emilia_titan@yahoo.com

Abstract

The paper attempts to determine the influence of different quality of life indicators on migration in Europe based on data from Eurostat, World Bank Group, ILO, OECD and IOM and briefly deals with making classification of countries based on emigration and indicators of the ecological performance. In the first part there is made a correlation between emigration and the Gross Domestic Product, a multiple regression using the „ecological” indexes and then a cluster analysis is being implemented. In the second part it is shown the econometric model which will determine what variables are relevant in the research.

Keywords: migration, quality of life, econometric model, cluster analysis

J.E.L. Classification O15, I20, I13, J12, J13, J15, R15, C38

1. Introduction

The purpose of this study is to give a brief overview of the evolution of European migration, using indicators that are not that „worn out”. [4]

The hypotheses from which we start count the fact that the evolution of migration is greatly influenced by the quality of life. Therefore, some indices that refer to the quality of life will be analyzed so we can determine how significant their influence is. [5] The main idea of this study is to take into consideration other variables that make people live their countries. [1]

Quality of life refers to the well-being of individuals and societies and it is used in many contexts that include development,

healthcare, politics and so forth. This means that the indices are from a wide range of fields, including wealth, employment, built environment, physical and mental health, education, recreation and leisure time, social belonging. [3] Quality of life and migration together are rarely seen in studies, only a few papers attempting to do a comprehensive analysis of those two. Usually, those that are preoccupied with this subject come from the United States of America. In Europe, we can't find studies that are really exploring this topic. And so, this paper is trying to generate a general view over this matter. [7]

2. Data and methods

We used the econometric model in order to determine which index is more important in influencing migration in the European countries. [2] The main indicators that I took to analyze for the quality of life are from different fields like fertility, mortality, marriage and divorce, health, education and training, social protection, environment. The relationship between the variables was analyzed using simple and multiple regressions. [6] We used ten indicators that are essential in expressing the quality of life: life expectancy by age and sex, infant mortality, proportion of live births outside marriage, live births by mother's age at last birthday and legal marital status, divorces, marriages, health care expenditure (euro per inhabitant), pension, investments in education and training, foreign language learning (average number of foreign languages learned per pupil), urban population exposure to air pollution.

Most indices were obtained from the Eurostat and the countries chosen for this

study are: Belgium, Bulgaria, Czech Republic, Denmark, Germany, Estonia, Ireland, Spain, France, Italy, Cyprus, Latvia, Lithuania, Luxembourg, Hungary, Malta, Netherlands, Austria, Poland, Portugal, Romania [10], Slovenia, Slovakia, Finland, Sweden, United Kingdom, Iceland, Norway, Switzerland, Croatia, Moldova [9] (most countries from the European Union). [8] [11] [12] [13]

The data was registered from 2002, 2007 and 2011. Statistical data processing was conducted using SPSS software and Statgraphics Centurion.

For the data systematization when using migration, we also took the population data, so we could balance the size of the countries, while comparing them.

3. Results and discussion

We first made a correlation between the Gross Domestic Product and emigration so we could see if the global economic crisis background had a hard influence over the migration in Europe. [6]

Figure 1.

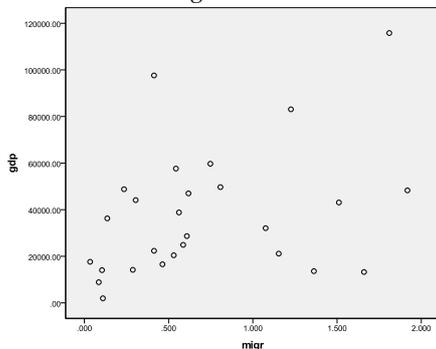

Table 1.

		gdp	emigr
gdp	Pearson Correlation	1	.362
	Sig. (2-tailed)		.064
	N	27	27
emigr	Pearson Correlation	.362	1
	Sig. (2-tailed)	.064	
	N	27	27

The scatter plot is giving a slightly idea of how the two comparable data sets agree with each other. This table shows Pearson product moment correlations between the pair of

variables. These correlation coefficients range between -1 and +1 and measure the strength of the linear relationship between the variables. The third number in each location of the table is a P-value which tests the statistical significance of the estimated correlations. So, the following pairs of variables have P-values approximately 0.05 and a medium correlation of 36%.

Next, we made a multiple regression between emigration and the 5 indicators that establishes the ecological performance of the European countries: Environmental Performance Index, Happy Planet Index, Climate Change Performance Index, Biodiversity and Renewable Energy Systems.

According to Reader’s Digest the “greenest” countries in 2010 were Sweden, Switzerland and Norway. [14]

Table 2.

Model Summary ^b					
Model	R	R Square	Adjusted R Square	Std. Err of the Estimate	Durbin Watson
1	.470 ^a	.221	.016	.61275	2.083

a. Predictors: (Constant), RES, Biodiv, CCPI, HPI, EPI

b. Dependent Variable: emigr_2010

ANOVA ^b						
Model		SS	df	MS	F	Sig.
1	Regression	2.020	5	.404	1.076	.405 ^a
	Residual	7.134	19	.375		
	Total	9.154	24			

Coefficients ^a						
Model		Unstand. Coeff.		Stand. Coeff.	t	Sig.
		B	Std. Err	Beta		
1	(Const)	.251	.357		.704	.490
	EPI	-.032	.028	-.433	-	.257
						1.168

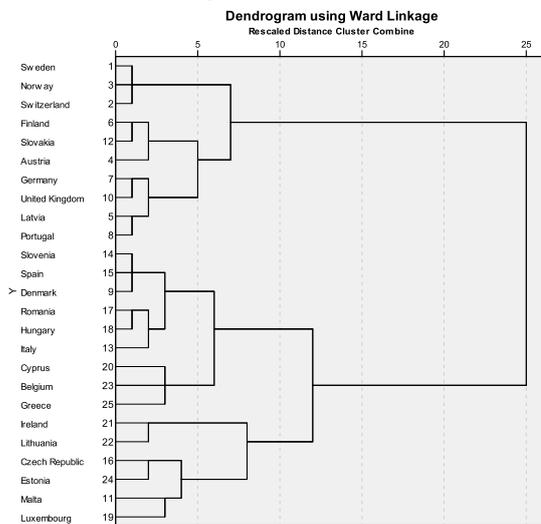

HPI	-.01	.017	-.135	-.578	.57
CCPI	.014	.018	.196	.800	.433
Biodiv	.022	.021	.299	1.004	.328
RES	.038	.018	.560	2.119	.048

a. Dependent Variable: emigr_2010

As we can see from the tables, the most relevant indicator is the Renewable Energy Systems and the value of R of 47% shows a medium link between the variables.

Then we applied the cluster analysis so we could see how those countries would form groups.

Figure 2.

Analyzing the dendrogram, if we took a distance between 10 and 15, we could group the countries into 3 clusters:

- Cluster 1: Sweden, Norway, Switzerland, Finland, Slovakia, Austria, Germany, United Kingdom, Latvia, Portugal
- Cluster 2: Slovenia, Spain, Denmark, Romania, Hungary, Italy, Cyprus, Belgium, Greece
- Cluster 3: Ireland, Lithuania, Czech Republic, Estonia, Malta, Luxembourg

For the indices that we chose for the quality of life, we made simple and multiple regressions for relevancy. And we took data sets from 2002, 2007 and 2011, so that we can see if anything changed in the meanwhile.

The first index analyzed was life expectancy by age and sex:

Table 3.

Dependent variable: EMigr_2002

Independent variable: Life_expectancy_2002
Linear model: $Y = a + b \cdot X$

Coefficients

	Least Squares	Standard Error	T	P-Value
Parameter	Estimate	Error	Statistic	P-Value
Intercept	-4.85487	2.04538	-2.3735	0.0256
Slope	0.0704616	0.0269002	2.61937	0.0148

Analysis of Variance

Source	Sum of Squares	Df	Mean Square	F-Ratio	P-Value
Model	1.48738	1	1.48738	6.86	0.0148
Residual	5.41962	25	0.216785		
Total (Corr.)	6.907	26			

Correlation Coefficient = 0.464052

R-squared = 21.5344 percent

R-squared (adjusted for d.f.) = 18.3958 percent

Standard Error of Est. = 0.465602

Mean absolute error = 0.320366

Durbin-Watson statistic = 2.0835 (P=0.5665)

Lag 1 residual autocorrelation = -0.0485615

The output shows the results of fitting a linear model to describe the relationship between Migr_2002 and Life_expectancy_2002. The equation of the fitted model is

$$\text{Migr}_{2002} = -4.85487 + 0.0704616 * \text{Life_expectancy}_{2002}$$

Since the P-value in the ANOVA table is less than 0.05, there is a statistically significant relationship between Migr_2002 and Life_expectancy_2002 at the 95.0% confidence level. The R-Squared statistic indicates that the model as fitted explains 21.5344% of the variability in Migr_2002. The correlation coefficient equals 0.464052, indicating a relatively medium relationship between the variables. The Durbin-Watson (DW) statistic tests the residuals to determine if there is any significant correlation based on the order in which they occur in the data file. Since the P-value is greater than 0.05, there is no indication of serial autocorrelation in the residuals at the 95.0% confidence level.

We used the same method with the other indicators:

Infant mortality:

Table 4.

Marriages_2011	-0.0000075	0.000007	-1.072	0.296

Analysis of Variance

Source	Sum of Squares	Df	Mean Square	F-Ratio	P-Value
Model	1.5994	6	0.266567	0.82	0.5646
Residual	6.46854	20	0.323427		
Total (Corr.)	8.06794	26			

The equation of the fitted model is:

$$\text{Migr}_{2011} = -3.00603 + 0.0509208 * \text{Life_expectancy}_{2011} - 0.0000701944 * \text{Infant_mortality}_{2011} - 0.00396519 * \text{LivebirthsOM}_{2011} + 7.09497E-7 * \text{LivebirthsLMS}_{2011} + 0.00000944697 * \text{Divorces}_{2011} - 0.00000759043 * \text{Marriages}_{2011}$$

For those indicators we also took the first 5 countries with the greatest number of emigrants and the first 5 countries with the greatest number of imigrants and then compared their means, so we could check their suitability in this study.

If the indicators are relevant, then the mean of the countries with a large number of emigrants should be significantly smaller than the mean of the countries with a large number of imigrants.

The first 5 countries with a great proportion of emigrants were: Ireland, Luxembourg, Lithuania, Iceland and Latvia.

The first 5 countries with a great proportion of imigrants were: Luxembourg, Cyprus, Belgium, Malta and Austria.

As we suspected, in most of the cases the mean of the indicators of countries with emigrants was smaller than the other and if we would increase the number of countries compared then the difference would become more visible.

Life expectancy by age and sex:

$$\bar{y}_1 = 77.66 \text{ (emigrants)} < \bar{y}_2 \text{ (imigrants)} = 80.32$$

Infant mortality:

$$\bar{y}_1 = 110.8 \text{ (emigrants)} < \bar{y}_2 \text{ (imigrants)} = 157.6$$

Proportion of live births outside marriage:

$$\bar{y}_1 = 41.48 \text{ (emigrants)} > \bar{y}_2 \text{ (imigrants)} = 32.82$$

Live births by mother's age at last birthday and legal marital status:

$$\bar{y}_1 = 1.21 \text{ (emigrants)} > \bar{y}_2 \text{ (imigrants)} = 1.08$$

Divorces:

$$\bar{y}_1 = 4.74 \text{ (emigrants)} < \bar{y}_2 \text{ (imigrants)} = 5.02$$

Marriages:

$$\bar{y}_1 = 2.36 \text{ (emigrants)} > \bar{y}_2 \text{ (imigrants)} = 1.9$$

Health care expenditure (euro per inhabitant):

Total (Corr.)	10.0466	27			

$$\text{mig2007} = 1.24881 - 0.0237144 * \text{exposure}_{\text{toairpollution}}$$

4. Conclusion

The most influential indicators that were evaluated in the study are life expectancy by age and sex, foreign language learning (average number of foreign languages learned per pupil), pension and urban population exposure to air pollution and by the evolution of the period of ten years, there weren't significant changes that could be notable. Only life expectancy by age and sex became less relevant by the passage of time. So, we can conclude that the determination of leaving a country is not purely based on the level of income or a hard economic background.

Abstract

As well known, globalization is a process that encompasses the causes, course, and consequences of transnational and transcultural human activities, within a global network of economic, social and knowledge and human capital free migration.

From the perspective of sustainable development that implies rational and holistic researches of market and society, meaning free intergovernmental global cooperation in the context of institutional complexity of nation state actors ,issues measured in the form of general and specific globalization indexes.

In this framework, as it happens in reality where the utility ,rationality and externalities are primordially to social adaptive complexity in the energy centres approach of globalization inspired from Romanian interwar researcher Constantin Rădulescu Motru, is important to understand globalisation as a complex network of energy centres, a space of interactions between rational agents that manifest conscious, character and rationality of economic, social, politic and cultural consequences.

Keywords: globality, globalism, economic rationality, social cultural complexity

JEL code : F63 , Q01

1. Introduction.

Globalization is a concept perceived differently by people in time and space.

For an ordinary informed individual globalization is seen from the perspective of

global competition impact on the competitiveness of the national economy meaning either an increase or decrease in living standard, while for the uninformed people, especially those who live in isolation and poverty globalization means nothing.

For a manager, globalization is a competitive institutional regulated space of transnational practices risk management a potential tool for maximizing the economic (efficiency), financial (profit) and social (utility) excellence function, while for a politician is the struggle arena for the strategic geopolitical domination or a global institutional framework for promoting nation-state interests.

The last but not the least globalization is a scientific research topic: from the perspective of sustainable development globalization is a concept that reveals the interconnection between the real natural sciences and social humanistic disciplines within a complex network of principles, processes and values sustained by rational economic and civil society agents pursuing the efficient resource allocation and social development

In this framework, one possible approach of globalization could be emphasized as a network of energy centres inspired from the Romanian psychologist Constantin Rădulescu Motru, to affirm the importance of rational character and personality of nations states perceived as unitary rational agents in the process of promoting the national interest on the global stage.

2. Globalization - theoretical and practical approaches

Semantically speaking, the notion of globalization is closely related to notions of globality (considered a neutral formula of

international notion which defines a working method of intergovernmental cooperation) and globalism (specific definition class of ideological term of imperialism, in which a part dominates all other parties).

Thus globalization term refers to the continuous, dynamic and progressive integration of nation states from economically, financially, politically and culturally point of view because the problems facing humanity are global rather than national.

From a larger perspective, globalization is both a concept, a reality condition and an socio cultural process that encompasses the causes, course, and consequences of transnational and transcultural integration of nation states actors.

Determined by the by Christianity and Great Geographical Discoveries spillovers as well the impact of the three waves of agrarian, industrial and knowledge revolution globalization is characterized by flows of goods, services and people, meaning deepening of economic, commercial integration, transfer of policies and knowledge exchanges across borders, global political negotiation of national interest in the spirit of the fact that “interdependencies respect the independence of parts”[1]

It is a borderless world of formal and informal rules in which the free migration of economic, financial, social, technologic, knowledge and human capital generate global positive and negative spillovers in the context of a socio cultural and politic historic process of transition to risk society, illustrated by the exchange of ideas, experiences and general human aspirations in which the unique and unrepeatable national patrimony enriches the heritage of universal values[2],[3]

In this respect, the impact of globalization is vast in time space, and that reveals some economic, political, and cultural issues as such:

-the implications of global actors behaviour (World Bank, IMF and OMC) on the unequal distribution of globalization costs and benefits. [4], [5]

-the issues generated by post communism cold war politics encouraging the intergovernmental cooperation and reducing the political hegemony of supra state institutions influence[6],[7] ;

-the implications of global city culture as well as the environmental issues of the U.N. environmental global program Agenda 21. [8],[9]

All of these imply a deepening of globalization cost benefit distribution analysis in terms of the North South discrepancies and supranational -national contradiction, in the way of the necessary reform of so called Washington Consensus ,on the relationship between the global “autarchic” macroeconomic treatment and the real living consumer standard, between a global approach and a deepen reconsidering of real national specific conditions, the respect of the sovereignty of nation state constitutionality, its economic policy and national culture to diminish the costs of over indoctrination risk of the presumed free choosing human being that has duties and rights written in state constitution as well in his conscience.

The reality of globalization is sad : despite of the apparent victory of free markets ideology, and the pretention that globalization is an instrument of closeness, appear two isolated worlds, each with specific problems: on one hand it is about the globalization of richness that exploit business, travel and educational opportunities protecting its own citizens' rights and on the other hand there is another globalization of poverty and loneliness, which also deserve respect which implies the need to regulate markets and global reform of global economic, financial and democratic institutions.

In the same time globalization is a topic of scientific researches related to conceptual and applicative issues such as:

- the related concepts of centre and periphery in the historical evolution of the world as a global system global [10];

-competitive transnational practices of circumscribed aspects of economic, political and cultural management in which private agents manifests as capitalists, bureaucrats and cultural[11];

-multidimensional aspects of the network society and its technological space time compression –the perception of physical space disappearing in the context of accelerating of communication speed-[12],[13]

-the ideas of reflexive approach of globalization in the context of a social cultural adaptive historic process from traditional to industrial and risk society suggesting the risk of forgetting of traditional values in the favour of postmodern individualistic values[14].

-the implications of civilization clash and free migration of economic, financial, technologic cultural, and human capital in the context of so called channels Ethnoscapas, Technoscapas, Financescapas, Mediascapas, Ideoscapas [15], [16]

-the last but not the least is about the applicative side of globalization by so called general and specific indexes of globalization.

On one hand is about the conceptual structure of economic, political, social and cultural globalization indexes (*A.T. Kearney/Foreign Policy Magazine Globalization Index, CGSR Index* elaborated by the Centre for the Study of Globalisation and Regionalisation, *KOF Index* from Zurich Swiss Economic Institute and Maastricht[17].

On the other hand, based on the general indexes of globalization some researchers constructed indexes specific aspects of rational and complexity aspects of globalization.

Thus, firstly, the complexity side of globalization reveals the some specific indexes such as *Global index* based on OECD human rights issues elaborated by M. Raab [18], the *New Globalization Index of University Study Migration* invented by P. Vujakovici[19], or the *Excellence Managerial Performance Index* proposed by Economist Intelligence Unit with Ernst and Young Group[20].

Secondly, the rational, economic side of globalization is presented by the so called *G Index* from WMRC-World Markets Research Centre[21], the *Index of Goods and Capital Markets Integration* elaborated by Andersen and Herbertsson.[22].

An interesting approach of practical indexing of globalization could be the essay of Kluver and Fu in the context of *Cultural Media Exchanges*. [23]

3. Globalization – a complex network of socio economic energy centres

Given the of triple bottom line and triple top line objectives of economic, social and environmental sustainable development, the globalization illustrates both like concrete reality and a imagined idealistic, social construct as a set of principles, tools and actors involved in interactive technical economic sense and integrative socio cultural process addressing the global mankind's issues through optimizing of global market externalities in the economic, social, ecological and cultural environmental as well as considering the impact of complex adaptive system dynamics on global institutions that have established the principles and mechanisms of economic, political and cultural relations between nation states. [24], [25] [26]

From this perspective, the essence of globalization is of an environment of intensification of global interconnections between all states both in terms of quantity (volume of commercial transactions, capital flows) and quality (exchange of ideas through IT) within a complex network between a variety of players at different levels of decision (macro, micro or meso-economic) continuously or temporarily, in a rationally deductive or inductive experimental manner.

In this framework globalization means a distinction to make between two approaches pricing the of cost – benefit distribution on efficient resource allocation maximization, cultural exchange ideas integrated to global reality processes and values that governing the interactions between nature, market and society.

Thus, globalization is presented through the principles of deduction and induction researches (formal, structural, efficient and final causes versus “physicist” principles of Complex Adaptive Systems vision of world) integrated in a set of interdependencies between economic and institutional global agents (nation states, individuals, multinationals, NGOs, institutional investors, criminal organizations, media), in the natural and anthropogenic environment.

The sustainable development approach of globalization reveals two important issues.

Firstly, as it was mentioned by Martin Shaw at a scientific seminar entitled “America’s Choice - Liberty Or Sustainable Development?” the sustainable globalisation raised the question of supra state institutions bad influence on national policy and politics as the case of global Agenda 21 Programme. This strategy leading to so called intelligent strategies highlights the possible conspiration between politicians and suspected unofficial multinational interested groups. .

From his point of view this global strategy is in contradiction with the spirit of national constitutional base of nation state the only one that can defend the presumed free people that has obligations and rights written in the fundamental supreme law as well in the national values and conscience.

Secondly is the impact of so called energy centre concept mentioned by the Romanian psychologist Constantin Radulescu Motru in his book “The Christian Power of the Soul “[27]

From this perspective, the history of mankind was long time dominated by the conquer obsession of exterior material world by through experimental inductive methods, an illusion marked by the influence of physics on other sciences in so called entropic time scale and adaptive metabolism of human personality.

But in the opinion of author, the real necessary environment needed to be conquered is the soul character and conscience-that special laboratory of Christian faith metaphysical intuitions, intentions, hypothesis, thoughts and aspirations that help the adaptive personality actions into a direction of utility maximisation and realising the externalities spill-over consequences, in the context of general relations between people in the social economic and natural environment.

In this framework, as it happens in the global reality where the utility rationality and externalities are however primordially to social adaptive complexity, in the energy centres approach is important to understand globalization not only in the way of globalism but also in the form of intergovernmental global partnership of nation states – energy centres- not only the spirit of apparent cybernetics time compression of informational speed but also its reason d’être of what is happen in time -

that space of interactions between rational agents that manifest conscious, character and rationality of economic, social, politic and cultural spill-overs consequences.

Aspects of International Banking Globalization

Botiș Sorina

Transilvania University Brașov, Faculty of Economics and Business Administration
sorina.botis@unitbv.ro

Abstract

Affected by changes in the global economic climate, the banking industry adapts, increasing its possibilities of access to funds by entering the capital markets, in direct competition with securities companies, insurance companies, mutual funds, pension funds and also, diversifying its portfolio of products and services using specific tools adapted to new markets, increasing its profitability and reducing their risks as a result of activities like financial markets transactions and generating revenue through commissions.

The main objective of this paper is to highlight the recent evolution and the major consequences of banking globalization, the growth of banking mergers and acquisitions, the major contributing factors to international banking sector consolidation, the role of banks in the international transmission of shocks and how the banking markets are affected by the recent financial crisis.

Key words: banking globalization, financial group, mergers, acquisitions, crisis

J.E.L. Classification: F6, G21

1. Introduction

Speaking about the economic dimension of globalization, we can say, that is the catalyst of globalization process in the other fields, using trade, manufacturing, financial markets and technology as major instruments.

The term „globalization” indicates besides spreading significance, that of interdependence, the states are no longer isolated or autonomous, but interconnected.

Economically speaking, Meghnad Desai defines globalization as “...an increased interdependence and integration of different economies in the world”, emphasizing the

central role of mutual dependence between states.[1]. The high degree of integration of financial markets, coupled with the liberalization of capital flows, has led to increased interdependence between developed and developing economies in all world regions, with widespread effects, including a pronounced state of instability, accompanied by volatility and uncertainty in the most markets(capital markets, oil markets, money and foreign exchange markets, labor markets).

2.Global integration in the banking industry.

Affected by changes in the global economic climate, the banking industry adapts, increasing its possibilities of access to funds by entering the capital markets, in direct competition with securities companies, insurance companies, mutual funds, pension funds and also, diversifying its portfolio of products and services using specific tools adapted to new markets, increasing its profitability and reducing their risks as a result of activities like financial markets transactions and generating revenue through commissions.

Banking globalization is perceived: by the formation of large international financial groups, within which the banking activity is highly diversified, internationalized, competition becomes global and changes in this segment determined banks to act far beyond the traditional activity restricted to the establishment of bank deposits and granting loans: by the involvement of foreign capital in banking and credit sector in different world regions, leading to a spatial reconfiguration and a national banking markets expansion: by industrial-scale reorganization of banking activity as a whole: by unprecedented diversification and internationalization of banking products and services portfolio.

To be competitive, beginning with the 1990s, banks proceed to a reconsideration of the applied strategies by passing a profound reorganization process, consisting in the internalization of banking system on the one hand, and in the high concentration of banking activity on the other hand.

The internalization of banking systems, has been achieved through aggressive policy, part of the development policy of banks, a policy of subsidiaries implantation (banks, leasing companies and other financial services providers), branches, private banking centers, in the world financial new items.

On 1 January 2011, 630 branches of credit institutes were resident in the euro area. These branches accounted for 9,9% of all euro area credit institutions. The largest share of these branches was located in Germany (17,5%), Estonia (61,1%) and Belgium (54,7%), having the largest proportion of foreign branches in the relation to the total number of credit institutions. The head offices of the majority of the foreign branches in euro area countries were located either in another euro area country (64,4%), or in the United Kingdom (14,6%).[2]

At the same time, on 1 January 2011, there were 263 branches of foreign credit institutions resident in non-euro area EU Member States. Of these, the largest proportion (51,7%), was located in the United Kingdom. The head offices of the majority of the foreign branches in non-euro area EU Member States were located either in euro area countries (52,2%), or either non-euro area EU Member States (20,2%).[2]

The most recent example coming from Industrial & Commercial Bank of China(ICBC), the third largest bank in the world ranked by total assets. ICBC moved up to third place in the new world ranking in September 2012. In December 2011, ICBC occupied only the sixth position.[3] In 2013 ICBC is the largest bank in term of market capitalization (market cap., US\$b237.97, at January 25, 2013), profitability and customer deposits, with over 286 million individual and corporate customers, about 409.000 employees and 18.000 outlets including 239 overseas branches. Four of the largest banks are Chinese financial institutions: ICBC, China Construction Bank, Agricultural Bank of China, Bank of China.[4]

ICBC expansion in emerging markets was achieved by opening new subsidiaries in Eastern Europe, Latin America and Middle East.

Thus, in Latin America opened in December 2012, a subsidiary in Peru, being in November 2012, the first Chinese bank who enter on the banking market in Argentina.

In Europe opens branch in Warsaw(2012) and Barcelona, a „private banking” Centre in Paris, in November 2012.

In the Middle East, opens subsidiaries in Saudi Arabia and Kuwait, in January 2012.

As of the end of June 2012, 252 overseas institutions had been set up in 34 economies and continues to expand with the rapid growth of emerging markets, with China’s massive investments in oil and mining companies assets from Latin America, South America and Africa, in countries such as Argentina (oil producing), Peru (iron ore reserves), Brazil (petroleum), in an effort to ensure enormous amount of raw materials needed to sustain economic growth in China.

China now equals US in having four banks in the top 10 by Tier 1 capital, and ICBC has entered the top three worldwide for the first time.[5]

3. Mergers and acquisitions in the international banking sector

The term „mergers and acquisitions”, or simply M&A, denotes a broad range of formally distinct transactions.

An „acquisition” is defined as a transaction, when a company (acquirer) gains ownership control over another company (target), but both remain legally independent entities.

On contrary, after a „merger”, one or both merging entities legally cease to exist; the shareholders of the merged companies obtain agreed stakes in a single successor entity.

It is a distinction without a real difference because mergers and acquisitions both result in combined entities. M&A usually require shareholder and regulatory approvals. The factors influencing M&A, include strategic fit, cost and revenue synergies and acces to talented employees, occupying a dominant place in the international financial exchange market.[6]

The banking activity is dominated by

monopolies, consortia, trade unions and other banking alliances, resulting from the unification of banks, thus forming new power centres.[7]

Table 1. Regions by total tier 1/total assets/total pre-tax profits 2011

Country	Tier 1 (\$bn)	Assets (\$bn)	Pre-tax profits (\$bn)
US	1059.9	13,341.0	131.5

According to the Lisbon Group, the international banking sector is following the trend of the economy, which means that integration processes, technological, economic, capital concentration, are more intense in most developed three regions, North America, Western Europe, Japan and newly industrialized countries of South an Southeast Asia.

Industrialised Europe has been the primary destination for cross-border lending activity for the past three decades. The US is the second destination, followed in the past decade, by entire regions like Asia and Pacific Countries, emerging Europe and Latin America.

The major factors contributing to European banking sector consolidation, through a large number of mergers and acquisitions, were technological advances, the globalization of financial markets, enhanced supervision of credit system, the creation of a single financial market in the European Union and the introduction of the euro, market liberalization, economic reforms, even banks' desire to increase in size.

The result was a constant growth of mergers and acquisitions in the EU banking sector. In the same time the number of credit institutions in the euro area and in the EU decreases further, from approximately 12.000 at the end of 1990 to 7.000 at the end of 2004, to 5.998 in February 2013 in EU banking.[2]

The table shows the number of credit institutions by country.

The first merger in EU took place in June 2005 when UniCredit merget with German Group HVB, which is itself formed by the combination of Bavarian banks Bayerische Hypotheken-und Wechsel-Bank and Bayerische Vereinsbank in 1998. Integration with the HVB Group was reinforced by the merger with Bank Austria Creditanstalt in the year 2000 and enable further growth for the UniCredit Group. The company has its registered office in Rome, with approximately 40 million customers and operations in 22 countries. UniCredit's core markets are Italy, Austria, Russia and Southern Germany, being the largest financial group in Eastern Europe. The company has investment banking divisions in London, Milan, Munich, Vienna, Moscow, Budapest and Warsaw.[8]

Deutsche Bank (DB) is currently the largest bank in the world with assets of EUR2.186 trillion (US\$2.810 trillion). In 2012 was awarded the title of Best Foreign Global Investment Bank by Euromoney magazine and won six awards from Global Finance including Best Corporate Bank, Best Foreign Exchange Bank and Best Credit Derivates Provider. Mitsubishi UFJ Financial Group (MUFG) is the second largest

financial institution in the world with assets of US\$2.803 trillion. The Bank of Tokyo-Mitsubishi UFJ is the main banking arm of MUFG.[3]

American banking transformation become possible after the changes in the banking and financial law. Introducing in the 1990s the following legislations, Riegle-Neal Interstate Banking and Branching Efficiency Act of 1994, played the big role in the acceleration of the mergers and acquisitions process in the USA, allowed buying interstate companies possessing a bank, banking mergers in different states, opening new branches in the other states and running bank activity in a form of the agent of the other bank.

The American banking industry has experienced an unprecedented number of mergers and acquisitions on a belief that gains can accrue through expense reduction (Wells Fargo estimated an annual cost savings of \$1 billion from its acquisition of First Interstate), increased market power, reduced earnings volatility, during the banking consolidation process of the 90s.

More than 1500 mergers took place in the US banking sector between 1993-1996 years.

But the banking consolidation process was proceeding with different intensity, as a part

of restructuring and the reform of commercial banking and the increase of the banks size and the value of mergers and acquisitions. At the end of 90s, each of nationwide banks had less a hundred branches, while the leaders in the group had a chain of several thousand branches.

Despite this tendency, the number of bank mergers and acquisitions in the USA was growing very slowly in the next few years. The number of banks M&A transactions between 2000-2004, increased only from 213 in 2000, to 215 in 2004.[9]

The financial crisis spawned bankruptcies, restructuring of companies and financial institutions, mergers and takeovers, direct financial support significant funding from the US government, and approved \$700 billion to be used only in order to save American financial institutions from the crisis effects. In 2012, Citigroup received, along with Bank of America, the largest state support of \$7,5 billion, down 32,5% from 2011.[5]

Many of these institutions are or were publicly traded, their exit from the market not only affects the credibility of the US capital market but also the stock trading volume, the price volatility.

Table 3. The major banking company merged in the last five years

Source: Institute of Mergers, Acquisitions and Alliance(IMAA) www.imaa-institute.org

In Central and Eastern Europe, the foreign subsidiaries do not always bring profits, even the banking markets remained stable in 2011.

CEE banking markets continue to be dominated by foreign investors with: UniCredit, Erste, Raiffeisen, KBC and SG controlling a combined 35% of total banking assets in the region. Although the number of banks making losses (34 out of Top 200 banks in CEE) increased slightly against the year before the profitability ratios remained stable with combined return on equity (ROE) close to 7,6%, and return on assets (ROA) exceeding 0,8%. [10]

Poland remained the single largest banking market in the region, with assets worth EUR 293 billion and holding the 30% share. [10]

In the present, the foreign acquisitions are not an option for the international banking groups hit by the financial crisis, the trend is to sell subsidiaries as part of restructuring plans.

The prime beneficiary of the restructuring plans in Europe, was Russia's Sberbank, the largest bank in Russia, buying the Central and Eastern European network of Austria's Volksbank in 2011. [11]

For example, branch in Romania of Citigroup, the banking group with the largest network, during the restructuring program, has identified 21 global markets, including Romania, where there will be restructuring, cuts or even closing their activity, in the perspective of profit targets for 2015.

In Romania, Citigroup following a repositioning plan, involving business efficiency and reduce costs, restructured the consumer banking sector, positioning itself in the segment of companies.

Raiffeisen Bank Romania will acquire the retail portfolio of Citigroup Romania. The transaction will be completed in the third

quarter of 2013. The agreement signed between the two banks, provides the assumption by Raiffeisen Bank Romania (part of Austrian Raiffeisen Bank International), a portfolio of over 100.000 clients, with assets of RON460 million (over EUR90 million) and over RON770 million (over EUR175 million), in deposits according to data from December 31, 2012, and all employees of CitiBank retail banking division. [12]

4. Conclusions

International banking activity is an important component of a broader process of financial globalization and integration.

More radical steps are needed in reforming the structure, ownership and incentives for banks to make them more attractive long-term investment.

Globalization of banking and other forms of financial services may influence regulatory and macroeconomic challenges for the countries involved.

Mergers and acquisitions in banking sector become familiar in the majority of all the countries in the world. A large number of international and domestic banks all over the world, are engaged in mergers and acquisitions activities. [13]

In the present, the foreign acquisitions are not an option for the banks, the trend is heading the other way, as selling subsidiaries as part of restructuring plans.

World economy in recent decades has been characterized by a decrease in the exchange of goods between rich economies with high growth rates in North America, Western Europe, Asia and rest of the world, especially Africa.

According to estimates, this trend will increase in the future. Thus, participation of regions like Africa, Middle East, Latin

America and Eastern Europe, will decrease from 39,2% in 1970 to 6,4% in 1990 and reach 5% in 2020.[5]

The financial crisis has led to a number of institutional responses that have resulted in a series of measures to enhance control over the remaining areas outside the jurisdiction of central banks and supervisory committees capitalmarkets. In the same time, the requirements for financing and risk and rating methodologies used in the financial decision rules, had revised.

The ten largest banks in the world, hold over \$25,6 trillion in combined assets (the exchange rate on December 7, 2012) .[14]

Table 4.Top 10 banks in world ranked by total assets 2012

Ran k	Bank	Total assets(US\$b)
1	Deutsche Bank	2,809.89
2	Mitsubishi UFJ Financial Goup	2,803.42
3	Industrial&Comme rcial Bank of China	2,763.59
4	HSBC Holding	2,721.06
5	Barclays PLC	2,584.30
6	BNP Paribas	2,562.99
7	Japan Post Bank	2,513.21
8	JPMorgan Chase & Co	2,321.28
9	Credit Agricole SA	2,317.12
10	Royal Bank of Scotland Group	2,225.14

Source: Top Banks in the World 2012

The banks with large derivates businesses such as Deutche Bank, the three largest French banks, have all seen sharp rises in market risk-weighted assets.

Restructured banks, such as Royal Bank of Scotland, have reduced market risk exposure substantially, but the internalization of banking influences cross-border risk-sharing.[5]

The recent crisis has revealed the major deficiencies in the manner in which international banks have conducted their bussines and have managed financial risks.

For the world economy and the international banking industry, globalization is both a beneficial and a challenging process, inevitable and irreversible in the same time, with benefits only for the countries that best manage their economies.

Abstract

In this article we intend to identify the evolution of our country's foreign trade and the trials by which Romania can diversify its commercial relations with partner countries. This article aims Romania's commercial reality in the new global economic context. Methodologically we pursued the evolution of Romania's external trade at global level, extra-EU and intra-EU, volume of commercial flows between Romania and its main partners.

The research finally proposes a modality of approach targeted to finding solutions to diversify Romania's commercial relations with possible target countries. Regarding the risks of this methodology, taking into account that there is no clear model of selection for the analyzed countries, and the final proposals can only have a general character. Thus, we show a few possible improvements that can be made, such as identifying criteria for selecting target countries, external and internal analysis of selected countries.

Keywords: foreign trade, economic growth, global development, trade policy.

JEL Classification: F13; Q56; O47; R11.

Introduction

In the 21st century in the context of globalization that entered in all the aspects of life, trade is an activity with a central role. Trade relations between countries are a key point in evolution and development of the world.

Entry into the European Union has brought important changes in Romania's foreign trade policy. Of course, adoption of EU trade policy and alignment to the single market means significant advantages, but also considerable costs [3].

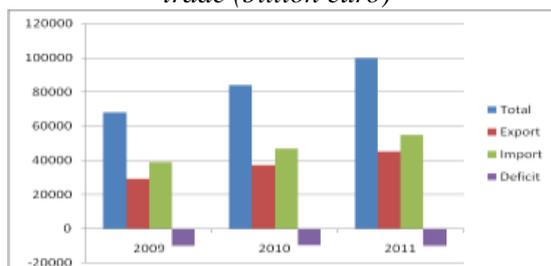

After joining the European Union in 2007, Romania adopted the common commercial policy, losing its sovereignty in this plan. Although Romania's trade relations with the EU are obviously based on foreign trade, the key to sustainable development leading to significant increases in exports is finding non-EU partners that Romania could have successful relationships with.

Access to products on the Community market, consistent technical and financial assistance to Romania, application of EU regulations and standards in all areas are on the one hand considerable pluses, but the risk of suppression of domestic production, price levels, loss of sovereignty of trade policies bring unavoidable drawbacks [7].

Evolution of external trade of Romania

For an overview of the evolution of Romanian foreign trade and its structure, we analyzed for the period 2009-2011 amounts exports, imports, the overall economy, intra- and extra-EU. During the analyzed period, the evolution of the total value of international trade recorded a decrease of about 25% in 2009 over the previous year and an increase by almost 24% and 19% respectively in 2010 and 2011 (see figure 1).

Figure 1 – The total value of international trade (billion euro)

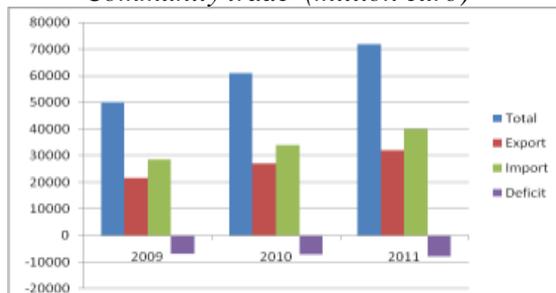

Source: authors based on data taken from www.eurostat.ro

Followed the same trend was evident in the evolution of exports and imports. Thus, a decrease of 14% in 2009 compared to 2008 exports was followed by successive increases of nearly 30% and 20% for subsequent years. Imports showed a significant decrease in 2009 over 30%, but were followed by two increases in 2010 and 2011, with 20% and 17%. Referring to the deficit, there was a big increase in 2009, almost 60%, following a decrease and an increase in percentage of under 5%. According to data that could be allowed to access, the total value of international trade of Romania was 7,402.7 million euros, up 5.1% from the same period last year, while exports registered an increase to 3472,1 million euros (+1.6%), and imports to 3930.6 million euros (+8.3%). In these circumstances, Romania's trade deficit increased by 117.0% from the level of -211.3 million (31 January 2011), at -458.5 million (31 January 2012) [9].

Following the same trend as the total value of foreign trade of Romania, the values of total intra-EU trade in 2009 decreased compared to 2008 and successive increases in 2010 and 2011 (see figure 2).

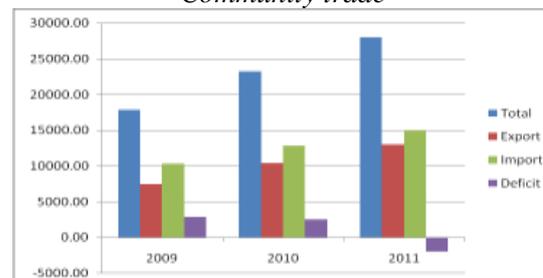

Figure 2 – The total value of intra-Community trade (million euro)

Source: authors based on data taken from www.eurostat.ro

The total value of intra-Community trade in 2009 dropped by over 20% and increased in 2010 and 2011 by 21% and 17.9%. Exports declined in 2009 by almost 9% and had increases of 25% and 19% in the next 2 years. Imports registered a sharp decline in 2009, nearly 30% and successive increases of 19% and 17% in 2010 and 2011. The latest data which could access, in January 2012, total intra-EU trade of Romania went up by 7.4% to 5414.1 million, of which exports has increased by 4.2%, being of 2559.3 million and imports by 10.4%, amounting to 2854.8 million. Romania's negative trade balance in the relationship with partners from European Union (EU) increased by 128.5% in January 2012 compared to the corresponding period of the previous year from EUR -129.3 million to -295, 5 million euros [4]. For the period analyzed, 2009-2011, international trade had an extra-similar evolution, as shown in the table below (see figure 3).

Figure 3 – The total value of extra-Community trade

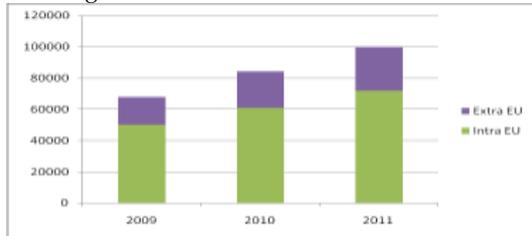

Source: authors based on data taken from www.eurostat.ro

The total amount of extra trade fell by 35% in 2009 over the previous year, increasing by 30% in 2010 and in 2011 by 20%. Exports decreased by 25% in the first analyzed year and increased sequentially by nearly 40% in 2010 and 25% in 2011. Extra-EU trade deficit decreased continuously with 60%, 17% and 20% in the three years analyzed. The latest data which could be accessed, in January 2012, total extra-EU trade amounted to 1988.6 million euros, 0.8% less than the same period of 2011, of which exports 912.8 million (-5.1%) and imports 1075.8 million euros (+3.1%). For the same two periods of analysis, the trade deficit Romania-non EU countries increased from -82.0 million to the level of -163.0 million (98.8%).[8] The table presented below (see figure 4) reflects the evolution of

intra and extra trade shares, from both the total volume of foreign trade of Romania, and the exports and imports.

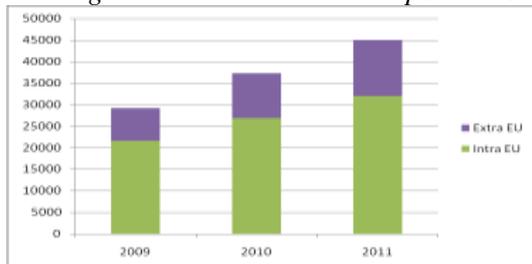

Figure 4 – Intra and extra trade shares

Source: authors based on data taken from www.eurostat.ro

In the total volume of foreign trade of Romania, intra-Community trade has a higher share, slightly down from 73.76% in 2009 to 71.95% in 2011. If exports are largely maintained at the same proportions, the same declining trend continues, from 74.33% as intra exports represented in 2009, to 71.12% for the last analyzed year (see figure 5).

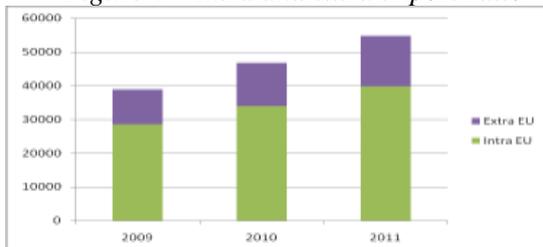

Figure 5 – Intra and extra export ratio

Source: authors based on data taken from www.eurostat.ro

Import structure keeps the same coordinates, with a slightly attenuated decline in the share of intra-Community trade, from 73.34% to 72.64% (see figure 6).

Figure 6 – Intra and extra import ratio

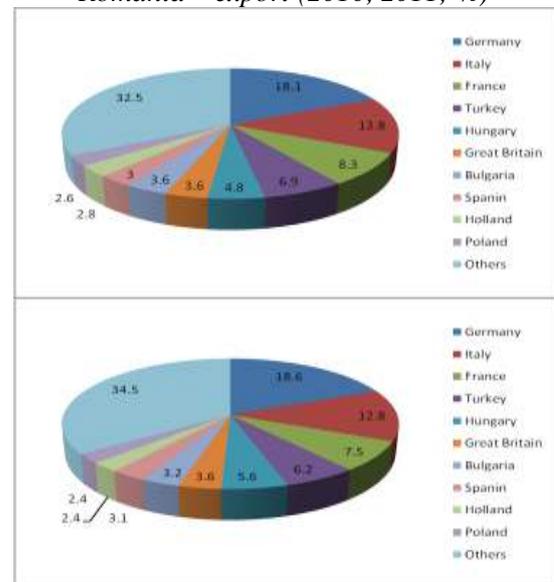

Source: authors based on data taken from www.eurostat.ro

However, variations in the structure of imports are relatively lower than for exports.

Main foreign trade partners of Romania

In this part we aimed to identify what are the main countries in which Romania exports, which are key partners from which it imports, where there are shortages and where the trade balance surplus. In the year 2011, Romania's exports and imports with European states had a rate of 87.6% and 88.1% for imports, percentages similar to those in 2010 to 88.8% of total exports, respectively 87.2 % of total imports.

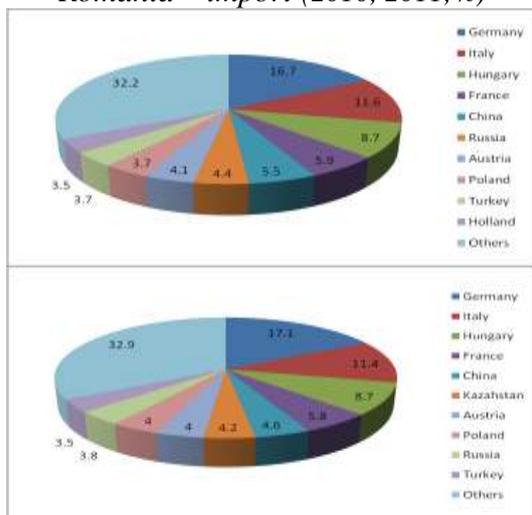

Figure 7 – Main trade partners of Romania – export (2010, 2011, %)

Source: authors based on data taken from www.eurostat.ro

According to data presented above (see figure 7) we can see that there is no change from one year to another between the 10 European partner countries; there is a decline in exports to Italy, France and Turkey, and an increase in exports to Germany, Hungary and the Netherlands; outside the European Union is only Turkey, in fourth position, with exports declining, share of total Romanian exports in the first 10 partners fell by 2.1%.

Figure 8 - Main trade partners of Romania – import (2010, 2011,%)

Source: authors based on data taken from www.eurostat.ro

Analyzing the situation of Romania's main partners (see figure 8) we can see that nine of the ten states are top in both years, with an outstanding good share of imports from Kazakhstan with 4.2% (position 6) in 2011, pushing Netherlands out of the top 10 partner countries. It also shows increasing share of imports from Germany or Poland, while imports from China or Russia are declining.

China, Russia and Turkey appear as top partners in 2010 and in 2011 and Kazakhstan appear to countries outside the European Union and the total weight of the top 10 partners decreased from 67.8% to 67.1%.

Conclusions

Adoption by Romania of EU trade policy has clearly led to significant changes in Romania's foreign trade policy in the following areas: full liberalization of trade between Romania and other EU countries, customs duties alignment of our country, against third countries, to the EU, which generally involves a lower level, particularly for industrial products.

Harmonization with the EU's WTO commitments on trade in goods and services and accession to the WTO Agreement on public procurement in the country turned Romania from beneficiary of GSP (generalized system of preferences) to customs preferences donor country.

Withdrawal of Global System of Trade Preferences (GSTP) among developing countries by abolishing preferential trade agreements with third countries and other agreements with these countries has led to a major national commercial chance. Suspension of the status of developing country and, consequently, the advantages enjoyed by Romania in commercial policy measures, under this statute, Romania withdrawal from agreements with CEFTA, EFTA free trade agreements with Turkey, Israel, free trade agreements with the Western Balkan countries, the extent to which the EU has concluded agreements with these countries are just some elements that distinguish our country in international trade agreements. Since the EU has no free trade agreement with Moldova until the date of Romania's accession to the EU, free trade regime between Romania and Republic of Moldova was canceled; Romania's participation to preferential and non-preferential trade agreements of the EU, participation agreements to preferred the euro-Mediterranean partnership; the partnership between the EU and African, Caribbean and Pacific (ACP); Romania's access to EU free trade agreements with Latin American countries, the Persian Gulf and other countries with which the EU will conclude such agreements will determine Romania to be more vigilant when dealing with external trade.

China and her Influence on the New World Order in the Context of the Nuclear Threats of North Coreea

Culiță Gica Gherghina
Universitatea Constantin Brâncoveanu Pitești
ggculita@yahoo.com

Abstract

The end of the Cold War has put the world in a new stage of reevaluation. A new world order is needed, mostly because everyone wants to identify on which side he is going to be. The main actors of this are United States of America and China. But European Union, Japan and Rusia have their own part of the deal, not to mention many other Arabic countries like Iran or Soudit Arabia. In this paper we want to analyze China`s main reasons to ask for such a position, to see what can sustain that and what will be her strong points as well as her point of view in the recent nuclear crisis.

Key words: China, Cold War, New World Order, nuclear crisis, superpower.

J.E.L. Clasification: F02, F51.

1. Introduction

The extension of Asian communism (China and North Korea in 1949) was aimed to turn it into an alternative world system. It was unsuccessful due to increased polycentrism of communist centers, by leaving the Soviet bloc countries like Yugoslavia and Albania, by accelerating Chinese-Soviet dispute in the '60s, Kennedy's government policies (1960-1963) and also Johnson's (1963-1968) to support Hungary, Czechoslovakia and Romania in a different manner from the Soviet matrix [1].

Quite important Cold War are important in the relaxation periods of the historical era, but we have to distinguish between a state initiatives (initiatives of U.S. President Richard Nixon and Henry Kissinger in 1972-1973, by the "Chinese card") and "thaw" in Eastern relations to the West, led by the superpowers USA and U.R.S.S.

By U.R.S.S. unparticipating in UNO

meetings, because of Western legal non-recognition of China as a legitimate power, U.S. send a combatant body under the United Nations mandate.

UNO contingents (actually American) rejected North Korean troops to Chinese border, where Mao Zedong intervenos because of the "imperialist aggression". General McArthur, American military leader on the Korean front, who wanted to use nuclear weapons against Communist China, was withdrawn from operational command by President Harry S. Truman.

Gradually, China is not a satellite of Moscow, Khrushchev's de-Stalinization more is rejected by Mao who is committed to economic growth through the "Great Leap Forward" and later will establish communist society through cultural revolution.

Communist victory in China (1949) and late U.S. recognition of communist Beijing (1979) is a key equation in the dynamics of the Cold War. In Asia there are models of communist revolution in the nationalist patterns represented by antijaponese Maoism, by Ho Chi Minh's fight against the French in Indochina (1945-1954) and during the 60's by US-Vietnamese confrontation.

To discourage the extension of the Soviet communism and Asian power, U.S. signed network pacts, as said in reference literature) with Japan, South Korea, Taiwan and the Philippines. Thus, ANZUS was the Security Treaty between Australia and New Zealand and the USA (San Francisco, March 1, 1951) which said that an attack against one member of the pact was an aggression against all.

It is important to note that the relaxation in communism/capitalism dispute is not a unitary process, consistent, quite often this phenomenon is caused by the threat of mutual destruction, economic development issues and the emergence of new power centers in the structure of the two blocks, such as RP China or France and Germany.

2. Reasons that sustain China’s global influence

China put in an impass again the world order, requiring rearranging of global influences. One reason is that a quarter of Earth's population lives in China, hence arose all sorts of debates on the future of China as a world power. Its economy has had an impressive momentum over the past 30 years, this being undoubtedly a significant force. However, can an increase of 30 years mean development forever?

In order to get an idea about the importance that 1.3 billion people suddenly enter into the world capitalist there are enough some data and some logic: the new colossus economic growth is 10% per year, It thus doubling their GDP every seven years [2].

From where did she go? 500 years ago China was the most advanced civilization on Earth, then froze. Marx described it as rotten, semicivilisation, that vegetates stuck in jaws time. Now at the age of 60 years of communism, China revives a staggering pace, and the world shuddered under the threat of its rule. Largest urban construction program ever seen, the biggest foreign investment and sustained the highest growth rate, the largest coal, steel and cement production in the world, and superlatives can continue[3].

Dozens of cities megalopolis (each of which can accommodate a population greater than that of England) are growing, with highways, magnetic levitation trains, huge malls and thousands of stylish skyscrapers.

Three hundred million mobile phones in use and two hundred million Internet users. Here are produced almost all the toys of the world, two thirds of copiers and microwaves, DVDs and shoes.

Over half of the world's existing cranes are working in China, building cities for migrants from rural largest zones in history.

Consumption also increases to an unprecedented scale, savings too, forming a middle class increasingly receiving free market opportunities to meet individual aspirations.

Economic freedom increases, although many people live in China without an elected government than the rest of the world. Country remains communist, but provides

great business opportunities, and that on the long term. Economic freedom creates political freedom, so many Western analysts expect an advance of democracy in the next decade, for example the organization of free elections in the regions.

3. A new cold war or a new alliance against North Coreea?

The world is overwhelmed by the economic strength of China, very difficult to compete with. By using simple products, Asian dragon dominates the world market. Despite numerous predictions, the Chinese economy does not seem to be affected by the crisis. On the contrary, it lends intelligently the Americans so that they continue to consume their products.

Some announces a new Cold War in which China to replace Russia, recalling that the New Empire Middle possesses sophisticated nuclear facilities, that has the largest army in the world and its budget for defense increases by 10% per year. Then, China is still, despite recently discovered relative freedom, a totalitarian power such a threatening one. In addition, China has serious problems with human rights, pointing out the many repressive actions, internal large cleavages (about 800 million poor), a severely altered natural environment and an early social security system.

At the moment, China is one of the largest oil consumer in the world, although annual consumption per capita is one and a half barrel, much lower than ten barrels which consumes a Spanish for example. On the other hand, the number of cars will increase tenfold over the next fifteen years, which implies an unprecedented increase in oil imports.

Besides this mentioned above, plus increased industrialization taking place in China, create opportunities for it to become in a few years the crude oil-importing country, which worries the West because, according to current calculations, there will not be enough oil to cover future needs of this colossus. This will generate serious strategic conflicts with the Western powers, particularly the United States, aiming control of the „black gold”.

There was no wonder the Chinese strategy aimed at signing agreements last year and

achieving considerable investment in Central Asia, an area that the United States is trying to dominate, and if Americans fail to gain control of energy reserves that China needs in the coming years, this will provide world leadership in the twenty-first century. In the light of this, the president of China declared on 7 April, 2013, that „no country has the right to throw Asia in to chaos”[4].

On the other hand, the events from the beginning of the millennium, that is taking over anti-terrorist operations in Afghanistan in 2001 already says a lot. Once the U.S. is proposing Hamid Karzai the country's President, a former adviser to the "Unocal" oil company signed with the presidents of Turkmenistan and Pakistan the agreement for the construction of coveted pipeline. In short, the United States won in this area largely crucial battle in the fight with China.

Another aspect deals with China's coal needs, which are also considerable. So far no electricity was the main brake on development of the country, but this began to change with the opening of hundreds of power plants and thermal performance of which coal consumption increased to 1.4 billion tons annually. China is the main importer of steel, nickel and aluminum. Domestic consumption of raw materials coming from outside the state is so great that the question is because there are not enough ships.

4. A few of the China's little problems

China bets now, at the beginning of the new decade, that can keep balance forever. It relies on being able to gradually shift resources from coastal regions into the country, without encountering resistance from the coastal area and without facing internal unrest.

The problem is that even though China seems to be a country with capitalistic private property, banks and all that entails capitalism, is not a real capitalism in the sense that capital markets do not determine distribution. What matters are the relationships and not necessarily good business plans.

China has grown extraordinarily in the last 30 years. The idea that such growth rates can last indefinitely violates the basic principles of economics. At one time,

business cycles, letting poor business aside, it will throw off. Then, the smallest performance gap will stop the growth momentum. There are structural limits growth and China is close to them.

Future progress of China, and its development as a major power will depend so largely, and the skill with which the ruling elites will solve two related problems that the current generation of leaders shift power to a younger team and that of meeting the growing tension between economic and political system of the country. Even a tripling of GDP would leave China's population still in last place in terms of per capita income, not to mention the real poverty as a significant part of the Chinese population.

Even under the most favorable circumstances, it is highly unlikely that this country is becoming truly competitive in terms of the key dimensions of world power.

Yet China is really about to become the dominant regional power in East Asia, already the dominant geopolitical mainland. Military and economic power makes its immediate neighbors, except India, seem even smaller. Therefore, China's continued assertion is very natural in accordance with its historical, geographical and economic headquarters.

However, divergent interests between the U.S. and China in the Pacific could lead to military confrontation, a second Cold War it could be imminent, with the geostrategic center of gravity moving from Europe and the Middle East to Asia. Strong arguments are China's investments of 30 billion dollars in 2006, in the defense industry and military capacity development-oriented to design strength away: missiles, submarines and fighter jets[5].

Is it an evidence of a belligerent spirit the allocation of 10% more each year to defense budget? China realizes that if he wants to be credible politically it must be military strong, not just economically. A reason that the European Union does not seem to share as long as most member countries face the strategic problem of investing in defense industry, research and the creation of a joint military force.

It is true, China is ranked fourth in the world in the defense budget and has the largest army in the world - 2.5 million

people. But even in these circumstances, China spends on defense than 10% of what the U.S. Congress allocated annually for Pentagon.

Chinese wisdom says to postpone battles which are not sure he can win. China must focus on a strategy for further growth. Once created economic foundation, China could move to another stage to have a more offensive stance in international politics. At present China can not afford to scare current economic partners, depending on foreign investment, particularly the U.S., Europe, Japan and the Asian "tigers", Chinese movements are carefully watched and would immediately amend any hazardous military policy or policy accompanied by imperialist flavor.

Despite alarmist voices, it is most likely that competition between China and the U.S. will not be military but economically expressed. A rivalry likely to be cut, as in the economic war between the U.S. and the European Union on the export of cheese, bananas, steel or subsidies for Boeing or Airbus, by means of negotiation and compromise in the WTO, to which China belongs and since 2001 as well as Chinese officials, ordinary Chinese seem to be rather oriented towards a better life and success in business, although recent antijapanese events in China, showed that there is a full tank of nationalism that can escape from communist control.

5. Conclusions

Various estimations from internal collapse and bank implosion to economic and military strengthen will inevitably lead to a conflict with the current global superpower, the U.S., feeding the strategies and visions for the future of China and the configuration of international relations in the century which just begun[5].

Some analysts already foresee a decline of U.S. and Chinese triumph. Some of them were quick to announce that after Europe world domination since the seventeenth century and of America since the twentieth century, we are witnessing the next great global paradigm shift by moving the center of power in Asia with representatives of China, India and Japan.

Perhaps the most honest would be to

admit that it is more likely to develop power centers competing U.S. at regional level like China and India in Asia, or the European Union on the old continent being possible and reemergence of Russia. These power centers will not be autonomous but connected by networks that interconnect them by common interests.

U.S. does not seem to be prepared and animated by the desire to hand over to China. Among the 500 largest companies in the world, only 15 are Chinese, most of them American and European. Despite globalization, the U.S. is still the world's largest producer, covering 75% of its own consumption needs. Other countries and regions of the world can take the place of China, if they manage to produce cheaper and better quality. Indian Bangalore region has a second Silicon Valley, the location of all the major companies that produce and offers leading technology.

Arnold Toynbee, in his study compared to the 26 civilizations that have marked human history, captures the causes that led to the genesis, growth and decline of great empires and civilizations dominant throughout history. We are aware that a dominant source of lifting power in the world, but also their decline was acquired or that the loss of internal cohesion and a great creativity and vitality. U.S. still seem to lack them, while China can not claim that is very high in all these chapters. However, the U.S. budget deficit and the presence of 500,000 foreign U.S. military warns dissipation of resources, expansion and unbridled ambitions, are causes that led to the collapse of other great powers[5].

Undoubtedly, China is a great power. The question is how much. Currently, no country can develop outside reality of globalization and international networks. Conflict as a conventional war is not inevitable, especially when interdependence is so great. The total level of U.S. investment in China is now 48 billion dollars. China not only benefit from American investments, investing itself in 2009, one billion U.S. dollars. U.S. exports to China increased by 1600 times in the last 15 years. China has in its reserve banks 600 billion dollars. Most American and global corporation, Wal-Mart, imported annually goods worth \$ 18 billion produced in China. EU exports to China increased by 600% in 15

years.

Strained political relations between Japan and China have prevented 28,000 Japanese companies to invest in Dalian region in south-western China, opening its branch of production. Similarly, Taiwanese investment in mainland China and mutual profits do not seem to take into account political frictions.

Despite all this, in this moment the powers of the world are forced to allie for stopping one cause, stopping the mad North Coreean leader. The threats to the world peace can not be left without response, the nuclear crisis cannot be left to degenerate and all we need right now is to have the necessary peace to fight with the ongoing economic crisis. This is dispute of high vain and the leaders of the world should have the maturity to stop it.

Abstract

With critical phase overcoming the economic crisis of 2008, maritime trade is back on the rise, materializing a favorable labor market in shipping.

Worldwide, the study by BIMCO (Baltic and International Maritime Council) shows that in the year 2010, the supply of seafarers now provides a total of 624,062 officers and 747,000 of ratings.

Considering an annual growth of global fleet by 2.3%, a prediction was made of the number of seafarers in the world for 2015 showing that compared with 2010, supply will rise by 6%.

Knowing that labor market in the shipping market is open and highly competitive and has some features that surround other areas is very important to analyze the factors influencing labor supply in shipping sector.

This paper are trying to present some characteristics of labor supply which should take into account all stakeholders in the business of shipping.

Key words: supply, seafarer, labor market.

J.E.L.classification: J21, J22

1. Introduction

Under all conditions of time and space, the shipping activity involves like any economic activity, the labor factor, designed to take advantage on his interest resources. Careful analysis of the evolution of the global economy in recent decades shows that

among the major problems that should receive attention include imbalances in the labor market. Discrepancies between supply and demand for labor is manifested in every sector, especially in the field of shipping, taking into account the current conditions of the external environment dominated by globalization processes.

Globalization of national economies has produced important changes in shipping: appeared new types of ships, importing or exporting new areas, new sea routes as a result of embargoes imposed by certain countries, new policies on training of seafarers [1]. But all these changes together with the use in an increasing proportion of new technologies in all activities of the shipping sector led to the importance of studying the supply-demand ratio of labor market.

Knowing that labor market in the shipping market is open and highly competitive and has some features that surround other areas is very important to analyze the factors that led to the deficit or surplus on labor market.

Analysis of labor supply is essential in providing dynamic economic interdependence. Knowledge of supply can help identify means to ensure labor market equilibrium. The advantage is that achieving this balance can lead to the development of shipping sector and promoting employment policies.

2. Characteristics of labor supply

Labor supply is the ability to work on which an individual or group of people is

disposed to use under the existing social and economic conditions at a time. [2]

Supply of seafarers is tightly associated with the scale of the world fleets which is linked with world economy's climates.

At the microeconomic level, the emergence of labor supply is shaped by real wage (in the classical theory) or the nominal wage (in Keynesian theory).

Labor supply is strongly influenced by the institutional framework and in particular the extent of the services of social benefits (pension, health, unemployment-compensation system).

Specificity labor supply in shipping resulting from:

a) Seafarers has a high degree of specialization

In order to perform a specific function shipboard personnel must have certain specialization courses of training conducted to ensure knowledge and skills. Specialization courses are organized and run by training centers, except those organized by the university for preparing maritime officer or naval engineering.

The high degree of specialization of labor which operates in the naval sector represent an obstacle to labor market supply which to fulfill this requirement must sacrifice financial resources and time.

b) Working conditions onboard ships

Maritime work differs from other diverse activities by unity in diversity - meaning that a crew of a vessel may be composed of sailors whose nationality often differ. In shipping, sometimes prevails the interest owner who seeks to hire crew vessels, in compliance with the minimum international law in this field, seafarers willing to accept toughest working conditions.

Because of the specific working conditions existing in shipping, labor supply is less numerous than in other areas. The factors that determine this specific working conditions are: long period at sea away from family, conditions onboard a ship, workload, with shorter turns that repeated etc.

Working conditions in the naval sector require guaranteeing minimum employment and decent life on board. Factors that causes specificity of work of seafarers determine that working staff in shipping need to have inclination to pursue this profession.

c) Risks taken by seafarers

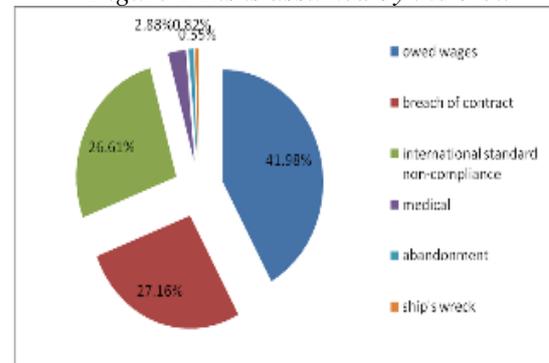

In recent years, one of the causes of decrease labor supply is the risk in shipping and this mainly due to accidents at sea followed by criminalizing seafarers guilty obligation to pay damages or even deprivation of liberty. Approximately 80-85% of accidents at sea are due to human factors.

Errors due to:

- lack of adaptation to conditions at sea (40% of accidents occur in the first 10-12 hours of departure). In the first 3 to 4 days or 7 to 8 days increases number of accidents;
- prejudice of lack of danger in known areas (10% of accidents);
- lack of attention (due to the first two cases), stress, burnout;
- abusive use of radar navigation in areas of input, output, channels, straits;
- objective risk factors - weather conditions, technical failures, erroneous maneuver of other ships.

Following the completion of a study by the International Transport Workers' Federation in the Black Sea, between 01.01.2012-31.05.2012, were identified the major problems faced crews, on the first place being situated wages paid by employers.

Figure 1 Risks assumed by the crew

Source: ITF study, *Black Sea of Shame*, 2012, p.5

Another risk factor is breach of contract signed by the crew with crewing agency, a factor which may be removed by affiliation of seafarers to a union that can protect their rights. The main risks arising in case of abandonment ship or ship's wreck when can result even loss of life. All these elements can be translated into risks that have an impact on labor supply in the maritime sector.

d) Age structure is a barrier to entry for seafarers

An important feature of the labor supply in shipping sector is age of seafarer. Thus, the crew, in particular, the largest supply is from people under 35 who otherwise are most sought by employers. For those over 45 years age represents a serious barrier to entry on the labor market, especially for ratings and auxiliary staff. It is noted, that in the 2010 in the Eastern European countries, 43% of officers and 54% of ratings has over 40 years.

Table 1 Age structure for seafarers from Eastern Europe

Year Age	Officers			
	< 31	31-40	41-50	> 50
2000	29%	34%	30%	7%
2005	25%	34%	31%	5%
2010	21%	30%	27%	16%
Year Age	Ratings			
	< 31	31-40	41-50	> 50
2000	25%	20%	32%	22%
2005	20%	20%	34%	20%
2010	17%	22%	39%	15%

Source: Organisation for Economic Co-operation and Development, *Availability and Training of Seafarers*, Precious Associates Limited, 2003, p.49 and Baltic and International Maritime Council, *Study on Eu Seafarers Employment*, London, 2010, p.42

Shortening the time of service at sea mean, for the company, increasing crew costs and training costs. Another consequence represents significant reduction of personnel with great experience that can lead to increased instability in the management of staff and managerial level knowledge loss resulting from early retirements. All these are costs that cannot be recovered and unfortunately all these factors contribute to negative perceptions of work in shipping, making it increasingly difficult recruiting specialists.

On the other hand, employees too old to be re-oriented and other population groups unable to occupy skilled positions will be seen in a position to appeal to unemployment compensation or social welfare if they do not find to work in areas of low or medium skilled or not accept such jobs.

In circumstances where countries of the second "circle" [3] develops a base of skilled and highly skilled workforce, cheap, they become attractive for large transnational companies will not hesitate take advantage of

this opportunity.

In the long term, these changes can lead to divisions based on ethnicity, gender, age, depending on the ability of segments of the population to integrate in the new scenery of the labor market in shipping.

e) Different study period

Educational institutions along with specialized training centers of seafarers determines many of the characteristics of labor supply and acts as a basic condition of economic performance. Education proves to be one of the main factors determining the supply of labor to behave as a "reverse demand".

In Romania there are four institutions which train officers, ratings and personnel for related activities in shipping industries. In other states, institutions forming officers do not take the form of a higher education but of maritime colleges (offering vocational education). The advantage of the colleges is the time lag between the entry and the graduation, while the higher education institution advantage is the bachelor's degree that can be used on other labor markets.

In the EU there are 551 institutions providing training of personnel involved in the shipping industry.

Given the characteristics of labor supply in shipping sector described above, we can determine the default external and internal factors of naval industry that can influence labor supply development:

- inability of governments to take concrete measures for young graduates marine institutes to carry out practical training on board ships (Cadet) and thus to enter to the labor market in shipping. There is a large gap between numbers of employed cadets and graduates from maritime institutes;
- standardization of skills and implicitly of the educational environment or background, as a result of the STCW 95 Convention;
- heterogeneous social policies, with direct consequences on personal development through retirement withdrawals for certain officers and ratings;
- free movement of labor in the shipping sector is still affected by the policies of the ship's flag, cultural and social differences or other factors likely to affect the functionality of the crews on ships;

- inability of the seafarers to work in other areas than shipping through acquired knowledge that cannot be used in competitively on other labor market.

3. Conclusion

With critical phase overcoming the economic crisis of 2008, maritime trade is back on the rise, materializing a favorable labor market in shipping.

In order to secure a quantity of quality seafarers stably for future, it is expected that greater people than before will enter and work for shipping sector.

In conclusion, it can be said that there is a need to make further attempts in support seafaring life and shipping among young people. Motives are not only to get a living, but also to receive good working conditions and the high status of the shipping sector. So it is said that the attraction to become a seafarer as a vocation is high. Looks that improvement in working mode and conditions could result to reduction in the ratio of drop outs from the seafaring vocation.

Abstract

In actual context of crisis prolongation becomes very important to find the triggering elements for economic and financial incentive on global scale. In present globalization framework, as authors have asserted, the optimum model for economic incentive is not the credit rebound but the prices diminishing attitude in order to equilibrate the power purchasing of real demand with the real values of aggregate incomes on markets. Afterwards, as the incomes are contracting in crisis phases and the normal attitude regarding the consumption recovery should not the credit incentive but the prices general deflation based on real production restructuring policies.

Key words: globalization, financial system, crisis, economic system.

J.E.L. Classification Code : F62

1. Induction in globalization framework theory

The globalization process is no longer a static frame assessed as being positive or negative only by the quality of perception at glance, but this phenomenon should be seen as a dynamic process irreversible, but mainly described by its dynamic factors and features [3]. Thus, the most coherent picture of economic globalization as process should be assured by a long term tendencies approach, compared in parameters only to a statistic

picture of an economic, financial and social stage of global economy. These tendencies compound in its structure not only the statistic references but all that theories, politics and applicable strategies in economic, monetary or financial dimensions on global level. Starting with the new perspective regarding the relevance on nations in global economic and financial frame as being complementary to OECD classification, we can consider as being relevant for an integrative perspective to distinguish between: *supply-side economics* (those economies based on export strategies), *demand-side economics* (those economies based on domestic demand, capital export and technological export strategies) and *resource supporting countries* (those economics based on resource scarcity strategies) [7]. This classification is meant to split global economy as global system in interdependent components from functional perspective, getting thus the possibility to think about proper policies and strategies worldwide as a response for a global network of economic and financial connection and interactions [7].

Therefore, the national economies are in functional perspective global system components interacting toward similar targets, so it should be considered and evaluated only in connection with global network, coming together with other components to define in dynamic manner the economic, financial and social parameters. Moreover, when are debating the crisis fundamentals we should treat as we systemic components all economies in a global

network, because as we have seen in last decade, the causal chain have a complex determination, as a result of a interaction of many parameters imperative to be considered together on a global scale.

2. The contemporary crisis and its determinative factors

Analyzing the recent crisis example started on 2007, it can be stated that the first stage countries that have faced the crisis direct effects in financial and economic terms were the demand-side countries, which have based their position on global network mostly on domestic demand and on the capital and technological export. In their case the gap resulted from comparing the real values (as on mortgage values example) with the market bubbled values have first triggered a major financial crisis, and further a collapse of investment system as a corrective response to over appraisal tendencies on the estates market. [6]

The demand increasing based on credit behavior enhancement, have conducted to an inappropriate credit maturities (comparing the borrowers and lenders aspirations) tied to banking risk dilution and derivatives excessive usage. From that point on the bank competition became hard and the response was the inappropriate increase of mortgages providing as bubble the decreasing potential related to real values of aggregate income on domestic market. When the market values bubble blown up the investment system attached to the financial intermediation system, dominated by the demand-side economies capital export, have triggered the negative effects toward supply-side economics, hungry for capital, affecting in chain also the companies and house holdings. The next stage of crisis mechanism was the demand breakage, the values diminishing on markets together with credit guarantee system, this attitude affecting on a long time the revision of risk factors and the credit default swap rates, coming not to incentive the real economy but to block it. Thinking in this manner is proper to consider that the first stage of a financial syncope is triggered by the investment sluggish tendency, as it has been induced by the demand-side economics. Thus, the first crises stage the demand crisis, which is based on capital movement

sluggish, as a crisis stimulus transmitted from financial side to real economy [6].

In the next stage, after the liquidity deficit is installed on markets as investments changing behavior, the production crisis is coming to face a supply contraction, in this phase becoming clear and vivid the organic connection between financial system and real economy. There will be affected the supply-side countries delaying in their reaction as a reactive behavior to the market. The demand diminishing attitude installed in developed countries, which are the best consumers for developing countries as pricing competitive advantage beneficiary, will trigger significant gaps in exports for this type of economies, and further the sluggish trends in GDP increases. But this is not fair because the cheap demand from developed countries is supported throughout the good consuming times, as a „competitive advantage”, by the lower living standards for labor market in developing countries, so this could be considered as an „elitist” behavior. The capital export is not looking for higher profits but finally will subsidy indirectly the cheapest consumption in developed countries. The output contraction moment will launch a supply crisis, depicted by more severe effects as economic decreasing and social disturbance (as unemployment or living standards dropping), the production restrictions determining the trade parameters assessment and a new bargain on international level, but on unequal positions as always. [8]

In this regard, considering the entire framework, it seems that in a period of a profound crisis as systemic one either in financial or economic side of global economy, any try to launch back the consumption based on credit enhancement should be a wrong and unsustainable decision. This is inapplicable first because the developed countries will draw back their investment to protect as instinctively the internal demand, and second because entering into a diminishing demand spiral the developing countries will face hard landing positions in stocks due to their sluggish export. At least on short time horizon this intention to support the demand through credit will stimulate but unsustainable the economy recovery [4].

This theory is sustained by the lack of market or production system reaction in 2009, when the monetary policies in almost of the countries had been relaxed till where the interest rates went so down close to negative earnings, but without any significant result on medium on long term as the time passing has proved. The simultaneously increasing of risk premium rates (as *Credit Default Swap* rates) suggest more the lack of trust on markets and its connection with the demand and consumption appetite than a lack of liquidity of financial system. From this perspective a solution but radical for crisis overcome is a general deflation as an option for a new assessment wave on market values in order to rebuild the fundamentals for real economy and its financing sources. But the deflation of course will affect the production system which will be forced not only to restructure their outcome system but the go deeper in structure of costs despite on the investment politics on medium and long terms which will generate an un-investment position from financial markets. This should trigger the real consumption values in order to reduce the panic in investors' opinion. Additional to these desiderata should be imperative to bargain new dues for long term credits together with a real restructuring of production sector.

For a country like USA the optimum model for economic incentive is not the credit rebound but the prices diminishing attitude in order to equilibrate the power purchasing of real demand with the real value of aggregate incomes on markets. Afterwards, as the incomes are contracting in crisis phases and the normal attitude regarding the consumption recovery should not the credit incentive but the prices general deflation based on real production restructuring policies. The capital injection into an overheated production system debated from real demand on market, especially on long term investment goods will not get to a sustainable effect but will just enlarge the lack of trust in real market values, defying the economic cycles (see the Kitchin cycles).

According to Frederick W. Taylor theory the real solution for economic efficiency should be find not in the financial direction but in a production organization policy, as the main economic fundamental in order to

take advantages from technological advance [11].

Following this ration the technological advance should produce efficiency in cost terms not like today when the new technologies were irrelevant to market prices. When the spiral of credit is getting faster the real consumption curve will be affected by an artificial appetite for demand, and further will trigger an artificial inflation not correlated with the economic efficiency rations. As example we should remember the Opel corporation case where the most modern cars plant built at the begging of 2008 have a strange effect on final cars prices getting higher than before up to 10%, in contradiction with Taylor efficiency principles. Implementing new technologies we should get lower prices, good for demand burst and spending incentive attitude not on credit but based on real incomes of house holdings.

In conclusion the globalization phenomenon is defined by the interactions recorded between nations and economic and financial entities, being moved by two driving forces as: (1) the world trade and (2) the financial market integration tendency. The economies are connected into a global network, on regions levels, first through goods fluxes and second through capital flows. However, when the positive results from economic side are used in speculative manner the fragile equilibrium between those three main types of economies as it has been described above, will be affected on a long term in the disruption of real values facing induced market values. First the capital oriented countries are directing their excessive capital flows toward developing countries but mainly on speculative ways neglecting the economic reasons. Throughout the period when the artificial demand is supported and stimulated by the credit expansion the developing countries evolving profitable on a positive market perception, getting earnings from this situation. But when the aggregate income will not cover anymore the capital promised interests and the mortgage markets becomes pessimistic, the capital flows are retracted being suddenly drawn back by investors in spite of economic efficiency. And here comes the problem, when the developing countries have not the

same resilience to the capital drawing back generalized attitude.

3. Conclusions

When the capacity of economies to react is so heterogeneous the crisis forms and further evolutions are different. The strong capital countries will suffer in first crisis stage on a short time in lack of capital returning from investment places. Their policy will support the capital drawing back, desiring a domestic proper liquidity. The next effect will be the upper price for capital export toward developing countries trying thus to recover the losses from financial system together with different speculative attacks on young markets or currencies. The supply side economics will be further affected by this attitude of demand side economics, getting an expensive access to financial resources in order to sustain the production stocks and economy overheating, just to avoid hard landings. So we can see even a spiral here, triggered by capital flows, coming from supply side economics as more expensive resources and lower demand and going toward supply side economics, facing the stock increasing and lack of liquidity on economic input. That spiral should be disrupted not based on credit recovery or on capital injections in bail out economies, but should take under consideration the real equilibrium between market values and real values determined by real incomes and spoiled by long term financed consumption. [10]. The solutions for crisis disruption in a global context could find appropriate first the production restructuring policies and second the technological insertions in order to recover the economic efficiency. The world should start to learn how to work together in a viable economic and financial network, understanding the deep connections established already between economies, regions and world trade components.

Reducing Public Debt in the Aftermath of the Financial Crisis: Renewing with Financial Repression

Halep Maria

Doctoral School ASE Bucarest – International Business

mariahalep@yahoo.com

Abstract

Since the 2008 financial crisis burst, public finance accounts in developed economies have been continuously deteriorating; both fiscal and monetary policies are reaching their limits, while unemployment rates are soaring and GDP growth is fragile, if not inexistent. The aim of this article is to consider the options at the hand of developed economies for reducing the public debt burden.

Section 1 draws a picture on the general economic outlook in the developed economies and emerging countries. Section 2 considers the different ways in which a country's debt burden can be diminished. Section 3 defines the concept of debt financial repression and its main features. Section 4 focuses on researchers' work on historical data, to measure the debt erosion after WW2 and section 5 analyses the current economic situation and tries to assess whether the outlook is similar and whether a similar eroding process is worth considering. Section 6 concludes.

Key Words: debt liquidation, financial repression, public debt, macro prudential policies, real interest rates

JEL Classification: E4, E6, F4, H6, N10

1. Introduction

Since the burst of the financial crisis in 2008, public finance accounts in developed economies have been continuously deteriorating, while central banks' interest rates have been moving closer and closer to the zero bound.

Both fiscal and monetary policies are reaching their limits, while unemployment rates are still high and GDP growth is fragile,

if not inexistent. Moreover, these economies face an even more difficult challenge, an ageing population, which makes them vulnerable in case of a negative shock. The Euro Zone is the political and economical area the most pointed out for its serious public debt problems and obstacles met in the financial stability target. Indeed, public debt accumulation is starting to weigh on the monetary policy, whose main role is to ensure price stability on a medium and long term. Concerns about public and private debt sustainability arise in many economies of the world and political pressure is rising, as austerity policies, used on a large scale since 2010, are proving inefficient and people rebels against harsh measures such as expense cuts and increased taxation [8].

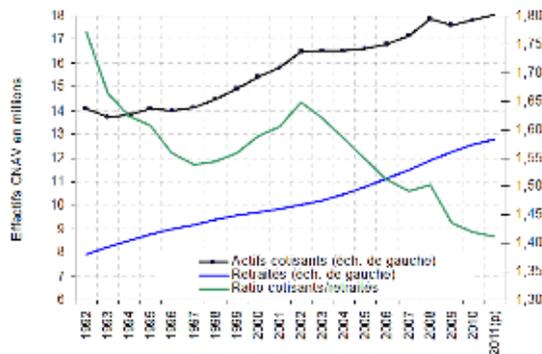

This article aims to analyse the different ways in which a nation's debt can be diminished and more specifically, analyses the concept of financial repression and its relevance in the current state of the developed world.

2. General economic outlook in the developed world

Before the crisis, the main features of the developed economies were a record climb of the private debt, notably that of households and of financial institutions. Once the crisis burst, public deficits accumulated rapidly, as governments embarked in banks and other financial institutions rescue plans, unemployment benefits soared and fiscal revenues dropped as profits disappeared and the basis for social charges taxation contracted. Notwithstanding, the population ageing phenomenon is gaining field, worsening the already gloomy economic outlook by increasing health care and retirement benefits for an ageing population. For instance, in France, the tax payer/retired

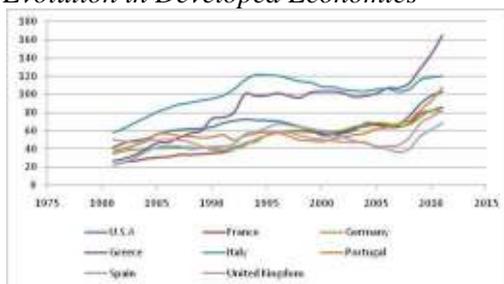

persons ratio decreased from 1,75 in 1992 to 1,4 in 2010. And still, France has one of the highest birth rates in the developed world. The following chart testifies for the ageing population trend.

Chart no 1: Tax payers/retired persons ratio evolution

Source : www.securite-sociale.fr/

Chart no 2: Public debt/GDP Ratio Evolution in Developed Economies

Source: author’s calculations, IMF public debt database

Factors having enabled public debt development.

The accumulation of public debt necessitates sustained government bonds emission. This was made possible by various factors:

A. an important demand coming from the private sector, less keen to invest in risky projects, therefore interested in state bonds, perceived as safe assets.

B. The bias of banking and insurance regulation towards government bond detention. Indeed, capital stock requirements in Basel II and Basel III regulation support public bonds, as they are considered very liquid and are supposed to carry an almost zero default risk.

C. Quantitative easing policies lead by central banks help encouraging public bonds demand. Central banks buy public bonds or accept them as guaranties when financing financial institutions. Therefore, in the context of inexistent growth in the aftermath of a financial bubble crash, possessing public debt in their assets enables banks to get access to central banks financing resources.

3. Possible theoretical measures available for reducing debt/GDP ratio

In order to reduce the debt/GDP ratio, various methods are available, but their acceptance is variable across time and considering the economic context. Among these means, the most common are: a. Significant fiscal adjustment/austerity policies; b. Economic growth; c. General increase in the inflation rate; d. Financial repression and some inflation; e. Explicit default or private/public debt restructuring (i.e. partial default)[5].

These methods may be combined, but it is generally accepted that fiscal adjustment is particularly painful in the short term and very difficult to implement from a political point of view. Examples are abundant for Greece, Spain and Portugal, where strikes and public discontentment are becoming usual. Romania also had to put up with a severe expense cut after the crisis, but protests are less virulent than in other developed economies in Europe.

Explicit default and/or public debt restructuring are also possible, it has been tested on Greece recently, but consequences were harmful for the peripheral European countries, suffering from general European Contagion. Generally, default or restructuring is not a viable solution, as, for a developed country, defaulting is stigmatizing. In this context, the debt burden will have to be contained in one way or another. Moreover, the situation is being complicated by an important indebtedness of the private sector as well, notably banks, creating a vicious circle between the latest and national governments.

4. Financial repression definition and main features

Financial repression is composed by a set of measures aimed at taxing savings indirectly and transferring value from savers to borrowers.

Among the main features, Reinhart C. [5] notes:

- a. Explicit or implicit ceilings on government debts, made possible by regulation, preferential borrowing rates for credits granted to governments or local authorities and a low interest rate target monetary policy
- b. The creation of a captive domestic audience, by restricting capital account movements, requiring high non remunerated reserves by the central bank or, prudential regulatory measures requiring domestic institutions to hold public debt in their portfolios.

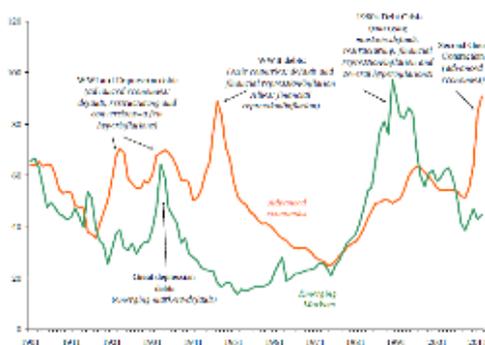

The result is negative real interest rates, which allow public debt erosion.

5. Debt liquidation process in recent history

Reinhart and Sbrancia[6] analyzed public debt patterns in recent history and found the following:

In normal times, public debt/GDP ratios evolutions are uncorrelated between countries, unless a major even, such as war or major financial distress, disturbs the individual pattern of a country's debt.

Chart no 3: Surges in Public Debts, 1900-2011

Source: Reinhart, C., Sbrancia, B., “The liquidation of government debt”, NBER WP 16893 march 2011,

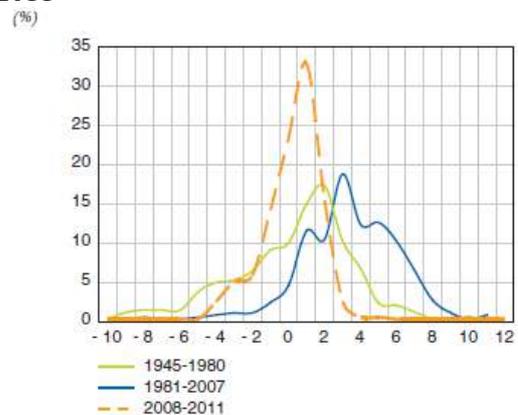

In this chart we notice 5 peaks. Three episodes (World War I, World War II, and

the Second Great Contraction, 2008-present) are almost exclusively advanced economy debt peaks; one is unique to emerging markets (1980s debt crisis followed by the transition economies' collapses); and the Great Depression of the 1930s is common to both groups. While WW1 and the 1930 Great Depression debts were mainly reduced by widespread default and explicit restructurings, as well as rampant inflation, the World War II debt overhang was importantly liquidated via the combination of financial repression and inflation, as shall be documented subsequently. This was possible because debts were mainly domestic and denominated in domestic currencies.

When analysing that period it is useful to recall that the “laissez faire” policy that predominated until WW1 was far gone and the Era of the Bretton Woods Arrangements of fixed exchange rates and tightly controlled domestic and international capital markets was in place. In that context, and considering major economic dislocations, scarcities, etc. which prevailed in the aftermath of the WWII, we witness a combination of very low nominal interest rates and inflationary spurts of varying degrees across the advanced economies. The results were negative interest rates, which made possible a rapid debt/GDP ratio reduction.

Indeed, low nominal interest rates reduce government expenses and interests related to public debt. Moreover, negative real interest rates allow government debt reduction in real terms, by transferring value from creditors to debtors, hereinafter the state.

Chart no 4 : Real interest rates frequency distribution in advanced economies, 1945 - 2011

Source:, Reinhardt, C., Sbrancia, B., “The liquidation of government debt, NBER WP 16893 march 2011, <http://www.nber.org/papers/w16893>

Unlike fiscal adjustment, highly unpopular and costly for politicians, financial repression is more opaque to the general public and, therefore, it is far easier to implement and to be accepted, it is therefore much alike an indirect tax.

Between, 1945 and 1980, for about 30 years, real interest rates were on average negative, in both developed and developing countries (see chart no 4).

If financial repression operated through public debt detention, it was mainly supported by even lower returns on savings, capital account moves restrictions and, particularly, generalized negative returns on government bonds almost all over the world.

