so, the increase of the deposits of the population is significant. The explanation is that in the first part of this period in 2008 and 2009 the Romanians' income have continued to grow but the consumption has been drastically reduced. Specialists consider that a part of this difference between the money earned and the money spent has been placed in bank deposits [1].

A massive growth of the deposits has been noticed during the first two years of the crisis followed by a slowing down and then by a rally of the advance in the last years of 2011. From the very first year of the crisis this evolution has been paralleled by a drastic decrease of the consumption when the stores halved their sales.

Another explanation for doubling the deposits of the population is firstly due to the increase of the confidence in banks. In other

words, if until 2008 the money have been ‘salted away’ Romanians have gradually started to take it and deposit it in a bank.

The financial crisis has generated people’s fear for tomorrow’s safety determining them to start saving and stop spending [2].

From this point of view specialists are convinced that Romanians have now much more cash than at the beginning of the crisis. This is one of the paradoxes of this financial disaster.

Due to the lack of funds from the mother banks the financial institutions in Romania have been forced to use local funding. This strategy has lead to the fact that banks have tried to attract more and more money from both the population and the companies by means of increasing the interests for the deposits. This factor and the macroeconomic environment have created the favorable environment for the development of this saving behavior.

Chart No. 1. The Evolution of the Amount of the Guaranteed Deposits and the Guarantee Ceiling

Source: www.fgdb.ro

In comparison with 2009 one can notice a 1.4% increase of the guaranteed deposits in the total amount of deposits as a consequence of their rapid growth in comparison with the amount of the unguaranteed deposits.

Chart No. 2. The Evolution of the Amount of the Guaranteed Deposits (thousands lei)

Sursa: www.fgdb.ro

From the chart above one can notice that the amount of the guaranteed deposits has slightly increased for both private and legal persons at the end of 2010 in comparison with the previous year. The doubling of the guarantee ceiling of the deposits for both categories has become a fact on 31 December 2010. This fact has not influenced the deponents’ behavior.

3. 2011 – A Reference Year for the Saving Process

As far as 2011 is concerned, on 31 December 2011 the total value of the deposits on the whole banking system has reached the peak of the last years, 309.4 billion lei respectively (the equivalent of a 3.2% increase). The positive dynamics of the total value of the deposits has been mainly determined by the ascending evolution of the population’s deposits in lei, an evolution registered at the level of the credit institutions joining the GFBD (an annual variation of +11.6%, respectively an absolute increase of 6.9 billion lei).

On 31 December 2011 the 33 credit institutions joining the GFBD accumulated 92.5% of the total value of the deposits on the whole banking system in Romania, respectively 286.2 billion lei (an increase by 2% in comparison with the value registered on 31 December 2010). 106.7 billion lei out of this sum have gone to the population and the rest to the legal persons [3].

Chart No. 3 The Evolution of the Value of the Guaranteed Deposits per Currency and Titulars in 2011

Sursa: www.fgdb.ro

As far as the categories of deponents are concerned, 2011 has been characterized by the accentuated increase of the total value of the population’s deposits in comparison with those of the legal persons (the absolute increase of the total value of the population’s

deposits on the whole banking system has been over 12 times higher than in the case of the legal persons). At the level of the credit institutions joining the GFBD, the evolutions of the two components have been opposite. **The value of the population’s deposits** has increased in each of the two terms of 2011 whereas the deposits of the legal persons have only partially recovered from the remission in the first term in 2011.

From the point of view of the denomination currency in 2011 the deposits in national currency at the credit institutions joining the GFBD have continued to hold the majority share (53.6% on 31 December 2011). In comparison with the end of the previous year these have registered an increase by 5% whereas the total value of the deposits denominated in foreign currency has diminished by 1.3%.

As far as the guarantee of the deposits is concerned, at the beginning of 2011 there have been major changes of some essential coordinates regarding the deponents’ protection. Among these we can mention the doubling of the guarantee ceiling from the lei equivalent of 50,000 Euros to 100,000 Euros starting with 30 December 2010 and thus pursuing the development of the deponents’ confidence and the stimulation of the saving process.

On 31 December 2011 the values of both the guaranteed and the unguaranteed deposits (the majority of the unguaranteed deposits is represented by those deposits belonging to the entities having the necessary knowledge and experience for the evaluation of the non-refundable risk of the placements; this category includes: the credit institutions, the financial institutions, the insurance companies, the collective placement organisms, the pension funds, the central and local public authorities, the big companies, etc.) were having equal shares in the total value of the deposits at the credit institutions joining the GFBD.