The liquidation effect is calculated by applying the negative real interest rates to the public debt portfolio basis, for the years characterized by negative real interest rates [6]. Results are presented in the following table. For instance, for the UK and the U.S, the annual liquidation rate is around 3,4%. In a decade, it accounts for 34% of the public debt, not taking into account the cumulative effects [6].

Table1. Magnitude of the liquidation of public debt effect, 1945 – 1980, selected countries

Country	Period	Reference measure of revenues coming from a liquidation effect	
		In GDP %	In Fiscal revenues %
Australia	1945-1968, 1971, 1978	5,1	20,3
Belgium	1945 -1974	2,5	18,6
Ireland	1965-1990	2,0	10,3
Italy	1945-1970	5,3	127,5
South Africa	1945-1974	1,2	8,9
UK	1945-1980	3,6	0,3
USA	1945-1980	3,2	18,9

6. Debt liquidation in current developed world.

This section analyzes the after 2008 world outlook and develops an investigation to consider whether today’s situation presents the characteristics of a financial repression era.

Firstly, banks and national individuals are more and more encouraged to hold national public debt, similar to a creation of a captive public. For instance, some peripheral European countries’ banks, but not only, have in recent years liquidated foreign assets and replaced them with public government bonds, as it is proved to be the case for Spain, Portugal, Ireland and, to a less extent, UK.

Chart no 5 : Public debt portfolio hold by local banks, 2008-2010, in GDP %

Source:Reinhardt, « Le retour de la répression financière », *Dette publique, politique monétaire et stabilité financière*, Banque de France, Revue de la stabilité financière, N° 16, April 2012

Examples are abundant, both in the developed and in the developing world. In Japan, 2010 saw the cancelling of the National Post Office privatization, as well as the raising of deposits’ ceilings [5]. The new in place government cancelled the 2007 privatization project. Japan Post Office manages a huge deposits system; it is the first financial conglomerate in the world. Considering that, traditionally, Japanese Post invest 75% of its assets in national government bonds and that depositors prefer holding their economies in guaranteed State establishments, cancelling the privatization of this institution makes it a beautiful prey to being captive to government public debt.

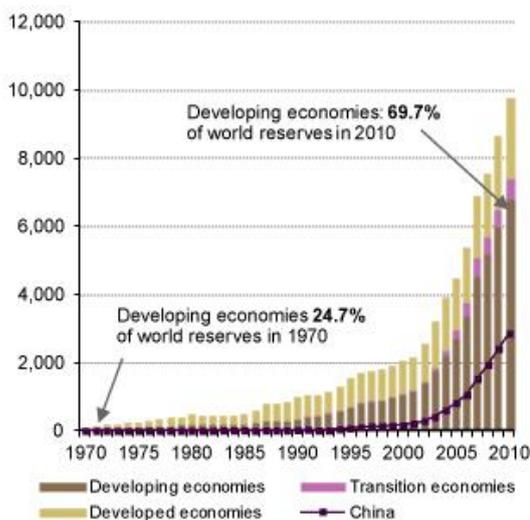

This is particularly true in Japan, where most public debt is held by Japanese households or institutions.

Thirdly, interest rates are maintained particularly low, by massive bonds purchase and monetary easing policies by major central banks around the world, at that point that it is becoming doubtful whether the information contained in the bond prices reflects real risk [4].

Fourthly, macro-prudential policies encourage banks and insurers to hold very liquid, non risky assets, which are, surprisingly, public domestic bonds. Basel III is particularly biased toward government bond detention and reinforces the vicious dependence between governments and financial institutions.

Finally, it is worth noticing a considerable change in the emerging markets capital account management policies, which is not neutral for the current situation in developed countries. Emerging markets are export oriented and low stable exchange rates allow them to maintain their price competitiveness. Classically, when high return expectations from foreign investors appear, foreign short term portfolio investments climb up, putting a pressure on exchange rates, which eventually appreciate, thus damaging the exports activities. Central banks intervene by buying massive quantities of foreign government bonds, and therefore indirectly contributing to maintain high demand on developed countries government bonds.[3]

Chart no 6. Reserves of developing developed and transition economies and China

Source :World Economic Outlook 2011 database

But these massive interventions of emerging economies’ central banks are costly and only have a short term effect, so, usually, emerging economies combine foreign treasury bonds purchase with some capital account control measures. While the IMF historically prohibited capital account controls, it recently softened its view, allowing capital account management policies under certain circumstances [1,2]. What is certain is that it’s the first time, since the Bretton Woods arrangement broke up, that international community is so permissive towards emerging markets’ capital account measures. This time, the context makes these measures acceptable for developed countries as well, because they keep investors from developed countries captive in the developed markets, where real interest rates are very low, and even negative.

7. Conclusions

Since 2008, potential growth has been continuously diminishing and economies don’t turn at their full capacities.

Public and private debts in developed economies are situated at historical heights and pressure is rising on central banks and governments to contain public debt interest expenses, but also to start reducing the Debt/GDP ratio. Fiscal adjustments in Europe have proved very painful for population, costly from a political point of view and inefficient, considering the poor achievements of these countries and their suffering economies.

In this context, financial repression appears to be a viable and acceptable solution in order to start reducing the debt burden weighing on developed economies. Recent measures adopted in different parts of the world, and namely in Europe, testify for financial repression coming-back. In the recent Cyprus crisis [7], financial repression goes even further and takes the form of a deposits freeze, followed by deposits taxation. Indeed, when the European Union granted Cyprus a rescue plan of €10 billion on March 17th it asked Cyprus to partly finance the deal. Cyprus achieved this by seizing deposits and taxing them at 6,75% up to 100 000€ and at 9,90% for the exceeding surplus. We could

judge that Cyprus’ case is marginal, considering the fact that banking deposits, for the most part held by Russian investors, account for four times its’ annual GDP and were probably subject to fiscal fraud. However, the Cyprus case opens the way to moral hazard . How can the European Union justify in front of its citizens the rescue of Cyprus, considering the deposits composition and property? While this crisis is far from closed, it represents an interesting path to understand financial repression forms in today’s world.

As Carmen Reinhardt expressed it in her research paper, what we are experiencing today is maybe only the visible part of a huge iceberg.

Monetary Policy Efficiency and Challenges Lying Ahead in the Aftermath of the Financial Crisis

Halep Maria

Doctoral School ASE Bucarest – International Business and Economics

mariahalep@yahoo.com

Abstract

Since the 2008 financial crisis burst, central banks have had an increasing role in ensuring liquidity on financial markets, acting as lender of last resort and maintaining a general, though still fragile equilibrium. Once the interest rate cuts were no more enough to ease monetary policy, unconventional measures replaced them, generally known under the name of “quantitative easing”. Monetary policy increased in importance as governments’ latitude to conduct public and fiscal policies to sustain general demand are very limited in a context of generally high deficits and public indebtedness.

This study assesses the limits and eventual risks of prolonged accommodative monetary policies deployed in developed and emerging economies throughout the world. Among the main risks, we analyse: the implications for effective balance sheet repair in advanced economies; the consequences of global monetary policy spillovers to emerging market economies; and the resulting longer-term risks for central banks, namely inflation risks.

Key Words: monetary policies, central banks, quantitative easing, inflation, balance sheets

JEL Classification: E41, E44, E51, E52, E58,

1. Introduction

Since the burst of the 2008 financial crisis, public finance accounts in developed economies have been continuously deteriorating, while central banks’ interest rates have been moving closer and closer to the zero bound.

Fiscal policies feasibility in developed countries is very limited, as public deficits

are being banned, public and private indebtedness reach historical heights and GDP growth is fragile, if not inexistent. In this context, monetary policy remains the only available tool to redress economy.

The next sections analyse what monetary policy can do and cannot do, according to the economic and political context, and assess the main risks associated with prolonged accommodative monetary policy.

2. Accommodative monetary policy benefits in the short term

Accommodating monetary policy definitely has some benefits in the short term. Undeniably, without decisive and repeated central banks’ intervention, a financial meltdown would have probably occurred after the Lehman Brothers episode in late 2008. Easing monetary policy enables private and public sector balance sheet repair in the short term, by preventing disorderly deleveraging and bankruptcies. Furthermore, it reduces debt servicing costs, may support asset prices, output and employment. It was completely true in the aftermath of the 2008 events.

However, the reasoning weakens in the long term, when it comes to suffering, depressed economies, having undergone an important financial crisis and economic slowdown..

Over indebted economic agents do not wish to borrow in order to spend, and an impaired financial system is less effective in transmitting the policy stance to the rest of the economy. This means that, in order to have the same short-term effect on aggregate demand, monetary accommodation will naturally be pushed further. But this cannot substitute for direct corrective action to address debt burdens and impaired balance sheets. Ultimately, this means that monetary

policy, while undeniably helped preventing a financial and economic meltdown of the size of what we have known during the Great Depression, it alone cannot solve solvency problems, fiscal policies and structural reforms must be implemented.

3. Conventional and unconventional monetary policy instruments

Traditionally, three main instruments are generally used to conduct monetary policy: Reserve Requirements, Open Market Operations (OMO) and Standing Facilities.

Reserve requirements take the form of a minimum reserve deposit requirement held at the National Central Bank. They generally take the form of a percentage applied to the previous period's average level of commercial banks' deposits/liabilities base. In practice, this instrument is not really used.

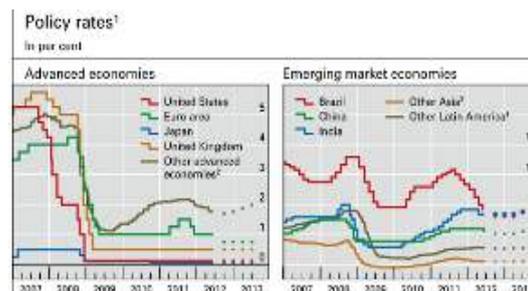

OMOs are the primary instrument used to maintain the policy rate, while at the same time ensuring that there is sufficient liquidity in the banking system to satisfy banks' demand for required reserves and settlement balances. Among the main OMO, we note: Bilateral Repurchase Operations, Foreign Exchange Swaps, Outright Purchase/Sale of Debt Securities.

Standing facilities are aimed at providing and absorbing overnight liquidity, signal the general stance of monetary policy and bound overnight market interest rates. In the Euro Zone, standing facilities take two forms, marginal lending facility in order to obtain overnight liquidity from the central bank, against the presentation of sufficient eligible assets and deposit facilities in order to make overnight deposits with the central bank.

Since July 2012, the ECB doesn't remunerate deposit facilities anymore.

These three instruments are included in the conventional monetary policy instruments. However, once the zero bound has been reached, and in the context of a high risk aversion and fragile economic recovery, central banks had to deploy some “unconventional measures”.

Graphic no° 1: Central banks' interest rates in developed and emerging economies.

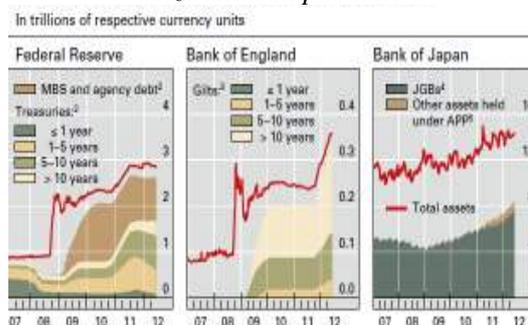

Source: BIS Annual Report 2012

All major advanced economies' central banks embarked in large scale asset purchase programs, aimed at lowering long-term interest rates and financial risk premia, especially in the Euro Zone. The Bank of England and the Bank of Japan increased their asset purchase programs over the period, by £125 billion and ¥30 trillion, respectively (see graphic no° 1).

The large-scale asset purchases implemented from late 2008 considerably increased central banks' outright holdings of longer-term securities, in particular of government bonds, contributing to the drop of long-term interest rates to very low levels;

The graphic below illustrates United States, UK, and Japan's central banks' balance sheet increase starting from 2008.

Graphic no° 2 : Central banks' balance sheet size and composition

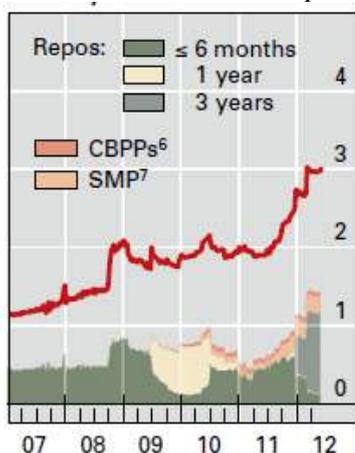

Source: Datastream

In the Euro Area, the problem was intensified by rapid increases in bold yields for some euro area sovereigns, pushing the ECB to take decisive measures: i)conducting two three-year longer-term refinancing operations (LTROs), one in December 2011 and one in February 2012, with full allotment, ii)widening the range of collateral assets accepted in refinancing operations and iii) lowering the required reserve ratio. As a consequence of these measures, the net increase observed in the size of the assets on

the Euro System’s balance sheet of roughly 500 billion €. The maturity also increased with these two LTRO, as the scale of other, shorter-term refinancing operations was reduced at the same time.

However, ECB balance sheet started to go down beginning of 2013, as banks started reimbursing the LTRO programs, as shown in graphic no. 4.

Graphic no°4 : Euro Zone balance sheet evolution

Source: goldsilverworlds.com

4. Limits and risks associated with over – accommodating monetary policies

The main risks associated with prolonged over-accommodating monetary policies concern implications for balance sheet repair, global financial and price stability as well as central bank’s credibility and autonomy.

i) Monetary policy and effects on balance sheet repair

Prolonged accommodative monetary policy may postpone balance sheet repair and the return to sustained growth, by hiding balance sheet problems and the urgent need to address them, and even reducing the opportunity cost of holding non-performing loans, leading to a credit misallocation. Moreover, observed loss provisions are very low in major developed countries’ banks, despite the poor macro-economic conditions.

Secondly, low short term and long term interest rates may sustain excessive risk-taking. While counteracting widespread risk aversion was one important motivation for the exceptional monetary accommodation provided by central banks in response to the global financial crisis, low interest rates can over time promote the build-up of financial vulnerabilities by triggering a search for yield in unwelcome segments. This is particularly true today as real interest rates are close to zero, and mostly negative in advanced economies [1].

Thirdly, lax monetary policy may distort financial markets’ operating, by changing the dynamics of overnight money markets, which may complicate the exit from monetary accommodation. Large-scale asset purchases, intended to lower long-term interest rates and financial market risk spreads, ultimately also weakens market signals, as long term yields on government bonds are a key benchmark for financial intermediation. We can indeed start doubting on the capacity of bond prices in reflecting private agents’ decisions and anticipations, as central banks become major operators in these markets and influence bonds’ yields [6].

ii) Accommodative monetary policy and emerging economies

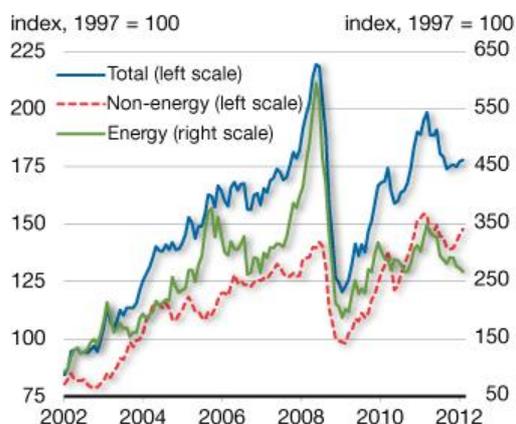

While prolonged monetary easing probably has only limited potency to revive growth in the advanced economies, its global spillover effects may be substantial. Unceasingly large interest rate differentials (Graphic no.1) sustain capital and credit flows to fast-growing emerging market economies and put upward pressures on their exchange rates. This makes it more difficult for emerging market central banks to pursue

their domestic stabilisation objectives. Interest rates have been raised only hesitantly in response to overheating domestic macroeconomic and financial conditions out of concerns that this would widen interest rate differentials and further boost capital inflows. As a result, monetary policy in emerging market economies may be systematically too permissive, though a new wave of capital account control measures has shown up in the past few years, and, for the first time, both the IMF and developed countries are more permissive than in the past, because measures in developing countries keep investors from developed countries captive in the developed markets, where real interest rates are very low, and even negative [4,5].

The prevailing loose global monetary conditions have been fuelling credit and asset price booms in some emerging market economies, creating risks of rising financial imbalances similar to those seen in advanced economies in the years immediately preceding the crisis. Their unwinding would have significant negative repercussions, also globally as a result of the increased weight of emerging market economies in the world economy and in investment portfolios.

Loose global monetary policy has probably also contributed to the strength of commodity prices since 2009, as illustrated in graphic no.5.

Graphic no° 5: Commodity prices, 1997 - 2012

Source: <http://www.budget.gc.ca/2012/pla/n/chap2-eng.html>

Commodity prices are set in global auction markets and are very sensitive to global

demand conditions, which are in turn shaped by the global monetary policy stance. The growing role of financial investors in commodity markets may have further raised the sensitivity of prices to monetary conditions [2].

The growing relevance of monetary policy spill-overs suggests that central banks need to take better account of the global implications of their actions. In a highly globalised world, a more global monetary policy perspective is also called for to ensure lasting price and financial stability called for to ensure lasting price and financial stability

iii) Monetary policy and long term risks for central banks

Currently, long term anticipations do not point out raising inflation risks, in both advanced and emerging economies, as suggested by market indicators and consumer surveys.

Graphic no° 6: Inflation expectations in developed and emerging markets

1 Five-year inflation expectations five years ahead; monthly averages

2 Six- to 10-year-ahead mean consensus forecasts of consumer price inflation.

Source: Bloomberg

In the long run, central banks' credibility and autonomy may be affected as monetary policy interferes with fiscal policy, the separation between them becoming blurry[1]. However, one must understand why recent quantitative easing as well as loose monetary policy did not alter inflation anticipations, and we shall make a point on the Euro Zone's case, though other economies are eligible to the same reasoning. It is mainly because an increase in the money base does not necessarily increases money supply in the economy.

While the monetary base is highly liquid money that consists of coins, paper money (both as bank vault cash and as currency circulating in the public),

and commercial banks' reserves with the central bank, the money supply is formed by the aggregation of banks and central banks balance sheets. It is compound of demand deposits and currency in circulation. Bank's reserves with the central bank are not included in the money supply, as they are the asset of the bank and the liability of the central bank, thus compensating themselves.

Thus, money supply does not fully depend on central bank's actions, but also on commercial banks' behaviour and the demand prevailing in the economy. If banks decide to grant few credits to the economy, or if the demand is poor, money supply will not increase, irrespective of central bank's monetary policy, because the commercial banks liquidity surplus will transform in central banks reserves. It is exactly what is currently happening in the Euro Zone, where investment is suffering and global demand morose. Capacities are not used at their full potential, firms are deleveraging and households postpone their consumption decisions and increase their savings[3].

That being said, banks do hold reserves in their assets, and, theoretically, these assets could be poured into the economy, generating a money supply increase and, subsequently inflation or financial bubbles.

Therefore, despite current low inflation rate risks, central banks must conduct sterilization policies, i.e. absorbing surplus liquidities by selling bonds and securities held in their balance sheets.

5. Conclusions

The global monetary policy position is unusually accommodative. Interest rates are well below traditional benchmark measures. At the same time, central bank balance sheets have reached an unprecedented size.

As fiscal policies become useless as economies embark in austerity policies in order to return to equilibrium, sustained monetary easing is the last weapon at governments' disposal. However, there are things that monetary policy can do and cannot do. While it can ensure market liquidity, prevent disorderly deleveraging and bankruptcies deleveraging, monetary policy does not tackle solvency, nor structural problems. It cannot be used as a substitute for those policy measures that can address the

root causes of financial fragility and economic weakness.

The combination of fragile growth and exceptionally low interest rates in advanced economies, and efforts to manage the spillovers in emerging market economies, has helped to extend monetary easing globally.

The resulting risks of a build-up of financial imbalances and increasing inflationary pressures in emerging market economies might have significant negative repercussions on the global economy. Therefore, there is an urgent need for central banks to take better account of the global spillovers from their domestic monetary policies to ensure lasting financial and price stability.

Moreover, central banks need to take into account longer-term risks influencing their credibility and operational independence. This would complicate the eventual exit from monetary accommodation and may even threaten central banks' credibility and operational autonomy. This concern is reinforced by political economy risks arising from the combination of balance sheet policies that have blurred the line between monetary and fiscal policies, on the one hand, and the risk of unsustainable fiscal positions, on the other.

Finally, central banks need to take into account inflation risks carried by their unconventional policies, despite current low expectations of inflation.

The Regionalism – Challenges on the Multilateral Trading System

Kicsi Rozalia Iuliana
„Ștefan cel Mare” University of Suceava
rozaliak@seap.usv.ro

Abstract

The regionalism has changed into a real phenomenon with incidents impossible to be ignored, as regards the wide-world economy configuration; such phenomenon cannot be overlooked, not even under estimated, since it significantly influences both the type of trade relationships, as well as the economic policy options. Within the after war period, as especially starting with the nineties, a significant inflow has occurred as regards the regional trade agreements, which carry out various shapes, determined by the “mosaic” of relationships that are established between the states that focus all their efforts towards the direction on reaching the common objectives. In such circumstances, the relationship between regionalism and the multilateral trade system has determined significant debates and controversies on the international level.

Keywords: preferential liberalization, multilateralism, regionalization

JEL Classification: F13

1. Introductory regards

The non-discriminating multilateral trade represented the major goal of GATT, goal that was “inherited” by its successor, meaning WTO; as matter of fact, such goal was far away of being “universal”; many countries have yet maintained different levels of protection, giving treatments more favorable to certain trading partners, upon basis of some preferential trade agreements, and less favorable to others. The preferential trade is not a new concept; the colonial imperials have been extended starting with XIXth century and the beginning of XXth century, and can be assimilated to some preferential trading blocks, since they applied various facilities to the exports towards or

from colonies; otherwise, one of the faculties of reasoning that determined the high powers to reach new territories consisted in ensuring the outlets for the own merchandise on one hand, and in ensuring some supply sources with raw materials or merchandise that they haven't disposed until that time, on the other hand [1].

The regionalism, seen as up-to-date, doesn't mean “an invention” exclusively post-war; the first episode occurred in the second half of the XIXth century, having the origins in Europe, as well. During that time, the intra-European trade has significantly been increased, owning an essential weight within the world trade. Until the beginning of XXth century, Europe has already functioned as a unique market in some aspects; the industrial revolution and the technological progress have made easier the inter-states trade development and the trend towards the free regions formation and the customs unions.

The First World War interrupted the trend previously invoked; the customs duties, quantitative restrictions, prohibitions and checks of changes were quickly established in the entire Europe, in the view of protecting the industries related to the national security. After ending the conflict, the confederate states, especially Great Britain and France, have refused to extend the MFN over Germany and combatant countries, thus blocking the possibility to restore the pre-war “liberal economy order”.

The occurrence of the second episode of regionalization, carried out during the inter-war period of time, has been frequently related directly to the impossibility of re-joining the liberal order at multilateral level; in such circumstances, the efforts on regional level have been seasonable. [2]

After the Second World War, although emphasizing a well-organized frame for the non-discriminating multilateral trade, many of the world states have continued to be

interested of the preferential or discriminating trade, issue proven by the statistical data that revealed an increase upon the trade flows concentration, on the regional or trans-regional level, tendency that have been more emphasized starting with the eighties.

2. The waves of regionalization

This phenomenon has known various phases over the time, known in the specialty literature under the name of *values of the regionalization*. [3]

The first “wave” of the “early” regionalism during the fifties – seventies, was launched by the creation of European Economic Community, by means of the Treaty of Rome (1957), and followed by a series of cooperation initiatives at the regional level between countries in progress of development. At that time, the United States of America militated in favor of the multilateralism; notwithstanding, they have supported the integrationist process in West Europe, thus seeing a counter-weight to the USSR ascension and what it signified on one hand; on the other hand, this was seen as instrument in multilateralism promotion, considering that a united Europe might facilitate the progress of negotiations within GATT. Under the momentum of European Common Market, the regionalism has been disseminated in Africa, Latin America and other regions; the countries in progress of development, which implemented the policy of imports substitution, have aimed towards the reduction of costs generated by this type of industrialization, by exploiting the scale economies achieved after the preferential opening of market. Nevertheless, by the end of the 60s, their attempts have failed, especially because the industries allotment was intended to be carried out by bureaucratic negotiations. [4]

At the end of the 80s, the regionalism came out on the world arena, forcefully imposing in the nineties; this type of “new regionalism” represented the solution of the structural changes that have been carried out on the world economy, as consequence of the globalization process. In parallel to the gradual liberalization of the trade, the part of direct foreign investments in the global economy was amplified: the investment

flows have outmatched the trade flows, and the extended size of the market made easier such progress [5]. “The engine” was represented by the entrance of United States in “the field”, this time in quality of essential “player”. The decision of USA on preferential exploring and approaching the trade relationships was significant, considering that in the previous decades, this was a fervent supporter of the multilateralism. Diverting from the principle of non-discrimination, promoted by the Most Favored Nation Provision, USA negotiated free-exchange agreements with Israel and Canada (CUSTA - Canada - US Free Trade Area), after which this launched the proposal for a free exchange hemispheric region (*Enterprise for the Americas Initiative*); subsequently, an agreement was signed together with Canada and Mexico in order to establish NAFTA. It is appreciated that “this conversion” of USA to regionalism does not represent just the catalyzer, but also the factor that involves steadiness and lastingness for *the second wave* of the regionalism [6]. The most underlying situation of “transition” in the American politics actually relies in the USA concern towards the erosion of its hegemony within the economic and politics world sphere. [7]

As regards Europe, the integrationist process has continued in both the successive enlargement, as well in the deepness; the European “preferentialism” was also extended. Regarding Asia, Latin America and Africa, the old preferential agreements have been restarted, as well as the new established ones [8]. By means of “Europe 1992” programme, and the integrationist scheme, of which protagonist was USA, the idea according to which the regionalism was “a must have” was agreed. In this way, a new opinion current appeared in Asia, current that supported the need of creating a new trade block, of whose epicenter should be Japan, as a counterweight to those blocks created around the United States; on the other hand, the old preferential schemes were emphasized at the level of all continents, and the new preferential schemes occurred [9]. Notwithstanding, the success of negotiations carried out within Uruguay Round and creating the WTO, as successor of GATT, have represented a reaffirmation of the employment of most states, towards the

principle of non-discrimination, within the international trade. [10]

The second wave of regionalism proves some qualitative changes towards the previous. The first consists in the transition to a “closed regionalism” to an opened one. Most of the trade blocks established in the sixties – seventies were underlying on the policy of imports substitution and imposing some high external barriers; the new wave is though characterized by a higher opening towards the external part, and a higher availability on supporting, as comparing to control, specific to the international trade. Most of the trade blocks are directed moreover to exterior, rather than interior; exception is related to European Union, which manifests an obvious orientation towards interior. This natural trend of EU as regards the intra-Community relationships can also be explained in relationship to the integrationist process intensity; being the customs union, this will involve, besides the trade regime within the preferential inter-regional feature, a common external trade politics; all the other blocks are carrying out activities under the shape of the free trade area, fact that offers to the members the possibility on applying the own trade politics towards the third parties. One should not ignore either the fact that the trade policy of EU have had a protectionist character more pronounced as comparing to other states, especially other developed states; moreover, the economies within the West Europe have had levels of development and economic structures relatively similar, issue that gave favored the occurrence and intensification of the intra-branch trade.[11]

Such trend of opening has continued in the situation of the most important trade blocks, thus removing the fear of a potential changing of them into “trade fortress”.

Another significant feature consists in the trade blocks occurrence, where the partners are both the developed countries, as well as the states in progress of development (NAFTA, UE).

In the last decade and a half, the attraction for the preferential trade has been high, as regards the great majority of the world countries, no matter their level of development of their economic potential. In this way, if over the long existence of GATT, this received only 123 notifications of

regional trade agreements, starting with 1995, from the creation of WTO, over 300 regional preferential trade agreements were notified, as covering the trade of assets and services. Almost all the WTO member states have notified the participation in at least one integrationist scheme. [12]

R. Pomfret spoke about *the third wave of regionalization*, “born” at the beginning of 2000 and that continues many of the trends registered in those previous. For this time, “the leader” is represented by the East Asia, stimulated on one hand by the economic growth power of China, and on the other hand, by the perception according to which during the crisis of 1997, the international economic institutions “have abandoned” this region. The failure marked by WTO in Seattle in 1999 and the reduction of APEC significance have stimulated new initiatives in the direction of trade liberalization in the Asia-Pacific region. A series of countries included in the region negotiated mutual bilateral agreements (Japan – Singapore, China – ASEAN etc.), example followed by USA, which on its turn, negotiated the bilateral trade agreements, with countries that are friend, as Jordan, Morocco or Australia. As regards Europe, the integrationist process has been extended by the adherence of twelve new states to European Union (2004, 2007). Although sometimes the third wave was regarded as the recrudescence of regionalism, one might notice that many of these bilateral agreements have been not concluded underlying on the geographical proximity criterion. Besides the trade issues, the third wave will include the liberalization measures of the financial sector, fact that denotes a trend on deepening the integrationist processes. [13]

3. The preferential liberalization and the multilateral liberalization – antagonism or complementarity?

Within the post-war time, the multilateral trade system was represented by Most Favored Nations Provisions, by means of which the GATT, and then WTO, promoted the non-discrimination as regards the international trade relationships, thus establishing the basis of a new world trade order. As previously mentioned, the development of the trade relationships upon

basis of the non-discriminating aspects was doubled by a process of trade regionalization, usually to the regional level. In other words, the multilateral trade system that was emphasized under the GATT or WTO “patronage” and the regional agreements have in a way the same objective, meaning the liberalization of the trade, with the difference that the first wishes to be a non-discriminating, while the regional trade agreements are known, by their type, as discriminating. GATT has accepted these preferential agreements, respectively the free exchange regions and the customs unions, as a derogation of Most Favored Nations Provisions, with the condition of respecting the provisions foreseen in the Article XXIV (with the previous completions). The motivation, as results in the Agreement text, might be given by the idea that “the contracting parts” admit the necessity of the free trade development, by volunteer agreements, of more emphasized integration between the partner economies or countries to such agreements, with the conditions that the customs unions and the free exchange regions to aim towards facilitation of trade between the member states, and not on the creation of “the fortress”, by the growth of the protection level as related to the third parties states. [14]

The relationship between regionalism and the multilateral trade system has determined debates and controversies on international level, for both the economists and politicians, as well.

The analysis of regionalism evolution on world scale during the post-war time has revealed two essential aspects that lead towards the conclusion that the free global exchange has needed “the regionalism multilateralization” already existing or potentially existing in the future [15]:

- The regionalism has remained here; the architecture of the world trade is directly influenced by the existence of unilateral, bilateral or multilateral mosaic agreements – *a spaghetti bowl* of trade transactions. It is less probable that such fact might change; contrariwise, it is quite possible that such mosaic might become “more and more colored”.

- None can precisely argue that fact that such “clue” of trade flows is the most efficient way on organizing the world trade.

In generally, the preferential trade agreements are regarded as some “exclusivist clubs” [16] that promote a discriminating treatment towards the third parties, and which might affect in a negative way the countries “excluded” (defalcation of trade, deterioration of exchange terms etc.), as previously mentioned. The enlargement of the negative effects depended upon the level of extension of the trade defalcation and upon the structure of the economies excluded in the sectors, where the trade pattern modification can take place. As a rule, the negative effects over the third parties are less significant, in the situation of the trade blocks that produced a trade defalcation of low amplitude, a liberalization of the trade by the rest of the world, and have tried to face the external competition, by means of the members’ efficiency improvement. [16]

Although owning older origins, and after the Second World War, the regionalism has been existing in its prosperity period of time; as regards the post-war decades, the international trade system has known a proliferation of the preferential trade agreements. In the same period of time, an accentuated trend occurred at world level, as regards the economies opening directions, trend promoted and supported by GATT and its successor, WTO, by the most favored nation’s provision. The six decades of tax reductions, as almost two decades of negotiations on issues of non-taxing barriers, have determined significant results in the direction of “conversion” of most world countries, to the idea of multilateral trade liberalism. Notwithstanding, the discrimination materialized in various types of integrationist schemes is still persisting; the preferential treatments that the member states enjoy, even if apparently non-significant, might generate distortions and costs, especially for those remained outside these schemes. It is surprisingly that most of the WTO member states are partners within at least one preferential trade agreements.

The strength that such phenomenon reached has naturally generated the questions related to the effects over the multilateral trade system; as regards the literature dedicate to this topic, the syntagms *building blocks* and *stumbling blocks* are already well known; by these, one has tried to emphasize “the relationships” with the multilateralism.

Over the time, many theoretical models were built, by which solving a issue was carried out, issue related to the effect of discriminating trade policy effect over the progress of multilateral trade system. The issues has remained yet opened, especially that there are quite few “consecrated” integrationist schemes, most of them being of relatively recent calendar data. Alan Winters started a study dedicated to this topic (published in 1996, under the aegis of World Bank), by the same question: “Will the forces that the preferential trades agreements launch encourage or not the trend towards a more free global trade? We haven’t achieved yet an answer at this question”. [17]

4. Conclusions

The regionalism has become a challenge for the future; it is outlined as result of the most WTO member states for the preferential liberalization of the trade exchanges; during the post-war period of time, the successive waves of regionalization have transformed “the pattern” of the world trade.

The antagonist or complementarily relationship between regionalism and multilateralism has determined many debates occurrence; the integrationist schemes represent a reality of the world landscape and their part within the world economy design, which cannot be ignored. The reality has proven that demarches of liberalization upon preferential basis have been increased, in a rhythm more accentuated rather than the multilateral level; a great part of the world trade flows intensification consists in the direct consequence of the agreements negotiated at the regional and trans-regional level. The dual nature of the preferential trade schemes or the mixture between the free exchange and protectionism will offer them a specific feature, of potential trade “fortresses”. At first sight, one might be tempted to believe that the people will be divided in the future into a low number of trade blocks, polarized around the high powers. Actually, *regarded as stricto sensu*, only the European Union might be classified as “trade block”; the other integrationist groups will enjoy of a higher flexibility as regards the external policy options. Moreover, it seems that after “the consumption” of all cooperation resources at

the regional level, most of countries, as especially of the existing groups, have directed towards the trans-regional cooperation, usually on world scale; in the context, it is not difficult to imagine the “magnets” that might polarize, though it is difficult to imagine how the polarization regions might be delimited; this is done how much more so each country is member within at least one preferential agreement. Moreover, during the history, the world power balance has known changes; currently, one might speak about that “Triad” and the economic progress of China and of all other countries within the Asian region might reconfigure this *status quo*. One should not ignore that all countries related, from various reasons, to the preferential liberalization have also assumed agreements within the WTO, thus registering on the multilateralism line. The value of the indicators that quantify the level of market opening does not suggest a closing trend, but contrary, a trend more and more emphasized over the trade blocks existing within the world trade.

Abstract

The development of medical tourism has been encouraged by travel agencies and mass-media, which describe the practice of traveling across international borders to receive healthcare services in an original way, where, due to availability and modern medical techniques, the necessity harmoniously blends with relaxation.

More and more public persons state that they undergo medical treatments in foreign countries and then they become the image of the clinics which treated them.

All these elements have succeeded to add so much credibility to this phenomenon that the future of medical tourism looks ever more promising today, some countries posting an annual increase of this kind of tourism of 30%; this means that medical tourism is, for sure, a part of the next level of globalization.

Key words: niche tourism, medical tourism, management, sustainable development, promotion, marketing.

J.E.L. Classification: I13, I15, M37, R11

1. Introduction

Tourism has long been recognized as an economic development strategy which generates incomes and is regarded as one of the fastest growing industries in the world. For this reason, all countries are looking for ways of establishing business relations and of attracting tourists.

Much like in other areas of social life, the right to health of the individual constitutes a national priority and therefore the medical tourism phenomenon stands out. This has a great impact not only on patients, but also on the society due to socio-economic implications on the business environment and healthcare sectors as well.

The diseases are a part of everyone's existence nowadays; however, the human being has yet to accept defeat and removed barriers to a healthy life and, in this existence seeking, the distance is a minor hurdle, especially when modernity makes available so many facilities.

Medical tourism is thousands years old and those who travelled for healthcare or for treating certain illnesses were the reach people.

Currently however, due the development of transport, to communication swiftness and to information access increase, the financial barriers have been lifted. There are many people who accept being treated in a foreign country as the medical services from which they benefit are cheaper than in their own country.

2. The medical tourism

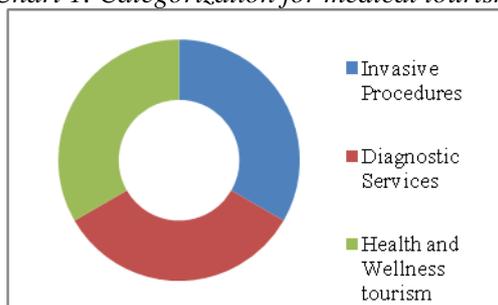

Because they pay a great attention to social and economic development, people living in present-day society lead a stressful and unbalanced life [1]. This phenomenon is reflected into tourism and hospitality business by the increase of tourists' interest for health and wellbeing improvement during the holidays. The time dedicated to health is

increasing as a percentage as well, people investing more and more money to maintain their health [2].

The increasing trend of travelling abroad for medical services, known as “medical tourism”, is expected to further grow exponentially over the next decade. This fact is due to the easiness of people getting information and the specialized medical websites come to their help. Those practicing such tourism are interested in the following services: dental treatment, cosmetic surgery, cardiac surgery, organ transplantation, orthopedic surgery, fertilization, and various tests to maintain or improve their health [3].

Medical tourism is practiced by people travelling outside their city of residence, with the aim of regaining or maintaining their health, as a result of certain medical treatments. Researchers have tried to distinguish between "health tourism", "medical tourism" and "wellness tourism"[4].

Chart 1. Categorization for medical tourism

Source: Bookman & Bookman, 2007[5]

The most popular reasons why people prefer treatments outside Romania are:

- Access to treatment which they cannot have in their home country;
- Treatments are often 60% cheaper abroad;
- Due to the endowments of hospitals and specializations that foreign doctors have, the recovery period is much shorter;
- Tourists have greater confidence in the reputation that some clinics or certain foreign doctors have gained (e.g. they prefer plastic surgery to the doctor who had operated their favourite celebrity, regardless of costs);
- In some countries, the time spent on the waiting list for a particular type of surgery is very high, while the

disease can progress. Therefore the patients prefer to undergo surgery abroad.

Table 1: The most famous medical tourism destinations worldwide

Asia & Africa	Europe	South America
Thailand	Hungary	Columbia
India	Turkey	Cuba
Malaysia	Romania	Brasil
Jordan	Czech Republic	Mexico
United Arab Emirates	Portugal	Costa Rica
Israel	Ukraine	Argentina
Singapore	Cyprus	Peru
South Africa	Germany	Guatemala
Hong Kong	Austria	Uruguay

Source: www.mymed.ro, accessed 01.03.2013

Besides the above mentioned advantages, it is necessary to have in mind the potential "risks" that tourists have. The main reasons for which some people refuse to travel abroad for treatment are:

- Lack of money - when the state or NGOs do not finance the surgery (in this case, the person in question opens a bank account and begins to make public his/hers problem, waiting for donations)
- Medical services may not be of the highest quality;
- Inability to remain under the post operator supervision of doctors who carried out the therapy;
- The compensation in case of medical malpractice is difficult to obtain;
- The language barrier - most of the times, the patient needs an attendant and a translator in order to understand the doctor’s message, and this implies new costs;
- The risk of choosing a particular clinic or a particular doctor just because he has partnerships with specialized travel agencies or because he had invested in advertising, and not only because he provides the best services;

- The risk of acquiring infections with particular to a certain area diseases.

When they choose the more expensive health care services, tourists expect a high quality of medical services, superior care from doctors, hotel-like accommodation, good quality food, last generation equipments, continuous monitoring of the evolution of therapy.

3. The needs of a tourist who travels to another country in order to improve his health

In tourism there are plenty of services and facilities involving a wide range of development agents. They are divided into two main categories: public sector and private sector.

The private sector is directly involved in meeting the needs of tourists [6], especially looking for profit. The cooperation between small units and operators and the large ones is mainly determined by different opportunities that exist between various tourism sectors.

Besides direct involvement in tourism operations, the private sector can provide the necessary capital for development process (market research, the study of travel preferences etc.).

Quoting Vellas [7], the main ways of marketing tourism products by travel agencies are: editing advertising materials and making advertising campaigns.

In order for a person to travel for medical purposes, he needs the support of several companies.

First, in order to move a severe case, the services of a *particular carrier* are being used. Some examples of air ambulance services are [8]:

1. **Alpha Medical:** Air ambulance services in the UK and worldwide. They provide a 24/7 air ambulance service throughout the UK and abroad – supported by a fleet of road ambulances to ensure that every patient benefits from an appropriate level of professional medical care from the beginning of the journey to the end..

2. **European Air Ambulance (EAA)** is one of the largest specialized air ambulance service providers in Europe, offering worldwide air ambulance repatriation with outstanding end-to-end patient care.

3. **ADAC-Ambulance Service:** Worldwide air ambulance service. The ADAC-Ambulance Service (ADAC) offers a worldwide ambulance service on ground and in the air and operates its own fleet of ambulance aircraft equipped with the most advanced IC equipment.

Another important service is *accommodation*, which often takes place in the hospital where the surgery occurs. The patient's attendant can also stay here.

Diet is specific to the disease the tourist is suffering from, being included in the treatment package and provided by the hospital / clinic.

All the necessary arrangements can be handled by *specialized agencies* practicing this type of niche tourism. They provide information about hospitals / private clinics / doctors: fees, location, specializations. Since each patient is a special case, they adapt their packages to the needs of the tourist (the country that will perform the treatment varies, for a longer or a shorter period, the need to return to the clinic for post operative control, the type of treatment).

Other companies provide, control or limit development such as providing basic infrastructure, planning or legislation. All these activities are responsibilities of the public sector, the government being required to pursue the public interest and to provide the goods and services whose cost cannot be borne by individuals.

Also, an important role in tourism growth and development is played by international and intergovernmental organizations.

To facilitate the access of Romanian citizens to treatments in European Union countries, CNAS (Romanian National Social Insurance House) has adopted E-type standard forms Regulation. These are: E 104, E 106, E107, E 108, E109, E 112 , E 115, E 116, E 117, E 118, E 120, E 121, E 123, E 124, E 125, E 126, E 127 and can be downloaded for free from the official website of CNAS. Out of these, the most important are [9]:

- E 104 - an attestation concerning the aggregate periods of insurance, employment or residence realized on the territory of an EU Member State.
- E 106 - providing medical services for persons residing in another state than the competent State; it is useful to those who need treatment in a country other than that in which they pay their insurance.
- E 107 - request for the European Health Insurance card / temporary certificate to replace the card.
- The E 109 form is used for registration of the worker's family members who do not reside together with him.
- E 115 for working inability.
- E 112 - certifies that, for objective reasons, the insured cannot receive treatment in due time in hospitals in Romania and has the right to call upon the services of a clinic in the EU area.
- E 117 for granting cash benefits in case of maternity and working inability.
- E 120 generates invoice based refunds.
- E 126 establishes the rates for reimbursement of medical benefits.

Another document that gives the holder the right to medical services in the European Union [10] is the *European card of social health insurance*. It can be used by a person in need of medical services during a temporary stay in a EU / EEA Member State and could replace a health insurance for travelling abroad[11].

4. Conclusions

Travel and tourism currently represent a global market of huge dimensions, where there is consumer demand for a vast range of products and services.

Since tourism as an activity, has become increasingly diversified, we focus on niche tourism, its challenges and trends.

Branch of the niche tourism, the medical tourism registers the highest and fastest grow, being a win-win situation both for economic agents involved (which boost their profits) and for tourists-patients (who improve their health and further on, their

lifestyle). It is also important to note that unlike other forms of tourism, the medical one is not always practiced for fun, but driven by need.

Fortunately, international barriers are gradually removed, so anyone can have access to quality medical treatment at low costs, creating competition among institutions providing medical services.

In the Spotlight of the Financial Globalization

Lupu Iulia
Criste Adina

“Victor Slăvescu” Centre for Financial and Monetary Research, Romanian Academy

iulia_lupu@icfm.ro

a.criste@icfm.ro

Abstract

The financial globalization, driven by different forces, brings some potential benefits, and at the same time may generate important risks. The main actors - financial markets, international financial organizations and states have been concerned about the development of globalization in the recent decades. The innovations and the technological changes in the financial system have encouraged the financial integration of markets in a globalized context. Although the exposure of the national financial markets to crises and contagion increases, the studies show that the net effect of the financial globalization remains positive. The challenge is to accomplish the integration process into the international financial system so as to obtain the maximum amount of benefits and opportunities, while the risk is minimized, being that the instruments available for the governments become more limited.

Keywords: financial globalization, crisis, financial markets

JEL codes: F30, F65

1. Introduction

Financial globalization is a present-day topic, both in academic and business sectors. In this era, when finance is reigning and dictates the behavior of business leaders, where businesses close their doors even if their business are going well, where investors are robbed by unscrupulous financial operators, the world is more uncertain than ever.

Generally, the financial globalization is defined as the integration of the national financial markets in the international

financial markets and institutions system. This process requires the government to liberalize the country's national financial sector and the capital account. The financial globalization is characterized by a process of integration of the international financial markets under the double impact of the international financial liberalization and of the increased international capital mobility.

Financial globalization is a process with two dimensions. On the one hand, the financial globalization is characterized by an increasing volume of cross-border financial transactions. On the other hand, it is characterized by a succession of institutional and legislative reforms that have been made for the liberalization and deregulation of the international capital markets and hence of the national financial systems.

The international financial integration is one of the major trends of the contemporary economic movement. The traditional vision on the financial integration advantages is described in the Figure no. 1. However, it should be noted that this trend is far from being a historical novelty.

Figure no. 1 – Traditional vision on the financial integration advantages

Financial globalization	→	Efficient allocation of capital	→	GDP growth	↑
		Increase of the ratio capital to labor		Consumption volatility	↓
		International risk sharing			

Source: authors' adaptation

The recent wave of financial globalization

has really begun since the mid of 1980s, due to the relaxation of restrictions on capital movements decided by many countries, supposing that international financial flows would stimulate economic growth and smooth consumption. The expected benefits were substantial, especially for the developing countries, which in general, are more capital-poor than others and have their income growth more volatile.

2. The facts' interpretation

The financial globalization's effects have not been established in a probative way. There are no formal empirical evidence, as we often hear, that the financial globalization is at the origin of the financial crises that world has experienced over the past thirty years, but it is equally difficult to find strong evidence of the macroeconomic benefits it would bring.

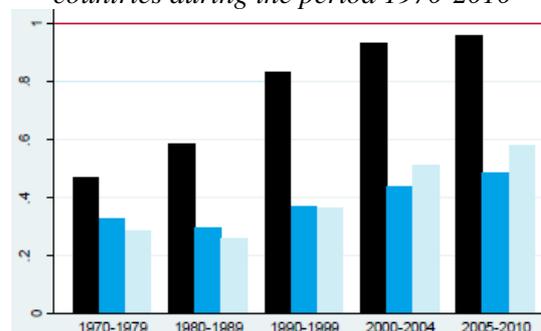

The idea that the financial globalization affects growth mostly in an indirect way has important implications for the empirical analysis of its benefits. Strengthening of the institutions, improving the market discipline and enhancement of the financial circuits takes time and it is also to see the growth results. Certainly, on relatively short periods, it seems easier to identify the costs than the benefits of the financial globalization. More fundamentally, even over long enough periods, it can be difficult to empirically identify such productivity gains associated with the financial globalization if structural and institutional variables and also the macroeconomic policies are included in the regressions that attempt to explain the international growth.

The measurements made in the recent years, emphasize that the financial openness has increased lately. Chinn and Ito index [2, 1] - KAOPEN - is based on the IMF's *Annual Report on Exchange Arrangements and Exchange Restrictions (AREAER)* and is considered the most representative index, while the other existing indices are closely correlated with it.

The latest version of the KAOPEN index, published in March 2012, covers 182 countries for the period 1970-2010. According to this index, the financial openness has increased steadily over time, recording higher values in the industrialized

countries (see Figure no. 2).

Figure no. 2 – Chinn and Ito financial openness index - evolution by groups of countries during the period 1970-2010

Legend: first column - industrialized countries, second column - less developed countries, third column – emerging countries
Note: For easier comparison, the index was indexed to 1.

Source: Note on financial openness index Chinn and Ito, March 2012

3. The financial globalization and the crises

The financial globalization is driven by different forces (governments, lenders, investors, financial institutions) and potential benefits (for developing countries - more liquid, more stable, and better governed financial markets), and at the same time may result in important risks (contagion, crisis).

The financial globalization has been accompanied by the development of new markets and new practices. These developments are causing failures of the financial systems and financial instability.

The main actors - financial markets, international financial organizations and states have been concerned about the development of globalization in the recent decades. For countries from Asia and Latin America (especially Mexico) it has been observed a difference between the productive economic performance and the national financial system that did not correspond to an integrated and globalized financial system, oriented towards stability and economic development. The innovations and the technological changes in the financial system have encouraged the financial integration of markets in a globalized context.

The low cost of capital and the possibility

of increasing the borrowed capital were obvious advantages for the developing countries, due to the fast pace of liberalization in the emerging markets from Latin America, East Asia and Eastern Europe.

The introduction of the euro in 1999 has contributed to the internationalization of financial markets in developed countries, being the most important event before the current crisis.

When a country's financial system is liberalized, it becomes subject to a financial discipline imposed by the foreign and local investors. Given the ability of the foreign capital to move more quickly between different countries, their role in establishing the financial discipline is more efficient. The national capital tends to have more restrictions on international investments.

The main reason why foreign investors are interested to hold assets in emerging countries is their high performance. However, the amount of foreign capital flowing from the rich countries to the emerging countries is still below the expectations predicted by theory, especially due to the institutional and political risks specific to emerging markets.

When we have a massive impact of the foreign capital into the country, by increasing the dependence on this capital, the economy becomes more fragile and exposed to the crisis by creating funding difficulties, especially if the economic situation is not a solid one.

Globalization can lead to crises and for countries with good economic situation, largely because of the international financial system imperfections.

If the crises are often associated with the financial liberalization, studies show that they are complex and are not only a consequence of globalization, but also an aftermath of various local factors. Statistics show that for a long time, the financial markets are characterized by crisis, both in times of economic integration and disintegration periods.

In addition to crises generated in one country, the financial globalization can lead to financial crisis through the contagion phenomenon. Thus, the main feature of the crisis that occurred during 1990s, in the transition countries, is that they passed over

and affected several countries (crises in East Asia, Mexico, Russia and so on).

The economic literature in the field of financial globalization is quite extensive and began to be visible in the early 1990s, drawing attention to the risk associated with the international financial integration. Historical overviews of the main examples of how crises affected the developed countries are presented in [3] and [4].

The crises that affected the emerging markets in the 1990s have led to less optimistic remarks on the financial integration of these countries - [5], [6], [7].

An analysis of the current crisis, with a foray into the pre-crisis period (1999-2007) and an analysis of the financial globalization after the crisis are well made in [8]. In the author's view, the financial globalization has contributed to an increasing asymmetry on credit growth and external position of the country, which has played an important role in propagating the crisis. Once appeared, the financial globalization has played a buffer role for some countries, while for others it has amplified the crisis. Another conclusion of the study is that the global crisis has shown that the international financial integration increases the costs of the economic policies' and regulations' failure, both in prevention and crisis management.

A new opinion appeared in UNCTAD report in 2012 *Development-led Globalization: Towards Sustainable and Inclusive Development Paths*: the globalization driven by the financial sector has led to uneven results, unstable and unfair, therefore is proposed a new path - globalization driven by development [9].

A new agenda based on three levels has emerged.

- The first tier requires enabling the developing countries to mobilize their domestic resources, strengthening their productive capacities and thus enjoying gains in a fair manner.
- A second level involves creating more robust multilateral structures that generate collective responses to the challenges ahead.
- A final tier involves strengthening regional links, including South-South cooperation to consolidate the stability and open new opportunities for growth.

4. A final remark

The crisis or the wave of crises in recent years can be seen as an opportunity for testing the financial globalization model. If the panic created by the crisis triggered in 2007 has known peak intensity between august 2008 and spring 2009, the next stage of the crisis is still ongoing, and Europe is the center of the current phase.

Although the exposure of the national financial markets to the crises and contagion increases, the studies show that the net effect of the financial globalization remains positive.

The challenge is to accomplish the integration process into the international financial system so as to obtain the maximum amount of benefits and opportunities, while the risk is minimized, being that the instruments available for the governments become more limited.

LSP and Communication Skills for Economics Students

Maruntelu Carmen-Liliana

Dumitrascu Elena

Facultatea de Litere, Universitatea Ovidius, Constanta

liliana_maruntelu@yahoo.com

elena_mam2006@yahoo.com

Abstract

The professional profile of a modern qualified economist should include well-developed communication skills and high foreign language proficiency to help him achieve success in the modern highly competitive global work arena. In the process of educating future economists special emphasis on Language for Business becomes necessary. Economic graduates require an ever-increasing range of skills to maintain relevance with the global environment of the new millennium. Communication skills are a vital component of this, recognized by academia and economic environment alike. Multilingual skills are considered a salient element in the make-up of the new global economist. Language for specific purposes focuses the learner's attention on the particular terminology and communication skills required in the international professional field. Communication skills development is discussed in the paper, with examples given of different methods of teaching and assessment.

Keywords: language for specific purposes, communication skills, economics education.

J.E.L. Classification: Z00

1. Introduction

Teaching a foreign language to non-linguistic students means achieving a variety of objectives: acquiring knowledge about the language, developing and practicing all four language skills, getting language and cultural awareness, integrating specialist knowledge

and communicative skills and even enriching overall knowledge.

The importance of this issue can be proved by needs analysis showing that employers put skills in making prompt decisions in changing situations, deductive thinking, application and evaluation among the most essential requirements while recruiting economists, managers, etc. Unfortunately, in the secondary schools thought processes are not developed to an extent to make logical reasoning. So developing creative thinking university teachers can help students to make a success in the employment market.

2. The Global Economist and Language for Specific Purpose

Globalization of the world economy requires professionals and specialists in various areas to communicate effectively in foreign languages. The success is conditional on their ability to manage language and cultural barriers, i.e. on the language skills and competences with respect to their professional areas. Teaching foreign languages to non-linguist students is a difficult but challenging task. There is hardly any branch where students would not need foreign languages (L2) for understanding of professional texts and where they would do without the skills to communicate effectively in the tasks connected with their study or work situations.[1] The study of languages for specific purposes (LSP) is highly students-centred, focused on learners' professional linguistic needs, as well as teaching materials production. In general, it puts great emphasis on the practical outputs of language learning. LSP have to deal with a number of “sub-languages”, i.e. language of business, science and technology, humanities etc., which makes it complicated

to outline a methodology that would apply to all disciplines and professional activities the learners are involved in. As a result, the LSP methodology always integrates the language learning and subject learning approaches.

Globalization directly influences economy's needs; a global economist must be able to easily cross national and cultural boundaries. This in turn directly affects economic education. A common code for communication is required. Those education institutions, which meet the language requirements for the new global economist, will be ready to face the new millennium.

H.P. Jensen states that employers want:

a number of new competencies, with an emphasis on an increased ability to communicate...and good foreign language skills [2].

There is a clear necessity for effective foreign language communication skills for economists in the current globalised environment. A course in Languages for Specific Purposes (LSP) will enhance foreign language training and an economics student's communication skills. It will also aid in the globalization of education and the internationalisation of practicing economists. The foreign language (especially English) has become a major medium for communication across borders globally; a deficiency in this area may result in barriers for graduates' personal and professional development. LSP focuses the learner's attention on the language and communication requirements in a particular professional field. The concept of LSP achieves more in the education of economics students by focusing the learner's attention on the particular terminology and communication skills required in the professional field. Various examples in the economics field can be found, including **corporate speak**, **business speak**, **management speak**, **workplace jargon**, or **commercialese**.

3. Communication Skills

Teaching foreign languages to economists is a delicate and demanding matter in terms of content, methods and techniques, and deciding which are appropriate for this particular area of economics and a foreign language. That is, the aim in such an interdisciplinary course is to develop and

master relevant communication and professional skills, using a foreign language as a means and a kind of mediator in shaping future economists.

To achieve this goal, LSP teachers have to plan the course they teach and provide the materials for it. Rarely is it possible to use a particular textbook without the need for supplementary material, and sometimes no really suitable published materials exist for certain learners' needs. The role of LSP teachers thus involves choosing suitable published materials from a variety of reliable and valid sources, adapting materials when published ones are not suitable, and even writing new materials if nothing suitable exists.

An analysis of literature shows that oral communication has been identified as a *learnable skill* [3]. Furthermore, communication skills development has been demonstrated through the use of various methods, such as class discussions and others. While the study of famous speeches, learning oral communication theories and techniques from textbooks will still be beneficial, it should be noted that the literature has indicated that experiential methods have generally yielded better results than purely didactic means.

Presentations

The student's knowledge base is amplified by allocating class projects for presentations. However, students will not place any great emphasis on presentation, and with it oral communication skills, if presentation and communication is not allocated a significant share for the exercise's marks. Furthermore, as much as many students dislike giving presentations, it is better that they experience a *dry run* in their education than to be suddenly confronted in the workplace. Group projects and presentations encourage and enhance the interpersonal skills of the student members and should be emphasised early in the education curricula. This should be considered in particular as teamwork is recognised as a core skill in economy, and communication with team members needs to be effective.

Role-play

It is very important for the students to be immersed in simulated work environments. Students' attention can be focused by means

of context-specific enactments or role-play, in possible future work situations, thus engaging them in active learning just *by doing*.

It is important to use pseudo environments to simulate meetings with clients/developers/peers/etc, as this will also allow students to interact with different levels of business communication, as well as engaging in non-verbal communication. Oral communication skills are needed not just for internal company matters, but also when dealing with external issues.

Video

Video/audio grading dramatically improves presentation skills in students. For example, student presentations can be filmed and then graded with dubbing from the teacher and a feedback sheet [6]. Importantly, this provides pertinent educational feedback to the student so that he/she can actually see and hear the positives and negatives of his/her presentation. Additionally, it is not momentary as the student can revisit his/her performance.

According to an Irish study, instructors in communications need to review and update methods due to the rapid advances in communications technology [4].

International Elements

Communication skills training, while focused on the dominant culture of the host university's country, should also take into consideration variations in intercultural communication. With globalisation becoming commonplace, graduates need to have an understanding of international communication. This includes aspects such as implicit language and cross-cultural idiosyncrasies, or risk being isolated, and is particularly relevant in dealings between native English speakers and non-native English speakers.

Active Involvement of the Learner

Littlewood explained several elements that help the learner reinforce learning. These four parts are:

- The classroom must be conducive to communication and learning.
- Learning has to be relevant to learners' interests and needs.
- Both processes and products are important in the classroom.
- Learners must engage in active roles in the classroom [5].

Engaging learners will help assist and stimulate successful and purposeful learning by the students. Involving the learners directly, in particular, will bring about a stronger sense of responsibility in the future graduates that they can take beyond the university and into the work arena. This is especially important in engaging learners of a foreign language as a Second Language (ESL) and Languages for Specific Purposes (ESP) as it involves new vocabulary.

The Fun Part in Education

Economics education involves a great deal of stress rather than fun. Many students fail to turn up to classes because they ultimately become displeased with the manner of the lectures, strongly suggesting that the students fail to see the relevance of attendance and, at times, the relevance of the topic being taught. Many economics students are not especially motivated to learn certain subjects, primarily because they have no real idea why they may need all this information. They also do not know whether all of the material is actually required for their career.

Team-teaching Co operations

Team-teaching cooperation between a subject expert and a foreign language teacher can be employed for the benefit of learners who will make the most of this integration. Overseas experience already indicates that the synergy from team-teaching can significantly improve the written and communication skills of most students, particularly oral presentations and report writing, and that it generated a positive experience for all with a focus on students' needs and interests.

4. Communication Skills Assessment

Nowadays, the didactics of foreign languages is completely modified by new fundamental factors: the multilinguistic competence as well as the cultural aspects of the linguistic competences. We are actually present at the *unavoidable re- composition of the evaluation background*. The scientific researches of the evaluation go through this meaningful and promising development. We take into account three orientations and this competence which represent a real challenge as well as a new aspect which the new type of evaluation should highlight: the actual

linguistic aspect, the multilinguistic and social cultural aspects.

Due to this new type of portfolio, we can experiment *an evaluation based on positive criteria*, thus allowing being evaluated what the student is able to do at the levels of understanding, production, interaction, cultural mediation. This first change is the *indispensable key of the new evaluation of competences*. All these criteria are strongly related to the cognitive capacities and thus, to the complexity of the attitude adopted by the student.

The second point of view is related to the notion of obligation and in this respect refers to *an evaluation of scenarios*. It is not a question of evaluating only the language but also the originality of the attitude towards the language and personal resources, i.e. the strategies used by teachers for the success of the didactical act.

The third point of view is related to the evaluation of the multilinguistic repertoire as well as the aspects of cultural mediation.

The types of written papers, the consigns, the questions will be thus oriented so that each of them should have its own subject individualizing the exam in its technical profile. An entire multitude of questions addressed to the economics student is taken into consideration, so that he/she could evaluate himself/herself. In this respect, there is a series of common questions which can be asked either by the teacher or by the student:

- What is being evaluated?
- Which are the communication competences which are taken into account in the first year of studies for the specialized languages?
- Which is the bilingual repertoire?
- What should the competences of the cultural communication contain?

At the common questions we could add those which regard only the student and in this case we only deal with two categories of students:

- the first category is formed by students who study foreign languages for two years in order to learn the specialized terminology and to obtain a certificate of linguistic competence necessary for the final degree exam.
- the second category, of course less numerous, is formed by students who want to go abroad for a time of probation through

ERASMUS/SOCRATES scholarships and who are interested in a pragmatic vocabulary: How to find a place to live in? How to open an account? How to choose courses?

For the socio-linguistic aspect it is necessary that the teacher should take into consideration these *markers* of social relations which regard the different situational aspects (introducing oneself, a personal CV, a letter of intention or candidanship). We will take into consideration three domains:

1. the concrete domain of the daily life, in which students should know the everyday language (in the subway station, the secretarial office of the University, student hostel, etc.).
2. the specialized domain: each authentic situation in different contexts, in a bank, a telephone conversation, expressions which can represent real obstacles. There is a specific vocabulary for each situation (Le Rip for the banking domain, RU for college).
3. the familiar domain is strongly related to the socio-linguistic competence cited above and these words are enough present in the French and English vocabularies and their acknowledgment can represent an obstacle for the comprehension of the language.

That is why the training of these students will take into consideration their orientation towards the completion of complex vocabulary for an oral examination, in which we can use multiple audio-visual ways such as recording cassettes, didactical films, as well as self-recordings as a way of self-correction of their own mistakes and self evaluation.

The attestation

The questions which can be put to candidates will refer to their own status, studies, fields of interests, and their future profession. The evaluation will be done according to the evaluation chart with a mark schedule. The examiner writes on this evaluation chart the final mark which corresponds to the different criteria.

The first test

Examples of questions:

-Have you ever worked in a firm in the domain of your study? (Are you working at present?)

-Where and in what kind of a firm?

-What is/was your job about? What do you actually do?

-Which are the fields of interest?

-Are you a member of an association?

-Do you practice sports? Do you like music? How do you spend your free time?

-What kind of a future job do you wish to have? Which are the main reasons? Is/Will be your job difficult? Why?

-What skills are necessary for this specific job?

-What skills do you possess?

-What kind of advice would you give to someone who wants to work in this field?

-Are foreign languages useful in your job?

-Do you think it's important to know one or two foreign languages in order to succeed in the professional life?

-Do you like to work alone or as a part of a team?

-Which one of the following do you prefer: a small of a big firm?

-Which place do you prefer: office, house, abroad, your own country?

-What about the work program: regular hours, variable hours, weekend hours?

-Give a reason for your motivation!

-Which is your main interest in a job?

-Remuneration?

-The interest and the use of work?

The second test

This can be related to a **simulation interview** in which the candidate meets bilingual collocutor, the examiner who wants to know an aspect of his/her country, starting from a document *written in the mother tongue*. The candidate should offer information about his/her country, region, town, and answer a few questions, give suggestions about the social and economic aspect and be able to speak about the social climate.

The climate for the objectives of the foreign languages study has risen in the past twenty years and we can also notice an intensification of the didactics and

Methodists studies over evaluation. Indeed, in order to evaluate each teacher we should compare the objectives with the results. At the end of the 87s Sibylle Bolton publishes a book on evaluation. According to this study, the learning objectives must be defined as *behavior objectives* which mean that the tests must take into consideration the factors which influence the language behavior. Even though they could not be named by this generic term, these objectives can only be communicative.

In her book *Evaluation*, published in 2001, Christine Tagliante highlights these objectives underlying the specific importance of the general objectives “they are centered on the *learner* and they indicate in the ability terms, the final results of the course of a single unit of a course of a map shot.”

Communication skills have been identified as multidimensional and so it becomes crucial to classify how they will be assessed in the students' work. Furthermore, the particular communication skills required in a profession are usually poorly defined. One study identified that communication skills assessment must:

- Be formal so that it occurs at specific times and contributes to a student's marks.
- Provide feedback to be educational.
- Involve active participation by students in actual communication situations.
- Tackle student insights so that skills are identified and developed [6].

Individual feedback is important for improving the education of students. However, there needs to be prudent identification and clear operational definitions of the rating dimensions so that the same standards are applied to all students: consistency and accuracy. It is vital that the student understands what is expected and what will be assessed ahead of time to facilitate education, learning and the generation of desirable characteristics, thereby delivering formative (feed-back) and summative (evaluation) assessment [6]. The oral communication element also needs to fit in well with the subject at hand.

5. Conclusions

Language and communication skills are recognised as important elements in the education of the modern economists,

including language for specific purposes. Yet, there seems to be limited implementation of foreign languages courses globally, despite its current *lingua franca* status. Those institutions that have already implemented multilingual and communication elements will be at the forefront of providing the demands of economy and society.

The incorporation of several components of the fundamentals of emotional intelligence in education will facilitate advanced communication skills.

The incorporation of language and communication improvement courses is an important element of continuous learning, and will ultimately contribute to the process of life-long learning.

The Evolution Of Romania’ Foreign Direct Investment During The Current Crisis Period

Mițac Mirela Claudia

Ovidius University of Constanta, Faculty of Economics Sciences

mirela_mitac2002@yahoo.com

Abstract

In a world of increasing globalization, where political, economic and technological barriers are rapidly disappearing, the ability of a country to participate in global economic activity is an important indicator of its performance and competitiveness. In order to remain competitive, modern business relationships extend well beyond the traditional foreign exchange of goods and services, increasing reliance of enterprises on mergers, partnerships, joint ventures, licensing agreements, and other forms of business cooperation realized through foreign direct investments.

Because of the globalization phenomenon the foreign direct investments flows can vary considerably from one year to another, as they are often influenced by large mergers and acquisitions and also by economic development of each country.

In this paper is presented the evolution of foreign direct investment in Romania during the current crisis period, which started in 2008 and their impact over the exports and imports of foreign direct investments enterprises.

Key words: foreign direct investment, crisis, trade, economic activity

J.E.L. classification: F21.

1. Introduction

Foreign Direct Investments (FDI) may be seen by the economists as an alternative economic strategy, adopted by those enterprises that invest to establish a new plant, or alternatively, purchase existing assets of a foreign enterprise. These enterprises seek to complement or substitute external trade, by producing goods and

services in countries other than where the enterprise was first established.

There are two kinds of FDI: namely, the creation of productive assets by foreigners, or the purchase of existing assets by foreigners (for example, through acquisitions, mergers, takeovers). FDI differs from portfolio investments because it is made with the purpose of having control, or an effective voice, in the management of the enterprise concerned and a lasting interest in the enterprise. Direct investment not only includes the initial acquisition of equity capital, but also subsequent capital transactions between the foreign investor and domestic and affiliated enterprises. [Eurostat]

2. The situation of the Foreign Direct Investment on European Union (EU)

Due to the statistics, provided by Eurostat, the foreign direct investment for the European Union - 27 in relation to year-end stocks, annual flows and income results that foreign direct investment flows experience recovery in 2011 after a downturn in 2008-2010. (see below table 1 and table 2).

Table 1. Outward FDI flows of EU-27

-eur 1.000 milion-				
Year	2008	2009	2010	2011
Region:				
Extra EU-27	383,5	316,5	145,6	369,9

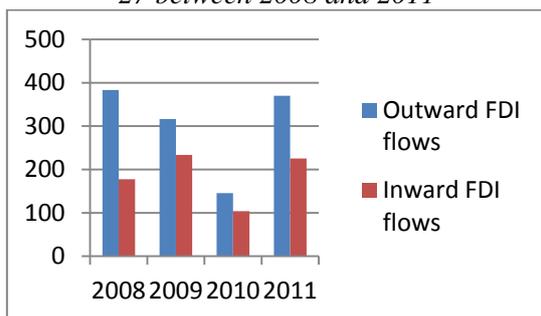

Source: Eurostat (online data code: bop_fdi_main)

Table 2. Inward FDI flows of EU-27

-eur 1.000 milion-				
Year	2008	2009	2010	2011
Region:				
Extra EU-27	177,7	233,6	103,9	225,3

Source: Eurostat (online data code: bop_fdi_main)

Figure 1 The evolution of FDI flows on EU – 27 between 2008 and 2011

Due to a Eurostat research covering the period from 2008 to 2010, EU-27 foreign direct investments flows were largely affected by the global financial and economic crisis. The peak of the negative impact of crisis was in 2010, when both outward and inward flows of foreign direct investments halved when compared with the previous year.

In 2011, EU-27 foreign direct investments flows showed signs of recovery following the recent financial and economic crisis started in 2008, both on outward and inward flows.

Outward flows of foreign direct investments increased in 2011 for the first time in four years, rising by 154 % when compared with 2010, which may reflect the start of a global economic recovery.

At the same time, *inward flows* of foreign direct investments also more than doubled compared with the previous year up 117 %.

But, despite the large increases in EU-27 foreign direct investments flows in 2011, these gains only partially compensated the considerable declines that were recorded during the crisis (2008 to 2010). As a result, EU-27 foreign direct investments flows with the rest of the world still remained, in 2011, well below their record peaks of 2007 for both inward and outward flows.

3. The situation of the Foreign Direct Investments in Romania between 2008 and 2011

3.1. The evolution on Foreign Direct Investments stock in period 2008 - 2011

The National Bank of Romania published, on regularly basis, the FDI statistical survey, which was compiled based on the

International Monetary Fund Balance of Payments Manual, 5th edition.

The value of total FDI stock at the end of the year is calculated by adding to the initial net FDI stock the positive/negative value differences arising from both revaluations – following the change in the exchange rate and some asset prices – and accounting restatements of the initial stocks of some reporting enterprises and equity stakes, reinvested earnings/net loss and net credit from investors by FDI enterprises' activity.

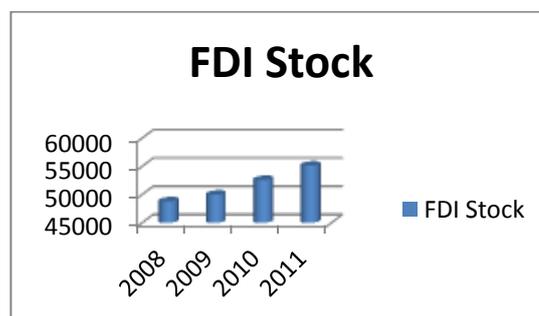

The evolution of FDI stock between 2008 and 2011 is presented in Table 3 and Figure 2.

Table 3. The evolution of FDI stock between 2008 - 2011

EUR million				
Year	2008	2009	2010	2011
TOTAL	48.798	49.984	52.585	55.139

Source: www.bnr.ro

Figure 2 The evolution of Romania's FDI flows between 2008 and 2011

Source: www.bnr.ro

In Romania, the evolution of FDI flows was ascendent, in period 2009 – 2011, after the downfall from the beginning of 2008. As of year-end 2011, final FDI stock came in at EUR 55.139 million, up with 4,90 percent from end-2010, up with 10,31% from end 2009 and with 13,00% from end 2008, what show a certain recurrence in investments flows.

3.2. Foreign direct investments stock by country of origin

Another important statistics made by the National Bank of Romania' surveys is the distribution of FDI took into account the country of origin of the direct holder of at least 10 percent in the resident direct

investment enterprises' share capital on an “immediate country basis”. [1]

Top 10 countries by the share of total FDI stock as at 31 December is presented for every year in the analysed period (end 2008 – end 2011), in Table nr. 4.

Table 4. Foreign direct investment in Romania by country of origin end 2008 - end 2011

EUR million

Others	8.746	16,7	Others	8.832	16,1

Source: www.bnr.ro

In this top 10 range it could be observed the importance of The Netherlands, who took the first place in period 2009 – 2011, replacing Austria, who kept the first place in 2008, (respectively 21,7 percent in 2011, up from 20,7 % at the end of 2010, nearly equal to the percentage from 2009 when grew with 3 percent from the quota held at the end of 2008).

Top 6 countries by the share (at least 5%) of total FDI stock in almost all examined period are: the Netherlands (21,7% in 2011, 20,7% in 2010, 21,8% in 2009 and,

respectively, 17,2% in 2008), Austria (17,5% in 2011, 17,8% in 2010, 18,1% in 2009 and, respectively, 18,8% in 2008), Germany (11,4% in 2011, 12,2% in 2010, 13,4% in 2009 and, respectively, 15,4% in 2008), France (9,1% in 2011, 8,3% in 2010, 8,5% in 2009 and, respectively, 8,8% in 2008), Italy (6,1% in 2011, 5,3% in 2010, 5,1% in 2009 and, respectively, 6,5% in 2008) and Greece (5,3% in 2011, 5,7% in 2010, 6,6% in 2009 and, respectively, 8,8% in 2008).

3.3. Foreign direct investment stock distribution by development region

Another important distribution of FDI made by National Bank of Romania is by development region (evolution for the period 2008 – 2011 is presented in Table nr. 5), but, the analysis of regional FDI dispersion should also take into consideration that the statistical research located FDI by registered office, which is not always the same as the business place.

From a territorial point of view, FDI went mainly to Bucharest-Ilfov region (over 61 percent in all years), other development regions benefiting from significant FDI inflows being CENTER region (over 7,4% in all period, and 8,5 percent in 2011), SOUTH-EAST region (more that 5,4% percent), SOUTH-MUNTENIA region (over 7 percent) and WEST region (over 5,4 percent).

NORTH-EAST region is the least attractive to foreign investors, having only 2,9 percent of foreign direct investment in 2011.

Table 5. Foreign direct investment in Romania in period 2008 – 2011. Stock distribution by development region

EUR million								
Year Region	2008		2009		2010		2011

3.5. FDI stock by main economic activity

By economic activity, the majority of FDI went to industry (over 41% of total FDI in all years and in 2011 – 44,4 percent of total). Other activities that have attracted significant foreign direct investment are financial intermediation and insurance, which include banks, non-banks and insurance companies and account around 20 percent of total FDI stock in period 2008 - 2011, construction and real estate (more than 10 percent), trade (over 12 percent) and IT and communications (more than 5 percent).

Table 6. Foreign direct investment in Romania in period 2008 – 2011 Distribution by main economic activity

3.6. Exports and imports of FDI enterprises

The overall activity of foreign direct investment enterprises had a positive impact on Romania's trade balance, contributing, every year, with more than 69 percent to total exports and with more 60,1 percent to total imports.

The export/import activities of FDI enterprises refer to companies investigated exhaustively (over 20 employees) by the National Bank of Romania. Export/import data economy-wide, taken into consideration in determining the relative size, are reported by operators having exceeded the reporting thresholds for 2008 - 2011 set for Intrastat

declarations.[1]

*) excluding exports and imports of NACE divisions: 84 – Public administration, 97/98 – Household activities and 99 – Extraterritorial activities

Note: Exports and imports are aggregated by the activity of companies, according to NACE Rev. 2.

4. Conclusions

During the period 2008 to 2010, EU-27 foreign direct investments flows were largely affected by the global financial and economic crisis. In 2010, both outward and inward flows of foreign direct investments halved when compared with the previous year.

In Romania the foreign direct investments flows, were, also, affected by the current crisis, the recovery was a more rapidly than the recovery of the foreign direct investments flows of EU-27.

All the figures for 2011, presented in Table 1. to Table 6 show signs of a recovery of foreign direct investment in EU-27 (both outward and inward) and in Romania (inward).

The overall activity of foreign direct investment enterprises had a positive impact on Romania's economy after the beginning of crisis in 2008, and especially over Romania's trade balance (industry and trade having an important role), contributing, every year, with more than 69 percent to total exports and with more 60,1 percent to total imports.

In my opinion, taking into account, that the country of origin of the direct holder of Romania' Foreign Direct Investments are members of European Union and that the European Union economy started to recover from the current financial crisis, the volume of foreign direct investments made by European Union member states in Romania will increase in the next period, with positive impact on the future Romania's trade balance.

The increasing of foreign direct investments stocks in Romania will have, also, a positive impact over the development of Romanian economy taking into account that in the past the foreign direct investments flows were made, mainly, in industry (with over 41% of total volume of foreign direct investments made in Romania), in trade (with over 12% of total volume of foreign direct investments made in Romania) and in financial intermediation and insurance (with over 18% of total volume of foreign direct investments made in Romania).

Figures of Speech in Legal Rhetoric

Popa George Dorel

Faculty of Law, Administrative Sciences and Sociology

„Ovidius” University, Constanta

popageorgedrd@yahoo.com

Abstract

Rhetoric is a complex science that headlines in social sciences system for over two thousand years. Conceptual reflections and practices in the field of "rhetoric" with obvious multi and interdisciplinary character existed from the beginning of the law and politics. We could start the analysis of the definition of the rhetoric with the famous ancient thinker Aristotle who, in his famous work "The Rhetoric" shows that rhetoric is "the faculty of discovering the specific procedures (rhetorical ones) which in each case is unique, in order to convince the listeners.

Key words: rhetoric, figure of speech, orator, listeners;

JEL Classification: Law and Economics General; K 19;

1. Introduction.

Each speech, in order to be convincing and to have persuasive power must include a set of norms, rules and techniques that will be found in all eras of humanity. A special place in this system has the reasoning techniques. Action argument is to show (prove) and its outcome. Using other words, action argument consists of all the arguments made in order to support a claim. Argument is obviously a part of rhetoric, but throughout history the two elements - rhetoric and argumentation - were often separated and studied by specialists. This theoretical separation was due for a long time (since antiquity to modern times) and the fact that rhetorical theorists have been concerned with the formal aspects of oratory. Classical period brought significant changes in this area. Another important issue in this respect is the problem of the audience. The people

which is addressed the speech of the speaker is a crucial element. Rhetoric, according to the specialists in this domain, is addressed to people having high education but also to people without training. In this regard, it is a huge difference between juridical rhetoric and scientific discourse. For juridical rhetoric the best audience is average audience. But even it may be ideal audience, the argument would be in principle just as rigorous as a scientific demonstration. Exact sciences exclude speech figures, pathos and other language strategies. In fact, in most many cases, the speaker is forced to take account of subjective character of his audience, to persuade. Therefore have to separate the concepts of argument and demonstration. The concept is a chain of reasoning, linked necessarily by its author (see demonstrations of math etc). It is very rarely possible to prove something in mathematics or exact sciences than to implement these elements to rhetoric. In reality, very often the orator chooses to stage their arguments based on a strategy to captivate and persuade the public.

Speech is always largely subjective. While is not necessarily manipulative, he is always rhetorical, tending to persuasion, either because want to educate the public (if pedagogy), or because there is an antagonism within the dialogue (if it is judiciary rhetoric), or at least some divergence of opinions. It is hard to measure the effectiveness of a speech when recipients are numerous. In this respect, sometime are used polls. Rhetoric as science was controversial since antique Greek. For example, the rhetoric has been banned in the Greek city of Sparta. Even in the city of Athens hadn't the best situation. The practice of rhetoric was allowed but not exhaustively. There have been many theories and against the science of rhetoric. Rhetoric is sometimes underrated as a science. This situation exists because it is considered that it adds nothing new to the

process of knowledge. Furthermore, some theorists consider that rhetoric distorts reality. Thinking is a proper attribute of each human being. Human communication has a subjective character and distorts sometime the reality. Therefore according to some theory, rhetoric and rationality should be totally separate. This theory, however, is not currently total supported by everybody. This is because there are many specialists who appreciate the rhetorical functions. Often, during a presentation or a good speech, speaker led to the clarification of ideas and viewpoints explanation using rhetorical techniques. Often the rhetoric has been criticized because it is a tool that can in any way distort fair presentation of the facts. A speaker can distort reality through deliberate selection of details that serve to a point. Moreover, the speaker may omit some important issues in order to achieve their own goals at the expense of truth. Undoubtedly, if a speaker has an intentionally false view, we are dealing with an ethical issue and for that exists the personal responsibility. An interpretation takes place in any discourse, public speaking or presentation. This interpretation is inevitable. It is primarily the personality of the speaker involved in the discourse. It will have a preference regarding the selection of topics that are discussed. During the speech will proceed to a certain arrangement and will address in a particular style. This style is unique to each speaker due to the personality. In addition, each speaker has a tendency to explain certain phenomena or words in his way. This is because every man has his own baggage of knowledge or system of values. Evaluation criteria surrounding world differs from person to person. Therefore, rhetoric can sometimes be deeply subjective and can warp reality.

2. Rhetorical figures and their importance in the art of oratory.

Rhetoric art, including legal rhetoric to achieve their goals uses several types of techniques and specific methods (own methods). The figure of speech used in rhetoric begins to be appreciated as an ornament of language, though often this ornament is part of a well-structured speech. Among these techniques stands out the most important techniques, so-called “rhetorical

figures”. Even if it is a formal and brief analysis we find out the existence of three types of figures:

a. Construction figures are different from all different figures and refer especially to syntax and word location. Among numerous existing figures from dictionaries and treatises, is important to refer to the most important.

b. Figures of meaning, some of which are called "tropes" have as main purposes to multiply and amplify the meanings of a word using it in a different context than in usual situations.

c. Figures of thinking carry their wider elements of enunciation and professionally using of the complex phenomena of thinking in composing a well-structured argumentation.

3. Figures of words as part of figures of meaning.

In the analysis, even if it is a summary figure, there are figures of meaning, refers to the replacement of words in semantic purposes. Neologisms are words in a language borrowed recently from another language or recently created in that language by its own means. Creations serve to fill some of the gaps in dictionaries of different areas. To talk about neologism, word must have clear novelty elements otherwise we cannot discuss about a neologism. Neologisms are designed to impress people who are part of the auditor. Sort of the antithesis, archaisms are words or phrases with no usage at the time being. The use of archaisms and neologisms in speech involves the use of old or new words or phrases that are not used every day. The intention is clearly to impress and surprise audiences with terms or phrases with medieval or classical “color”. Using of these kinds of words is dedicated to the people with a great culture. Used by a speaker in excess may create a snobbery impression.

4. Figures of meaning (so called tropes).

The term "trop" comes from the Greek word “tropos”, which has the meaning of conversion, change the meaning of a term [1]. Basically, this conversion is aimed at reversing, changing the meaning of a certain

word. In other words, tropes are procedures to replace a word or a set of words, with another term or another expression. The main form that appears "trop" within a speech is metaphor (figure of speech which arises by implied comparison by replacing the word object of comparison). In fact, the comparison is often used by orators and lawyers in their efforts to convince the auditors. This is a figure of meaning without being considered the most important figure. Meaningful comparison is not very sharp and full subjectivity as in the metaphor itself. Statements in the front of judges such as "under the influence of extreme emotion defendant acted like a robot" or "the evidence presented by the prosecution is like a sand castle" provides images that can be easily identified by their color and which may influence the judges and the crowd and can lead to desired results by speakers.

Metaphor is more subtle and more powerful and lead to strong emotions that can be exploited for the benefit of speakers. The same effect occurs when the prosecution lawyer said in court about the accused person charged with the crime of family abandonment that "Mr. Smith, who was in front of you, has a heart of ice." In this case, the lawyer starts from the fact that ice is cold and by this analogy judges who compose the jury must perceive a lack of sensitivity and humanity of Mr. Smith, who has no feelings for the family that he left.

Although not directly related to classical rhetoric, the image or the symbol may be used for rhetorical purposes. Symbol or emblem is often used to achieve different goals. Use of the symbol and emblem consist in metaphorical representation of an object or a sign. Justice is often represented by a balance, metaphor with direct reference to the notion of justice. Similarly, a heart pierced by an arrow showing love, while a hand with two fingers rose in the form of the letter "V" stands for victory.

5. Figures of intensity – amplification and euphemism.

Amplification - very often, the orators tend to increase different adjectives in their speeches [2]. They are using, hyperboles (exaggerations and emphasis), both to glorify, as well as to depreciate a person or a

situation. Hyperbole is a figure generally considered a bit difficult and exist a real fear in using it. Hyperbole particularly characterizes language of the snobs, using precious speeches of past centuries. Thus, adjectives such as "formidable", "great", "awesome" or "fantastic" or even exasperating repetition of "super" are now considered unbearable. To qualify somebody as "brilliant" or "total zero" highlight real limited spirit and a real poor vocabulary rather than a figure of speech having success among listeners. A student asking "Sir, please help me to pass this exam, because I am dead cold, the cold makes me suffer like a martyr and drove me crazy in the last week" will lead to the opposite result. There are a plenty of hyperboles that go up to impossible and the unreal situations and will be useless in the effort of a lawyer to win "the heart of judges". So, phrases such as "my client is an Angel and her husband is the Devil himself" or "is not the fault of my client that the car accident happened because maybe he consumed some alcohol but the fog that night you could cut it with a knife", will definitely lead to opposite results.

Euphemism or significant attenuation is other figures distinguished by the fact that dilutes the shocking elements, crude or ridiculous of an idea. According to most dictionaries, euphemism is a word or expression in speech or in writing, replacing a word or phrase unpleasant, offensive, indecent or obscene, respecting the parallelism of meaning. Function of euphemism is to avoid contradiction, taboos and conflicts. For experienced lawyers, there is never a situation "extremely damaged", but a "serious" no "strikes", but "social conflicts", no "prison" but "places of detention" nor "thief" but "person convicted for theft", "trafficking of influence" but "lobby". Euphemism is used to eliminates fear or unnecessary conflicts and generally to remain courteous and cautious.

6. Conclusions.

Beyond these means and methods, rhetoric must be understood in its true scientifically sense. In all social orders, all ages and all political regimes, power of the word inspired respect and very often fear for dictators and tyrants. Activities of the

speakers' endowed with the gift of speech was carefully monitored by rulers of the times. In all regimes without democracy and respect for universally recognized values, gifted orators actions were sometimes appreciated as subversive and dangerous [3]. However, even if often been blamed or illegal, the rhetoric has been and will continue to exist in various forms. It will be used to achieve the various goals - to win the political battle to persuade and manipulate the masses or to disseminate the values of humanity.

Local Police in Romania

Popa George Dorel

Faculty of Law, Administrative Sciences and Sociology

„Ovidius” University, Constanta

popageorgedrd@yahoo.com

Abstract

Safety and public order in each country from Eastern Europe has suffered, after the collapse of communism significant changes, specific to the transition to a democratic society where the rule of law, citizen rights and freedoms are guaranteed. Romania took part at this international process after 1989. In the context of globalization effects, the present world faces a pronounced mobility of people, capital flows, trade and information. All these processes have led to benefits and positive developments, but also the emergence of new threats to the rule of law and human rights. In this context, the appearance of the local police is an important step forward. It is important that in future, the Romanian state more clearly define the tasks of institutions and agencies with responsibilities in the field of public order and safety. This process would essentially help to remove duplication and double competences in the case of many institutions.

Key words: local police, law, order, public safety; law enforcement bodies;

JEL Classification: Law and Economics General; K 19;

1. Introduction.

Romania suffered multiple changes and modernization in the legislative domain, harmonization with the EU legal system after the collapse of the communist system. Sometime the modernization of the system brought few inconveniences and shortcomings. Often, civil society, the media and even ordinary citizens observed multiple controls carried out by the state agencies have conducted at one and the same company, not necessarily in malicious way.

In this context the "gaps" in existing Romanian legislation and often changing the law on public order and safety bring serious disservice to the state institutions and the ways perform their tasks. There are few cases in which, within a few years, basic laws in daily activities of state institutions urged to ensure public order and security have undergone significant changes.

2. Purposes, tasks and principles of the local police in Romania

Local police are established in order to protect the fundamental rights and freedoms of individuals, private and public property, prevention and detection of crimes and other antisocial acts (petty offenses). According to local police Act, this police force is operating in the following areas [1]:

- a) ensure public order and safety and security of public and private property;
- b) monitoring the traffic on public roads;
- c) control of the construction discipline and control over the outdoor advertising;
- d) environmental protection in the area of responsibility;
- e) the manner in which street commerce is carried out in the area of responsibility;
- f) the registration of the citizens;
- g) any other fields determined by law.

Activity carried on by local police on a daily basis is conducted on the basis of well-established principles of law:

- the principle of legality, is the principle that all activities are conducted by the local police based on law.
- the principles of trust, is the principle that in everyday life, as a provider of public safety, local police should attract the sympathy and confidence of the citizens.
- the principles of predictability, is the principle that local police activity can be anticipated by the community. As well, the activity is conducted based on public

expectations and requirements, depending on the evolution of the operational situation in an area.

- the principles of proximity and proportionality is the principle that compel local police activity to be located in the "vicinity" of the citizen having as main goal meeting of the public request. Proportionality refers to the need, the volume and intensity of activity to be harmonized with existing operational situation at a given time in a given area.

- the principle of openness and transparency, and quality refers to actions taken by local police to be easily known to the general public either directly or through the media.

- the principle of efficiency and effectiveness, requires that local police actions have maximum results, desired by the community, in terms of volume, limited only by human and material resources.

- the principle of responsibility and accountability, requires a high sense of civic attitude. Local police should perform their duties considering permanent legal and social effects of his actions, which must be in compliance with the law.

- the principles of impartiality and non-discrimination refers to impartiality, objectivity and equal treatment of all who come in contact with local police [2].

Local Police operates daily in the interest of the local community, and based solely on legal provisions of the Romanian law. Moreover, regulation of the executive authority of the local public administration is the main "sources" of actions and measures undertaken by the local police in performing its tasks set by law. Moreover, each local police must operate in accordance with the regulations specific to each domain. Local police actions are set by administrative actions in local and central public administration authorities.

To fulfill the duties specific, it is preferable that each local police to be established by each city hall taking in account the establishment of an adequate number of general directions, directions, services, offices and departments. All the organization way is determined by the number of citizens, the existed problems of and not last taking into account the financial possibilities of each city hall. It is essential

the opinion of the local Public Order Commission - the entity that directly manages issues related to maintaining public order and safety in each administrative area. In the course of their daily activity the local police may face situations beyond their legal competence. In this case, the local police officers are obliged to communicate immediately to authorized institutions the identified situation (the report will be addressed to Romanian police, prosecutors' offices, etc.) The report of the local police officer will refer to data and information related to the violation of law which acknowledged while performing daily tasks and activities. Act no. 155 from 2010 concerning the local police, expressly states that "in the exercise of its duties, local police cooperates with national police units, respectively territorial structures of Romanian Police, the Romanian Gendarmerie, the Border Police and the General Inspectorate for Emergency Situations". Local police cooperates with other central public administration authorities and local governmental organizations and with individuals and companies under the provisions of law". Moreover, in special circumstances, local police may expressly request the intervention of the competent territorial units of national police or Romanian Gendarmerie (county police inspectorates, mobile gendarmerie or brigades of gendarmes etc.) For any situation that is beyond the jurisdiction or responsibility of local police this force might "call" for the help of appropriate law enforcement body. According to the needs and peculiarities of each area, local police can conclude with other authorities and institutions protocols of cooperation or collaboration (e.g. county school inspectorates, environmental state units, the State Inspectorate in Construction etc.). These protocols come to support the institutions and obviously bring benefits for the community. Signed protocols will be established and will create concrete ways of cooperation with national police and other institutions that is offering support to local police in performing specific tasks or activities. Moreover, the continuous exchange of information between abovementioned institutions, continuously providing of the specialized assistance in

specific cases and supporting each other in certain situations, substantially increase efficiency of the activities of these institutions under conditions of decreasing costs.

3. Organization and function way of the local police.

According to Law no. 155 of 2010, local police are organized and function through local authority decision as a functional compartment within specialized apparatus of the Mayor or General Mayor (in the case of the General Mayor of Bucharest) or public institution local interest, with legal personality. Romanian legislator agreed to let the local authorities to organize local police as the entity with its own legal personality or as a specialized compartment within the apparatus of the Mayor.

If we are speaking about the capital of the country, the law stipulates that local police will be organized by a decision of the General Council of Bucharest (in terms of the local police of Bucharest) and the decision of each territorial sector of the capital (local police to be set up in each sector).

A local police officer can be detached from one unit to another. Posting can be done under the conditions mentioned in the resolutions adopted by the respective councils, taking into account the agreements between the administrative-territorial units. By law, administrative-territorial unit that supports local police officer will conclude written agreements with each administrative-territorial unit receiving these local police services. To avoid any interruptions of a financial nature, administrative and territorial unit that detaches police must specify clearly in the local budget funding sources for these police officers detachment. In this way, will be avoided any financial inconvenience for the local police officer and for the local police unit.

Specific powers to local police

1. His duties in the field of public order and safety, and the guard movable and immovable state property or private property. Local police have powers in commercial and recreational areas (shopping malls, large shopping centers, holiday villages, amusement parks, etc.), In parks, squares, cemeteries, and also other public places.

These responsibilities are set out in the plan of public order and safety, according to the Romanian law. This document is a key element in organization and function way of each local police unit. Normally, this plan should be thinking out annually taking in account the opinion of each local authority.

2. In the field of traffic on public roads, local police have a number of responsibilities. The local police control the conditions and integrity of the traffic signs (signs, traffic lights, road markings). Immediately inform the local authorities about irregularities on the proper functioning of traffic lights, signs and road markings situation.

3. In the area of building discipline and billboards. Local police carried out checks and controls to identify unauthorized constructions or buildings under construction or under demolition process. Local police should monitor permanently the situation of provisional or temporary buildings.

4. In the field of environmental protection, local police have a number of responsibilities [3]. Local police will check how the legal provisions in force regarding procedures for lifting, transporting and storage of household and industrial waste are followed in the area of competence.

5. In the field of street commerce, local police has a number of attributes control concerning how marketing activities are conducted by individuals and companies.

6. In the area of records of people, local police have power to establish contraventions and apply sanctions (fines or warnings) to the persons who do not comply with the legal domicile, residence and identity documents.

4. Other specific function way of the local police in Romania.

Local police which is structured in functional departments with responsibilities in the field of road traffic concluded protocols with the database administrator [4]. In this way is provided necessary technical and personnel training for this work, in order to bring the database imposed penalty points due to the detection of road to driving offenses. The local police implements the measures specified in Romanian law. Minutes of the contravention of the police officers with responsibilities in traffic

offenses involving the application of penalty points shall be notified within 24 hours. But the duties of local police will not end here. The copy of the minutes will be communicated to regional structures of the Romanian Police to be entered in the database. This process will take place based on the protocol signed between the parties. In Bucharest, all the records that include complementary contravention sanctions, imposing penalty points under the legislation on public roads will be communicated to the traffic police brigade. These minutes might be communicated, as well to the competent territorial police stations to be placed in the data bases. The local police structures designate staff responsible for the introduction of penalty points in the database that will work for one year together with nominees from the traffic police, in order to specialize. The local police specializing in road traffic exercise their powers with specialized structures of Romanian Police, for a period of one year (no less) from the date of setting up local police unit within administrative-territorial subdivision. Local police and employees of local police with responsibilities in the security of goods and goals of local interest will be provided with free uniform and appropriate personal protective equipment specific for the tasks they perform. In specific situations where, as a result of the exercise of duties service, were damaged or destroyed clothing or other personal property, the police officers are entitled to appropriate compensation.

Staff Uniform is provided by the local authority. The specific form and content of markings, and its legitimation document are those stipulated in the Framework Regulation for organizing and functioning of the local police. As well, the specific signs to be used for the local police cars should be established by Framework Regulation. Upon termination of service or employment, the local police staff is required to submit, as soon as is possible, the uniform, the insignia, the protective equipment and the documents of identification. Termination of service of local police for reasons attributable to themselves, within 5 years after completion of the initial training program referred to the Romanian law it shall entail the payment of tuition fee costs in proportion to the remainder.

5. Conclusions.

To improve the quality of the public service offered by the local police in Romania is an urgent need to improve the technical means available to local police units and widespread use of effective technological items (cameras, alarms and warning elements, embedded devices patrol police and gendarmerie novel local police, etc.).

Last but not least, the local police must achieve a quantum leap in terms of improving the quality of services provided to citizens. Satisfactions of the citizens should be the main criterion of evaluation for each local police officer. Reducing bureaucracy and improving working conditions for all units involved in ensuring public order and safety, contribute decisively to achieving a quality public service. Then time to time the public opinion may be evaluated using polls or questioners. This goal, of high quality of public service can be achieved by taking into account the need to permanently improve the speed of reaction of the local police and by increasing the transparency of the activities to ensure public order and safety. Partnership based on correct principles with the media, can provide much-needed transparency, given accurate and timely information for citizens and companies.

The Cybernetic System of National Economy and Foreign Investment

Popa Suzana

University of Pitesti, Faculty of Economics

suzanaciuca@yahoo.com

Abstract

The cybernetic approach of the national economy system requires an analysis from the systemic point of view of its structure and function, of its interaction with the other systems from our environment, in this way emphasizing the component systems, their functions, as well as the purposes of the respective subsystems.

Key words: national economy, systemic approach, cybernetic system, macroeconomic sectors, foreign investment.

JEL Classification: E10, E22, O11

Introduction

According to a classification of the most valuable concepts that emerged in our century, the concept of system and systemic thinking could occupy one of the first places. The systemic approach has, undoubtedly, great practical and theoretical valences. In the strict sense of the word, it can not be considered a science, but more a scientific methodology focused on the idea of system or systemic thinking and that originally includes methods and concepts deriving from different scientific domains.

The concept of system lies in the centre of the systemic approach and of the system analysis, and it can be defined as a mixture of interconnected elements having a common goal. The system features are different from those of the component elements (subsystems), thus, any system has a series of properties which can not be inferred directly from the study of its component subsystems.

The cybernetic approach

Cybernetics, defined as the managing science of the complex systems, studies the managing processes inside the complex and

dynamic systems. More exactly, the economic cybernetics analyses the economy, as well as the structure and function of its component parts as systems where management processes are unfolded, the transmission and the information transformation are achieved. It studies the function and the economic development as a managing system and, more precisely, the decision and computational mechanisms / techniques needed to manage the economic processes.

The economic cybernetics proposes both the unitary representation of the economy as a complex and dynamic system, and the approach of its component subsystems, of the technical, economical and organizational structures, common to the function and development of these subsystems. The economic cybernetics studies the processes that are carried out at the economic agents level (elementary entities or aggregated entities of the economic system), with a view to promote these management methods and to create some decision systems that take into account the requirements of the economic legislation and to determine their presence within the economic reality[1].

As a branch of the economic cybernetics, the cybernetics of macroeconomic systems studies the economic systems at the macroeconomic level, the mechanisms used for the function of aggregate markets, the role and functions of these markets when it is about the regulation or self-regulation of the respective systems[2]. In order to emphasize the specificity of the processes and phenomena which are carried out at the macro level, the economy is analysed and structured in sectors according to some features. At the level of these sectors, there can be formed connections and bonds between the components that are directed and guided through the market mechanisms. Such a structure of the economy gives the possibility of using the circular flow models

in order to underline the quantitative relationships that can be established between the different parts of the national economy systems in the complex process of achieving the macroeconomic balance.

The macroeconomic sectors

The economy may be regarded, at the macroeconomic level, as a dynamic system, made up of a multitude of systems linked together by direct and indirect connections of different types, every subsystem having its own evolution and objectives which are conditioned by the accomplishment of social welfare. Taking into account a very aggregate variant, the general structure of the cybernetic system of the national economy have the following sectors[3]:

1. The accommodations sector

The accommodations sector is formed by the totality of the cybernetic systems of the individual accommodations (the consumers) from the microeconomic level. The simultaneous treatment of individual accommodations leads to an aggregate behavior of the accommodations sector, as a result of the interconnected function between millions of accommodations that exist within the national economy. The private propriety is dominating, and certain factors such as work, are either in the direct propriety of the individuals within the accommodations, or belong to them indirectly through the shares that they hold and that give them the quality of owners. The incomes of the accommodations sector, together with the possible loans taken from the financial market (consumer credits) are spent by the accommodations sector to purchase goods and services. A part of these total incomes is used by the sector in order to pay the taxes.

The savings represent that part of the total incomes of the accommodation sector which is used neither for purchasing goods and services nor for paying the taxes. The accommodations are inclined to save from a lot of reasons. From the income saved, they can increase the consumption during the periods when lower total incomes are achieved, they can offer education to their children or increase their accumulated wealth.

2. The companies sector (private, productive)

The firms sector, called the real productive sector, is made up of a multitude of enterprises of the economy which belong to the individuals either directly (they own them) or indirectly (hold shares to the respective firms). The main economic activity of the firms sector is based on the production of goods and services, achieved through the consumption of capital goods and of work (production factors). The goods and services designed to the consumption are those that the firms send them to the goods and services market in order to be purchased and then consumed by the accommodations sector. The capital goods refer to cars, equipments, installations, means of transportation etc., that are not completely consumed in the production sector, but they are used in a variety of manufacturing cycles in order to market goods and services designed to consumption.

The firms can produce, besides goods and services designed to the personal consumption (final) also capital goods designed to the productive consumption, thus, contributing to the growth of total stock of capital existent in the economy.

3. The public sector

The public, also called governmental sector, consists of the totality of central and local institutions, as well as of the enterprises (administrations, national societies, etc.) found under the state ownership that achieve public goods and services, such as defense, education, health, administration etc., and also goods and services designed to the consumption of other sectors of the economy (highways, communication networks, schools, etc.) and that are too costly to be accomplished by the firms sector.

The public sector purchases from the private sector goods and services that are used in order to achieve public goods. For instance, the public sector can buy from firms stationary for administration, tanks and bombproof machines for defense, computers for education etc. Although, these goods and services coming from the firms sector are considered, at the level of the public sector, resources which are used to produce goods and „public” services. Some other time, the public sector itself can realize goods and services through the enterprises found under the state propriety, using for this hired

resources from the production factors market (including work).

4. The external sector

The material flows (such as imports and exports) and the financial flows between the national economy and the rest of the world are realized through the external sector. If one neglects this sector within the economy, one can say that it is a closed economy; on the contrary, one can speak about an open economy.

Any economy needs some goods and services that the internal productive sector does not accomplish them or accomplish them in insufficient quantities, so these goods and services are to be imported; at the same time, any economy can produce additional goods and services which can sell them on the world market, so they are exported. It is noticed that the respective flows input and output mainly from the firms sector, but the public sector can also make imports and exports.

In order to make imports, both sectors should pay a part of their incomes, while for exports they receive incomes from the exterior.

A certain difficulty is represented by the currency used to make these mutual payments. The national economies have different currency, a fact which weights the trade exchanges (e.g. one of the main reasons of introducing the euro in some of the European Union countries is given by the facilities it creates when it is about the payments of the export and import flows).

In order to solve the transformation of foreign currency into internal currency and vice versa, there are currency intermediaries within the financial sector (banks or exchange offices) that, on the financial market (more precisely on one of its components called currency market), they make exchanges between different currency. Thus, the external sector uses the currency market only to make currency transformations needed to the right course of the exports and imports.

In addition to these trade flows, any economy has inputs and outputs of capital flows. These are generally formed by foreign investments made by the residents of other states in the internal economy or on the international financial markets. These capital flows are also transformed; the inputs are

transformed into internal currency, and the outputs into an international recognized currency or into the respective country currency.

5. The financial sector

Generally, all the sectors lend and save funds. The important thing is that these processes determine a balance: if certain sectors save more than they spend, a funds surplus can be created; this surplus is used to cover the funds deficit from the other sectors. On the other hand, other sectors, which spend more than they save, have a funds deficit, they borrow these funds from those which have a surplus.

The financial sector is the one that achieves the funds transfer from the sectors which have a funds surplus to those which have a deficit. At the same time, the financial sector insures the interest payment deserved to those who lend funds from the received incomes from those who borrow funds.

The financial sector is made up of the multitude of different types of banks and of other financial intermediaries (insurance companies, investments funds, retirement funds etc.) that exist within an economy. The annual savings accumulation of the sectors which have additional funds allows the realization of investments funds used by the sectors which they have a funds deficit to develop the productive activities.

Usually, the sectors that save most are the accommodation sector and the public sector. The accommodation sector constitutes the most important sector which creates a funds surplus. The savings achieved by this sector go to the other sectors and bring to the accommodations sector a redundant income due to the interest paid by these sectors. The most frequently used forms of saving are: the formation of savings accounts, the purchase of firms and corporations bonds, the purchase of insurance policies, contributions to the pension scheme etc.

The sectors which lend the biggest funds are the public and private sectors. The funds transfer between these sectors is made, as a rule, on the financial market. On this market, the funds offer of those who save is equal to the funds demand of those who lend for a given level of the interest rate. If the funds demand is temporarily higher than the funds offer, the competition between sectors to obtain funds from a rather limited offer will

raise the price of funds, that is, the interest rates. Generally, higher interest rates will encourage savings, and they will discourage the borrowers until the demand and offer are again balanced for a new level of interest rates.

Foreign investment and the sustainable development of each cybernetic system called national economy

This paper addresses, in a complex manner, the system of domestic economy. This approach is simultaneously economic in content and cybernetic through the systemic vision of the structure and its operation, its interaction with other systems in the environment. The economic system is in a period dominated by the principle of managerial pragmatism, a period graphically called by John Kenneth Galbraith “the age of practical judgment”, whose new features, values and principles are changing almost entirely and continuously, no less than the resources, products and services of the new economy.

From Adam Smith’s “predictors and squanderers”, to the under-consumption balanced by excess investment, by overestimating the ubiquitous Malthusian investor, to the detriment of a normal consumer, from Ricardo’s compensation of labour demand by reinvesting capital to the Keynesian type of inverse correlation of interest rates and investment levels, an economic concept linked to economic growth centering on material and financial resources was shaped, and so it has become more and more necessary with every innovative approach; thus, investment occupied a more extensive area, in economic thought and theory. Over the last two centuries, the theories of foreign investment have shifted to the center of economic growth analyses, and in the last half-century, the explanatory models have multiplied exponentially, but the structural impact has permanently been under the dynamics and the avalanche of an increasing number of novel exogenous or factorial variables, which were nevertheless rejected by the statistical tests of stability of modelled and parametric correlations.

In parallel with the quantitative evolution, there have also been deep qualitative changes, stemming from the desire of

exhaustively know the investment phenomenon, exacerbated by the unsuccessful attempts to find universal, complex, comprehensive unifying models, either systematic or formal logical and causal. The type of modeling which sought to synthetically express investment phenomena, initially statistical, and later econometric, has gradually been replaced by smaller, pragmatic solutions, with an obvious impact in simulation and forecasting, as embodied by parsimonious models, relatively unstable compared with the rapid changes in global economy[4]. The investments triggered off by the entrepreneur, a key player of the economy, have been and still remain linked, over the past century as well, with economic growth and recession.

If an enterprise is defined as a practical manner of organizing a business, where products and services are performed and provided, jobs are generated, contributing to gross or net domestic product and import, to export and especially to sustainable economic development, a foreign or international investment implies the existence of at least two economic agents, an issuing agent and a receptor one, located in different national economic spaces, and the existence of an investment flow from the issuer to the recipient. The investments flows can be directed towards a receiver or destination economy (inflow), conceptually representing investment inputs, or can be generated by an issuing economy, or an investment source (outflow), meaning investment outflows.

Closely related to the connection between the issuer and the receiver of the investment flow, one can distinguish between foreign portfolio investment (FPI) and foreign direct investment (FDI), where the former possess a high migration potential, a completely unstable character, redefining itself as “hot money”, while the latter category involves a long-term relationship and implies a lasting interest and control performed by a resident entity of one economy in an enterprise resident in another economy, thus bringing the host country a great deal of advantages and benefits (from the chain effects of growth, development and optimization, to stable financial resources, from the transfer of managerial skills and improved technical expertise to greater adaptability, from better targeting the export to the markets of goods

and services, to financing local research and development capabilities, etc.).

Conclusions

Knowing the cybernetic system called national or domestic economy, or macroeconomic knowledge involves a continuous, rigorous and coherent insight system.

The onset of theoretical investigation consists in looking for characteristic variables, to be found in the system of national accounts (SNA), renamed the European System of Accounts (ESA) in the area of the same name. To understand the role and importance of each topic and economic sector of the SNA, as a cybernetic system or subsystem, viewed separately or within the framework of national economy, its interdependencies with other topics or sectors, and the functions of the various markets that form at this level as elements of the regulation and self-regulation processes, as well as in controlling, directing and guiding those systems towards achieving its own ends, and the general economic objective, it is necessary to first study and summarize the models of circular flows in economy, the model of the representative agent, those based on genetic algorithms, or, more simply, on agents. Then, a conceptual and functional reference is in order, even a limited one, concerning the investment multiplier, which designates a selected factor, which indicates to what extent an initial economic impulse (a separate and independent variable) influences an explanatory value (investment as a dependent variable), at the same time as a necessary reference to the investment accelerator, equally defined by a selected factor, which this time quantifies the rate at which investments fluctuate in relation to another explanatory variable, the two concepts then coming together as the multiplier-accelerator to merge the regulation/control and stabilization mechanisms, as well as the advantages of the two previous models, which have become, in practice, the most often invoked and applied models. The modelling of an economic cybernetic system is synthesized by means of three main classes of models, namely the balance between aggregate demand and aggregate supply,

economic growth models, and models of economic cycles and fluctuations. A systemic understanding of the economy has been possible by deepening the study of the classical factors, and the neo-factors, as well as the entrepreneurial paradigm. The originality of the theoretical synthesis, with a role in the in-depth understanding of the investment phenomenon, lies in this approach centered on the entrepreneur and entrepreneurship [5].

This systematic conceptual approach was intended to restructure and continuously reshape the hierarchy of the factors or explanatory variables of the economic phenomenon of investment in general. The major conclusion of this extended theoretical approach was that Romania's transition to a new cybernetic system of real economy (a modern market economy, integrated into the EU), should seek to adjust all the subsystems to the requirements of the external environment in which they operate, respectively by:

- the partial or total sustainable transformation of the *production subsystem* (clean and sustainable technologies),
- the gradual technological and informational transformation of the *subsystem generated by the balance of demand and supply* (products from another category of resources),
- ensuring better coverage of the *labour market subsystem*,
- setting up and applying a new ethical system to the *subsystem of profitability*,
- applying a new morality to the processes of the *subsystem of forming and distribution of income, and even of the profits of foreign direct investment*.

The Theories of the Comparative and the Competitive Advantages in the International Trade

Popa Suzana

University of Pitesti, The Faculty of Economics

suzanaciuca@yahoo.com

Abstract

The traditional theories – the classic and the neo-classic ones – are based on certain hypotheses, which simplify the analysis of causes and effects of international trade. Some of them are specific to the classic theory, some to the neo-classic theory and others can be found to both models.

Although the international trade based on staples still reflects the abundance of natural resources in the partner countries, the trade based on manufactured products put into practice even less the principles of neo-classic theory. More often the nature of commercial flows is even contrary to that recommended by this one. It has been noticed that many countries export and import at the same time products for which they hold comparative advantage.

Key words: international trade, the theory of comparative advantage, the theory of competitive advantage

JEL Classification: F1, F4

Introduction

The intensification of intra-industrial trade led to confusion among the followers of neoclassic theory and made them analyse the characteristics of the world market, the differentiation of products and the way of manifestation to world demands.

In the vast body of literature on this issue, there are a lot of approaches of the notion **competitiveness**. Generally, the notion of competitiveness encompasses all the elements that give to an economic entity a superior position on the market in relation to the competitive entities. [1]

The Theory of the Comparative Advantage

Adam Smith, the classic of the political economy, realized that a nation's wealth is based on its productive capacity. Starting from this general conception, the English economist created the theory of the absolute comparative advantage regarding the international trade. „If a foreign country can provide us cheaper goods than those produced by us - as Adam Smith said – it is better for us to buy them from that country, as part of the product of our activity, used in a way of which we can take certain advantage”[2]. This theme conveys the idea of shifting the role of work division from that of a productive unity to that of a nation. The international work division contributes to a significant production surplus under autarchy conditions (if this exists). From the surplus obtained due to the work division, all the participants in the exchange benefit, thus they have an absolute comparative advantage.

The commercial relations between countries have found a new theoretical approach in David Ricardo's work. Taking over from Smith's theory the idea of the essential role of the work international division, Ricardo lays the foundations of his theory about foreign trade with the help of some concepts, such as: comparative cost, relative value, relative price, relative advantage. Therefore, the Ricardians' theory is known as the theory of relative comparative advantage.

„The same rule that regulates the relative value of goods within a country –Ricardo says- regulates at the same time the relative value of the goods exchanged between two or more countries. In a system of perfect freedom of trade every country naturally dedicates its capital and work to those types of activities which are the most advantageous for it. This aim of pushing the individual advantage is admirably related to the universal good of everyone.” [3]

The theory of the relative comparative advantage, founded by D. Ricardo, preserves its theoretical-methodological value. Reformulating the Ricardian's principle concerning the relative comparative advantage, the economist Paul A. Samuelson, laureate of the Nobel Prize in 1970, stated: „ Even if one out of two regions is absolutely more efficient in producing all the goods comparing to the other region, if every one of them specializes itself to produce all the goods for which they have a comparative advantage, then the trade will be mutually profitable, for both regions. This simple principle constitutes the real basis of international trade.” [4]

The Theory of the Competitive Advantage

Almost half a century later, in order to delimit the terms of competitiveness and comparative advantage, Michael Porter introduces the notion of **competitive advantage**[5]. Porter offers to the competitive advantage a larger sphere of comprehension than that of the **comparative advantage**, the former being determined by the factors and demands' conditions, by the existence of connected industries and by common support as well as by the firms' strategies and markets' structure. Porter's approach is situated between the traditional approach regarding competitiveness and the attempts of improving the classical theory of the comparative advantage. Despite of being innovating, Porter's conception is simply a systematization of the positive theories regarding the markets' structure and the international trade in a speech obviously normative. The notion of competitive advantage denotes nothing else but the competitiveness from the normative perspective. By reuniting the rates of nominal and effective assistance as well as the domestic costs of the factors known as indicators of sectorial competitiveness, it is implicitly admitted the fact that the comparative advantage represents an element of competitiveness.

In 1989, Porter proposed a model that explained the countries' role in identifying and maintaining the competitive advantages of the firms on international markets. The model starts from the following premises[5]:

- a country can influence the competitive advantages within an industrial sector, where a certain number of firms compete;
- even for the transnational societies, a country can provide different competitive advantages, as natural country or host country;
- competitiveness has a dynamic character (*Schumpeter*). The innovations represent the motive force in such a continuous change and determine the firms to abandon the inertia they are used to.

A country's capacity to progress from the economic point of view depends largely on the enterprises' position in the respective economic section exposed to the international competition. This represents the part of the economy where there is the potential of attaining high levels and production increase. The capacity to export from these high industrial branches that permits imports in the less productive branches is essential to the economic growth.

The national economies pass through a number of development levels that reflect the characteristic sources of a country's advantage in the international competition as well as the nature and the measure of successful industrial branches[6]. Porter identifies four distinct levels:

- the level of advantages based on the factorial endowment;
- the level of advantages based on investments;
- the level of advantages based on innovation;
- the level of advantages based on national wealth.

The Comparative Analysis of the Two Theories

One of the most ambitious claims made by Porter's theory was that it constituted a more relevant theory by replacing the simplistic perceptions of the classical and neoclassical theories. It was explicitly launched the idea according to which a „ new paradigm” had been created by replacing the „ old” concept of comparative advantage with the more dynamic concept of competitive advantage.

The comparative advantage has been described as offering a static approach of the international trade based on the relative endowment with production factors. The notion of comparative advantage is a fundamental concept of economy that made Paul Samuelson, the laureate of the Nobel prize, declare as being the only statement from all social sciences which is evidently true and never devoid of importance.

The competitive advantage is a more complex and more dynamic concept which is based on innovation and new technologies.

In this context one can underline four of the most important elements that derive from Porter's theory:

- the first one, a misunderstanding of the comparative advantage within his theory and a return to an old point of view and to a long rejected explanation of trade;
- the second element refers to the statement according to which his theory introduces new elements in analysing the theory of international trade, but this one is not deeply founded because the economists had previously seen these elements;
- the third element refers to the omission that appears from Porter's position as a „competitive” defender against the comparative advantage, makes the others misunderstand his position regarding the governmental involvement;
- finally, it is evident that, by rejecting the comparative advantage, Porter relies on the weight of his logic in creating the elements for the proposed model of development.

Porter's “attack” to the comparative advantage demonstrates, perhaps, to a certain extent (according to his critics) a fundamental misunderstanding, encountered in the confusion which is made between the role of the absolute and relative productivity as to the trade determination. Porter states that , wishing to counterattack the external competition and to export, an industry must attain the standards of an „**absolute productivity**”.

Probably, due to a (deliberately) less exact understanding of the comparative advantage, Porter considers that his theory represents a new paradigm in the field of international

trade. As a matter of fact, as we have already shown, the modern theories realised from the comparative advantage perspective, largely approached the elements analysed by the ACN theory. The trade based on the technological disparity has been debated by Posner[7] and Vernon[8] offering a dynamic extension of the comparative advantage theory in the model of the product life cycle at the international level. The importance of the production factors mobility was recognized by Mundell [9] ever since 1957. Dardoff, Ethier and Krueger (1984) elaborated different articles showing the great economists' concern for this field, long before Porter. Consequently, his statement according to which he invented (discovered) a new paradigm of international trade can not be sustained. The theory of the comparative advantage does not provide a revealing explanation as to the intra-industrial trade, between countries having the same level of endowment from the production factors' point of view , according to Porter's statements. Although, this idea had also been declared long ago by other economists concerned with this domain, who explained this type of trade as a result to the scale economy. [10]

A series of analysts consider that Porter appears in rather surprising positions by the statements made within his theory. Thus, Warr[11] shows that this theory refers to the importance of differentiated goods production and especially of those belonging to the high-tech industry and it shows the decrease in importance of the comparative costs, fact which apparently justifies the waste of public expenditures or/ and of protectionist policies in the attempt of promoting the early development of top industries. This interpretation of competitive advantage menaces to encourage policies which will waste the resources already limited of the developing countries. Nowhere within his theory, Porter does not embrace the idea that governments can use mindlessly the public expenditures, the protection and administrative measures instead of elaborating more efficient policies in the field of different industries. Generally, Porter was known as a well-known opponent of the governmental intervention [12].

Porter denies the fact that a superior competitiveness can be obtained through the comparative advantage and insists on the fact

that firms must produce superior products in order to compete at the global level.

The Effects of Risk Events on the Efficiency of Financial Market

Săveanu Cristina

Doctoral School of Economics

University “Al.I.Cuza” Iasi

cristina.saveanu@yahoo.com

Abstract

Starting from the network of relationships between the participants on the financial market and the need to match the offer with the demand, the financial mechanism must work efficiently. Nowadays the concept of efficiency is a central issue of market research. Taking into account the real economy, this paper tries to reveal the effects of risk on the efficiency of financial market. The approach of the subject has a double perspective: the negative effects of risk on the efficiency of the financial market and the positive ones.

Key words: efficiency, risk, financial market

J.E.L. Classification: G14, G32, E44 .

1. Introduction

The current financial context is definitely one of the best examples to illustrate the effects of financial market's risk events.

According to the Financial Stability Report for 2012 [1] issued by the National Bank of Romania, the financial environment has become more strained, the financial markets' volatility has increased and the investors' perception has worsened amid the sovereign debt crisis and the persistent uncertainties about global growth prospects. Rating agencies have downgraded the marks for many EU countries. All these facts lead us to the conclusion that the financial risk has negative implications as direct effects. It also has positive effects and they are represented by all the solutions and tools developed and implemented in order to counter the negative effects.

2. The negative effects of risk events

The manifestation of risk on financial

market does not mean that it can be exactly located and framed in a certain typology, but involves assessing its impact and its contagion effect that leads to systemic risk.

Risk is actually the manifestation of systemic financial instability. This state of financial instability reaches systemic dimensions through different mechanisms: contagion, slow accumulation of financial imbalances and the occurrence of systemic shocks [2]. Under these circumstances, the failure of a market through the collapse of economic agents generates other markets collapse, even if the risks taken were different, leading to a phenomenon called "blocking chain". Such imbalances generate systemic risk because they are not corrected at the right time and become generalized. Once they become generalized they become global shocks, affecting a large number of financial markets, being impossible to restore the balance on the basis of market self-regulation mechanisms.

There are certain characteristics of markets and financial systems that generate a higher probability of developing systemic risk: externalities and asymmetric information.

Externalities are significant due to the fact that they are more important on financial market than in other sectors, because of the complex and dynamic network of mutual exposures of major financial intermediaries [2], meaning that in normal times, the multiple interconnections between market participants is an effective mechanism in the process of risk division, and in times of tension, turns into an instability transmission channel, generating consequences on third parties, thus systemic risk being greater than the sum of the various risks taken individually.

Information asymmetry occurs because financial systems mobilize funds from businesses which do not know or are not

fully informed about investment opportunities. They enter into relationships with agents who know the possibilities of doing business and are willing to work but do not have the required capital, between them occurring phenomena such as agency problem and adverse selection.

The state of instability of the financial system in the economy can be measured by using macroeconomic indicators that reflects the tensions between the main components of the financial system: financial intermediaries, money market, stocks and bonds, foreign exchange etc.. To study the instability condition is used the "composite indicator of systemic stress" (Composite Indicator of Systemic Stress CISS), built by D. Hollo, K. Kremer and M. Lo Duca [3]. Based on this indicator was concluded that systemic crisis began in September 2008, particularly through bankruptcy of "Lehman Brothers".

Financial crises occur amid a state of widespread financial instability. Financial stability itself is defined in terms of appearance or crisis.

If the financial system does not fulfill its role, the real economy suffers losses. Financial crises as a result of risk events are actually those economic conditions characterized by widespread failures of businesses, lower incomes and prices. Due to economic interdependence these effects are widely transmitted by the contagion and are generally accompanied by financial disturbances, both at micro and macro level.

A financial crisis usually includes a currency crisis, a banking crisis and a debt crisis.

There are several economic theories on the causes of financial crises [4]. The first category identifies as causes predictable events due to inconsistent policies. A second category refers to the interaction between private sector behavior and compromises made by governments, and the third generation of theories brings the idea that crises were generated by the banking system. The crisis we face today is part of the third generation, being classified as a twin crises of banking and currency type.

Financial crises have significant implications on the economy and can be summarized as follows [4]:

- additional budget expenditure due to recapitalization of financial institutions

affected by systemic shock and of the deposit guarantee schemes;

- damage on the effectiveness of monetary policy, the transmission mechanism being severely altered;
- slow growth or even loss of gross domestic product by: restricting production, rising cost of financial intermediation, which can fuel the development of the phenomenon of adverse selection;
- reducing the wealth and/or income through impairment of financial investments (partial loss of bank deposits and reduction of the value of stock portfolios) and the loss of disposable income (by reducing wages as a result of reduced demand for labor and tax increases to achieve budgetary resources covering government spending shock occasioned by limiting systemic spread of the financial sector).

3. The Benefits and positive effects of risk events

Besides negative effects, financial crisis caused a mobilization phenomenon in order to create and develop the necessary analytical tools to formulate and apply policy to ensure financial stability.

The first aspect [2] was the understanding of all aspects concerning the organization and functioning of modern financial systems (elements, function, efficiency parameters, etc..) and of the risks that they generate. This fact imposed the understanding of the essence of some major changes - financial innovation - and the prediction of how these modern financial products may occur in credit process of (credit default swaps or CDS).

Crises have shown the need and importance of timely referral tension and imbalances and the importance of analytical tools necessary to evaluate new financial products, and risk involved.

Second, the crisis demonstrated the need for models, not only the ones that reflects emerging systemic risks in the banking sector, but also models that allow to explain how non-bank financial intermediaries contribute to the transmission of the financial instability.

Third, the postulate of efficiency of financial markets was reviewed. Economic research has shown that the assessment and accounting of assets, financing arrangements of firms and the brokerage process have some major shortcomings that diminish the efficiency of financial markets - contrary to the widespread belief in market efficiency.

The crises have increased the importance of the macroeconomic stress tests (stress tests), tests based on an extreme but plausible macroeconomic scenario, which examine its punctual effect on banks.

Meanwhile, the financial crisis led to systemic risk regulation.

There have been developed five models for systemic risk assessment [5]:

- aggregate indicators of imbalances, which are either macroeconomic data, or monetary data sheet and which are used to signal the strengthening of risk in the financial sector or the economy as a whole;
- indicators of financial markets based on risk appetite and liquidity conditions;
- indicators of risk concentration in the financial system, considered very important because they bring into question contagion;
- macroeconomic stress tests, for each national and international economies which are focused on two risk factors for the financial system: economies of scale on the demand side (network effect) and the fact that poor development of the economy and financial conditions influence each other (adverse feedback effect);
- integrated monitoring systems, which are in fact models of exposure of all elements presented above, through a certain representation (such as risk maps [6]) or through a set of compounds.

Complex systems theory deals with the impossibility of direct risks. Therefore, instead of trying to eliminate or directly limiting risk, a more effective solution may be to create, within the system, some safety nets that allow the survival of financial institutions even in case of strong shocks. And in fact, this is the philosophy of Basel III concerning funds and liquidity of financial institutions. It is also desired to create a rapid procedure for adjudicating

bankruptcies, improving recovery plans and creating ad hoc reserve funds.

At the same time in order to solve the problems of contagion, it is expected that financial transactions will be concentrated in central clearing houses. This way, the counterparty risk can be managed more efficiently and recovery operations can be faster.

Crisis phenomena as effects of increased risk events have increased the importance of the macroprudentiality concept.

Macroprudential policies consist of measures to ensure the health of the financial system or prevent out-of-control problem from one part of the financial system [7]. G20 recommendations on macro-prudential policy, take into account three activities [5]: identification and monitoring of systemic risk, building a set of indicators for the macroprudential policy, institutional arrangements for policy coordination.

In the same category we can include awareness of the beneficial effects that have quality, quantity and speed of information, this fact involving the submission of efforts to improve data collection, stress tests quality and harmonization of accounting rules to better reflect the economic value of assets in the portfolio.

The current crisis has also revealed the dangers of excessive debt and debt multiplication phenomena. For example, lending to a wide range of economic agents (households of sophisticated financial intermediaries) that do not have sufficient income, own funds or guarantees, was a major cause of instability. Consequently, it became necessary to use administrative tools such as loan-to-value ratio (loan amount to the value of goods purchased) and capping debt relative to income.

Basically, the financial crisis has generated a process of reform. New rules on economic governance in the EU entered into force in late 2011, continuing the process begun in 2010 to strengthen the monitoring and prevention of macroeconomic imbalances, fiscal and competitiveness gaps between EU countries.

The new framework focuses on two components (NBR report on financial stability, 2012): fiscal and macroeconomic surveillance. It also strengthens the Stability and Growth Pact (SGP), this new regulatory

framework targeting multiple components of the financial stability [1]:

A. Strengthening the existing framework for monitoring and correcting fiscal slippages:

- preventive side of the SGP: Member States must ensure the achievement of medium-term budgetary objectives in order to ensure fiscal sustainability, in this sense being envisaged a maximum level for the annual increase in public spending;
- corrective side of the SGP: the start of the excessive deficit procedure (EDP) may result in overrunning the limit of budgetary deficit and public debt.
- minimum requirements concerning budgetary frameworks: Member States must ensure the existence of minimum fiscal standards.

B. the introduction of macroeconomic imbalances procedure aimed to monitor and correct the macroeconomic imbalances:

- a monitoring and early warning system (a set of indicators established in order to highlight the possible macroeconomic slippage). European Commission (EC) analyzes the set of indicators and prepares The report on the alert mechanism based on their analysis. EC may decide to deepen the analysis for specific risk areas and may propose measures for member States;
- the preventive role of the EC is to decide the issue of recommendations in the early stages of formation imbalances;
- the corrective side is represented by the excessive imbalance procedure which can be opened for Member States where there is a severe macroeconomic slippage.

C. Introducing measures to strengthen the new framework by applying penalties for breach of the EC European Council decisions.

According to Governor Isarescu a viable financial system reform should address market failures sources on two levels.

The first level refers to the coverage of financial institutions activity in order to preclude involvement in certain risky activities and to protect their essential functions; reintroduction of the separation of commercial banking activity from investment

activity (according to the original version of the Glass-Steagall Act) and introducing Volcker Rule severe restrictions on operations on their own;

The second level refers to the size of the financial institutions. Starting from the issue of "too big to fail" it is found that bankruptcy law is inadequate and requires a special frame building solutions, which do not cause unacceptable risks to the economy;

At the same time it is envisaged the creation of a banking union. This process involves the simultaneous implementation of four pillars:

- harmonization of the regulatory framework and banking supervision in terms of a single set of regulations;
- transferred from the national to the European level of the main responsibilities of supervision in terms of a single mechanism of supervision;
- harmonization and centralization of deposit insurance by a single scheme for the guarantee of bank deposits;
- introduction of common provisions to ensure legal support necessary to manage bank failures problems through a single bank crisis resolution mechanism.

4. Conclusions

Risk effects and the present financial crisis lessons have been and will be a landmark for the future development of financial stability.

Financial reform measures should not seek to circumvent the market, but to ensure its proper functioning.

A higher degree of certainty should not be achieved at the expense of lower efficiency and a lower capacity of the financial system to support robust economic growth in terms of financial globalization.

Consequently, transnational cooperation is essential through mechanisms and new techniques for achieving information exchange and harmonization of approaches to solve the problems of the banks in difficulty.

From Tulips to Black Swans – Have the Financial Rules Changed?

Stoian Andrei

The Academy of Economic Studies

Abstract

From the tulip mania back in the 17th century in Holland up to the US subprime crisis considered by many a “black swan” – the unpredictable and improbable event that had such a great impact, the financial world has been hit by many crises. This paper emphasizes the idea that although most of the economists did not predict the crises coming, the signs that eventually led to the dramatic outcomes were present and one should learn from these unfortunate events in order to better prevent and manage any future financial disasters.

Key words: financial crisis, subprime market, asymmetric information

JEL classification: F30, F65, G01

1. Introduction

Ever since the births of the financial world, there have been diverse developments that changed the landscape and brought turmoil among the participants. As the role, the interconnections and the magnitude of the financial architecture increased over time, more parties with a lesser involvement got linked to the system and started sharing both benefits but also the risks a off a crisis. Nowadays most of the world is connected through the capital flows and problems affecting one country are spreading to the entire region and even to a global scale.

Financial crises have appeared since the 17th century, the first recorded one being the tulip mania in the Nederland in 1637, when speculators bid up the prices of rare tulip bulbs to stratospheric levels [8]. While historians continue to debate the consequences of this bit of speculative fever

(and some economists even deny it was a bubble, arguing that all bubbles are driven by fundamentals), it set the stage for larger bubbles whose destructive effects are not in doubt.

During the 19th century, both U.S. and England suffered several economic recessions with bank failures and financial markets in distress. The first part of the 20th century was no different, and once could emphasize the Great Depression or the ‘73 oil crises that led to the stock market crash.

Starting with the last 2 decades, the crises intensified and increased significantly in magnitude. Since the Mexican crisis in 1994 and 1995 the financial markets have frequently been hit by severe crises. Since 1945 there has been no decade with as many financial crises as the 1990s and beginning of the 2000s [2]. Adding to this the latest US subprime crisis, which some considered to be a “black swan” event and the European sovereign debt crisis, makes it more obvious that the turmoil can affect anyone, even countries which were prior to the crises considered to be models.

2. Structuring the causes

All the crises that have appeared, although different in nature have very many similarities and the pattern seems to repeat itself over the course of history. From the inexplicable increase of the prices of tulip bulbs back in the 17th century to the unrealistic increase in home prices in the US up to 2006 (the European crisis that followed is considered to be a spill-over from the one in US), neither people around the globe, nor economists (with very few notable exceptions), have managed to identify the signs that let the build up of bubbles, which

eventually burst into crises with huge economic impacts.

By performing an analysis of the previously enumerated crises, one can outline certain behaviours in respect to the causes that led to the events. The particular “assets” that were the starting basis of the crises are of particular importance as they can suggest what was the origin in each case.

The bulbs in the “tulip mania”, stocks in the Great Depression, oil in the 73’ oil crisis, currencies in the Asian crisis from 97’, home prices in the US subprime turmoil were all “assets” that either were overvalued or rose unsustainably in price and led to the build up of bubbles that produced important effects when they burst.

Therefore, the causes that led to the crises can be split into two main categories: the particular ones, specific to each of the crises and the common ones, which we can identify in most crises and which can provide a solution to the prevention and better management of future financial issues.

Focusing on the common causes that led to the crises throughout history, one can highlight the unsustainable increase in the prices for a particular asset - a feature that applies to both advanced countries and also to emerging economies. For the EMEs, the structural weaknesses are also to be taken into account. Among these we can stress the limited financial development, the faulty governance structures, over-regulated markets, external liabilities denominated extensively into a foreign stronger currency or the fear of floating the exchange rate [3].

The increase in prices for that particular asset should trigger some flags for the regulators and authorities in that particular market in order to include some additional supervision and countercyclical measures in that area, so that a full scale event can be prevented.

Also, speculative actions without economic sustainability should be discouraged through specific measures as they exacerbate the booms, while creating panic by initiating the capital flight.

3. Issues to be addressed

By an analysis of the development in the crises that have occurred one can identify several common issues that should be

addressed in order to prevent future failures in the financial system. Namely, the following can be stressed out.

3.1. Asymmetric Information

This can be defined as the existence of more or superior information for one party in comparison to another, related to a particular transaction. This can lead to a harmful situation as one party can take advantage of the other party's lack of information.

As per Mishkin [6], the asymmetric information view of financial crises, defines a financial crisis to be a nonlinear disruption to financial markets in which the asymmetric information problems of adverse selection and moral hazard become much worse, so that financial markets are no longer able to efficiently channel funds to those who have the most productive investment opportunities.

Adverse selection is an immoral behaviour that takes place before a transaction based on a surplus of information that one party has. A buyer does not know if a seller is selling the security because of a sudden need for liquidity, or because the seller is trying to get rid of the toxic assets, which can lead to market illiquidity [5].

Moral hazard occurs when a party protected from risk behaves differently than it would behave if it were fully exposed to the risk. Moral hazard arises because an individual or institution does not take the full consequences and responsibilities of its actions, and thus, has a tendency to act less carefully than it otherwise would, leaving another party (usually the government) to hold some responsibility for the consequences of those actions. The ‘too big to fail’ is a very good example in the US subprime crisis.

3.2 Sudden stops

A sudden stop is an event in which local economies lose access to international capital markets, as foreign creditors become panicked due to financial turmoil (e.g. financial crises), thus stopping lending to local economies. Sudden stops are usually described as periods that include at least one observation where the year-on-year fall in capital flows is at least two standard

deviations below its sample mean as per Calvo et al [1].

3.3 Capital flight

Capital flight occurs when assets or money rapidly flow out of a particular country, due to an event that has some economic consequences. Such events could be either an increase in taxes on capital or the government defaulting on its debt that alarms investors and causes them to decrease the value of the assets they possess in that country, or just to lose confidence in its economic strength.

The main effect is wealth disappearance, together with a sharp reduction in the exchange rate of the affected country (for variable exchange rate regimes this takes the form of depreciation, for fixed exchange rate regimes this leads to a forced devaluation from the original peg rate). Another consequence of capital flight is the sharp decrease in the purchasing power of the country's assets which creates problems for importing goods and for paying foreign debt.

3.4 Free rider problem

A free rider is someone who benefits from resources, goods, or services and does not pay the costs associated however can still take advantage (free ride off) of them. The investors acquiring a piece of information will not be able to benefit from the entire increase in value of their assets as others will also benefit, without having paid [4].

3.5 Global Imbalances

In the current globalised world, the current account imbalances that may appear seem to be less and less taken accountable for the macroeconomic and financial stress, as the gross financial flows have started to outweigh in importance the net ones.

The factors that emphasise the global imbalances also imply that the gross international financial flows are at the heart of any assessment of risks related to the financial stability [7]

An important view, especially related to the US Financial Crisis is that the excess of savings versus investments in the emerging markets (and one could outline the Asian

countries, especially China) which was echoed in corresponding current account surpluses was a very important pressure factor on the world interest rates, which were driven down.

This was considered by some of the economists to be the main factor encouraging the credit boom, lowering the risk premia and increasing the prices of assets in the US, in the years preceding the crisis.

Still, the most important part of inflows coming into the United States came from Europe, while surplus countries (China, Japan, OPEC Countries) accounted for a much smaller portion. Furthermore, the latter group invested mostly in US bonds and other similar safe assets.

From this perspective, one could say that the global imbalances were not one of the main causes preceding the crisis; however they did fuel it by an important amount.

3.6 Deregulation

Most of the new financial instruments that are being “invented” do not fall under the regulations in place. This is one of the exact reasons why the new instruments are created, so that they can avoid certain regulatory requirements or prohibitions that would normally apply. Furthermore, in the boom period, one could notice a tendency towards deregulation and a pressure to relax the financial constraints, as the private sector is taking advantage of the momentum.

Still, most of the crises have shown that there is always a shortfall in this domain, and especially during a boom period, in order to lower the magnitude of cycles, the governments and regulatory bodies should impose additional controls in order to increase the prevention and decrease the potential risks.

4. Conclusions

Financial crises have occurred in many instances throughout history, still no actual solution has been found in order to prevent them. Most crises have taken the economic environment by surprise, although the built up of events and facts, together with a similar unfolding that have amplified the impact and effects can be traced in most of them.

One cannot anticipate the particular event, area or industry that may lead to the crises, however, by determining which were the common causes and the common developments that added to the creation and amplification of these financial turbulences can assist in a better anticipation and management and further help identifying solution in diminishing the effects.

Regulations imposed by national governments or rules created by international bodies that everybody should obey are the final act in order to prevent future financial disasters. As the world is moving towards a more globalized stage, with ever more increased interconnections between regions, states and companies, any disruption in a particular area is very likely to rapidly spread to a larger scale. However, in order to implement this, a very important role is to identify the main features of pre-crisis, during the crisis and after the crisis events that have the most important influence and that create the negative effects which need to be eluded. These effects have shown that the financial turbulences can also have an important social impact which should not be disregarded.

By analyzing the history of crises, one can see that many of the fundamental principles remain the same, still the occurrence has not changed, and moreover the crises seem to appear more frequently and with a greater impact within the last decades. Therefore all common causes should be addressed in order to minimise the potential appearance and effects that a full scale financial crisis could have on the economic environment.

Strategy of Competitive Forces in the Air Transport

Utureanu Simona-Luize

Faculty of Economic Science, Ovidius University of Constanta
simona_utureanu@yahoo.com

Abstract

The aviation industry plays an important role for their customers and for the economy in general. However, the value created by the airline companies does not reflect in the company's profitability.

Nevertheless, the demand for airline transport services will continue to increase, especially in the developing economies. This will require the substitution and the extension of the existing capacity.

Keywords: airline industry, profitability
J.E.L. Classification: L93, M20

1. Introduction

The aviation is a vital part of the world economy which is increasingly globalized, helping the growth of the international commerce, tourism and international investments, as well as connection people among different continent.

Airlines all worldwide transport over 2.6 million passages every year and 48 million tons of goods. Providing these services creates 8.4 million jobs directly in the airline industry and contributes with 539 milliard dollars to the world GDP. Comparing it with other industries, the contribution of air transport to the world GDP is bigger than the one of pharmaceutical industry (445 milliard dollars), of the textile industry (236 milliard dollars), or of the automotive industry (484 milliard dollars), and it is about half compared with the chemical industry (977 milliard dollars) and smaller than the contribution of the food and beverage industry (1.162 milliard dollars).

If we would compare a country's GDP, the air transport would be on the 19th place in the world, approximately equal with Switzerland or Poland.

From the 8.4 million jobs created by the

airline industry:

- 0.8 million people are working in the civil airline industry, in manufacturing of aircrafts and engines.
- 2.2 million people are working for the airline companies and handling agents, including the flight and maintenance crew.
- 0.5 million are employed by the airport operators, working in airport management, maintenance and security.
- 4.9 million have other job at the airport – for example in shops, restaurants, hotels and governmental border patrol agents.

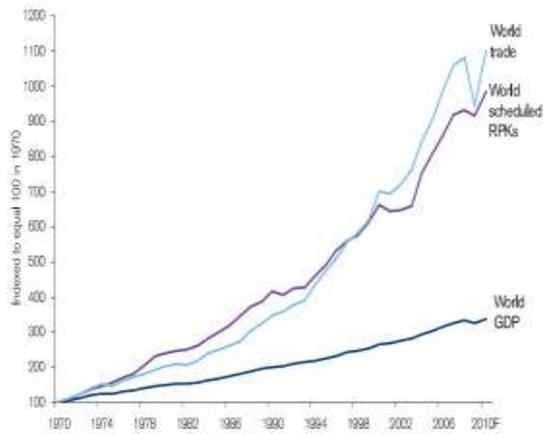

In Europe, air transport offers 7.8 million jobs and 475 billion euro to the European Union's GDP, which is equivalent to 3.9% of the GDP of EU. But more important is the fact that it ensures Europe's connection to the rest of the world.

The airports from EU serve approximately 12314 routes. Almost 23% from the EU trade with other parts of the world is done by air.

2. The Background of the Aviation Industry

In the last 40 years the air transport activity, as measured by RPKs (revenue passenger kilometers), increased 10 times worldwide. This is an expansion which is three time bigger than the world savings, which partially reflects the high elasticity of air traffic income. This also facilitated the globalization. The air transport followed the same trend as the worldwide trade. This was one of the economic fields with the most rapid increase.

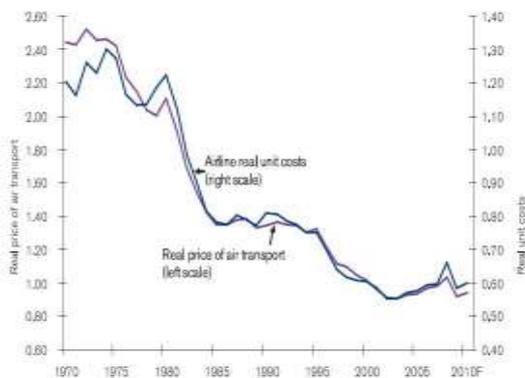

Figure 1 The expend of the air traffic over the past 40 years

Source: IATA Report – Vision 2050

The cost of the air transport services decrease with more than 60%. The inflation adjusted price for the consumers dropped in a similar manner. This drop has been caused by better technologies and more complex operational management. The degree of utilization of the aircraft increased (with 20%), also the transport distance, the average number of daily flight hours increased.

Figure 2 The real cost of air transport

Source: IATA – Vision 2050

Despite this fact, the majority of the airline companies did only succeed to recover their capital spending in 8-10 years. This does not mean that they did not try to increase the operational efficiency (externalizing the ground maintenance and handling activities), they introduced more sophisticated management methods, the aircraft utilization degree increased, they added additional income (from charges of the previously included services; sells of additional products and services to the passages), they introduced a larger range of fidelity programs for their clients and

established alliances with worldwide coverage.

3. “Porter’s five forces” in the Airline Industry

The success of the competitive strategy of a company depends on the environment in which it operates and on the way in which it connects with its environment. Even if the relevant environment is very large, containing social and economic forces, the key aspect of the environment of a company is the industry in which it operates. The industry's structure has a strong influence on defining the rules of the competitive game and the strategy of the company.

The situation of the competition in an industry depends on five basic competitive forces.

The Five Forces model, introduced by Michael Porter, shows the reasons for which the company’s profitability is so low: because of the competition, the new entrants, the clients and the negotiation power with the provider, but also the threat of substitution.

Profitability is influenced by the collective power of the five forces, also by their interaction. These forces model the actors’ behavior and determine the total value created in the industry, but also the way in which this created value is spread among them.

Intensity of rivalry

The specific economic characteristics of the airline industry which determine rivalry are:

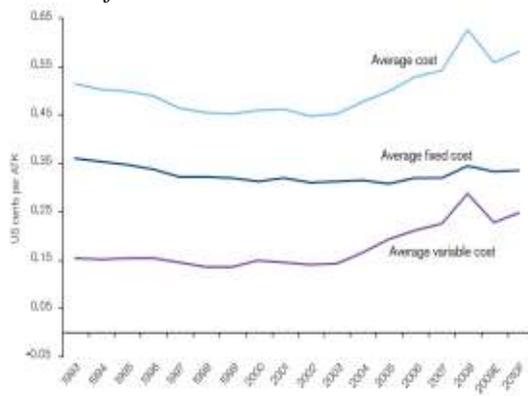

Product Perishability – the transport capacity is available only for a period of time regardless of it being used or not. The costs for assuring the capacity create pressure upon the price.

Similar Products – the products offered by airline companies are very similar. Other industries managed to offer product differentiation through branding, different quality, or technical specifications. In the airline industry this did not happen in a significant amount because of the safety standards.

Low marginal cost structure – is the fixed cost of the aircrafts. The average cost per available seat kilometer (ASK) decreases if

the aircraft capacity increases. The marginal costs for additional transported passages are very low, which strengthens the update of the prices. The variable costs per aircraft are also significant and have been increasing (e.g. fuel price).

Figure 3 Relative high proportion of fixed costs over short term

Source: IATA Report – Vision 2050

Restriction for Market Exit – reducing the transport capacity and the market exit of some companies are two key mechanisms for adjustment. In the airline industry none of these two regulation mechanisms is used.

There are a series of restriction which limit the capacity of airline companies to reduce the global capacity on some routes.

The airline companies are obliged to take responsibility for a capital loss in the case in which they sell aircrafts in a recession period. The leasing contract clauses are as expensive in decline period. Keeping unutilized units is also expensive, but avoids capital loss.

Capacity – can only be gradually increased (the size or the number of aircrafts, flight hours, gates or airstrips number).

Industry Increase – it was generally rapid, but volatile and very heterogeneous on geographical regions. Its volatility caused short repetitive periods of profitability, even when the average yield was reduced.

Heterogeneity of companies - rivals tend to compete more aggressively, partially because they perceive differently the impact of their competitive moves.

On the individual markets, the airline companies can be on different positions. Operating flights between two cities can be the primary market for a certain airline company which offers direct flight, but the same market can be only a marginal market

for another airline which provides services through a transit connection. Between these kind of competitors, heterogeneous, the ability to avoid competition through the price is less likely.

The airline companies operate in the political context specific to their origin market. Operating on an international market, they compete with companies which operate under different conditions. This fact can affect the competitive interaction between them in a way which is not related to their efficiency.

The Threat of New Entrants

The restriction on entering the air transport market plays an important role for the new comers, but they are very low for the existing operators. The restrictions on entering this industry are very small.

Entering the market happens periodically, especially through existing airline companies extending their services on new markets.

The scale economies are the result of the demand, meaning it is easier for an existing company with a powerful brand, a high number of flight direction and a lot of connections to generate demand.

Accessing the distribution channels is easier now than it used to be in the past. GDSs (Global Distribution Systems) and the internet allow now the new companies to make their flight offers known and to sell them on a high number of websites and tourist agents. This is a big changed compared to the past, when the reservation systems and the tourism agents were controlled by the already existing operators.

Some preexisting rights related to movement, which benefit the existing operators, also exist in the governmental agreements in the international air transportation sector.

The Customers Negotiation Power

The negotiation power of the customers of an airline company is big and it is still increasing. This is influenced by a number of factors: the channels power, the power of the final consumers.

The tourism agents, traditionally, were the dominant channel for airline companies. Their role has changed. For individual,

recreation and some business traveler, websites took the place of the tourism agents. For corporate clients the tourism agents are still important, but they have changed their strategy in order to reduce the costs for their customers.

Recreation website became the dominant sells channel, mostly for flight tickets with low price. They allow easy comparison of the price for different airline companies and they increased the transparency of the prices.

Global distribution systems (GDS) collect data from airline companies and provide it to the tourism agents and recreation websites. Some of them also have their own aggregation websites through which they directly sell tickets to final customers.

The Suppliers' Negotiation Power

The negotiation power of the supplier is big. Some of them can record capital yield bigger than the biggest airline companies.

The aircraft manufacturers – In the last decades there has been a strong consolidation of the market for the aircraft manufacturers. If in 1992 there were 15 aircraft manufacturers in USA, today there are only three left. Regarding the production of commercial aircrafts, the two giants – Boeing and Airbus – allocate very big funds for research and development, this fact is impossible for small manufacturers.

The work force – Airline companies are dependent of their skilled employees, especially pilots and technical personal. Network airlines are sensitive at activities interruptions in their hubs. In companies usually exists different unions for different types of personal (syndicates), each of them having the capability of disrupting the activity.

Airports – their primary impact on the structure of the airline industry was through constraining the capacity imposed by the existing infrastructure and by the operational practices.

The Threat of Substitutes

In the past, the threat of replacing the aircraft travel (the airline transport service) with other means of transportation played a moderate role. Now certain segments started becoming important. Their substitution

depends on the ration cost/benefit of other means of transportation compared with the air transport.

High speed trains for short distances which run on European and Japanese train tracks compete with the air transport. Additionally, they can offer point-to-point connections.

Private airplanes (regarding time-share programs) can compete with scheduled flights of airline companies, especially on the business and first class sector, mainly for locations with low density traffic.

Phone / Internet / Video conference technology – offer high quality condition, making possible communication without the need for people to travel.

4. Conclusions

This paper suggests that the capital invested is not used optimally. The airline companies invest the biggest amount of their assets in the aviation industry, but they are not capable of generating a sufficient yield for this capital. There are airline companies that have created positive yield for their investors (network airlines and low-cost airlines). However, the aviation industry as a whole did not succeed to accomplish the level of its yield that the investors expected. The inefficient utilization of the existing capital will increase the cost of accumulating new capital to substitute and extend the current levels of the capacity, and maybe discourage completely new investors.

International Investments, Comparative Analysis Romania-European Union

Vîrlănuță Florina Oana

Economics and Business Faculty, “Dunarea de Jos” University of Galati

florina.paun@ugal.ro, florinaoana27@yahoo.com

Abstract

Annual preliminary estimates for 2012 confirm a slowdown in foreign direct investment activity worldwide, after a short period of strong recovery in 2011. FDI outflows have increased by more than 10%, compared to growth of 24% in 2010 and remained well below the historical high reached in 2007. Despite this slowdown, FDI outflows remained globally over the figure recorded in 2000. This trend is due in part to the growing importance of cross-border investments in several emerging economies in the last decade. In this paperwork we intend to achieve a comparative analysis Romania-European Union regarding international investment position, foreign investment flows. Thus we analyzed the flow of foreign direct investment in Romania in 2008-2012, and causes poor attractiveness for foreign investors in our country. Also, we analyzed and compared to EU countries in terms of foreign investment.

Keywords: international investment position, foreign investment, efficiency, economic growth

Jel Code: E22, E63, F21

Introduction

Investing is the process of startup money for profit and is presented in two main forms, namely: direct costs (buildings, equipment, etc.) and indirect costs (the actions and operations) and foreign direct investment is a process by which people in a country (the source country) acquire ownership of assets in order to control the production, distribution and other activities of a company in another country (host country).

There was a time when economists considered FDI as a substitute trade. By

building factories in foreign countries was a way to overcome tariff barriers. Today, economists believe FDI and trade as mostly complementary in that a business can use a factory to supply a country neighboring markets.

Foreign direct investment is an important factor for economic growth in developing countries, this argues for the importance of domestic investments in the economic growth, foreign direct investment with only a potentiating role of internal efforts.

Investment Position in European Union

The new rules of governance of the European Union have focused on its corrective side, application or risk severe financial penalties (up to 0.1% of GDP) and less preventive component.

Therefore, this procedure together with its two components, preventive and corrective creates a better economic monitoring in each state, allowing timely identification and correction of adverse developments.[5]

Preventive component that has a hazard prevention system called warning mechanism, macroeconomic indicators through 10, with the main instrument a dashboard that shows external imbalances and competitiveness, as well as internal ones.

External imbalances

- Average current account balance over the last three years is not out of band maximum variation between -4% of GDP and 6% of GDP;
- Net international investment position is not less than 35% of GDP;
- Real effective exchange rate is not out of the range of between -5% and +5% for euro area respectively -11% and +11% for the rest of the EU Member States in the last 3 years;

- The share of exports in world exports of a country is not reduced by more than 6% over the past five years;
- Nominal unit cost of labor (expressed as a ratio of average pay of an employee and real GDP per number of persons employed) not increase by more than 9% for the euro area and 12% for the rest of the EU Member States the last 3 years.
- Public debt should not exceed 60% of GDP;
- Average unemployment rate should not exceed 10% in the last 3 years.

European Commission presents an annual report to alert mechanism, published February 14, 2013, which identifies 12 EU Member States macroeconomic risks that require in-depth analysis: Belgium, Bulgaria, Cyprus, Denmark, Finland, France, Italy, UK, Slovenia, Spain, Sweden and Hungary. States enjoying a program of financial assistance from the EU and IMF - Romania, Greece, Ireland and Portugal - is already under a reinforced economic surveillance.

Internal imbalances

- Private sector lending must not exceed 15% of GDP;
- Real housing prices should not rise more than 6% per year;

Table No1 Scoreboard

2012	I. External imbalances and competitiveness				
	Current account balance (% GDP)	Net investment position (% GDP)	Change in real effective exchange rates (%)	Dynamics of export market shares (%)	Costs nominal unit labor (%)
Romania	-6,6	-64,2	-10,4	21,4	22,1
Belgium	-0,6	77,8	1,3	-15,4	8,5
Bulgaria	-11,1	-97,7	10,4	15,8	27,8
Denmark	3,9	10,3	0,9	-15,3	11
Germany	5,9	38,4	-2,9	-8,3	6,6

Sweden	6,3	2,6	237	40	7,6
England	3,4	3,3	212	80	7

Source: World Bank Report, <http://www.worldbank.org>

By analyzing the 10 indicators in the year 2012 it is noted that Romania has no internal macroeconomic imbalances, but it appears three external imbalances, the indicator for "costs nominal unit labor" correcting the following developments next year.

So, Romanian imbalance is emphasized further by the net investment position in 2011 with a considerable gap to the maximum allowed, although small patches (about 63% of GDP) than the current account deficit which is slightly below the lower limit of the variation.

Net investment position, ranking first three EU countries that are seriously affected by this external imbalance is:

1. Hungary, with a correction from the year 2011 to -108.5 -112% of GDP next year;
2. Portugal, with a correction from the 2011 to -103.5 -107.5% of GDP in 2012;
3. Ireland, with a percentage of 90.9% of GDP in 2011 increased to 92.2% of GDP in 2012.

If we were to define investment position, we say it is a necessary tool in the design of macroeconomic policies for external financing. This actually reflects the indebtedness of a country foreign debt structure, the situation of FDI and portfolio's stock of external financial assets and liabilities and in calculating its count changes in exchange rates, international prices other financial adjustments.

Although the euro zone economy is delicate, investment flows to Europe has continued to grow in 2011, investment projects being at a number higher than pre-crisis period, the number of projects increased by a share of 2% in 2011 compared to previous year.

The U.S. also stay ahead in terms of investment in Europe, exceeding by 26% the total number of investment projects and projects developed by this increased 6% in 2011, reaching the highest level in 10 years.

Specialists consider that Europe will overcome current economic problems faced due to the increased level of attractiveness. After China, Western Europe is regarded as the most attractive destination for FDI and Central and Eastern Europe ranks third.

The most attractive European countries currently-Switzerland, Sweden and Germany - ranks 3, 5 and 9. These countries have an export-oriented economy and maintain fiscal discipline. Prospects for European countries with financial problems seem to be dependent on how well they are prepared to recover. Ireland (20) Iceland (26) and Italy (40) seem to be doing better in this respect than Portugal (41) Spain (39) and Greece (58), which still scares investors.

After significant declines in 2010, FDI flows from all European countries doubled in 2011. FDI flows from the EU to the rest of the world came to 370 billion in 2011, having fallen from 316 billion in 2009 to 146 billion

in 2010. Foreign direct investment in the European Union in the world (inflows) stood at 225 billion in 2011, having fallen from 234 billion in 2009 to 104 billion in 2010.

Half of EU investment in the world came from the U.S. in 2011. EU investment increased in 2011 from the point of view of all partners except Russia. In 2011, EU investment principal destinations were the United States (111 billion), offshore financial centers (59 billion), Switzerland (32 billion), Brazil (28 billion), China (18 billion), Canada and India (both 12 billion). A decrease of 2 billion investments has been with Russia in 2011.

In 2012, the main investors in the European Union were: United States (115 billion), Switzerland (34 billion), and offshore financial centers (16 billion), Canada (7 billion), Hong Kong (6 billion), Japan and Brazil (both 5 billion).

Luxembourg, with investment of 110 billion, was the largest investor outside the European Union in 2011, followed by the UK (89 billion), Germany (34 billion), France (21 billion), Spain (19 billion) and Belgium (16 billion). Luxembourg (with 86 billion) was also the largest recipient of foreign investment from outside the EU, the Swedish (16 billion), Spain (15 billion), United Kingdom (14 billion), France (12 billion) and Germany (11 billion).[9] The role of Luxembourg in EU FDI is mainly explained by the importance of financial intermediation activity.

As in previous years, the EU was a net investor in the rest of the world, FDI outflows higher than inflows of 145 billion Euros. Between Member States of the European Union, the United Kingdom was the largest net investor outside the European Union with net investment of 75 billion, followed by Luxembourg (25 billion), Germany (23 billion) and France (9 billion).

Foreign direct investment in Romania

Global economic crisis caused a significant decrease in FDI inflows, in Romania. Start of this economic crisis is felt in Romania, especially in the second half of 2008 and with it, one can feel the lack of confidence of foreign investors. [2]

In terms of government programs and strategies for economic and social reform

insufficiently documented as priorities for strategic vision, effective privatization of inefficient assets or privatizations of different types of sectors, most FDI aimed at privatization of assets effective, the remains of the losers.

Study team auditing and financial consulting company Ernst & Young in the European Attractiveness Survey report 2012 states that Romania is among the top six European countries for attracting investment in the next three years. This study is based on analysis of various factors such as: the advantage of growth rates of GDP compared to the EU average promising and valuing human capital.

The study is based on a methodology that includes analyzing the number of foreign investment projects carried out in 2011 and analysis software, perceptions of the attractiveness of European countries for foreign investment

According to provisional data provided by the National Bank, foreign direct investment continued to decline in 2012, with a decrease rate of 15.61% in the first quarter of this year, net inflows of foreign direct investment reached a value of 400 million, from EUR 474 million in the first quarter of 2011.

This decrease in the flow of foreign capital actually represents a decrease of interest of foreign investors in the national economy as it is perceived as having a high degree of risk and exposure to foreign markets.[4]

An attractive market for foreign investors and foreign capital is, first, that the domestic capital market.

Romania due to political and economic instability has lost several opportunities, namely large investment companies Mercedes, Michelin, Swarovski, who have developed businesses in other EU countries. In this sense I think we should set a strategy for attracting foreign investors in Romania.

Measures stimulating foreign investment include all government actions that lead to increased profit potential and reduce investment risks it entails. Foreign investors need to give specific guarantees national trade regime, to protect their property and invested capital and to facilitate the transfer of earnings.

The institutional framework for attracting foreign investments in Romania began with

the establishment of the Romanian Agency for Investment Promotion and Economic Aid Abroad (July 25, 1990), which operated until 1991, when it was founded ARD (Romanian Development Agency).

This had a major role in promoting and attracting FDI. Currently, the promotion and attracting foreign capital deals Romanian Agency for Foreign Investments (ARIS). FDI legislation changed in 2007, by adopting a new investment law that would replace the old, thus in line with EU legislation.

The innovations of this law refers to the principles of the law, of which the most important is equality of treatment between Romanian and foreign investments and local government involvement in supporting and promoting foreign investment and creation of technical staff.

As regards foreign direct investment regime in other countries in Central and Eastern Europe, the facilities offered by these foreign investors are varied:

- an income tax varies between 18% and 40%. Hungary lies at the lower and upper limit is Bulgaria and Slovakia.
- Hungary, Slovenia and Poland provide facilities for major investment in certain areas (industrial zones, free economic zones, priority areas, disadvantaged areas).
- Hungary granted an exemption for 100% profit tax for investments in production capacity, made in priority areas (regions where unemployment is over 15%).
- In Poland, the investments between 350,000 and 2 million Euros, made in special economic zones benefit from exemptions from income tax of 100% in the first 10 years and 50% in the coming years.
- In countries like Slovakia, Slovenia and the Czech Republic to provide facilities for foreign companies that hire unemployed people, creates jobs and pays special attention to training the local workforce.
- Assets constituting a contribution to capital are exempt from customs duties - Czech Republic, Croatia, Poland, Lithuania, and Estonia.

Facilities are a key element in stimulating interest in shaping foreign investors power, according to which a particular position to

obtain competitive as international investment magnet. They were originally granted by a law organic nature. The facility is much diversified as measures and instruments, all with direct and immediate impact on the behavior of foreign investors. Therefore, according to the cyclical evolution from one stage to another, the facilities are often modified to meet the interests of every moment.

Conclusions

After analysis the evolution of FDI flows in Romania during 1990-2011, we concluded that the economic, legislative and institutional stability, and various facilities provided, can greatly influence investor decisions. Size, attractiveness and clarity of presentation offer investment projects have a major role in determining the volume of foreign capital inflows. Also, a significant role in attracting foreign investors and agencies they have to promote foreign direct investment.

At present, Romania, EU member, but last position came as the country with the greatest economic and social differences from other Europeans. Gross domestic product per capita, labor productivity, exports, the average wage in Romania are among the lowest in the European Union. Hence one important conclusion: Romania's economic efforts must not fall, but rather to be amplified.

There is no goal more important than economic development in Romania, based on the most of opportunities offered by EU accession makes it a real "magnet" for foreign investors. EU accession has brought an improvement in the Romanian business environment, improvement that began to be felt in regard to a more stable legal framework and the existence of more transparent business practice.

Challenges for ECB's Monetary Policy in the Post-Crisis Period

Andrieş Andreea

“Alexandru Ioan Cuza University” of Iaşi

Doctoral School of Economics and Business Administration

andreea_andries01@yahoo.com

Abstract

The unprecedented effects of the current global crisis have generated a broad range of complex challenges for central banks, many of them being unique. Using a qualitative approach, this paper aims to highlight the main difficulties with which central banks will face in the post-crisis period, insisting on what is specific to the European monetary authority. The main conclusions of the study are as follows: 1) the most important common challenges for major central banks and not only, include: adequate implementation of exit strategies from unconventional measures, setting up the monetary policy framework so as to ensure that both price stability and financial stability are achieved; the management of asset price bubbles; 2) in addition to those mentioned above, the ECB is faced with the urgent needs to manage the sovereign debt crisis with caution and firmness and restore confidence in the financial markets and in the economy.

Key words: EMU, monetary policy, financial crisis, sovereign debt

J.E.L Classification: E52

1. Introduction

Since the establishment of the European Monetary Union, elaboration and implementation of the single monetary policy has been a constant challenge for the European Central Bank, if we take into account at least the following two reasons: diversity of the economies from multiple perspectives or the absence of a fiscal union.

The purpose of the present study is to outline the complexity of the main challenges for the ECB in the post-crisis period, also by presenting common challenges for major central banks.

With the onset of the current crisis, the challenges for the ECB have boosted substantially. In addition to the difficulties faced by the majority of central banks in developed countries (level close to zero of monetary policy interest rate or malfunctioning of the financial markets which have made imminent the introduction of non-standard measures), the European monetary authority must face maybe the greatest challenge - the sovereign debt crisis - not just in the light of the present implications, but of the effects in the long term. In the same vein, if we consider the relationship between monetary policy and fiscal policy, it is necessary to manage it with great caution, especially in order to avoid the infringement of the independence of the European Central Bank.

Other important challenges for the ECB are the following: the implications of maintaining too long the present level (unprecedented) of the monetary policy interest rate, the need to reduce the degree of heterogeneity in the sphere of monetary policy impulses or configuring with maximum precision of all the dimensions of the withdrawal process from unconventional measures.

The rest of the paper is structured as follows: section two reviews the specialized literature in the field approached; section three outlines common challenges for central banks in the post-crisis period; section four points out some insights on the main forthcoming challenges for the European monetary authority; section five concludes and presents future research directions.

2. Literature review

Considering the fact that the current economic and financial crisis is still ongoing, the literature on the challenges for the ECB in the post-crisis period is found in an early stage of formation. However, we can observe a general consensus regarding one of the challenges with great weight and with long-term bearing namely the proper management of the sovereign debt crisis together with the other 17 fiscal authorities [1, 7, 9].

If we consider the standard monetary policy framework, Stark draws attention on maintaining too long the present level of the key interest rate focusing on the potentiating of the risk channel's functionality contoured in the context of the subprime crisis [4].

On the same issue, but from another relevant perspective, Praet analyses the excess liquidity in the banking system obtained by means of very low interest rates, with reference to the so-called "instrument instability" phenomenon in policymaking: "the need to apply larger and larger doses of the same policy interventions only to see their macroeconomic influence becoming more and more tenuous. Monetary policy is a relatively blunt instrument that will not in itself change the fundamental course of economic developments, when imbalances are plural and lie outside its sphere of responsibilities" [7].

Also, the significant expansion of the ECB's balance sheet with government bonds, imposes in the post-crisis period a reconfiguration of the monetary policy - fiscal policy report, with possible implications for the central bank's independence and its credibility, specialized opinions insisting that "monetary policy is not and cannot be a substitute for sustainable fiscal policies, structural reforms and adequate governance" [6].

From a different optic, namely that of regulations, ECB's officials analyse the interaction between specific liquidity standards of Basel III and the single monetary policy, for example, by pointing out that "in jurisdictions where the set of assets eligible for central bank operations is broader than the one qualifying for the fulfilment of liquidity standards, one

may witness an increased reliance on central bank refinancing using less liquid assets as collateral" [5].

Based on the foregoing, it can be seen that though the current global crisis is still under way, the range of challenges for the European Central Bank is already very large, complex and with important implications in the medium and long term.

3. Common challenges for central banks in the post-crisis period

If we consider challenges for central banks both during the recent turmoil and looming during the ex-post turbulences, the current global crisis is a very prolific one. Taking into account the fact that there is a high degree of similarity between the effects of the actual crisis and the reactions of central banks from developed economies, we believe it is useful to first sketch some common challenges for the monetary authorities and then highlight the ones specific to the European Central Bank.

In conditions in which central banks from developed economies (the United States of America, the Euro Zone, Japan, United Kingdom) and not only, have been faced with major deficiencies in financial markets and/or the impossibility of reducing the level of monetary policy interest rate beyond the threshold of 0%, they have appealed (temporary) to the unconventional monetary policy framework. Consequently, one of the major challenges facing central banks, including the ECB, is to identify with great precision the coordinates of exit strategies (time of implementation, choice of pace, duration, etc.).

Moreover, the coordinates of withdrawal strategies are difficult to identify in the absence of experience (except for Japan), but also due to the fact that central banks are trying to avoid, on the one hand, the distortion of markets' natural functioning mechanisms (in terms of maintaining too long the non-standard measures), and on the other hand, damaging a fragile economic growth (in terms of too early withdrawal of non-standard measures).

In the same vein on the very low level of monetary policy interest rates and central bank's extended balance sheets, there is the danger of confrontation with the inflationary risk with well-known negative effects. Thus, it is inevitable a reconfiguration of the relationship between monetary and fiscal policy that does not affect the independence of the central banks and their credibility.

On the other hand, the general monetary policy framework (strategy, objectives, instruments, transmission mechanism) is found within a process of transformation that will try to answer as best as possible to the need of insuring both price stability and financial stability in an optimal monetary "mix", that is why the task of central banks is one so complex and provocative.

Last but not least, the current crisis has prompted considerable controversy (without reaching a consensus) regarding the mode of action of central banks in terms of asset price bubbles in the sense of "leaning against the wind" or "cleaning up" after the bubble burst.

Therefore, in the post-crisis times, one of the most important common concerns for central banks stands in assuring both price stability and financial stability with only one instrument, which is currently not working at its normal parameters, namely the monetary policy interest rate.

4. Insights into the main forthcoming challenges for the European monetary authority

In addition to the previously mentioned challenges, the current global crisis is an important factor of amplification of what can be the greatest difficulty facing the ECB since its establishment, namely the sovereign debt crisis.

It should be noted, however, that sovereign debt issues do not constitute a reflect of some euro's weaknesses, but of the misguided policies in the past (in terms of non-compliance with the conditions enshrined in the Maastricht Treaty referring to the fiscal sustainability) implemented in certain countries in the European Monetary Union (Greece, Portugal, Spain, Italy).

Therefore, if in the period prior to the crisis, the absence of the fiscal union constituted a potentiating factor of asymmetries in the transmission of monetary policy decisions in the financial and real plan, the ECB's present task to manage the issue of sovereign debt crisis together with 17 distinct fiscal "umbrellas" is not easy at all, especially if we take into account phenomena like the ageing population.

Moreover, the restoration of euro's stability and the normal functionality of the propagation mechanism of monetary impulses depend crucially on restoring fiscal soundness and sustainability.

An important step in managing the sovereign debt crisis was made in 6 September 2012, when it was announced the concrete possibility to take Outright Monetary Transactions (OMTs) aimed to restore the normal transmission of monetary policy that has had the effect of stress diminishing in the financial markets. In the same vein, despite the officials' statements from the European Central Bank according to which Outright Monetary Transactions will not affect central bank's independence (OMTs not being a form of "disguised" financing of governments) and will not lead to inflation, concerns about the transformation of the relationship between monetary policy and fiscal policy at the expense of the first, still persist.

In terms of time horizon, in the short term, one of the major concerns of the ECB is carrying out successfully the European Banking Union, considering the fact that funding through banks is prevalent in the EU, on the one hand and consequences of banking crises like the one in Ireland, on the other hand. On the medium and long term, in addition to the problem of sovereign debt, the euro area enlargement is still a big challenge for the ECB, if we consider the following: the current configuration of the euro area is not included in the category of optimal currency area; the recent crisis has led to a loss of competitiveness in the countries that have recently joined the EMU; the lack of homogeneity of countries and the asymmetry in the transmission of monetary impulses still impede an optimal functioning of the euro area.

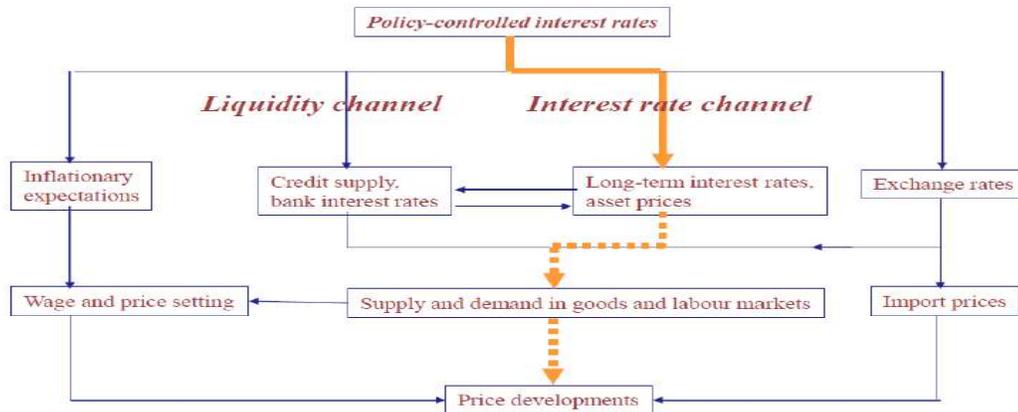

Moreover, the economic and financial characteristics of the candidate countries do not seem to relieve the burden of the ECB, on the contrary (the inflationist potential is higher, the soundness of public finances and structural reforms are still shaky and require a considerable period for curing and not only), which is why we consider that the ECB will probably be more prudent, especially given the example of the too early accession to the euro zone of countries such as Greece.

From another perspective, since the onset of the effects of the actual crisis, ECB’s efforts have focused on the proper functionality of the transmission mechanism of monetary policy

decisions, including the introduction of non-standard measures.

With the major malfunctions occurring at the level of the interest rate channel, the ECB was forced to open a new channel, namely the liquidity channel (with new financial effects and challenges in terms of managing it) (see Figure 1) in order to restore the normal functionality of the monetary transmission mechanism, and despite the lack of experience in using it, the results in the financial markets were favourable. However, one must have in mind that liquidity doesn’t solve structural problems and can’t be used infinitely.

Figure 1. Transmission channels of ECB’s monetary policy

Source: [1]

Because the effects of the global crisis have influenced the evolution of GDP and inflation, it was naturally for the monetary policy transmission mechanism to know the influence of new factors with significant weight as it is the sovereign debt, making more difficult the ECB’s main task. [8] Thus, in Figure 2 and Figure 3 one may remark a more powerful

impact of the monetary policy shock upon the GDP compared to inflation, but also the stronger impact in states under sovereign stress (Greece, Ireland, Italy, Portugal and Spain) mainly through the credit channel, compared to other countries (Austria, Belgium, Finland, France, Germany, Luxembourg, Netherlands).

Figure 2. Countries under sovereign stress

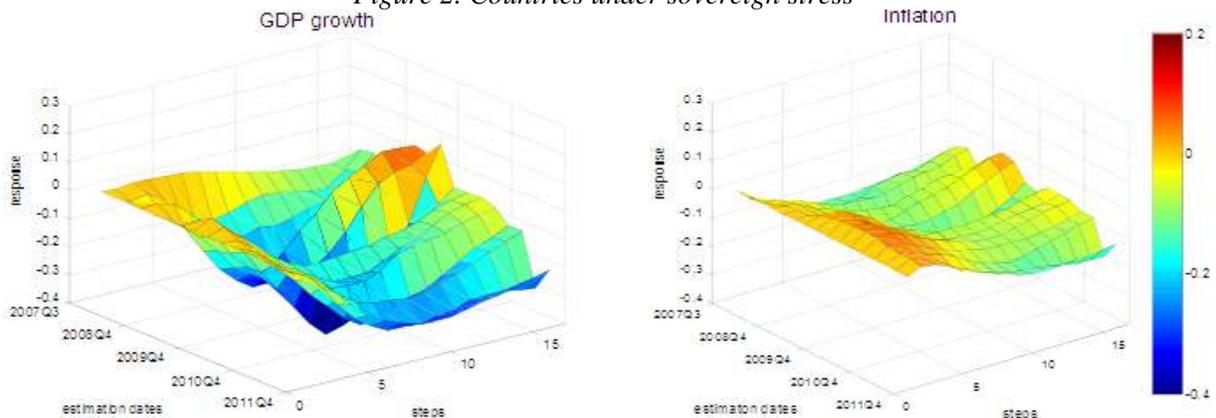

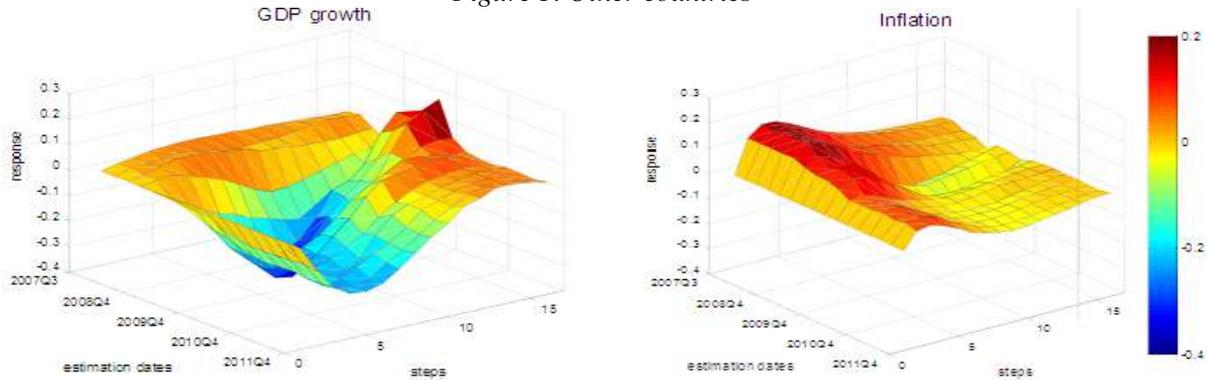

Figure 3. Other countries

Source: [8], p.35

From the perspective of trust which is so important in the transmission of monetary policy, amid increased aversion to risk (after the current crisis erupted) banks have preferred to keep liquidity at the ECB thus decreasing the volume of transactions and contributing to increased risk premiums. (See Figure 4) As a

result, according to those mentioned in the specialized literature, higher risk premiums, accompanied by higher volatilities of interest rates make more difficult the work of the European Central Bank and obstruct the normal functionality of the transmission mechanism of monetary policy.

Figure 4. Evolution of the recourse to deposit facility in the euro area and 3-month Euribor over OIS, in the period 2007-2013

Source: [1]

Moreover, at trust chapter it must be underlined also the worrying evolution of the Economic Sentiment Indicator (provided by Eurostat) which is of course unfavourable to the monetary transmission. Therefore, considerable efforts are needed on the part of the European monetary authority and not only, in order to install a solid confidence in financial markets and in the economy in general, so that the evolution of interest rates to be consistent with the economic and financial fundamentals and to allow a good and symmetrical transmission of monetary impulses of the European Central Bank.

4. Conclusions

The present work outlined some major concerns for central banks from developed economies and not only, for the period after the present turmoil (very low level or close to zero of the monetary policy interest rate and the danger of maintaining it for too long, substantial expansion of central banks' balance sheets, the difficult process to implement exit strategies from unconventional measures, adequate treatment on the formation of asset price bubbles, the reconfiguration of the

monetary policy framework in order to ensure that both price stability and financial stability are achieved and others) to highlight even more the complexity of the challenges for the European monetary authority.