In Romania the substantial increase of the credit ceiling has led to the extension of coverage ensured by GFBD. The data of 31 December 2011 show that for a ceiling of 100,000 Euros the sum associated with the maximum potential compensations in the case of the unavailability of the deposits represents approximately 79% out of the total value of the guaranteed deposits, respectively 113.2 billion lei (an annual variation of +8.7%).

The value of the population’s guaranteed deposits has had an ascending trajectory throughout 2011 with a more rapid rhythm than in 2010 (an annual variation of +7.8% in 2011 in comparison with +5.4% in 2010). In fact, we can even talk about opposite senses of evolution since the annual variation of the value of the population’s guaranteed deposits has been +4.5% in 2011 and +2.4% in 2010.

Chart No. 4. The dynamics of the population’s guaranteed deposits in relationship with the guarantee ceiling

Source: www.fgdb.ro

As shown in Chart No. 4, 83.8% out of the total guaranteed deposits of the population represents the accumulated value of those deposits at the very most equal with the guarantee ceiling. Their holders are the potential beneficiaries of compensations limited by the available deposits.

On 31 December 2011 the value of the guaranteed deposits of the legal persons reached 36.6 billion, a sum representing 20.4% of the total value of the deposits of the legal persons at the credit institutions joining the GFBD, thus witnessing an 8% increase in nominal terms (+4.7% in real terms) in comparison with the same value on 31 December 2010. This mainly happens in the case of the deposits in lei with values higher than the guarantee ceiling [4].

Chart No. 5. The dynamics of the guaranteed deposits of the legal persons in relationship with the guarantee ceiling

Source: www.fgdb.ro

In relative terms, the annual variation of the guarantee deposits in lei reached +8.5% and that of the deposits in foreign currency has been lower representing +5.4%.

The national currency guaranteed deposits of the legal persons have preserved their major share in the total value of the deposits of this category of deponents, respectively 73.4% on 31 December 2011. This aspect reflects the confidence in the national currency.

4. The Quality of the Saving Process in 2012

On **30 June 2012** the deposits of the whole banking system reached a total amount of 316.6 billion lei with 8.1%, over the same value in 2011. According to a GFBD study the population's deposits reached 120.8 billion lei (a value with 2.5 billion lei higher than the one at the end of March) and the rest of 198.8 billion lei belonged to the legal persons with an increase of 1.9% during the second term of the year. This evolution is due to the increase of the amount of the deposits on the whole of the credit institutions joining the Fund. These sums have compensated the withdrawals from the branches of the foreign banks in Romania in the respective period [5].

Another thing worth noticing is the fact that in the term of the year the deposits in foreign currency have rapidly grown especially the ones in lei; this is a characteristic of both the credit institutions joining the Fund and of the branches of the foreign banks. In addition, the deposits in foreign currency of over 100,000 Euros have contributed the most to the evolution of the deposits of the legal persons. We should also mention the fact that the number of the deponents from the category of private persons has witnessed an increase in comparison with those of the legal persons.

92.5% of the total value of the banking deposits belongs to the portfolio of the 33 credit institutions joining the Fund.

The Fund data collected from the banks show that during the term of the year the deposits in foreign currency have represented the population's favorable saving instrument since these deposits have progressed much more rapidly than those in national currency. Nevertheless, at the end of the year the deposits in lei have witnessed a more accelerated dynamics in comparison with those in foreign currency.

Charter No. 6 The dynamics of the total value of the deposits in the banking system (billion lei, the end of the period)

Source: Piața Financiară, no. 9/2012, p.14

The data above show that in the first period of the year the dynamics of the deposits has been much more accentuated than that of the credits and the 'appetite' for saving has increased. Likewise, according to the statistics in the field another defining tendency has been the promotion of the long-term deposits often harmonized with an investment fund.

5. Conclusions

In spite of all the positive results regarding the saving process Romania has to reconsider its measures of economic policy so that the saving process could be encouraged.

The banks from Romania pay a special attention to the segmentation of customers and to the creation of personalized products and services combining the flexibility of the savings accounts with the profitability of the deposit products.

The interest of the banks is directed towards the stimulation of the long-term savings behavior, but also towards the consolidation of the deposit portfolios and the facilities involved in the saving process.

Innovation in Financial Systems. The Quest For Sustainability

Voicu-Dorobanțu Roxana
Bucharest University of Economic Studies, Romania
rovodo@gmail.com

Abstract

The paper focuses on the trials and tribulations the financial systems are facing in the current economic environment, in order to increase their economic sustainability, but also improve their social sustainability. As desperate times (characterized by an endemic crisis, reaching from the financial systems into the globalized economic network) require ‘desperate measures’, there is a certain need for improvement and innovation in instruments and behaviours exhibited by the actors in a financial system.