In essence, it is worth noting that maybe the great and specific challenge for the ECB since the launch of the euro is the adequate management of the sovereign debt crisis in the absence of a single fiscal union and under the conditions of a financial and economic environment marked by uncertainty and fragility and a generalized mistrust.

Last but not least, it is imperative the need for submission of substantial efforts to strengthen the euro (to avoid in the future the question of dismantling the euro zone or of manifesting the redenomination risk).

In terms of future research directions, we consider analysing the evolution of ECB's monetary policy framework in the post-crisis period (with special focus on the monetary policy transmission mechanism) and the implications of Eurosystem's outright transactions in the secondary markets for government bonds upon the relationship between the European Central Bank's monetary policy and fiscal policy.

From the National Cabotage to the “Blue Belt”

Abstract

The EU Council initiated the public debate on the “Blue Belt” pilot project which took place in 2011 and was designed to promote shipping between ports within the EU (“small distance shipping”).

The purpose of the “Blue Belt” concept is to create an area of maritime transport without frontiers, for intra-EU trade by simplifying and speeding up the administrative procedures based on the use of modern monitoring technical capabilities.

Key words: Blue Belt, national cabotage, international cabotage, European Union cabotage

J.E.L. classification: K33 - International Law

1. Introduction

In the current framework, the intra-EU maritime transport, the free movement of goods and vessels from EU ports is still subject to complex administrative procedures. The council conclusions of 30 March 2009 (doc. 8079/09) expressed its support to the goal of expanding the internal market in transport by sea between EU ports in simplifying and speeding up administrative procedures.

Controls and administrative tasks do not allow intra-EU maritime transport to provide fair competition conditions in relation to other means of transport. Complex and lengthy customs procedures, which are not harmoniously applied in the EU, also lack the coordination of shipboard controls, leading not only to delays and increased costs for transport companies but also to the disruption of the free movement of goods within the EU.

In addition, from the point of view of the various authorities dealing with their ships

arriving or departing from EU ports, better coordination, better information sharing and avoiding the duplication of controls for the same goods in EU ports would allow an improved use of resources and would improve the operation of ports. According to the 2011 Transport White Paper, a "Blue Belt" on the seas around Europe will simplify the formalities applied to ships moving between EU ports.

The concept of "Blue Belt" aims to monitor the shipping utilization capacity in order to create a genuine maritime transport space without barriers.

The objective of this concept is to further simplify administrative procedures through the use of new technical capabilities to further integrate intra-EU maritime transport in a global network by providing a rapid transit of goods within EU ports from and consistent monitoring of ships and goods transported international waters.

On 7 June 2012, the European transport ministers have stressed the importance of the "Blue Belt" pilot project within the Council (Transport, Telecommunications and Energy). On this occasion, all delegations supported the continuation of the implementation and further development of "Blue Belt" services in order to eliminate unnecessary administrative obstacles in the way of transport and maritime trade. The message was clear: "If we want to strengthen maritime transport, there are required fewer burdens and less bureaucracy". A debate on the "Blue Belt" pilot project began.

2. The “Blue Belt” pilot project

The pilot project was implemented by the European Maritime Safety Agency (EMSA), which has used the maritime information exchange SafeSeaNet in order to transmit customs vessel traffic data.

During the project assessment, it has been concluded that the proposed approach (i.e. the “Blue Belt”) allowed the effective monitoring of ship movements. Its application also led to simplified procedures [1].

The debates that took place in this respect were, generally, in favor of the implementation and further development of the “Blue Belt” concept.

The integration of “Blue Belt” services in an appropriate legal framework had broad support. There have been views according to which:

a) it is necessary to evaluate the costs and benefits before proceeding to the legislative activity;

b) it is necessary to avoid the duplication of work and it is necessary to ensure efficiency in terms of costs;

c) it is necessary to apply more flexible customs procedures in Customs law and it is necessary to review EU customs legislation;

d) some Member States have asked for a clearer focus on the ultimate objective of creating a genuine internal shipping market.

In order to improve the collaboration between the authorities concerned, some Member States stressed that awareness on the “Blue Belt” concept should be done through proper information. In this case, there was revealed the crucial role incumbent on customs authorities.

Most delegations were in favor of broadening the scope of services through one interface beyond the communication between ships, ship operators and national authorities, including all stakeholders in the maritime transport sector, provided that sensitive data protection is ensured.

There is a difference of opinion and a warning to a very hasty enlargement before acquiring sufficient experience regarding the current rules on the single interface which will apply from the second half of 2015.

The Presidency summarized the views of Member States in a summary report [2]. The “Blue Belt” concept and the launch of a pilot project were approved by the Council in December 2010 [3].

The Commission included the “Blue Belt” initiative in the White Paper Roadmap to a Single European Transport Area [4].

3. The national cabotage

According to art. 125, paragraph (1), letter c of G.O. no. 42/1997 (R1), cabotage [5] is the carriage of goods and passengers between two or more ports, on Romanian inland waterways.

Access to maritime cabotage is dependent on flag, but different laws apply to the different types of cabotage: in the case of mainland cabotage and cruise ships, the law of the flag state applies, but if the ship is less than 650 gross tonnes the law of the host state can apply. In the case of island cabotage, the law of the host state applies. Nothing has yet been settled for offshore cabotage, i.e. for non-navigable structures erected on the continental shelf.

Coastal shipping [6] (shipping near the coast) is generally performed by:

- ships with a maximum capacity of 100 TRB, which do not bear away from their port to a distance of more than 65 miles;
- barges or other means of navigation of any tonnage, hauled;
- vessels and ships of any tonnage which usually does not leave ports and basins.

Cabotage and international tramp vessel services have been excluded from the rules implementing Articles 81 and 82 of the Treaty originally laid down in Regulation (EEC) No 4056/86 and subsequently in Regulation (EC) No 1/2003. They are currently the only remaining sectors to be excluded from the Community competition implementing rules. The lack of effective enforcement powers for these sectors is an anomaly from a regulatory point of view.

For example, for a truck registered in the RO, a course with a DE-DE load is considered cabotage; instead a DE-FR or a DE-RO course is not cabotage.

Short sea trade means the navigation executed between the national ports of the same sea (Toulou-Marseille, Constanta - Sulina). Long sea trade includes navigation between national ports located in different seas (Bordeaux, Marseilles).

4. The international cabotage

International cabotage means coastal navigation between the ports of different countries. UK divides "cabotage" in home trade and foreign trade, which is identical

with the long distance navigation. In France and Italy, "cabotage" is international and national; the latter is divided in terms of customs in small and great cabotage.

The transportation of goods by "cabotage" is based on a permit granted by the customs, subject to customs control; in case of transit, the goods transported by "cabotage" will be presented to the customs, at destination, within the deadline provided by the law. Transport and towage in national "cabotage" are usually reserved for national ships.

Vessel masters who do "small cabotage" are not required to have a patent higher than "captain of cabotage". Maritime transports in "cabotage" do not comply with the restrictions of the last paragraph of Art. 5 of the Hague Rules. Long-distance vessels are granted this right only for "determined goods" which are not part of normal commercial shipments during normal trade operations.

5. Community cabotage

Having regard to the Treaty establishing the European Economic Community, and in particular Article 84 (2) thereof, having regard to the amended proposal of the Commission [7], having regard to the opinions of the European Parliament [8], having regard to the opinion of the Economic and Social Committee [9], on 12 June 1992, the European Parliament adopted its Resolution on the liberalization of maritime cabotage and its economic and social consequences. This resolution is in accordance with Article 61 of the Treaty freedom to provide services in the field of maritime transport is to be governed by the provisions of the Title relating to transport. They had in view the fact that the abolition of restrictions on the provision of maritime transport services within Member States is necessary for the establishment of the internal market; whereas the internal market will comprise an area in which the free movement of goods, persons, services and capital is ensured; therefore freedom to provide services should be applied to maritime transport within Member States. The beneficiaries of this freedom should be Community shipowners operating vessels registered in and flying the flag of a Member State whether or not it has a coastline. By means of this resolution, this freedom is

extended to vessels also registered in Euros once that register is approved. In order to avoid distortion of competition, Community shipowners exercising the freedom to provide cabotage services should comply with all the conditions for carrying out cabotage in the Member State in which their vessels are registered; whereas Community shipowners operating ships registered in a Member State who do not have the right to carry out cabotage in that State should nevertheless be beneficiaries of this Regulation during a transitional period. The implementation of this freedom should be gradual and not necessarily provided for in a uniform way for all services concerned, taking into account the nature of certain specific services and the extent of the effort that certain economies in the Community showing differences in development will have to sustain.

The introduction of public services entailing certain rights and obligations for the shipowners concerned may be justified in order to ensure the adequacy of regular transport services to, from and between islands, provided that there is no distinction on the grounds of nationality or residence. Provisions should be adopted so that safeguard measures can be taken as regards maritime transport markets affected by a serious disturbance or in the event of an emergency; whereas, for this purpose, suitable decision-making procedures should be introduced. In view of the need to ensure the proper functioning of the internal market and of possible adaptations in the light of experience, the Commission should report on the implementation of this Regulation and if necessary submit additional proposals [11].

These devices imposed (by the European Community) the adoption of a normative act on the matter, entitled Regulation (EEC) no. 3577/92 of the Council of 7 December 1992, applying the principle of freedom to provide services to maritime transport within Member States (maritime cabotage) [10].

Maritime cabotage was liberalized on 1 January 1993. In the case of France, Italy, Greece, Portugal and Spain, territorial cabotage will be liberalized gradually according to a specific program for each type of transport service. In these countries, territorial and inter-insular cabotage was not liberalized until 1999 [12].

This exception was applied until 2004 for regular passenger services and craft services with a gross tonnage less than 650 tonnes for Greece.

6. The cabotage licence

The cabotage licence [12] is a document issued by customs to a shipping company, which allows the loading, carriage and unloading of goods without payment of customs fees, on condition that the transport is made between national ports and the handling of goods is made in a special berth.

To avoid taxes for such goods, when loading them, a document called "transit act," which accompanies the goods to the port of discharge, is issued. This act, which replaces a customs declaration, certifies that the goods are intended for domestic consumption and that they will not be unloaded in any foreign port; in the port of unloading, this document is customs evidence that the merchandise does not come from import.

7. Conclusions

Modernizing the European transport system requires combining several initiatives at all levels. It is expected that, in the next decade, the Commission prepares appropriate legislative proposals, which will include key initiatives and proposals in this regard.

Each of these proposals must be preceded by a thorough impact assessment; the EU added value and the principle of subsidiarity will be taken into account.

An increase in transport competitiveness is expected when applying the Blue Belt concept; also, taking into account the main objectives of the EU transport policies this will help reduce the GHG emissions from transport with at least 60% by 2050.

From a legal perspective, cabotage is defined as "navigation below the limits of a long course". In terms of customs, "cabotage" is defined as the transport of native goods from a port to another port belonging to the same state, to a confederation of states or to different states, linked by customs union, using for this purpose an international maritime route or with access to such a route. "Cabotage" is divided into "national cabotage" and "international cabotage".

Elements of Maritime Labor Law

Anechitoae Constantin

anechitoae@yahoo.com

Buzarna-Tihenea (Gâlbează) Alina

The Faculty of Law, Administrative Sciences and Sociology, Ovidius University of Constanta

alina_buzarna84@yahoo.com

Abstract

Maritime labor law covers issues such as the minimum requirements for the seafarers working on board, employment conditions, accommodation, recreational facilities, food and cooking, health protection, medical care, welfare, protection through social security and compliance and enforcement of rul.

Key words: Maritime, labor, legislation, employment agreement

J.E.L. classification: K33 - International Law

1. Introduction

Maritime labor legislation, adopted by the International Labor Organization, seeks to ensure decent working and living conditions on board and limit social dumping, ensuring fair competition conditions for ship owners, conditions that respect the seafarers' rights.

2. Primary legislation

In international law, the seafarers' employment relationships are expressly provided for in the Convention no. 22 of 24th June 1926 on the seafarers' terms of employment and they are applied to all vessels registered in the Member State which has ratified this Convention and to the ship owners, commanders and seafarers of these vessels.

The Convention shall not apply to:

- a) warships;
- b) government vessels not engaged in commercial purposes;
- c) vessels engaged in coastal trade transport;
- d) pleasure yachts;
- e) Indian vessels;

f) fishing vessels;

g) vessels less than 100 gross registered tons or 300 square meters or vessels engaged in domestic transport, with tonnage under the tonnage limit prescribed by the national legislation for the special status of these vessels, in force upon the adoption of this Convention.

According to article 3 of the Convention, the name and the circumstances in which the employment contract is signed should be provided for in the national legislation, so as to ensure the control of the competent authority.

The Standards of the International Labor Organization regarding sailors have a *certain originality compared* with those related to workers, generally *being adopted in special sessions - called maritime sessions* and entering into force in specific circumstances [1]. Every four years, two sessions of the International Labour Conference take place: a normal one in June and, another one, called the „maritime”, takes place either in spring or in fall

3. *Maritime Labor Convention* - MLC no. 186/2006

The interest of the International Labor Organization to develop a new instrument in order to regroup all maritime conventions was materialized once with the adoption of Convention no. 186/2006 on maritime labor, signed on 23rd February 2006, at Geneva. This Convention, described by some analysts as *a charter of the seafarers' fundamental rights*, contains clear regulations, which are also flexible enough to uniformly allow Member States to establish the seafarers' rights and obligations [2].

The new Convention consolidates and updates the 68 maritime conventions and

recommendations of the International Labor Organization adopted in 1920.

The Maritime Labor Convention - MLC of 2006 was adopted by the International Labor Organization (ILO) with unanimous votes. It applies to international shipping and covers key issues such as the minimum requirements for seafarers to work on a vessels (Title I of MLC), the conditions of employment (Title II, MLC), accommodation, recreational facilities, food and catering (Title III, MLC), health protection, medical care and social services (Title IV), and its compliance and implementation (Title V) in order to ensure decent working and living conditions on board and the procedures for implementing them.

The Convention can be seen as the first maritime labor code for more than 1.2 million seafarers worldwide, as well as for ship owners and maritime nations across the globe.

The Convention will enter into force after its ratification by the 30 member countries of the International Maritime Organization representing at least 33% of the world gross tonnage. At the moment, 22 countries representing over 45% of the world's tonnage have ratified the MLC [3].

3.1. The provisions of the *Maritime Labor Convention* - MLC no. 186/2006

As ILO generally recognizes and explicitly declares, the maritime industry is “the first truly global industrial area” which “requires an international legal response, properly articulated – global standards applicable to the whole area”.

The Maritime Labor Convention, adopted in 2006, contains comprehensive provisions relating to the employment protection and the rights of all seafarers, irrespective of nationality and flag.

MLC seeks the creation of decent working conditions for seafarers and ensures fair competition for quality ship owners. It sets out the seafarers' rights to decent work for a wide range of situations and it was intended to be globally applicable, easily understandable, updatable and uniformly enforced. It has been designed to become a global instrument known as “the fourth pillar” of the international regulatory regime

for quality shipping, complementing the three major conventions of the International Maritime Organization (IMO):

- The International Convention for the Safety of Life at Sea (SOLAS);
- The International Convention on Standards of Training, Certification and Watchkeeping for Seafarers (STCW Convention);
- The International Convention for the Prevention of Pollution from Ships (MARPOL).

MLC has four titles that refer to the rights of seafarers:

- Title 1. Minimum requirements for seafarers to work on a ship;
- Title 2. Conditions of employment;
- Title 3. Accommodation, recreational facilities, food and catering;
- Title 4. Health protection, medical care, welfare and social security protection.

In addition, Title 5 of the MLC provides for mechanisms that improve the supervision at all levels, from vessel, company, flag State and port State to the State provider of workforce and the ILO system for worldwide uniform compliance and control. Indeed, in addition to a solid set of rules, it was needed a more effective system of law enforcement control and compliance in order to eliminate substandard vessels, for reasons of vessels safety and security and for environmental protection.

The task force on maritime employment and competitiveness recommended the implementation of the MLC. This task force is an independent body created by Vice President Siim Kallas, in July 2010, and it completed its work in June 2011, by publishing a report [4] containing policy recommendations on how to promote the seafaring profession in Europe.

4. The European Union's interest in maritime labor

The EU Member States and the Commission supported the ILO's work in this area since the very beginning. The European Union considers valuable the MLC contribution because this convention aims to establish several fair competition conditions in the maritime field globally, by setting common minimum standards for all flags and seafarers.

In this respect, the EU has already adopted the Council Decision 2007/431/EC of 7th June 2007, authorizing the ratification by the Member States, in the interest of the European Community, of the ILO Convention of 2006 on maritime labor [5]. Some Member States have already ratified this Convention (Spain, Bulgaria, Luxembourg, Denmark, Latvia and the Netherlands), while others are about to do it. In fact, the national laws of Member States are generally more protective and more detailed than the ILO standards. In order to maintain consistency between the international and national standards and to ratify the Convention, it is required the prior completion of a vast and long review of the national legislation.

Also, the EU adopted the Council Directive 2009/13/EC of 16th February 2009, implementing the Agreement between the European Community Shipowners Associations (ECSA) and the European Transport Workers' Federation (ETF) on the Convention of 2006 on maritime Labor and amending the Directive 1999/63/EC [6]. The Directive 2009/13/EC is a significant achievement of the sectoral social dialogue and this proposal aims to ensure that it has adequate means of ensuring its implementation throughout the Union.

To this end, it also provides for the obligation of Member States to implement the Directive 2009/13/EC, when they exercise their powers as flag States. In the current situation, through the Directive 2009/13/EC, the European legislation has been aligned with the international standards set by the MLC. This directive takes over the relevant provisions of the MLC contained in Titles I, II, III and IV (mentioned above), which establish the seafarers' rights.

4.1. European social partners

However, because the European social partners which wish to implement the agreement by a Council decision under Article 155 of TFEU do not have the power to include in their agreement the provisions to ensure the implementation contained in title V of the MLC, they addressed the Commission asking it to do so. This is precisely the goal proposed by this initiative, in connection to flag State responsibilities.

This initiative is part of the EU policy on maritime professions. In fact, as outlined in the Commission Communication to the European Parliament, the Council, the European Economic and Social Committee and the Committee of the Regions, entitled “Strategic goals and recommendations for the EU’s maritime transport policy until 2018”, the EU has a real interest in making maritime professions more attractive for Europeans through activities involving, as appropriate, the Commission, the Member States and the maritime industry. This directly affects the implementation of the MLC, which brings considerable improvement of working and living conditions on board.

This Communication stresses that the existing agreement between the European social partners on the implementation of the key elements of this Convention demonstrates the overwhelming support for this initiative by the maritime industry and, therefore, shares the actions of the European Union and of its Member States which should aim at:

- the move towards the rapid ratification of MLC by Member States and the immediate adoption of the Commission proposals by the agreement of social partners on the implementation of the Convention key elements into EU law;
- the actual enforcement of the new rules through appropriate measures, including the control requirements for the flag and the port State [7].

The White Paper “Roadmap to a Single European Transport Area - Towards a competitive and efficient transport system in terms of resources” [8] underscores the importance of the social agenda for maritime transport, both to promote employment and to increase safety; the Commission Staff working Document accompanying the White Paper anticipates launching a proposal aimed at ensuring the effective implementation of the MLC.

5. Social standards based on ILO conventions

Currently, during the controls applied by port States, there are already carried out inspections on the social standards based on the ILO conventions, particularly the *ILO Convention no. 147/1976* concerning the

Minimum Standards in Merchant Ships relating to [9]:

- Convention no. 7/1920 on the minimum age (maritime employment);
- Convention no. 23/1926 on the Repatriation of Seamen;
- Convention no. 22/1926 on the terms of seafarers' employment;
- Convention no. 53/1936 on officers' Competency Certificates (Articles 3 and 4);
- Convention no. 58/1936 on the minimum age (maritime employment) (revised);
- Convention no. 68/1946 on (crew's) nutrition and dining area (on board) (Article 5);
- Convention no. 73/1946 on (seafarers') medical examination;
- Convention no. 87/1948 concerning Freedom of Association and Protection of the Right to Organize;
- Convention no. 92/1949 on the Accommodation of Crews (Revised);
- Convention no. 98/1949 on the application of the right to organize and bargain collectively;
- Convention no. 134/1970 on preventing accidents (seafarers' employment) (Articles 4 and 7);
- Convention no. 138/1973 on the minimum age (maritime employment).

These conventions have been reinforced by the MLC (2006), but they are still in force, because it would be possible for some parties to favor their continuation, without the ratification of the MLC.

6. Conclusions

Therefore, by controlling flag and port States, the EU must ensure the application of the MLC standards regarding Maritime Labor on board of all ships entering EU ports, regardless of the seafarers' nationality.

The enforcement of the MLC standards by flag and port State control should also be considered as a way to limit social dumping, which is a deterioration cause of the working conditions on board; at the same time, it penalizes ship owners not providing decent working conditions in accordance with the International Labor Organization.

Abstract

Financial integration, the greatest achievement of the European Union, offer many advantages both in terms of the financial sector and also the private sector. The purpose of this article is to highlight in which way the recent crisis has affected financial integration and also the manner in which the common market influenced the triggering of financial turmoil.

Literature renders the positive effects who can be felt as a result of financial integration, but in the circumstances of the crisis were highlighted and some disadvantages of such a process. Analyzing movements in the money market, sovereign debt market and retail banking, we see that financial integration was one in development, evolution who has been affected by the recent crisis.

We conclude that liberalization was the trigger factor of recent crisis, but the reforms undertaken in this sense can ensure an sound financial integration, an sustainable economic environment and economic growth.

Keywords: financial integration, financial crisis, reform.

J.E.L classification.: F41, F51, F53.

1.Introduction

Financial integration ensures the transmission of monetary policy, the proper functioning of the payment system and ensure financial system in the European Union. Over time, various measures were taken to ensure a high level of integration and have been observed, especially after the introduction of the euro, significant developments in this plan. But the triggering of recent financial and economic crisis has reduced the increases rhythm of this process,

highlighting also a series of destabilizing elements that can accompany financial integration. Reducing transaction costs, the diversification of investment portfolio, risk dissipation, increase competitiveness are just some of the benefits of financial integration, but have been identified and a series of destabilizing elements of this process such as uncontrolled liberalization of the capital, weaknesses of regulations and excessive risk taking.

The article continue to highlight he ways in which the recent international crisis has affected the money market, of bonds and banking market and the measures that have been taken by the appropriate authorities to reduce the negative effects of the crisis, ensuring financial integration and a business climate favorable to economic growth. The article ends with conclusions.

2.European financial integration and the recent crisis

Of the Eurosystem, financial integration is seen as a situation where no discrimination is made between economic agents, having free access to capital. Price convergence means not integration, it is necessary but not a sufficient condition [1].

Financial integration - seen essentially as a common capital market and financial services represent the greatest achievement the European Union of the last decade. Aiming achieve this integration were initiated several processes (including the euro) but were interrupted and resumed by the recent international financial crisis and more recently by the European sovereign debt crisis.

Creating a common financial market involves a series of significant advantages, including control of all sources of capital. This surveillance performed on capital was recovered in interest rates which have been

leveled and have become more stable, creating an environment where new opportunities are available to both companies and households. From here the harmonize financial benefits have expanded in terms of reduction of unemployment rate and economic growth.

The introduction of the euro has significantly pulsed achieving financial integration by reducing transaction costs, increasing investment resources, reducing risks and rates of exchange between currencies, but also brought market confidence, which has favored the development of direct investment and of entire investment portfolio.

All these elements, together with a central bank, focused on ensuring price stability, helps develop financial innovation useful in carry out the activities in the real market. Also, an integrated financial system ensures proper transmission of monetary policy in the euro area.

In addition to this last item, financial integration will increase the Eurosystem responsibilities in ensuring financial stability and of payment system, will determine the modernization of the financial system and contribute to the growth of non-inflationary economic climate [2].

Moreover, the stability and an adequate supervision of the market facilitate the appropriate allocation of resources, diversification of assets and an increased competition between financial institutions leading to a reduction in intermediation costs [1].

In literature is appreciated that a more integrated financial market is beneficial to an sustainable economic growth. Both financial integration and also financial innovations have beneficial effects on financial efficiency and on real market [3]. Moreover, an long-term positive impacts on economic growth is observed in the reduction of market volatility.

Contrary to this statement, are authors who believes that a common financial market, characterized by greater mobility of capital, leading to an increase risks, speculation in the market and macroeconomic instability [4] and [5]. Same idea compart and Papademos, which recognizes that positive effects may be accompanied by inconveniences in risk

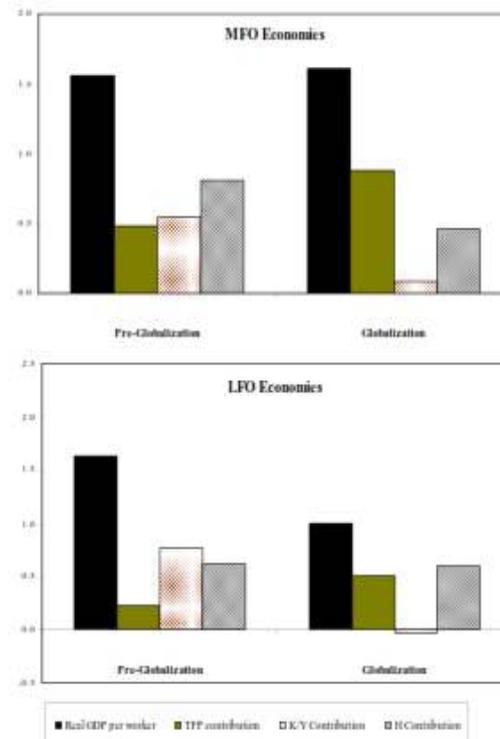

management plan and can not be independent of the business model practiced by banks or risks taken individually [3].

Contrary to these economists, the authors Abdilahi and Katsushi argue that financial integration is beneficial to economic growth, in these circumstances will be registered positive effects in terms of economic performance. They also said that accelerating the integration process will reduce the negative effects of the crisis and will avoid such situations in future [6].

Financial integration through the financial system channel the financial resources necessary for economic growth: ensures trade fluidization, portfolio diversification and risk reduction. Also, financial innovation reduces the production of information asymmetries, reduce transaction costs and increase competitiveness, all of this are possible only through an integrated market.

Studies undertaken shows that financial integration generates direct positive effects on productivity growth and the economy [7].

Figure 1. Growth Accounting for More and Less Financially Open Economies

Source: M. Ayhan Kose, Eswar S. Prasad, and Marco E. Terrones, *Does Openness to International Financial Flows Raise Productivity Growth?* 2008 International Monetary Fund, p.33

In addition to these advantages generated

by the financial integration, recent economic and financial crisis highlighted and weaknesses of a common market. Thus, it was shown how the financial integration develop volatility in market conditions through contagion effects generated by the absorption of capital flows, lack of fiscal integration, inadequacies in financial supervision plan and regulation.

Thus, the integration process can be mentioned among the **causes** of recent international financial crisis. Especially if this affirmation can be supported by the transfer of credit risk through financial innovations facilitated by liberalization of capital within the single market [3]. But, however, the contribution of financial innovation and integration was not so severe that they can be unic responsible for producing the recent financial crisis.

González-Páramo claim that the recent financial turmoil has shown that the interconnection between financial markets and the dependence by an integrated market, to which is added an under-regulation and complexity of financial instruments can contribute to decrease market efficiency, the emergence of systemic risk and the turbulence transmission to the entire financial system [4]. Even if financial integration is not a destabilizing force in itself, the risks of the underlying stability of a strong financial integration can produce economic imbalances.

Another example in emphasizing the possible destabilizing effect of integration refers to the banking integration, making direct reference to information asymmetries, assuming risks and underestimating the risk of contagion. Even though at the level of private sector, the effects of banking integration are major, an acceleration of this process causes major firms to take big risks, exacerbating the effect of financial crises on the corporate sector.

The simultaneous development and in an exaggerated manner of economic growth, of liquidity, financial integration, while is registered an relaxation in the regulatory plan may lead to crisis [2].

The global crisis has shown that international financial integration increased monetary policy costs and the failure of reglementation, both in the pre-crisis and in the management of severe financial stress

situations [8].

Analyzing movements in the money market, sovereign debt market and retail banking, we can see that the process of financial integration was in development and sustainable, a trend which has been affected by recent crisis.

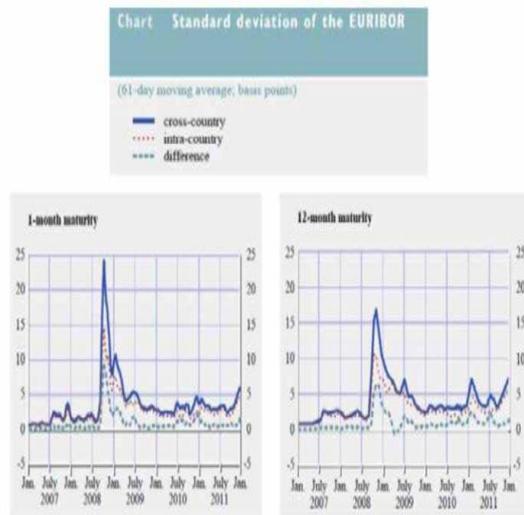

It is obvious that European financial integration has not manifested uniformly in all market sectors. For example, the integration from the retail banking remained limited in terms of legal elements, institutional and regulatory. However, the measures taken in this purpose make financial integration to progress [9].

The recent crisis has affected the level of integration of the different sectors of the economy, especially the interbanking sector, which was the most integrated in the euro area [2]. Financial integration has been affected directly by creating an inequitable institutional framework: banks in countries with fiscal problems were faced by raising financing costs, which were reflected in increasing sovereign risk. Moreover, the government financed bank bonds (an instrument widely used in crisis times) and these have different values depending on national fiscal situation. Lack of liquidity caused the call to private sector funding, concomitantly with much higher sovereign risk exposure [10].

Monetary market, the most integrated system before the crisis, was and the most affected. The differences between the standard deviation of EURIBOR rates have reached levels unimagined, while the market participans were accorded expensive loans to other participants. Mistrust in market was felt in repo market prices, price risk depending more on the geographical origin and the goods brought under warranty.

During 2011, the developments in the euro area money market were characterised by two phases: (i) a temporary moderation in the money market tensions in the first half of the year, with a gradual decrease in the excess liquidity in the system and higher money market activity; and (ii) a serious worsening of money market conditions in the second half of 2011, owing to the intensification of the sovereign debt crisis.

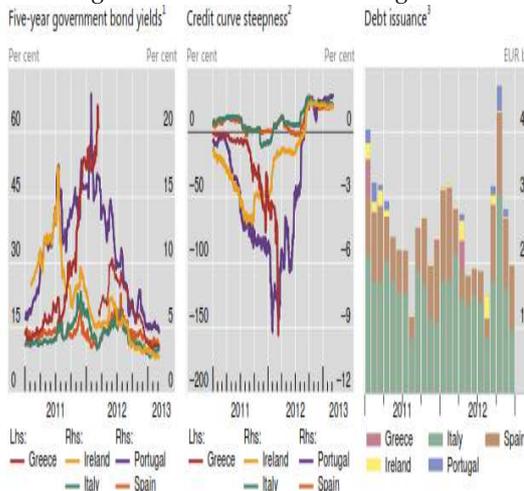

Figure 2. Money market rates: financial crisis stress and cross-border dispersion

Source: Benoît Cœuré: *The way back to financial integration*, Bank of International Settlements, 2013, p. 3.

Another market affected by the crisis, with repercussions on sovereign debt was **bonds market**, both corporate as well as public. Taking into account the credit risks, of price, to which is added the specific risks of each instrument caused the increase of country risk.

Figure 3. Euro area sovereigns

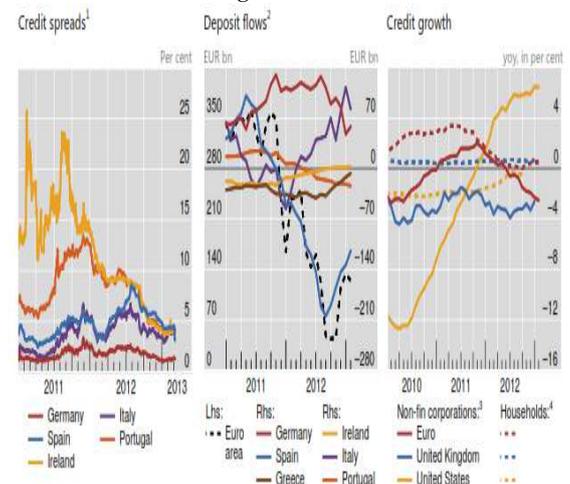

Source: *International banking and financial market development*, Bank for International Settlements 2013, p. 9

Contrary to the last market, **equity markets** was less affected by the crisis and judging in term of integration. As about **banking market**, and it has been affected by the crisis, observing differences in the euro

area in storage costs which will be transferred later in the prices of loans.

Figure 4. Indicators of bank funding and credit growth

Source: *International banking and financial market development*, Bank for International Settlements 2013, p. 10

To remedy such negative effects and to ensure the transmission of monetary policy in an appropriate manner, the Eurosystem has adopted a series of non-conventional measures. All measures have been taken to accumulate market liquidity, avoiding improper transactions of assets and to reduce long-term lending.

Stability, proper functioning of financial markets and an increase in its level of integration will depend on the success, more complete and resilient economic governance framework. This effort is ongoing; some steps have been taken, others are under way, but more will need to come.

Financial integration was seriously affected by the recent crisis and the measures to be taken to remedy this situation must be expedited. To this purpose, mobilizing capital flows of private markets and the improvements from supervision plan, regulation and crisis management at the local level are essential.

Significant changes have been made in this regard, such as the creation of the European Financial Stability Facility, the European Stability Mechanism, three European Supervisory Authorities and the European Systemic Risk Board.

In this sense, [1] believes that a banking union will be suitable for ensuring a proper

financial integration in which it holds an important place the central monetary authority. A banking union, which is based on new regulatory standards will help to reduce the risks which reverberated on financial stability, ensuring a more integrated market.

In the same plan of consolidation of euro-zone on long-term, Rodrigues consider it must be secured an fiscal solidarity to support sovereign debt, achieve an financial reform, together with the policy decisions to ensure financial stability and economic growth, ensuring nominal convergence between member states of euro-zone - all these being subordinated to democratic decision at european level [11]. According to the same researcher, the items listed should be the principles whose application can eliminate the negative effects of the recent crisis and to restore the credibility and the conditions of creating an appropriate European integration.

In his turn, European financial integration is a process that calls for increased monitoring of elements who affecting financial stability, among them mentioning the appropriate allocation of funds, risk control from the financial institutions, market discipline, concentration of investments and the effects of globalization [2]. In 2005, the same author specify that the whole process of integration is the responsibility of the ECB and the Eurosystem, these elements emphasizing very much on supervision, regulation and stability. During this process is requested the existence of interconnections between market forces and of public authorities.

However, financial integration that has occurred since the introduction of the euro has significantly increased living standards, financial stability and economic one . Knight recognized that the integration process has been affected by the recent crisis experience, but of these events can be extracted conclusions and lessons conducive to undertaking measures to remedy any inconvenience and lead to a more stable and resistant integration [9].

The first lesson extracted from recent crisis shows that in order to ensure sound financial integration in future monetary policies issued by the European Central Bank are vital, they can maintain an relevant

monetary conduct, the interbank market liquidity and the control of interest rates. It is also necessary to ensure financial market transparency by reducing the complexity of products, disseminate complete information on risks taken by investors and highlight the interconnections between credit risk, the market risk and liquidity risk.

An financial integration require and an stability of the financial sector and, for this, it impose a greater communication and cooperation between market participants, both the official sector involvement as well private one.

All reforms undertaken to reduce the negative effects of the crisis and avoid such situations i future, will have the effect of ensuring financial stability, while increasing the level of financial integration. It is therefore very important, at least at the European level, to be implemented fully and quickly the regulatory and supervision reform and to ensure a stable and robust financial system.

The measures taken should aim at increasing transparency, reducing the complexity of financial products, improving corporate governance and effectiveness risk management. It should also be intensified the supervision at the micro and macroeconomic level and the revision of crisis management regime. Many of these issues have been achieved, but the process of restructuring is underway.

Mersch considers that banking union requires building an integrated financial framework to ensure financial stability [10]. In this endeavor, it is necessary to establish a Single Supervisory Mechanism (SSM) in the European Union and a Single Resolution Mechanism (SRM). These two pillars should ensure stability of the system by standardizing practices at European level for a single supervision model (SSM) and create a fair competitive environment (SRM).

As it stated and Draghi providing financial integration is part of the post-crisis harmonization, as one of the priorities of the European Union authorities [12].

3. Conclusions

Introduction of the euro, together with all the measures undertaken at European Union level have determined registering of

significant progress in term of financial integration over time. The Enhanced supervision on capital, the harmonization of interest rates, reducing transaction costs, increasing direct investment, portfolio diversification, etc. are just some of the advantages that can accompany the process of financial.

However, recent economic and financial crisis has highlighted some disadvantages of creating a single market: the interconnections between financial markets, the complexity of financial instruments, poor regulation and supervision, uncontrolled liberalization of capital, excessive risk taking, etc.-all contributing to the destabilization of financial sector and the propagation of tension situations.

The movements off the money market , the sovereign debt market and retail banking, showed that the process of financial integration was sustainable and in development, evolution which has been affected by recent crisis. The measures taken to remedy this situation aimed to mobilize capital flows, enhancements in terms of supervision and regulation, changes in organizational structure and institutional, assuming new responsibilities of the central monetary authority, but also achieve an bank union and an fiscal union . Actions should aim at to increase transparency, reducing the complexity of financial products, improving corporate governance and effectiveness risk management. Should also be intensified supervision of at micro and macroeconomic level and revised crisis management regime. Many of these issues were touched, but the process of restructuring is underway.

Since the the financial integration process is accompanied by numerous benefits and the ongoing reform aims to eliminate disadvantages of this process, ensuring financial integration is part of the post-crisis harmonizationit represents one of the priorities of the European Union authorities.

Abstract

The new global order stands to be trapped in a spiral of change, which became increasingly complex and fast. The aim of this paper is to picture the transformation of the European banking model dictated by the experience of the last financial crisis. We note the contribution of innovation, securitization and regulation to present and future banking structural adjustments, pointing out a series of issues which captured the overwhelming implications on the “health” of the system. We also included in our study some evidence from 7 European countries (Bulgaria, Czech Republic, Hungary, Latvia, Lithuania, Poland and Romania). To conclude, we summarize the multiple faces of banking reconfiguration, we argue that risks are still present in this industry and we define our position in favor of traditional and safe practices.

Keywords: financial crisis, financial education, banking model, securitization.

J.E.L. Classification: G01, G21, G32.

1. Introduction

The current financial crisis has reflected mainly on the financial markets, so the propagation on emerging economies has been relatively quick, through the transmission channels, amplifying the contagion feature of risks. In the light of powerful tensions, vulnerability and losses, the banking industry suffered important transformation in order to adapt, to survive and to recover. We highlight the importance of the topic related to the significant presence of banking in Europe and its economic role. The banking

model has been adjusted in terms of objective, infrastructure, activities and performance (through regulation). So, the main question is: are we trying to reinvent banking or just to bring it back to its origins?

2. Reconfiguration of the European Banking Business Model

Starting June 2007, the financial crisis hit the banking industry in the U.S. and later, all over the world. In this context, a series of questions (mainly regarding the role of regulation) have appeared. Seen as a failure of the free market, of deregulation and fragmentation, the financial crisis put to the test the stability of the banking systems.

Risk evaluation, not a priority, the lack of financial education, the ignorance and the performance-based remuneration packages generated new requirements in terms of regulation, high capital and liquidity costs and new visions associated to daily activities.

The motivation is related to efficient risk management, in order to assure stability and solidity of the national systems. Starting 2008, we are assisting to massive losses and profitability shortages, panics, and lack of confidence.

The classical business model is based on systematic development through major financing sources. But, the efficiency is influenced by an optimal combination of factors (human, financial and working capital).

Deregulation and financial innovation have contributed to an intensive transformation of the banking business model, on several dimensions, such as: financing practices, non-interest incomes preference, the size of the banking activity and corporate governance, with great impact on the real economy.

Financial innovation had a major role in banking through the permissive framework created, as the banks managed to transfer risks off-balance sheet, collecting new risks in the same time [1].

As we can see in Table no.1, the volume of securitization in Europe followed an increasing trend ex-ante the financial crisis, the maximum being reached in 2008 – a volume almost 5 times higher compared to 2001. Starting 2009, the balance sheets have been suffering an adjustment process and associated to this action, the securitization has decreased. Considered an option for extension of financing, securitization has another advantage. The possibility of risk transfer through CDSs facilitates lending activity (capital requirements reduce). As a result, financial innovation shows that the lending channel is being inefficient in normal times (before 2007). In the banking systems, speculation determines off-balance sheet flows. One author [2] argues that traditional banking business model has suffered a negative transformation through limited incentives for risk coverage. From a structural point of view, securitization transposed banking credits (illiquid assets) into tradable securities. At the individual level, the benefits referred to credit risk diversification (geographically and on activity sectors), reduced capital regulation pressures and the additional financing. Insolvency risk has decreased; capitalization and profit followed an inverse trend.

Table no.1 Securitization in Europe
(€million)

Year	Value	Year	Value
2001	152.60	2007	453.71
2002	157.70	2008	711.13
2003	217.30	2009	414.08
2004	243.50	2010	382.92
2005	327.00	2011	371.98
2006	481.00	2012 T2	126.85

Source: *** Association for Financial Markets in Europe (AFME) (2010): *Securitization Data Report: Q2 2012*

From a different point of view, we sustain that securitization has limited some risks (considered static) and generated new ones (dynamics, with high impact on the banking

activity). Relaxing banking conditions creates the risk of balance sheet degradation, through debt accumulation, and contributes to the transfer of the banking institution in the systemic importance category. Paradoxically, the credit risk increases.

In some studies [3], [4], [5], [6], the phenomenon is explained. The banks are not stimulated to monitor the credits once they have been sold, the effects of the new liquidity derived from these transactions, affects decisions regarding new risk-taking.

We consider that financial innovation had an important contribution in the banking systems (both in terms of progress and risks), related to diversification, time per transaction, portfolios' development. The most important aspects are the transfer of the perspective from the traditional approach to the modern view, respectively the application of a new set of motivations towards risk-taking preference.

In the last years, we assisted to an easy form of financial capitalism, relationship banking moved to transaction banking. Due to this movement, one of the solutions proposed is the clear distinction between banking activities: investments vs. retail.

The interconnectedness between banking systems and financial markets has generated an increase of non-interests incomes, announcing a new trend: diversification of income sources, destined to make the total income more stable.

Vulnerabilities rising at the international level have led to a higher volatility on the global financial market. According to data from Table no. 2, the trading income has known large fluctuations in the last years.

Some voices argue that in stress times, the variation of these income sources is normal, but the effect is double [7]. We assist to a reduction of the traditional income based on interest rates. However, analyzing the previous studies, we observe that an increase of non-interest income can't be associated with a decrease of income volatility [8], [9], [10].

A new practice implemented by credit institutions is the measurement of risk-adjusted performance.

Table no.2: Evolution of the trading income growth rate in the selected countries, during 2009-2012 (%)

The reason involves objective performance comparability associated to different risk levels, respectively transactions output-risk profiles [11].

It is relevant to mention that credit risk has been the main challenge within the banking systems in the last few years, registering high growth rates and volumes. The European emerging countries have been affected by the financial crisis, through contagion channels. The banking systems experienced a deterioration of bank asset portfolios. The implication of monetary authorities in various agreements to ensure financial stability has served as an anchor of credibility and macroeconomic stabilization (See Table no.3).

The increase of systemic risk has been caused by a translation into the business banking model from *originate and hold* form to *originate and distribute* form. In the traditional model, banks use term deposits to support long-term lending. Mainly, the associated risks are liquidity risk, interest rate risk and credit risk. In the actual model, banks have tried to avoid the exposure to these risks, by selling assets. At the

individual level, banking risks have increased based on low interest in monitoring off-balance sheets items and low credit quality. At the aggregate level, the risk combination represents a precondition for the creation of the speculative bubble. Among the reasons which have generated a new business model we mention low profitability, risk management limits and bank leverage.

Central bank supervision, applied both for banks and non-financial corporations, has the role to clean the banking business model, limiting the toxic trends (such as excessive lending). It is desirable to adopt efficient long term risk practices, in order to ensure sustainable development and responsible financial intermediation activity. Commercial banks results show their limits, the vulnerable spots and announce the new trends - high provisioning costs, financial deleveraging and low risk appetite.

Thus, banks have initiated measures to control costs by scaling network outlets but also by delaying or reducing investment programs. Increasing interest margins, sales of fixed assets and the purchase of government bonds were among the most common strategies put in place by banks to improve their short-term financial position. (See Table no.4 and 5).

The leverage ratio indicates that in the last years the additional resources were properly used, so economic profitability is still higher than the cost of new resources.

Other studies sustain that banking systems have deviated from the normality position (the financial intermediary function) through which are protected the interests of stakeholders, to an extreme one – the profit vision of banks placed on a high level creating imbalances and negative effects for other categories (shareholders, clients, authorities) [12].

We note profit vs. client dilemma, transaction vs. relationship dilemma and we position in favor of traditional resource producer.

There are some voices that militate for reconfiguration of the relationship between subsidiary and mother bank, respectively the legal transformation of subsidiary into an independent entity, in order to reduce systemic risk. The separation of financial resources, regulation and capital and liquidity requirements will increase the power of the host country.

The objective is that strategy and support areas to be the bridge between the subsidiary and the group. Similarly, Erkki Liikanen, the Governor of Central Bank of Finland analyzes the proposal of total separation of investment and retail activities. From a risk perspective, the process aims to limit contagion among banks or to put to quarantine the subsidiary which presents a higher probability of default.

We consider Schumpeter's belief about innovation very actual and applicable: the works of the (financial) system and the dynamics of innovation include a significant doze of creativity with disruptive effect in the business environment, where companies, procedures and products are being replaced by new ones. The microeconomic level is the most affected but the contagion potential is higher within the aggregate processes. Additional correlations and common movements of the economic agents facilitate the distribution of negative effects and the shifting from micro to macro.

Financial innovation has often been associated with greed, as human characteristics, prevailing in the speculative activities. Economic discipline highlights two

faces of greed, as follows: seeking for profit maximizing, the competition manifested in healthy legal environment places greed as a promoter of innovation and economic growth, but, in relaxing regulation mood, greed degenerates into activities based on fake profits, fraud and financial corruption.

Recently, we have experienced the power and the effects of the precedents created in the process of risk management. The main risk is related to the confidence of the public into the banking systems.

The situation from Cyprus can be analyzed from different perspectives:

- *Reduced decisional power and high dependence on the International Monetary Fund, the European Central Bank and the European Commission transpose in a legal form of financial nationalization – deposit taxation;*
- *The banking exuberance manifested ex-ante the financial crisis directly affects financial situations of the clients, generates new risks in the national banking systems, indirectly amplifies the risk of recession in the European countries and creates panics at the global level;*
- *Determines political conflicts (based on the international profile of clients – Cyprus is a fiscal paradise which holds money from clients all over Europe);*
- *Amplifies the risk of instability in the Euro zone.*

The German Chancellor Merkel (2013) sustains that the actual banking business model of Cyprus is a failure. The whole situation increases the mistrust in the capacity of the banking systems to protect clients, through loss of control over its activities. On long term we estimate a descendent trend of savings in the context of present tensions, uncertainty and visible political influences in crisis management.

In essence, the client pays for the error of the banking system. How fair is that? Some of the proposed solutions *tailored to the clients' needs*, trying to beat the competition coming from the non-banking entities. Swedish banks transpose into practice the policy *putting customers first, promoting banking business model called back to the future* (a mixture between traditional and modern, with a good risk management orientated to all stakeholders). Even in the

recent context, Handelsbanken continues the expansion process through new units designed to bring more clients and to maintain loyalty.

A fundamental lesson that should be learned from this financial crisis involves moderation as a key coordinate for rational behavior.

The most stringent challenges of the European banking systems are related to regulation and efficient monitoring of the risk, a sustained rhythm of real convergence process and economic recovery reforms.

3. Conclusion

The recent financial crisis has changed the climate in which operates the actors of the financial markets, affecting the relationship between customers and banks, companies or individuals. Great giants of the financial markets, so-called too-big-to-fail entities (TBTF), became an obsessive concern for the government and monetary authorities, considering that business size, market power and complexity are major issues related to the management of an institution. These characteristics should be handled in a specific manner, without threatening the robustness and resilience of the banking system as a whole. Flexibility transpose into sustainability.

Summarizing, the new banking business model can be analyzed based on the following coordinates:

- Strategic reconfiguration;
- Capital reconfiguration (financial capital - costs, working capital - infrastructure, human capital- staff);
- Activity reconfiguration - (embracing the traditional activities, moderation, risk-adjusted performance);
- Management risk reconfiguration.

Changes in the financial environment are necessary due to the amplification of contagion risk in the monetary union, especially considering the latest events manifested in Europe. The sovereign debt crisis has severe implications on the banking system stability, questions the integrity of the Euro zone and generates conflicts among countries.

The unprecedented size of the current turmoil is a warning for both decision makers

and participants to the financial systems, in terms of examples and lessons learned. In order to prevent imbalances and to reduce the consequences, the key aspects refer to a high level of transparency and an efficient communication between all parties.

The Impact of the Economic Crisis on the Cohesion Policy

Badoiu Catalina Mihaela
Bucharest University of Economic Studies
catalina.badoiu@gmail.com

Abstract

“One basic formula for understanding the Community is this: Take five broken empires, add the sixth one later, and make one big neo-colonial empire out of it all.” [Professor Johan Galtung, Norwegian sociologist]

The EU represents a unique economic and political partnership, formally recognised on 1 November 1993 through the Maastricht Treaty, uniting 27 States around common political, economic, cultural and social values – a Community which evolves towards the Economic and Monetary Union, based on internal and external policy cooperation between States.

Based on these priorities, but being aware of the numerous differences between Member States/regions regarding the level of development, the EU assumes the task of reducing the existing gaps through a common regional policy, aiming to reinforce economic and social cohesion.

This paper intends to examine the effects of the economic crisis on the cohesion policy 2007-2013 and the measures adopted by the EU in order to reduce them.

Keywords: economic crisis, cohesion policy, European Social Fund, Cohesion Fund, European Union, impact

J.E.L. Classification: G 01, F 50, O 52.

1. Introduction

„The European Union is one of the most prosperous and competitive areas of the world, both from the point of view of the level of economic development, and from that of the potential for development. Nevertheless, the existence and persistence of development and productivity disparities between Member States and their regions represent a major structural weakness, which could pose a threat to the very durability of

the European structure. The enlargement of 2004/2007 led to an increase of the gaps within the EU, due to the significant differences in economic development between the old and the new Member States.” [1]

2. General framework of the economic and social cohesion policy

“The economic and social cohesion policy comprises all EU’s actions which aim at achieving a harmonious and balanced economic development of the Union, especially by reducing the disparities between its different regions/States, by promoting equal opportunities and sustainable development. This will lead to increased competitiveness and will generate higher revenues, thus providing benefits for the economy of the entire EU.” [1]

The evolution of the EU cohesion policy

1951- The establishment of the European Coal and Steel Community (ECSC), resulting in the liberalisation of the steel industry.

1957- As early as the drafting of the Treaty of Rome, the document that laid the foundations of the future European Economic Community, precise references were made to the elimination of the economic gaps between regions. The objective of the EEC was to promote “a harmonious development of economic activities, a continuous and balanced expansion, an increase in stability, an accelerated raising of the standard of living and closer relations between the States belonging to it.” (Art. 2 TEEC) [2]

Among the concrete methods for achieving these objectives, the Treaty also mentioned “the creation of a European Social Fund in order to improve employment opportunities for workers and to contribute to the raising of their standard of living.” (Art. 3 TEEC)

1958- The European Social Fund and the European Agricultural Guidance and Guarantee Fund were established.

1975- After Denmark, Ireland and Great Britain joined the Community, the **European Regional Development Fund (ERDF)** was created. Thus, the concept of redistribution between the rich and the poorer areas of the Community appears for the first time. The allocated budget was 1.4 billion currency units (ECU) for the period 1975-1977 (around 4% of the budget), which was going to be distributed, by quotas, among the 9 Member States. Eligible actions: 1. investments in small enterprises which created at least 10 jobs; 2. investments in infrastructure linked to point 1; 3. investments in the infrastructure of mountainous areas.

In the period **1975-1985** the ERDF budget increased by 10 times, from ECU 258 million to ECU 2290 million, and its share in the Community budget doubled, from 4.8% to 7.5%. [3]

1986-1987- The concept of economic and social cohesion was introduced in the Treaty, with a view to helping the last States that joined the Community (Spain and Portugal) to face the challenges of the single market.

1988- The first reform of the Structural Funds, corresponding to the Jacques Delors package, led to redefining the objectives of the Structural Funds, i.e. of the ESF (1958), EAGGF (1962) and ERDF (1975), under the umbrella of the cohesion policy.

1989- The principle of multi-annual programming is introduced in the system of granting Structural Funds, based on establishing priority objectives and finalizing the system of partnerships between Member States.

1992- It is decided to double the budgets for disadvantaged regions: Spain received ECU 10.2 billion, Italy ECU 8.5 billion, Greece ECU 7.5 billion, Ireland ECU 4.46 billion – these funds were granted for promoting the structural development and adaptation of less developed regions (according to Priority Objective 1).

1993- This year marks the reform of the Structural Funds through the Treaty of Maastricht, **economic and social cohesion** being mentioned for the first time among the general objectives. A new financial instrument is created, named the Cohesion

Fund, which is specifically dedicated to supporting less developed EU Member States.

1995- Through the accession of Sweden and Finland, sparsely populated regions started to receive funding.

1997- The Treaty of Amsterdam (signed in 1997, in force since 1999) lays the basis for the principles of the *European Employment Strategy*.

1999- Berlin- The second reform of the Structural Funds, with a focus on supporting disadvantaged social groups and regions. As a result, a new set of regulations for the period 2000-2006 is drawn up, and two new structural pre-accession instruments are introduced, namely the Instrument for Structural Policies for Pre-Accession (ISPA26) and the Special Accession Programme for Agriculture and Rural Development (SAPARD27).

The reform of the regional development policy for 2007-2013

The enlargement of the European Union to 27 Member States brought numerous challenges to economic competitiveness, with the existing gaps between Member States and their regions increasing strongly.

For the period 2007-2013, the cohesion policy is financed from the EU budget through 3 structural instruments: the European Regional Development Fund (ERDF), the European Social Fund (ESF) and the Cohesion Fund (CF). In addition to this, there are the following complementary actions: the European Agricultural Fund for Rural Development (EAFRD) and the European Fisheries Fund (EFF).

Objectives of the EU cohesion policy

The main objective is to **achieve convergence**, i.e. to reduce the disparities which exist between different EU regions and Member States with a GDP per capita under 75% of the Community average and the regions affected by the so-called “statistical effect”.

Thus, under the current financial perspective, approximately 80% of the Structural Funds are earmarked for this objective (according to the EU Treaty).

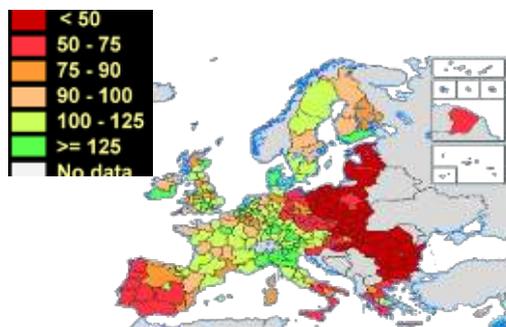

Regional competitiveness and

employment is the second objective, financed by 15% of the budget dedicated to Structural and Cohesion Funds. It covers the regions which are not eligible under the convergence objective.

The two objectives are closely connected, as improving cohesion throughout the EU depends largely on increasing competitiveness.

European territorial cooperation is the objective financed by only 5% of the budget dedicated to Structural and Cohesion Funds, and concerns transnational, cross-border and interregional cooperation.

Fig. 1. Regions covered by the Convergence Objective

Source: Eurostat

In order to achieve the 3 objectives during the period 2007-2013, EU allocated the sum of EUR 347 billion in the 27 Member States, representing 35% of the total EU budget for the same period (EUR 975 billion).

2. Cohesion policy – one step away from the end of the programming period

According to the Strategic report 2013 [4] on the implementation of the 2007-2013 cohesion policy programmes – which summarises the 27 strategic reports presented by the Member States at the end of 2012 – the following results have been recorded:

a. Employment – almost 400 000 jobs have been created to date, with the largest numbers reported in Great Britain, Italy, Germany, Spain, Poland and Hungary, including:

- more than 15 600 research jobs (9 500 since 2010);
- more than 167 000 jobs in SMEs (69 100

since 2010).

In 2011, the Member States reported that 2.4 million people receiving assistance through the European Social Fund found a new job.

b. Research

- 53 240 research and technological development projects and 16 000 cooperation projects between enterprises and research institutions;

- nearly 1.9 million people who now have access to broadband networks (mainly in Spain, France, Ireland and Italy).

c. Transport: over 5 000 transport projects launched, 460 km of roads and 334 km of rail in the TEN network.

d. Education: over 19 000 educational infrastructure projects have been financed;

e. Renewable energy: over 2.6 million people benefiting from water supply services and another 5.7 million people targeted by waste water projects;

f. Among the participants in ESF actions there are 15 million young people under the age of 24, a number which increased abruptly in 2010 and 2011, as a result of the economic crisis. In countries like Germany, France and Hungary, young people account for at least 40% of the total number of participants.

g. As far as lifelong learning is concerned, the ESF supported around 5 million young people. So far, over 14.5 million final recipients were covered and a broad range of target groups reached in the area of social inclusion. 18% of participants were from groups which are particularly vulnerable on the labour market.

h. Based on the overall ESF goal regarding equal opportunities and increasing the number of women on the labour market, 52% of the participants in projects financed through this fund are women. In Cyprus, Estonia, Lithuania and Latvia they amount to more than 60%.

Although this is an interim report, offering an overview of the progress recorded in the main strategic sectors, it “provides an invaluable snapshot of a policy that is delivering across most of the EU’s priorities

and investing in growth when it is most desperately needed. [...] But we also have lessons to learn: **results are sometimes patchy** and Member States need to speed up their efforts to use the EU resources. As we look ahead to the new programming period, we expect Member States and regions to focus the policy even more on results and priorities that will have the greatest impact”, as the Commissioner for Regional Policy Johannes Hahn declared.

3. The impact of the global crisis on the cohesion policy

Breaking out in the USA at the end of 2007, due to the collapse of the real estate market and of the banking system, the mortgage crisis spread rapidly and became in no time a major worldwide concern.

As an important buyer of “toxic assets” from the portfolios of American banks, the European banking system initiated its decline. The main impetus factors:

- the strong increase of commodity prices (for example, oil price increased by over 100% between 2007 and 2008);
- the strong appreciation of the euro against the dollar (by 33% in the period 2006-2008);
- the delayed effect of interest rates (8 subsequent growths in the period 2006-2007, from 2% to 4%).

According to the fifth “Report on economic, social and territorial cohesion of 2010” [5], the economic crisis hit regions specialised in manufacturing, in particular, and the highest increases in unemployment were recorded in regions highly dependent on construction. Regions specialised in tourism, most of them with a GDP per capita below the EU average, have not yet been affected significantly, just as regions with large shares of public employment. In the same way, regions specialised in financial and business services, most of them situated around capital cities or developing metropolitan regions, have been affected to an average extent in terms of the impact on GDP and employment.

The estimates of the last cohesion report indicated the fact that at the level of NUTS 2 regions, 64 convergence regions (CONV) and 15 transition regions (TRANZ) faced the

crisis better than the EU average, whereas many regions from Ireland (where the unemployment rate had reached 12.8%), Southern Finland, Northern and Central Italy, which had previously been in a developing stage, were particularly affected. Nevertheless, **the performance of the convergence regions varied extensively**. The recession was particularly severe in the Baltic States, Greece, Ireland, Portugal and Spain. Although the Baltic States and Ireland are recording economic growth, Portugal and Spain are still in recession in 2012, a recovery of their economic situation not being estimated until 2014, while Cyprus and Greece are still facing the decline of the GDP. [6]

Employment in the EU declined significantly in the period 2007-2012, up to 6 000 jobs being lost. Whereas in 2009 the unemployment rate is 8.1%, in January 2013 it reaches 10.8%. The lowest unemployment rate is recorded in Austria (4.9%), and the highest in Greece (27%) – November 2012.

Thus, the crisis increases the economic disparities (the role of the cohesion policy is heavily undermined); the latest data indicate differences between regions of 3.5 to 10.5 percentage points (between the States situated in the North and South of the Eurozone).

The business environment is also strongly affected by the recession, with total investments (gross fixed capital formation) dropping from 21% of GDP in 2008 to 18% in 2012.

EU’s anti-crisis measures plan [4]

“With the crisis, EU cohesion policy funds have become even more important as a source of investment across the Union. The European Social Fund is delivering crucial support to our human capital, especially helping young people to maximise their chances of a successful career. The preparation of the next generation of programmes is a unique opportunity to underpin our growth and jobs strategy with significant financial support. Social and human capital investment needs to play an important role in this”, declared the Commissioner for Employment, Social Affairs and Inclusion, Lázsló Andor.

As part of their response to the financial

crisis, the EU institutions agreed to a set of measures to promote simplification and improve the flow of EU funding:

- the simplification of national and regional procedures, reducing the time for paying advances to public authorities and enterprises that benefit from state aid (Bulgaria, Cyprus, Ireland, Hungary, Spain, Italy, Lithuania, Latvia, Slovenia, United Kingdom);
- the reduction of national co-financing within the limits of a regulatory ceiling (Spain, Greece, Ireland, Italy, Lithuania, Portugal and, to a lesser extent, Belgium, France and United Kingdom);
- the temporary increase of the co-financing rates – up to 95% – for Member States with the greatest budgetary difficulties (Greece, Hungary, Ireland, Latvia, Portugal and Romania);
- although the decrease of national public financing results in the reduction of the total investment volume, the goal is to keep national budgets away from the pressures of the crisis, ensuring at the same time continued investments in projects with growth and job creation potential;
- almost EUR 36 billion, or 11% of the total funds, were channelled towards innovation, research and development, general business assistance, sustainable energy, cultural and social infrastructure;
- the creation of a task force to help Greece implement the EU and IMF adjustment programme in order to speed up the absorption of EU funds.

4. Conclusions

It is undeniable that the EU has been facing serious difficulties in this period of crisis, and that the effects of the economic downturn at a global and national level had an impact on job supply and demand. However, the sums allocated for active policy measures concerning the labour market actually increased during the crisis. This may be due to the anti-crisis measures implemented by each Member State facing difficulties, to the support from IMF, but also to the European Social Fund, which contributed to longer-term structural changes on labour markets. According to the evaluation of the reaction of the ESF to the

economic and financial crisis [5], for a smooth application of the programme the following measures are recommended: “phasing out crisis-related measures where they risk impeding active measures to combat long-term structural unemployment; and strengthening the ESF’s focus on structural measures and vulnerable groups.”

Moreover, the ESF will have to be fully in line with Europe 2020 Strategy, with a view to achieving the 5 proposed objectives on employment, research, education, the fight against poverty and energy/climate. All this will be based on the system of economic governance, which aims to coordinate policy actions carried out at EU and national level. In this way, the European vision according to which “the crisis can make us stronger” may find its application in practice.

Abstract

What could be more interesting in a European Union than to know our rights and freedoms and in a positive way to enjoy these privileges.?

Being European is not a random attribute; the merit belongs to European parents who named reality more than fifty years ago.

To speak of the beginning of European status include the recall of the Treaties of Paris, Rome, Maastricht, treaties that attest freedom of movement within the Community.

Keywords: European Union, fundamental rights, European citizenship

J.E.L.Classification: K32

1. Introduction

Comprehensive concept, freedom in the light of European history causes questions such as: "What is Europe? What will be its future?,,

It is true that European unity premises ideas originated back in antiquity, but we can not dispute the fact that Europe was reborn under the impression of the intellectuals of those days.

The Genesis of Europeanism shows the importance of studying this issue because to speak of freedom of movement means to question also the origin of this right. [7]

Freedom of movement is a natural given that we today's Europeans know daily and that yesterday's Europeans had won through efforts and real solidarity.

To thank Europe's parents for freedoms we enjoy is too little, but we can at least respect and not prejudice such fundamental values that we enjoy as citizens of Europe.

2. Freedom of movement of goods, persons, services and capital

The Schuman Plan was for some just a crazy dream (a collaboration between the two rival great powers) but one who has become a reality that we all live. In Europe there were the first economic regions of the world. European cooperation is linked to the name of Jean Monnet and Robert Schuman. [11]

We must not forget that the immediate goal was to maintain peace between the two rival forces. ECSC had a historical role in the the Franco-German reconciliation The political goal - joining Germany to Europe and eliminate disagreements with France on strategic areas of the Ruhr and Saar was masked by the economic objective. It is clear that the process of political unification was achieved through economic instruments. [1]

From the fact that the Community invoked economic reason to start integration one should not deduce that it was an exclusively economic process . At that time, however, the economical argument was preferred at the expense of the political one. Machiavelli's famous line: *the end justifies the means* is relatively applicable as practically it was a political goal, achieved through economic means. [12]

Compared with other international organizations at the time, the main novelty lies in the supranational character of the Community, represented by the transfer of powers to an institution - High Authority - responsible for making decisions independently of the consensus of Member States. There is a transfer of sovereignty from Member States to the Community. [6]

Based on the *Spaak Report* the Treaty establishing the European Economic Community and the Treaty establishing the European Atomic Energy Community were drafted. According to the latter, all tariffs and quantitative barriers applied between

Member States ought to have been eliminated. France was interested to impose a community project to reuse peaceful atomic energy and wanted Euratom project. Germany opined as positive in terms of achieving the EEC. The commitment that states assumed by ratifying the EEC Treaty was to create a common market based on free movement of goods, services, people and capital.

Do not forget that in European history there has never been a merger of this magnitude, the originality of this creation completes its value historically. The current European Union was the product of a conspiracy of elites with good intentions and results. The world order must be looked at both as a factual situation (achieved during centuries by people sacrifice towards peace), but also as an obligation that we contemporaries have to follow. [12]

Analyzed from both historical and present and multidisciplinary perspective as well, the study again demonstrates the topicality of the subject

The approach is not possible without a serious incursion through the ways essential elements of the freedom of movement of goods, persons, services and capital are defined internationally

Using methods of comparison, analytical, critical, objective but subjective, deductive and inductive, we focused both on theoretical implications of the study but also its influence on knowledge in the field. [2]

Objective assessment of the contents was given through the study and practice of the European Court of Justice in the field. Journal articles studied turn into a special documentary base, as human resource management issues in relation to the four freedoms are addressed.

Given that human existence is indisputably linked to the freedom of movement we can not dissociate it from its specific correlative exceptions. [5]

Topicality of the subject influences European knowledge as it brings together in a single certified material useful data and simplifies research on information subject to study.

Evolution from 6 to 27 countries and institutional improvement were not overlooked, not even developing ideas on the major stages of the formation of the

European Communities. European construction is today in the process, as long as there are countries that want to join the big European family. The fact is that the European Union will remain a force in a world that is moving more rapidly towards globalization.

The action of the study focuses analytically on the presentation of the European Coal and Steel Community which today is no longer effective because states have not considered appropriate to extend the treaty since 2002. [10]

Starting from the idea that the internal market is based on the four freedoms, we considered that the work worth a foray into European paradise, is a real challenge for laymen and beyond.

To better understand what the mechanic of the freedom of movement is, which actually forms the core of the work, the emphasis is on the grand image of liberalization of the movement of goods, persons, services and capital. [11]

Through our given answers, we argued that the European Union is a free, borderless space, where freedom of movement of goods, persons, services and capital is granted

However, the liberalization of movement prone to criminal behavior and therefore measures to prevent and integration of new technologies for border control are required.

Freedom of movement offers offenders access in different EU countries so bodies such as Frontex, Europol acts as an FBI Europe.

Terrorist threats, human trafficking - organized crime – generally, are citizen safety aspects and therefore their analysis could not be avoided ..

We found that European Union is not to be confused with the Schengen area and that to Romania this became the number one target on the priority list. [3]

Although theoretically, we talk of the principle of non-discrimination, the practice challenges the values of liberty and equality of opportunity. The age, sex, qualification, are some of the requirements imposed indirectly to candidates for a job. Testimony give official documents and statistics highlighting examples of discrimination in this regard, with employers not deterred by legal sanctions.

On the list of topics are situations of unemployment, illegal labor and within the chapter on goods liberalization measures of European standardization and eco-labeling are of great interest. Also, not all goods can move freely in the Union, but only those that meet the criteria set by European standards and in addition we define and specify the prohibited goods in the single market.

Restrictions on the free movement of goods, and any taxes or measures having equivalent effect to them are restricted.

Starting from the great magnitude of the phenomenon of freedom of movement, from its advantages and disadvantages, we believe that research and conclusions drawn from this study will contribute to the knowledge of field regulations both in theoretical and practical aspect.

The date of January 1st, 2007 will remain in history as the date of the accession to the EU. In connection with this last statement, however, some clarifications are necessary. Since I believe that Romania belonged to the European history, geography, traditions and culture.

Romania has been politically integrated in the new Euro-world part of the club of the most select states. [8]

It remains to be seen how the regional political and economic Europe map it will look in the near future, how it will correct cracks between large and small countries, how one can merge strong and weak states in order to reach a common goal.

We decide the answer, on the infallible land of Europe today. The question to consider is to know how to keep what Monnet proposed and we realized in the last 50 years, as the current political and economic situations require.

The EU is the successful laboratory of experiences regarding unification. We started from a collaboration between two rival countries to speak today about 27 accessions and many more in the near future.

Jean Monnet himself concluded that from an economic union, states will want to go to a political one. History has proven that union between peoples remains close only if based on common values.

The current European Union was the product of a conspiracy of elites with good intentions and results.

Basic conditions for expansion were laid

down by the Treaty of Rome and later in the Treaty on European Union, Article 49: Any European State which respects the principles set out in Article 6 (1) may apply to join the European Union. Article 6 (1) provides that the Union is based on the principles of liberty, democracy, respect for human rights and fundamental freedoms, and the rule of law, principles common to the Member States. [10]

The calendar of EU accession of each candidate country depends on the progress in the accession procedure according to the criteria defined in Copenhagen in 1993. [4]

a) stable institutions guaranteeing democracy, the rule of law, human rights and respect for and protection of minorities (political criterion).

b) a market economy and capacity to cope with competitive pressure and market forces within the single internal market (economic criterion).

c) ability to assume the obligations of membership, in particular subscribe to the aims of political, economic and monetary policy.

Membership requires according to the European Council in Madrid -1995 - not only the adoption of the *acquis communautaire*, but also creating and developing legal and administrative structures necessary for the implementation of European policies. Therefore, to the Copenhagen criteria, a 4th criterion was added:

d) administrative capacity to implement the *acquis communautaire*.

Any citizen or EU citizen has the right to move and to reside freely within the territory of the Member States.

Freedom of movement and residence may be granted, in accordance with the Treaty establishing the European Community, to third country nationals residing legally in a Member State. (Charter of Fundamental Rights of the European Union - Article 45)

The first global consecration of the principle of free movement of persons was made by the Universal Declaration of Human Rights that states in Article 13 that everyone has the right to freedom of movement and residence within the borders of each state. In Europe this right was included in the Treaty of Rome which held abolition, as between Member States, of obstacles to the free movement of persons, services and capital.

Free movement of persons constitutes one of the fundamental freedoms guaranteed by Community law, an essential element of the internal market and European citizenship, as defined by the Single European Act. [9]

The concept of “European citizenship”, introduced by the Maastricht Treaty recognized the right of free movement and residence within the EU citizens. All Member States have adopted, except Great Britain, in 1989 the Social Charter of fundamental rights of workers and have subscribed to the Social Chapter of the Maastricht Treaty, adopting the 1994 Directive on the establishment of Labour Councils in transnational firms. The chapter on free movement of persons began to be negotiated in 2002, in Brussels, at the first Conference of Accession.

3. Conclusions

The Conclusions we stopped at are few because there are some challenges in our discussion topic and themes of thought, so that I conclude with the following questions that deserve treatment in the future:

Where can I travel? Why do we need border acts? What services we can provide in the Union? May we set up a company in another European country?

I hope that this study will make a modest contribution to disseminate European law among those interested in this very important and contemporary issue.

Considering the contents recorded in the study the following recommendations are required: to clarify the meaning of concepts of freedom of movement not only through rules, but also by implementing it to the mind of citizens, developing a strategy in favor of the European citizen in the sense of bringing to their attention their Rights and freedoms in a more practical and convenient manner such as informing through the media.

It is true that treaties, conventions and many other treats and regulations govern freedoms available to European citizens, but many people who generally know them, do not know how to apply them. It is a vast range of people who either do not have access to the media or are disinterested.

I propose that theme of free movement of goods, persons, services and capital no longer be on the table of officials but to be carefully debated by citizens. And this would

happen only when today's governments will facilitate access to information also in deprived areas, because in fact, the situation is worrisome. Lack of information on the other hand leads to criminal behavior. [11]

To inform the public of free movement in particular is not only sufficient but also necessary in a democratic society. “Do you want to know the European Union?” remains an invitation to all who wish to move freely in the European spirit. That is why, even for these benefits, we should thank the founders of Europe of yesterday for the Europe today.

The Role of the Approval Procedure of Economic and Social Activities with Environmental Impact

Brasoveanu Florica
University Ovidius of Constanta
Faculty of Law, Administrative Sciences and Sociology
floriordache@yahoo.com

Abstract

Starting from the idea that it is better to prevent environmental damage than to repair the damage already caused, the state introduced the environmental impact assessment procedure of economic and social activities as the basis for their authorization and operation.

Evaluation of potential environmental consequences and, on this basis, the development of measures aimed at eliminating or reducing their allowable limits, have become compulsory for social-economic activities so that future generations can benefit from a healthy and clean environment.

Keywords: *Environmental protection, Environmental permit, Pollution*

J.E.L classification.: K32

1. Introduction

An original objective of this procedure is to contribute to, more or less effective, the public and private decision makers to integrate the environment into their strategy and avoid actions and activities that degrade the environment irreparably. [6] Therefore, the impact study has a twofold purpose corresponding to the application of two fundamental principles of environmental law:

- the principle of prevention and
- the principle of sustainable development.

To satisfy the imperative for sustainable economic development demands, imperiously, a restructuring of agriculture, energy use and industrial production according to the model of nature. Industrial processes are required to use

very efficient material and energy and generate small amounts of waste. [7]

In turn agriculture will be based entirely on free services provided by ecosystems and thus give up on an almost exclusive dependence on man-made substitutes. Finally, in all systems, products and services prices should reflect the environmental costs of its provision. [12]

In order to fulfill its essential mission, public interest, public administration, its authorities should have some privileges, powers or special rights to prevail over individuals and "defeat their tendencies to ignore the laws." [13]

With that legal capacity, administrative authorities issue normative or individual administrative acts that enjoy direct execution, by default with the possibility, if necessary, to take administrative preventive, punitive, or of enforcement measures of constraint.

In a democratic state, the Administrated are able to appeal in administrative courts against the administrative acts improperly issued.

2. The role of the approval procedure of economic and social activities with environmental impact

The whole procedure of issuing regulatory acts has got an original goal that is the contribution, more or less effective of both private and public decision factors to integrate environment into their strategy in order to avoid that their work irreversibly degrade environment, in accordance with two fundamental principles, prevention and sustainable development. [9]

The Institution of their impact study expresses, in principle, the requirement that the person requesting the issuance of an administrative permit, provide an assessment

of its environmental effects of the project; it is focused on four main elements

1 - analysis of the initial state of the site and its environment (inventory of what exists) ;

2 - assessment of possible effects from the impact on site and the environment ;

3- social-economic justification and may be supplemented by additional requirements by specific provisions of normative acts . [2]

This procedure is particularly prevalent in all countries and subject to significant administrative practice. All states have a law on the environment, that automatically integrates the EIA provisions.

Hoping to discern its purpose, the study seeks to reflect the possible issuance regime, categories, liability and settling of the administrative act issued by environmental authorities. [10]

Precisely in order to ensure sustainable development of the environment, as desired by the administrative act issued by environment agencies , Government Emergency Ordinance no.195/2005 regulates the environmental protection based on the general principles contained in its content.

In this respect, the order contains general provisions on obligations of natural and legal persons in the field of environmental protection, permits, approvals and environmental permits required for activities, system products, toxic substances and waste of any kind legal status, and sanctions for failure to comply with the law.

Environmental protection is a general obligation of all individuals and businesses that operate in Romania, according to the Constitution which enshrines "the right of everyone to a healthy and ecologically balanced environment". These are their main obligations :

a) requesting and obtaining regulatory acts, or environmental approvals, environmental agreements, environmental permits / integrated environment authorizations and abide the conditions imposed by the administrative bodies

b) ensuring their own surveillance systems of installations, processes and self-monitoring emissions and reporting to environmental authority for self-monitoring results

c) own specialized organization structures for environmental protection, for legal persons performing significant impact on the environment;

d) implementation of the measures imposed by the inspection authorities;

e) incur the cost of damages caused and elimination of the consequences they produce, according to the "polluter pays" rule.

Natural and legal persons exploring for or exploiting underground resources are required to carry out remediation of the soil, subsoil and terrestrial ecosystems that have been affected and notify the competent authorities of accidental occurrence of any events that could endanger the environment and to address these situations. [14]

Under the “polluter pays” rule, individuals or companies are held responsible for cases when pollution occurs.

Liability for environmental damage is objective. The Objective nature of the liability is determined by the fact that the polluter is held responsible whether or not there was any fault of theirs to the production of pollution.

Natural and legal persons who operate or intend to carry out an environmental impact activity are required to apply for and obtain the release of the environmental / integrated environmental authorization environmental / integrated environmental permit, according to regulations governing special procedures. [9]

Permits, authorizations, environmental agreements are acts. They are issued only if the plans, programs, projects activities to be carried out or are underway provide prevention, reduction, elimination or offset adverse environmental consequences, according to the best available techniques and legal provisions . [17]

Before starting the procedure for authorization of activities that impact the environment, for the adoption of plans and programs in the areas specifically mentioned by law, an environmental assessment aimed at "integrating the objectives and requirements of environmental protection in the preparation and adoption of certain plans and programs, taking into account the environmental report and the results of these consultations in decision making and

informing of the decision, as required by law " is required

Regulatory documents are issued by the environmental protection authorities according to differentiated procedures established by special acts, depending on the environmental impact of projects and activities subject to authorization.

Another important issue is public participation in decision-making, environmental authorities have the obligation to provide information and public participation in environmental decision-making, methods established by government decision; public consultation is mandatory for issuing regulatory acts proceedings. [1]

Regarding the enforcement regime, it is by the civil, administrative and / or criminal law, depending on the offense committed. [16]

Civilian regime covers damage caused by pollution. The damage is estimated by measurable negative effect on human health product, property, the environment as a whole and not on whether or not the fault of the operator. [14]

Injury coverage is usually through monetary compensation, in nature repairs, being, in most cases, impossible. [4]

Contravention Liability is drawn when one of the acts representing offenses, according to the ordinance is committed by the business owner

Pollution problem and therefore protecting the environment should be approached in the broader context of future economic growth model . Like any factor of production, the environment has a value and a price that must be recognized and taken into consideration as such. If the main cause of degradation of the ecosphere is related to the forms of production and consumption of the industrial type society, the solutions must be sought from economic positions, without diminishing the importance of other agents of social, moral, cultural nature and not least, the importance of resources offered by positive law. [13]

In this context come the regulations on prevention and integrated control in our country, amended by Emergency Ordinance no. 152 of 10 November 2005 concerning integrated pollution prevention and control.

The interpenetration, dependence and completion of the items in different branches of environmental law, administrative law,

European law, constitutional law, civil and criminal, highlighting the complexity of the administrative act, whether normative or individual are obvious.

Given that the with the environmental protection at the moment the focus is on prevention of unwanted effects detrimental to natural and human components of the environment or the environment as a whole, the proceedings prior authorization and the obligation to conduct a study about the consequences of human actions on the environment and possible solutions to be taken to reduce or eliminate their effects, are particularly effective legal means for the achievement of immediate and long-term objectives of sustainable development. [12]

The Authorization procedure is based on the principle of precaution at the environmental decision and prevention of environmental risks and producing damage. [3]

Part of the authorization procedure, the evaluation of environmental impact is a process that identifies, describes and establishes direct and collateral, cumulative, principal and secondary effects of a project over the health of people and environment. [15]

There fore, the impact assessment procedure is a process under national environmental law that requires that public and private projects with significant environmental impact activities by their nature, size or location, undergo a process of assessing of these effects before the release of the environmental agreement. [17]

The administrative act becomes administrative regulation (environmental permit, authorization / integrated environmental permit, an environmental, etc.), It is issued by the competent authorities for environmental protection, for those interested in directly / indirectly; those it addresses to become responsible to comply with measures imposed by it, in the collaboration between the issuer and the receiver to achieve the goal "a Clean Romania".

3. Conclusions

At the end we bring out a series of de lege ferenda proposals, aimed at improving the environmental protection process in our country

1. Modifying rule 7, paragraph (1) of O.U.G. 34/2002 on the prevention, reduction and pollution prevention and control : although integrated environmental authorization is issued by the Regional Environmental Protection Agencies, annual reconfirmation (as OU NO. 195 of 2005) to be made by the County Environmental Protection Agencies, as they know better the conditions of the environment .

2. Setting a procedure when changing of the owner of an environmental impact activities the EO 195/2005 rules that in this case, environmental authorisation, balance environmental and compliance program are to be reexamined. Ministerial Order no. 876/2004 on approving the authorization procedure of environmental impact activities, refers to in Article 23 that the environmental permit is transferred to the new owner without incurring environmental review provided for in law.

3. Although it is intended to simplify the procedure for issuing Environmental agreements, order MAPM 860/2002 regarding the approval of the procedure of environmental impact assessment and environmental permitting, makes the procedure for issuing them to take in at best case approx. 3 months from the date of submission to the Environmental Protection Agency.

In any legal system, an important part of environmental legislation is devoted to regulating their own organizational framework of environmental protection. This legal regulation is based on the idea that the organizational system to which we refer is called to act, above all, in the public interest and for the whole society.

Thus, the state administrative bodies will work to achieve tasks set by the legal rules. This is because the protection and improvement of conditions of environment is, above all, a national problem that expresses both public and private interest.

Given these interests, the internal structure of the national organization in the field of environmental protection shall include the following elements :

- competent environmental authorities, which act primarily to satisfy the interest of the whole society, in terms of public interest

- private businesses that are potential pollutants, but also victims of pollution, thus expressing all special interests ;

- individuals already operating in their natural and artificial environment, who are the first victims of pollution but can be polluters, thus expressing some interests.

On the Economic Development of Romania as a Member of EU in the Frame of the Global Economic Crisis

Bucur Iulia Andreea
“Vasile Alecsandri” University of Bacău
iuliaandreea_c@yahoo.co.uk

Abstract

Each country has its specific features and because of that, the evolutions of some indicators such as inflation, real exchange rate, current account, GDP, competitiveness, employment, and others, as well as trends determinants of real economic imbalances and improvement of divergence differs compared to other countries.

In this paper we investigate, in a retrospective analysis, how Romania reacts as a member state of the European Union on its road to European Monetary Union amid intensifying the effects of the global economic crisis, and particularly those who included euro area.

Key words: economic growth, current account deficit, export and import of goods and services, foreign direct investment, Romanian banking system

J.E.L. Code: F36, F43, G21, H62, O11

1. Introduction

Looking back the Romanian economy trends, we consider appropriate to remember the economic boom during 2003 and 2008, characterized by an average annual growth of over 6.5 per cent reaching 7 per cent in 2008. This situation combined with the Romanian accession process to the EU on the 1st of January 2007, has led to an improvement in poverty reduction, its absolute level decreased from 25.1 per cent in 2003 to 13.8 per cent in 2006, and since 2007 it began to rise sharply to the level of 43.1 per cent in 2009 (Figure 1). A significant part of the internal absorption market boom was driven by the increased foreign direct investments (FDI) favored by low investment risk perception in Romania in the perspective of EU accession.

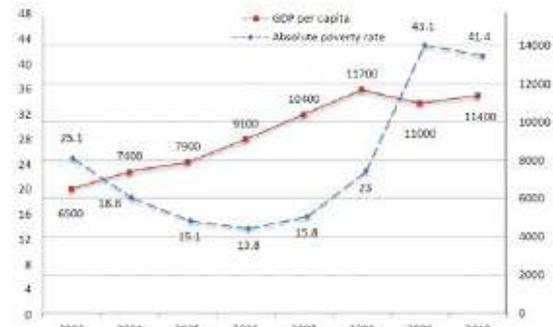

Figure 1. Economic growth and absolute poverty rate in Romania, 2003-2010

Source: Own calculations, using World Bank, Eurostat and National Institute of Statistics data

2. Current account deficit of the balance of payments trends

Strong economic growth has been accompanied by increasing current account imbalance. Since 2003, Romania has experienced a gradual increase in the current account deficit of the balance of payments (Table 1 and Figure 2), which amounted to a maximum of 16,714 million euro in 2007. Widening negative balance of current account was driven mainly by the trade balance and also by the increasing scarcity of goods and services and by the income balance. Unfavorable effect of those three components on the current account was improved to some extent by the positive current transfers.

In 2008 the negative balance of the current account fell by only 1.8 per cent from the previous year and in 2009, due to significant reduction of deficits in goods and services and income, however limited by the decreasing of current transfers, we are witnesses to the lowest level since 2003, of 4,913 million euro.

Also, in 2010 Romania registered a negative balance of the current account of the balance of payments, of 5,518 million euro

and in 2011, a slightly higher one, of 5,682 million euro, situation supported by the improved trade balance due to rebound in external demand and domestic demand contraction, but limited by the reducing of

the current transfers surplus. Trade deficit reduction mitigated the negative impact of Romanian workers abroad transfers on the current account in the context of deteriorating labor market in the euro area.

Table 1. The evolution of the current account deficit of the balance of payments in Romania, 2003-2011

	2003	2004	2005	2006	2007	2008	2009	2010	2011
Current account (net) (mil. euro)	-3,060	-5,099	-6,888	-10,156	-16,714	-16,157	-4,913	-5,518	-5,682
Goods and services	-3,893	-5,536	-8,155	-11,755	-17,413	-18,450	-7,165	-7,196	-7,083
Income	-1,195	-2,535	-2,326	-3,246	-4,127	-3,683	-1,902	-1,914	-2,336
Current transfers	2,028	2,972	3,593	4,845	4,826	5,976	4,154	3,592	3,737

The share of current account deficit to GDP (%)	-5.8	-8.4	-8.6	-10.4	-13.4	-11.6	-4.2	-4.4	-4.2

Source: NBR, *Balance of payments and international investment position of Romania, Annual Reports 2004-2011*, Eurostat available data and own calculations

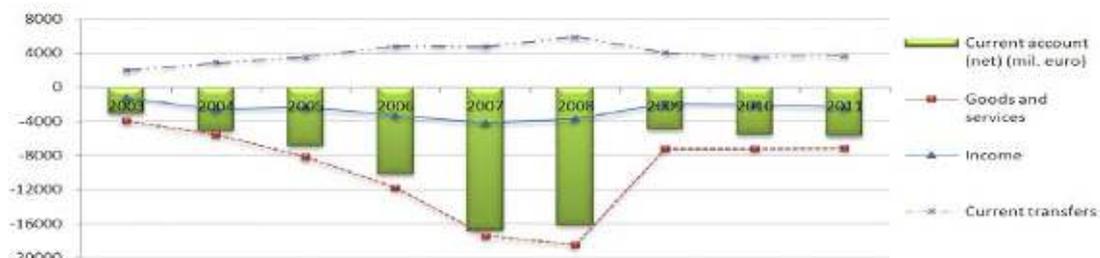

Figure 2. The evolution of the current account deficit of the balance of payments in Romania, 2003-2011

Source: Own calculations, using NBR and Eurostat available data

Although exports of goods and services in Romania have increased at a rapid pace during 2003 and 2008, domestic demand grew even faster, a situation that has pushed the current account deficit from 5.8 per cent of GDP in 2003 up to 13.4 per cent of GDP in 2008. Economic activity declined significantly since the fourth quarter of 2008. Real GDP growth raised from an average of 9 per cent (from the previous quarter) in the first three quarters of 2008 to 13 per cent in the last quarter. The decline was mainly

driven by lower domestic demand and also by exports decrease.

In 2009 the sharp decline of GDP continues simultaneously with rising unemployment and sharp rise in poverty. Both import and export of goods and services decreased significantly in 2009 compared to the previous year, and later in 2010 and 2011 both indicators revert to an upward trend (Table 2 and Figure 3). This has influenced the current account deficit that declined again since 2009 until present.

Table 2. The evolution of export and import of goods and services in Romania, 2003-2011

	2003	2004	2005	2006	2007	2008	2009	2010	2011
Export of goods and services	18,284	21,883	26,401	31,553	36,547	42,532	36,170	44,043	52,332

As a result, the share of current account deficit of balance of payments as a share of

GDP of Romania in the period 2003-2011 is as follows:

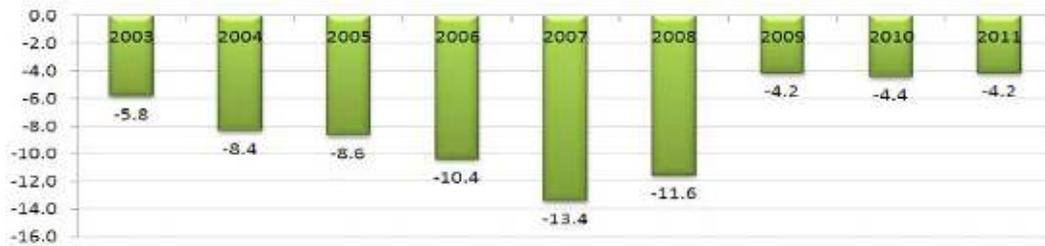

Figure 3. The evolution of the current account-to-GDP ratio in Romania, 2003-2011
Source: Own calculations, using Eurostat available data

Although significant external deficits may be partially caused by the alignment of an economy like Romania one, most of this magnitude raises questions of sustainability, especially if they persist for long periods.

A significant part of the deficit was financed by net inflows of other investments

in the form of external loans of the banking and nonbanking sectors. In this context, Romania's international investment position deteriorated significantly from -24.7 per cent of GDP in 2003 to -60.5 per cent of GDP in 2011.

Table 3. The evolution of net international investment position of Romania, 2003-2011

	2003	2004	2005	2006	2007	2008	2009	2010	2011

Also, the net foreign direct investment recorded during 2003 and 2011 an oscillatory evolving, reaching 9,059 million euro (9.3 per cent of GDP) in 2006, the year before Romania accession to EU and in 2008 a maximum level of 9,496 million euro (6.8

per cent of GDP). Since 2008, amidst strong global and European imbalances, the trend of net FDI in Romania was a considerable reduction, as well as the share of net FDI in GDP, in 2011 their level being 1,920 million euro, about 1.4 per cent of GDP.

Table 4. The evolution of FDI flows in Romania, 2003-2011

	2003	2004	2005	2006	2007	2008	2009	2010	2011

Source: NBR, *Balance of payments and international investment position of Romania, Annual Reports 2004-2011*

The shock wave of the global crisis has provided certain economic imbalances and vulnerabilities increasingly large in Romanian economy, rooted in poor economic management and as a result of the unfinished

agenda of governance reforms and public sector.

Overheating of internal and external imbalances was reinforced by pro-cyclical nature of fiscal policy in Romania, with no

medium-term orientation, and also by the frequent public sector wage increases combined with an increase in employment in this sector [6].

Result of fiscal consolidation efforts during 2003 and 2005 that led to a reduction in the budget deficit to 1.2 per cent of GDP in 2005, it gradually increased again and reached 9 per cent of GDP in 2009. This reflects the strong crisis of public finances and demonstrates weak link between budgetary and development planning. Public expenditure grew at a rapid pace compared to fiscal revenues whose share in GDP has gradually deteriorated after Romania joined the EU, in the frame of the global crisis, situation unaccompanied by a corresponding increase in the quantity and quality of public services.

3. The evolution of the banking system in Romania

Financial markets have been seriously affected by the global crisis and economic recession, stock market losing 65 per cent of its peak value, in august 2008. As financial market conditions worsened, fiscal deficit financing focused more on short maturities. Also the rapid deterioration of Romania macro environment created risks to financial and banking stability.

All these have brought real challenges to Romania’s monetary policy relatively restrictive by raising the reserve requirement (or cash reserve ratio) by central bank (National bank of Romania) and interest rates in an attempt to alleviate inflationary pressures.

Eliminating some administrative measures to curb non-governmental credit growth led to a relaxation of credit policy, banks being encouraged to develop their own lending policies given their profile and risk strategy. Expansion of non-governmental credit to non-banking customers, amid increased income of the population and also the relative easing credit conditions, was manifested not only in 2007 but in the first half of next year, local money market situation became tense since the second half of 2008, especially in august, in the frame of U.S. problems expansion in the world economy.

Romania’s financial system dominated by commercial banks played an important role in the overheating of the internal market. During 2003 and 2007, total system assets have doubled, from about 36 per cent to 74 per cent of GDP, banking sector having 83 per cent of total assets. *Dominance of foreign-owned banks in the Romanian system will increase the unfavorable situation due to further turmoil in international financial markets (Table 5).*

Table 5. Romanian banking system structure based on capital/endowment (%), 2005-2011

	dec.2005	dec.2006	dec.2007	dec.2008	dec.2009	dec.2010	dec.2011

CREDITCOOP	0.0	0.0	1.0	0.9	0.8	0.7	0.7
TOTAL CREDIT INSTITUTIONS	100.0						

Source: NBR

Amid the uncertainty caused by the global crisis and risk aversion of banks, *lending to*

the private sector decreased in intensity, loan balance variation reaching into negative

values, despite monetary policy measures taken by the central bank. Thus, from the second half of 2008, the lending process is restricted considerably, especially in retail, credit became less accessible and more expensive and the deposit created rate is reduced. It was, on the one hand, the Romanian banking sector response to the international financial market uncertainties at the time, leading to a limitation of funding for subsidiaries in Romania from foreign parent banks, and therefore reduce the rating of the country, and on the other hand was

also due to the implementation of *new regulations imposed by the central bank on lending to individuals* [5].

Deteriorating loan portfolio quality (Figure 4), mainly due to economic recession and rising unemployment and to the high level of interest charged by banks, increases the vulnerability of the Romanian banking system. However, banks have sufficient own resources to cover any unexpected losses from credit risk remained uncovered by the provisions made and realization of collateral to the borrowers.

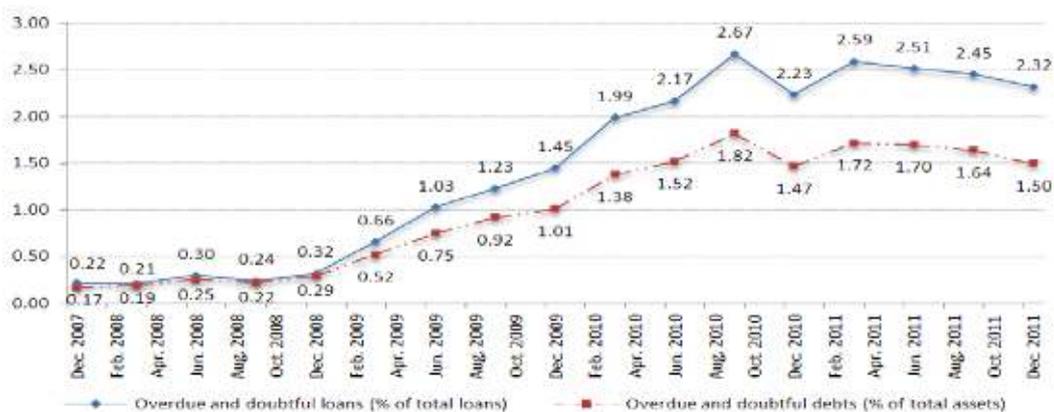

Figure 4. Overdue and doubtful loans and receivables in Romania, dec.2007-dec.2011

Source: Own calculations, using NBR available data

Deteriorating economic climate since 2009 strongly influenced the Romanian banking system. In the general context of the global economic crisis, manifested virulent, factors such as unemployment and uncertainties in the labor market, reduced income, restricted exports, diminishing FDIs, decrease in the market value of land and buildings, and so on, affect the performance of credit institution [3]. Romanian banking sector, “with levels of capitalization, solvency and liquidity consistent with prudential requirements” [2], absorbed the shock of crisis fairly well, but with the cost of much reduced performance, of the risk associated with particular emphasis on the dynamics and persistence of nonperforming loans, of prolonged inhibition of credit demand and of a relatively high dependence of external financing. Vienna Agreement concluded between NBR and 9 parent banks of the main credit institutions with foreign ownership in Romania, which states that they should not reduce their exposure to less than 95 per cent from baseline in March 2009,

was a stabilizing factor for Romanian banking sector.

During 2010 and 2011, the Romanian economy continued to feel the effects of adverse economic and financial environment at the global level and also in the euro area. Although a number of areas which until 2008 were the engines of economic growth, such as real estate activities, financial and banking activities, imports of automobiles, metallurgy, chemical, automotive, and others, experienced declines during 2009 and 2011, there are areas such as IT, telecommunications, food and medicines, public services, and others, which were able, to some extent, to support positive economic growth at the local level [1].

4. Final remarks

Romania’s macroeconomic imbalances accumulated before the onset of the global crisis and the euro area imposed certain corrections in the public sector, overlapped on the private sector ones, including the banking sector ones.

A significant role in correcting imbalances, in order to restore the public finances stability and to secure it on medium and long term, and also to stimulate public sector reform, has the financing agreement signed between Romania and the European Union, the International Monetary Fund and also other international financial institutions, signed in April 2009 and completed in Spring 2011.

Thus, efforts materialized in maintaining the current account deficit at a moderate level and reducing budget deficit have paved the resumption of economic growth since 2011.

Abstract

The migration in the European Union is an effect of the income differences between member states, but also a result of the globalization trend. Still, in the Western-European countries not all the citizens that migrate generate the brain drain phenomenon and many of them are just recognized as cheap workforce and are considered providers for jobs with the lowest level of qualifications. This paper aims to create a classification of EU-15 countries based on the level of education of the immigrants and analyse the remittances sent by Romanian immigrants. Based on data provided by OECD, Eurostat, World Bank, the paper's findings provides valuable information regarding the exchange of workforce in the EU. The main methods of refining data are Principal Component Analysis and the multiple regression. The paper's results can be considered a good start point for a wider vision over migration's social reasons in the EU.

Key words: migration, remittances, brain drain, labour market

J.E.L. classification: C01, F22, F24, J61

1. Introduction

In the European context, migration is the main source that intends to minimize the impact of the negative rate of natural increase, so even though the difference between crude rate birth and crude death birth is below 0, their population is increasing. The trend in the EU is that the Western countries, usually the members of

EU before 2004 attract immigrants from the Eastern bloc, the new 12 countries that joined the EU after 2004. These countries suffer from loss of workforce and, unfortunately, there is a lack of balance between the number of people emigrating from EU-12 and the number of people immigrating in EU-12. This disequilibrium is clearly observed in the EU-12 economy and the capital invested in developing and raising the workforce to its maturity doesn't find a return on investment in the home country. Still, remittances are a way through sending countries may recuperate the financial gap created by emigrants.

2. Literature review

Migration is researched very much at the moment, being a topic of interest for many scientists, economists and countries. Given the global context facilitated by technology it is obvious why this phenomenon raises the necessity of studies. In this article, our focus is on the Western European countries which joined the European Union before 2004, namely the EU-15 versus the Eastern European countries which joined the European Union after 2004, namely the EU-12 corresponding to countries which receive immigrants versus countries which face brain drain and loss of human capital in the interior of the European Union. Our aim is to see how the high skilled and low skilled population choose the countries where to emigrate, what are the factors that determine that step and which is the impact into the country of adoption. Firstly, highly skilled migrants are defined as the number of foreign-born labour force with completed ISCED 5-6 education levels, residing in a

certain region.

Secondly, we have to mention the fact that migration generates changes in labour supply and in productivity and availability of human resources on the market. On short term, migration can lead to severe effects over the human capital of the country that provides the workers. On the medium term, migration can enhance productivity by enabling acquiring of new skills [7]. The entries in the EU 15 countries were different: asylum seekers, people from ex-colonies, illegal or unauthorised entries and, of course, Eastern European workers [8]. Migration patterns show that $\frac{1}{4}$ of the global highly skilled migrants are attracted by EU-15 countries and almost 50% of the migrants in EU 15 come from Eastern Europe, Turkey and Northern Africa. Migration is driven by many factors: income disparities, geographic proximity, and historical links [7]. According to [8] in the past 15 years, the foreign population in EU 15 has increased by 10 million people and 60% out of them are in Spain, Italy, Greece and Portugal. Regarding the relationship between native citizens and immigrants, we can outline the fact that it is tensioned by the completion on the labour market and by the concerns about the fiscal burden on public services [6].

Thirdly, [8] discuss the fact that particularly the Eastern European countries are traditionally highly educated, but still the opportunities for the immigrants coming from these countries are scant, even though there are also looked into the aspects that are relevant for the individual himself. It is also mentioned that in Spain and Italy the proportion of new immigrants who are overeducated for their jobs is much higher than in other countries and it appears there is a trade-off between the risk of unemployment and the access to highly qualified jobs. Also there is an interesting effect that may take place: if the qualified individuals do not obtain a job matching their skills, they can also compete with low qualified individuals in order to avoid unemployment. In countries like Italy and Spain, where the demand for unskilled labour is very large this is very likely to happen. On the other hand, in countries like Denmark and the Netherlands this is not so likely because the highly skilled workers can wait until there is an available position for them as the benefits are generous

there [8]. Moreover, given the actual economic climate in the EU, the highly skilled workers are safer in confronting the economic crisis because of their qualification and thanks to the investments made by the employer in their training, while this is not reliable for low skilled workers. In addition, in Spain, for example, regarding the low skilled workers, we can notice a professional mobility from the areas affected by the economic crisis (e.g. constructions) to areas that are still profitable (e.g.: agriculture) [10].

Besides all these points, we have to mention the remittances. European Commission defines remittances as cross-border person-to-person payments of relatively low value. Specialists consider that migration and remittances certainly reduce the pressure on the number of workplaces available for the home workforce, generate new development opportunities and diminish poverty. At the same time, they stimulate imports and higher prices for housing for example, increasing the inequality, eventually.

3. Principal Component Analysis

First of all, we would like to check a few variables that may indicate that some of the EU-15 countries are more attractive for highly skilled workers and some for low skilled workers. Therefore, we took into consideration the Global Competitiveness Index [15] – the “Brain Drain” indicator, from the Pillar Labour Market Efficiency. Moreover, we considered the same Index for collecting the data regarding the proportion of agriculture sector in the GSP of each country. The correlation between them is 0.44, a positive correlation, showing a medium connection. So, as the brain drain ranking is growing closer to 142, the proportion of agriculture sector in the GDP is also growing. Below are the results, sorting the countries by the first indicator:

Table 1. Brain drain ranking and agriculture proportion in EU 15 countries

Country	Brain Drain Ranking (out of 142)	Agriculture (%GDP)
United Kingdom	4	1
Sweden	6	2
The Netherlands	11	2
Finland	13	3
Luxemburg	16	0
Belgium	17	1
Austria	27	2
Denmark	29	1
Germany	31	1
Ireland	34	1
France	43	2
Spain	54	3
Portugal	80	2
Italy	105	2
Greece	119	3

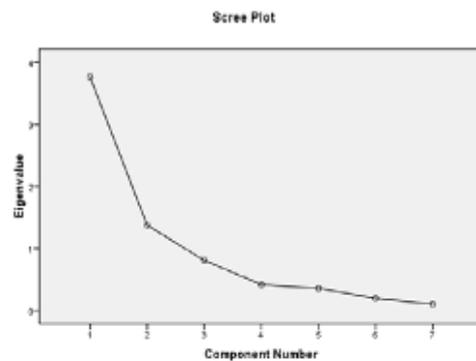

Source: World Economic Forum - Global Competitiveness Report (http://www3.weforum.org/docs/WEF_GCR_Report_2011-12.pdf)

Given this table, we can conclude the fact that countries like United Kingdom, Sweden, and The Netherlands will attract more highly qualified individuals, as their brain drain ranking is better and higher than the other EU15 countries. At the same time the proportion of agriculture in the GDP is quite low, which indicates a lack necessity of low qualified workforce. At the opposite pole, Spain, Portugal, Italy and Greece have a lower Brain Drain ranking and a higher proportion of agriculture in the GDP which means a higher need for low qualified individuals to work in this area. In order to validate this hypothesis we use the principal component analysis and we classify the profile of EU-15 countries after 7 variables: *average wage/person; social help in case of unemployment; employment rate* (percentage, for the population aged 15-64); *highly-skilled population* (% of population, ISCED levels 5 and 6); *GDP per capita; brain drain attractiveness* (ranking); *competitiveness*

level (rank). The data is provided by EUROSTAT and Global Competitiveness Index, and refers to the year 2011.

Firstly, we registered a KMO index of 0.739, appropriate for performing a Principal Component Analysis. In the correlation matrix of the standardized variables we can notice both positive and negative correlations with some stronger than others. The Communalities table reveals the fact that 4 out of 7 are relevant for the common factors having a value over 0.782. The Scree Plot and the Total Variance Explained Table show the fact that there are only two components needed in order to explain all the variables.

Figure 1. Scree Plot

Source: Own calculations- SPSS output

Moreover, based on the information provided by the Component Matrix, we can structure the information based on the average wage, competitiveness of the country, the brain drain rank and the percentage of highly skilled population as the first component (as they are strongly correlated with it) and the other 3 variables are to be structured in the second component as they are correlated with it. Therefore, we can name the first component as *Education and wage component* and the second component as *Economic climate of the country*. In the end, based on the cluster analysis we can classify the EU-15 countries in two main groups, considering the analysis developed: one group contains Italy, Greece, Portugal, Spain and the other group –the other countries. In conclusion, there is a polarity between these groups of countries, motivated mainly by the education and the strategy of attracting a certain type of workforce. The connection between education and competitiveness is high

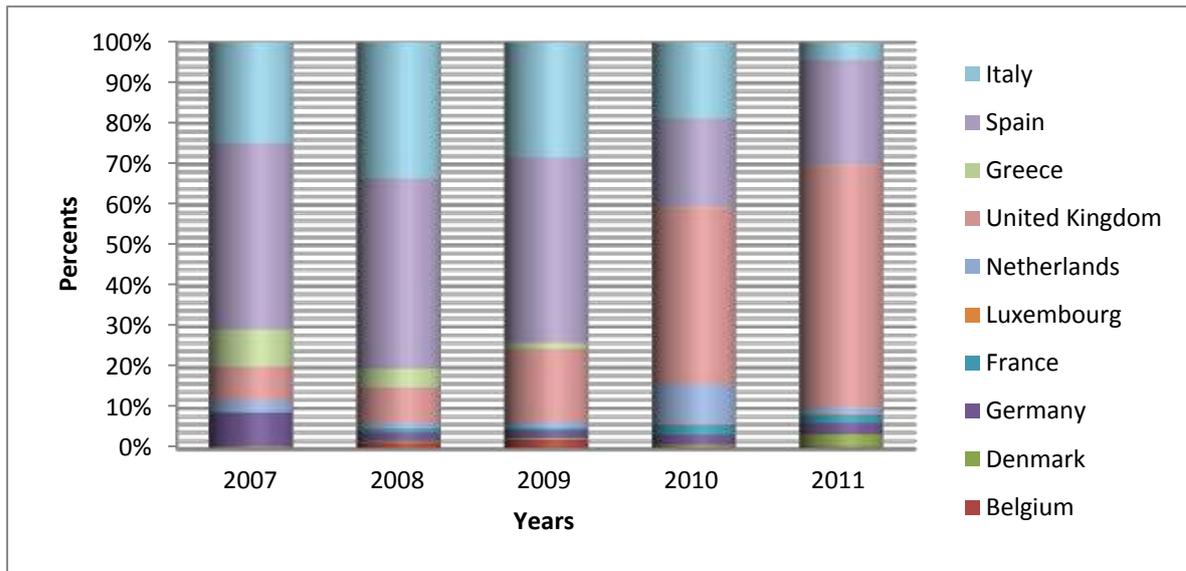

because the more the population is qualified, the more competitive the country becomes.

4. Remittances from EU-15 to Romania

In the second part of the paper, we shall analyze the connection between the level of

remittances (REM) sent by Romanian employees and workers living in the EU-15 countries. The following table shows the level of remittances based on Eurostat data received by Romania in the last years:

Table 2. Remittance level from EU to Romania

Source: Eurostat Database and own calculations

As we can notice from Table 2, between 2007 and 2009, Italy and Spain have been the main providers of remittances to Romania. Given the high number of Romanians living in these two countries the connection is obvious. Still, it is very important to notice the fact that since 2009, the sums of money have strongly diminished, while UK has become the leader, continuing the trend in 2011 as well. This is due to the economic crisis, the high rate of unemployment in Italy and Spain and the fact that UK, situated in the second cluster, has attracted many high skilled individuals, who earn more than the low skilled workforce in Italy and Spain. The same happens with the remittances coming from Greece, but at a lower scale. It is worth mentioning Netherlands who have reached a high scale of remittances in 2010, while the other countries have a fluctuating sum of money as remittances.

We have built an econometric model considering that the remittances depend on the medium wages in the EU-15 (WAG), the

unemployment rate (UnEM), the GDP per capita for EU-15. The data is collected from Eurostat database and World Bank and the econometric model is:

$$REM = \beta_0 + \beta_1 * WAG + \beta_2 * UnEM + \beta_3 * GDP + \varepsilon$$

The set of data refers to the years 2003-2010 [13][14][16]. In addition, we consider the null hypothesis H0: remittances are not significantly influenced by the 3 other factors and do not depend on them with the contrary hypothesis H1: remittances are significantly influenced by the 3 other factors, for a confidence level of 95%.

The findings of the multiple regression model show that the dependence between the level of remittances and the 3 other factors considered is high, as the Multiple R=0.946. Moreover, 89,5% of the variation of remittances is based on these 3 factors. The model is valid as SignF=0.019 < 0.05. So, we shall accept the hypothesis H1, with a probability of 95%.

As expected, the connection between

REM and the level of WAGES is positive, as when the wages are higher, the level of remittance is higher. Given that the high-skilled immigrants have better wages and the lower skilled are opposite, we can conclude the fact that the higher skilled immigrants send back to Romania a larger sum of money.

Moreover, the correlation between REM (the level of remittances) and the unemployment rate is negative. We can add the fact that the unemployment rate for the high-skilled professionals is lower than the one for low-skilled therefore, given all these information, the qualified individuals have a better remittance rate than the under qualified. Last, but not least, the connection between the remittances and the GDP per capita variation in the EU-15 countries is positively correlated to the variation of remittances. So, they vary in the same way.

Except from the model presented, our paper wanted to see if we can find a connection between the clusters we previously analyzed and the level of remittances sent from that certain clusters or countries. The econometric model was the same and the period considered was 2007-2011, because of lack of previous data. Still, countries like Austria, Finland, Sweden and Portugal have had brakes in time series and data unavailable regarding the remittance sent to Romania, therefore it was impossible to consider working in the two clusters that emerged at paragraph 3. We have also tried to work only with a few countries from each cluster, but even though the correlation was strong, the model had a p-value that was not small enough to validate the alternate hypothesis.

5. Conclusions

In this paper, the authors have tried to indicate the way the EU-15 countries divide into countries that attract high skilled individuals versus low skilled individuals. Moreover, we analyzed the connection between the sums of money as remittances sent home by Romanian citizens living in the EU-15 countries. On the one hand, the international debate over the impact of remittances over the receiving countries is very vast and it is obvious that they contribute to the development of that certain

countries. On the other hand, the EU-15 countries progress with the important contribution of high skilled professionals that immigrate in search for a better life. So the difference between the sums of money invested by the Eastern European countries in teaching that workforce and the remittance they receive may not be so large. Some of the countries, namely Greece, Italy, Spain and Portugal rely on low skilled immigrants, but given their country profile, this type of immigrants are suitable for enabling their advancement in agriculture and constructions, for example. All in all, it is important for the Eastern European countries, namely the EU-12, to continue to develop, to increase their economies and to provide for their workforce a suitable environment so that they remain in their home country. At the same time, the globalization trend will enable the migration to continue whatsoever and so, the remittances will continue to be a subject for research and debate.

FDI Impact on CEECs Development under the EU Integration

Carp Lenuța

„Alexandru Ioan Cuza” University of Iasi
lenutza_carp@yahoo.com

Abstract

The EU integration has had a strong impact on the degree of attractiveness for the countries situated in the Central and Eastern Europe (CEE). Foreign direct investments (FDI) are widely recognized as major catalysts of economic growth. This paper aims to emphasize the favorable impact of EU integration the former transition economies (Romania, Bulgaria, Czech Republic, Hungary and Poland) through the dynamic analysis of the macroeconomic indicators. Using a Granger causality test, the article will highlight, in the case of Romania, the existence of a strong a positive correlation between FDI, trade and GDP growth. Further analysis will be expanded by including in the sample both developing and developed countries. The results will allow us to draw important conclusions regarding the role of foreign investments.

Key words: FDI, integration, economic growth, Granger Causality

J.E.L Classification: F15, F21, F43

1. Introduction

The process of economic integration in the EU has determined major transformations for the CEECs. These countries have passed through significant changes and structural transformations from a centrally planned economy to a free market economic system.

The national business environment and the macroeconomic policies implemented by these economies have had a strong influence during the transition period. In consequence, some of the CEECs started earlier the transition process and involved less changes in their internal economic system, basically due their sound and stable politic environment.

The integration in the global EU market

generates important advantages for these economies: access to other international markets, development of the internal economy through a significant increase of the volume of FDI and trade, internationalization of production.

EU integration involves, in the meantime, the enhancement of degree of market openness, using as fundamental channel the foreign flows, both economic and commercial. On the other side, the increase of the interdependencies among european economies highlighted the necessity of sound macroeconomic policies which ensure the protection of their economies in front of the worldwide turbulences and imbalances, like in the case of the current economic and financial crisis.

The present paper is structured in the following sections: the second part of the paper will present theoretically the most important determinants of foreign investments in the selected economies, the third is dedicated to the major challenges these economies have gone through before and after the EU integration, meanwhile the last sections of the article will focuss on the econometric model and the discussion of its results. The last two sections of the paper are dedicated to the conclusions and the relevant references for the paper.

2. Determinants of foreign investements in CEECs – literature review

The theoretical and empirical literature has focussed intensively on the analysis of the major determinants of foreign direct investments. Reference [18] has provided one of the first classifications of the determinants of FDI based on its own perspective, in exogenous and endogenous.

The endogeneous factors of FDI inflows are related to the macroeconomic environment stability, based on appropriate economic and financial politics which ensure

the surveillance and regulation of the business environment by policy makers and the corresponding institutions.

During the transition period for CEECs and before the integration into EU market, the policy makers highlighted the necessity of the transparency of the internal business environment. The absence of the transparency is often associated with an economic and political framework characterized by a high level of corruption, instability and vulnerability to their economy. This represents one of the major reasons why Czech Republic, Hungary and Poland accessed the EU market before Romania and Bulgaria, the business and economic decisions stimulated the decrease of the corruption and enhanced the development of their economies. In these countries, foreign commercial (trade) and financial flows (FDI) recorded a strong increase, exerting a positive contribution to their development.

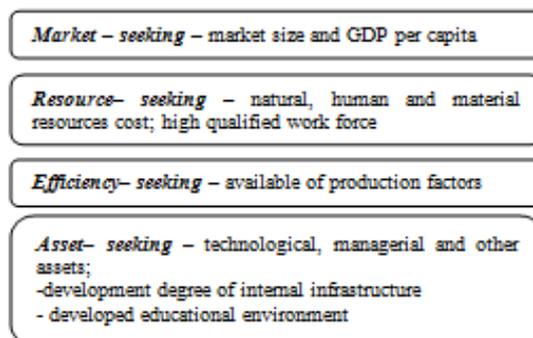

However, Romania and Bulgaria are trying to make progress regarding the corruption system and to adopt and implement policies and strategies which will stimulate the increase of the attracted volume of FDI and trade, by offering to foreign investors comparative advantages by contrast to other markets.

The exogenous determinants of FDI are strongly related to the competition in the national market and to the authorities capacity to provide superior investment opportunities for multinationals. Reference [7] concentrated his attention on the macroeconomic and political aspects of the beneficiary country, as key factors in the establishment of the investment decisions.

If we consider the aspects they are related to, FDI determinants can be classified into policy related factors and the gravity factors ([6]), emphasizing the importance of the regulations and laws in the labour market, employment and financial markets efficiency, in concordance with the impact of EU integration on the national economy.

The theoretical literature on the determinants of FDI allows us to present them by type of FDI as in the figure below.

Figure 1. FDI determinants by type of investment inflows

Source: made by author based on the relevant literature ([7],[1], [17])

A specific determinant for former soviet countries from Central and Eastern Europe is the privatization process of the enterprises owned by the state through the participation of strategic investors, whose acquisitions represented a significant share of the inflows of FDI in these economies [16]. This process has had a strong impact on the degree of attractiveness of CEECs for foreign investments, stimulating the economic growth by directing these flows to the economic sectors which provide the business environment to obtain higher economic growth rates.

One of the most important determinants of FDI attractiveness in this region is represented by their location (geographical proximity to the Western markets – [12]). Along with this, can be added other economic determinants like low corporate tax rates, low wages and access to EU subsidies.

Hungary, Czech Republic and Poland were part of the first wave of EU candidate countries, due to the fact that they have achieved macroeconomic stabilization and carried out economic reforms the most advanced. In CEECs, the acquisitions represented an important share in the total volume of FDI. From time to time, investment incentives have been introduced, sometimes they still seem to retain their attractiveness for individual countries competing for FDI. By contrast, Romania and Bulgaria suffered many years from policy immobility and periodic economic crises. However, the transformation in their policy structure has stimulated their acceptance in the second wave of candidate countries [8].

Reference [13] have shown that FDI projects in CEEC are very heterogeneous, presenting different characteristics in terms

of magnitude, objectives, technology, geographical location, ownership and control structures.

Reference [1] implemented one of the most important empirical analysis of the determinants FDI in CEECs, using a gravity model, based on data for FDI from 18 market economies and 11 transition countries. They showed that FDI is highly influenced by the host country risk, size, labor costs and distance. Other authors studied the major determinants of FDI over the period 1993 – 1999, emphasizing the positive correlation between GDP per capita and trade openness of host country, among the latter and FDI inflows [9].

Regarding the determinants of FDI flows in CEECs, many authors have focussed on the institutional aspects during the transition period: infrastructure changes, legal and business environment, political risk.

On the other hand, the major importance of the economic indicators – market size, productivity, labor market, macroeconomic stability and trade openness cannot be neglected and have benefited of intensive attention from the researchers ([17]; [4]; [3]; [2]).

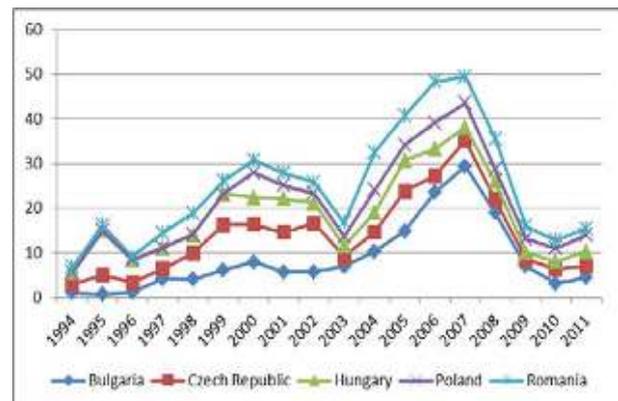

Their analysis emphasized particularly the importance of the market variables and concentrated on providing an index which includes characteristics for the transition period [17].

However, other economists like [4] developed their analysis by revealing the fact that investors are cautious when they decide to invest in the transition economy, taking into consideration the level of the political risk (corruption, stability of institutions, bureaucracy).

4. Major transformations in CEECs along with the EU integration

CEECs have been appreciated for a long time as a promising destination for the foreign capital, especially after the transition period to the market economy when these economies started to attract increased numbers of FDI inflows ([10], [15]).

Figure 2. Dynamic of FDI in CEECs during 1994 - 2011

Source: made by author based on data from World Bank Database (<http://data.worldbank.org/indicator/BX.KLT.DINV.CD.WD/countries/1W?display=graph>)

The dynamic of the FDI inflows in CEECs emphasizes an ascending trend during the past twenty years, transforming the foreign capital inflows during the transition period. Foreign direct investment have become one of the most important factors in the restructuring and privatization of their economies. FDI inflows registered a positive evolution in periods before and after the EU integration.

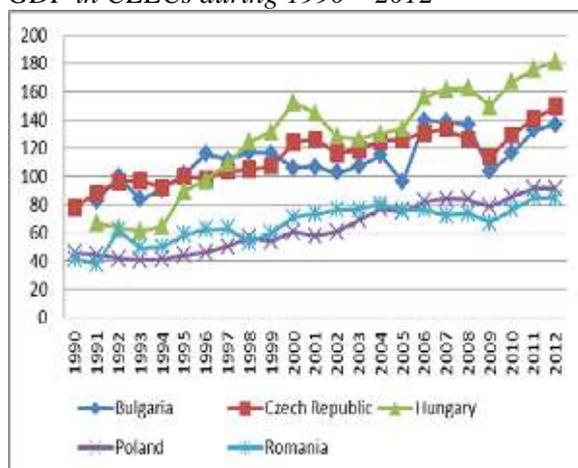

The EU integration of CEECs stimulated the development of the economy and increased the opportunities for them to achieve higher economic growth rates. EU integration implies the abolition of trade barriers and financial flows, of market entry, creating according both static and dynamic effects.

The static externalities generated by the economic integration are reflected in trade creation, as a result of free movements of goods among the member states and trade diversion, due to the involvement of other countries in the commercial relationships. On the other side, the dynamic effects are reflected in an ascending trend of the competition which will stimulate the efficient allocation of the resources. In the same time, these effects are emphasized by enlarged markets with important beneficiaries and investors who stimulate the development of the national economy through adopting and implementing equipments and technologies developed by innovations. These changes in the internal structure led the business environment to higher productivity rates and faster growth [5].

The integration into the European structures is reflected in CEECs by the free

movement of capitals – human, commercial and financial. These will led their economies to trade liberalisation between EU and CEEC, stimulating the increase of international volume of exports and imports.

Figure 3. Evolution of the share of trade in GDP in CEECs during 1990 – 2012

Source: made by author based on UNECE Database
(<http://w3.unece.org/pxweb/dialog/Saveshow.asp?lang=1>)

The affirmation that the EU integration generates free movements of capitals and flows, both financial and commercial is confirmed by the figure above. Since the beginning of the transition period to market economies and over the last two decades, trade recorded an increasing share in the total volume of GDP, stimulated by adopting and implementing sound and stable macroeconomic policies.

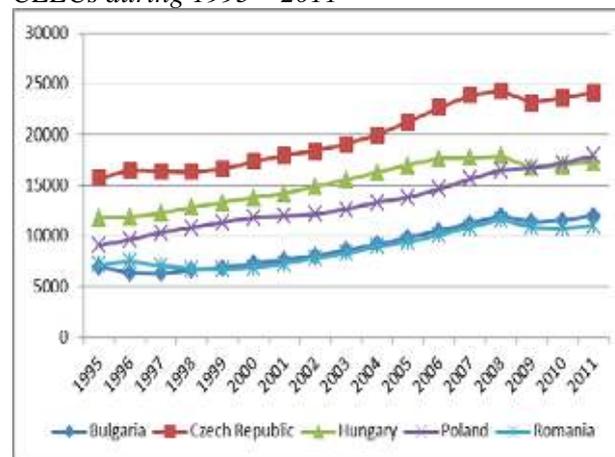

The positive implications of the EU integration of the CEECs considering FDI can be reflected in the transparency in the legal field, since these economies adopted the EU *aquis communautaire*. The national legal environment will be characterized by the sound and stable economic and political environment, stimulating the development of the business area and creating the appropriate conditions for foreign investors to expand their activities ([14], [15]).

During the last decades, the CEECs have known an ascending trend for FDI. At the beginning, the volume of FDI attracted was small because these countries have a weak institutional framework, the economic and political environment was unstable and the internal financial and political system was

not able to guarantee an active role of the authorities in guiding their economies.

The attraction of an increased volume of FDI has become one of the main objectives of national policy, the policy makers focussing on liberalizing their economies. FDI are widely recognized for their positive externalities generated in the economy, stimulating the economies to make improvements in the political stability, reflected both in higher volume of foreign flows and superior economic growth rates.

Figure 4. Dynamic of the GDP per capita in CEECs during 1995 – 2011

Source: made by author. based on UNECE Database
(<http://w3.unece.org/pxweb/dialog/Saveshow.asp>)

GDP per capita is one of the most important indicators and has had a strong ascending trend during the transition period to market economies and accelerated under the influence of the integration into the european single market.

5. The methodology

The process of EU integration has led in most of the european countries to their development, through foreign financial and commercial inflows. As we saw above, the selected countries have known a positive evolution regarding the dynamic of trade share in GDP and the FDI inflows.

In this paper, we carried out a Granger causality analysis, through which we aim to emphasize the existence of bidirectional or unidirectional correlation between the variables selected. The economic and

financial implications of the European integration is usually appreciated through free movements of financial and human capital, of people. We have selected variables regarding the labor market, trade and FDI for Romania, over the period 1995 – 2011, due to the availability of the data from the World Bank database and UNECE statistical database:

- FDI inflows (millions USD);
- Trade share in GDP (%);
- GDP growth (%);
- Total employment (million persons).

6. Results and discussion

Granger causality test involves the stationarity of the selected variables.

The first step of the analysis carried out in this paper will be the determination of level of integration for the variables included in the analysis. For this purpose we used the Augmented Dickey – Fuller test and obtained the following levels of integration:

Table 1. Augmented - Dickey Fuller test results

Indicator	Level	First/ Second difference
FDI	-1.552904	-4.096155
Employment_ total	-2.015291	-3.095400/ -6.204117
GDP growth	-2.844075	-5.505772
Trade share in GDP	-1.244459	-3.428093/ -5.533140

Note: significant variables at 5 % level

The results of the ADF test show that FDI inflows and the GDP growth rate are stationary at level. Granger causality test will be implemented after we make all the other variables stationary.

The results obtained after carrying out the Granger causality test highlight the existence of a strong unidirectional causality between trade and GDP growth and the strong impact FDI have on the trade share in GDP. On the other side, the empirical analysis has revealed an unidirectional correlation between GDP growth and trade. The EU integration determined strong correlations between the European economies involved, based on the expansion of the commercial and financial relationships.

The application of the Granger causality test has led us to the following results:

Table 2. Granger causality test results

Null hypothesis	F – statistic	Prob.
Trade does not Granger Cause GDP growth	1.63713	0.2777
GDP growth does not Granger Cause trade	6.87572	0.0228
FDI does not Granger Cause GDP growth	1.86093	0.2370
GDP growth does not Granger Cause FDI	0.52551	0.6807
Employment_ total does not Granger Cause GDP growth	0.13619	0.9342
GDP does not Granger Cause employment_ total	1.58454	0.3041
FDI does not Granger Cause trade	7.71902	0.0175
Trade does not Granger Cause FDI	0.04966	0.9840
Employment_ total does not Granger Cause trade	1.42882	0.3385
Trade does not Granger Cause employment_ total	1.33834	0.3610
Employment_ total does not Granger Cause FDI	0.07364	0.9716
FDI does not Granger Cause employment_ total	0.45821	0.7234

According to the analysis we have made, in Romania, foreign capital inflows determine a strong and positive impact on the share of trade in GDP. FDI inflows and the expansion of the activities of multinationals stimulate the development of their businesses and their economies, exerting a positive contribution on the dynamic of the national trade, through the increase of the interdependencies between international markets.

Granger Causality results showed the complete absence of any type of direct connection between FDI and employment, trade and employment, GDP growth and employment.

7. Conclusion

The economic theory sustains that EU integration stimulates the development of the countries part of the European community. The analysis implemented in the current paper has showed, that the European integration process generates an ascending trend of foreign financial and commercial flows, along with the favorable dynamic of the GDP per capita in the selected countries.

Granger Causality study has emphasized the fact that FDI inflows generate a strong and significant impact on the trade share in GDP. In the same time, the increased volume of the national trade enhances the progress of the internal economy, reflected into the GDP growth rate. Based on the results, we can sustain the indirect relationship between GDP growth, FDI and trade.

Foreign financial and commercial capital inflows supported the Romanian economy through the transition period and in its transformation into a market economy. However, these foreign inflows helped the national economy to develop and to expand its interrelationships with the global market.

Further analysis will be implemented by including in the sample more CEECs using other advanced econometric techniques or making a comparative analysis between developed and emergent economies.

Analysis of the Degree of Absorption of EU Funds, 2007-2013

Ciobanu Carmen Liliana

Doctoral School of Economics and Business Administration

Faculty of Economics and Business Administration

Alexandru Ioan Cuza University of Iasi.

carmenciobanu@ymail.com

Abstract

European funds have not made enough progress, the sustainable absorption being thus a challenge, the absorption rates being very low with real problems in the implementation of approved projects. The internal absorption rate at the end of 2012 was 16.23% and the external absorption rate (money received the European Commission in Romania) of 6.3%.

Keywords: funds, budget, programs, absorption, payments.

J.E.L. Code.: C13, C15, F36

1. Introduction

For the period 2007-2013 there were three financial instruments known as Structural Funds including:

- The European Regional Development Fund (ERDF): support for SMEs, transport, environment, energy, education, health, tourism, research and development, territorial cooperation - aims at removing regional disparities on the principle of sustainable development.
- European Social Fund (ESF): aims to achieve the strategic objectives of employment in education and training, adaptability of workers and enterprises, social inclusion, increasing administrative efficiency.
- Cohesion Fund (CF): large infrastructure of transport and environment.

Regionalization is a solution to reducing development disparities while ensuring facilitating a better absorption of EU funds, it involves determining the number, profile, surfaces and residences of development

regions.

Every seven years regional policy is reviewed by the EU institutions. Theories, concepts, models used, field specialists, procedures, participants, involved agencies, authorities, the degree of involvement in promoting programs, insufficient access to funds have created confusions leading to a decreased level regarding absorption of structural funds. Through accomplished studies, through reports, statistics, samples, case studies, questionnaires, the conclusion was - low absorption in terms of attracting structural funds in Romania.

2. European funds

The central objective of the European Union - economic and social cohesion can be achieved through Structural Funds - under the influence of continuous changes.

The European Social Fund (FSE) – is the main instrument of the European Union through which is aimed to attain the occupation strategic objectives.

European Regional Development Fund (FEDR), aims at eliminating regional disparities and is materialized in financing productive investments, infrastructure on the principle of durable development.

Specific operational programs [3]

1. Sectorial Operational Program The Increase of Economic Competitiveness (POS CCE) aims to increase companies' productivity through modernization and innovation support for existing companies and by creating new ones.

2. Regional Operational Program (POR) supports, social, territorially balanced and durable development of Romania's regions.

3. Sectorial Operational Program Human Resources Development (POS DRU) aims to develop human capital and increasing competitiveness, by linking education and lifelong learning with the labor market and ensuring increased opportunities for future participation on a modern, flexible labor market.

4. Sectorial Operational Program Environment Infrastructure seeks to improve the living standards and the environment, focusing on compliance with EU environmental legislation.

5. Sectorial Operational Program Transport Infrastructure (POS T) is targeting a developed infrastructure, modern and sustainable, able to facilitate safe and efficient movement of people and goods at national and European level and to contribute positively and significantly to Romania’s economic development.

6. Technical Assistance Operational Program (PO AT) supports coordination and implementation of regional funds in Romania, guarantees a reliable management and monitoring system and provides the transmission of general messaging referring to structural instruments designed to ensure the implementation of Structural Instruments in Romania.

7. Development of Administrative Capacity Operational Program (PO DCA) was designed to contribute significantly to the implementation of the thematic priority "Building an efficient administrative capacity", to address horizontal management issues at all levels of public administration, to improve the decentralization process of service delivery in certain priority sectors, improving the quality and efficiency of service delivery.

8. The National Program for Rural Development (PNDR) represents a platform for economic diversification of rural communities. Breeding animals and forestry remain crucial factors for land use and the management of natural resources in rural areas of the EU.

9. Fishing Operational Program – The European Fishing Fund is the financial instrument for the fishing sector of public financial assistance participating in the financing of projects undertaken by companies, by public authorities and

organizations in all economic activities that are part of the fishing sector: catching, ports, growth, processing, marketing, heritage etc.

3. The situation of projects and payments performed during 2007 - December 31st, 2012

The measured absorption is the external one, meaning the sum of payment requests submitted by Romania to the European Commission.

Statistical units are operational programs and the variables used in the analysis of correlation are: allocated budget (mil lei), submitted projects, approved projects, contracted projects and payments to beneficiaries (mil lei).

Tabel 1 Proiecte și Programe

Progr	Buget alocat (mil lei)	Proiect depuse	Proiect aproba	Contr	Plăți (mil lei)	Grad abs
POS T	20631	154	93	87	1884.76	9.14
POS Mediu	20391	634	363	346	4041.26	19.82
POR	16836	8221	3690	3319	6490.57	38.55
POS DRU	15707	10375	3061	2449	5485.53	34.92

TOT	86815	36069	11405	9222	20972.36	24.16

Source: <http://www.fonduri-ue.ro/>

The methodology used is principal component analysis and the objective of this study is to analyze the correlation between the allocated budget (mil lei), submitted projects, approved projects, projects contracted and payments to beneficiaries (mil lei) on operational programs for 2007-2013.

3.1. Correlation Matrix

Modul de realizare a analizei componențelor și rezultatele s-au obținut utilizând programul SPSS, prin introducerea și prelucrarea datelor, obținându-se următoarele rezultate: The way of achieving the components analysis and results were obtained using SPSS software through data entry and processing, yielding the following results:

Tabel 2 Correlation Matrix^a

	Buget_ alocat	Proiecte _depose	Proiecte _aprob	Proiecte_ contract	Plati_ben eficiari
Buget alocat	1,000	,151	,236	,259	,702
Proiecte _depose	,151	1,000	,941	,872	,513
Proiecte _aprob	,236	,941	1,000	,986	,706
Proiecte_ contract	,259	,872	,986	1,000	,770
Plati_ben eficiari	,702	,513	,706	,770	1,000

a. Determinant = 6.72E-006

Source: Author

The correlation matrix provides information on the 'strength' of the relationship between variables. From the analysis of the correlation matrix is noted that the strongest connection, 0986 is between the variable of approved projects and that of contracted projects, followed by the strong correlation of 0.941 between projects submitted and approved projects. From the analysis of the correlation matrix we deduce the fact that in order to characterize the initial data we need about three artificial variables. Total information content of the original data, which is actually the generalized variance calculated as determinant of covariance matrix is 6.72-006.

3.2. KMO (Kaiser-Meyer-Olkin)

Tabel 3 KMO and Bartlett's Test

Kaiser-Meyer-Olkin Measure of Sampling Adequacy.			,482
	Approx. Chi-Square		41,688
Bartlett's Test of Sphericity	df		10
	Sig.		,000

Source: Author

Since Sig value = 0 < than 0.05, rejects the H0 hypothesis and accepts the H1 hypothesis (variables are dependent). Thus there is a probability of 0.95 to be statistically significant links between statistical variables considered. Calculation of KMO statistics very close to 0.5 shows that between statistical variables are relatively weak connections, the principal components analysis can still be applied.

3.3. Communalities Chart

Tabel 4 Communalities

	Initial	Extraction
Buget_alocat	1,000	,942
Proiecte_depose	1,000	,911
Proiecte_aprobate	1,000	,998
Proiecte_contractate	1,000	,972

Plati_beneficiari	1,000	,918
-------------------	-------	------

Extraction Method: Principal Component Analysis.

Source: Author

Initial commonality is 1 being calculated before downsizing. From this chart it appears the fact that all major variables used contribute to explain artificial variables subsequently obtained with a quantity of information recovered by over 40%, as shown in column Extraction.

From its analysis it can be observed that variable 3 has a major contribution to explaining the artificial variables obtained subsequently. The amount of information recovered from this variable is of 0.998, followed closely by the 4th variable which recovers 0.972 of the information as evidenced by the extraction column in the chart above.

3.4. Total Variance Explained

It is noted that in order to recover the largest possible amount of information from the initial data we need two main components. These correspond to the largest own values, own values above 1, and the corresponding own values represent the corresponding variances of the two components retained. The two own values retained, with values above 1, are to be found in the Initial own values column and are, in descending order, 3,581 and 1,160.

Using two main components, the total amount of information recovered is 94.829% of the initial information, as shown in the Cumulative% column. Of the two main components, the first covers 71.62% of the final version, the second component 23.21%. For the given example, the first factorial axis explains $3.581 / 5 = 71.620\%$ of the total variance of the cloud of points. The first two factorial axes together explain 94.829% of the total variance. Since in this example there are two factorial axes that match the chosen criterion with $\lambda > 2$, we are going to choose the axis 1 and 2 for the interpretation of the ACP.

Tabel 5 Total Variance Explained

Component	Initial Eigenvalues			Extraction Sums of Squared Loadings		
	Total	% of Variance	Cumulative %	Total	% of Variance	Cumulative %
1	3,581	71,620	71,620	3,581	71,620	71,620
2	1,160	23,210	94,829	1,160	23,210	94,829
3	,230	4,606	99,435			

4	,028	,560	99,995			
5	,000	,005	100,000

Coordonatele variabilelor pe primele două axe factoriale

Tabel 6 Component Matrix^a

	Component	
	1	2
Buget_ alocat	,469	,850
Pr depuse	,876	-,380
Pr aprobate	,965	-,259
Pr contractate	,966	-,194
Plati benefic	,854	,435

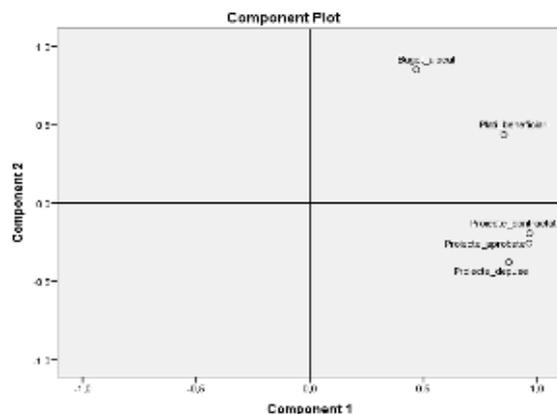

Extraction Method: Principal Component Analysis.

2 components extracted.

Source: Author

The values in the chart above show the position of variables on factorial axis. Variables "Submitted projects", "Approved projects" and "Contracted projects" have positive coordinates on the first factorial axis and a negative coordinate on the second factorial axis. Variables "Allocated budget" and "Beneficiaries payments" have positive coordinates on both factorial axes.

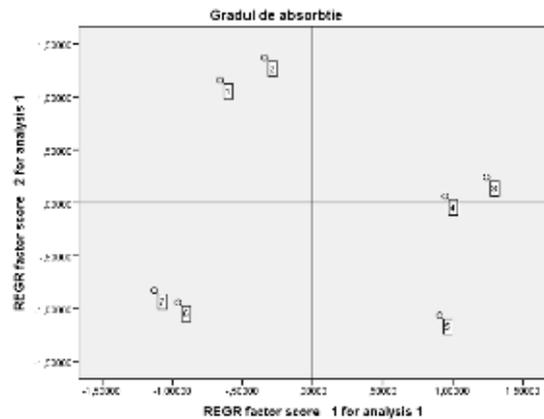

Tabel 7

Source: Author

The first factorial axis shows a positive correlation between all variables: allocated budget, submitted projects, approved projects, contracted projects, payments to beneficiaries. We do not have negative correlations. For the second factorial axis, it is shown that there is a strong link between the beneficiaries payment variables, contracted projects, approved projects. The allocated budget variable is poorly correlated both with the first factorial axis and at the second factorial axis.

Tabel 8

Source: Author

The position of the operational programs on the two factorial axes and the correlation of these results with the position of statistical variables allows the enunciation of the following conclusions:

The first factorial axis shows a differentiation of programs in terms of projects, POS, POR (3), on the one hand, and PO AT (7), on the other hand. The biggest differences between the programs in terms of the variables analyzed are highlighted by this factorial axis. Principal components analysis revealed the large differences that exist between operational programs in terms of projects submitted. The biggest differences can be found in allocated budget and the number of submitted projects. We have differences on the statistical units between POS T, POS Environment and PO AT.

The second factorial axis shows POS Transport and POS Environment programs, which are characterized by low levels of projects submitted unlike the following: POS CCE and POD CA.

3.5. Descriptive Statistics

The descriptive Statistics chart contains information about each variable analyzed independently. From the chart we find out that the variable for the allocated budget is of 12402.1429 where we can conclude that even though we analyze the operational programs from an accessing point of view, the allocated budget is on average quite high. The average value of projects submitted is 5152.7143, 1629.2857 is that of approved projects, projects contracted with an average of 1317,

4286 and beneficiaries payments an average of 2996.0514.

Tabel 9 Descriptive Statistics

	Mean	Std. Deviation	N
Buget_alocat	12402,1429	8461,37693	7
Proiecte_depuse	5152,7143	6086,16304	7

Proiecte_contractate	1317,4286	1379,65054	7
Plati_beneficiari	2996,0514	2469,64072	7

Source: Author

4. Conclusions

The low level of the absorption capacity of EU funds could be due to the following problems: poor information on the level of economic actors, poor management, corruption, bureaucracy, changes in documentation, of data submission on the way, "Failures to the Guidelines for Applicants ", lack of a motivation system of involved personnel in the structural funds, lack of standardized documents and procedures for the various management authorities, public procurement and project appraisal with long periods of evaluation, leading to delays. [1]

Some solutions for increasing the absorption of structural funds could be: stimulating and motivating competent

experts, outsourcing evaluation and monitoring of projects, compliance and shortening the duration of the project evaluation, verification of claims for reimbursement, monitoring and controlling of projects by state institutions , simplification, standardization and transparency of procedures and regulations in various programs, speeding and use of technical assistance provisions of the Guidelines for Applicants and correlation with existing situations, publishing guidelines and annexes at least one month before launching calls for proposals, achieving consistent analysis cost-benefit for all funding programs, expanding the range of eligible expenses, identifying and unlocking the amounts allocated to unfeasible projects. [2]

Gross Domestic Product and the Investment percent in Romania and in the European Union

Constantin Sanda

Transilvania University of Brasov

Faculty of Economic Sciences and Business Administration

sanda.constantin@unitbv.ro

Abstract

The paper presents the evolution of two of the most important indicators for economic development.

The indicators took into consideration in this research refers to Gross Domestic Product(GDP) and the investment by institutional sector in percent of Gross Domestic Product.

The analyze was made also for Romania and for the European Union 27 countries during a period of five years, meaning from 2007 to 2011, information available on Eurostat.

There were used statistical methods to analyze those two major indicators and the data were taken from the european site of statistics Eurostat.

At the end of the paper it was presented some conclusions and also a point of view for the last period of 2012 from eurostat newsreales, euro indicators, published in march 2013.

Key words: Gross Domestic Product, investment, development

J.E.L.classification: F36

1. Introduction

The economic development is strictly link with the investments fond allocated for this. Investments represents the most important aspect that should take into consideration by governments in order to obtain a real development in all sectors, economic, social, education, health, and so on [3].

Allocating funds for investments is a very important problem and it must be a priority for governments in order to ensure the economic growth of their countries.

Thus the paper takes into consideration analyses of Gross Domestic Product per person (GDP/person)

The analyze was made in evolution for five years between 2007 and 2011 and refers also for the situation in Romania and in the European Union.

It was also analyze Investment by institutional sector --%- of Gross Domestic Product, also in its evolution in those years took into consideration and also in comparison Romania and the European Union.

The two indicators analyzed in the paper are defined at the European Union level as in follows [2]:

GDP (gross domestic product) is an indicator for a nation's economic situation. It reflects the total value of all goods and services produced less the value of goods and services used for intermediate consumption in their production. Expressing GDP in PPS (purchasing power standards) eliminates differences in price levels between countries, and calculations on a per head basis allows for the comparison of economies significantly different in absolute size. Investment by institutional sector in % of Gross Domestic Product indicator shows the investment for the total economy, government, business as well as household sectors.

The other indicator took into consideration, investment by institutional sector in percent of Gross Domestic Product, gives the share of GDP that is used for gross investment (rather than being used for e.g. consumption or exports). It is defined as gross fixed capital formation (GFCF) expressed as a percentage of GDP for the government, business and households sectors. GFCF consists of resident producers' acquisitions, less disposals of fixed assets plus certain additions to the value of non-

produced assets realised by productive activity, such as improvements to land. Fixed assets comprise, for example, dwellings, other buildings and structures (roads, bridges etc.), machinery and equipment, but also intangible assets such as computer software.

2. Analyses

The GDP/person in Romania and in the European Union evolution is presented in Table 1 [1]:

Table1: The GDP/person in Romania and in the European Union evolution

	2007	2008	2009	2010	2011
Romania	25000	25000	23500	24500	25100
EU-27 countries	5800	6500	5500	5800	7184

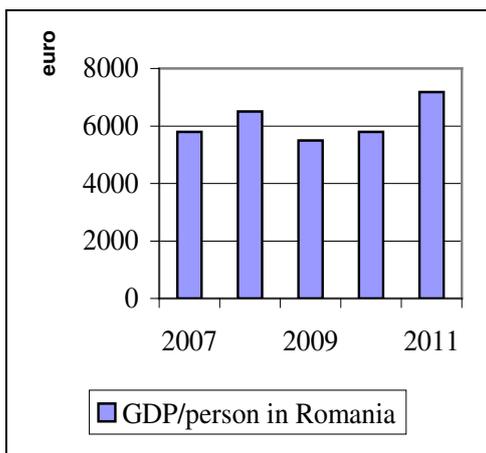

Data source: EUROSTAT

The GDP/person in Romania increase in 2008 comparison with the previous year 2007, from 25000 Euro to 25000 euro per person, meaning with 0%.

In the next year was registered a decrease with 1500 euro per person (with 6% less than in 2008).

In the following years it was an increase of GDP/person, reaching in 2011 at 25100 euro/person, meaning with 0,4% more than in 2007.

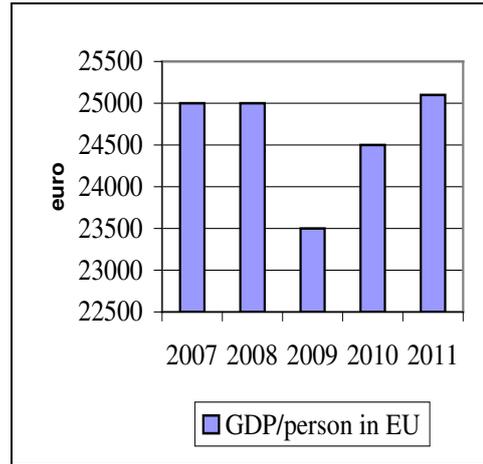

Figure 1. GDP/person in Romania

Data source: EUROSTAT

Almost the same situation registered in the European Union as shown in Figure 2:

Figure 2. GDP/person in European Union

Data source: EUROSTAT

In the European Union the evolution of GDP/person has almost the same trend but with small differences from one year to another.

Thus, in the first two years of analyses, 2007 and 2008, the GDP/person was almost constant at 5800 Euro. In the next year 2009 was registered a decrease with 1000 Euro, meaning with 17% less than the previous year.

In the following two years the GDP/person increase with 1000 Euro (17%) in 2010 comparison with 2009 and with 1384 Euro (23,86%) in 2011 comparison with 2010.

The prediction for the next three years shows that GDP/person will decrease, both for Romania and for the European Union, reaching in 2014 at 24470 in Romania and 24470 in the European Union.

Investment by institutional sector % of Gross Domestic Product in Romania and in the European Union evolution is presented in Table 2 [1]:

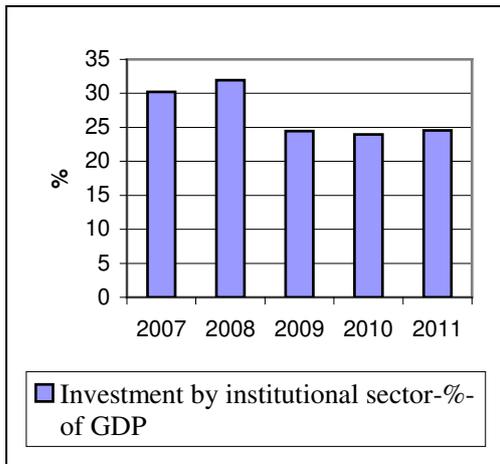

Table 2: Investment by institutional sector % of GDP in Romania and in the European Union

	2007	2008	2009	2010	2011
Romania	21,59	21,43	19,27	18,82	18,9
EU-27 countries	30,2	31,92	24,43	23,96	24,56

Data source: EUROSTAT

Investment by institutional sector % of Gross Domestic Product in Romania had an evolution shown in Figure 3:

Figure 3. Investment by institutional sector -%- of GDP in Romania

Data source: EUROSTAT

We can observe that the percent of investment by institutional sector in GDP in Romania increase in 2008 comparison with 2007 with 1,72%.

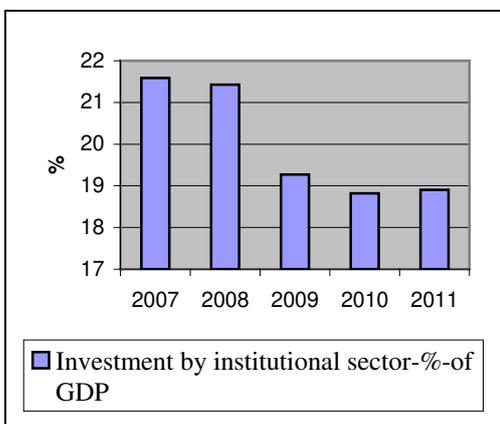

In the next two years it was registered a decrease with 7,49% in 2009 comparison with 2008 and with 0,47% in 2010 comparison with the previous year 2009.

In the last year of analyze 2011 the percent of investment by institutional sector in GDP start to increase, meaning with 0,6% comparison with the previous year 2010.

We can see also that in the last year of analyze the percent of investment by institutional sector in GDP decrease dramatically, with 5,64%.

In the European Union the situation is not necessarily the same, as we can see in Figure no 4:

Figure 4. Investment by institutional sector -%- of GDP in EU

Data source: EUROSTAT

In the European Union we can observe that the percent of investment by institutional sector in GDP decrease very few in 2008 comparison with the previous year 2007, only with 0,16%. The decrease continues during the next two years, with 2,16% in 2009 comparison with 2008 and with 0,45% in 2010 comparison with the previous year 2009.

In the last year of analyze it was a very small increase, with only 0,08%.

Also, in the last year 2011 we can observe that comparison with the first year of analyze, the percent of investment by institutional sector in GDP decrease with 2,69%.

3. Conclusion

We can observe that GDP in Romania and in the European Union had different evolution.

In Romania, the GDP/person fluctuated during the analyzed period, but, in the last year we can see that the indicator level increase comparison with the first year of analyze.

In the European Union was constant for the first two years, than registered a decrease for the following two years and in the last year of analyze increase and rich to approximately the same value as in the first year of analyze.

The other indicator took into consideration, investment by institutional sector -%- of gross domestic product had almost the same trend also in Romania and in the European Union, meaning that the indicator decrease for the first years but registered an increase in the last year.

We have to specify that the indicator did not reach the first year level.

In the same time we have to specify also, that even if the level of investment by institutional sector -%- of gross domestic product was higher in Romania than in the European Union as a percent, it was determined to a different level of GDP.

In the eurostat newsreals[2],euro indicators published on 6 of march 2013 it is specify that the EU 27 external current account recorded a surplus of 34.1 billion euro (1.0% of GDP) in the fourth quarter of 2012 compared with a surplus of 24.7 bn(0.8% of GDP) in the fourth quarter of

2011, according to first estimates from Eurostat, the statistical office of the European Union. In the fourth quarter of 2012, compared with the fourth quarter of 2011, the deficit of the goods account turned into a surplus (+5.1bn euro compared with -15.6bn), while the surplus of the services account slightly increased (+36.9 bn compared with +35.7bn) and the deficit of the current transfers account dropped (-19.1 bn compared with -22.8 bn). The surplus of the income account fell (+11.2bn compared with +27.4bn). On 6-th of march the same year 2013 in the same publication it was specify that GDP fell by 0.6% in the euro area (EU17) and by 0.5% in the EU27 during the fourth quarter of 2012, compared with the previous quarter, according to second estimates published by Eurostat, the statistical office of the European Union. In the third quarter of 2012, growth rates were -0.1% and +0.1% respectively.

Compared with the same quarter of the previous year, GDP fell by 0.9% in the euro

area and by 0.6% in the EU27 in the fourth quarter of 2012, after -0.6% and -0.4% respectively in the previous quarter. During the fourth quarter of 2012, GDP in the United States was stable compared with the previous quarter (after +0.8% in the third quarter of 2012). Compared with the same quarter of the previous year, GDP rose by 1.6% in the United States (after +2.6% in the previous quarter). Over the whole year 2012, GDP fell by 0.6% in the euro area and by 0.3% in the EU27.

Abstract

The financial crisis that has broken out in 2007, and spread throughout Europe since 2008, has been reflecting on the economic activity and employment, generating economic downturn. Gradually, the European crisis has turned into a social one, by transferring the financial problems into the social field. The objective of this article is to highlight some important effects arising from the financial crisis developments and have social and political implications across European countries. The view that the solution to the European crisis would be the application of the austerity policies has proved to be unsustainable, given that such measures have strained the relations between countries and also within countries. In the future, it remains the risk that the imbalances accumulation in the euro area, and more extended, in the European Union, would generate a polarization phenomenon in Europe by increasing the political dissensions between countries, and thereby would affect the default implementation of the European project.

Keywords: austerity policies, unemployment, economic downturn, European governance, political crisis.

J.E.L. Classification: E 24, F 15.

1. Introduction

During the last few years, since 2008, the European countries have been going through difficult moments as the financial turbulences and the vulnerabilities of the European project have turned into a sovereign debt crisis in some European countries. At the beginning of the crisis there was the fearing

of bankruptcy, and therefore the financial and political authorities have gone towards eliminating the risk factors of the banking system. The crisis has gradually turned from a financial crisis to an economic crisis, and Europe has moved into economic recession, with unemployment rising at higher levels than before.

The consequences of this recession are complex, but the social and political ones are crucial. In this paper we present some important social and political implications generated by the European sovereign debts as well as by the austerity policies applied in order to exit from crisis. The view that the solution to the European crisis would be the application of the austerity policies has proved to be unsustainable, given that such measures have strained the relations between countries and also within countries.

In the future, it remains the risk that the imbalances accumulation in the European Union, would generate a polarization phenomenon in the continent, more specifically between the German block and the other European countries, by increasing the political dissensions between countries, and thereby would affect the default implementation of the European project.

2. From the euro sovereign debts crisis to the political crisis

The sovereign debts and the austerity programmes imposed to peripheral euro zone's countries have induced and protracted the economic recession which was reflected by the decreasing of the economic activity and massive unemployment in some countries.

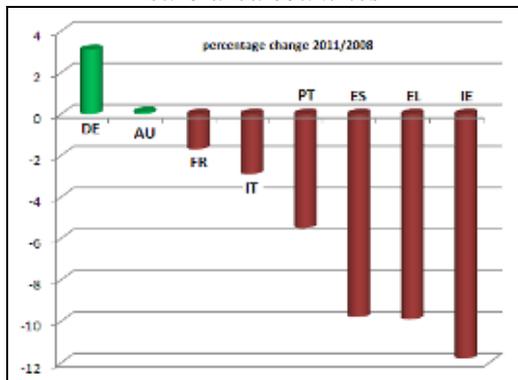

The general macroeconomic "picture" of the economic recession and of the austerity programs implementing effects is rendered

by the developments concerning several relevant macroeconomic indicators, taking into account the nominal GDP growth rate, the general government balance, the employment rate, and also the unemployment rate. The analysis is performed based on Eurostat and Ameco data, for several countries from the euro area: Germany, France, Austria, Italy, Spain, Greece, Ireland, and Portugal.

The uncertainty shock and the persistent sovereign debt crisis, which reflect the high deleveraging needs in the public and private sector, have engendered a decrease of the economic activity in most of the European countries, cutting back on spending, investment and employment for households and corporations.

In Figure No. 1, we illustrate the differences between euro area countries, concerning the dynamics of employment rate, measured as the percentage change for 2011 against 2008. Admittedly, the peripheral countries have been the most affected, while Germany and Austria recorded positive changes.

Figure No. 1. Employment rate in several euro area countries

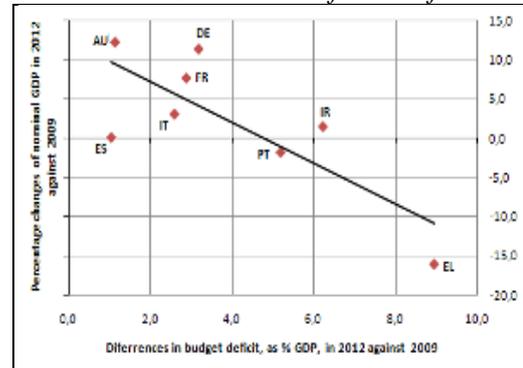

Source: Eurostat Data; authors' calculations
Note: DE – Germany; AU – Austria; FR – France; IT – Italy; PT – Portugal; ES - Spain; EL - Greece; IE - Ireland

This picture strengthens the idea that the German solution regarding the euro debt crisis, based on the application of the austerity measures has failed. Even the European Commission noticed that such a policy has deepened the economic recession, mainly in the peripheral countries [6].

De Grauwe and Ji argue that there is a strong negative correlation between the austerity programmes and the GDP growth:

the countries which have implemented the strongest austerity measures have also recorded the strongest declines of economic activity reflected by GDP [5]. This idea is sustained by empirical evidence.

Figure No. 2. The relation between the nominal GDP and the fiscal deficit

Source: Authors' calculations based on Eurostat Data; Ameco Data, for 2012 concerning the fiscal deficit

Note: DE – Germany; AU – Austria; FR – France; IT – Italy; PT – Portugal; ES - Spain; EL - Greece; IE - Ireland

As it turned out (Figure No. 2), Greece, Portugal, and Ireland have substantially reduced their deficits since 2009, despite the fact that their economies were stagnant or contracting. The data shows that there is a negative correlation between the intensity of the austerity measures (considered here as a reflection of the differences between the budget deficit level in 2012 and those corresponding for the 2009) and the economic performance, because the austerity measures implemented in these countries have depressed their economies: the more is decreasing the budget deficit, the more is decreasing the economic activity.

Paul Krugman said that the austerity is a bad policy when the interest rate is near zero lower bound, the economy enters in a liquidity trap and thus the narrowing effects of the fiscal consolidation on the demand can't be offset by a monetary expansion [8]. The large fiscal consolidation didn't increase the confidence and economic growth, but has deepened the recession in the peripheral countries.

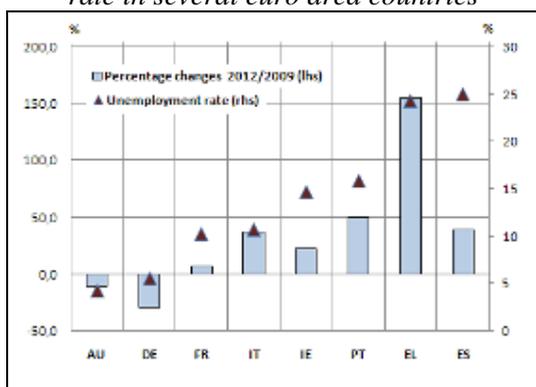

The severe austerity programs introduced in the Southern Eurozone countries since 2011, which have destroyed the social protection and safety nets, engender the risk

of social tensions in Europe, between countries and between social classes, with a direct repercussion on the viability of the European project.

The economic recession is reflected not only by the GDP growth rate contraction, but also by the increasing of the unemployment rate.

Figure No. 3 illustrates the dramatic evolution of the unemployment rate in 2012 against 2009, in Greece, with the largest increasing, above 150%. Large numbers have been recorded in Portugal, Spain and Italy. The result of these changes is also reflected by the level of the unemployment rate: Spain and Greece are the most affected countries, with levels of this indicator near 25%, in 2012. At the opposite side, Germany and Austria have improved the unemployment rate.

Figure No. 3. The evolution of unemployment rate in several euro area countries

Source: Eurostat Data; authors' calculations
Note: DE – Germany; AU – Austria; FR – France; IT – Italy; PT – Portugal; ES - Spain; EL - Greece; IE - Ireland

Generally speaking, the strong increase in unemployment means important social and psychological burdens, with longer-term implications.

The younger people affected by this problem lose the opportunity to pursue their chosen career and the risks derived from this refers to the youthful energy, a positive feature for younger, that is directed towards delinquency, or to the development of the anti-state movements. In Italy, Greece, Portugal and Spain, the people under 25 years old are reported unemployed at a level above 30 percent.

Unemployment has also larger influences,

since it does not affect just one person, but the other family members and relatives, and the consequences can be catastrophic in the social and psychological fields.

The European crisis and the austerity measures promoted by Germany have amplified the social tensions, engendering strong protests among people, and even the developing of several radical groupings. For example, in Italy have emerged radical parties, which opposed to the austerity program implementation, and Greece has already developed a radical right movement. Thus, the unemployment crisis is a political one, and it could affect, through social and political issues, the course of the monetary integration process in Europe.

At the European level, the current major priority should be dealing with the demand led recession in some European countries, not with their budgetary position.

3. The policy crisis implications upon the European project viability

The European construction has a strong German "footprint" made by the European Central Bank policy itself, which pursues as a priority the price stability objective, and the euro area authorities, especially from the "hard core", are focused primarily on the financial aspects of the crisis. But the financial crisis has been worryingly expanded in the social life, creating a fundamental dilemma for driving the euro area: pursuing the price stability, as an objective of the euro area monetary authority, or stimulating the economic activity, as a broader objective of the European policy-makers, in order to correct the excessive unemployment levels. This dilemma call into the question an inveterate problem, but fundamental one, about the viability of a monetary area functioning comprising countries which have major differences on economic outcomes, especially on the unemployment levels and its dynamics.

From the political level debate regarding the identification of the proper solutions for the European crisis, assuming that the distribution of the crisis burden should be made at the country level, it outlines two opposing directions, which actually highlight the dual structure of the euro area, and, more generally, the European Union. On the one

hand, countries that are financially “stronger”, considered that the “weaker” countries should bear the debt burden by implementing tightening policies. On the other hand, the “weaker” countries deemed that the developed economies of Europe have to bear the debt burden by supporting further lending activity, although the risk of default has increased. This difference has kept tensions between countries creating a vicious circle: the European crisis has been fuelled by the political tensions which in turn has deepened the crisis.

Besides the vision regarding the way of sharing the crisis burden between countries, if we considered the burden sharing between social classes, it would arise the conflict between the middle and the lower social class, on the one side, and the wealthy social class, on the other side. Namely, the middle and lower social class should bear the crisis burden by reducing the public expenditures which they benefit, or the debt burden should be assimilated by the “elite” of the society, increasing its taxes and regulations [7].

The conditions induced by the current crisis faced by the euro area are a test for the sustainability of the monetary integration in Europe. The political crisis is revealed by the tensions arising between the euro area countries and by the reactions of other countries concerning the policy pursued by the developed European countries. Such a situation questions the development of a European political community, which should be extended beyond the institutional framework. If the tensions between countries are increasing, then the European common institutions will lose their legitimacy and the European Union member states will begin to formulate their own internal and external policies.

4. Conclusions

Analyzing the current and especially the potential effects triggered by the austerity policies in the economic and social fields, it is noticed that the objective of the financial stability should be permanently reported on the economic and social conditions. If the financial stability is achieved at the cost of a higher unemployment, then it cannot be a priority.

The persistent unemployment recorded in

the European countries undermines the political power of the governments to pursue the required policies for managing the financial system. It is hard to imagine a common European policy at this moment, because the differences between countries on the unemployment rates make difficult the governance by common policies.

The failures concerning the eurozone governance, caused by the global financial and economic crisis, and amplified by the sovereign debt crisis and by the derived economic downturn, have revived the importance of the political will, which was, at the beginning, the fundament for the single currency project.

There is a trend for a chain-exhibiting occurrence: the national economic problems, which are undoubtedly a priority for the national authorities, which are weakening the national motivation for remaining in the euro area, consequently dragging along a feeling of distrust on the idea of common governance in this union.

Basically, the European crisis is threefold: the sovereign debt crisis, the unemployment crisis induced by the economic downturn, and the crisis of countries’ inability to find common solutions.

As Friedman [7] signals, the problem of solving the European crisis is not the lack of solutions and ideas, but the lack of a common agreement about who will pay, geographically and socially, the price. The tensions between countries and those between the social classes are engendered by the lack of the authentic common solutions.

The economic and social burdens, unequally distributed across countries and also across social classes, represent an important threat facing the European Union in the near future. The test for Europe is not the sovereign debt, but the social problems management.

Challenges of the National Bank of Romania’s Monetary Policy on the Road to the Euro Area

Damian Monica

„Ovidius” University of Constanța, Faculty of Economic Sciences

mOnicadamian@yahoo.com

Abstract

Romania’s accession to the European Union implies adopting the euro currency, which is conditioned by the participation in the Exchange Rate Mechanism II (ERM II) for at least two years.

The participation in the ERM II has implications upon the monetary policy: on the one hand, the exchange rate variation must fit the $\pm 15\%$ fluctuation band around the central parity, while on the other hand, the fulfilment of the inflation criteria is necessary.

The first part of the paper focuses on the challenges of the National Bank of Romania’s monetary policy which issue from the Maastricht convergence criteria.

In the second part of the paper we highlighted the necessity of coordination of monetary and fiscal policy in the ERM II period, being essential for achieving inflation criteria and government deficit criteria. The fiscal policy must strive, simultaneously, the budget deficit and inflation decrease.

Key words: Exchange Rate Mechanism II, convergence criteria, monetary policy

JEL Classification: E52, E31, E58

1.Introduction

The countries which acceded to the European Union in the years 2004 and 2007 have become members of the Economic and Monetary Union with derogation regarding the adoption of the euro currency, the moment of accession to the euro area not being explicitly specified. Among these, only

five countries have adopted the European currency (Slovenia - 2007, Malta and Cyprus - 2008, Slovakia - 2009, Estonia - 2011), currently being a number of seventeen countries which form the euro area. The other states, including Romania, have committed to adopt the euro currency in the moment of the fulfilment of the sustainable convergence criteria.

The fulfilment of these criteria implies a series of challenges for the mix of macroeconomic policies, as a result of the existence of the conflict between the convergence criteria. In reality, we observe a heterogeneousness in the choosing of the monetary regime in the euro area accession countries. Some countries have opted for the currency board (Bulgaria, Lithuania), while others have chosen the inflation targeting and a more flexible exchange rate (the Czech Republic, Hungary, Poland, Romania).

This heterogeneousness is explained by the fact that economies of these countries are different, the choosing of the monetary policy being based on its capacity to fulfill the nominal convergence and, especially, the monetary criteria. The monetary criteria (the inflation, the exchange rate and long term interest rate) represent the primary preoccupation of the central banks in the countries on the road to the euro area. But the main challenge which the monetary authorities of the countries which apply a flexible exchange rate will face is the simultaneous assurance of the price stability and exchange rate stability in the period of the participation in the Exchange Rate Mechanism II.

Thus, an essential role in the fulfilment of the convergence process will fall on the policy of the National Bank of Romania

(NBR), the paper concentrating itself upon *the challenges of the monetary policy of the NBR* which result from the Maastricht convergence criteria.

2. Romania's participation in the Exchange Rate Mechanism II and the implication upon the monetary policy

The adoption of the euro currency by Romania is conditioned by the participation in the Exchange Rate Mechanism II for at least two years, being considered the ante-chamber of the integration to the euro area.

According to the 2012-2015 Convergence Program, the commitment to adopt the Euro in 2015 is maintained, the moment of *Romania's entry into ERM II* not being specified.

According to the European Union's Treaty, during the Exchange Rate Mechanism II a country can not adopt the following monetary regimes: the fully floating exchange rates, the crawling and anchored pegs, other than the euro.

During the participation in the Exchange Rate Mechanism II, Romania is obliged, according to the Maastricht Treaty, to respect the exchange rate fluctuation band of $\pm 15\%$. Consequently, the strict inflation targeting is no longer viable, but a more flexible form is necessary to ensure the fulfilment of the two criteria: the price stability and exchange rate criteria.

This flexible variant of the inflation targeting includes a strategy based on a single instrument, examined by Jonas [9] and a strategy with two instruments, proposed by Orłowski and Rybinski [13]. The first strategy is based on the use of the interest rate for the realization of the two objectives, while Orłowski and Rybinski [13] propose the realization of the inflation target through the adjustment of the interest rate and the stabilization of the exchange rate through interventions on the foreign exchange market.

According to the European Council's Resolution in 1997, during the ERM II the exchange rate stability is subordinated to the primary objective of the monetary policy, the price stability being a condition prior for the currency stability. Thus, the necessity of the realization of the inflation rate level

compatible with the Maastricht price stability criteria is being imposed, so that fluctuation margins provided in the Exchange Rate Mechanism II are respected. In this sense, *the conflict between the two objectives represents a challenge for the monetary policy of the NBR*.

The increase of the nominal interest rate in order to alleviate the inflationary pressures can determine an increase of the interest rate differential vis-à-vis the euro area which encourages the speculative capital inflow and, therefore, the leu currency is appreciated against the European currency.

Although the nominal appreciation has a positive impact upon the inflation rate, taking into consideration that the imported goods with the highest average in the consumer's basket (foods) is very large, the capital inflow have negative effects upon the inflation target through the liquidities increase. Also, a nominal appreciation too large on a short-term leads to losing the external competitiveness and therefore, to the increase of the current account deficit.

In the June 2009 - May 2011 period, the leu exchange rate against the euro has fluctuated between -1.94% and 2.98% compared to the reference level (the month of May 2009), indicating a high stability of the national currency, facilitating the fixation of the central parity in the ERM II entry moment.

The nominal appreciation of the national currency during the ERM II can also be the result of the manifestation of the Balassa-Samuelson effect, the real appreciation realizing itself through the exchange rate and, less through the inflation differential.

The interventions on the foreign exchange market (currency purchases and the sterilization of the liquidity in the national currency) can be used for the prevention of the appreciation of the national currency, but this option is considered to be inefficient, because it does not permit the diminishment of the interest rate, being an incentive for the capital inflow. In case the exchange rate isn't in line with the equilibrium exchange rate, despite the effectuated interventions, *the central parity will be revalued* according with the state of the economy.

In our opinion, *in order to realize the exchange rate stability objective, a*

combination of the two methods aforementioned is necessary, using with priority the interest rate. We consider that the appeal to the intervention operations on the foreign exchange market should be effectuated in case the reduction of the interest rate has not been sufficient to alleviate the appreciation of national currency.

A second situation which might appear during the ERM II refers to the depreciation of the leu and the risk of breaking the inferior limit of the variation interval, an increase of the interest rate being necessary then. In this case the exchange rate stability is in concordance with the inflation target, but the restrictiveness of the monetary policy reduces the aggregate demand with negative effect on the economic growth.

The low level of the interest rates is not a sufficient condition to maintain the exchange rate stability. For instance, the stability of the Czech koruna in the recent years isn't only due to the low interest rate level, but also because of national bank's credibility to maintain the inflation rate at a low level.

Thus, the credibility of the national bank is a necessary condition for the fulfilment of the two nominal convergence criteria: the inflation and the exchange rate. We consider that *the National Bank of Romania must strive in order to win the credibility through the fulfilment of the proposed inflation target.*

In the opinion of the governor of the NBR, after the ERM II entry it is possible to maintain the direct inflation targeting or the adoption of the exchange rate targeting, the second variant being used as to not generate conflicts between objectives, considering the increase of the degree of openness (approximately 66% in the year 2010), the exchange rate becoming the main monetary transmission channel. His opinion is backed up by Hungary's experience, which in the year 2001 it has adopted the direct inflation targeting strategy and a mechanism similar with the ERM II (with a fluctuation band of $\pm 15\%$ around the central parity). In order to protect the rate's fluctuation band, the National Bank of Hungary had to sacrifice the inflation target in the years 2003 – 2004 [8].

We consider that *the exchange rate targeting isn't viable for the ERM II entry,*

because the catching-up process will also continue after this moment, which means that in order to fulfill the inflation criteria, the nominal appreciation of the leu is necessary. On the other hand, in the condition of the liberalization of the capital flows, an exchange rate requires the loss of the monetary autonomy and, implicitly, the control of the inflation. Therefore, *we consider that flexible inflation targeting aimed the fulfilling of both conflicting criteria is appropriate for Romania during the participation in the Exchange Rate Mechanism II.*

Borowski et.al. [2] has examined two ways to reduce the inflation rate during the participation in the Exchange Rate Mechanism II in Poland: the increase of the interest rate and the nominal appreciation. The results of the simulation show that the impact of a shock of the exchange rate is produced after eight months, while in the case of a shock of the interest rate the effect appears after sixteen months. The reduction of the inflation rate by 0.5 percentage points can be realized either through the increase of the interest rate by 1% or through the appreciation of the national currency by 2.5%. The author concludes that the interest rate policy is less efficient during the ERM II.

In our opinion, the reduction of the inflation rate during the ERM II will be done in **three ways**:

1. If there are inflationary pressures provoked by supply-side factors (the hike in the oil price), their moderation will be realized through *the increase of the interest rate* in order to anchor the inflationary expectations.
2. In case of the price increase are caused by demand-side factors, the inflation reduction will be realized through *raising minimum reserve requirement, the application of a preventive credit policy in the case of consumption credits and/or the restrictiveness of the fiscal policy*, these measures not being accompanied by the interest rates increase. Their maintenance at a low level is necessary for the fulfilment of the other convergence criteria.

3. Although the depreciation of the leu by 15% is permitted, we consider that the nominal appreciation is necessary for the fulfilment of the inflation criteria. This necessity is imposed, on the one hand by the real appreciation of the national currency as a result of the real convergence process and on the other hand, the exchange rate variations reflect themselves faster on the prices, compared with the interest rate, in which case the monetary impulses transmit themselves with a certain delay. In the case of the appearance of the too strong appreciation or depreciation of the leu, the NBR will intervene on the foreign exchange market, so that the national currency to be appreciated by a few percentage points, a favourable situation for the two nominal convergence criteria.

3.The coordination of the monetary policy with the fiscal policy in the context of the fulfilment of the convergence criteria

The accession to the euro area implies a mix of economic policies which will ensure the fulfilment of the five nominal convergence criteria provided in the Maastricht Treaty. The monetary policy can not ensure the price stability without the support of the other components of the macroeconomic policy – the fiscal policy and the income policy. In the period prior to the entry in the euro area, the fiscal policy will have a crucial role in the maintenance of the economic stability.

Empirical studies demonstrate the relationship between the fiscal deficit and inflation. Thus, Catão and Terrones [4], Fisher, Sahay and Vegh [7] have shown that there's a strong relationship between the fiscal deficit and inflation in the countries with a high inflation and developing countries, and it rules out this relationship in the case of developed countries and countries with a low inflation. This link is explained through the fact that the budget deficit is financed through monetary creation – seigniorage. According to the Maastricht Treaty, the monetary finance of the budget

deficit is forbidden. In case the financing is realized through loans, the budget deficit does not have an inflationary character. On the contrary, the loans from commercial banks restrict the liquidity in the bank system and, therefore, determine the increase of the interest rate.

The negative impact of the fiscal deficit upon the inflation rate highlights the necessity of the fiscal consolidation, as it is presented in the convergence criteria of the Maastricht Treaty. But Vierra [16] investigating the inflationary effects of the budget deficit in six countries of the European Union suggests that the relationship between the two variables is inverted in the case of a majority of studied countries, meaning that the inflation leads to the increase of the deficit. The lack of empirical evidence concerning the monetisation of the fiscal deficit is explained by the change of objectives of the monetary policies in the beginning of the eighties (the entry in the European Monetary System) towards the price stability and the fiscal consolidation and the higher independence of the central banks.

The reduction of the budgetary deficit is realized through the application of a restrictive monetary policy, through the increase of fiscality and/or the reduction of public expenditure, with effect upon the aggregate demand, in the sense of its reduction and, implicitly, upon the inflation rate. But we must specify that the increase of the indirect taxes (VAT, excises), as a measurement for the reduction of the budget deficit, have a negative influence upon the price consumer and, as a consequence, the impossibility of the fulfilment of the inflation criteria.

In the opposition, *the direct tax increase* reduces the income and decreases, as a result, the inflationary pressures, but this measure *isn't always efficient*. In case the population doesn't pay its fiscal obligations, the sums which represent unpaid taxes can be destined for consumption.

In our opinion, in order to fulfil of the two aforementioned objectives, *the adjustment of the budget deficit must be based on the reduction of budget expenditure*, because the tax increase can have an inflationary character.

A successful fiscal consolidation must be based on the reduction of the public consumption and not on the diminishment of public investments which can be beneficial for the long term economic growth. The experience of the new member states of the EMU shows that the decrease of the inflation rate through the promotion of a restrictive fiscal policy has permitted the relaxation of the monetary policy and consequently, the convergence of the interest rates.

The reduction of the aggregate demand, as a result of the tightening of the fiscal policy, determines the diminishment of the money demand and, therefore, the decrease of the interest rates, thus eliminating the incentive for the capital inflow [17]. In the author's opinion, the restrictiveness of the fiscal policy through the increase of income can determine the extension of the fiscal expenditure, the effect being null. On the other hand, the decrease of expenditure in a strong economy isn't a very popular measure.

The empirical studies highlight the bi-univocal relationship between inflation and the increase of public expenditure, Ezirim et. al. [5] suggesting the fact that the fiscal policy is an appropriate instrument for combating inflation in the United States. In order to reduce the inflation, the government should properly reduce the level of public expenditure.