The paper suggests two possible ways regarding the approach to sustainability, in particular social sustainability, for the financial systems. These creative methods rely mostly on the possibility to improve financial inclusion, to reduce risks related to non payments and, in the end, to ensure that the financial system is not an enhancer of poverty, but rather a solution to alleviate it.

Key words: financial systems, innovation, sustainability

J.E.L. Classification: G15

Introduction

More and more individuals are financially excluded, living on or under the poverty threshold, particularly during the aftereffects of a financial crisis becoming chronic and worldwide spread. Therefore, creativity and innovation in preserving the number of financially sound clients of a system that is already under a lot of pressure is both capitalistic in its profit oriented understanding, but nonetheless its effects are positive in terms of social involvement of the institutions. The purpose of the paper is not to discuss the morals of CSR or its hidden causes, but to underline best practices in

terms of increasing sustainability and improving the life of the community as related to financial systems. If the main cause of these actions is related to preserving the profit margin, preserving or increasing the number of clients, improving the tax collection rate or the corporate image of the financial institutions is beside the point.

The starting point of any discussion about socially sustainable financial system is the number of individuals currently outside them, hereby considered financially excluded. Financial inclusion is defined in HM Treasury (2007) and the Scottish Executive (2005) as ensuring universal access to financial services and products, allowing daily funds management in an efficient, safe and reliable planning for the future and reducing financial pressure, by managing finances so as to provide protection against short-term variations in income and expenses and the opportunity to benefit from long-term opportunities, reducing situations where unexpected events result in high financial difficulties scale.

Although in its initial definition, financial inclusion only refers to access to financial products and services in recent years, one can observe a bending toward expanding the concept and those who, although they have access, it difficult to use the services and products mentioned mainly from understanding products. In general, as can be seen from the definition, financial exclusion does not refer solely to hold a basic account (allowing payments for goods and services and withdrawing cash, but does not assume the existence of an overdraft). We can even divide the financially excluded in:

- Individuals who would like a basic account (Basic Bank Account - BBA), but have been denied the application for various reasons
- Individuals who do not want a basic account – in which case this self-exclusions should consider them as extraneous to the analysis. Another situation where we cannot

talk about financial exclusion is when individuals refuse to open a BBA due to lack of confidence in complex financial institutions, which may stem from a lack of basic financial education.

In literature there can be found six types of financial exclusion (Kempson and Whyley (2000)):

1. Exclusion through lack of physical access - lack of banks and / or ATM in the area (in which case it may be e-banking), the possibility of connecting to the Internet, access to mobile networks, etc..
2. Exclusion through lack of access - denying access to people perceived as having a high risk of certain products
3. Conditional exclusion - there are a number of conditions attached to products or services that are inaccessible to a certain social
4. Exclude the price - the products are available, but the price at which they are offered them unaffordable for a social category
5. Exclusion by marketing - the sales and marketing efforts are geared towards a specific group, which limits access to information for other social
6. Self-exclusion

Kempson et al (2004) shows that the financial exclusion occurs when low-income social groups, such as those from ethnic minorities, are prevalent or the number of people dependent on welfare is high. Another important element of financial exclusion is age, those in the tails of the age distribution being the most vulnerable, such as young or old (Kempson and Whyley, 1999). The same group of authors, Kempson et al (2004) identified history in relation to the financial environment as a determinant of financial exclusion, as is the case in Sweden and Germany, in addition to items such as number of parents / persons in families (single parent families are more vulnerable or as well as elderly singles), age at which the individuals leave the education system (common tendency is that people with higher levels of education are less vulnerable to financial exclusion). Other determinants of financial exclusion may relate to the location by dealing with physical access (remote communities - a situation which may be solved via the successful application of electronic finance, except that isolation

involves lack of Internet access and / or electricity) or the deprivation of the region concerned. Whyley Kempson (2004), the Treasury Select Committee - UK (2006) and Citizens Advice (2006) note that people belonging to rural communities are less likely to have a basic account, unless it is the effect of the implementation of public policies, such as paying social benefits, pensions, taxes exclusively through electronic channels and / or fundamental financial products. In literature, one can identify a number of factors affecting financial inclusion, divided into two categories:

- institutional factors (whether it is financial institutions related to central and local government, such as tax collectors, or institutions as organization, i.e. banks) - increasing competition in the banking products and services provided by all channels, which enhances the search for new market niches for banks and technology advances basically e-banking and mobile banking, which help reduce barriers to physical , resulting in the phenomenon known as, financial desertification '(Sinclair, 2001) and
- personal factors (related to individual actions and perceptions thereof).