The interest rates increase amid the inflationary expectations exercise negative influences upon the budget deficit through the increase of expenditure with the interest afferent to the public debt. Thus, *during the ERM II the monetary policy must reduce the interest rate, necessary for the reduction of the budget deficit and the stability of the exchange rate, the inflationary shocks being absorbed by the fiscal policy.*

Borowski and Brzoza-Brzezina [3] suggest as an optimal moment for the restrictiveness of the fiscal policy – the period prior to the entry in the ERM II. In this case, the fulfilment of the budget deficit criteria, the credibility of the exchange rate policy and the reduction of the inflation rate at the proper moment (in the middle of the ERM II period) are being assured. The author specifies that the early application of a restrictive fiscal policy does not assure the fulfilment of the inflation criteria, because

the disinflationary effect can disappear in the moment of the evaluation of the convergence criteria. We consider *that the restrictive fiscal policy can be applied in any given moment before the ERM II entry*, because the reduction of the inflation is done in a sustainable way, according to the Maastricht Treaty, which means that if the level of the inflation rate was reduced before the moment of the evaluation, it will be maintained even after that moment.

For the fulfilment of the inflation target, a balanced income policy is also necessary to ensure the correlation between the wages in the public sector with the ones in the private sector and with the labour productivity evolution. The wages increases in a rhythm superior to labour productivity generates the unit labour costs increase, which will have effects on consumer prices.

We consider that the *coordination of the monetary policy with the fiscal policy is essential for the fulfilment of both the inflation criteria and the deficit criteria.* The objective of the fiscal policy is to reduce the budget expenditure in order to reduce the budget deficit and to alleviate the aggregate demand, while the objective of the monetary policy is represented by the reduction of the interest rate with the purpose of fulfilling the fiscal and exchange rate stability criteria.

4. Conclusions

The monetary policy strategy which will be lead by the NBR during the participation in the ERM II will be directed towards price stability, as a main objective, with the simultaneously maintenance of the exchange rate stability.

Romania's participation in the Exchange Rate Mechanism II has implications on the monetary policy: on the one hand it must reduce the inflation rate, while on the other hand it must respect the provided fluctuation band. Thus, the reduction of the interest rate differential is imposed in order to ensure the exchange rate stability, but this measure isn't in concordance with the inflation criteria. Thus, the diminishment of the interest rate will be done by monitoring the approximately constant maintenance of its real level. In case the interest rate differential maintains itself at a high level, stimulating,

thus, the speculative capital inflow, the central bank intervenes in order to avoid a strong appreciation of the leu.

The Relationship Between FDI and Convergence Under the Current Evolution of the Global Economy. Aspects Regarding The New Member States.

Dârzan Mihaela
Romanian - American University
mihaela.darzan@yahoo.com

Abstract

Government policies have a significant effect over the impact that investments have on the economic and social environment.

Trade measures to reduce or eliminate transaction costs, the increase in efficiency as a result of competitiveness, capital flows from west and labor mobility are factors that supported regional integration. All countries are making efforts to satisfy the requirements of investors, but also to support and develop their regional advantages

The expansion of European Union involved new states in the process of economic growth and development. The final objective of any NMS is to adopt the euro, but for achieving this, they should observe economic conditions, that must be sustained long term

Key words: foreign direct investments, real convergence, sigma convergence, New Member States

J.E.L. Classification: E22, O11

1. Introduction

Government policies have a significant effect over the impact that investments have on the economic and social environment.

Capital flows are directed into countries that have lower wage levels and abundant natural resources. Taking into account these considerations, it can be explained the situation during 1990-2000. Studies have shown an increase in FDI flows in Central Eastern European Countries and Baltic Countries. During 1990-1994 these countries received 95% of total FDI inflows per capita for transition economies. During 1995-1998

it was a slight decline, reaching 84%, at the end of this period.

This process of foreign capital flows to developing countries, is the result of a wide range of determinants. Over time, studies have shown the main reasons behind the decisions of foreign investors and states' efforts to attracts them.

In choosing the best investment options are considered aspects of the market, available natural resources and efficiency resulting from capital investments.[1] In terms of *market choice* we are dealing with horizontal FDI; for the investors some important aspect were the size and the features of the local and regional markets, and especially the removal of tariff barriers and lower transport costs (major impediments that convince them to give up to exports and to operate from the host country). Firms that invest abroad seek *available resources* of the host country (raw materials, labor, natural resources). In contrast to horizontal FDI, vertical FDI suppose reallocation of part of the production chain, managing to cut the cost of labor and hence the manufacturing cost. The foreign direct investments' decision was also influenced by those regions where it can be exploited the advantage of economies of scale (which involves a *higher level of efficiency*). In this case they preferred the new members of European Union.

2. FDI determinants

In 2000, the announcement regarding membership deepening of the 12 EU countries also influenced the direct capital investment. [2] The interest of investors has shifted to country risk, assessed in terms of development of private sector, industry, gross reserves, level of corruption. Bevan and Estrin noted a discrepancy between the levels

of development of future new EU members and believe that an extension of time of accession (to the date set), due to increasing demands of the Union (if some states will not fully meet expectations) would cause not only for the FDI in those countries, even for all economy, discrediting the capacities of the Community.

After EU enlargement in 2004 FDI flows to new members have intensified due to positive perception on increasing the efficiency of the market in these countries.[3] If government policy to attract foreign investors operates, the number and flows of FDI may rise, and previous FDI flows could be a good background for present FDI.

Effects of the efforts made are not being exhausted when attracting investors, but are perpetual, because investment decision is based on prospective partners and on positive externalities that previous investors contributed to improving knowledge and specialization of national workforce.

Regarding the manner in which states are mobilizing to attract foreign capital flows it can be said that countries are competing on 3 areas: liberalization, promotion and competitiveness. [4]

Liberalization involves reducing trade barriers for foreign investors. Developing countries' governments work towards creating an appropriate framework for FDI. As a result, over the past 20 years were concluded regional integration treaties, which require the adoption of bilateral and multilateral trade, designed to increase the attractiveness of these economies. The goal is not only the willingness to learn from the experience of developed countries, but especially to obtain funds for growth. The mission of these governments is difficult because they have to create a harmonious domestic market, without acting against national companies.

Besides increasing openness of economies, Central and Eastern European states, are trying **to promote their own image**, in order to convince foreign investors, interested on the size and degree of market development, but also of financial incentives and tax.

Governments of host countries must develop an environment based on **competitiveness** and prosper both for foreign and domestic investors. This implies the

existence of an adequate legislation, efficient partnership between the public and private sectors and of course, a good infrastructure.

To conclude the analysis of the determinants of FDI can be said that host countries, based on regional advantages (market size and low costs of labor and accessing resources), are trying to satisfy the investors' requirements (a good infrastructure, reformed institutions, coherent policies, financial and fiscal facilities, fair and predictable economic environment).

3. The effects of FDI flows

Foreign capital flows should be directed towards upgrading and increasing training and qualification of labor force for the benefit of maximizing positive effects, among which may be mentioned:

- economic growth sustained on investments in a new production capacity that can generate new jobs, new taxpayers or privatization, leading to an increase in efficiency for business;
- a higher competitiveness and internal development for the sector in which the investment is made, or the branch from which the new investor is purchasing;
- especially the restructuring and privatization of companies that require large capital flows;
- an increase in budget revenues, due to new contributors;
- improving living standards, lower prices and diversification due to the rise of competition.

4. The relationship FDI – convergence under the current global evolution

The expansion of European Union involved new states in the process of economic growth and development, but as we can see it was a slow down after the accession, on the one hand due to the economic crisis, but also due to a more relaxed economic policy. The convergence of NMS to the EU it's a gradually process that requires substantial efforts especially under current circumstances – the global crises. Any new Member State has the ultimate objective of adopting the single currency, but for achieving this step some economic

conditions should be observed to be sustain for a long-run.

The requirements of The Maastricht Treaty are the framework conditions that each state must meet. At first, all NMS focused on issues of nominal convergence, but they discovered that only if they achieve to sustain those issues it's a way to get to real convergence.

In the economic literature, real convergence is measured using the coefficient of variation of GDP / capita, known as *sigma convergence*. [5] It covers two types of convergence: absolute (not taking into account the initial conditions from which leaves countries) and conditional (even if you don't take into account the initial conditions, countries must have the same fundamental structural characteristics). [6] Even though this type of convergence primarily involves reducing the variance between GDP/capita of some countries, I have expanded a little the analysis on the real disposable income of households and the productivity per hour.

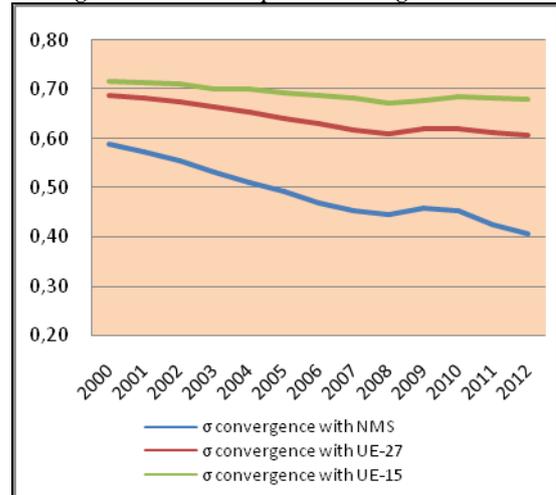

For computing the sigma convergence it was used the formula:

$$\sigma_t = \sqrt{\frac{1}{n} \sum_{i=1}^n (X_{it} - X_t)^2 / X_t},$$

where n is the number of states; X_{it} represents the value of the indicator analysed for country t ; X_t is the average value of the indicator against which it is compared. [7]

As we expected, during the last 12 years, the convergence between NMS and UE-27 average occurred more quickly, then between NMS and UE-15. It's harder to come closer to the trend of old members.

Figure 1. GDP/capita convergence

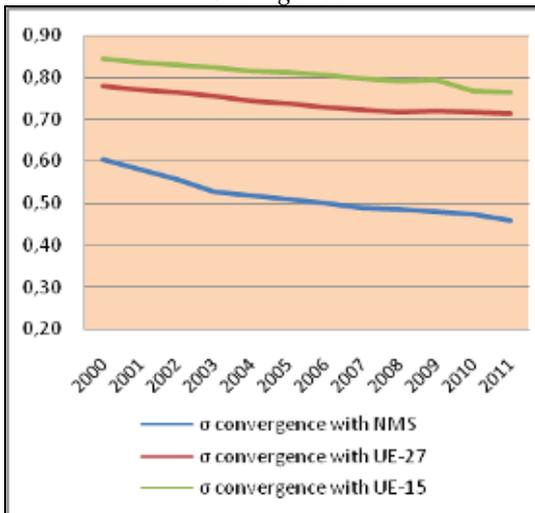

Processing after Eurostat Database

As it can be seen in Figure.1, during 2000-2012 sigma coefficient moved from 0.72 to only 0.68. Differences existing at the time of accession in the EU-15 and new members cannot be easily overcome. There is a slight change of trend in 2008, followed by a modest rebound that does not keep for long, meaning that in recent years we can not decide on the speed or the enhance of this process. The values of this indicator captured best economic contraction caused by the crisis.

In early 2000s the convergence of productivity per hour was very low. This hasn't improved significantly. In the figure below it can be seen only a very small change (less than 0.10).

This shows that productivity is a chapter that needs a change, and it won't progress unless NMS support, initiate and implement research and development projects (they don't have to expect only technologies transfers from developed countries). To reduce the gap in terms of this indicator, developing countries should increase the performance and skills of their workers to manage to face off the big European market challenges.

Figure 2. Productivity per hour worked convergence

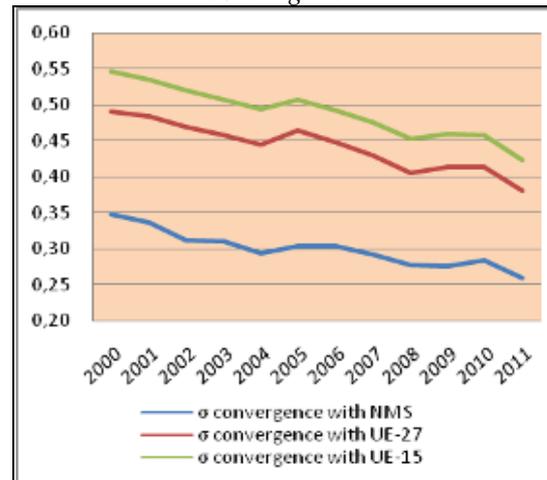

Processing after Eurostat Database

Finally, the analysis of household disposable income has the fastest catching. In the late 2011, while the EU-27 had an increase of 34%, compared to 2000, for NMS it was much higher. Among the leading countries there are: Lithuania (from approx. 6.400, to approx. 12,600, an increase of over 96%), Romania (from approx. 3.850, to approx. 7,500, an increase of 94%), Latvia (from approx. 5.400, to approx. 10,000, about 85%), Estonia (from approx. 6.350, to approx. 10,900, an increase of over 70%), Slovakia (from approx. 7.400, to approx. 13,500, an increase 82%).

The level of sigma convergence decreases more for this indicator, as it can be seen in Figure 3; reduction is observed both in relation to the EU-27 and EU-15 (it comes to less than 0.45 for sigma convergence with old members, and below 0.4 in relation to the average of the European Union).

Figure 3. Disposable income per capita convergence

Processing after Eurostat Database

Comparing to the other 2 graphs, the last one shows us a tortuous course of convergence, showing that despite the reduction in differences the evolution wasn't smooth and unhindered. The real disposable income of households in the NMS had a different change compared to the other countries. In 2009, revenue decreased for most Europeans. This was mostly felt in Latvia, Lithuania and Romania. Thus, in the figure above it can be seen the divergence during that period (the value of sigma convergence increased).

In Figure 2. and 3. distances between straight is relatively constant, a different situation can be observed for Figure 1., which shows a more pronounced increase convergence with EU-27 compared to EU-15 (that and because of higher discrepancies of the EU in terms of GDP / capita).

Lack of real convergence in some peripheral economies can turn, less flexible and unable to eliminate shocks affecting them. Due to divergent structures asymmetric shocks will gain and convergence will be reduced, which will lead to a different impact of monetary policy.

5. Conclusions

Convergence is a common goal for all new member states. Integration involved a combination of factors, which increased benefits to these countries until the crisis started. Trade measures to reduce or eliminate transaction costs, increasing efficiency as result of intensifying

competitiveness, capital flows from west, labor mobility are factors that supported regional integration. At the time of the last wave of accession, those countries were less developed than the EU-15 (the GDP per capita was 40% of the European average). Previous analyzes have shown positive effects occurred as a result of intensifying relations with the EU, but as I said before the differences in development between the new and the old group have been felt only after 2008. When the old states felt compelled to restrict relations and to show a higher degree of caution and their support for the new members began to diminish, most NMS started to be more vulnerable, and imminent changes occurred affecting them more and more, having a negative impact on the hole economy, reducing most of the investments and bringing these countries at a level that they thought it was left behind forever.

All NMS must retry to coordinate their efforts for overcome the current situation and to convince foreign investors to trust again in those economies because, as it could be seen during the analysis, this capital flows are not enough, but are representing an important support for a future development.

An Analysis of the Energy Efficiency of the EU Economy in the Context of Sustainable Development

Ghita Simona

Academy of Economic Studies in Bucharest - Department of Statistics and Econometrics
simona.ghita@csie.ase.ro

Abstract

In the context of the accentuation of the negative impact of human activity on the environment, the energy efficiency issue becomes more and more important. The European Union has developed a package of policy measures in the field of energy in which energy efficiency is seen as a key that can provide fulfillment of other major EU targets.

This paper analyzes the level and evolution of statistical indicators of energy efficiency at EU level, in relation to the rate of economic growth and research and development activity.

Keywords: Energy Intensity of the Economy, Real GDP per capita growth rate, R&D expenditure, Gross Inland Consumption of Energy.

J.E.L. classification: O31, Q43, Q50.

1. Introduction

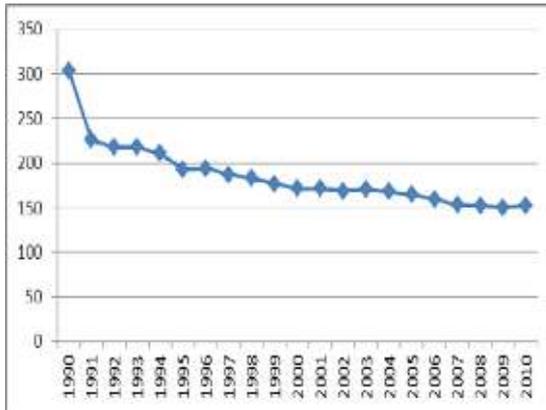

The deepening global warming, increased intensity and frequency of extreme weather events, increased pollution, depletion of non-renewable resources - are just some of the harmful effects of human activity on the environment [1]. However, they speeded up the transition to a sustainable economic development, monitored at EU level through the European Strategy for Sustainable Development. In this strategy, energy plays an important role. Among the key objectives of European energy policy we mention: increasing energy efficiency, increasing the share of renewable energy, reducing emissions of greenhouse gases and others. Research - development and innovation activity brings its contribution to improving energy efficiency, increasing the competitiveness of the European economy as

a whole, to create new jobs in a knowledge-based economy [8]. European Commission undertook a series of ambitious targets in energy domain for the EU economy, by 2020: reducing emissions of greenhouse gases by 20%, improving energy efficiency by 20%, reaching a 20% share for renewable energy, reaching a level of 10% for bio-fuels. Energy efficiency can also provide a reduction in economic sensitivity to climate change or to energy price changes [7].

2. Energy Intensity of the Economy.

One of the EUROSTAT statistical indicators that monitor the efficiency of measures taken in European countries in order to implement the European Strategy on Energy is Energy Intensity of the Economy. The indicator is calculated as a ratio between the Gross Inland Consumption of Energy and the Gross Domestic Product (GDP), corresponding to a given year [10]. The indicator is used to quantify the energy efficiency in general terms, addressed by the energy consumption of an economy. Since the EUROSTAT definition of the indicator “the Gross Inland Consumption of Energy” were taking into account five different types of energy (coal, electricity, oil, natural gas and renewable energy sources), expressed in different units of measure, in order to ensure the comparability it was used a standard unit of measurement - kilogram of oil equivalent [11].

Figure 1. The Energy Intensity of the Economy at European Union level (kg of oil equivalent per 1 000 EUR), between 1990 and 2010

Source: made by the authors, based on data available on EUROSTAT Database.

The Energy Intensity of the Economy at European Union level had a favorable evolution during the last two decades. The indicator value decreased by 50% (in 2010 the Energy Intensity of the Economy in European Union was half of its value in 1990). Along the entire period the indicator value decreased by 3,4% in average per year, but the average relative decrease was higher in 1990-2000 decade (-5,57%) than in 2001-2010 decade (-1,32%). In 2010 the highest value of the indicator was registered in Bulgaria, followed by Estonia and Romania. At the opposite side there are Denmark, Ireland and UK, countries with lower values of the energy intensity of the economy [6].

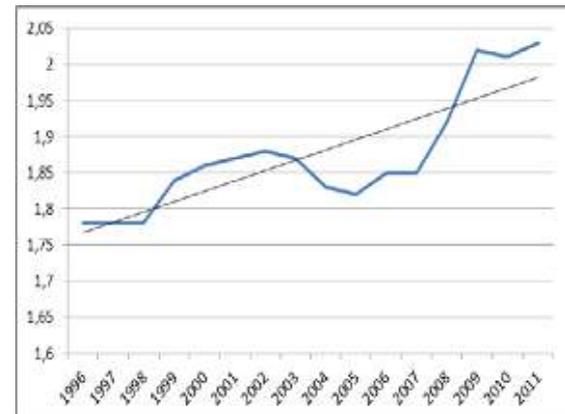

3. R&D expenditure

We cannot talk about energy efficiency without a determined research-development-innovation activity. "Research and experimental development (R&D) comprise creative work undertaken on a systematic basis in order to increase the stock of knowledge, including knowledge of man, culture and society and the use of this stock of knowledge to devise new applications" [11]. The evolution of Research and Development sector in a country strongly depends on the education management system, in a knowledge-based society [4]. One of the EUROSTAT indicators that characterize the research-development activity is GERD – Gross Domestic Expenditure on R&D, as a percentage of GDP [10].

In the last 15 years we can see – in the next chart – that the evolution of the indicators was fluctuating at EU level. Thus,

between 1996 and 2002 the R&D expenditure as a percentage of GDP increased from 1,78% (in 1996) to 1,88% (in 2002). It was followed by a decrease until the beginning of the financial global crisis. Then EU countries have realized, however, that research-development can be a viable solution for ending the crisis. So the indicator level recorded the strongest growth in 2007-2011 period (maximum value: 2,03% of GDP in 2011).

Figure 2. Total R&D Expenditure (% of GDP)

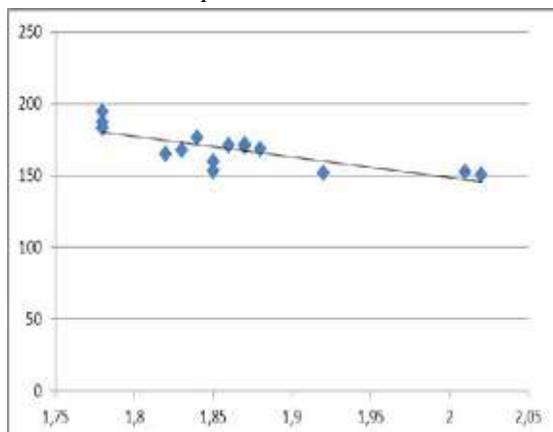

Source: made by the authors, based on data available on EUROSTAT Database.

In the first part of the last decade, growth indices of real earnings recorded lower values than those of real expenditure of the population. In the second part of the decade (after 2005) the evolution of the two indicators is similar. Indices have values above unit on almost the entire period, except for the years of financial crisis.

4. The correlation between R&D expenditure and the energy intensity of the economy

Analyzing the next scatter, the correlation between the R&D expenditure as a percent of GDP and the energy intensity of economy, in 1996 - 2011 period was a rather strong and negative one, (the correlation coefficient was -0,788 and it was statistically significant for more than 95% confidence level) [2] [3]. The growth of R&D expenditure was accompanied by a decrease in the energy intensity of the economy.

Figure 3. The correlation between the R&D expenditure (% of GDP) and the energy intensity of the economy (kg of oil equivalent per 1 000 EUR), between 1996 and 2010, at European Union level.

Source: made by the authors, based on data available on EUROSTAT Database.

Table 1. The coefficient of correlation between R&D expenditure and the energy intensity of the economy.

	Total R&D Expenditure	Energy intensity of economy
Total R&D Expenditure	1	
Energy intensity of economy	-0,78835	1

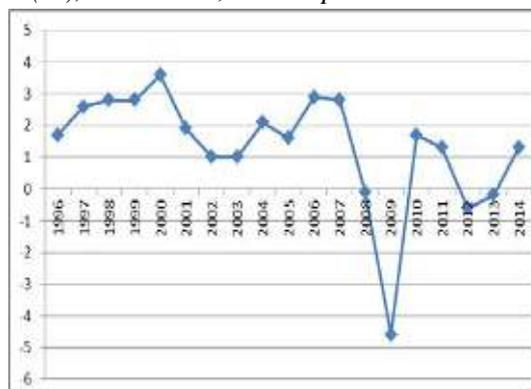

Source: made by the authors, based on data available on EUROSTAT Database.

5. Real GDP per capita growth rate and its connection to the energy intensity of the economy.

Real GDP per capita growth is a EUROSTAT indicator characterizing the dynamics of an economy. EU economy recorded a downward trend in terms of this indicator. One of the peaks of development was manifested in 2000 (+3.6%), while the second peak - less high - occurred in 2006-2007 (+2.9%). There was a period of slowing economic growth between 2002 and 2005. After 2007 the global financial and economic crisis was felt in a very strong decrease in real GDP per capita growth rates, when the EU economy registered a negative growth (-4.6% in 2009). Since then, the EU economy has recovered in 2010 and 2011, going back

to a positive growth. Unfortunately, specialists' forecasts indicate a return of financial crisis in the years 2013 and 2014, when real GDP per capita growth will be negative again.

Figure 4. Real GDP per capita growth rate (%), 1996-2014, at European Union level

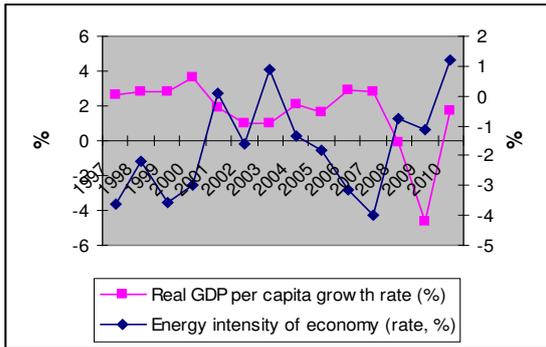

Source: made by the authors, based on data available on EUROSTAT Database.

Note: 2013, 2014 – predicted values.

One of the specific objectives of the implementation of the European Strategy for Sustainable Development of the EU is to ensure the independence between the economic development, on one hand and energy and resource consumption, in general, on the other hand. In other words, the economic growth in EU countries must no longer be produced by resources overuse, by increasing resource consumption. Due to the slowdown in GDP growth and a decrease in energy consumption during the same period, it was achieved absolute decoupling between energy consumption and economic growth. Development of energy intensity has a strong link with the dynamics of economic cycles [9].

Figure 5. The comparative evolution of Real GDP per capita growth rate (%) and Energy Intensity of the Economy growth rate (%), 1997-2010, at European Union level

Source: made by the authors, based on data available on EUROSTAT Database.

In support of this idea we have examined the correlation between real GDP per capita growth rate and Energy intensity of the economy. Over the period analyzed (1996-2010) the correlation between the two indicators is positive, medium intensity, which shows that throughout the period there has been a decoupling between economic growth and energy consumption [5]. Analyzing this correlation in time sequences, we have noticed that there were some different developments. Please note that the results are indicative and should be interpreted with caution due to limited information in the sub-samples. The period 1996-2000 was characterized by a strong negative correlation between the two analyzed indicators; economic growth was accompanied by a reduction in the energy intensity of the EU economy.

Table 2. The coefficient of correlation between real GDP per capita growth rate and the energy intensity of the economy (1996-2000).

1996-2000	
<i>Real GDP per capita growth rate</i>	<i>Energy intensity of economy</i>
<i>Real GDP per capita growth rate</i>	1
<i>Energy intensity of economy</i>	-0,93962

Source: made by the authors, based on data available on EUROSTAT Database.

In the next sub-period (2001-2006)

continues the same type of correlation between real GDP per capita growth rate and Energy intensity of economy, however, although the correlation is negative, it decreases in intensity from the previous period. It is a period of some stability in the rate of economic development, on a background of lower energy intensity of the EU economy.

Table 3. The coefficient of correlation between real GDP per capita growth rate and the energy intensity of the economy (2001-2006).

2001-2006	
<i>Real GDP per capita growth rate</i>	<i>Energy intensity of economy</i>
<i>Real GDP per capita growth rate</i>	1
<i>Energy intensity of economy</i>	-0,69757

Source: made by the authors, based on data available on EUROSTAT Database.

In the last sequence of time (2007-2010) the meaning of the correlation between the two indicators has changed, becoming a very strong and positive correlation. The explanation is that in this period there was a strong economic recession, a strong decrease in the rate of economic development, naturally accompanied by a reduction in energy consumption. Decoupling between the evolutions of the two indicators manifested in the first two sub-periods of time analyzed.

Table 4. The coefficient of correlation between real GDP per capita growth rate and the energy intensity of the economy (2007-2010).

2007-2010	
<i>Real GDP per capita growth rate</i>	<i>Energy intensity of economy</i>
<i>Real GDP per capita growth rate</i>	1
<i>Energy intensity of economy</i>	0,96784

Source: made by the authors, based on data available on EUROSTAT Database.

6. Conclusions.

The issue of energy efficiency gains new amplitude under the impact of the undesirable effects of economic development on the environment. Therefore the European Commission has granted an important place in the European Strategy for Sustainable Development. Our analysis focused on a number of indicators used by EUROSTAT in the system of sustainable development indicators: real GDP per capita growth rate, energy intensity of the economy, R & D expenditure as percent of GDP.

The correlation between the R&D expenditure as a percent of GDP and the energy intensity of EU economy, in 1996 - 2011 period was a rather strong and negative one, which means that the growth of R&D expenditure was accompanied by a decrease in the energy intensity of the economy.

Examining the correlation between real GDP per capita growth rate and Energy intensity of the economy, we have noticed that this correlation have had some different developments during time sequences. Over the period 1996-2010 the correlation between the two indicators was positive, medium intensity. The sub-period 1996-2000 was characterized by a strong negative correlation between the analyzed indicators, when the economic growth was accompanied by a reduction in the energy intensity of the EU economy. In the next sub-period 2001-2006 continues the same type of correlation between real GDP per capita growth rate and Energy intensity of economy, with lower intensity compared to the previous period.

Finally, in the last sequence of time (2007-2010) the meaning of the correlation between the two indicators has changed, becoming a very strong and positive correlation.

Operational Risk Disclosures in Hungarian Commercial Banks

Herghiligiú Roxana

Alexandru Ioan Cuza University of Iasi

Faculty of Economics and Business Administration

roxana_herghiligiú@yahoo.com

Abstract

This paper aims to assess the current operational risk disclosure in Hungarian banks. Therefore, we focus on the operational risk items that Hungarian banks disclose and if they comply with the requirements of the International Bank of Settlements. The survey methodology was adopted by testing the annual financial reports for Hungarian commercial banks. The analysis shows that Hungarian banks, primarily, do not meet the requirements of the International Bank of Settlement, relating to operational risk disclosure, and there are many discrepancies between Hungarian banks relating to the format of the financial report, which presents the operational risk disclosures. Commercial banks in Hungary have different approaches of showing the disclosures of operational risk. Accordingly, they do not disclose the same types of information. Our study advice Hungarian commercial banks to enhance current operational risk disclosure practices. The contribution of this paper is to highlight the Hungarian commercial approaches of the operational risk disclosures.

Keywords: operational risk, disclosure, banking, Basel II, International Bank of Settlement

J.E.L. Classification: G21

1. Introduction

Mandatory disclosure is an important tool intended to allow market participants to assess operational risk [1]. The annual reports of the banks are a tool which should show the key indicators of operational risk, because a major task of the banks is to measure and manage the risks that arise from their business activities.

Under Pillar 3 financial institutions are required to provide detailed information on their capital structure and adequacy, as well as information on the size and assessment of risk exposures.

In this paper we examine the quantity and quality of operational risk measurements and management information that it is currently provided by Hungarian banks' annual reports and assess the results in the light of the disclosure requirements of operational risk as put forward by Basel Committee on Banking Supervision.

The importance of this study consists in detecting the concept and de adequacy of the operational risk disclosure and the nature of the contiguity of the banking activity and imposed by this nature. And through the participation of financial statements contain a high level of disclosure to operational risk in order to enhance the transparency of banks and to strenghten the market system by encouraging banks to provide the public and maket participants the information they need in order to assess the financial position of banks and the performance and activities and exposure to economic risk. The importance of this consists in the fact that the weak practices in operational risk management were the part, from many reasons, for the failure of banks and banking crisis in the world.

The purpose of this study is to measure the current level of disclosure for the Hungarian banks in operational risk, through the examination of annual financial for Hungarian commercial banks and if the current practices comply with Bank of International Settlements.

2. Previous study

Following the widespread recongnition of the importance of operational risk in banking and the knowldge that operational risk

exhibits characteristics fundamentally different from those of other risks, an increasing amount of academic research has been devoted to this issue

One study [2] shows an investigation of operational risk disclosure practice for the years 1998 to 2001, a sample period in which the concern about operational risk started to increase but related disclosure was not mandatory. Their findings indicate that institutions with a lower equity-ratio and/or which are less profitable choose a higher level of disclosure with respect to operational risk, in order to assure the market that operational risks are well managed. This study also shows that there was a significant increase in the extent of operational risk disclosure, measured by word count.

Another study [1] examines the value of operational risk disclosure through the controversial SEC requirement which required major hedge funds to register as investment advisors and file Form ADV disclosures. The study highlights that leverage and ownership structures suggest that lenders and equity investors were already aware of operational risk but operational risk does not mediate flow-performance relationships. Investors either lack this information or regard it as immaterial. This investigation suggests that regulators should account for the endogenous production of information and the marginal benefit of disclosure to different investment clienteles.

Other paper [3] aims to highlight the role and significance of asymmetric information in contributing to financial contagion. Moreover she emphasises the importance of greater disclosure requirements and the need for the disclosure of information relating to “close links”, such disclosure being considered vital in assisting the regulator in identifying potential sources of material risks, it illustrates the fact that incentives, such as the reduction in the levels of capital to be retained by institutions, which have the potential to facilitate market based regulation may not necessarily serve as suitable means in the realization of some of objectives included in Basel II. This study concludes that information disclosure should be encouraged for several reasons, amongst which include the fact that imperfect information is considered to be a cause of market failure, which reduces the

maximization potential of regulatory competition and also because disclosure requirements would contribute to the reduction of risks which could be generated when granting reduced capital level rewards to banks who may have poor management systems.

Haija and Hayek [4] study the items of operational risk that Jordanian commercial banks disclose and if they comply with the central bank of Jordan requirements. They test the annual financial reports for 12 Jordanian commercial banks. They show that Jordanian banks meet the requirements of the central bank of Jordan, relating to operational risk disclosure, but there are many discrepancies between the way the commercial banks organise their information in their annual reports. Therefore, they advise Jordanian banks to enhance current operational risk disclosures practices.

3. Research Design

3.1. Research Factors

We will use a model created by Haija and Hayek. This model includes the following three variables:

- Definition issues, which includes: operational risk definitions; operational risk measurement system; information on key risk indicators; technology and system risk; risk of human error; legal risk and other operational risk.
- Hierarchical issues, which includes: risk management framework; establishing operational risk committee; operational risk management department.
- Regulatory issues include: operational capital charge as % of minimum regulatory capital; operational risk exposure (by business line, if available) unexpected loss from operational risk.

3.2. Sample Selection

In our case we include all Hungarian commercial banks. Therefore the study population consists in all 33 Hungarian commercial banks.

Table 1, Table 2 and Table 3 show the disclosure items for all Hungarian banks and if they abide by our research factors.

Table 3. Summary

Disclosure Item	% percentage
Risk Management Framework	18.18%
Operational risk definition	27.27%
Establishing operational risk Committee	18.18%
Policies, process and procedures	6.06%
Operational Management Departement	6.06%
Operational risk capital charge as % of minimum regulatory capital	15.15%
Operational risk exposure (by business line)	9.09%
Operational risk measurement systems	3.03%
Information on the models used to manage and measure operational risk	33.33%
Information on Key risk indicators (KRI)	9.09%
Unexpected loss from operational risk	0%
Tehnology and system risk	0%
Risk of Human Error	0%
Legal risk & other operational risk	3.03%

% percentage: equal the existence of item in banks divided on total number of banks

The previous tables show the disclosure items for all Hungarian banks and if they abide by our research factors to each factor from annual report for each bank.

First of all, by analysing Hungarian

commercial banks annual reports, we provide evidence that both extent and content of disclosures on operational risk of the banks are very poor, reflecting the lack of concern of managers of the banks, of supervisors and

of other agents, relating to operational risk disclosures.

Second of all, there are many dissonances referring at the approaches of exposing the main information about operational risk. There are few banks which manifest interest in disclosing information about their operational risk.

Finally, the area of operational risk disclosure is poor in Hungary, because banks are still in the process of developing operational management departments, operational management framework, procedures and processes.

Conclusions

Hungarian commercial banks have a poor disclosure of operational risk. Moreover, our study expose that the preponderance of Hungarian commercial banks do not give information about operational risk. Most of annual reports of Hungarian commercial bank do not even mention about operational risk. Furthermore, we recommend that Hungarian central bank should impose to commercial banks to include in their annual report the main information about operational risk and to enhance the disclosure of operational risk

European Banking Integration in the Aftermath of the Global Crisis: the Case of the New EU Member Countries

Iluț Bogdan

„Alexandru Ioan Cuza” University of Iași, Romania
Faculty of Economics and Business Administration
ilut2k@yahoo.ro

Abstract

One of the most important components of the European financial system is represented by the banking sector, especially in the case of the new EU member states, where the economy is almost exclusively financed through this channel. The banking integration process thus has a vital importance for the creation of a fully functional and efficient European Union. In this context, the aim of our research is to underline the main characteristics regarding the development and integration of the new EU member countries banking sector, especially taking into account the recent events determined by the global financial crisis and its aftermath. In order to achieve this, we have used a qualitative analysis based on structural indicators of the banking system that underline the main characteristics of the analysed countries.

Key words: European integration, banking sectors, law of one price

J.E.L. classification: G21, F15, F39, N24

1. Introduction

The completion of the European common market cannot take place without a fully integrated financial system, this being one of the main concerns for the EU policy and decision makers in the last two decades. Although the creation and adoption of the European single currency has speed-up and deepened this process in some financial segments, the completion of this process is still a far reaching goal. One of the least integrated financial sectors is represented by the banking sector, this being more obvious in the case of the new EU member countries.

The integration of the banking sector is of the up-most importance, as especially in the case of the new EU member countries, the economy is financed through this channel, and thus the achievement of a long term economic and sustainable growth is directly linked to the deepening of this sector integration. The recent financial, economic and sovereign debt crisis has underlined even more this idea, as banks operating at a pan-European level have played an important role in the contagion process.

Taking all these into account the aim of our research is to underline the main characteristics regarding the development and integration of the new EU member countries banking sector, especially taking into account the recent events determined by the global financial crisis and its aftermath.

In order to achieve this, we have used a qualitative analysis based on structural indicators of the banking system that underline the main characteristics of the analysed countries. The sample is composed from the Central and Eastern European Union member countries, namely: Poland, Czech Republic, Slovenia, Slovakia, Hungary, Romania and Bulgaria.

The reminder of the paper is organised as follows: the second part is dedicated to a literature review, the third part details the methodological approach, the fourth part underlines the characteristics of the analysed banking sectors, the fifth part presents the challenges faced in the banking integration process in the case of the analysed countries, while part six contains the concluding remarks.

2. Review of the academic literature

The dynamics of the European Union banking sector have been studied deeply in

the last two decades, a large body of literature being focused on related subject, employing both qualitative and quantitative approaches (see: [1]). One quick conclusion that can be draw from this large body of literature is that the banking sector of the EU has undergone through tremendous changes in the last decades. It all started with the deregulation of the capital markets, determined by the London Stock Exchange Big Bang in the eighties, followed by the European Commission initiatives materialised in the banking directives that aimed to stimulate cross-border banking activities and finally by the development of the Lamfalussy process and the subsequent proposal for the creation of a banking union in the aftermath of the global financial crisis. These impactful events that have succeeded in a short period of time have exercised a tremendous pressure on the business model of the EU banks, the enlargement to 27 members presenting yet another simulating incentive for pan-European development and competition.

Thus, in the face of these challenges the banks operating in the European Union have diversified their portfolios, universalising their operations and aiming rather for a general public (both retail and corporate) then a specific niche. As a result European bank provide customers with a wide range of products and services beside the traditional ones: insurance products, investment products like fund units, private banking and wealth management services and nevertheless portfolio management and advisory services. The liberalisation and deregulation of the financial sectors has also prompted an increased competition for banks from non-banking actors, thus the boundaries between banks and other financial agents have become more blur [2]. As mentioned earlier the extension to 27 members has provided the opportunity for Western European banks to develop their cross-border activities in the new member countries, as these markets are far from reaching their full potential. This has lead also to an increase of the competition level in the case of the new EU member countries banking sector [3].

Although the legislative initiatives at the European level have aimed an improvement of the overall integration level of the banking sectors the progresses registered are far ([4],

[5]) from the ones achieved in the case of the monetary and bonds markets ([6], [7]).

The academic literature identifies a series of challenges that prevent the deepening of the banking integration process, these being more obvious in the case of the new EU member states. Thus, these challenges are represented by the characteristics of the national business environment [8], the socio-demographic barriers that exist that tend to be enhanced by the heterogeneous juridical and fiscal frameworks, that is specific to each member country and nevertheless the different impact that the recent global crisis had on the national macroeconomic environment ([9], [10], [11]).

3. Methodological considerations

In order to underline the progresses made in the banking integration process by the sample countries we have employed in our analysis the law of one price.

Thus, according to the law of one price, as a result of the integration process the nominal interest rates should converge toward the lowest registered level that exists in the case of the analysed countries [6].

In order to completely underline this complex process we will also take a look at the changes that have been registered in the competition level from the analysed banking sectors, as a deepening of the integration process should point out to an increased competition level, as entry barriers are removed and the cost for accessing these new banking markets drops significantly.

In order to establish the dynamics of the competition on the banking sectors from the new European Union member states we will take into consideration two main indicators.

The first indicator that we will use is the *CR5 Index*, which represents the percentage that the top five banks are having in the total assets of the system and which reflect the concentration degree of the market. The indicator is calculated based on the formula:

$$CR5 = \frac{A_1 + A_2 + A_3 + A_4 + A_5}{AT} \cdot 100$$

where A_1 , A_2 , A_3 , A_4 and A_5 represent the value of the assets held by the top five banks in the system and A_T represent the value of

the total assets of the banking system. It can take values between 0.1% and 100%, where the low value represents a highly dispersed market and 100% represents an oligopoly or monopoly.

The second index that we will use is the *Herfindahl–Hirschman Index*, which underlines the degree of competition which exists on the market and is calculated based on the following formula:

$$H = \sum_{i=1}^N s_i^2$$

where s_i is the market share (in our case the value of banking actives) of firm (bank) i and N represents the number of banks that exist in a certain market. It can take values between 0 and 10000. If the values are below 100 it underlines the existence of a highly competitive market, if the value is below 1000 it reflects a dispersed market, if the value is between 1000 and 1800 it indicates a relative moderate concentration in the market and if the value is above 1800 indicates a highly concentrated market.

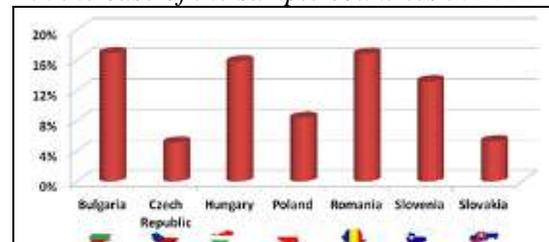

4. Development of the banking sectors from the new EU member states

The characteristics of the banking sectors from the analysed countries have been influenced on the one hand by the European integration process and lately by the recent global financial crisis.

In the aftermath of the global financial crisis an important problem has been represented by the increase of the non-performing loans ration in total loans. This has affected directly the profitability of the banking institutions and their business strategies, as banks have been faced also with a diminishing of the customer base in the context of macroeconomic depression. The dynamic of the non-performing loans is however different in the case of the analysed countries. Thus, we can observe from figure 1 that the highest level of non-performing loans is registered in the case of Romania, Hungary and Bulgaria. This evolution was determined in the case of Romania and Bulgaria especially as an effect of the macroeconomic environment depreciation, while in the case of Hungary it was determined by the depreciation of the forint compared with the euro and especially the

Swiss franc, most of the mortgages being denominated in these currencies. At the other end of the spectrum are the banks operating in the Czech Republic, Poland and Slovakia. In the case of Poland the low level of non-performing loans can be attributed to the ability of the government to maintain a stable macroeconomic environment during the international financial crisis and its aftermath, while in the case of the Czech Republic and Slovakia it was the strict regulations imposed by their Central Banks that prevented banks from overexposing them in the credit boom period and thus the number of clients that have defaulted on their loans was relatively low.

Figure 1. The ratio of non-performing loans in the case of the sample countries in 2012

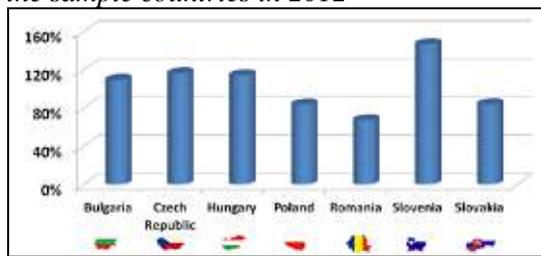

Source: author calculation based on ECB data

Another good indicator for the banking sectors of the new EU member states is represented by the intermediation level, calculated as the ratio of total banking assets to the gross domestic product.

Analysing figure 2 we can observe that the countries from our sample are registering a somehow similar intermediation level. Still, we must underline that Romania is registering the lowest level for this indicators, this being attributed to the late start of the banking privatisation process, that got momentum only at the start of the new millennium, and the late macroeconomic stabilisation that occurred only since 2004-2005. In the case of Poland the low intermediation level is attributed to negative re-evaluation of the banking assets in the aftermath of the global financial crisis and a slightly increasing GDP, a similar explanation being also valid for Slovakia.

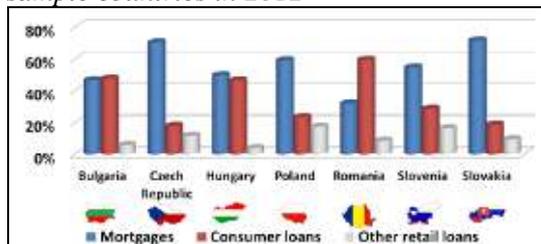

Figure 2. Intermediation level in the case of the sample countries in 2012

Source: author calculation based on ECB data

Another interesting indicator is represented by the retail loans structure of the analysed banking sectors (figure 3). In order to facilitate the analysis we have grouped the retail loans in three categories: mortgages, consumer loans and other retail loans. We can observe that in most of the analysed countries mortgages represent the main category of retail loans followed by consumer loans.

Figure 3. Loans structure in the case of the sample countries in 2012

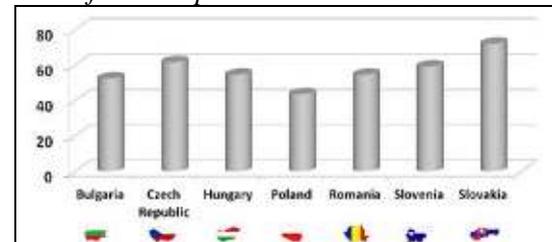

Source: author calculation based on ECB data

A particular case is registered in the Bulgaria and Romania, where consumer loans have the highest share, this being more obvious in Romania. This evolution of the loans structure can be attributed to the macroeconomic instability registered in Romania and Bulgaria until 2004-2005, that determined banks to focus their crediting activity more on the consumer loans, that were granted for a short period of time and at high interest. Also, the impossibility to obtain a stabilisation of the inflation rate, that made almost impossible to grant mortgage loans at a reasonable interest rate. This is the reason why mortgages in these countries are granted almost exclusively at an adjusting interest rate. Nevertheless the loans structure influenced the ratio of non-performing loans, as clients mostly defaulted on their consumer

loans, Bulgaria and Romania registering as presented previous a high level of non-performing loans.

Figure 4. CR-5 on the banking sector in the case of the sample countries in 2012

Source: author calculation based on ECB data

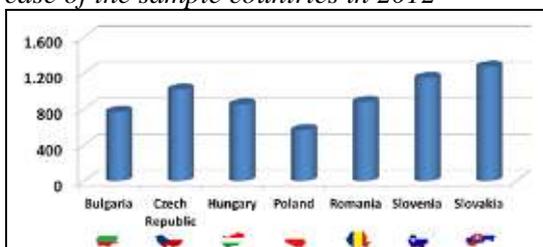

Regarding the concentration of the market, we can observe from figure 4 that the share of the five largest banks from the analysed countries held between 60 and 80 percent of the total banking assets in the case of the analysed countries. These levels are comparable with the ones obtained in the case of the Western European Union banking sectors. This also underlines the importance of relationship banking, as many banks have developed branches in these countries, but were unable to obtain a significant market share. Most of the pan-European groups that have a major market share in these countries have acquired local banks before the EU ascension process.

The Herfindahl–Hirschman index underlines the competition level that exists in the case of the analysed banking sectors. Analysing figure 4 we can observe that the concentration level of the banking sectors from the analysed countries are extremely low this underling that there is a good competition level. The best results are registered in the case of Poland where there are active over 50 banking institutions and, except for the big five, the banking market is fairly split between the rest of the banks.

Overall we can conclude that the banking sectors of the analysed countries have registered a solid development in the last decade, however the most important characteristic being that they are far from achieving their maximal potential. This is best underlined by the intermediation level that does not exceed 120%, while in the case of the Western European Union member countries this ratio is well above 240%. Also, a big challenge on the short to medium term

is represented by the high ratio of non-performing loans, the banks needing a solid rebound strategy as the macroeconomic recovery being still a long way ahead.

Figure 4. CR-5 on the banking sector in the case of the sample countries in 2012

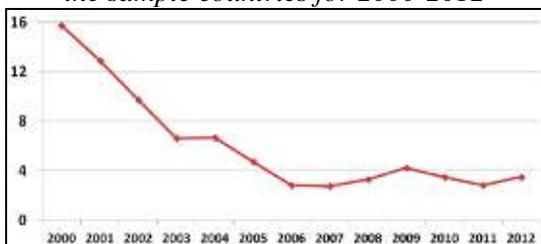

Source: author calculation based on ECB data

5. Challenges in the banking integration process

We will start our analysis by comparing the convergence of the average interest rates for retail loans. We have taken into consideration these interest rates because the retail loans represent one of the main categories of loans granted by the banks operating in the analysed countries and directly affect the European citizens from these countries. Thus the benefits of the banking integration process should be felt directly by anyone who contracts a loan from the bank, as the interest rates should decrease with the deepening of the integration process toward the lowest value registered on the market according to the law of one price.

Figure 5. Convergence of the average interest rates for retail loans in the case of the sample countries for 2000-2012

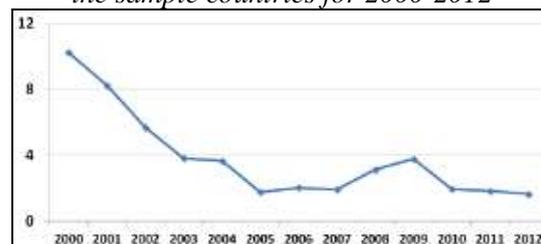

Source: author calculation based on ECB data

Despite the initial negative impact of the global financial crisis we can observe from the convergence analysis on the average interest rates for retail loans, calculated as the standard deviation for the interest rates, that

in the aftermath of the crisis the banking integration process has continued to deepen in the case of the analysed countries.

In this context it becomes interesting to analyze the evolution of the average interest rates for retail deposits, in order to confirm the previous registered results (figure 6).

Figure 6. Convergence of the average interest rates for retail deposits in the case of the sample countries for 2000-2012

Source: author calculation based on ECB data

From figure 6 we can observe that also in the case of the average retail deposits the same convergence as in the case of the retail loans can be observed. Also in this case we can observe that the global financial crisis had a negative impact on the convergence process, while in the aftermath the convergence process continued.

The positive evolution can be attributed especially to the stabilisation of the macroeconomic environment and to a lesser extent to the development and expansion of the banking activity. On the contrary the freezing of the loaning operations has also impacted the convergence process, contributing to the diminishing of the standard deviation, as interest rates tend to be diminishing as a result of the relaxation of the monetary policy [11].

6. Conclusions

Concluding, the results of our analysis underline that even after more than two decades since the fall of the communism in Central and Eastern Europe and the successful completion of the EU ascension process, the banking sectors of the analysed countries are far from forming a homogenous club as they are portrait most of the times. Thus, the obtained results underline that during the analysed period the sample countries have registered notable progresses

in the banking integration process, despite the negative impact of the global financial crisis.

Although the banking sectors of the analysed countries have undergone through a processes of reform, privatisation and EU ascension there is still room for improvement, both in the case of the banking integration process and the development of these banking sectors. Probably the most important challenge will be the deepening of the banking integration process beyond the result achievable through the stabilisation of the macroeconomic environment and in the context of a possible banking union.

Abstract

In the European space, human rights issues is inevitably linked to the Council of Europe, acting in support of democratic ideals, providing the universality of human rights by promoting common standards in all member states, in the benefit of all citizens, regardless of their origin. Among Council of Europe activities, the development of numerous human rights programs occupies an important place.

Legal instruments are also operating in the conventions and agreements concluded within the Council of Europe, and the most important are: European Convention on Human Rights, European Social Charter, European code of social security and European Convention on Social Security.

Keywords: forced labour, compulsory labour, people trafficking

Classification J.E.L.: K31

1. Introduction

The actual implementation of human rights cannot be separated from the idea of the existence of an united Europe, with clear objectives, whose fulfillment is nothing less than the foundation of ensuring, promoting, respecting, guarantee, protection and effective realization of human rights.

The Council of Europe is the first organization of political Cooperation and it can be seen in the following that the Council's role is not restricted military and economical field but social and cultural one.

More than that, the Council of Europe came into being long time before the European Union, as an independent organization, dealing with the vast field of

democratic security, which cannot be secured without the protection and promotion of human rights.

In their parallel and consecutive development and evolution, the Council of Europe and European Union adopted and developed numerous documents and common programs and sometimes till the overlapping of the content of legislation, which is based on the principle of respect for fundamental human rights.

The present work aims to establish the role and evolution of the Council of Europe in the field of human rights protection and insurance, so, we will refer to: European Convention on Human Rights, European Social Charter (revised), European code of social security and European Convention on Social Security.

2. Council of Europe

From the beginning we must distinguish between the European Council and the Council of Europe because, in some cases there have been confusions between the two of them.

So, the European Council represents one of the European Union institutions which brings together the representatives of the Governments of the Member States, being the main decision organization of European Union, while, the Council of Europe is a political organizational of intergovernmental and parliamentary cooperation, which was founded by the treaty signed in London, on 10th May, 1949, by ten European states: Belgium, Denmark, France, Iceland, Italy, Luxembourg, Great Britain, Norway, Netherlands, Sweden.

Those who want to be members of this organization must accept the principles of the rule of law and the principle according to

which, each person under its jurisdiction must enjoy the human rights and fundamental freedoms plus the sincere desire of the participants—the members, to compete effectively in achieving the purpose of the Council.

This Council has the Committee of Ministers in its structure, which is the decision organization of the European Council and the Parliamentary Assembly (called Consultative Assembly until 1974) which is a consultative organization without law making power. Besides the two main organizations, in the European Council structure there are also the European Court of Human Rights, the General Secretariat, the Congress of Local and Regional Authorities.

Till the present, the European Council developed a number of over 200 European conventions and agreements, and these documents are the real source of the regional international law (especially in human rights issues) some of which are open to ratification for the states which are not members of this organizations.

These are binding conventions and agreements only for the states that sign, ratify or accede to them.

Besides these conventions, the European Council adopted a series of recommendations which haven't got a judicial power, but they offer strands of organizations and, in many situations, these recommendations have become conventions and agreements.

Since 1950, the European Council „equips” Europe with an „European Convention on Human Rights” establishing the legal protection mechanisms at European level.

European Convention on Human Rights and Fundamental Freedoms was adopted on 4th November 1950, in Rome and came into force on 3rd September 1953.

This convention is also judged to be a fundamental document on human rights protection and guarantee by both, the instituted and procedure and through a wide range of rights and freedoms, devoting them the recognition and guarantee.

It is considered the most important legal instrument in the conventional system of the European Council[1].

Although reiterates a number of rights enshrined in the Universal Declaration of Human Rights (we mention some of these:

the right to life, prohibition of slavery, respecting the right to privacy, the freedom of thought), the European Convention brings some developments and concretizations in fields like: right to freedom and security, the right to found a union, prohibition of forced or compulsory labour.

Concerning the prohibition of forced or compulsory labour it can be seen that this European Convention took certain terms from the International Labour Organization Convention, number 29/1930 regarding the forced or compulsory labour, convention which was adopted in the 14th session of International Labour Conference. This convention is also among the eight fundamental conventions of International Labour Organization.

In the specialty literature, the forced labour is also called „modern slavery”[2], which refers to underpaid work, the work performed in high-risk of accidents conditions and in certain situations to trafficking people. Sometimes, the forced labour is performed by the migrant workers. A lot of migrant workers are exposed to the risk of exploitation and abuse because most employers don't respect international labour standards [3].

Under the art.4, par. 2 from the European Convention, no one can be constrained to perform a forced or compulsory labour; by exception of this rule, it is not considered forced or compulsory labour:

-any work required to be done in the ordinary course of detention imposed or during conditional release from such detention

-any service of a military character or, in case of conscientious objectors in countries where they are recognized, service exacted instead of compulsory military service

-any service exacted in case of an emergency or calamity threatening the life or well-being of the community.

-any work or service which forms part of normal civic obligations.

Regarding the right to establish a union, referred to in Article 11 from the Convention[4], it can be drawn just the idea that any person has the right to establish a union and to join a union but not the right of trade unions to function freely.

The compliance with the Convention is provided by the existence and functioning of the European Court of Human Rights, composed of a number of judges equal to the one of the contracting parties.

Under the art.35 of the Convention, it can be seen that you cannot go to the European Court on Human Rights only after the exhaustion of the ways of internal appeal.

The European Convention on Human Rights covers only civil and political human rights. Therefore, the Council of Europe, in its effort to regulate and protect the economic, social and cultural human rights adopted, in Turin, on 18th October, 1961, the European Social Charter (came into force in 1965). Among the most important human rights covered by the Charter can be mentioned: the right to work, union rights, negotiation, the social security.

This document sets out 19[5] rights that the Contracting States undertake to guarantee.

In other news, this book can be considered a mixed text because it includes declarative part, which set social polity objectives to be pursued by Member States of the Council of Europe and part legal, listing obligations for a State ratifies. One of the obligations of Member States is to submit periodic reports for consideration to a committee of experts.

Moreover, the European Social Charter is a summary of international labour law, as it is produced mainly by the International Labour Organization.

Council of Europe's concern about this international document led to the revision of such content Social Charter in 1996, was reinstated in the document adopted in Strasbourg on 3 May 1996, known as the European Social Charter (revised).

In its new redaction, the document we refer, appears as a set of core labour rights and social security. In addition to the 19 rights, which are defined by the European Social Charter, the new revised Charter adds another 12 rights.

In the legal doctrine this document is considered to be one of the „major Council of Europe treaties in human rights, an European reference tool in social cohesion”.

The Council of Europe adopted (among those presented above) the European code of

social security (1964) and the European Convention on Social Security (1972).

This way, the European code of social security is the only legal instrument which defines European social security rules. It was adopted in 1964 but came into force on 17 th March 1968. This code also establishes minimal protection levels, which the states must provide them in nine social security fields and it has as a purpose, the harmonization of social security systems of the Member States of the Council of Europe [6].

Otherwise, the Code was revised, so that was opened for signature on November 6, 1990[7].

After a period of four years from the development of the European code of social security, the European Convention on Social Security (adopted in 1972 came into force in 1977) came in addition to it. This Convention has as a foundation, the fourth principles of the international[8] Law of social security meaning: equal treatment in social security between domestic and foreign people, maintenance of rights acquired abroad, the uniqueness of the applicable law as well as the transfer of benefits between the countries concerned.

This Convention applies to all fellow Contracting States, stateless persons residing in their territory and their family members and survivors [9] and covers all social security benefits.

3. Conclusions

From the analysis made, we can conclude that European community and the world one have reached a stage of evolution, where the development and security of human existence can't be unilaterally treated. In this context, the human development cannot be provided without offering it safety: at the same time, safety is not guaranteed without development and both can't be guaranteed without the respect for human rights.

For this reason, it is necessary to target the need to coordinate the efforts of all states to achieve the best interests of the international and European community, respectively the protection of human rights and freedoms.

In this context, the fundamental rights represent the convergent point which is based

on the European Convention on Human Rights, at the level of the Council of Europe, legal text that represents a reference point in any democratic legal system.

The Council is aware that legal norms, tools and mechanisms for the protection of human rights have little effect if European citizens are not informed of their existence and scope.

According to the content of this paper and analyzing the content of the European Convention on Human Rights, but especially, observing the mechanisms of action of the Council of Europe we can conclude that, in terms of protection and providing human rights, these are much safer than anywhere in the world.

Trade integration of the Central and Eastern European economies with the Euro area

Marinaş Marius-Corneliu

Bucharest University of Economic Studies, Department of Economics
marinasmarius@yahoo.fr

Abstract

The objective of this study is to examine the intensity of the trade linkages between the CEE economies and the countries belonging to the core and periphery of the euro area, in terms of the symmetry of the shocks and costs of the adopting euro currency. The trade represents a transmission channel for the external shocks towards the CEE emerging economies, and thus the macroeconomic evolutions from monetary union will influence the exports of the new EU member countries and their economic growth process. The first part of the study examines the significance of the trade integration based on the theory of the optimum currency areas, making references to the results found in the economic literature. In the second section, I have determined the degree of trade integration with the Euro zone countries, first of all making an analysis for Romania's case and then of the other CEE economies.

Key words: trade integration; Euro area; business cycle synchronization; external shocks.

JEL Classification: E42; F15.

1. Introduction

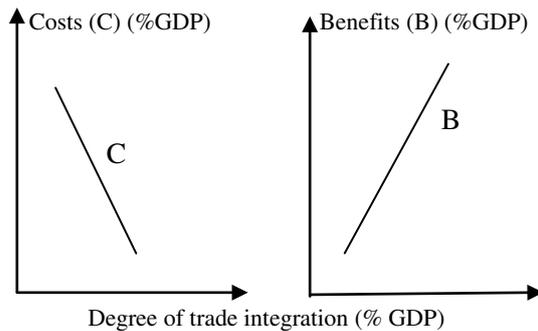

Robert McKinnon proposed an important criterion for the stability of a monetary area, namely the degree of trade integration between the economies forming a monetary union [4]. The motivation to include this criterion was based on the correlation between the efficiency of the macroeconomic policies and the degree of economic openness. Thus, the more an economy is open in terms of trade, the lower are the benefits generated by the national currency's nominal depreciation, as the prices of the imported goods will rise, thus influencing the

raise of the prices for final domestic goods. Consequently, there will not be a significant real depreciation of the national currency, and thus the benefits of a common currency will get increased. The more the internal prices react to a greater extent to the modification of the exchange rate (a significant “pass-through” effect), the more the exchange rate affects inflation only, and not the external competitiveness [7].

The increase of a country's trade integration degree favors the decision to adopt a common currency, as it influences the related costs and benefits (figure 1):

- a) the costs (in terms of loss of economic stability as a consequence of giving up their own monetary policy) are the lower so as the degree of trade integration is higher. The explanation is that the effects of the shocks recorded in the trade partner countries will be transmitted faster in their own economy, thus reducing the efficiency of using the rate of exchange to adjust those external shocks.
- b) the benefits (in terms of efficiency benefits of the common monetary policy) will be more important so as the degree of trade integration with the monetary area is higher. That economy will record benefits generated by the removal of uncertainty and transaction costs specific to the foreign trade operations under the terms of a flexible rate of exchange.

Figure 1. The influence of the trade integration upon the joining to a monetary union

Beside the direct influence of the trade integration degree upon the adoption of a single currency, there is also an indirect influence, which is the effect of the degree of correlation between the business cycles. Regarding this, there are two views in the economic literature: an optimistic view and a pessimistic view. In the optimistic view, the trade in the European Union countries is an intra-industry trade to a great extent, so that most of the aggregate demand shocks affect the countries from this economic union in the same way. If a unique market is made, most of the demand shocks will tend to have a symmetric effect. According to this approach, the increase of the trade integration degree will lead to a convergence of the economic structures and to the occurrence of asymmetric shocks.

Therefore the degree of business cycles synchronization and the benefits of adopting the single currency will get increased. In the pessimistic view, the trade integration results in a regional concentration of the industrial activities and in the occurrence of asymmetric shocks, thus reducing the degree of correlation of the business cycles. The empirical evidence of Frankel and Rose [2] support the optimistic approach. Frankel and Rose asserted that the countries with the strong economic relations tend to record a higher business cycles correlation, claiming that the emphasis of the trade integration due to the monetary unification will generate the better synchronization of the economic cycles closer to the specificity of an optimum currency area.

The CEE countries have recorded a fast increase of exports, despite of the national currencies appreciation tendency from the period previous to the economic crisis, as a result of the foreign investments, of the privatization process, of reducing the commercial barriers along with entering EU

and maintenance of competitive advantages related to the taxation level or to the labour costs. As the direct foreign investments have contributed to the CEE economies' integration in the global channel of products, then the share of the intra-industry trade will be closer to the level recorded by the most important trade partners from the Euro area. Under these terms, those economies accession to the Euro area should not be accompanied by additional costs in terms of trade. However, the results obtained in the economic literature are contradictory. On the one hand, de Grauwe and Mongelli [3] asserted that the emphasis of the trade relations between the structurally divergent economies (such as the Euro zone and some of the CEE economies) will increase the probability to form a heterogeneous monetary union. On the other hand, Bussiere and the others [1] settled that the CEE economies are characterized by a degree of trade integration which is superior to that of the monetary union, this fact reducing the costs for the adoption of the unique currency.

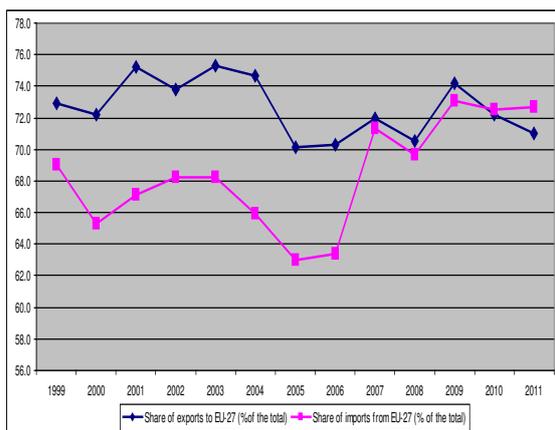

This finding confirms the results of the analysis made by Zumer and Melitz [8], according to which the new EU member countries have an exports structure more diversified, thus providing a higher resistance to the action of some shocks specific to a certain activity sector. A significant factor which influences the relation between the trade integration and the business cycles synchronization is constituted by the intra/inter-industry feature of the trade. According to a study made by Munkácsi [5], some of the new EU member countries (such as Hungary and the Czech Republic) record a share of the intra-industry trade superior to the cohesion countries, thus increasing the probability of occurrence of more symmetric shocks with the Euro zone countries. As the CEE economies are quite open from a commercial point of view, then one of the economic growth engines is represented by the foreign exchanges, mainly with the Euro zone economies.

2. The degree of trade integration

Romania's economy is relatively less open in terms of trade compared to other CEE countries, but the trade is especially made with the Euro area core countries. In this

regard, Romania was the ninth economy in EU in 2011 in terms of the share of the exports towards EU-27 (71% of the total) and the eighth in terms of the share of the imports from EU-27 (72.7% of the total imports). During the period 1999-2011, the share of Romania's exports to EU was quite stable, ranging between 70.1% and 75.3%. The Romanian accession to the EU does not generate an increase of the share of exports above the levels recorded during the period 2003-2004 (figure 2). In contrast, the share of imports was decisively influenced by the accession to the European Union, as a consequence of the elimination of the custom duties and the weak competitiveness of some of the domestic final products. Thus, the share of imports from EU increased in 2007 by 8 percents in comparison with the previous year, after which it was limited to approximately 73%.

Figure 2. The evolution of trade exchanges between Romania and EU-27

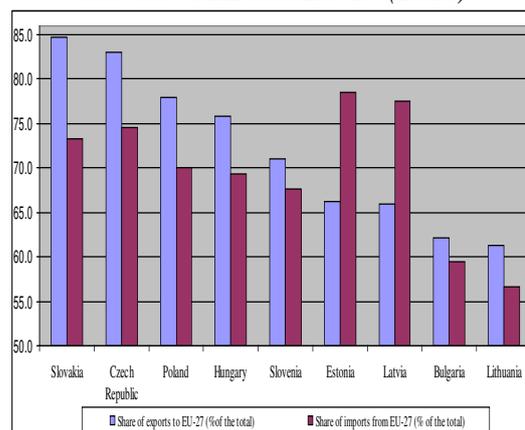

Data source: Eurostat

Among the ten economies which are the most integrated with EU-27, six of them are from CEE, both in terms of imports and also of exports. These economies' accession to EU has rather influenced, as in the case of Romania, the imports and less the exports to the other countries from the economic union. Thus, in 2004 relative to 2003, the share of the imports from EU increased by 8.9 percents in the Czech Republic, by 8.7 percents in Estonia, and by 7.4 percents in Lithuania. However, the increase of the dependence on European imports was temporary in most of the CEE economies, the most significant decreases being recorded by Slovenia (by 14.4 percents in 2011 if

compared to 2004) and Lithuania, in this case the decrease being by approximately 7 percents.

According to figure 3, it results that Estonia and Latvia imported over 77% of the goods from EU-27 in 2011, while Lithuania recorded the lowest dependence on European Union, its share being of 56.7% of the total. With reference to exports, over 83% of the Slovenian and Czech external market is European Union, while Hungary's and Poland's exports are at least 76% to the other economies of the union. The Baltic States recorded a reorientation of exports towards countries outside EU-27, the share of the European exports decreasing by 14-15 percents in 2011 compared to 2003-2004. As in the case of imports, Lithuania is the least integrated CEE economy also in terms of exports to the other EU countries.

Figure 3. The share of trade exchanges between CEE and EU-27 (2011)

Data source: Eurostat

Among the European Union countries, the CEE economies (except the Baltic States) are the most integrated with the economies of the monetary union, especially with the core ones (Germany, France, Italy, Austria, the Netherlands, Belgium and Luxembourg). Thus, in 2011 approximately 54% of the exports and 52% of the imports of the Romanian economy were made with the Euro zone countries, yet these values being lower compared to 2004, when approximately 60% of the foreign trade was made with the countries from the current monetary union. In 2011 five out the first ten destination countries for the Romanian exports/imports were from euro area (i.e. 44.5% of the total exports, 41.5% of the total imports), thus

confirming higher trade integration, especially with the economies forming the Euro zone core. However, if compared to 2004, the share of these economies in the total Romanian exports decrease by approximately 6.5 percents, as a consequence of the decrease of exports to Italy, by approximately 9.3 percents in 2011.

Germany is the main trade partner of Romania, although the share of exports to this economy decreased from 21.4% of the total in 1999 up to 13.7% in 2008. The fiscal stimulus packages of the German economy have contributed to the increase of demand for Romanian products, their share reaching 18.6% in 2011. According to the data included in Table 1, it results that more than a half of the Romanian exports to EU-27 are made with the most important Euro zone economies – Germany, France and Italy –, which produce approximately two thirds of this area's output. The economic shocks which will influence these economies will be transmitted through trade also in the Romanian economy and they will become more symmetric.

Table 1. The most important trade partners of Romania from the Euro area

2004		2007		2011	
Share in the total exports	Share in the total imports	Share in the total exports	Share in the total imports	Share in the total exports	Share in the total imports
Italy 21.2%	Italy 17.2%	Italy 17.1%	Germany 17.2%	Germany 18.6%	Germany 17.1%

Data source: Eurostat

The integration with the Euro area core economies does not constitute a feature of the Romanian economy only, also being a feature of the other CEE economies, except the Baltic States. Surprisingly, during the last 11 years, the new member countries have reduced their exposure upon the important economies of the monetary union, meanwhile increasing the integration with the other EU economies, including other economies within the same group. Thus, the share of exports to the Euro zone core has reduced by 24 percents in Hungary, and by approximately

20 percents in Romania and Slovenia, in 2010 compared to 1999. Since 2008 a slight increase of exports to the reference economies has been recorded, as a consequence of Germany's foreign demand increase. As a matter of fact, this economy represents the main trade partner of the Czech Republic (31.5% of the total exports), Poland (25.7%), Hungary (23.1%), Slovakia (19.6%) and Slovenia (17.1%), while the Baltic States' and Bulgaria's dependence on Germany is by maximum 10.4% of total exports. Nevertheless, the high trade integration with Germany does not constitute a consequence of the economic integration, this being a characteristic of most of the CEE economies even before 2000. For example, in 1999 Germany was the main external market for 8 CEE economies (including Lithuania and Latvia), the Czech Republic exporting 40.5% of the total to that economy.

According to the data included in Table 2, it results that the macroeconomic evolutions of the monetary union core has a significant influence upon the exports of the CEE economies (except the Baltic States), thus contributing either to their re-launch when the core passes through an economic expansion period, or to their decrease when, for example, the core applies certain budget austerity measures [6]. In order to illustrate the possible contagion effects in terms of trade, I have also considered the group of periphery economies of the monetary union (with 12 members) including Ireland, Portugal, Spain and Greece. Bulgaria is the CEE economy which is the most integrated with the Euro zone periphery, exporting 8.3% to it in 2010, under the terms in which the shares of the other economies range between 0.6% (Estonia) and 4.1% (Romania). As a consequence, the increase of unemployment and the decrease of revenues in economies such as Spain and Greece will only marginally influence the total exports of the new CEE member countries.

Table 2. The degree of trade integration of the CEE countries with the core and periphery of the Euro area

		1999	2005	2008	2010

Data source: Eurostat

Beside the influence upon the trade relations with the countries from the monetary union, the CEE countries' accession to the European Union has generated the reorientation of a part of the exports towards economies from the same group, which are characterized by a closer development level, having a similar geographical position. Thus, the CEE economies exported at least 13.5% of the total to the other economies from same region in 2010, while in 1999 only the Czech Republic recorded a share higher than 10% of the total. Slovakia is the most integrated, exporting over 31% of the total to the other six economies, while the share of Hungary's exports increased by 10 percents within seven years only. As a consequence, the group of the seven CEE countries will develop synchronized in terms of trade, due both to the dependence on the same group of economies (the Euro area core) and also to the trade integration with economies from the same region.

Conclusions

In this study I have demonstrated that there is a strong trade integration between the Central and Eastern European countries with the rest of Europe, especially with those belonging to the core of the monetary union.

According to the optimum currency area theory, this situation will reduce the costs of monetary integration for CEE economies. However, the degree of trade integration with the euro area is important and in absence of the transition to the single currency. Thus, increasing of the demand in the euro area will generate a significant impact on highly integrated economies with monetary union, stimulating the recovery of these countries. Also austerity measures promoted in the monetary union will affect in a greater extent the growth process of the more integrated countries.

Business Cycles Synchronization with the Euro Area. The Case of CEE Countries

Marinaş Marius-Corneliu

Bucharest University of Economic Studies, Department of Economics

marinasmarius@yahoo.fr

Abstract

The optimum currency area theory and the economic literature settled that the convergence of the business cycles is one of the most important criteria in establishing the costs and the benefits of the adhesion to a monetary union. If the action of various types of economic shocks, respectively the speed in neutralizing them is very similar among economies, then their own monetary policy will no longer be necessary as those shocks may be adjusted by means of a common monetary policy. Thus, the costs for giving up their own currency get decreased, thus increasing the benefits of the monetary integration. In this study, I have proposed to estimate the correlation of the CEE countries' business cycles with the average of the Euro area, in order to establish the extent of the potential costs generated by the loss of monetary independence.

Key words: business cycle synchronization; Hodrick-Prescott filter; statistic correlation; Euro area

JEL Classification: E32; F15.

1. Introduction

The business cycle synchronization is both the result of certain specific evolutions, and also it becomes a condition for a higher symmetry of the way in which the shocks will be transmitted in those economies. Consequently, this criterion is important not only for the monetary union member economies, but also for those outside it, especially if those economies are highly integrated with the Euro area core, as in the case of most of the CEE economies. In order to explain the usefulness of the convergence of the CEE economies' business cycles with those of the monetary union, I have divided

this study into three sections. The first one is a brief presentation of the main conclusions drawn from the economic literature. As the business cycle cannot be directly noticed, the objective of the second section was to explain the meaning of the Hodrick-Prescott econometric filter, used to extract the GDP cyclical component. Once the business cycles extracted, I have calculated, in the third section, the degree of business cycles synchronization and I have made a comparison between the situation of the CEE economies and that of the core and periphery economies of the euro area.

2. The literature review

The economic literature has caught the positive impact of the accession to Euro area upon the business cycles synchronization. Thus, Micco and the others [10] showed that the accession to the monetary union led to an emphasis of the bilateral trade, and the companies' benefits were superior to the economic costs generated by the loss of monetary policy independence. Baldwin [4] estimated that the introduction of Euro currency led to decreasing transaction costs, which inducing the more commercial and financial relations between the member economies and, consequently, the improvement of the synchronization between the business cycles. Afonso and Furceri [1] emphasized that the Euro currency introduction generated the increase of the degree of synchronization of the business cycles for all the Euro area countries, except Germany, while Mink and others [11] estimated that there were no records of an obvious increasing tendency of the business cycles correlation, especially as a consequence of the influence from Germany, France and Italy. Gayer [5] draw the conclusion that Greece, Finland, Belgium and Ireland had business cycles weakly

correlated with that of the Euro area economy. Based on the cluster analysis, Kappler [8] identified the following country groups of the monetary union: 1. Austria, Germany and the Netherlands; 2. France, Belgium, Italy and Spain; 3. Greece and Portugal. Gogas and Kothroulas [6] estimated that the common monetary policy tends to destabilize the economies from euro area periphery, as they are less correlated with the group of the three biggest countries, which achieve 60% of the entire Euro area GDP. Aguiar and Soares [2] studied the correlation between the business cycles by means of the wavelet transformation and they identified the existence of a convergence of the periphery economies to the Euro zone core, but with different speeds. The studies which analyzed the business cycles synchronization between the new member countries and the Euro area showed inferior results compared to the Euro zone core, and, respectively, superior results if compared to some periphery economies, such as Greece. The results outline the fact that there is not a homogenous group of the new member states, but most of them are rather correlated with Germany than with the Euro area.

3. The Hodrick-Prescott filter

The simplest way to estimate the business cycles synchronization is to extract the cyclical component of an aggregate indicator such as GDP, industrial production or certain components of the GDP and to calculate the statistic correlation between the business cycles by means of the Pearson or Spearman coefficients. This method was used by authors such as Artis and Zhang [3], Socol and Socol [12], Levasseur [9], Kappler et al. [8] and Gogas and Kothroulas [6]. The business cycle represents the fluctuation of the real GDP around the trend constituting the potential GDP. The changes of the trends are explained as being the result of the factors influencing the long run aggregate supply (capital stock, employment, total factor productivity), while the changes of the cyclical component are the effect of the short-term demand and supply shocks. In this section, I have used a univariate method to identify the business cycle, based on the Hodrick-Prescott filter. It was introduced by R. J. Hodrick and E. C. Prescott [7] and it

supposes the decomposition of a data series in two unnoticeable components, i.e. the trend and the cyclical component. This statistic method is based on solving a problem related to the minimization of a function related to the mean square deviations of the cyclical component and the changes of the trend's increasing rhythm:

HP=

$$\min_{y_t^*} \left\{ \sum_{t=1}^T [(y_t - y_t^*)^2] + \lambda \cdot \sum_{t=1}^T [(y_t^* - y_{t-1}^*) - (y_{t-1}^* - y_{t-2}^*)]^2 \right\}$$

where:

T represents the total number of observations; y_t – time series; y_t^* - the trend of the time series; $y_t - y_t^*$ constitutes the cyclical component of the time series; λ – penalty coefficient of the sum between the variations of the time series trend's increasing rhythm, which determines the degree of smoothness for the trend component.

In this study, I have applied the Hodrick-Prescott filter in the case of seven CEE countries (Romania, Bulgaria, the Czech Republic, Poland, Hungary, Slovenia and Slovakia), of the current Euro area with 17 members and of nine Euro area economies (Germany, France, Austria, the Netherlands, Italy, Spain, Portugal, Greece, Ireland). I have used the GDP data series in constant prices (millions of euro) with 2000 as a fixed base. For 16 out of the 17 entities included in the analysis, the data series covers the period 1998:Q1-2011:Q1, namely 53 observations, while 45 observations were available for Greece starting with the 1st quarter of 2000. Before using the filters to extract the cyclical component, I proceeded to eliminate seasonality by using the TRAMO/SEATS solution provided by the Eviews 7 software.

4. The correlation between the business cycles

The most often used method to estimate the convergence between the business cycles in the case of two countries A and B is to calculate their statistic correlation. From a conceptual point of view, a correlation coefficient surprises two features of the relation between two business cycles – synchronization and amplitude of their variation. Thus, the existence of a perfect concordance of the recessionary and inflationary gaps for two economies reveals

two perfectly synchronized business cycles. However, there is a very low probability that A and B are perfectly correlated, because the amplitude with which each economy grows above its potential or decreases below its level is important. Consequently, the correlation between the business cycles is influenced both by the nature of the output gaps of the two economies, and also by their variation.

The statistic correlation may be calculated based on some values which are contemporary or which are delayed with certain lags. If the business cycle of country B (for example, a CEE country which is not part of the Euro area) depends on the business cycle of country A (for example, the monetary union) then the study of the temporally delayed correlation could be more relevant. From the point of view of the optimum currency area theory, the analysis of the contemporary correlation between the business cycles is more useful, irrespective of the nature of the relation between the economies constituting a monetary union. The main motivation is to study the way in which the ECB monetary policy decisions are influenced by the macroeconomic evolutions of each member state. The lower the contemporary correlation with the countries being part of the Euro area core, the more asymmetric impact of the common monetary policy upon the member countries, thus increasing the costs for the shocks stabilization in the case of the uncorrelated economies.

The Pearson coefficient of the correlation between the business cycles of the countries A and B are calculated as a ratio between their covariance and the product between their mean square deviations. By normalization, the coefficient may take values ranging between -1 and 1, the first one corresponding to a perfect displacement in different ways of the business cycles, and the second one to a perfect tendency of the two countries to move in the same way. In the case of a value close to zero, there is not a linear relation between the business cycles of the countries A and B. As the coefficient is symmetric, it results that cannot be established a dependence relation between the economies A and B. Moreover, the correlation between A and B may be *spurious*, if these economies are

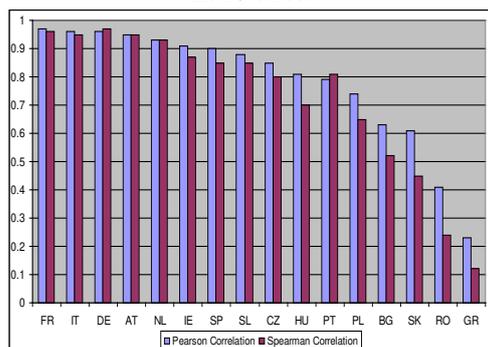

simultaneously influenced by a third country. For example, along with the accession to European Union the CEE countries have become more correlated with each other, as they are simultaneously influenced through the commercial and financial channel by the countries constituting the Euro area core. The Spearman coefficient represents a non-parametric measure of the correlation between two ordinal variables, also taking values between -1 and 1. For all the cases, the values of each variable are arranged, from the lowest to the highest. This assessment supposes the allocation of values indicating the hierarchy within a data series and that is the reason why this coefficient is also called the rank correlation coefficient.

In order to catch, in its dynamics, the changes of the business cycles synchronization between countries A and B, I have made an analysis for two sub-periods and for a *rolling window* with 5 years. Dividing the analyzed period into sub-periods aims to outline the variation of the correlation according to certain specific economic events. Thus, in this section, I have analyzed the correlation of the business cycles between countries A and B both for the entire period 1998:1-2011:1, and also for the sub-periods 1998:1-2004:4 and 2005:1-2011:1. Both sub-periods include recessionary output gap and also inflationary ones, ensuring accuracy of the obtained results. If the correlation coefficient is higher in the second sub-period in comparison with the first one, then the business cycles of countries A and B will be more synchronized. The rolling window method for 5 years has been chosen both to be able to make an accurate estimate of the correlation coefficients for each 20 quarters, and also to outline the temporal dynamics of the convergence between the business cycles. However, the results obtain may be influenced by the extreme values of the used variables, so that unrealistic results may be obtained (*biased estimation*). By applying this technique, were calculated approximately 34 correlation coefficients between countries A and B calculated starting with the periods 1998:1-2002:4, 1998:2-2003:1, the last one corresponding to the interval between 2006:2-2011:1. Similarly, the increasing tendency of the correlation coefficients will suggest a better

synchronization between the business cycles of the economies A and B.

Firstly, I have calculated the Pearson and Spearman correlation coefficients between the national business cycles (for the 16 countries) and the business cycle of the Euro zone with 17 members, for the entire period 1998:1-2011:1 (figure 1).

Figure 1. Business cycle correlation with Euro area

Data source: Eurostat

The results obtained confirm an extremely high correlation between the business cycles of the Euro zone core countries and the business cycle of the entire monetary union. Its most important three economies (Germany, France and Italy) have a correlation coefficient which takes the values between 93% and 98%. Beside these, Austria and the Netherlands record higher correlations of the business cycles. As for the five economies, there are no significant differences with reference to the types of the statistic correlation of the business cycles. Among the Euro area periphery economies, Ireland and Spain have been the most correlated with the Euro area, as the correlation coefficients took values close to 90%. On the contrary, Portugal's business cycle has been correlated by 81% with the Euro area, while Greece was the most divergent economy of the monetary union. Among the new EU member countries, Slovenia, the Czech Republic and Hungary recorded higher correlations compared to Portugal and close to 90%. The least correlated economies with the Euro area have been Romania, Bulgaria and Slovakia, the last one despite the fact that it adopted the Euro currency since the beginning of 2009. With reference to the optimum currency area theory, Romania would be the most

vulnerable if it would join to the Euro area especially because of the fact that it has not strong enough domestic mechanisms to adjust certain asymmetric shocks.

The analysis of the business cycle synchronization for the entire considered period cannot outline the changes generated by some factors, such as the adoption of the single currency, EU's successive enlargements or the influence of the capital flows from the period 2005-2008. Theoretically, these factors may induce a higher correlation of the Euro area periphery countries and of the emerging Central and Eastern European economies with the Euro area core economies. Calculating the business cycles correlation with the Euro area for two approximately equal periods of time (1998:1-2004:4 and 2005:1-2011:1) it results some differences related to the results from the entire analyzed interval (table 1). Thus, there is an emphasis of the business cycle synchronization with the Euro area during the second period in comparison with the first one in the case of all economies included in this study. For example, Germany, France, Italy, Austria and the Netherlands were correlated between 95% and 98% with the Euro area.

Among the periphery countries, Portugal and Greece recorded better results during the second sub-period, the correlation coefficients being higher to those calculated for the entire period, while Spain's and Ireland's business cycle correlation was quite similar, during the second period, to that recorded during the entire analyzed period. As for the EU emerging economies, all of them recorded a higher business cycle correlation along with the accession to EU and with the emphasis of the degree of commercial and financial integration with the Euro area core economies. Generally, their correlation coefficients for the second sub-period are higher than those calculated for the entire interval. Thus, the business cycles of Hungary, Slovenia and the Czech Republic have become as correlated with the Euro area as the periphery economies. If during the first sub-period, the evolutions of Romania, Greece and Slovakia were negatively correlated with the Euro area, during the second sub-period positive correlations only were recorded, higher for the third economy and lower for Greece. The

business cycle correlation in Romania was 69% during the period 2005:1-2011:1, this value being close to those of Bulgaria, but higher than in Greece.

Note: (P) – Pearson correlation; (S) – Spearman correlation

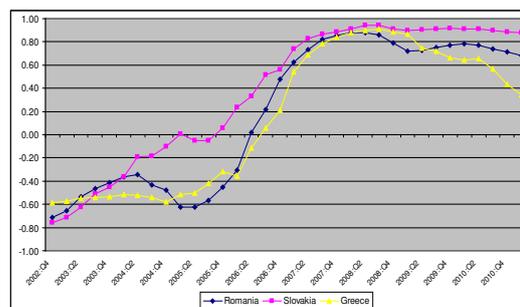

Data source: Eurostat

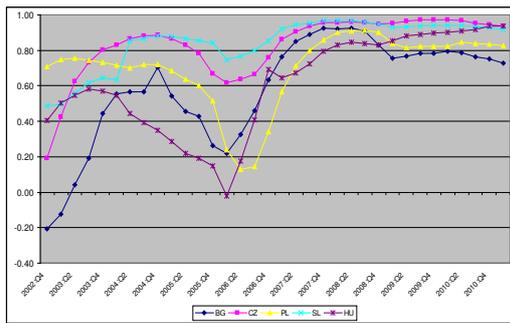

The analysis for the two sub-periods allows the examination of the hypothesis related to the endogeneity of the optimum currency area theory. Since business cycles become more correlated with the Euro area along with the use of a single currency or increasing trade integration, the business cycle synchronization criterion should not be considered ex ante, but ex post, ie after joining to the monetary union. Consequently, the costs of a common monetary policy will be reduced subsequently to the adoption of the single currency. Another method used in the economic literature to estimate the dynamics of the business cycle synchronization degree is to calculate a rolling window correlation for a five-year interval. The results obtained record a progressive increase of the business cycle correlation with the Euro area until the occurrence of the economic and financial crisis, after which a synchronization decreasing tendency was recorded for most of the less competitive economies. Thus, during the periods 2003:2-2008:1 and 2003:3-2008:2 all economies recorded a high business cycle correlation with the Euro zone, and the correlation coefficients were ranging between 90% (Romania) and 99%

(Spain, Italy and Austria). Along with the occurrence of the crisis, the degree of business cycles synchronization with the Euro area was significantly reduced in Greece, Romania and Bulgaria, while in the other economies it was at least 86% (Poland). Therefore increasing the business cycle correlation of the three economies was temporary only, because these neutralize with difficulty the shock induced by the global crisis, what prolonged the economic recession.

In order to outline the differences between the economies included in this study, I have built two charts, the first one including the countries characterized by a negative business cycle correlation during the first sub-period (1998:1-2004:4), and the second one including the other CEE countries. Starting with the five-year business cycle finished in the 3rd quarter of 2006, the synchronization with the Euro area has significantly increased in most of the economies included in the figures below. Thus, Greece and Romania passed from a negative correlation to a positive one, which is though not statistically significant and then to a significantly positive one, while in Poland, Bulgaria and Hungary the correlation increased from approximately 30%, up to over 90%. Hungary is the only economy in which the maximum was recorded at the end of the period, the business cycle correlation being by 5 percent higher than before the economic crisis. Slovenia is, also, a more special case, as the business cycle correlation with the Euro area was higher than 90% starting with the business cycle finished in 2007.

Figure 2. CEE and Greece business cycle synchronization with the Euro area (rolling window correlation – 5 years)

Data source: Eurostat

From the perspective of the optimum currency area theory, it is more important the evolution of the correlation coefficients starting with the 1st quarter of 2007, which corresponds to a full 5 year interval of using the Euro currency. The results obtained confirmed the favorable influence of a common currency upon the business cycle correlation within the Euro area. Nevertheless, as long as there are economies encountering problems in adjusting the negative shocks upon output, then the optimality of the Euro area will decrease.

Conclusions

According to the analysis performed in this study it results that the Central and Eastern Europe countries are heterogeneous in terms of convergence with the euro area business cycles. Thus, Hungary, Czech Republic and Slovenia tend to be more synchronized with the core of the monetary union, while Romania, Bulgaria and Greece Slovakia had higher performance compared to Greece, but lower than Portugal. At first glance, this conclusion assumes that there are higher costs of monetary integration for the less synchronized economies. However, an endogeneity approach of the optimum currency area theory argues that such situation can be improved within the monetary union, because using a single currency increases the economic linkages and business cycles synchronization, which would ex-post increase the benefits of the monetary integration.

Abstract

The multitude of difficult national problems, of economic, financial, social, cultural nature etc. deepened and intensified in the Member States of the euro area, in the current context of the global financial and economic crisis, have generated, in many states, the emergence and the exacerbation of discussions concerning the opportunity to exit from the euro zone and even from the European Union, given that some states have been forced to seek financial aid from the European Union and from international financial institutions, in burdensome terms.

At the same time, constrained by the effects of the global financial and economic crisis, the European leaders rethink the whole project of the European Union.

In these conditions, we consider of great and present interest our paper, where we have highlighted some aspects and causes of the problems being faced by some euro zone countries.

Key words: crisis, euro zone, contagion effect, indebtedness, heterogeneity

J.E.L. Classification: F15, F 34, F 36, G01

1. Introduction

The creation of the Economic and Monetary Union (EMU) has been put into practice progressively and on the basis of well-established rules. The developments within EMU have caused and will continue

to determine the direction of the European integration and thus, the form of the new European architecture. Given the emergence and the amplification of discussions concerning the euro zone breakup scenario, many European politicians perceive the building of a more integrated hard core of the European Union as an unavoidable trend.

The year 1999, when the euro has been launched, characterized as the most important event in the history of the international monetary system after the Breton Woods Conference was seen either as the starting point of a period of unprecedented growth and prosperity in Europe, either as a very expensive historical failure.

Currently, the EMU faces many problems, exacerbated by the economic and financial global crisis which overlapped the crises in the countries from the euro area (overfinancialization crisis of an economy [1], sovereign debt crisis, banking crisis, balance of payments crisis, etc.).

In the period since the start of this important process, the creation of the EMU, we realize that there have not been analyzed deeply enough the consequences of an EMU both for the countries participating to the euro area and for the European Union (EU) countries not participating in the EMU, but also for the countries outside the EU, who wish to join the euro zone.

2. A highlight of some problems faced by the euro area Member States

In order to be part of the EMU, both the original countries and those that have joined later the EMU had, at least theoretically, to meet the same conditions. Nevertheless, there are many countries in the euro zone that have failed to meet some of the convergence criteria at the moment when they have joined the euro area. Thus, in 2000 (prior to its entry into the euro area), Greece had a general government gross debt as a percentage of GDP of 103, 7% [2] well above the nominal convergence criteria for this indicator. The entry of Cyprus into the euro zone has not either been based on the fulfillment of all the convergence criteria, this country having not fulfilled the criterion on the general government gross debt as a percentage of GDP. Thus, before the entry of Cyprus into the euro zone, in 2006, this indicator was 65.3% [3]. Malta did not fulfill either the criterion on the general government gross debt as a percentage of GDP, and she has fulfilled the budget deficit criterion only a year before its joining the euro zone [3]. Italy, Spain, Netherlands, Austria, Belgium, Germany did not fulfill the criterion on the general government gross debt as a percentage of GDP at the moment of their entry into the euro zone [4], while Ireland, Denmark and Portugal have almost met this criterion in 1998, an year before their joining the euro zone [4]).

In this situation, the global financial and economic crisis has led to a deepening and intensification of the various problems (economic, financial, social, cultural, etc.) already faced by the euro area countries. In this context, there have been brought to light the structural deficiencies of some economies of the euro area, emphasizing the differences between them (the deficiencies in the relationship between the banking system and the real economy, the architectural flaws of the monetary union etc.).

Thus, in the recent years in the European Union, including in the euro area, there have been exacerbated a number of problems such as: the slowdown of economic growth, the amplification of the risk of reducing the credit supply toward the real sector, the increase in intensity of the sovereign debt crisis proliferating the risk of spreading, by contagion, of its effects, etc.

The avalanche of unbearable problems faced by the European countries in the recent

years, their constraint to seek financial aid, accompanied by tough austerity conditions led to more and more discussions on the feasibility and appropriateness to exit the euro area and even the European Union, of several countries. Such ideas have been taken into consideration in Greece, Portugal, Spain, Italy, Cyprus, Great Britain etc. Even in Germany most people think the country would be better outside the euro area.

Theoretically there is no provision in the European Union treaties for "expulsion" of a country from the euro area or from the European Union. The analysts and the official sources say that a country could be deprived, de facto, by the statute of euro state by closing its access to the European Central Bank (ECB) operations, which would force that country to issue its own currency for resumption of money circulation in the economy in order to pay wages.

The exit of a country from the euro zone (we think, particularly, of Greece and Cyprus) is unlikely because of the many disadvantages and perils. The central issue is the general chaos at local and regional level – implicitly with political, financial, economic and social impact.

No one can say exactly what will be the consequences of a country leaving the euro zone, but some effects can be predicted.

The first effect will materialize in problems of the banks in the country, with spillover effects in the countries where they have offices and branches. The contagion effect will affect other foreign-owned banks in other countries.

We consider that an important effect will be of psychological nature. The public reaction in the case of an announcement of a state leaving the euro area will be the decisive element during future events. The highest probability is that the human reaction is represented by lack of confidence and panic. Most likely if the public found out, that the authorities of that state prepare the exit from the euro area, the resulting panic could lead to acceleration of the process. The banks will suffer massive loss of credibility. Depositors will feel constantly threatened by the danger of losing their savings. This will lead to massive withdrawals of deposits and finally to complete freeze in lending. Practically the banking activity will collapse.

As you know, the banks are the transmission channels of capital flows in the economy, or, with their collapse, the economic activity will return, finally, suddenly or gradually, to barter exchange.

Investors will lose confidence in the euro, and also local currencies will not be able to survive without the assistance of national central banks. The costs will be seen in public indebtedness.

The stock exchanges will collapse one after another, due to a major spillover effect in all European Union countries. Currency devaluations will affect all social classes, and the state will not be able to honor its obligations to employees or to social assisted categories. Even obtaining loans by the government will become more difficult both in terms of credit conditions and of the cost of borrowing, which will increase significantly. Unemployment will also increase and consumption will be affected. Companies will also record high losses. There will be a general loss of confidence, which will make very difficult economic and financial exchanges in that economy and in the European Union. In some countries facing the same major problems as the country leaving the euro area, similar effects will occur, which will multiply the estimated costs of leaving the Union (or the euro zone) even of a single country.

At the political and economic level, the exit of a country from the euro zone will entail its isolation, thus creating the possibility of an attack on its resources from creditors who will require their funds back.

At the same time, the resources in the banks of that country will not necessarily be directed to its territory, but to other areas of the European Union and the world, thus occurring disorder in terms of financial, human, capital formation values, etc.

In general, the crisis situation from the country combined with the costs of the euro zone exit will determine at the social level, discontent and social revolts that may extend to other countries in the region.

We think that a possible exit of a country from the euro zone, will happen only if the entire European and global context will agree and will consider the country is ready for such a step.

In order to get a more complete picture of the problems that the countries from the euro

area are facing, it is important to succinctly present the situation of some countries that have considered the possibility of leaving the euro zone. Thus, Greece, with a small economy heavily indebted to euro zone countries, is the first country that has needed massive financial assistance from the European Union and the international financial institutions. In order to avoid bankruptcy, Greece has received a huge financial help, provided either by directed "injection" or through debt cancellation by private creditors.

Portugal, heavily indebted to Spain, passes also through a serious recession, having been forced to sign, in May 2011, an austerity plan with the European Union and the International Monetary Fund (IMF).

Ireland, a small country, but with an important financial sector, with high economic growth until 2008, has entered into recession because of the housing bubble that devastated the country's banking sector. This is the second country that has concluded a financial aid plan with European Union and the IMF, accompanied also, as in the case of Greece, by harsh conditions imposed by the international creditors.

Spain, having debts to Germany and France, and passing through a deep recession, managed to avoid a plan of global assistance for its economy by obtaining in June 2012 a credit line for its banking sector from the euro zone.

The euro zone crisis shows that for analyzing the situation of a country, the indebtedness of the private sector has great importance. Thus, Spain and Ireland, countries with relatively low public debt, but with private huge debts has been hit hard by the crisis.

Italy has also high debts. France is the most exposed to them.

Germany highly exposed to the debts of Spain, Greece, Ireland and Portugal would suffer if one of these countries would go bankrupt.

The sovereign debt crisis highlights the importance of the banking system for each country, and how important it is the state's and local capital's control in the domestic banking system, something that has not been taken into account in some European countries.

Netherlands, the fifth largest economy in the euro area faces major problems such as a mortgage debt of the highest in Europe, small exports, the European crisis, etc. Of the four largest Dutch banks, SNS Reaal and ABN Amro have been nationalized, and ING has received in 2008 funds that it has not still fully paid back to the state.

Direct or indirect subsidies granted by governments (which leads to increased public debt) and the use of very cheap lines from the central banks to the financial sector, in some cases meant to avoid bank bankruptcies, is a main issue in Europe.

The public debt crisis is not the main crisis showing in the euro area. According to some economists [1], the euro zone crisis is primarily a balance of payments crisis and a banking crisis. The original cause of the euro zone crisis can be found in the institutional arrangements and in some of the policies implemented. The situation is due to the heterogeneity between the member states of the European Monetary Union and it raises the problem of the divergence on making joint decisions with impact on the economic development. Thus, the adoption of a joint decision can produce contradictory effects between countries. For example, in the case of asymmetric shocks, due to structural differences at the level of EMU, the implementation of a single monetary policy meant to counteract the negative effects, will often have under-optimal effects, at least for some Member States [5].

Prof. D. Daianu stressed repeatedly that the euro zone crisis is connected with that of overfinancialization of economies [1]. Continuing this idea we mention that between the financial system (especially, the banking system), which assesses the economic performance and the risk characteristics of the economy, and the real economy, it must exist a "right" relationship, which has been neglected in the euro area countries.

The overfinancialization of some economies, in general, in this case of those from the euro area, can lead to the outburst of a financial crisis of vast proportions, if there is no effective regulation and supervision. Sometimes the fulfillment of these requirements is not enough. Thus, in the case of Cyprus, the large size of the financial system relative to the total economy of the

country has exacerbated the problems caused by the losses due to the debt cancellation program of Greece and the decline in the housing market. Going forward with the idea, it can be said that the Cypriot banks have been encouraged to invest in the government bonds of Greece. Thus, a few years after the adoption of the euro, Cyprus has come to the situation to be forced to seek financial aid from the euro zone whose operation is currently perceived as rigid and extremely compelling.

The agreement between Cyprus and the consortium consisting of the International Monetary Fund, the European Commission and the European Central Bank aims at removing the uncertainties and the danger of forcing Cyprus to exit the euro zone. The harsh conditions enforced on Cyprus by Germany and the IMF aim at reducing the country's oversized banking sector (about eight times the GDP). But if by this Agreement it will be destroyed the country's financial sector, which is the engine of the economy, affecting Cyprus's ability to pay back its foreign loans, then the negative effects over this country will be numerous and powerful.

Cyprus passes through a deep crisis considered a "systemic risk". The European proposals to close the second large bank of the country, Cyprus Popular Bank, in which the state holds 84% of shares, to restructure the Bank of Cyprus with large losses for depositors could have very extensive effects in Europe, and even around the world.

The policy strategy chosen in Cyprus is very similar to the solution, which has been adopted in the case of Iceland. Iceland allowed its three largest banks to fail as part of the solution to the banking crisis that struck the country in 2008. The Icelandic experience could hold many lessons for Cyprus, since the impact of the re-structuring could be similar. One of these refers to the fact that Cyprus will need to reinvent itself.

The Icelandic experience has also shown that capital controls, once in place, are difficult to dismantle. Capital controls should be carefully studied so as to minimize the strain on businesses, as well as the disincentives for the banking sector to effectively restructure. This will be the case, for instance, if restrictions on domestic transfers or on loan restructurings are

imposed. This type of restriction will not only deter depositors from undertaking a sensible diversification, but will also lead to complacency on the part of banks. [6]

There are alternative strategies for solving a banking and financial crisis. But there is a theoretical premise that is important to put in practice: the financial sector is based on trust. Whatever the plan is, it should be coherent and explained clearly and transparently, so that agents' expectations are anchored in the success of the plan from the outset. Destabilizing leaks or statements that are later withdrawn should be avoided. In the case of a banking crisis it is even more important for policy-makers to treat communication as an important component of the policy toolkit, because the communication strategy of policy-makers anchors expectations and builds credibility. What concerns the recent policy actions in Cyprus to resolve its banking crisis has shown that a well structured communication strategy has been conspicuously absent. [6]

We emphasize that given that in other European Union countries (Ireland, Iceland, Malta and Luxembourg), the financial assets exceed several times the GDP, the imbalances in this respect being even bigger than in Cyprus.

A connection can be made with the fact that everything happens in a period of control consolidation in the euro area financial sector, of implementation a comprehensive financial reform agenda in response to the financial crisis.

In the euro area, given that the banking system has shown major weaknesses during the crisis, it has been decided that the first area to work to is the banking integration. Thus, the European Commission requested the creation of the European Banking Union (EBU), which intends to achieve a substantial reform program in the field of the Single Market regulation, program, which is in progress [7].

By creating the EBU, the European Union wants to restore confidence in the euro. Also, the creation of EBU means ensuring a unique framework for handling "problem banks", the standardization of the schemes for guaranteeing banking deposits, as well as a mechanism of fiscal aid from governments.

The establishment of EBU is considered to be important in order to avoid the present

fragmentation of the euro area since during the last years there has been a phenomenon of banks' withdrawal from other countries, phenomenon that causes undesirable, dangerous and worrying effects (the complication of the effective monetary transmission mechanism in the euro area, the prevention of free movement of capitals, the isolation of problems banks from the euro area, etc.).

In the process of creating EBU, a series of divergent interests confront, namely those of the states from the euro area with those outside it, of the countries financially sound with those of the countries with problems that are ever more.

3. Conclusions

From the facts presented above, it can be concluded that in Europe a "bundle" of crisis gather way, such as the euro zone crisis, which is primarily a balance of payments crisis and a banking crisis, but also a sovereign debt crisis and a crisis of an economy overfinancialization.

It also can be noted that the euro zone crisis arises from inappropriate institutional arrangements and from the implementation of macroeconomic policies in an heterogeneous medium (the euro area Member States).

In this situation, it is not surprising that after a period of time, in some of the euro zone Member States, the national disequilibria enhanced and under the pressure of the international financial and economic crisis they have exploded. In the case of some countries, we can even say that their entry into the euro zone, at the moment when it had taken place, has been an error and that the geopolitical reasons prevailed at the expense of economic logic.

The functioning of the euro area is at present rigid and very burdensome. The austerity terms agreed by European Union member countries with the European Union and the international financial institutions for obtaining access to external financing are difficult to fulfill.

Due to the serious problems faced by an increasing number of euro area countries, they have taken into consideration the possibility of exit from this union, which will have important consequences for both parts.

The financial system of the euro area is growing larger and more integrated. The global financial integration and the European Union single market allowed, in some Member States, the banking sectors to exceed several times the national GDP. So, there have appeared institutions "too big to fail" and "too big to be saved."

On the other hand, the acceptance by Cyprus, in order to avoid the exit from the euro zone, of a considerable restructuring of its oversized banking system, in exchange of a bailout program, shatters the myth that some banks are too big to be allowed to collapse.

So, in order to keep the Member States inside the euro zone, we consider that the European Union should create another "European model" opposite to austerity, in general supporting the economic growth.

It should also be underlined that in order to cope with the threats to financial stability from the euro area, the European Union continues the euro area reform and consolidation plan, bringing substantial improvements and implementing complex financial reforms.

Under the pressure of the current economic and financial crisis, the European leaders rethink the whole project of the European Union. In the future, this stipulates giving up banks and the control of national budgets.

Faculty of Economics and Business Administration

nicoleta.moldovan@feaa.uvt.ro

carmen.corduneanu@feaa.uvt.ro

Abstract

This study is focused on the linkage between environmental taxes and economic competitiveness.

The performed research has emphasized that the environmental taxes determine additional costs at the level of the economic polluting activities, influencing on competitiveness through price. However, competitiveness is determined by a set of structural factors and it cannot be reduced only to the impact exercised on prices by the environmental policy, by means of the fiscal instrument.

In order to see if there is a relation between economic competitiveness and the fiscal instrument used for the implementation of the environmental policies we compared Global Competitiveness Index (GCI) to the value of the fiscal collections derived from the environmental taxes. According to the results, our analysis reflects that the economic competitiveness and environmental taxation at the level of the EU member states doesn't reflect a direct correlation between them.

Keywords: fiscal policy, economic competitiveness, environmental taxes.

J.E.L. Classification: E62, F43, F64.

1. Introduction

Derived from the ethics of responsibility, the „polluter pays” principle formulated by Pigou [6] underlies the environmental taxes. According to this, the negative externalities coming from the activity of any economic entity which pollutes must be internalized at their level. The internalization of the pollution costs by its originators is made

through fiscal, economic and regulation instruments.

Environmental taxation contains a set of heterogeneous fiscal measures [10] represented by the environmental taxes applied on the polluting products, the royalties which have an impact on the price of the natural resources, being designed to cover the costs for the environmental services, the positive measures represented by the tax credits, accelerated amortizations and exemptions pursuing to act on the company behaviour in order to influence the investment options, the environmental modulations under the form of exonerations, deductions, rate differentiations designed to orient the behaviours in favour of the environmental protection. These fiscal measures are applied on certain sectors or various sectors: energy, water, natural resources, transports, wastes, urban pollution, risk prevention and the fight against noise.

2. Taxes, instruments of the environmental policy

Do the environmental taxes serve for the fulfillment of the objectives specific to the environmental policy? Which is the relationship between environmental policies and competitiveness? How can competitiveness be integrated in the environmental policies? These are just a few questions to which experts are searching for an answer.

As a result of Kyoto Protocol signing in 1997, the member states decided to develop environmental policies which shouldn't increase the unit costs in economy excessively, but should be efficient regarding the resource allocation so that it shouldn't encumber competitiveness. Whereas the companies' decisions related to the

manufacturing technologies but also the citizens' decisions concerning the domestic energy consumption, are made according to the information included in prices and the tax can change the price and integrate the external costs, then the environmental taxes together with the economic instruments represented by the direct regulations, the certifications on the greenhouse gas emissions, the grants and financial benefits may represent an instrument of the environmental policy.

At the business environmental level there is however the fear that the environmental policies can reduce competitiveness and influence the economic growth negatively. This fear is not justified in the opinion of Porter [7], who affirms that the environmental policy might be beneficial for competitiveness, because the costs of conformity with such a policy can be fully balanced out through innovations generating competitive benefits which should allow companies in question to receive the “first mover advantage” in the area of technologies which have a market potential in the future. In his opinion, the strict standards on the products performance together with the product safety have an impact on the environment, contributing to the updating of technologies and the formation of competitiveness advantages. Subsequently, in a work published in 1991, he insisted on the fact that well-conceived environmental policies can generate efficiency incomes in production through innovation and therefore, an absolute advantage of innovating companies in regard to the non-standardized ones. Accordingly, Porter and Linde [8] suggested the quick enactment of some new environmental standards which, in authors' opinion, represent a competitiveness factor.

Although the regulation allows the direct targeting of the polluters, the encouragement of the innovating processes and competitiveness, however due to its inflexibility, the environmental taxes and markets of the greenhouse gas certifications are preferred. These economic instruments encourage the innovating processes and competitiveness implicitly, being more efficient from the economic perspective. Practically, through the environmental taxes we intend to change the behaviour of the polluting companies, by integrating the cost

of the produced damages in the price of the good or economic service generating the pollution, which destroys the environment respectively.

In comparison with the approaches based on regulation, there is also an economic approach based on the signal transmitted by prices on the market, as the environmental taxes are incorporated in the prices of the produced or traded economic goods as well as the manufacturing prices. Companies shall be interested in the polluting emissions' reduction when the cost of these efforts shall be lower than the fiscal cost. An alternative to the economic approach is the voluntary approach, consisting in the participation of the companies to public programs and negotiated agreements as they would be more successful regarding the impact on competitiveness. However, a study made by OCDE [5] recommends the caution concerning the specific instruments of the three approaches, as their economic efficiency is reduced due to the behaviour of certain companies trying to circumvent the regulations and environmental taxes. Accordingly, we consider that it would be more efficient for the environment protection to establish certain performance objectives on environment protection at the level of each company.

The environmental taxation brings resources to the budget without generating welfare losses because integrating the external costs in the equilibrium of markets presents a static efficiency but also a dynamic one through the fact that it encourages the reduction of these costs. In order to assort the environmental policies with competitiveness, the environmental taxes can be used to fund the decrease of taxes and fees on the working factor which is not related to the polluting emissions, but also the measures intended to support the structural competitiveness.

Introducing the environmental taxes can create competitiveness issues on short term at the sector level, but by fact that they force companies to replace the old technologies with new nonpolluting ones, we ensure a reconciliation of the environment policy with the one regarding the competitiveness support. The fact that the environmental policies imply for companies a cost related to the renunciation to the use of polluting

technologies, they are concerned with the impact on profitability. It is obvious that if the costs of the compensations related to the produced damages are higher than the costs needed to reduce or avoid pollution, then from the economic perspective, this costs' substitution is efficient.

3. The environmental taxation and competitiveness in the European Union

In order to prevent the emergence of unwanted modifications to the planet climate system, the political decision makers agreed that a general operative framework is needed to include political and economic measures designed to reduce the global warming and prevent the emergence of the climate changes. The objective of the United Nations Framework Convention on the climate changes in 1992 was “to achieve the stabilization of greenhouse gas concentrations in the atmosphere at a level that would prevent dangerous anthropogenic interference with the climate system.

The impact of the environmental policy on the economic competitiveness of companies, sectors of activity and competition on the internal market integrated to the regional level, represents one of the European Commission concerns in the last two decades [2]. The European Commission established that in order to get correct prices and create incentives for an economic behaviour in favour of the environment protection, the member states can use economic and fiscal instruments to internalize all the external environment costs contracted during the entire product lifecycle so that the environment favourable products shouldn't be disadvantaged from the point of view of the competition, in comparison with the products determining pollution and wastes [3].

The European Commission adverted that the economic decisions are largely made according to price signals. As the consumers adapt the purchase decisions according with the price changes and the companies determine the product design, the technological development and the organization of the manufacturing process largely according with the market prices, it is essential that these prices reflect the total

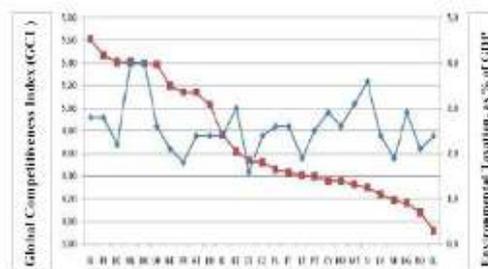

costs and benefits for man and society correctly [4].

The environmental taxes seem to present a serious challenge for company competitiveness, their existence implying that they are applied to all goods affecting the environment. On the other hand, they represent an incentive to improve the environment performances of the companies. In this case, the Business Council for Sustainable Development states that “a lot of the waste reduction programs and environmental programs for the business area economically healthy and offer positive rates of profitability in relative short periods of time” [9].

Notwithstanding, there is a significant discrepancy between such a conclusion and the business environment which considers that the environmental policy and especially the environmental taxes represent a major threat to the competitiveness increase. But if companies lose their competitiveness, they lose in their market share, become less profitable and eventually, they give up on business.

The analysis of the macroeconomic indicators calculated by various entities and foundation reveals the difficulty of highlighting all factors influencing on the economic competitiveness of the countries. In order to see if there is a relation between competitiveness and the fiscal instrument used for the implementation of the environmental policies we shall compare Global Competitiveness Index (GCI) to the value of the fiscal collections derived from the environmental taxes.

Figure 1. Global Competitiveness Index and environmental taxation at the level of the EU member states in 2010

Source: The World Economic Forum, Eurostat, data processed by the author.

States such as Netherlands and Denmark have the highest level of environmental taxes in GDP. Other states in the top of the European most competitive economies such as Sweden, Finland, Germany, and Great Britain have a high level of the environmental taxation. Instead, in the states which made the object of the last two extensions but also in certain states of the euro zone such as Greece, Portugal and Italy, the environment taxation is high. This observation is explainable because the environment taxes as they are currently established don't have an effect on the competitive position of the member states, the impact being at the sector and company level.

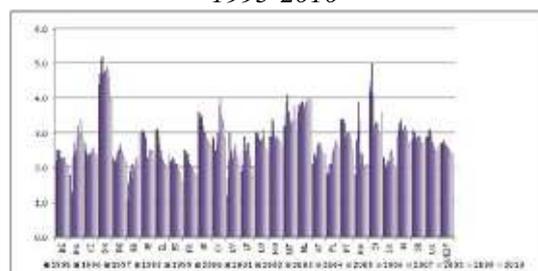

Although there is an instrument for the environmental policy implementation, however, in order to attenuate the negative effects on competitiveness, there are multiple exceptions and reductions to the sector level which vary from a state to another. Although the member states agree with the harmonization of the environmental taxation, it is difficult to achieve as it needs the existence of their unanimity. If a group of states agrees to coordinate its efforts towards harmonization the impact on competitiveness is not completely solved because there isn't the possibility of the practice of neither an external common tariff at their geographical border nor a control at the borders between states.

In order to have a global image on the use of the fiscal instrument concerning the environmental policy implementation in the EU member states, we shall analyze the value of the environment taxes in the gross domestic product and the total taxes taken respectively.

In the analyzed period (1995 – 2010), the value of the environment taxes in GDP at EU-27 level dropped by 0,3% against their decrease in 14 of the 27 member states. The analysis refinement at the level of the member states reflects the existence of some substantial differences. In 2010, the value of the environment taxes in GDP exceeded the European average of 2,4% both in some of the old member states and in those which made the object of the last two extensions. Denmark and Netherlands separate from the others with a value of 4%, being followed by Slovakia (3,6 %), Malta (3,1 %), Estonia (3

%), Bulgaria and Cyprus with 2,9 %. Values between 2,8 – 2,5% were registered by Finland, Sweden, Great Britain, Hungary, Poland, Italy and Portugal. Practically, it seems that this fiscal instrument is insufficiently used to support the environmental protection policy. Moreover, we must remark that their value is important in states with high Global Competitiveness Index, such as Sweden, Finland, Netherlands and Denmark. Therefore, we cannot consider that the decreased value in the 14 member states is caused by the fact that governments attached priority to competitiveness increase and to economies' opening, considering that the fiscal instrument would have a negative impact. For a more correct image, the analysis of the environmental taxes should be structurally refined at the level of the taxes on resources, the taxes paid by the industrial pollutants, the taxes on energy and transport.

Figure 2. The value of the environmental taxes in the gross domestic product, 1995-2010

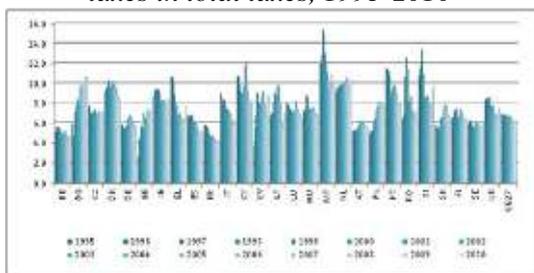

Source: <http://epp.eurostat.ec.europa.eu>, data processed by the author.

In the same period, at the EU27 level the value of the environmental taxes in total taxes dropped by 0,7%, given the fact that only in five member states their level is below the European average in 2010, namely in France, Belgium, Spain, Austria and Denmark. The highest values included between 10,7 – 9,2% were registered by Bulgaria, Slovenia, Netherlands and Malta, followed by another group of states represented by Latvia, Estonia, Ireland, Cyprus and Poland where the value was between 8,8 – 8,1%. In Portugal, Greece, Romania and Czech Republic the value of the environmental taxes in total taxes was between 7,9 – 7,1%. While in most member states the importance of the collections deriving from the environmental taxes decreased, in others they increased. However, although the increases were specific to some

of the new states against the increase of the fuel excises, there are old states such as Netherlands and Finland where the contribution of the environmental taxes to the national budget financing increased during the analyzed period.

Figure 3. The value of of the environmental taxes in total taxes, 1995-2010

Source: <http://epp.eurostat.ec.europa.eu>, data processed by the author.

In order to reduce the impact on competitiveness through price, the Union opted for the application of the “double dividend” principle to the environmental taxation. Practically, it consists in the reduction of other compulsory contributions such as the contributions related to social security paid by corporations or the reduction of the salary tax in order to balance out the fiscal cost generated by the introduction of the environmental taxes. A neutral effect on competitiveness would be if the environmental taxes apply not on the manufacturing place but on the consumption place, but we raise the question of the efficiency of achieving the intended objectives through the environmental protection policy. There are various other solutions and exceptions, by which we can limit the effects on competitiveness but the objective which must be taken into account is that by means of environmental taxation to encourage the formation of new less polluting technologies generating a big added value, the only ones capable to ensure both the real increase of competitiveness and the environmental protection.

The commission suggested the reform of the environmental taxes to simultaneously promote the economic growth, employment and a better quality of the environment. Actually, the suggestions aimed that the increase of the environmental taxes should be accompanied by a corresponding reduction of other taxes, so that the global fiscal pressure remains unchanged.

Denmark, Finland, Germany, Netherlands, Sweden and Great Britain ranked among the reform supporting countries. The reform supporting countries proceeded to the increase of the environmental taxes and used the additional incomes obtained in this way to fund the reduction of the taxes on salary incomes or other incomes obtained by natural persons, with the purpose of encouraging the employment. In the same time, they implemented measures referring to reductions of the tax rates or reimbursement schemes, in order to protect the manufacturers against any negative effect on competitiveness, deriving from the increase of the entry costs. The basic idea was the transfer of the tax burden from the working factor towards the use of the goods and other environmental harmful activities, as a result of the impact on the cost exercised by the environmental tax.

In order to study the efforts made by the member states in the direction of a reform on environmental taxes, we shall analyze, at the level of the above mentioned states, the value of the taxes on the workforce in comparison with the value of the environmental taxes in total taxes. The performed analysis emphasizes that in Denmark, Netherlands and Finland, during the analyzed period, a reduction of the fiscal pressure on the working factor occurred as the environmental taxes increased, being interrupted by a trend reversal in 2001 and during 2007–2009 respectively. Except a few years, in Sweden, Germany and Great Britain increased or decreased the pressure on the working factor concomitantly with the increase or decrease of the environmental taxes.

The introduction of new environmental taxes or the increase of the existing ones determined the member states to adopt different strategies to reduce the actual fiscal pressure on the industrial activities. As Etkins and Speck [1] noted, the common purpose of these policies was that of protecting the internal industries against the risk of losing the competitiveness as a result of the unilateral introduction of the environmental taxes, as any type of tax which is additionally added to the business costs could affect the international competitiveness of an activity or a sector.

An important aspect regarding the environmental taxes and competitiveness is represented by the way of using the fiscal incomes generated by their taxation. In the case in which these incomes are returned under a certain form to the environmental tax payer companies, then their competitiveness, on the whole, shan't suffer, even if certain gaps of competitiveness are identified at the sector level. In the case in which the incomes deriving from the levied environmental taxes aren't returned to the payer companies, then the effects generated on their competitiveness shouldn't be compared to the non-taxation situations, but to the effects caused by the increase of the same incomes and the achievement of the environment improvement through other possibilities.

The instauration of such taxes is designed to include the costs of the damages produced on the environment in the market prices of the goods and activities with a negative impact on the environment, the purpose of their implementation being that of increasing the incomes in order to fund the environmental policies, to induce environment less harmful models to the behaviour of the economic agents, and last but not least, to reduce the fiscal pressure on the workforce, for the unemployment reduction.

Conclusions

The effects of the environmental taxes on competitiveness can be attenuated by excepting or granting concessions for the vulnerable sectors, by performing certain adjustments of the customs or by the international harmonization of the taxes. Each of these approaches also implies some negative aspects: the first one diminishes the tax efficiency and increases the cost for achieving the presumed environment objectives; the second one presents the risk of disguised protectionism and may infringe on the international commercial standards; and the third one is difficult to negotiate, being perceived sometimes as coming in conflict with the principles of the fiscal sovereignty of the states and subsidiarity.

The ideal theoretical solution for the attenuation of the environmental tax effects on competitiveness implies their international harmonization. a step forwarded by the

European Commission back from 1991. But there were states which brought arguments against it, appealing to the principles of sovereignty and subsidiarity, based on the right of enacting their own taxes, so that the impossibility of reaching a unanimous agreement at the European Union level on this topic has generated the impossibility of enforcing the suggestion made by the European Commission.

Even in a presumed context of achievement of such a unanimous agreement at the level of the EU member states, the concerns regarding the competitiveness, existing in the OCDE member states but at the global level too, in our opinion, make the international harmonization of the environmental taxes a difficult and long-term process.

The Liquidity of the Financial System and the Sovereign Debt Crisis in Europe – Is There a Solution?

Nedelcu Monica Letitia

Faculty of Economics and Business Administration, “Alexandru Ioan Cuza” University of Iasi, Romania
nmonicaro@yahoo.com

Abstract

The financial crisis of 2007-2008 has brought to light the liquidity problem of the financial system. Trying to solve this challenge, the members of the European Monetary Union were confronted with the sovereign debt crisis, which exacerbated the gravity of the initial situation. This paper analyses the causes and effects of the sovereign debt crisis as well as the measures taken by the European Central Bank to minimize the negative effects. The analysis is used in order to identify possible solutions for this critical situation. The findings reveal the fact that there is no panacea solution, that situations differ from country to country and that there is no measure only with positive effects. The broader question is which steps have to be taken in order to avoid a worse situation in the long run.

Key Words: financial crisis, sovereign debt crisis, European Central Bank, liquidity risk, fiscal policy

J.E.L. Classification: E56, E62, G01, G12, H12, H63, N24

1. Introduction

The lack of liquidity is one of the major causes of the 2007-2008 financial crisis. The international financial regulation in force in 2007 was ignoring this dimension of the financial risk, being focused only on credit risk. But the globalization process combined with interlinks between credit risk and liquidity risk generated the extension of the risks to the systemic level. Contagion risk was also a consequence of the complexity and linkages of the financial system. The international regulation institutions created

the Basel III framework to respond to these major problems. Trying to eliminate the weaknesses of the old regulation, the new framework became too strict. For example, researchers and professionals alike consider that the list of assets qualified for LCR and NSFR is far too restrictive and encourage pro-cyclicality and concentration of risks. And this is exactly what the regulators want to eliminate.

Another doubtful situation concerns the fact that the sovereign bonds are quoted as high quality liquid assets. But after the beginning of the sovereign debt crisis in Europe it is hard to regard Greek bonds or Cypriot Bonds as high quality liquid assets. Considering this, it is important to determine whether the sovereign debt crisis in Europe will be a long term concern for the stability of the financial system.

Following this lead is justified to analyze causes and effects of this sovereign debt crisis, measures taken by the European Central Bank from the beginning of this critical period and solutions proposed by different researchers.

2. Causes of the sovereign debt crisis

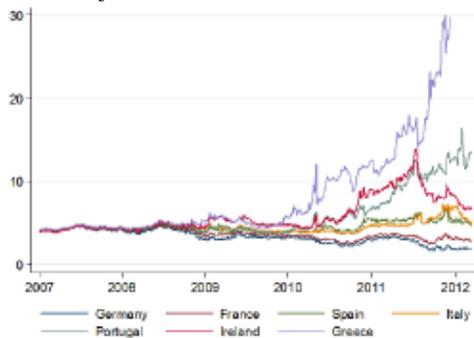

Till the end of 2009, when the new prime minister of Greece, George Papandreaou, announced that Greece's real budget deficit is 12.7 percent of GDP, and not 6 percent tabled by the previous government, the situation did not seem to be that bad. But from that moment, not only Greece, but also other periphery European countries, like Portugal, Italy, Spain and Ireland, with similar economic situation to Greece confirmed that the euro-zone was in a critical situation.

A perfectly valid statement is the one which argues that the roots of the debt crisis in Europe stand in the way the euro-zone was

designed [10,12]. The structure of the European Monetary Union (EMU) encourages members to run huge deficits. The fact that EMU members do not have their own currency that can deteriorate when selling large amounts of debt to global financial investors, enable them to be aware when a country’s deficit is getting dangerously high, no market feedback mechanism being there to signal this situation.

At the same time the euro-zone bonds were regarded as close substitutes for each other, despite the fact that the issuers were different. The investors treated all sovereign bonds issued in the Euro area as basically default-free. As shown in Figure 1, sovereign bond spreads among European countries before the fall of 2008 were minimums.

Especially, banks of the core European countries have turned into major holders of the sovereign debt of periphery countries. Following the numbers in Table 1, it is easy

to observe the dependence of the Euro-zone banks on the quality of the sovereign bonds issued by European periphery countries.

The financial crisis of 2007-2008 and the global economic downturn have exacerbated the levels of the euro-zone sovereign debt, reflecting the effects of automatic stabilizers, discretionary stimulus measures and official sector support to the financial sector. Beyond the initial liquidity crunch, many euro-area banks faced solvency problems, and national governments across the euro area stepped in to provide banks under their jurisdiction with funds or guarantees.

The IMF [14] estimates that total direct support for the financial sector, by the middle of 2011 amounted to roughly 6 percent of GDP in countries such as Greece and Belgium, 13 to 14 percent in the Netherlands and Germany, and 41 percent in Ireland. The level of sovereign debt in Ireland and Spain increased dramatically over this period, placing these countries next to Greece, Portugal and Italy. This situation is easier to follow observing the figures presented in Table 2.

The financial crisis period also revealed the fact that the euro area did not have a common crisis management and resolution framework. There were no backstops for sovereigns and banks, so that the crisis had severe effects on Greece, Ireland, Portugal, Spain, Italy and Cyprus [17].

Retrospectively looking, the major cause for the sovereign debt crisis in Europe was the external debts of the European countries which exposed the banks from the euro area to the sovereign risk as shown in Table 2 [2,22].

3. Effects of the sovereign debt crisis

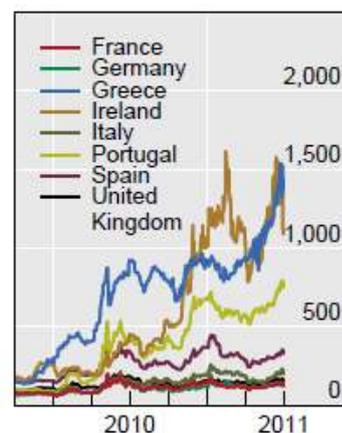

The most important effect of the sovereign debt crisis, combined with the financial crisis was the decreased liquidity of the sovereign bonds. If until the financial crisis the euro area sovereign bonds were considered without risk, regardless of the issuer, from that moment on important differences were observed between countries. Graphic 1 shows these gaps between issuers, identified as spreads for 10 year sovereign bonds. If the German had relatively constant sovereign bond yields, even with a decreasing trend in the last few years, this

was not the case for Greek or Portuguese spreads of the sovereign debt. Their yields increased dramatically after 2010.

This effect was determined by the loss of confidence of the investors in the capacity of sovereigns of the European Periphery countries to meet their obligations. This loss of confidence affected also the banks from the euro area. Graphic 2 reveals the five-year CDS premia on senior bonds issued by the major banks from the selected euro zone countries, which had similar trends as the spreads of the sovereign bonds.

In fact the sovereign debt crisis has determined an increase of the funding costs for the banks from the affected countries, and impaired their market access. Banks from Greece, Ireland and Portugal have seen their CDS premia rise to extremely high levels.

Graphic 2 – CDS premia for bank

Source: BIS Quarterly Review, Davies and Ng (2011), Datastream, Bloomberg.

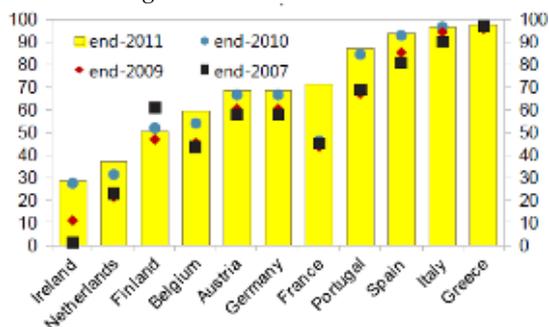

The banks from the European Periphery countries suffered a drain up of the liquidity through capital flows. During the crisis, the investors from these countries shifted funds into safer assets such as German bonds which have benefited from the safe haven status. There was a risk-averse "flight to quality" process.

Another consequence of the sovereign debt crisis doubled by the financial crisis was the increased demand from domestic banks for their own government debt. Graphic 3 illustrate these trends for the period 2007 – 2011.

A study conducted by Arslanalp and Tsuda [3] identified the factors that determined this trend as follows: the global

recession – that has reduced demand for bank loans and, as a result, the banks had as only alternative to accumulate government debt instead; bank deleveraging; Basel III and new financial regulations; rising home bias; the ECB’s long-term refinancing operations and changes in its collateral criteria.

*Graphic 3 – Euro area: Banks holdings of own government debt securities, 2007 – 2011

A Report of the Committee on the Global Financial System, conducted by Fabio Panetta from the Bank of Italy in July 2011, showed that sovereign risk adversely affect banks’ funding costs through several channels, due to the pervasive role of government debt in the financial system. These channels determine the following situations: the losses on holdings of government debt weaken banks’ balance sheets, increasing their riskiness and making funding more costly and difficult to obtain; higher sovereign risk reduces the value of the collateral banks can use to raise wholesale funding and central bank liquidity; sovereign downgrades generally flow through to lower ratings for domestic banks, increasing their wholesale funding costs, and potentially impairing their market access; a weakening of the sovereign reduces the funding benefits that banks derive from implicit and explicit government guarantees [20].

As the history of the recent crisis reveals there is a bilateral linkage and influence between liquidity risk and sovereign risk. This can determine a self-fulfilling crisis [1]. At the same time the inter-linkages of the euro-zone markets and the similarities between countries stimulate the contagion risk which will enable the systemic risk [11].

4. Measures taken by European Central Bank

Considering the internal and external exposures of the euro area banks to the sovereign debt, it is obvious that the default of a country, even the default of a sole one, will generate a dramatic situation. This is valid not only for the euro zone financial system, but also for the international financial system. To prevent the possible damages of a euro area country default, the European Central Bank took a series of measures since the beginning of the crisis.

One measure takes into consideration the establishment of the European Financial Stability Facility (EFSF). This facility was instituted in 2010 and later will be transformed into a permanent fund, the European Stabilization Mechanism (ESM) that will obtain funding from the participating countries and will provide loans to countries in difficulties. What is to blame about this measure is the fact that the amount collected from the euro zone countries is not enough to cover the needs of the system, if there are more countries in possible default. At the same time, if the rate for the loans is high that will be a signal to the market that there is a significant risk of default and that there is no trust in the success of the package. That will determine the investors not to buy sovereign bond issued by the country with problems. High interest rate also makes it more difficult for the governments to reduce their budget deficit and to slow down debt accumulation [8]. But above all an institutionalized bailout facility would create perverse incentives for countries to run up their balance sheets. The availability of emergency cash has the potential to weaken market discipline and create a moral hazard, since countries know that mismanagement of public finances would not carry heavy political or economic costs [10].

Another measure of the ECB was to take increasingly large deposits from commercial banks in surplus countries and to extend increasingly large loans to commercial banks in deficit countries. Willing not to aggravate the developing collateral squeeze, ECB also reduced its reserve requirements, and substantially relaxed its own collateral eligibility rules. These facts determined the flight of the credit risk from the balance

sheets of the commercial banks into the balance sheet of the ECB [2].

But all these measures address more the effects and not the causes of the crisis. From this perspective it is important to review other possible solutions.

5. Solutions to solve the sovereign debt crisis

As long as the main causes of the sovereign debt crisis stand in the way that the European Monetary Union was designed, the solution has to be there too.

The most adequate solution seems to be the fiscal union [10, 16, 23, 18, 8, 9]. But this is not a valid alternative if the euro zone countries want to maintain their fiscal sovereignty.

A second option is the monetization of the public deficit [23, 12]. This measure supposes that the governments will be allowed to create new money, and directly finance their deficits with that new money. But history reveals the fact that after the monetization of the public deficit there would be a rise in inflation, and hyperinflation would follow.

Some authors talk about Eurobonds, as a sustainable solution, representing an important mechanism of internalizing the externalities in the euro zone [23,16,18,6,8].

A Eurobond is an instrument with a collective underwriting guarantee from all euro-area countries. An advantage of this tool is the fact that it transforms the currently fragmented European capital market for sovereign bonds into one single and vast European government bond market similar to US Treasury. A collectively-backed bond is stronger than one backed by a single government and has the opportunity to become a global payment tool that all investors will wish to hold and a “safe haven” instrument. Its disadvantage arises from its possibility to raise the interest rates at which the most creditworthy members of the euro zone presently pay on their debt. The second disadvantage is that it could remove the disciplining effect of capital markets on the ability of member states to issue more debt and it could institutionalize a moral hazard situation [16].

A special solution that could be used to eliminate these disadvantages is the

conditional Eurobond. Conditional Eurobonds involve creation of a structure of escalating rates, proportional to the debt-GDP ratio of each country [8, 16, 18]. The question that arises is: will different conditions for Eurobonds not be considered by the market as signals of possible default and will not generate risk-averse attitude from the investors?

A desirable measure involves increasing the powers of the European Union to monitor fiscal policies of the national governments: private and public debt, current account imbalances, competitiveness measures, house prices [8, 22].

The banking federation is also taken into account by the specialists, as a viable alternative. This banking federation implies centralized supervision, centralized banking resolution, and centralized deposit insurance schemes [6, 17].

Last but not least aspect is the requirement for greater transparency about overall government debt levels in some countries so that policymakers, banks and other market participants can accurately assess the associated risks [20].

As the study reveals, taking into consideration different situations from country to country, there is no panacea solution for the crisis and there is no measure only with positive effects.

6. Conclusion

The financial crisis and sovereign debt crisis have shown that there is a bilateral linkage and influence between liquidity risk and sovereign risk. This can determine a self-fulfilling crisis. At the same time the inter-linkages of the euro-zone markets and the similarities between countries stimulate the contagion risk which will enable the systemic risk.

If the international financial regulators try to find the optimal framework to settle the financial system, what is to be done for the sovereign risk? In fact all the solutions concern important reduction in budget deficit and sovereign debt.

This important reduction supposes relatively long time and are mainly driven by decisive and lasting fiscal consolidation efforts, focused on reducing government expenditure, in particular, cuts in social

benefits and public wages [19].

On the other hand, robust real GDP growth also increases the likelihood of a major debt reduction because it helps countries to grow their way out of indebtedness. The question is how will the euro-zone act to stimulate economic growth nowdays?

The problem seems to be much deeper considering the results of recent studies which reveal that above a 90-100% of GDP threshold, public debt is, on average, harmful for growth [5]. In the same study confidence intervals for the debt turning point suggest that the negative growth effect of high debt may start already from levels of around 70-80% of GDP, which calls for even more prudent indebtedness policies.

The Effects of Creating the European Union Bank, on the Banking System in Romania

Neguriță Octav
Spiru Haret University
octavnegurita@yahoo.com

Abstract

The establishment of a mutual supervision of the banks within the European Union, entrusted to the European Central Bank, is the first stage of the banking union, desired by several countries in the attempt to prevent future crises. The purpose of this union is the supervision of the banks in Europe, identifying and correcting potential dangerous practices in their activities as well as the recapitalization of the financial system in safer conditions, the failure of insolvent financial institutions. Romania, as an EU state, joined the countries participating in the European Banking Union. As a state outside the euro zone, with a fragile banking system in front of the increasingly diverse problems of the economic crisis, Romania will not automatically assimilate the constraints posed by such a system. With the problems this implies, the adherence to this system may represent a step in the sustainable development of the national banking system.

Keywords: special regulations, mechanism, banking system, financing, regulatory framework

J.E.L. Classification: E5

1. Introduction

The establishment of a banking union for the euro area, but also for the banks in the European Union that want to be included in this framework, may represent one of the most ambitious European projects. This project intends to demonstrate the viability of the operation of the eurozone, and the evidence of the financial strength of the European Central Bank as an entirely operational institution. In the context where the banking market in Romania is dominated by credit institutions with capital in the euro

area, our country could benefit from such a financial mechanism that has the potential to strengthen the confidence in the banking system of the region. This concept, where there are many uncertainties regarding the form and its effects, should be analyzed, given that the application of this banking system is an important step towards a greater European integration on different levels, changing at the same time the role of central banks.

It does not have to be denied the fact that the emergence of this banking concept occurs simultaneously with the propagation and continuation of the sovereign debt crisis, affecting increasingly more EU countries. It was from here that emerged more criticism regarding the feasibility of this concept, having in the center the European Central Bank, provided that the main sustainability issues on the monetary plan appeared precisely in the euro area Member States. It was also drawn attention on the issue of common assumption by all the member countries of the losses of certain European banks.

Basically the project aims to centralize the banks' supervision at European level by the European Central Bank (ECB) and the European Banking Authority, using common banking rules at EU level. Also, it takes into account the establishment of a common fund to guarantee bank deposits. European institutions' officials claim that common supervisory measures would strengthen the confidence of depositors and of the markets, and would reduce the vulnerabilities of the European banking sector. [1]

One of the main negative aspects is the fact that it cannot be determined how sustainable is this project and if it works. One problem is avoiding the risks and the resumption of the intermediation at a more or less efficient level, but it is not hard to

predict how soon it can be implemented even in the euro area.

2. The need to amend the national banking system

After prolonged negotiations on the mechanisms of institutionalization of the European Banking Union it was in principle established the start of the first phase of the integrated banking supervision, starting March 2014. The other three elements of the Union do not have a specific timeframe to be applied. Romania is among the countries that are Banking Union Member States. One of the main provisions is represented by the monitoring of large banks by the European Central Bank not only within the euro area, but also in the non-euro national banking systems. What draws the attention is not only the rapid development of such measures, but also the essential character of the provisions of this Union, which reveal the importance of this new community bank concept, the more important for Romania.

Currently, in the national banking system, banks are still a sector with high privileges compared to other sectors. These have special regulations on bankruptcy, refinancing at low cost, and low capitalization requirements. Also, banking companies have the possibility to operate with a fractional reserve, allowing them to keep only a fraction of demand deposits in their deposits. The rest of these demand deposits can be used for crediting, even a few times. In this way, these privileges can only lead to the increase of the moral hazard on the banks, that already exists, as well as to financial risks, more difficult to anticipate in these circumstances. We can add the problem of limited capitalization of the banks, indicator that reaches 14% for Romania. [2]

There may be a concern regarding the association of the Romanian banking system with this Banking Union, since our country is not a member of the euro area. It is also the problem of the other non-euro countries that have adhered to this economic concept. This association comes naturally, especially that most of the banks' capital, in the domestic banking system, is held by banks from the euro area. Over 80% of the domestic banking sector is owned by banks from the Community, represented by the euro area. [3]

Therefore, avoiding this Union would have led to a complication of the economic situation, on the banking plan in our country, since most banks would operate under the supervision of some banking organizations that would evolve, in the other states, according to new financial principles.

Romania could benefit from such a mechanism that has the potential to strengthen the confidence in the banking system in the region, given that, the local market is dominated by credit institutions in the euro area capital. The main purpose of the European Banking Union is to break the link between heavily indebted governments and the banks facing their own difficulties, the central element of the debt crisis that hit Europe in early 2010. While there are more banks holding capital from the euro area, that by establishing this Union would give confidence to the respective banks, this would have a positive indirect effect on the banking system in Romania. [4]

In recent years, the emergence of the disintermediation phenomenon, as well as its impact on the real economy has become a concern in Europe. In Romania, the disintermediation process could consist of reducing funding provided to local branches by parent banks or reducing lending to the private sector. In the current context of the crisis, there has not been recorded in the Romanian banking system a trend, significantly enough to reduce funding by parent banks. This is also demonstrated by the relative degree of reliability of banking companies in Romania. In recent years, the solvency ratio has evolved between 14% - 15% representing higher levels of the prudential threshold of 10% recommended by the National Bank, after the outbreak of the international financial crisis. Those values represent, nevertheless a dose of economic optimism, especially since the credit institutions in our country have continuously evolved in an environment of austerity and uncertainty, by the persistence of the effects of the financial and economic crisis. According to the annual reports of NBR, domestic banks held an action to minimize possible spillover effects, trying to adapt both to the new regulatory framework oriented towards consolidation and to the current requirements of the financial markets. [5]

3. The ECB role within the banking system in Romania

By adhering to the mechanisms of the Banking Union, Romania has accepted subordination, at least partially of certain banking companies and under the supervision of the European Central Bank. The same as in Romania there is only one Central Bank (BNR) that sets rules for all the banks in the system, in Europe as well there should be only one central bank to impose rules for the banks in the system (ECB). Even if the relations with other countries outside the EU should be developed, the reality is that at this moment, Romania's economic exchanges are more than 80% with the European Union, which limits a lot the directions that Romania can take on future development. [6]

So far, the ECB has proved that, it is an institution that has successfully managed the contemporary economic fluctuations, especially the acute financial problems faced by several countries in the euro area. It has often been drawn the attention to the relatively passive role of the ECB within the national banking systems in the euro area, suggesting the idea of the modification of the monetary policy as stipulated. The establishment of the Unique Mechanism of Supervision comes to confirm the need to change the role of the European Central Bank, respectively the growing importance of this institution in the banking activity across the EU. The European Financial Stability Fund (EFSF) and now the ESM (European Stability Mechanism) are seen as useful means to mitigate the cost of the financing sovereign debt of countries in difficulty. Along with the Banking Union, the ESM could have the possibility to capitalize directly the banks in danger of insolvency.

In this context, the entry into force of the Fiscal Union Treaty, along with the attempts to institutionalize the European Banking Union is no longer accidental. This is explained by the fact that a banking union cannot work without tax arrangements, which means common resources for intervention and burden-sharing. The financial transaction tax is mentioned as supply source of a possible Eurozone budget. The transaction tax could be the source for the EU budget. Romania is a signatory state of the Tax

Treaty entered into force as of January 12, 2013.

Our country has a banking market generously dominated by foreign banking groups, overwhelmingly depending on the Eurozone markets. The economy is strongly dominated by the euro and it records a lower level of productivity and competitiveness, based on relatively fragile institutions in front of external economic pressures. The interest for the Banking Union is so natural, that once formed, it will influence the domestic banking system activity directly and indirectly.

There has often circulated the idea of a passive politics of the Romanian banking system towards the evolution, at least for the moment, of the European Banking Union. If the problems of banks in the euro area were solved, it would be great because they control most of the local banking system and automatically this would be more solid. However, things are much more complicated when we are dealing with them in terms of the relations between the national authorities, according to the percentage of the foreign bank capital involved, the relationship of economic power or the degree of euro integration.

Under these circumstances, it cannot be ignored the danger that this requirement of the ECB to optimize the banking groups in terms of liquidity and capital could induce resources movements, destabilizing our country. However, the ECB involvement in the "Vienna Initiative" was meant to stop such a phenomenon after the outbreak of the financial crisis in late 2008. The collective guarantee of the deposit, when established, will also raise a big problem. If it is imposed only for the euro area countries, the ECB will not be able to prevent cash outflows from economies outside the euro area, if the latter are perceived as less solid and the euro is intensely implemented, as it is the case of Romania. In order to prevent such a situation, the guarantee scheme should be extended and there should exist financing lines arrangements between the National Bank and the ECB. These latter could also imply a substantial participation of the European Central Bank to supply the ESM with resources.

Being included within the European Banking Union would mean, for Romania, to

have economic policies suitable for such a structure and, in addition, to participate with resources in financing the intervention devices in the Banking Union. But it cannot be denied the fact that Romania was able to absorb only 10% of EU resources that have been provided. This is an especially more worrying situation as Romania has the obligation to pay contributions to the EU budget. On the other hand, by direct participation in the Functioning of the Banking Union there would be required other national resources, which would increase public debt. [7]

On short and medium term, there is a worrying situation, considering that Romania is one of the EU states with the lowest level of public debt, especially related to the GDP. On long term, the perpetuation of the low level of absorption of EU funds, combined with weak contributions to the EU budget, and that of the Banking Union, may significantly degrade the national financial system. From here to the European Central Bank intervention, in the role of ultimate creditor for our country, there is only one step. [8]

Romania needs a rapid evolution of the performance in absorbing the European resources, in the use of public resources in general as well as in increasing tax revenues. This actually means the overall functioning of the economy, in order to benefit directly from participating to the European Banking Union. Such a development of performance of the domestic banking system would automatically lead to the adoption of the euro. Only considering these issues we can justify the sense of direct participation to the unique monitoring mechanism.

4. Issues on the application of the principles of the European Banking Union in the Romanian banking system

One of the issues raised by the actual existence of the Banking Union is the retention related to the supervision exercised by the European Central Bank. This idea is to limit that power, although within this project, the ECB should monitor all the major banks in and out the euro area. But since this institution is the only strength pillar in the debt crisis, it is not recommended to be

assigned another responsibility of such complexity.

Besides its role as central bank, the ECB has gained the role of principal financial support for indebted countries as well as that of financier of the banks hit by the crisis. This role is undermined by the financial balance and, on behalf of the Eurozone interest, contrary to its own status. In addition, there has not been reached a complete agreement with the EU States to confer the institution the necessary powers. If it recognizes the fact that the ECB is dealing with banks with systematic risk, then it should be given the right to impose measures, above the regulatory institutions in our country.

The responsibility to supervise without also having the power to intervene could represent a dangerous prerogative. This gives the feeling of a European regulation, but leaves all the power in the hands of the National Bank of Romania's authority. Therefore, if all goes well, then the ECB will have effectively no role. But, in the event of a crisis, the ECB could be held liable, which would represent a dangerous precedent in legal and political terms. [9]

Currently, the different structure of the banking system in Romania, the local regulations, and also the legal and judicial systems make it very difficult to apply a Community mechanism to guarantee deposits. Given that there are large European banking companies, comparable in terms of numbers to those of the national income in Romania, the domestic banking system could have serious problems in participating to deposit guarantees for all the banks in the States participating to the Union, limiting its activity.

One of the solutions would be primarily the development of the domestic capital market, so that the share of bank assets in gross domestic product to decrease and the debt accumulated in the banking system not to affect significantly the economic development of Romania. Another solution would be to establish a system of pooling the risks associated with the deposits only at the retail banks level, not including investment banks, whose risk is still too high.

Recent economic developments warn that there is a risk that the whole process of cross-border integration to be destroyed because of

the tendency of the European banks to self-isolate. This economic situation recommends and supports the creation of the European Banking Union as a means to protect the global banking system. The cross border integration process has been developed and enhanced over 20 years and it is in danger to be completely destroyed because of the containment measures taken by the banks in Europe. These have undergone a series of restructurings in an attempt to avoid another crisis.

According to the project of the Banking Union, the ECB will receive the power to authorize and withdraw banking licenses in Romania, to apply new rules on the requirements related to the banks' capital and to perform stress tests and field inspections. It will also have the authority to supervise banks' purchased or sold goods, and the right to impose sanctions for non-compliance in the Romanian banking system. This aspect has generated various criticisms, mainly related to the issue of national sovereignty over its own banking system and whether the ECB will be able to fully understand the specific problems of the banking activity in Romania. [10]

It is not very clear which will be the impact of the Banking Union package on our country that is not part of the euro area. All that it is said, is that our country should cooperate closely with the European Central Bank, with the possibility for this bank to have the same supervisory role in the other non-member states of the euro area. The involvement of the European Parliament or of other national legislative institutions will be limited to an advisory opinion role, which generates the problem of potential authority abuses from the ECB, which will assume the control and supervisory roles of the most important European banks.

The governing rules of the European Banking Authority, one of the three supervisors of the financial sector, created in 2011, is about to be substantially modified in this financial context. In the conditions when it is already known the influence of the European Parliament on the Banking Authority, and the limitation of its prerogatives, it would mean to limit the prerogatives of the European Parliament at the banking level. The attention is drawn on the risk regarding the management of the

extremely complex banking system, within the European Union by a single institution, with relative experience in this field. [11]

5. Conclusion

The establishment of a single supervisory authority is an essential condition in order to enable the direct recapitalization of the banks by the European Stability Mechanism. In this context, the European Council confirmed the month of June 2013 as the deadline for reaching an agreement on the national frameworks better harmonized, on the banking resolution and deposit guarantees. The Commission will introduce by summer time, a single resolution mechanism for the countries participating in the MSU. This mechanism, that will include an effective protection, aims to ensure the financial stability in case of bank failures and to minimize costs for the taxpayers. The European Council stated that the proposal should "be considered as a priority" for its adoption until the summer of 2014.

The European's Commission Project, which requires strengthening the supervisory responsibility at the level of the European Central Bank, for the larger banks in the community space, has caused serious disagreements. One of the friction points is the connection between the 17 Member States of the euro area and the ten states outside the Monetary Union, namely the right to vote in the future supervisory council of the ECB. In Romania, the euro area banks have a significant share in the banking system. In recent years, it has managed through its own important efforts to strengthen the prudential parameters even above the levels required in their home countries. Taking into account the expected developments, it is absolutely natural the desire to avoid the error of these indicators, at least on medium term.

Considering that the supervision of the banks with capital in the euro area, could be exercised both by an authority at European level (European Central Bank) or by the National Banking Authority (BNR), it is absolutely necessary to clarify the issues related to the decisions' ranking. The cooperation framework between the centralized supervision at EU level and the national supervisory authority, as well as the

harmonization of different points of view between the central supervisory authority at EU level and the one in our country, if it reaches such situations. [12] It is obvious the connection between the Fiscal Union Treaty and the establishment of the European Banking Union. Given that the European economies are characterized by an increasingly high degree of fiscal memory it is obvious the need to start a fiscal coordination action of the Community Member states that could go beyond the frontiers of the euro area. This is even more evident as the Banking Union targets both the euro zone countries and the non-euro member states wishing to participate in the scheme.

Corruption, with Emphasis on Health System

Pană Cristina Elena

Bucharest University of Economic Studies

crisrina_mace@yahoo.com

Nișulescu-Ashrafzadeh Ileana

Bucharest University of Economic Studies

nisulescu_ileana@yahoo.com

Abstract

For nearly 20 years, corruption in the health system damages the state budget and health insurance budget. This article is aimed at initiating a warning sign on to illegality and the factors that led to this situation.

According to the statistics on fraud in the health system, in 2004 they amounted to 1.6 billion Euros, and in 2012, since the financial crisis has led to drastic cuts in the budget of medical units, its value decreased to 300-400 million Euros.

To quantify the impact of corruption on the healthcare system, we used global indicators of corruption, but with direct impact on the health system, including: index of perception of corruption and overall integrity index.

Keywords: health system, transparency, corruption, index of perception of corruption, global integrity index.

Codes JEL: E02, I11, H 51, K42,

1. Introduction

Romania is one of the member countries of the European Union that has unsolved problems in managing corruption and bribery. Public transparency, monitoring, limiting and restricting are just a few chapters on corruption and fraud. Corruption in Romania has experienced exponential growth in recent years, and helped by the "bureaucracy of the public, and by the resignation of the control bodies, by an attitude of <<we can do nothing about it >>" [1].

According to the global corruption barometer in Romania, the most corrupt sectors are the political parties and customs, followed by judicial, legislative, police and medical system.

In low income countries, citizens tend to pay a significantly higher percentage of their income on bribes than those in high-income countries. Corruption creates a dramatic impact on the lives of low-income people; they are forced to pay bribes to obtain a public service to which they are entitled.

"Unspoken demand of bribes does not mean a form of corruption less damaging than a direct solicitation of bribery, especially if the refusal to pay means you will not receive the necessary medication to stay alive "[11] . According to the Global Barometer "corruption affects the lives of people around the world and is threatening their ability to enjoy human rights and public services" [11].

In Romania, corruption is manifested in various areas, and in varied and complex interactions, but it is dominant in the budget arena.

Corruption flourishes when there is no transparency, and accountability and transparency are basic conditions for integrity and preventing corruption.

Regarding health system transparency, none of the health units can meet the legal requirements of information. Under these conditions of opacity, we can not speak of improving the quality of services, combating fraud and obtaining efficient costs in the health system in Romania. Any analysis outside of the health system in Romania is facing the opacity of the National Health Insurance House and the Ministry of Health, which published very little of the information they hold. This does not allow stakeholders to analyze health system as a whole, the

situation of a sub-domain or that a particular county or supplier.

2. Research Methodology

This paper combines qualitative and quantitative research, using specific methods, document analysis and content analysis. To achieve the objectives we used a series of bibliographical sources which consist of books, accounting rules, tax and legal studies and articles published in various national and international organizations in the field. To this end, we collected data from Transparency International Global Corruption Barometer, Global Integrity and the European Commission, the European Anti-Fraud Office, in order to make a comparative analysis, of focus group type, in terms of healthcare, Romania, EU in 2011.

Variables were used on the dynamics of corruption, such as the index of corruption perception and the global integrity index.

3. The research results

As in any field hidden to glances and assessments, the risk of major slippage occurrences is very high. The most common ways to defraud the Romanian health system are:

- Preparation of fictitious prescriptions free or compensated filed with the County Settlement Houses (there were found in the system settled prescriptions for people who have not been to the doctor long periods of time, and even deaths)

- Illegal completing of prescriptions by pharmacists (the prescriptions is prepared by a doctor with 3-4 drugs, then, after the patient gets the medicines, the prescriptions are compiled with another 1-2 drugs for which they subsequently receive money from CNAS.

- In medical analysis laboratories a patient is actually given a small number of laboratory investigations, deductions being made for many more investigations that the patient did not have, or the investigations are conducted on behalf of another patient for uninsured persons.

- Sick leave granted without justification or for a longer period of time than necessary.

- The award of contracts by the procedure "negotiation without prior publication of a

contract notice", at a rate of 21.86% of all contracts awarded. Most times, they are generating unacceptably high costs for rehabilitation of health units.

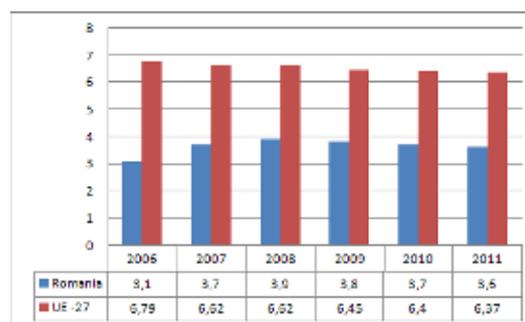

As you can see, one of the main methods of defrauding of public funds is targeting bogus prescriptions. They have made considerable profits to drugstore chains, at the expense of the state budget and it was a factor for stimulating growth in the number of pharmacies. Thus, there were in December 2011, a number of 7259 pharmacies, respectively 1,896 inhabitants per pharmacy, almost double compared to the EU average of 3,400 inhabitants per pharmacy.

Compared to the number of inhabitants, Greece occupies the first place in the EU with a pharmacy for 1110 residents, followed by Romania, and Belgium, with 1,988 inhabitants / pharmacy.

In order to determine the impact of corruption on the healthcare system, we used global indicators of corruption, but with the direct impact on the health system, including: index of perception of corruption and overall integrity index.

Corruption Perceptions Index (CPI) is an index based on data regarding corruption; it reflect the views of business people and analysts from around the world, including experts from the countries assessed (Figure 1).

Chart 1. Evolution of the index of corruption in Romania and the EU 2006-2011 (IPC)

Made by the authors. Source : Transparency International

European Union countries with a low score of the index in 2011, are the countries most affected by the economic and financial crisis, namely: Romania (position 24th), followed by Bulgaria, Italy and Greece. Globally, Romania ranks 75 out of 176

countries analyzed. In 2012, CPI increased from 3.6 in 2011 to 4.4, so the result is a lower perception of corruption by 0.03. If we compare CPI the evolution of Romania to the EU average -27 we see a reduction in this gap from 3.69 in 2006 to 2.77 in 2011.

Denmark, Finland and New Zealand are tied in first place, recording the highest CPI score of 9 points due to growth and the rules governing the behavior of people in public office. Afghanistan, North Korea and Somalia occupy last place with a score of 0.8 due to lack of responsible leadership of effective public institutions and lack of concern for corruption.

Globally, areas perceived to be most affected by corruption, are considered to be those shown in Table 1:

Table 1. Domains the most affected by corruption

Political parties	4
Parlament	3,7
Police	3,6
Legal/Judicial System	3,5
Businesses/ Private Sector	3,4
Customs	3,3
mass- media	3,2
Medical services	3,2

Made by the authors. Source :Transparency International

Corruption is seen frequently in many sectors from the political parties, police, and customs agents to healthcare, education etc.

This web of "corruption" that is present in all areas, more or less, affects daily life around the world threatening people's ability to benefit from public services. "When a government is corrupted at high-level the power to reform lays in the hands of those less able to do so." [9].

On a scale of 1 to 5.5 political parties fall into the category "extremely corrupt", [9] recording a score of 4.0. Perception of widespread corruption in terms of political parties transcends regions and even purchasing power.

Not all countries have indicated political parties as the most corrupt sector. In many countries of Central and Eastern Europe, including Bulgaria, Kosovo, Moldova, Romania, Serbia and Ukraine, customs

officials were considered to be the most corrupt.

Global Integrity Index (GII) quantifies the existence and effectiveness of anti-corruption mechanisms that promote public integrity. Integrity Indicators are assessing both the existence of laws, regulations and institutions meant to stop corruption, as well as their implementation and the free access of citizens to those mechanisms. Global Integrity Index can range between 0 and 100 (Table 2).

Table 2 Values of Global Integrity Index (GII)

Values of index	Interpretation
sub 60	very faint fight of corruption
(60 – 70]	faint fight of corruption
(70 – 80]	moderate fight of corruption
(80 – 90]	good fight of corruption
peste 90	Very good fight of corruption

Made by the authors. Source :Transparency International

In the year 2011, in South East Europe GII presented these values as in Table 3

Table 3 Index GII for South-East Europa

Romania	79*
Bulgaria	84*
Croatia	N/A
Bosnia and Herzegovina	61
Serbia	73
Montenegro	56**
Albania	74*
Macedonia	78
Greece	N/A

*data available 2010

** data available 2008

N/A data are not available .

Since the overall assessment in 2008, when it scored 80, Romania has changed very little in this area. Yet it occupies a leading position among the countries of Southeastern Europe. Elements of anti-corruption in the public sector exist, but they continue to be ineffective largely due to inadequate staff and low funding of the

system. Surveillance of public service remains weak, including ongoing challenge of political criteria and nepotism (in hiring key positions). Montenegro (56) and Bosnia and Herzegovina (61) occupy the last places because of the institutions which, though they should be the backbone of anti-corruption (the judiciary system, anti-corruption agency, the Central Election Commission) are facing problems, such as lack of capacity and strong political influence. The south-eastern Europe, Bulgaria has the highest score (84) fitting into the category of good fight against corruption. This is due to robust regulations governing public service.

4. Conclusions

Health is an area of major social impact, which may provide evidence for the adoption of policies, but it is also a fundamental value both for individuals and for society, being the main premise of fulfilling social roles by each of us. The health system has been for a long time in a state of prolonged crisis.

"Romania loses about 1.6 billion Euros annually because of fraud existing in the medical system in the form of informal payments made to medical personnel or by recording treatments which have not been made," according to data presented by Paul Vincke, President of the European Network of anti-corruption and fraud. [5]

According to existing studies worldwide waste of healthcare resources is caused by fraud and corruption (by up to 19-20%), administrative inefficiency (17%), errors and inefficiency of health care providers (12%), over consumption-or avoidable health services (40%), lack of coordination between institutions in the system (6%) and health care that could be prevented (6%), "explained Paul Vincke. [5].

According to national health officials, fraud size can be assessed only after a year from the introduction of the health card.

"Today, it is estimated that fraud in the healthcare system is about 10-20% of total revenues, and the introduction of the new system of "electronic prescriptions " will reduce bureaucracy in the health area and will allow medical prescriptions control and transparent use of money".[2].

Corruption makes economic growth difficult, inefficiently allocates national resources, weakens the administrative system efficiency, contributes to the decay of political system and undermines stability, democracy and national integration.

In our opinion, several factors leading to the emergence and flourishing of corruption are:

- Lack of transparency in government;
- Low salaries and promotion rate in functions based on "connections" and nepotism;
- Non-professionalism, incompetence of civil servants;
- The proliferation of bureaucracy.

Some other factors can also be added.

Lately, there is a lot of talk about the introduction of centralized procurement system for healthcare, which would help in the management and saving of funds.

Purchase of more equipment at the same auction would lead to lower prices because there is a much greater and stronger competition in the participating companies.

This centralized procurement would lead to more transparency in the public procurement. However, we should not minimize the impact of the time factor in the purchase decision. Will purchases be made in time or the system will cause other problems? Time will tell.

Mihail Manoilescu, a Professor of the Polytechnic School

Paiusan Robert

Bucharest University of Economic Studies

Abstract:

The paper focuses on Manoilescu's nomination as a Professor of Economics, Organization and Rationalization at the Polytechnic School of Bucharest in 1931 and his dismissal in 1944. The biographical sources include the archives of the institution.

Key words: Mihail Manoilescu, Polytechnic School, Professor, Economics.

JEL classification: B20, B31.

1. Introduction

Much has been written both during his lifetime and in these last decades about the multifaceted (scientific, didactic, political and publishing) activity of Mihail Manoilescu, the most advertised Romanian economist of the first half of the 20th century. This contribution focuses on his didactic activity carried on at the Polytechnic (later Politehnica) School of Bucharest between 1931-1944, in general, and of the circumstances of his appointment and dismissal from office, in particular.

2. Manoilescu, the Professor

Manoilescu acted as a professor at the Polytechnic School following a strange competition, he had not signed in. The competition for the professor in full vacancy at the Department of Economic Sciences, Organization and Rationalization with the Polytechnic School of Bucharest had been announced in March 1931. Two candidates had submitted their competition dossiers until the registration deadline: Adrian-Dumitrescu-Bumbesti and Ilie Gârbacea.

The Board of Education of the Polytechnic School designated in its 16 May 1931 meeting a commission consisting of three members to verify the titles and the

works of the competitors and to recommend the most appropriate candidate for said vacancy. The commission included Constantin Busila, Dumitru Busuiocescu, both professors in full of the Polytechnic School and Professor Gheorghe Tasca, a first-rank personality of the Romanian economic education of the age and, as will become apparent, the most subtle connoisseur of the candidates' activity. Tasca acted as full professor both at the Faculty of Law of the University of Bucharest (where the candidate Dumitrescu-Bumbesti had defended his doctorate in economics) and at the Academy of High Commercial and Industrial Studies, where candidate Garbacea had defended his doctorate. After designation of the competition commission, he would refer to the papers presented by the two candidates, of which he had requested copy [1].

Adrian Dumitrescu-Bumbesti had presented seven papers, including the doctoral thesis, focused on the themes of the development of the cooperation and the private credit in Romania. After describing each of them briefly, Tasca and the other members of the Commission reached the conclusion that they were out of the scope of the specialty of the referred department, and the candidate could not possibly prove – as required by law – and effective scientific activity in the least five years at least.

Ilie Garbacea was at the time of registration for the competition, a professor of industrial accounting and the study of industry and trades in Romania at the Commercial Academy in Cluj. He had presented four papers, including the doctoral thesis, on the profile of such disciplines. There was between the position in Cluj and that he applied for in Bucharest, as the Commission found, a 'very remote relationship'. This candidate could not prove either a scientific activity in the specialty the last five years.

The candidate who claimed the honour to fill in the vacant position, maintained the Commission, had to prove the in-depth knowledge of economic science, of the doctrines and of its method. Or, the two registered candidates were far from meeting such demands, and therefore they could not be appointed. Instead, as the report stated, the Commission proposed the appointment in the vacant position of Mihail Manoilescu, an engineer, an honors graduate of the Polytechnic School of Bucharest, ‘though he did not claim this teaching position’. This appointment was justified by the scientific activity of over 15 years (more precisely, 11 years, n.a.) when he approached the economic issues ‘with the power of a thorough connoisseur of the subject and of a passionate innovator’ [2].

If for the two candidates, we could only suppose who the main author of the report was, the appreciations on Manoilescu’s scientific activity certainly belonged to Tasca. The latter had not only a higher training in that line than the two members of the Commission, but he was accustomed for some time with Manoilescu’s economic ideas.

3. Manoilescu’s contribution

Tasca used to mention among his writings, first ‘Théorie du protectionnisme et de l’échange international’, published in Paris, in 1929. In a well-known review dated 1930, he was critical about some basic concepts introduced or redefined by Manoilescu, such as work productivity, net value, individual and national gain a.s.o. [3] This time, the tone of the appreciations was much more benevolent: the courage and boldness to elaborate a general theory of protection made honour to the author.

The theory built by Manoilescu started from three sentences, as Tasca called them, depending on the factors which determined the work quality, the opposition between the national and individual gain and the differences between the international and individual exchange. Even if some of us, Tasca concluded, in a prudent note, did not fully agree with his scientific approach, Manoilescu’s work remained the most brilliant economic book published by a Romanian author in the last decades [4].

Tasca’s comments would be resumed usually without citing the source, in many writings on this theme issued in the last decades.

Tasca’s change of attitude could be explained at least partially, by political aspects. As an ambassador of Romania in Germany and the Netherlands, professor Tasca felt he was bound to support the appointment of Manoilescu, a favourite at that time of King Charles II in the vacant position of the Polytechnic School. Later, after his fall from grace of the sovereign, Tasca would resume the polemic dialogue with him.

On 29 June 1931, the report of the Commission including the recommendation for the appointment of Manoilescu in the vacant position was approved during the meeting of the Board of Education. On 9 July, the director of the School addressed to the Minister of public instruction asking him to act in this respect. The minister informed him on 5 August that under the High Royal Decree no. 2843 of 1 August 1931, Manoilescu was appointed full professor at the Department of Economic Sciences, Organization and Rationalization starting with 1 September 1931 [5].

As a professor, Manoilescu was a dynamic and jolly presence, close to the students. He would speak freely, with wide digressions from the theme of the lecture, while keeping the text of the lecture on the chair. Year after year he attempted to bring new elements, in point of contents, and of the presentation of the courses. Florin Manoliu and Cristian Petrescu were among his assistants.

A topic that was constantly brought to the attention of the students was turning to value human personality, both at the level of the individual and at the national level. In every generation, he used to say to the students [6], the relation between the valuable young people and the mediocre ones maintained almost constant. Therefore, he pleaded for the careful widening of the number of students, considering that a sudden raise – claimed by some student organizations of the time – would inevitably lead to the degradation of the level of the educational process. The student engineers, as Manoilescu said, gathered a too high number of valuable young people, who were removed from other professions. Flattering for the

audience, even if not entirely confirmed by the statistics of that time, this fact could not be a reason of concern for the doctrinaire of Romania's industrialization, but – on the contrary – of real satisfaction.

An old custom required from the professors that in the inaugural lecture of every academic year, they should approach from an original perspective, a theme concerning the object of study, the methodology of the discipline and its interferences with other domains. The inaugural lectures delivered by Manoilescu between 1931-1937: *Method in economic sciences* (1931), *Economy, science, technics* (1932), *Economic science and the engineer's career* (1933), *Spiritual autarchy in economic science* (1934), *Economic science and collective ideals* (1935), *Mathematical method and the issue of human will in economy* (1936) and *Human will in economic science* (1937) would be published in the volume *Attempts in the philosophy of economic sciences*, edited in 1938. The volume was reviewed among others by I. Veverca in 'Economic and Statistic Annals', 7-10, 1938.

The academic lecture of political economy delivered by Manoilescu – including, besides the inaugural lectures, other 21 lectures – was lithographed first by a group of students and published in 1933 and 1934. The course was reviewed among others by M. Platareanu in the 'Economic and Statistic Annals', 4-6, 1933. The author continued to complete his lectures and edited them under the form of a *Course of political economy and rationalization*, Bucharest, 446 pp, in 1940.

His performance as a professor was affected by his many concerns and interests. Starting from here, some of his contemporaries reproached him, more or less directly, inconsistency and superficiality. The most vocal of his critics reproached him that not every economic heresy should be communicated to the students, despite the charm of novelty [7].

His removal from office had, just like his appointment, a political connotation. Before the end of the courses in June 1944, Manoilescu had joined his family in refuge at Breaza, where they watched greatly concerned the development of the war. The fast on-coming of the frontline to Romanian

borders was distressing for a public personality with Manoilescu's past. Under such conditions, mid-August the departure preparations for settlement in Portugal started, which represented a triple advantage to be a neutral country, geographically protected against any foreign invasion and with a political system ideologically close to Manoilescu. Besides, the Portuguese prime-minister Salazar was, at least declaratively, an admirer of his writings and had urged him eight years before to continue his professional career, if need be, in his country.

4. Adverse events and consequences

Acting in this sense, Manoilescu had a meeting on 23 August, in the morning, with the Ambassador of Portugal in Romania, who was at the time on Valea Prahovei. The latter assured him that he was instructed to grant for the whole Manoilescu family the entrance visa for Portugal, which would occur in a few days. His trip would take place by air from Bucharest. But, just like on so many previous occasions during his life, the events took an unexpected turn. After the act of 23 August and the transformation of Bucharest in a battlefield, the variant of travelling by plane became too risky. Another way seemed safer: boarding on a train with Romanian-German ethnics that would leave from Brasov to Germany on 26 August. Manoilescu was assured he would have a train compartment for the whole journey. But the declaration of war between the former allies Romania and Germany and the prospects of his internment as an enemy citizen (and, moreover, a former dignitary) in a German concentration camp removed this variant too. An important role was played in this episode, according to the family memories of his nephew [8], the fact that leaving the country in a German train was equal, under the given circumstances, with desertion to the enemy, which would have disqualified him morally.

After the beginning of the academic year, Manoilescu wrote to the rector of the Polytechnic School on 8 October that, for health reasons, he would settle temporarily in Breaza and requested for a 3-month leave starting with 1 November 1944 [9].

The new government in Bucharest made his intention known to judge the dignitaries of the former political regimes guilty for the

country disaster, and for the territorial losses incurred by Romania in 1940 and for the political approach to Nazi Germany. In this context, the former dignitary Manoilescu was arrested on 12 October 1944 and brought for hearings to the headquarters of the Police Prefecture of Bucharest. The Rector of Politehnica (where his application had been registered on 14 October) distantly notified that ‘as at the present you are under arrest, your application for leave is not approved’ [10].

Early February 1945, Manoilescu got ill of typhus exanthematicus and was transferred under guard to Colentina Hospital. There, he continued to be investigated between rounds of treatment. In the hospital, Manoilescu received the visit of his family and friends, with whom – according to a delation of his political adversaries – was eating delicatessen and was drinking champagne. Developing a *viveur* image, partying while the rest of the population was affected by the war and by indigence was meant to make him detestable to public opinion and to prepare his marginalization.

5. Conclusion

Still unrecovered, Manoilescu was reincarcerated at the police headquarters in Bucharest on 19 May 1945. Two weeks later, on 2 June 1945, the Rector of Politehnica ‘had the honour to inform him’ that he had been dismissed from the position of full professor starting with 24 May 1945,

according to the note received by the Ministry of National Education [11].

Economic Development and Migration in European Union

Prada Elena

The Bucharest Academy of Economic Studies

elena.prada@gmail.com

Abstract

This article is based on data provided by World Bank and deals with the question of how migration correlates with economic development of the countries where the migrants are living in. In order to prove that, I studied whether the International Migration Stock and Net Migration of several countries, including Romania, are related with Gross Domestic Product, as a variable regarding economic development, and I employed some other variables regarding education, health and employment, as they are the main reasons for migration decision of people.

Key words: migration, economic development, regression.

JEL classification: C21, F22, J01, O15, O30.

1. Introduction

Economic development refers to a series of measures or policies taken to ensure an optimal interaction between the four systems: economical, technical, human and environmental. Economic development is different from economic growth but is based on its components. Economic growth is a process of positive changes in the level of economic results commonly measured using the Gross Domestic Product indicator.

Douglas S. Massey[9] defined economic development as being the application of capital to raise human productivity, generate wealth and increase national income.

Migration represents the physical movement from one area to another, for a period a time or definitively. Migration plays an important role in economy, it has an impact on the welfare of households and its influence is reflected on labor market, as well. Labor market implies three major issues: employment, unemployment and

wages. The main link between migration and economic development is that higher level of development brings more mobility. Usually, people migrate for a better quality of life through higher paid jobs. The benefits of migration to origin countries are obtained mostly through remittances which represents personal flows from migrants to their families. As *Devesh Kapur*[7] considers, remittances are emerging as an important source of external development finance and are one of the most visible aspects of how international migration is reshaping the countries of origin. His is bringing an idea that remittances have become a new “development mantra”: governments and officials believe that money sent home by migrants can be a reason for local, regional and national development. Based on his idea, *Stephen Castles*[3] extended this notion of a “new mantra” and included the whole range of benefits that migration is said to bring development:

1. Money remittances: bigger than official development aid
2. Social remittances: migrants transfer home skills and attitudes for development
3. “Brain drain” which benefits both sending and receiving countries
4. Circular labor migration benefits: for receiving countries, origin countries and migrants
5. Economic development will reduce out-migration

The Report for 2008 on the level of remittances in the world economy of the World Bank presents the situation of cash flows and at the level of remittances within national economies where the gross domestic product is highly dependent on this type of incomes[1].

An OECD study based on OECD countries and non-OECD countries shows that the relationship between the total emigration rate and the income level of

origin countries follows an inverted U-shape relationship: total emigration rates are very low for low income countries, higher for lower-middle and upper-middle income countries, and decrease again for high income countries (although they remain higher than for low and lower-middle income countries). Second, this pattern is different for the migration rates of the tertiary educated, where no large differences in emigration rates for the three groups of developing and emerging countries is observed, while high income countries have noticeably lower emigration rates[5].

2. Data and Method

Data used for the study comes from World Bank database, unfortunately for some important variables there are limits on the availability of data.

All variables are analyzed for the year 2010 for 28 countries of the European Continent (Bulgaria, Romania, Latvia, Lithuania, Hungary, Croatia, Poland, Czech Republic, Slovak Republic, Portugal, Slovenia, Greece, Cyprus, Spain, Italy, France, Belgium, Germany, Netherlands, Austria, Finland, Ireland, United Kingdom, Denmark, Sweden, Iceland, Norway, and Luxembourg). Croatia in 2010 was in process of integration in European Union and she will become a member on 1st of July 2013.

Although there a limitation concerning data availability, I have found and used a series of variables for covering both economic development and migration in order to identify if there is a correlation between them.

As endogenous variables I have considered:

- *Net migration* is the difference between immigration to and emigration from a given area during the year (net migration is positive when there are more immigrants than emigrants and negative when there are more emigrants than immigrants). Since many countries either do not have accurate figures on immigration and emigration, or have no figures at all, net migration has to be estimated. It is usually estimated as the difference between the total population change and the natural increase during the year. Net migration gives no indication of the relative scale of the separate immigration and

emigration flows to and from a country; a country may report low net migration but experience high immigration and emigration flows.

- *International Migration Stock % of population* is the number of people born in a country other than that in which they live and it also includes refugees estimated for a particular period (usually a year) related to the total population of the receiving country.

Comparing these two variables we can conclude that the last one gives indication of the immigration stock of a country.

- The set of exogenous variables used are: *GDP per capita* – highlights the economic development of the analyzed countries;
- Compensation of employees and Unemployment Youth, ages between 15 to 24;

Compensation of employees (at current prices) (ESA95, 4.02) is defined as the total remuneration, in cash or in kind, payable by an employer to an employee in return for work done by the latter during the accounting period. Compensation of employees consists of wages and salaries, and of employers' social contributions.