Finally, it is necessary to define and electronic financial inclusion, defined as application of ICT to deliver innovative financial products and services when and where required, at a cost affordable for the general disadvantaged population and low income groups, which is now considered to be non-bankable (Chakravarti, 2009).

One of the fast growing industries in the financial sector is related to the provision of banking products and services via online and mobile means, generally known as on-line and/or mobile banking. In order to maintain market share, many ‘brick-and-mortar’ banks became ‘click-and-mortar’ by adding the Internet to their means of service delivery. The advantages of adopting Internet or mobile banking solutions are multiple: the product/service prices and the costs involved in their production are reduced. The fact that each customer can pay the bills and can check their account online or via mobile phone reduces the time taken to process a check after it has been filed or required to pay, which amounts to an increase in efficiency of up to 25%.

There are also a number of risks of accessing online banks (non-click-and-mortar or online only), the most frequently mentioned being the lack of security. Another risk is the fact that the value of a subsidiary will decrease, but not to zero, as expected in the reports from the "Internet era" (1995-1999). Since the late 90s, the Bank for International Settlements (BIS), proposed a set of basic principles for reducing risks in systems of electronic banking services and products such as:

- Creating a system for tracking electronic banking activities
- Creating a process management system and subcontracting relationships and dependencies with third parties
- Segregation of duties, databases and applications in the electronics and the rest of the banking system (as given up once the full integration of e-banking among the bank's usual activities)
- Existence of measures and controls the electronic authorization
- Possible existence of a clear audit of the electronic system, namely the e-banking transactions
- Authentication of each entity and counterparty data from electronic banking
- Responsibility for each transaction carried out online
- A system of comprehensive security control system
- Transaction integrity and information on e-banking
- Complete and transparent information on electronic banking
- Keeping customer information privacy principle
- Existence of continuity and contingency plans to ensure availability of electronic banking systems
- Incident response planning
- Supervisor's role to ensure a clear and accurate management structure, internal controls and contingency plans on e-banking activities.

The second topic of interest for financial institutions, apart from the novelty of alternative distribution channels is microfinancing, the buzz word of the beginning of the millennium. Defined by Otero (1999) as "providing financial services and products for people with low incomes

and who are their own employees", microfinance emerged in the 80s and extended in the 90s, also known as the 'decade of micro-financing' (Dichter, 1999). In its broad sense, it refers to a movement that aims to build a world in which low-income households have permanent access to a wide range of high quality financial products and services to finance activities, stabilize consumption and reduce risk, with the ultimate goal of reducing global poverty. Another definition of microfinance (Schreiner and Colombet, 2001) talks about improving access to micro deposits and micro-loans to low-income households neglected by the banking system, although in practice the term refers rather to provide microcredit via microfinance institutions (MFI) in turn defined as institutions providing financial services and products of the poor (MIX, 2005). It is considered that these have a dual mission (Markowski, 2002), although in the literature (Simanowitz and Walter, 2002) there are also opinions that the balance between the two sides is rather fragile (the double bottom line) and often leans to the capitalistic side: the social mission of providing financial services and products to low-income population and thus improve welfare for them and the commercial and mercantile mission to provide financial products and services in a sustainable manner financially / economically. Moreover, the IMF in a 2005 report noted that only 1% of MFI are financially sustainable, i.e. (Havers, 1996) cover their own financing costs, operating costs, credit risk and inflation, using fee income and interest. Claessens (2005) believes that the high transaction costs, low transaction volumes correlated with higher costs to increase penetration render MFIs economically inefficient. The IMF report examines the fact that those MFIs which have become financially sustainable tend not to finance the poorest population, leading to the idea that it is desirable that those institutions which promote the inclusion of the bottom quartile in terms of income should be supported in acquiring the capacity for self-support, and therefore be able to enhance their reach of more people affected by poverty. In this sense, balancing the social mission and the business side becomes imperative (Simanowitz and Walter, 2002),

by understanding market and financial institution clients (Morduch, 2004), the more that can generate high financial returns in the long term (Pawlak and Matula, 2004).

David Rodman considers 2009 to be a crucial year for the development of micro-financing, as the year of the two most important impact studies (Karlan, Zinman, 2009 and Banerjee, Duflo, Glennerster, Kinnan, 2009). They concluded that microcredit effects are diffuse, which is consistent with general research findings on microfinance (Aportelo, 1999; Burgess and Pande, 2003, Banerjee and Duflo, 2006), as well as micro-savings impact research (Karlan, 2008, Ashraf, Karlan, Yin, 2005 and 2008, Dupas and Robinson, 2009). Also in literature (Rogaly, 1996, Wright, 2000; Navajas et al, 2000; Chowdhury, Mosley and Simanowitz, 2004, Sinha, 1998), a number of negative factors that may be associated with an MFI are identified and namely:

- Focuses on a uni-sectoral approach to allocating resources to fight poverty
- Microcredit is not relevant for people with extreme poverty
- The definition of microfinance using a simplistic definition of poverty
- Changes and learning curve are not appropriate.
- There is an extreme emphasis on size, not quality.

Also one of the major problems is to quantify the effects in their dynamic evolution, both in the MFI's and the community it serves. Dimensions such as:

- Social performance of the system - the social mission, goals and strategies, governance, social performance, operational systems, alignment of mission
- Social responsibility - to customers, to staff and to the community and the environment
- Penetration - operating areas, the target group reached
- Quality of service and products - variety of products and services, matching customers' needs, services and non-financial and non-financial become socially relevant indicators in determining the rating of a microfinance institution.

The Asian Model of Community Involvement: Cashless banks and e-government

Asian countries have been moving for almost a decade towards a financial system without cash, especially after the emergence of new electronic financial products. The ultimate goal of such a development trajectory has been maintaining financial and economic stability, coupled with improving the efficiency of financial systems. A survey conducted in 2010 (The Economist, 2011) in 13 Asian markets reveals that the percentage of respondents who prefer a local bank increased compared to 2007, mainly in Hong Kong (to 76% from 55%), China (87% to 75%) and Taiwan (68% from 51%) at the expense of international financial services companies, which still suffer from deficiencies in their corporate image due to the economic and financial crisis. Moreover, under the influence of government policy to reduce payment costs caused by previous research which proved that in terms of social cost, a national payment system may comprise about 2-3% of GDP, and bring about 5% of the transaction (Gresvik and Haar, 2008, Khiaonarong and Liebenau, 2009), one can note an increase in the use of electronic financial products, to the detriment of traditional. If in developed countries, the introduction of electronic financial products, particularly in the period 1987-1999 reduced only in the European countries banks' operating costs by about \$ 32 billion, which represented a saving of 0.38% of GDP 12 countries (Humphrey et al, 2006), the development of such tools in the Asian countries started later: mobile banking products being implemented only since 2007. In recent years, the volume of transactions via traditional branches decreased by 27%, correlated with a similar increase of products and services online, while mobile products increased by 83%. A reduction of the amount of cash has implications at the National Bank, taking into account that the amount required to print a bill is between \$ 0.05 and \$ 0.08 (depending on security measures), added to a better traceability of cash flows, and thus a reduction in tax evasion, as was the case of Norway, which has the requirement to report any cash transactions of

more than NOK 100,000 (approximately \$ 16,000).

Singapore, the country with the most advanced e-government system, globally launched in 2002 (Kok, 2002) has substituted cash with smart cards issued by the government. Moreover, it provided financial support programs to improve the efficiency of the payment system, as mobile or internet transactions, and relaxed regulations on limiting the issuance of e-money by non-bank financial institutions (Monetary Authority of Singapore, 2002, 2004). Cases such as Thailand implemented systems to reduce charges for electronic payments, correlated with a reduction in transaction costs for them, leading to improved financial position of banking institutions. In Asia, there is however a certain heterogeneity in the distribution of electronic transactions versus using cash. Countries like Japan still have a high level of cash usage, statistics indicating that the average Japanese adult spends on average \$ 18,000 per year in cash.

Although the ultimate goal of such a best practice is to reduce financial exclusion, whether electronic or not, this is a collateral result of financial system development, and still the customer needs to sustain his own activities.

Conclusions

One of the main guidelines of the roadmap towards a financially inclusive, sustainable system is the need of a proper governmental involvement, through public policies meant to facilitate access to infrastructure and funds, foster innovation and transparency. However, of crucial importance is the involvement of companies and financial institutions, regardless of their ulterior motives, with an aim to include more and more people, in particular those in low-income households, at or under the poverty threshold or financially challenged in any other way, in a system meant to provide the minimum access to funds and the suitable mechanisms to foster entrepreneurship, and thus, indirectly, improve the community.