- education: *Primary school enrollment*;
- health and demographic: *fertility rate* (the expected number of children born per woman in her child-bearing years), *life expectancy at birth*.

Considering the methods involved in the existing literature the main influence on migration is reflected by GDP[6] or GNP used by *Rotte and Vogler*[14] instead of income or wage variable, where they've studied the migration from least developed countries (from Asia and Africa) to Germany, by comparing the OLS model with random effect panel model(two depending variables – asylum migration and inflow – in correlation with economic opportunities (GNP per capita ratio home/Germany), political situation and home country characteristics (urban population, distance to Germany)), they concluded that the total inflows reacted to political freedom and the distances is significant only for Asia.

According to World Bank Metadata, *GDP per capita* is the final result of the production activity of resident producer units and it is often considered an indicator of a country's economic development. As we can observe

from *Table 1*. Luxembourg has the highest per capita Gross Domestic Product, which clearly stands out from the other countries, at opposite stands Bulgaria and Romania.

Table 1. GDP per capita rating for year 2010. Source: World bank Database.

Top 5 countries with the highest GDP per capita		Last 5 countries with the lowest GDP per capita	
52222.5	Luxembourg	5633.9	Hungary
39970.2	Norway	5332.5	Lithuania
33943.1	Iceland	5011.2	Latvia
32631.1	Sweden	2636.7	Romania
30667.8	Denmark	2555.1	Bulgaria

A study based on data from Eurobarometers on multinomial Logit model is analyzing the macroeconomic determinants (GDP per capita, Unemployment rate, Years of schooling and Gini Index) of migration abroad intentions in Europe by comparing two moments of time: 2002(UE10) and 2005(UE15) – capturing the 2004 enlargement of UE[15], the conclusion was that young educated people tend to migrate between EU countries.

An OLS model regarding British Columbia Net Interprovincial Migration was described by Schrier and McRae[13], in this model the dependent variable, the estimated annual British Columbia net interprovincial migration from 1985 to 1998, is studied along unemployment rate and GDP for determining a prediction equation on Interprovincial Migration.

Yashiv and Levy[8] estimated OLS and Fixed Effects regression models to examine the effect of customary migration determinants on the flow of migrants to Israel Comparison between Israel, Europe and the United States 1990-2004.

3. Results from the OLS model

Gross Domestic product is a sign of economic development by measuring the growth of goods and services of a country, it covers the production of government,

households, and even the investments in goods.

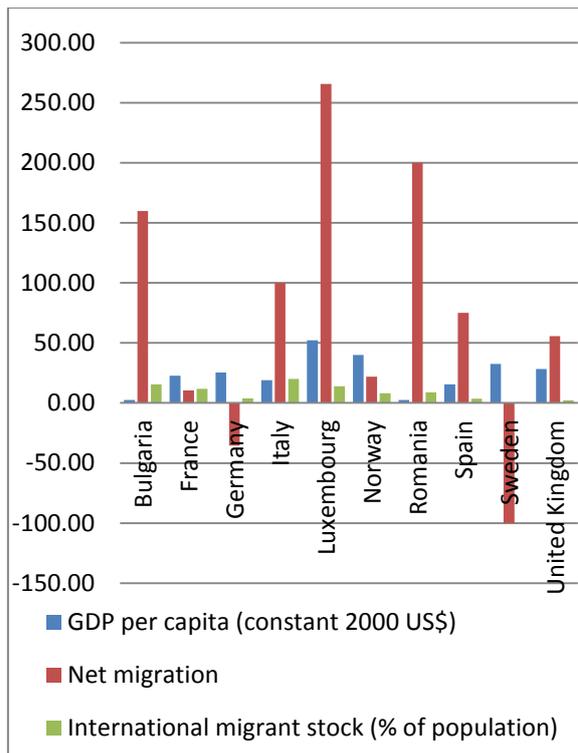

The correlation between GDP per capita and the migration variables: international migration stock and net migration can be shown by building a bar chart. For the figure below I have used the data from a few important countries implied in the migration phenomenon as sending and receiving migrants.

We can observe that for Sweden there are more migrants than immigrants, though has a high Gross Domestic Product per capita, probably this an effect of weather conditions, unfortunately there was not any available data for the net migration and international migrant stock besides the year 2010 to compare the evolution of those variables.

The outstanding country is Luxembourg which has the highest Net migration and the second highest international migrant stock, having more immigrants than migrants. It is renowned that Luxembourg has survived the financial crisis and still it is considered the country with the highest standard of living. Hence, people tend to migrate to countries that offer better living conditions.

Romania has a high net migration and comparing it with the international migration stock we can conclude that Romania is also a receiving country.

Figure 1. The correlation between GDP per capita, International Migration Stock and Net Migration. Source: World Bank Database.

Assuming that there is a correlation between the exogenous and the endogenous variable described above, first we need to show if there is any correlation between all the variables studied through Pearson Correlation Coefficient by analyzing if each dependent variable has a significant Pearson Correlation Coefficient with each independent variables.

As it shows in the table below:

- Net migration has strong linear correlation with life expectancy and unemployment youth ages 15 to 24 – if net migration is positive it means that life expectancy and unemployment youth ages 15 to 24 are reasons for migrating.
- International migrant stock has strong linear correlation with GDP per capita and primary school enrollment – it means that people settle into a country concerning its economic development and the opportunities of education.

Table 2. Pearson correlation between studied variables. Source: based on author's calculation.

Variables		Net migration	Internat. migrant stock
Comp. of employees	Correl.	-0.227	0.161
	Sig.	0.246	0.414
	N	28	28
Fertility rate	Correl.	-0.084	0.205
	Sig.	0.670	0.296
	N	28	28
GDP per capita	Correl.	0.080	0.651
	Sig.	0.686	0.000
	N	28	28
Life expect. at birth	Correl.	0.449	0.461
	Sig.	0.016	0.014
	N	28	28
School enroll.	Correl.	0.293	0.013
	Sig.	0.130	0.947
	N	28	28
Unempl. youth ages 15-24	Correl.	0.301	-0.160
	Sig.	0.120	0.415
	N	28	28
*. Correlation is significant at the 0.05 level (2-tailed).			

We can observe that there is a linear correlation between some variables and so we can proceed to the Ordinary Least Squares Multiple Regression Analysis, represented mathematically as:

$$Y' = \varepsilon_i + \beta_1 * X_1 + \beta_2 * X_2 + \beta_3 * X_3 + \dots + \beta_k * X_k$$

Where the Y' is the endogenous variable and X_k are the exogenous variables.

To explore the relation between migration and economic development I considered a various econometric models based on the two endogenous variables.

First model refers to the correlation between international migration stock and the exogenous variables and the second has as an endogenous variable net migration.

All OLS regressions described are synthesized below into a table, where we presented the coefficients and the significance of all the variable of the models above.

Table 3. The estimated linear regression results.

	The international migration stock(%)		The net migration	
	M1	Sig.	M2	Sig.
Constant	17.12	0.60	-1.301E7	0.00
Compens. of employees	0.319	0.02	-22555.0	0.07
GDP per capita	0.001	0.00	-5.25	0.67
Unempl. youth ages 15-24	0.26	0.03	28809.8	0.01
Fertility rate	-12.8	0.00	-725209.6	0.06
Primary School enrollment	0.175	0.43	4990.3	0.80
Life Expect. at birth	-0.33	0.47	175055.0	0.00
R ²	0.688 (68,8%)		0.627 (62,7%)	
F	7.708		5.881	
Sig. F.	0.000		0.001	
N	28		28	

Source: based on author's calculation.

We can observe that the Significance(Sig. F) of the models based on ANOVA test it is under $\alpha=0.05$ for both models, this confirm that there is a direct influence on migration and the independent variables considered. Both models show that there is a strong relation between the dependent variable and independent variable: over 60% of the variation of migration (represented by international migration stock and net migration) explains the variation of the variables included in models.

Regarding the model M1 it shown that if the country is developed and has a high GDP per capita, the international migration stock increase with 1% (0,001).

As for the second model M2, there is a low significance of linear connection between GDP and net migration.

Primary school enrollment has no significant importance on both models, despite the expectations.

Compensation if employees has strong influence for both models and we can conclude that the development level of a country has an influence on migration and also people tend to migrate where they are paid better.

The youth unemployment rate has a significant positive impact on both models, if it increases the exogenous variables are increasing, 2,6 % of population in case of the internal migration and about 28809 persons in case of the net migration.

Migration is strongly influenced of the employment factor, migrants are always tending to look for a secure and better paid job.

4. Conclusions

The financial crisis affected both the emerging countries, that are a part of European Union (or will be part of it as in case of Croatia), and the developed ones confronting with high unemployment rates.

In 2011 the youth unemployment rates were at unprecedented levels: in Spain 46,4%, in Greece 44,4%. As we know the sending countries are facing with high unemployment rate or low life expectancy rates as a measurement of welfare, and so the migrants tend to establish in more developed countries.

It is obvious that migration is a fact that cannot be denied by both sending and receiving countries. The migrant receiving countries are often developed countries and the sending countries are often developing countries. Migration is seen as a way to make use of the excess labor force and eventually reducing the unemployment rate in the developing countries.

Migration it is not an issue itself, it is a result, it shows that the sending countries are having issues at the economic levels which are reflected into the sociological levels.

Abstract

Microfinance in general and the microcredit especially has a major role in the economic growth of a country and an important social impact, supporting the social inclusion. Moreover, its role becomes more vital, if we take into account the major negative effects of the recent financial crisis, because it can significantly contribute to the creation of new jobs and new added-value generating activities. Such considerations make the development of the microfinance sector to be a priority on the working agenda of the European decision makers. On this background our research aims at underlining and discusses the recent evolutions but also the major characteristics of the European microfinance landscape. Through its content, our research seeks to highlight the vital necessity for supporting the development of the microfinance sector in the EU member countries for the recovery of the national economies.

Key words: microfinance institutions, micro lending, microenterprise, social inclusions, European countries

J.E.L. classification: G21, G23

1. Introduction

At the international level it is acknowledged that microfinance provides financial services to persons with a low income, that do not have access to traditional banking services [1]. Comparatively with the international practice of microfinance that refers equality to microloans, savings and insurances, in the European countries

microfinance is focused especially on microloans and the offer of other financial services is limited by the juridical framework. Moreover, it is noted that the preoccupations of the European Commission and the EU instruments for the supporting of the microfinance activities are focused exclusively on micro-lending [2, p. 36].

In the last years the European microfinance sector and especially the microloans have registered a significant expansion having an important contribution in the helping of the microenterprises, of the self-employment and also of the social inclusion. Despite these, the disparities between countries regarding the regulatory, institutional and commercial framework make the development of the European microfinance market to be in the incipient phase registering an important gap between the demand and supply of microloans [3].

In this context, our research aims at underling key facts and figures regarding the European microfinance sector, with a special focused on microloans, and brings into discussion the most important characteristics and evolutions of this sector in the context of the recent financial crisis. Because of the reduced availability of the data regarding the microfinance activities in Europe, our study is based on the statistical data obtained from the European Microfinance Network (EMN) surveys. Mainly we have been focused on the 2010-2011 survey, that has covered 154 microfinance institutions from 32 European countries, from which 18 were members of the European Union and the rest were member countries of the European Free Trade Association, EU candidate countries and other European countries.

Our study is structured as follows: the

second part of the paper aims to highlight some key features of the microfinance system in the European countries and to highlight the lending patterns practiced; the third part emphasizes some major evolutions recorded by the European market of microcredit and some implications of the recent financial crisis. Our research ends with conclusions.

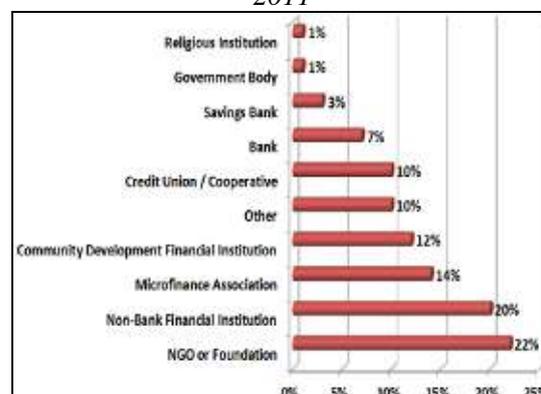

2. The European microfinance framework and micro-lending models

Microcredit is defined by the European Commission as the loans under 25.000 euro for micro-enterprises, unemployed or inactive persons that wish to be involved in an independent activity or do not have access to the traditional banking services [4; 5]. Through its destinations, the microcredit has a vital role in the sustainability of the micro-enterprises, the development of new income generating activities, the creation of new jobs and the sustainability of the social and financial inclusion. The major role of the microcredit results also if we take into account the key figures, that underline that 99% of the European start-ups are micro and small firms, while a third of these are created by unemployed persons [5, p. 5]. Overall, through its double role, economic and social, the microenterprise can have a major contribution to the fulfilment of the objectives stipulated in the Europe 2020 Strategy, the achievement of a smarter, more sustainable and more inclusive economic growth.

The economic reality from the EU member states underlines that the size of the microcredit varies significantly from one country to another, from values below to values above the threshold established by the European Commission. As a result in the European countries, especially in the EU member countries, there is no single definition for the microcredit, which makes for it to be granted by various entities, for example commercial banks, saving banks, cooperative banks and also non-banking entities like microfinance institutions, credit unions, foundations, not for profit associations that predominantly are active at national or regional level, or even on both levels. The diversity of the institutions from the European microcredit market is underlined in figure 1 that shows that most of

the institutions are NGOs or foundations (22%), Non-Bank Financial Institution (20%) and microfinance association (16%), while the lowest share is held by Savings Bank (3%), Government Body (1%) and Religious Institution (1%). The analysis in the case of the European countries, based on the survey made by the European Microfinance Network (EMN) for the period 2010-2011 underlines that in countries like Hungary or Spain over 50% from the institutions participating to the survey are NGOs or foundations. Comparatively, in countries like Albania, Belgium, Finland, Lithuania, Moldova, Romania, Serbia and Sweden the non-banking institutions are dominating while in Bulgaria and Croatia credit unions and cooperatives are in top. A different situation is registered in Great Britain where 80% of the institutions from the survey are Community Development Financial Institution. Overall, we can consider that from an institutional point of view the European microcredit market is characterised by a high degree of heterogeneity.

Figure 1. The ratio of the different type of institutions in the European countries for 2011

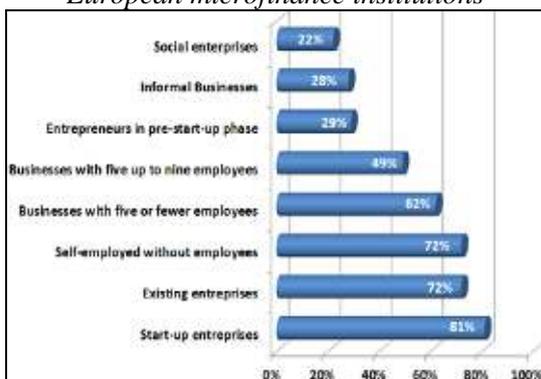

Source: [2]

According to the target groups, the survey undertaken by the European Microfinance Network underlines that some suppliers are targeting the bankable entrepreneurs (like start-ups and microenterprises), while other suppliers are targeting the non-bankable entrepreneurs, like financially excluded people. This diversification of the microcredit suppliers makes the microcredit practices to be not only different from one country to another but also from one institution to the next. In this context, the

European Commission has enhanced its preoccupations aimed at promoting and extending the best practices in the microfinance sector, publishing in 2011 an European Code of good conduct, the encompasses recommendations and norms regarding the granting of microcredit's [6].

Taking into account the type of business that the microfinance institutions are focused on (see figure 2), the results of the survey undertaken by the European Microfinance Network for the period 2010-2011 underlines that two thirds from these institutions are aiming start-ups (81%), the existing firms (72%), self-employed without employees (72%), while less than a third are aiming entrepreneurs in pre-start-up phase (29%), informal businesses (28%) and social enterprises (22%). The country analysis underlines significant differences, thus if in the case of most Eastern Europe countries the microfinance institutions are focused only on micro-lending, the situation is different in Western Europe where the institutions are focused on other operations. Such an orientation of the European institutions signals that they are in different stages of their business cycle, the Eastern European being more mature while the Western European being much younger (being founded after 2000) and aiming a wider range of operations.

Figure 2. Type of businesses aimed by the European microfinance institutions

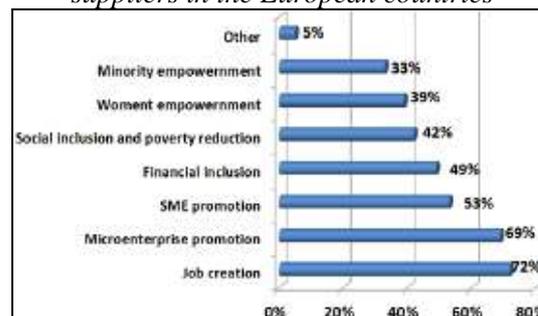

Source: [2]

Another significant aspect underlined by the survey undertaken by the European Microfinance Network (EMN) is represented by the main objectives of the European microfinance institutions. Thus, the results of the survey (see figure 3) underline that the main objectives of the microcredit suppliers

are: the creations of jobs (72% aiming such an objective), promoting micro enterprises (69%) and SMEs (53%), followed by the increase of the access to financial services (49%). A smaller percentage have mentioned as a main objective social inclusion and poverty reduction (42%) and women and minority empowerment (39% and 33% respectively).

Figure 3. Main objectives of the microcredit suppliers in the European countries

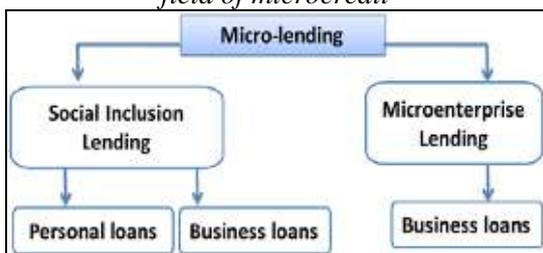

Source: based on data from [2]

In close correlation with the main objective of the European microcredit suppliers we can state that there are two lending models [2], *microenterprise lending* and *social inclusion lending* respectively (see figure 4). While *microenterprise lending* aims the granting of loans to bankable or nearly bankable microenterprises, *social inclusion lending* aims the self-employed individuals that because of their socio-economic status do not have access to banking services. If in the case of the microcredit size both categories are aiming the same amount (up to 25.000 euro), the differences appear in the destination of the microcredit, thus: *business microcredit* aims to support the microenterprises and the self-employed while *personal microcredit* aims the personal needs and consumption of the client.

Through the distribution of the two lending models the survey undertaken by EMN underlines that social inclusion lending is more practice by some microfinance institutions, like all the microfinance associations, 91% of the credit unions, 64% of the non-banking financial institutions. In the case of these institutions the clients under the poverty level represent 13% from the whole lending activity [2].

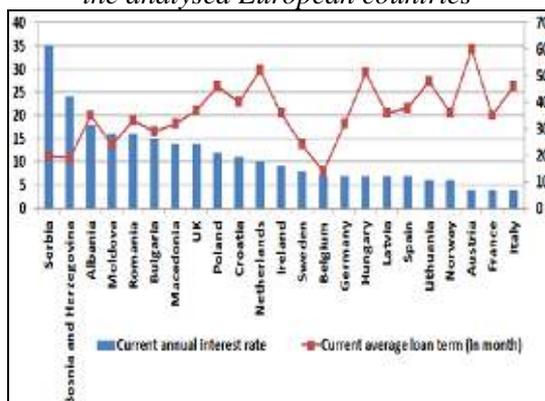

Figure 4. Lending models in the European field of microcredit

Source: [2, p. 16]

A significant characteristic of the European microcredit market is given by the average duration of loan and the interest rate charged. Regarding the period for which a microcredit is granted, this is between 6 months and 7 ½ years. According to the survey undertaken by EMN almost two thirds from the microfinance institutions are granting microloans up to three years. A cross-country analysis underlines the existence of major differences (see figure 5). Thus, comparatively with the Western European countries in some Eastern European countries that have the most developed microfinance sectors like Romania, Serbia and Bosnia-Herzegovina the period for which a microcredit is granted is extremely short as a large part of these loans are granted for the working capital, involving a smaller value and a shorter period.

Figure 5. Conditions for the microloans in the analysed European countries

Source: Based on data from [2]; [7]

Significant differences between the European countries are also registered in the case of the average annual interest rate for microcredit's (see figure 5). Thus, these are between 4% in Austria, France and Italy and 35% in Serbia. The size of the interest rate charged depends to a series of factors

specific to a country among which are: the juridical framework, the existence of usury laws, the inflation rate, the refinancing cost of the microfinance institutions etc. Overall in the case of the European countries analysed we can observe that the granting period is shorter in the countries where the average interest rate is higher and the average loan size is smaller.

3. Recent evolutions in the European microfinance landscape and the implications of the crisis

A first aspect that reflects the evolution of the European microcredit sector is given by the number of granted microloans and their volume. Thus, it is underlined that although the number of microfinance institutions included in the surveys undertaken by EMN in the period 2003-2011 has been different, the data in table 1 show an important development of the microloans sector. In this way we can observe a 7 time increase of the microloans number, from 27.000 in 2003 to 204.080 in 2011 and a 5 time growth of their volume, from 210 million euro to 1,047 million euro (see table 1).

Table 1. The evolution of the microcredit's in the European countries included in the sample, for the period 2003-2011

	Number	Value (million EUR)
2003	27.000	210
2004	35.553	295
2007	42.750	394
2008	90.605	802
2009	84.523	828
2010	178.572	779
2011	204.080	1.047

Source: [2]

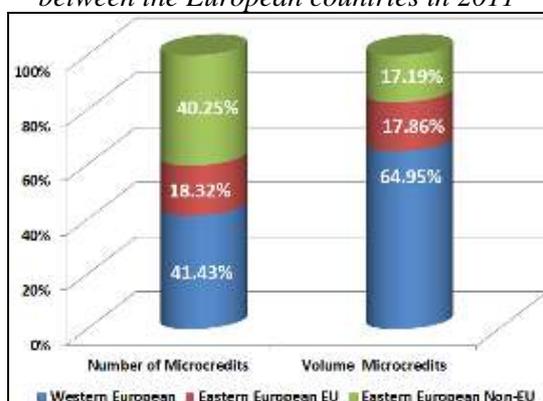

Comparatively with 2009, the survey underlines that the most important increase has been registered in Spain (a 560% increase), while in the case of the Eastern European countries Romania stands out, where the increase of the microloans has been especially the results of the financing through the European Progress Microfinance Facility [2].

The higher increase of the number of microloans comparatively with their volume in the EU countries has determined in 2011 compared with 2009 a decrease of the

average loan size from 9.641 euro to 7.129 euro [2]. The cross-country EU analysis underlines that in the Western European countries like Belgium, Finland and Ireland the average loan size is well above the EU average, while the Eastern European countries, especially Romania, Poland and Bulgaria register values well below the EU average loan value.

Through the distribution of the microloans on countries, the EMN survey underlines in 2011 the existence of high disparities. Thus, on the one hand, if in Western Europe the volume of microloans granted in 2011 by the microfinance institutions has been 680 million euro, representing 65% from the total volume of European microloans, while in the case of the Eastern European countries the volume of microloans has been of 368 million euro, representing 35% of total European microloans (see figure 6). On the other hand the significant discrepancies appear between the EU Western and Eastern member countries also in the case of the number of microloans but also on their volume (see figure 2). A clue of the regarding the discrepancies between these countries underlined by the EMN survey [2] is reflected by the average number of microloans per institution, that was around 1226 microloans in the case of the Western EU member countries comparatively with 1575 in the case of the Eastern EU member countries. This situation underlines that the microfinance institutions from the EU Eastern member countries are more developed and mature than their Western peers.

Figure 6. Distribution of the microcredit's between the European countries in 2011

Source: authors calculations based on data from [2]

The significant expansion of the European microfinance sector has been stopped in the context of the recent financial crisis. As we can observe from the data in table 1 the number of microloans has registered a negative increase of -7% in 2008 compared with 2009, for the first time since the EMN surveys stated in 2003. As a result of the economic recession, the increase of the firms' bankruptcies, the diminishing of the people's income, the microfinance institutions have registered a significant growth of the non-performing loans that has determined an increase of the risk aversion of the microcredit suppliers and implicitly the diminishing of their offer. On the other hand, microfinance institutions have faced increased difficulties in accessing the external financing sources as their price increased.

Regarding the demand for microloans, it can be anticipated an increase of this, both for social inclusion lending and for microenterprises lending, especially in the European countries with a high unemployment rate [8].

The significant difference between the demand and the supply of microloans and also the major problems faced by the microfinance institutions (for example the lack of institutional capacities, the lack of a regulatory framework, lack of access to funds for lending and the covering of the operational costs) [9] underline the necessity for the support of the European microfinance sector by the national public authorities and the European decision makers. The public support of the microfinance sector is not an easy solution taking into account that most of the European countries are faced with a significant deterioration of their public finances situation.

Regarding the actions of the decision makers at EU level, we can underline that in the context of the negative effects on the crisis on the microfinance sector, the European Commission has intensified its aiding efforts in this direction. In this way it is worth mentioning the setting-up in March 2010 for the first time at the EU level of a financing program for the European microfinance sector known as Progress Microfinance [10], that will allow the providers of microloans from the EU member countries to increase the volume of their

granted loans. Also, an important role in the supporting of the EU microfinance sector is played also by the initiatives of the European Commission [11]: JEREMIE (Joint European Resources for Micro to Medium Enterprises) through which the microcredit providers benefit from special guarantees and loans, and also JASMINE (Joint Action to Support Micro-finance Institutions in Europe), that aims the development of the microloans offer in the EU.

4. Conclusions

Through the content of our research we have aimed at synthetically underling the recent evolutions of the European microfinance market and its main characteristics. A series of key facts and data provided by the surveys undertaken by the European Microfinance Network show a significant expansion of the European microfinance sector, but the development of this being still in its early stages. Moreover we can acknowledge the existence of some major disparities, especially between the EU member countries determined mainly by the regulatory and institutional framework.

The recent financial crisis has left its mark also on the European microfinance sector, that has faced a series of major problems. On the other hand, if we take into account also the severe diminishing of the bank loans supply we can consider that the microfinance institutions would have the opportunity to extend their activity. But, the recovery and development of the European microfinance sector depends significantly on the support provided the national and European decision makers, both through the increasing of the available funds for the microfinance institutions and the encouragement of different persons to invests in this type of institutions.

As future research directions we consider of interest an empirical evaluation of the social and financial performances of the microfinance institutions from various EU member countries.

Moldova in the Eastern Partnership: Free Trade Attempts, Asymmetric Benefits

Sandu Ioana

*The Bucharest University of Economic Studies, Faculty of International Business and
Economics*

ioanamarina18@yahoo.com

Abstract

The European Neighbourhood Policy was launched in 2004 with the purpose of promoting security, democracy and shared prosperity at a regional scale, between the EU members and both Mediterranean and Eastern Balkans countries.

Shifting to a more practical approach through the Eastern Partnership, the EU has implemented specific procedures to help the poorest of its neighbours (Moldova, Georgia and Armenia) to overcome the gap of structural power and become more competitive on the regional market.

In this frame, Moldova was among the most obedient of the EU students, scrupulously doing her homework in liberalising trade and applying institutional reforms.

Notwithstanding, the EU has not answered equivalently to Moldova's efforts of opening its borders, as the gained benefits did not materialize into expected membership perspectives.

Keywords: conditionality, Eastern Partnership, trade liberalisation

J.E.L. classification: F19

Introduction

It is commonly acknowledged that a high level of trade liberalisation between states strongly reduces the possibility of conflict and increases their power of negotiation on a regional scale. Our attempt is to define to what extent such a perspective of cooperation is feasible and mutually beneficial when the two players are the EU and Moldova: a member of its neighbourhood.

Getting close to the EU by signing the

Association Agreement and identifying key sectors of the country's economy would bring Moldova a competitive advantage on the EU single market through the more recent and practical approach of a Deep and Comprehensive Free Trade Agreement Moldova-EU.

1. ENP: the shortcut to EU?

Ever since the Euromed Agreement (Barcelona, 1995), gaining access to the internal market and freedom of goods, services and capital under the prerequisite of successful implementation of political, economic and institutional reforms has been the main principle at stake for the countries in the European neighbourhood.

However, being deprived of the near prospect of joining the EU, countries like Armenia, Georgia and Moldova are convicted to 'never be major commercial targets for EU exporters and investors' [1], not only because of their size, but also due to their mainly agricultural exports to the Single Market. This controversy should be analysed from the point of view of both parties involved.

On the one hand, the Eastern partners are encouraged to open up their market to EU products along with a unilateral commitment to visa liberalisation (as for the case of Moldova) and enhancement of democratic principles.

Ongoing negotiations for Association Agreements have made the ex-soviet countries think of EU membership [2], as these types of formal arrangements have been considered the first step towards joining the European Community.

Nevertheless, direct financial support provided by the EU in the frame of the Eastern Partnership (600 million euros for 2010-2013) has proved to be less effective

than the trade preferences offered through the Generalised System of Preferences (GSP), as the latter has brought increased and diverse access to Western markets, as well as boosting exports [3].

On the other hand, the EU has set trade liberalisation with Eastern neighbours to a progressive opening of its market for industrial goods in five years from the signing of the Association Agreement. Special protocols regarding sensitive areas, such as agriculture, soft goods, coal and steel, were offering a slower and more limited cooperation, as these goods were essential to the exports of these countries, reflecting their medium-term comparative advantages.

Moreover, regulations on the quota protection by antidumping, safeguard policy and anti-subsidy measures were meant to protect EU producers of the foreign competition [4].

Consequently, given that the purpose of the European Partnership started in 2009 has been to 'accelerate political association and further economic integration' [5] between the EU and these countries (Armenia, Azerbaijan, Belarus, Georgia, Moldova and Ukraine), trading relations have revealed asymmetry in the mutual benefits of the

parties.

The tendency is to admit that 'the EU has a vital interest in seeing stability, better governance and economic development at its (...) borders' [6], advocating the positive conditionality rather than taking advantage of the free trade agreements with these countries or promoting the perspective of membership.

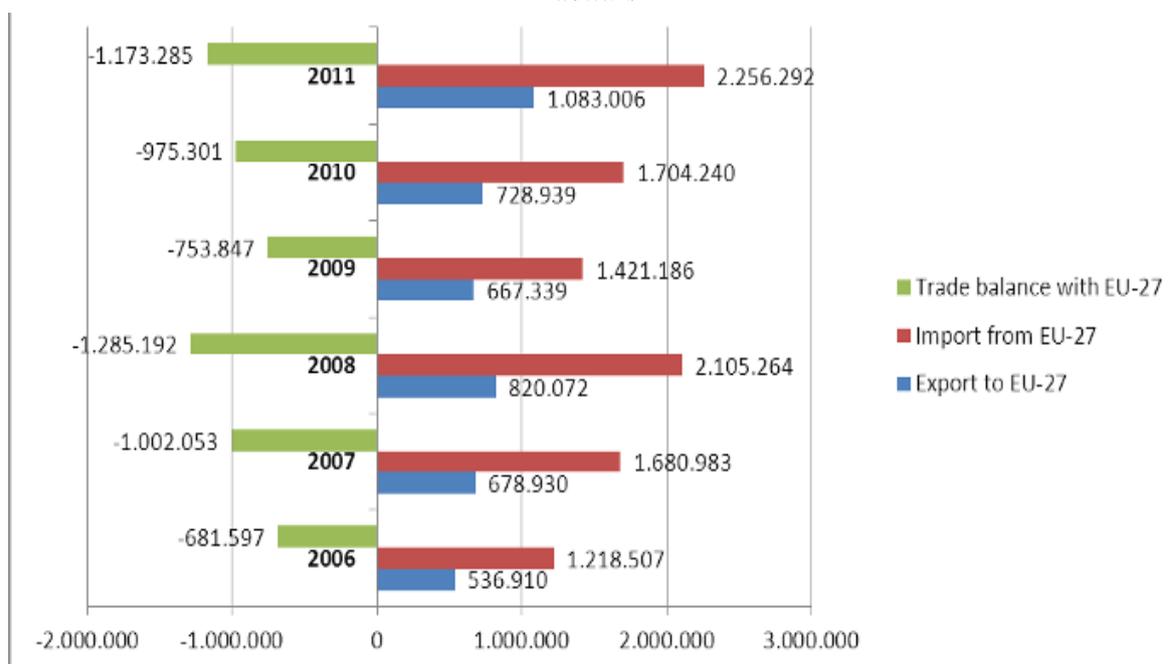

2. Moldova-EU and the DCFTA catalyst

Despite the political events of April 2009 - when parliamentary elections led to EU queries on the Moldavian commitment to political dialogue and reforms - Moldova has succeeded in overcoming the crisis and confirming the willing to foster measures to a steady economic development.

Therefore, a few months after the negotiations for an Association Agreement have started (in January 2010), the European Commission was already identifying a positive and dynamic evolution of trade flows [7] in the EU neighbourhood, particularly for the case of Eastern countries.

Measures to support a more deep economic integration have included, in the case of Moldova, unilateral trade preferences from the EU by December

Figure 1. Exports, imports and trade balance Moldova - EU27 between 2006 and 2011, million dollars

Source: Based on Ciucu, C., Chivrigă, V., Toderiță, A., Tornea, I., *Consecințele unei Zone de Liber-Schimb Aprofundate și Cuprinzătoare asupra economiei Republicii Moldova*, European Institute of Romania, 2011, pp. 34

2015, consisting of duty-free access and removal of quota for all goods, excepting a few agricultural goods. Thus Moldova has become the only country in the ENP having been granted such a preferential trading regime with the EU [8].

Part of the Association Agreement, the DCFTA (Deep and Comprehensive Free Trade Area) would involve not only 'WTO minus' provisions – concerning exclusively tariff reductions – but also efforts to comply with advanced rules for opening the services market, investment regimes and government procurement, as well as for adapting to EU technical and sanitary standards.

As for the field of labour migration, mobility partnerships were created to deal with issues such as illegal migration or border management (the latter has been addressed through the EUBAM mission), and Moldova has been among the pilot countries to sign it in June 2008.

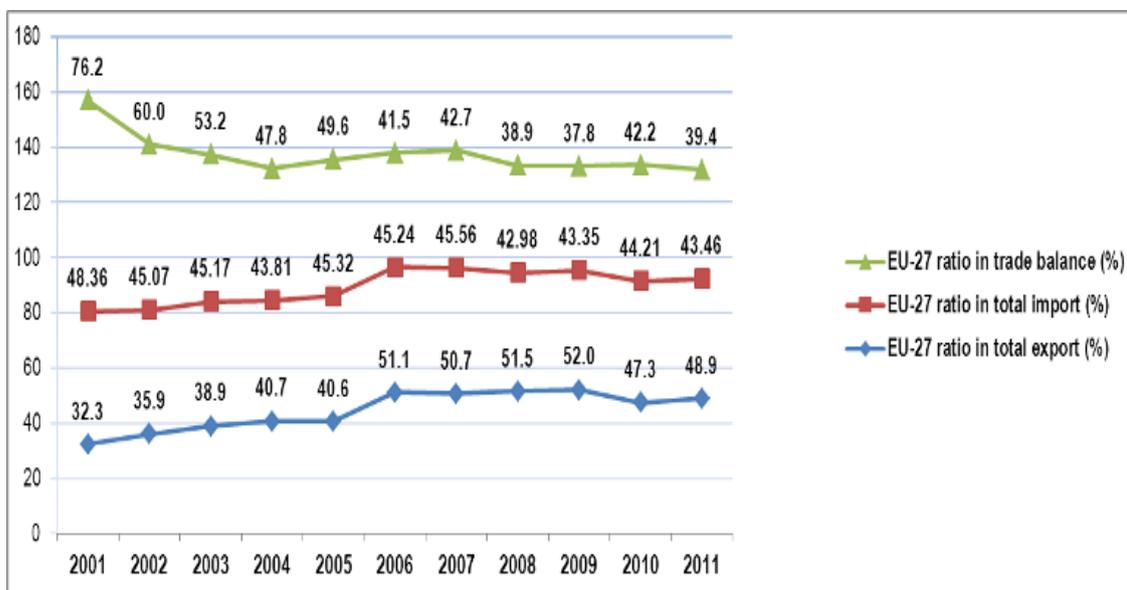

182.4 million dollars in 2001 to 1083 million dollars in 2011, whereas exports registered a five times growth: from 431.4 million dollars in 2001 to 2256.3 million dollars in 2011 [9] (the evolution of 2006-2011 is represented in Figure 1 above).

Out of the total 1651 million dollars increase in exports for the given period, 55% was represented by the growth of exports towards EU countries, while the increase of imports from the EU contributed by 42% to the total imports of Moldova (4299 million dollars). Trade with EU countries, as well as the total trade flows of Moldova have recorded high trade deficits within the last 11 years.

Given the more accelerated growth of the country's exports to EU, their ratio in total exportation flows from Moldova increased from 32% in 2001 to 49% in 2011, reaching a peak of 52% in 2008 and 2009 (Figure 2 below).

Even if, for 2010, exports to EU have grown slower than the ones to other destinations, in 2011 this situation improved

Figure 2. The ratio of trade flows to EU-27 in the total trade flows, %

Sursa: Based on Ciucu, C., Chivrigă, V., Toderiță, A., Tornea, I., *Ibidem*.

Pursuing the expected positive spillover effects of developing a free trade area with the EU through soft coordination, Moldova has been continuously adapting its trade policy ever since the initiation of the DCFTA in early 2012.

Nonetheless, progress in bilateral trade has been registering steady growth after 2000. Imports increased six times: from

by 1.5 percentage points. The reduced ratio of EU in the total Moldavian exports might be explained by the slower recovery of EU economies after the crisis, as compared to other trading partners, respectively reflected in a lower increase of demand in Moldavian goods versus other source destinations. Imports, on the other hand, have lessened in

ratio over the analysed period, from 48% in 2001 to 43% in 2011.

Exports towards EU have enhanced after the introduction of GSP+, in January 2006, by 94,3 million dollars up against 2005, their ratio in total exports rising by 10.5 percentage points, from 40.6% to 51.1%. This situation could have been equally due to the Russian embargo set in 2006 on Moldavian alcoholic beverages, animal and vegetable products. However, the next two years, exports to EU have increased by 140 million dollars, what can be only attributed to the GSP+ liberalisation.

Conclusions

Taking part in the Eastern Partnership has brought Moldova a strong belief in a new orientation towards the EU. The electoral crisis of 2009 has been successfully overcome, as the Alliance for European Integration has given proof of Moldova's willing to adhere to EU norms and regulations and comply with the European normative power.

Nevertheless, strong reforms are to be accomplished by the Moldavian authorities by the time all targets included in the Association Agreement will be fulfilled. The most challenging of all is the pathway to creating a Deep and Comprehensive Free Trade Area with the EU, comprising not only of liberalisation with the Single Market in the manufactured goods, but also a progressive free trade in agricultural goods, services, in adapting sanitary and technical procedures, as well as in defining the government procurement sector and investment regimes.

Trade flows against the EU has shown a steady growth in both exports and imports with member states since 2000. However, the EU does not seem to benefit in the same way from open trade relations with small countries such as Moldova, both because of the feeble dimension of the Moldavian market and of the types of goods imported from its neighbour (mostly alcoholic beverages, soft goods and some animal and vegetable products).

Along with the DCFTA agreement that would help Moldova gain some competitive advantages on the EU market, strong political reform is yet to be undertaken in order to

gain structural power of negotiation with the leaders of the giant Single Market.

Administrative Perspectives Concerning the European Economic Relations

Șeitan Silviu-Marius

Center of Financial and Monetary Research – Victor Slăvescu

Romanian Academy

silviuseitan@yahoo.com

Abstract

A possible European macroeconomic administrative pattern based on a higher administrative capacity of the macroeconomic system so that the portfolio of used administrative instruments fits the complexity of the system of transmission channels from the real economy, may be considered as solution for the macroeconomic administration of the problems caused by the current conjuncture. Within this context, the analysis will use as input the option of most EU member states to approach such pattern of the macroeconomic administration

Keywords: system, macroeconomic, regional, heterogeneity, sustainability.

JEL classification: R 11

1. Introduction

The starting point towards setting the objective of this study is the option of each EU member state to develop solutions specific to the national macroeconomic situation in order to administer the problems arising from the current macroeconomic conjuncture. The reason behind such option results from the following aspects characteristic to the current stage of the European process of integration:

- existence of a high level of heterogeneity within the European Union;
- existence of a high level of diversity among the macroeconomic effects manifesting in the different EU member states;
- existence of a high level of specificity of the macroeconomic administrative systems in the different EU member states;

- existence of a high level of diversity of the impact of the economic effects of the present conjuncture at the national macroeconomic level, due to the different levels of involvement in international economic relations.

A second input for our analysis is the matter of the different degrees of liberty of approaching such pattern of macroeconomic administration – the differences are given both by the particular level of involvement in the process of European integration, and by the level of development of the macroeconomic administrative system and of the real economy.

These key aspects yield the following results:

- implementation, with different results, of structurally different programs in order to administer the macroeconomic situations specific to each national macroeconomic level; this aspect will produce different levels of unavailability of the national macroeconomic systems to assume the commitments resulting from the continuation of the process of European integration;

- higher level of heterogeneity among the different macroeconomic entities composing the European Union.

Given these results, it will be necessary to review the progress of the process of European integration and to defend the European values acquired so far. A direct result of such approach, and a recommendation of this analysis, is the implementation, within the European Union, of a program of macroeconomic administration based on the following operational principles:

- limiting the increase of heterogeneity within the European Union;

- ensuring an optimal level of the administrative capacity to deal with the macroeconomic problems;

- consolidating, in good time, the macroeconomic administrative capacity, thus ensuring the efficacy of the intervention to administer a particular stimulus received as macroeconomic shock;

- preservation of the values already acquired by the European Union;

- ensuring a proper initial foundation for the expansion of the system of EU values;

- providing the channels for the expansion of the initial foundation by the implementation of programs which to expand the system of EU values.

With the view to implement specific programs associated to the mentioned operational principles, as recommendation in the acceptance of this paper, we propose the following programming elements that may support the continuation of the process of European integration:

- identification of sub-multitudes within the multitude associated to the European Union which to fit the possibility of implementing programs for the administration of the macroeconomic problems while:

- preserving the already acquired European values;

- ensuring the efficiency and efficacy of the administrative macroeconomic system;

- ensuring a maximal level of heterogeneity within the sub-multitude, which to provide for the possibility of administration under optimal conditions of efficiency and efficacy;

- in the spirit of the principle of subsidiarity (see Art.5 from the Maastricht Treaty [3], [6], completed by the stipulations from the Protocol of the Amsterdam Treaty and by the stipulations from the Lisbon Treaty), identification of the limits, determined according to the principles of maximal efficiency and maximal efficacy, between the administrative capacity at the level of the multitude, the administrative capacities at the level of the sub-multitudes and the administrative capacities at the national macroeconomic levels;

- assumption, at the level of EU macroeconomic cooperation, of a functional and optimal mix of regional-national administrative solutions;

- drawing up and implementing programs of macroeconomic administration according to the operational formula of the regional-national mix of administrative macroeconomic solutions;

- reviewing the progress of the process of European integration in agreement with the mandatory operational character of the regional-national mix of administrative solutions.

2. Case of the European Economic and Monetary Union

Associated to the mentioned elements of the macroeconomic administrative pattern, the pattern of EU organising in multitudes with the view to design and implement a regional-national mix of administrative solutions, also includes the condition that the direction of the process of integration coincides with a higher level of integration at the administrative level [6].

The recommendation, from the perspective of this analysis, is, however, to correlate the speed of the integration process with the real and normally acceptable possibilities to decrease the level of heterogeneity among the composing macroeconomic entities. Practically speaking, such decrease of the level of heterogeneity among the composing entities is limited in terms of value; this means that there will be a GEMmin (where GE is the level of heterogeneity) below which it is not possible to decrease further the level of heterogeneity without inducing adverse effects into the economic and social system of the particular macroeconomic entity.

In other words, from the beginning of the process of European integration, we need to accept this idea of a minimal level of heterogeneity between the macroeconomic entities composing the union system, which will be part of the sum of characteristics of the regional system of economic cooperation. In the case of the process of European integration, this situation will put forth the necessity to accept one of the following two generic scenarios:

- limiting the process of European integration to the pattern of economic cooperation having two multitudes formed according to the criterion of two distinct values of the level of heterogeneity, GE1 and

GE2. The finality of the process of European integration corresponds to the pattern of classification of the multitudes based on the limit values GE1Min and GE2Min: the possible continuation of the process of integration, after a medium or long (most probably long) interval, towards a GEunique whose threshold value will be GEMin; the condition of such continuation of the process of integration would be:

$$GE1Min \approx GE2Min,$$

- limiting, by design, the process of European integration to a single multitude corresponding to a GE, GEMin respectively, with the following relations in relation with the previous scenario:

$$GE > GE1$$

$$GE \geq GE2$$

and

$$GEMin > GE1Min$$

$$GEMin \geq GE2Min.$$

Regarding the formation of these multitudes of components included in the large multitude corresponding to the regional pattern of economic cooperation, we have the following relation: the larger is the number of entities composing the multitude, the higher will be GE and GEMin, respectively.

Regarding the depth of the process of economic integration (same as in the case of the processes of economic integration), the larger is the number of entities composing the multitude, the higher will be GE and GEMin, which, in terms of the administration of the internal risks of the system, will necessarily require a lower depth of the process of integration/economic cooperation.

Regarding the association between the analysed economic pattern and the current case of the European Union, in the acceptance of this analysis and given the current circumstance, it is more appropriate to continue the process of European integration according to the first scenario mentioned above: limiting, at this moment, in order to ensure the administrative capacity required by the current international macroeconomic situation, the process of European integration to the pattern of

economic cooperation with two multitudes established on the criterion of two distinct values of heterogeneity; the possible continuation of the process of integration will be resumed after the lapse of a medium or long period, when the minimal set of operational principles of the regional macroeconomic system will have been met, according to the previous statements.

Regarding the approach of the current situation, and from the perspective of the international risks, we need to take into consideration the possible depreciation of some already acquired European values, case in which the regional economic-administrative pattern may move closer to the second pattern presented above, i.e. limiting, by design, the process of European integration to a single multitude, accepting a higher GE and a corresponding higher GEMin, while the depth of the process of integration/economic cooperation will necessarily be lower.

All these economic and administrative patterns proposed for the construction of a regional pattern based on economic cooperation must lead, in the acceptance of this analysis, to the promotion of a single vision; this should also be the reason for the national macroeconomic affiliation to that particular system, i.e. acquiring a higher economic and social standard compared to the situation of non-affiliation to the regional system.

3. The necessity if reviewing the process of European integration given the current international context

Regarding the current state of the European Union, we have the case of the first scenario described above.

The current international macroeconomic situation revealed the following main problems within the European Union:

- the high level of heterogeneity of the composing national macroeconomic entities in relation with the depth and speed of the process of European integration, reason why it was not yet possible to establish a regional structure with an administrative capacity able to administer the risk, shocks and macroeconomic effects due to situations like the economic crises, or to allow the member states to establish their own operational

national systems of macroeconomic administration. This would join the institutional and political characters, which would compel the national states to get ready for the upper stages of the process of integration;

- in the acceptance of this analysis, these duties should be sized in agreement with the structural economic and social characteristics specific to each member state;

- lack of a program for the consolidation of the national macroeconomic administrative systems, which would allow the establishment of a consolidated regional administrative system by correlating the time and speed coordinates of the process of integration with the specific economic and social elements of each member state; this consolidated regional administrative system would be dimensioned in agreement with the administrative necessities resulting from the common problems, in relation with the depth of the process of European integration;

- existence of administrative deficiencies within the European institutions, deficiencies that support the perpetuation of the insufficient administrative capacity:

- lack of the function of banking monitoring within the European system of the Central Banks;

- insufficient administrative capacity of the function of control of the budgetary execution;

- insufficient correlation of the decisions regarding the destination of the funds from the unique budget with the actual requirements of enhancing the competitiveness of some economic and social sectors;

- insufficient preparation of the accession states and of the member states to approach important stages of the process of European integration (such as: insufficient pre-accession readying of the business environment in order to improve the absorption rate of the European funds; such as: insufficient post-accession readying of the business environment in order to assimilate the community acquis; insufficient preparation of the local public administration institutions to improve the absorption rate of the European funds). The main consequence of this aspect is the appearance of transmission channels for asymmetric

shocks, additional to those associated to the program of regional integration;

- failing to consider the level of heterogeneity of the existing and potential member states – level of heterogeneity that should be correlated with the depth and stages of the process of European integration; consequently, the macroeconomic heterogeneity of the member states induced, within the regional system, effects that propagated on the associated transmission channels, and which generated secondary effects that were multiplied by the current conjuncture.

The main result of this situation is the insufficient administrative capacity both at the European and at the national level to manage the current macroeconomic situation, with the resulting consequences.

Thus, the present moment is associated, macroeconomically, with priority, to the administration of the effects generated by the current international conjuncture; under the current given conditions of the administrative organisation of the European Union, this administrative issue has to be tackled both at the regional and at the national level.

From this perspective, it appears necessary to review the progress of the process of European integration particularly since the processes of administration of the current macroeconomic situation, to be implemented, presume drawing up programs of macroeconomic policies specific to the characteristic situation of each member state, both in terms of macroeconomic specificity and in terms of the elements delineating the evolution of the present conjuncture within the national boundaries.

Thus, in the acceptance of this analysis, we propose prioritizing, both at the regional and at the national scale, the main objective of administering the current macroeconomic situation; the secondary objectives would be the elimination of all risk factors by decreasing the system of transmission channels for the macroeconomic shocks and effects within the regional system to the normal level associated to the process of European integration. Next, the future progress of the process of European integration must be reviewed in terms of:

- setting the stages;

- setting the depth of the process.

Starting from the administrative pattern presented earlier, these coordinates will depend mainly on the number of multitudes composing the regional system and on the level of heterogeneity associated to this pattern.

In the acceptance of this analysis, the current macroeconomic stage of the process of European integration is due mainly to the fact that the political decision-making factor has been considered – and has therefore acted accordingly – as having a higher importance than the macroeconomic decision-making factor.

Starting from this aspect, as solution for the sustainable evolution of any macroeconomic system, we propose the establishment of a consolidated decision-making fundament, by the establishment, at the institutional and conceptual levels, of a medium of cooperation between the political decision-making factor and the macroeconomic decision-making factor, as essential factors, reciprocally independent and with equal weight, of the economic-social evolution.

4. Conclusions

Within such context, both the level of the macroeconomic entities forming the European system, and the level of the system of the European Union, in the acceptance of this analysis, should review the progress of the process of European integration starting from the following priorities:

- implementation of programs for the administration of the present risks and of the effects that have already been induced into the system;

- configuration of a macroeconomic administrative system having the minimal necessary capacity to administer the risks and the situations presumed by the complexity of the level of real economy development; given the main characteristics of the European system, in the acceptance of this study, such direction of action is optimally built starting from the implementation of specific national programs depending on the variety of the national macroeconomic systems; depending on the evolution of the process of European integration, this system should become unitary at the scale of the entire European macroeconomic system.

As final conclusion, the current pattern of the European Union must be reviewed and redesigned so as to ensure a correspondence between the current and potential resources on the one hand, and the assumed objective, on the other hand. The current functional deficiencies of the macroeconomic system of the European Union have been also emphasised by the risk phenomena at the international macroeconomic level, in the absence of which the designed pattern would have had a higher probability of implementation with a much lower degree of erosion.

Abstract

The purpose of this paper is to present methods of analysing local stakeholders and the development of a matrix to identify potential results of this group's activity, transposed in the local development document – “Local Strategy for Sustainable Development”. It establishes both the vision (model) of development for Baia Mare city and the priority development direction, strategic objectives and policies that will support the accomplishment of these objectives for 2008-2020. The products provided where the analysis of resources and local problems/needs which led to the identification of solutions or local development projects in specific areas .

Key-words: local development, strategy, stakeholder, cooperation, resources.

J.E.L. Classification: R11, R12, R58

1.Introduction

“Stakeholders” are defined as: “People or institutions, organizations, interest groups whose expectations are affected by a certain public policy, decision or activity or which might affect the public policy / decision / activity in case”[3].

The stakeholders are people, groups of people, institutions and/or groups of institutions which are interested, affected, preoccupied or involved in a certain issue.

The instruments for analysing the stakeholders involved (stakeholders), consistently developed during the last period especially due to the practitioners'

environment in the area of consultancy services, clarify the issue of applying Stakeholders' theory in the process of local development, therefore defining local stakeholders of development.

2. Organizational structuring and functioning criteria

Bibliographical sources, along with over 20 years of experience in local development planning at the level of Baia Mare city, led to a general “horizontal” classification of the categories of stakeholders involved in this process, presented in Figure 1.

This classification takes into account the type of organizational structure, specific interest and the purpose of its establishment and functioning.

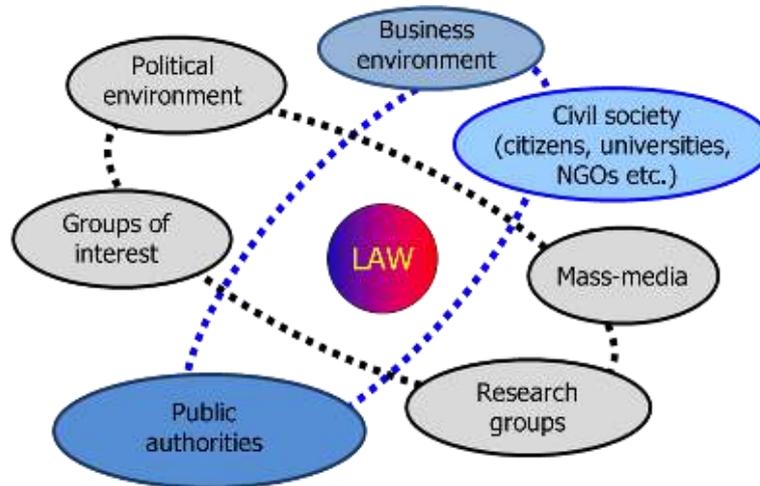

a. **Public authority institutions** have the role stipulated in their fundamental establishment and functioning documents (statute, norms, regulations established through legislative documents) and consider general benefits of the target group/community.

These structures can be:

a) Territorial, administrative / local authority institutions (Local Council, Town hall), having as operational area and administrative task the administrative-territorial unit. Their interests are of general territorial level, especially in the fields of infrastructure and public services.

b) Hierarchical-functional, sectorial–decentralized institutions(hierarchical level units), according to the activity fields (areas of development) of the public central administration (social-

Figure 1. General “horizontal” classification of the categories of stakeholders involved in local development, adapt.[2]

educational area: County School Inspectorate; environment field: County Agency for Environment protection).

- c) **Mixt** – institutions created by territorial public institutions for the administration/application of specific policies in certain development areas (Public Services for Social Assistance in the suborder of Local Councils that apply specific sectorial policies in the area of the administrative territory).
- b. **Business Environment** – private organizations created with the purpose to provide services and/or products required by the needs of the consumers and to obtain profit by selling them. They are characterized by focusing activities and applying results oriented management techniques – short-term operational objectives defined through immediate effect indicators.
- c. **Civil society** – it represents formal structures (universities, unions, church, non-governmental organizations) or informal structures (mutual support groups, clubs, informal cooperation networks), characterized by associations based on interests, common needs (professional and civic) and informal leaders, personalities in various activity fields.

3. “Stakeholders” Theory and instruments for analysing development stakeholders

Before identifying interested stakeholders/people/parties/factors known in specialized literature as “stakeholders”– it is first necessary to define them.

Although initially designed to analyse corporate management and ethics in business management, the Stakeholders Theory [2] became a strategic analysis instrument in public administration at global level.

This theory starts from the premises that public management decision must be taken in light of the impact they have upon factors that might be affected by the decision [2].

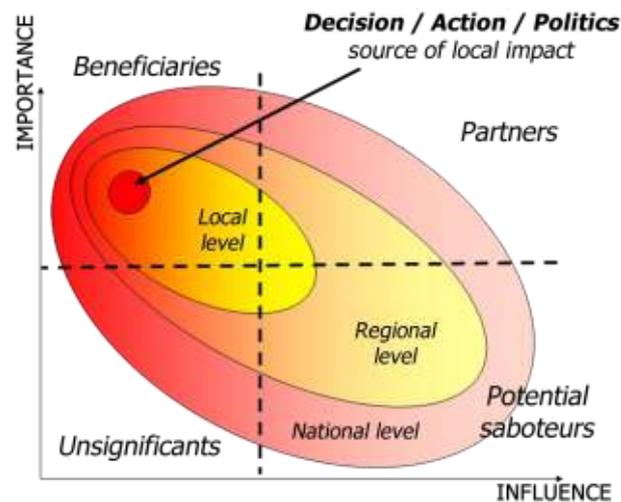

The purpose of the identification in the stakeholders’ analysis is the answer to the questions: for whom? with whom? does the local development process take place.

a. **Quantitative analysis** – a first step in the quantitative identification of the local development stakeholders is the assessment of the activity/decision/public policy impact upon them.

The result of the quantitative analysis is represented by a long list of institutions and people identified through brainstorming sessions or focus groups consisting of local administration team groups responsible with the process of developing public policies completed by statistics (for primary stakeholders) and contact data for institutions, organizations with roles or responsibilities clearly defined through their establishment and functioning documents.

b. **Qualitative analysis** – its purpose is to delimit as clearly as possible the importance and the influence each of these stakeholders must and/or can have upon the

Figure 2. Qualitative Matrix Analysis, adapt.[2]

subject/policy/decision taken.

In the context of this analysis, to position various stakeholders identified within the matrix of the qualitative analysis (Figure 2), the motivations and expectations of each interested factor will be considered, so that differences/divergences may be emphasized, followed by common points and benefits that the public decision/policy can bring for each of them, more than the supporting or opposing the respective subject.

The systemic approach in the stakeholders analysis does not stop at local level (internal system), but in accordance with the estimated impact of the local activity/decision/policy, it will be extended at micro-regional level (urban system), regional and (inter)national (i.e. correlating local development policies with regional and sectorial higher level priorities, as well as European Union development policies and identified global trends).

From a qualitative point of view, four major categories of local development stakeholders can be identified:

- a) Low importance or non-important/low influence – this defines local stakeholders “insignificant” for the analysed activity/decision/policy. Low importance or non-important/high influence – this defines the so-called potential “saboteurs” of the decision, due to interests contrary to the groups identified as “primary groups” for the issue analysed; practical experience shows the need for important resources for the “collaboration” with

this category of stakeholders involved in the process of local development and their “transformation” into active partners;

- b) Beneficiaries – in general, these are stakeholders identified as “primary” within the quantitative analysis at this stage, having great importance for the analysed activity/decision/policy, but with low influence capacity. This category of stakeholders of local development are the main target of facilitation services, community development;
- c) Real partners (active) / they are characterized both by a high level of importance for the analysed activity/decision/policy and by an expertise capacity and high representation level.

The purpose of the “stakeholders” analysis is to identify the positioning of the stakeholders quantitatively identified in the matrix presented above and in the use of community facilitation techniques for increasing the number of active partners in the process of analysis, decision and implementation of public policies.

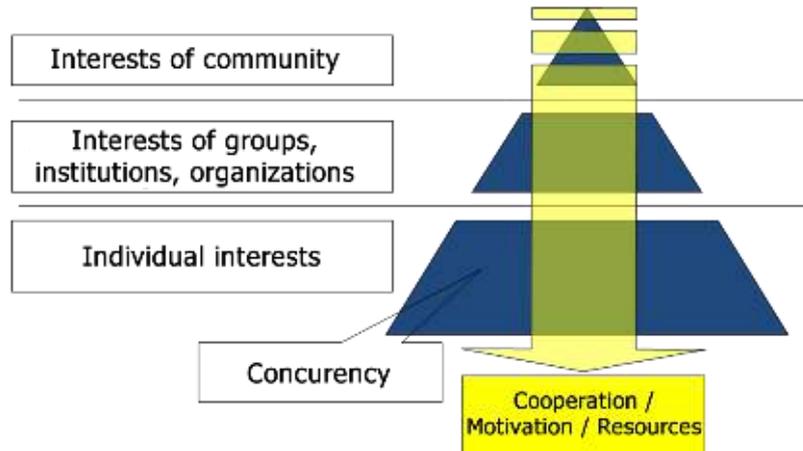

The sensitive and hard to delimit area of “common interest” (Figure 3) is based on the negotiation abilities of the local public administration team, founded upon the prior analysis of the real needs of the local stakeholders involved.

4. Criteria concerning the involvement level and role in the development process

Aim the place and role of the stakeholder in the local development structures (according to the model in Figure 3).

participatory identification of local needs and specific solutions applied through projects and local

Figure 3. Sensitive and hard to limit area of „common interest”, adapt.[1]

According to these criteria, stakeholders can play the following roles:

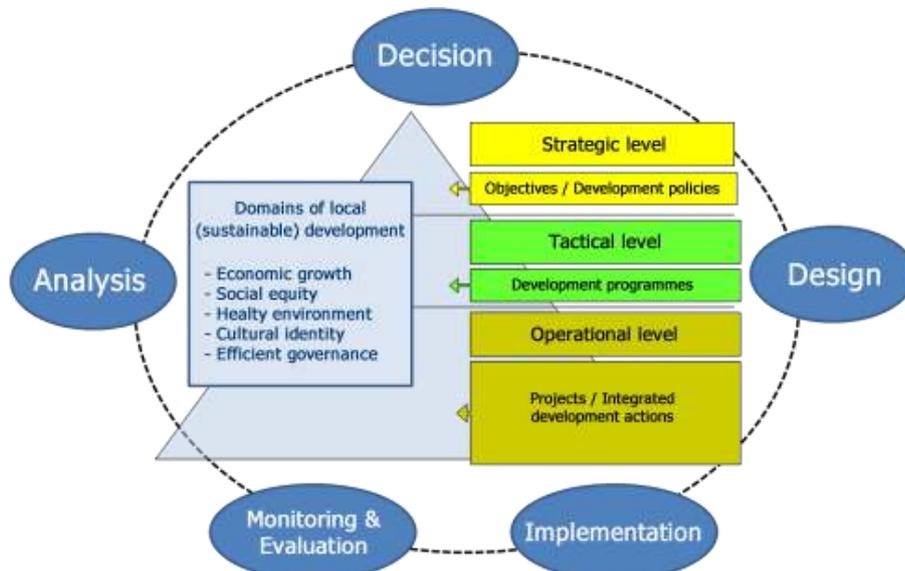

- *Strategic* – at the level of vision and elaboration of local development strategy characterized by defining long term objectives, projecting and application of local development policies ;
- *Tactical* – elaboration of specific objectives, sector objectives, general measures that have to be applied and implemented through specific development programs;
- *Operational* – at the level of

development actions.

It is also important to know the possibility of their involvement in the local development stages: analysis – decision – projecting/design – implementation – monitoring and evaluation, process presented in a separate chapter of this document.

The involvement of citizens in the strategic planning process represents much more than the simple participation of a part of community representatives. Attention must be granted also to the variety of groups interested in the development process but also their reason of interest. Involving

Figure 4. Model presenting the place and role of stakeholders in the local development structures, adapt.[1]

citizens in the strategic planning process and their permanent information helps ensure their support in this program and their common interest in accomplishing the proposed objectives.

5. The analysis of the local development process at Baia Mare City level

According to the theoretical models presented above, the following list present the means by which Baia Mare City level stakeholder analysis has permitted the institutional construction of the local development process formed by:

- Baia Mare City Hall – coordinator;
- Baia Mare City Hall Directors;
- Local Public Services Directors;
- Parliamentary Parties representatives in the Local Council;
- Important Employers’ Organizations representatives (representative economic operators);
- Representatives of important NGOs, universities;
- Project executive coordinator – Planning Integration, Development Service Director;
- Work Group coordinators – Local Experts (Public and Private).

This group’s activity results are transposed into the local development policy document, “Local Sustainable Development Strategy”, establishing for the 2008-2020 period the vision (model) for city development as well as the priority development directions, strategic objectives and policies supporting the achievement of these objectives.

The supplied product is in the planning phase, specific objectives and general

measures supporting these objectives finalize the “Local Sustainable Development Strategy”. The implementation phase supplies the reference terms for local development programs on priority fields, as well as criteria for delimitation and resource concentration, an also for prioritizing projects elaborated by the III-rd level, drawing up the “short project list” or the “Local Action Plan” [4].

The supplied products have been the resource analysis and the local problems/needs analysis (study of potential) leading to identification of solutions or the “long list” of local development projects on specific fields. Another important result would be the initiation of the forming process of cross-institution project teams and public-private partnerships.

From the “vertical” analysis (hierarchically – functional) of the presented structure one can observe the means by which all local development stakeholders have been involved in the local sustainable development planning , taking into account every structure’s type and interest (Fig. 5).

The “stakeholder” analysis must follow the dynamics of local development stakeholders as opposed to the public activity, decision and policy but in the same time it is also used during the monitoring and evaluation of the public information, consultation and facilitation results, permanently developed by the local public authority.

The final result of a stakeholder analysis can be concentrated in a matrix containing a synthetic presentation of collected and processed quantity and quality data.

Figure 5. Level of local sustainable development operational planning, adapt. [1]

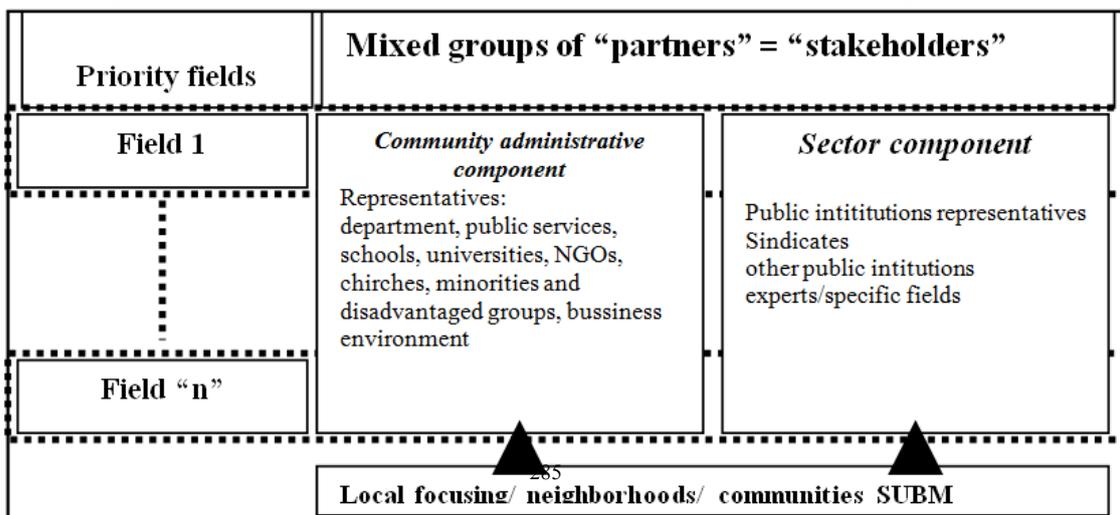

Table 1. Synthetic model used by Baia Mare City local public administration

Interested Factors	Category	Role	Impact / Importance	Influence
City Hall	IPA	S – O	5	5
Local Council Social Committee	IPA	S – d	3	5
Public Social Work Service	PAm	T – o	4	4
NGO – authorized social services providers	CS	O – i	3	2
NGO – representatives of social services beneficiaries	CS	O – p,i, m&e	5	2
University – social research	CS	T – a	3	4
Local enterprises working in projecting, constructions	BE	O – p, i	2	3

A synthetic model (excluding data and contact persons) used by the Local Public Administration of Baia Mare City is presented in table 1, and the abbreviations are: PA – public administration(or:IPA territory/administrative; sPA – hierarhically sectorial; mPA - mixt); BE –business environment ; CS – civil society; Functional role in the development process is defined by level of involvement: S – strategic; T – tactical; O – operational; x process stage: a – analysis; d – decision; p - projecting/ design; i – implementation ; m&e – monitoring and evaluation; o – entire process; Figures from 1 to 5 where 1 is the lowest level and 5 is the highest level of activity, decision, policy impact/importance for the interested factor; Figures from 1 to 5 where 1 is the lowest level and 5 is the highest level of influence that the interested factor can have on the activity, decision, debated policy.

The supplied products have been the resource analysis and the local problems/needs analysis (study of potential) leading to solution identification or the “long list” of local development projects on specific fields. Another important result would be the initiation of the forming process of cross-institution project teams and public-private partnerships. From the “vertical” analysis (hierarchically – functional) of the presented structure one can observe the means by which all local development stakeholders have been involved in the local sustainable development planning , taking into account every structure’s type and interest [4].

6. Conclusions

Basically, local development is grounded on a complex system that includes factors with major roles with respect to the

involvement in the decision-making process in a community, and who can significantly change the evolution course. These are the so-called stakeholders who mark their influences by applying strategies.

The issues related to the elaboration and application of local strategies consist in assuring the real participation of stakeholders in identifying needs, analysed problems, adopting and especially enforcing the public decisions. The real development of local communities should be based on their own strategic notions of development. Therefore, the selection of the development direction is made by the local government, considering their resources and the economic policies elaborated by the central government

Abstract

Sustainable approach to city development refers to maximizing the products added value, services created in/by communities and obtaining the synergic effect of: increasing economic competitiveness (technological but especially increasing the professionalism and active human resource attitude on the labour market), social equity, environment conservation and protection, local cultural identity (including by creating and promoting community brands), institutional development.

The purpose of the document is to present through a SWOT analysis the main results of the sustainable development strategic planning of Baia Mare City cultural environment, as well as a few results obtained from this planning.

Key-words: cultural development, strategy, community, SWOT analysis.

J.E.L. Classification: R11, R12, R58

1. Introduction

There is a professional agreement, almost general about the need of involvement from the public authorities in cultural policies and of increasing government support for culture, due to the wider definition attributed to “culture”. [2].

New approaches to public culture policies define the fact that:

- Cultural policies are not public policies,
- Cultural policies are not only

“policies for arts” but also for a higher quality life,

- Cultural policies must be embedded any development policy.

From this perspective, a “transverse”/ “integrating”/ “cross sector”/ “horizontal” approach is imperative, followed by a deep transformation of political thinking, succeeded by the establishment of adequate mechanisms and tools: in-government consulting procedures and mechanisms, cross - sector expert groups, etc.[1]

2. Cultural identity as a pole of sustainable local development

Intergovernmental Conference on Cultural Policies for Development in 1998 has adopted the Action Plan containing the following five objectives:

- *transforming cultural policy into a key component of the development strategy,*
- *promoting creativity and participation in cultural life,*
- *strengthening measures meant to keep cultural patrimony and to promote cultural industries,*
- *promoting cultural and linguistic diversity in the computerized society,*
- *increasing human and financial resource availability for cultural development.*

An assessment of own local cultural environments must be done for the purpose of diminishing the negative effects of globalization upon local culture, identifying both strengths and weaknesses and drafting consequent cultural policies.[5]

3. Strategic planning process of the “Cultural Identity” field in Baia Mare

The strategic planning process of the “Cultural Identity” field in Baia Mare was similar and parallel with the other fields of the sustainable approach to local development. Methodology stages are described in the strategic planning process of the Baia Mare City Sustainable Development Strategy.

Planning frame was ensured by the meetings of involved parties (representatives of local public administration, cultural public institutions, culture NGOs and business environment in the field) part of the CIVIC project initiated by Baia Mare City Hall during 2006 – 2008. [3]

The results of this process are described below.

1. Subfield: **Immobile cultural patrimony**

This names what in generic terms are called historical monuments and includes not only historical monuments but also historical sites. Immobile cultural patrimony is no limited to build patrimony, phrase excluding most of the archaeological sites.

Strengths:

- Existence of a rich and diverse ensemble of goods with immobile cultural patrimony value,
- Existence of a part of the historic architecture ensemble restored and functional for the local community,
- Existence of a ruling frame in the field concerning the territory improvement policy, ensures a mechanism that allows sustainable development of protected areas ,
- urban rehabilitation through rebuilding and developing the historical centre, cross-sector approach concerning the valuing of immobile cultural patrimony, especially in relation to tourism and hotel industry, civil constructions, transports, other consumer services,
- Involvement of local authorities in managing the immobile cultural patrimony goods existing in the territory.

Weaknesses:

- Lack of new work places and

diversifying occupational typology in the field of research, conservation, restoration, using and reusing monuments, sets and historical sites

- Lack of sufficient training and specialization programs for human resources through formal and informal education.

Strategic objective: efficient management of the immobile cultural patrimony, allowing free access and knowledge of local patrimony value cultural goods.

Directions for action:

- *Maintaining a competitive and actual urban management.*
- *Keeping/establishing priorities concerning restoration works*
- *Raised prioritizing of the professional training for specialists in the field of protecting immobile cultural patrimony,*
- *Public promotion of cultural patrimony, especially the immobile one, as a community value.*

2. Subfield: **Mobile cultural patrimony**

This comprehends only the ranked mobile goods, but, in order to establish strategic action directions, the main interest of the general administrator has to be pointed towards the institutions protecting these goods: museums – County Art Museum, County History and Archaeology Museum, County Ethnography Museum, Mineralogy Museum.

Strengths:

- Existence of a rich and diverse ensemble of goods with mobile cultural patrimony managed by museums (art, history, archaeology, ethnography, mineralogy) ,
- National/county and local financing for research, conservation, restoration and valuing of mobile cultural patrimony,
- Increase of consumption and diversifying of markets at local level interested in goods and services in the field,
- Initiation of bilateral regional and international collaborations with the purpose of protecting and valuing local mobile cultural patrimony.

Weaknesses:

- Maintaining an obsolete mentality

concerning the role of museums in local society,

- Lack of sufficient training and specialization programs for human resources through formal and informal education,
- Lack of a cross-sector approach concerning the valuing of mobile cultural patrimony,
- Insufficient involvement and accountability from local/county authorities in managing through museums the existing mobile cultural patrimony goods in the territory.

Strategic objective: Extensive and intensive usage of mobile cultural patrimony, allowing free and unmediated access to the knowledge of cultural goods with local patrimony value.

Directions for action:

- *Ensuring access to national cultural patrimony values, in order to consolidate local cultural identity and acknowledge the belonging to a common community cultural space.*
- *Prioritizing restoration works and valuing mobile cultural patrimony, taking into account promotion possibilities with the support of touristic services.*
- *Granting major priority to professional training of specialists in the field of mobile cultural patrimony protection.*
- *Public awareness increase (social marketing) in order to acknowledge the role of the local mobile cultural patrimony in keeping local cultural identity and social cohesion – transforming museums in cultural mediators, and in beneficiaries and creators of services on the cultural market.*
- *Expansion of collaboration relations with similar institutions in other countries, especially neighbouring countries part of the European Union.*
- *Including local museums and managed public collections in larger cultural ensembles – attraction poles for local visitors and tourists.*

3. Subfield: **Immaterial cultural patrimony**

This refers to the ensemble of practices, representations, expressions, knowledge, abilities that communities, groups and individuals recognize as being a part of their cultural inheritance, transmitted through generations and permanently recreated (traditions and oral expressions – language as their main vector/show arts/ social practices, rituals and festive events, knowledge and practices linked to nature and universe/traditional handicraft and others).

Strengths:

- The existence of rich and diverse traditions and forms of artistic expression, social practices, rituals and types of events as well as numerous traditional practices and knowledge manifested in ordinary life of groups and individuals, permanently used and recreated
- The local programs and initiatives for activating and revitalizing traditional crafts and specific occupations, stimulation and valuing immaterial patrimony of national minorities , ethnological research.

Weaknesses:

- Not using traditional crafts and knowledge in restoring monuments and other goods in the tangible cultural patrimony.
- Lack of specific ruling that protects intellectual property rights upon various forms of expression of the immaterial patrimony.
- Lack of a local “inventory”, according to the UNESCO Convention concerning the preservation of immaterial cultural patrimony.
- Reconsidering and inserting traditional objects and forms of expression in daily life (architecture, design, furniture, clothes, tools, etc.)
- Low local public interest for various forms of immaterial cultural patrimony, affecting this sector’s economic viability.
- Insufficient valuing of immaterial cultural patrimony in the cultural tourism context.
- Unclear and insufficiently known legal frame concerning qualification certification and developing activities in the field of traditional crafts.

- Inexistent professional organizations representing craftsmen and their general interests at local level
- Fiscal frame not stimulating private investments and micro, small and medium enterprises to value this potential.

Strategic objectives:

- Ensuring the viability of immaterial cultural patrimony at local level – respecting and protecting all forms and ways of expression, also through the prevention of extinction or destruction of some of them
- Revaluing and reinserting immaterial patrimony in local community and citizens’ life, especially young generations.
- Protecting origin, originality, authenticity as well as the rights of communities where these forms of cultural expression were born and rights of artisans (re) creating, perpetuating and transmitting them.

Directions for action:

- *Identification, documenting, researching and inventory of various elements of the local immaterial patrimony*
- *Preservation, promotion and valuing immaterial patrimony*
- *Authentically transmitting specific contents, especially through establishing programs in the formal and informal educational system*
- *Elaboration of special training programs for artisans and popular creators for learning techniques, materials and traditional expression forms, to combine them with modern design, in order to preserve authenticity and stimulate creativity and innovation.*
- *Correlation of organization frame of adult education/permanent with the one of training in traditional culture specific fields.*
- *Protecting the originality of creations, artisan products and other components of the immaterial patrimony (e.g., traditional medicine), from piracy and counterfeit.*
- *Developing offer and stimulating communities and creators through*

economic measures meant to motivate them and support their interest in preserving immaterial patrimony

- *Stimulation of public interest in consuming this type of goods*
- *Intensified cooperation and dialogue between creators, communities, organisms and organizations with responsibilities in the field, market and cultural industries in order to support the viability of local and national immaterial patrimony.*

4. Subfield: **Visual Arts**

This refers to graphic and plastic works such as: sculptures, paintings, engravings, lithography, monumental art, scenography, upholstery, ceramics, glass and metal plastics, drawings, design, other works of applied art photographic works as well as any other works express through process analogue to photography.

Strengths:

- The existence of a large number of active creators and of powerful nucleus of creators from all generations;
- The centennial existence of Baia Mare Artistic Center, reason for community pride;
- Public – public, public – private partnerships, with the purpose of expanding access to contemporary creation (organization of exhibitions and other events of the kind, youth artistic education, etc.);
- Circulation in other countries of creators and their works;
- Local funding of cultural projects;
- Large number of unconventional/alternative exhibition spaces for visual arts.

Weaknesses:

- Art market insufficiently developed for absorbing the offer in the field;
- Emphasize migration phenomenon among young artists;
- Low support of contemporary creation through specific public mechanisms (public acquisitions, material and fiscal facilities for developing human resources, creation, exposure and promotion);
- Low effectiveness of public art education programs;

- Inefficient public cultural marketing
- Substantial decrease in the number of public property workshops and spaces for creation;
- Insufficient involvement of artists associative structures in promoting specific social, occupational, financial rights.

Strategic objectives:

- Promoting the city creative potential, both contemporary creation as well as patrimony inheritance Baia Mare Artistic Centre/ Baia Mare Painting School
- Supporting creators in the field of visual arts through legal, economic and social measures
- Increasing visibility and importance of artistic creation in the life of local community.
- Increasing public access and art consumption at the level of various social-professional categories and development of specific market.

Directions for action:

- A new approach to local artistic education
- Protecting and supporting visual arts creators (e.g. protection of copyright)
- Stimulating intercultural dialogue and direct involvement of artists in drafting policies and establishing strategic objectives for the field of visual arts.
- Increasing public interest for visual arts through new forms of public education.[4]

4. Implemented projects

As the first results of this local planning, the first projects dedicated to the Culture subfield have been started and implemented.

a. Rehabilitation and promotion of cultural and historical identity – Citadel Market – Stephen Tower” - infrastructure project, contracted for funding in the Integrated Urban Development Plan (Regional Operational Plan, Axis 1 Supporting sustainable development of towns, Major Intervention Field 1.1. Integrated Urban Development Plans) having as a general objective the cultural – historical valuing and promotion of an urban public

space with mainly historical, cultural and religious destination, through modernizing and rehabilitation of the historical and public edifices in the Citadel Market.

The project proposes the valuing of the following resources in the area:

- Historical signification of the area; Value of historical monument; un-researched archaeological potential;
- Urban value; quality of natural environment, especially through valuing the protected long-standing trees; integration of Citadel Market in the historical and cultural patrimony of the Old City Area (Liberty Square, Peace Square, Art Museum, City Theatre, Butcher’s Bastion, History and Archaeology Museum); using information technology to connect the objective to the regional, national and European patrimony.

b. „CERAMICS” Project - international cooperation project, financed through the Interregional IV C Program,[4] sustaining the development of cooperation between towns with common cultural inheritance, confronted with the same difficulties and having the same goal to conserve and promote the field of ceramics and of small crafts in Europe.

The project activities have led to:

- Elaboration of a common diagnosis of the ceramics sector, with conclusions leading to the editing of a Best Practice Catalogue and recommendations for local support policies for the ceramics field, accomplished for every partner.
- Intensive experience exchanges between representatives of the ceramics field in the partner regions: Hungary, Romania, Portugal, Italy and Slovenia
- Elaboration of the Action Plan for the ceramics field and supporting it at local administrative and political level – Baia Mare Local Council.

5. Conclusions

Strategic planning is considered a process that is developed chronologically and systematically, enabling local communities to create their own image of their future,

drafting for this purpose the corresponding development stages according to the local resources available for achieving their established objectives.

Part of Baia Mare City Sustainable Development strategy, the cultural field is defining for what we are as an individual identity, community or nation, referring to inherited values. Even more important is the present forcing us to preserve these values, creatively use our available resources for the purpose of improving life and our evolution in European and Temporal context – the XXIst century!

The current strategy reflects a prognosis of the cultural development in the following period, supported by the Baia Mare City Sustainable development Strategy, by maintaining the major objectives and consistently promoting them but also through a new approach: inter – disciplinary approach leading to obtaining a quality cultural product, with civilizing, economic effects, influencing synergic fields – tourism or media.

Abstract

Economic development, initially understood and seen as a growth, receives in the 21st century a human side component, decreasing quantitative in favor of qualitative. The tourism industry has experienced a continuous growth, based on natural resources, with adverse effects, and now it's time for efforts to move toward finding a balance between tourism and the environment. Thus emerged the concept of sustainable tourism and, in a broader sense, sustainable development of tourism. This paper proposes a theoretical crossing in the literature, following growth, development and sustainability wire against the background of the relationship between tourism and environment, offering two solutions - tourism niche orientation and social responsibility.

Keywords: economic development, sustainable tourism, environment, social responsibility, niche tourism.

J.E.L. classification: Q01, Q56, L83, M14

1. Introduction

Although initial development was seen as an economic growth, while the idea of diversified development, coordinates of this imposing a reformulation of the concept.

We can look at development as a process of growth and modernization as a process of enlarging the opportunities- human development - and as a process to satisfy the whole range of current needs without

compromising the ability to meet their future-sustainable development.

Obviously qualitative character of the idea of economic development, unlike the quantity that underlie the concept of growth. Tourism niche, born as an alternative to mass tourism, it follows, tourists civic education. Thus, we speak of social responsibility, a phenomenon that provides to development a human aspect.

2. Sustainable economic development

Economic development is a multidimensional process involving major changes in social structures, popular attitudes and in national institutions, aiming at accelerating economic growth, reducing inequality and poverty eradication. Any development policy must take into consideration three basic objectives [4]:

- Increasing the feasibility and widespread distribution of goods that support the basic needs of life;
- Increasing levels of living, including additional high incomes, more jobs, better education, greater attention paid to cultural and humanistic values, respectively, generating a greater national and individual self-esteem;
- Increasing levels of economic and social opportunities that are available to individuals and nations.

The concept of sustainable development is one that has evolved over time. In 1987, the World Commission on Environment and Development defined sustainable development as a viable and

environmentally sustainable "Warranty needs of this generation without compromising the ability to meet their own needs come" [6].

At Rio de Janeiro, in 1992, the UN Conference on "Environment and Development" was discussed environmental protection and supporting a less destructive industrialization, and finding ways and means to replace intensive economic development with sustainable development.

Sustainable development is a concept that is expected to resolve the problems of contemporary society: poverty (in the midst of abundance) environmental degradation, loss of trust in institutions, uncontrolled expansion of urbanization, uncertainty about employment, youth alienation, removing traditional values, inflation, unemployment and other economic and financial crisis or geopolitical.

3. Tourism – environment binomial- the center of sustainable tourism development

Development of society in general subject, the environment in two main types of pressure: one is a direct result of population explosion and expansion of cities, recorded considerable growth of industry, agriculture and other fields, amplifying traffic and transport sitemelor and communication, intensive and extensive exploitation of natural resources and other, more aggressive piutin predominantly seasonal nature, arising from the use of the environment for tourism and leisure activities [3].

According to studies conducted by the World Tourism Organization, tourism effects are grouped into three categories [8]:

- Effects on overall development strategy of a country (area) or global effects;
- Partial effects on the national economy, the agents, sectors, variables and macro economic fundamentals;
- External effects in the socio-cultural, physical and human resources, with indirect economic results.

Tourism therefore not only affect economic and social development strategy of countries worldwide, but also at branch level.

In the context of economic implications is also the contribution of tourism to developing areas less rich in resources processing industries, but tourism resources natural and man who harnessed, can become tourist attractions and determine existing settlements development as tourist resorts or even the creation of new states. Are recovered through tourism also some areas cultural and historical tourism resources with great force tourist attraction [6].

Tourism developments show that the sector has a great economic impact being sometimes a primary source of national economic recovery for countries with important tourism resources. Tourism acts as a stimulating factor global economic system.

Through its specificity - service activity, manpower intensive, intelligence and creativity - tourism has an important contribution to achieving added value. Due to the complex linkages between the tourism industry and other sectors of the economy, tourism has an important effect driving, stimulating production in other areas.

Tourism development policies at the national level involves setting goals and efficiently use macroeconomic levers specific to this field. Are extra-economic objectives (those related to natural and anthropogenic exploitation potential of a country), and economic objectives (increased production, increased income).

Tourism is an economic activity particularly complex for tourism services incorporating content, along with specific services, and some other appropriate economic, giving the character a branch interference tourism and synthesis, hence the magnitude and complexity of linkages between tourism and parts of the economy [6].

From the latest research in the field, Rojo (2009) contrasts the economic development environment, the economic reality of the tourism industry in Andalusia, and Williams, Ponsford (2009) showed tourism-environment paradox by defining the relationship between the tourism industry and natural environment as one not easy and the one in the center of the future tourism policies.

4. Impact of tourism - environmental protection and natural resources

The environment can be defined as the totality of natural factors and those created by human activities which, in close interaction, affect the ecological balance, determines the living and working conditions for human and social development prospects [7].

Must be cultivated a special and permanent environment interest from both the locals and the tourists, thus the environment is considered as an integral part of the quality of tourism services.

Pressure that tourism, along with other components of economic and social environment exerts contribute to its destruction, making more than ever necessary planning rational scientific space. This development should be seen in relation to economic development and tourism development, and taking into account the requirements of the natural and anthropic [7].

Environmental protection is materialized in a series of actions and measures among which may be mentioned that the most important: a thorough knowledge of the interaction between the environment and socio-economic system and the natural system, providing the consequences of this interaction, rational use and maximum economy of natural resources, regardless of their origin, prevention and combating environmental degradation caused by man, and that caused by natural causes; harmonization immediate and future interests of society as a whole and businesses on the use of environmental factors: air, water, nature reserves and monuments, landscape.

More than any other field of activity, tourism is dependent on the environment, representing "raw material" subject and the ongoing activity and tourism, being his support frame, carrier resources. Tourism takes place in the environment and the environment, its quality can promote or deny tourism activities [5].

Environmental degradation and tourism resources is the result of two main groups of factors:

- Factors that are the direct result of economic development;
- Factors derived from the use of the environment for tourism and recreation.

The first group of factors, primarily resulting from increased industrial activities, agriculture and transport, affecting both the

environment and the general development of tourism activities, namely air, water, soil, vegetation, fauna, landscapes, nature and architectural monuments, etc. [3].

Regarding the second group, tourism as any human activity, as a consumer of space and tourist resources, participants involved in the degradation and pollution of the environment and tourism potential, either by direct pressure of tourists on the landscape, flora and fauna or other sights, you can partially or totally damaged, either through misconception recovery of areas and sightseeing points (endogenous pollution) [3].

Environmental quality and maintain a high level is a prerequisite for tourism competitiveness, particularly in relation to international tourism.

Tourism, as a field of activity, and policy makers in this area, incumbent special responsibilities on [7]:

- Avoid wastage of natural resources like water, air, soil, vegetation, considered until recently as inexhaustible;
- Preserving, protecting and improving human settlements (urban and rural), natural monuments, the historical vestiges, traditional architecture and so on;
- Planning, rational exploitation and conservation in the gaps, consistent with future tourist flows;
- Control the effects of tourism in order to prevent environmental degradation and use the best resource conditions.

Tourism can have positive and negative impacts, direct or indirect, tangible and intangible on the environment [2].

An effective strategy, a continuous monitoring and accountability of both local communities and tourists can minimize these effects.

5. Niche tourism and social responsibility - a sustainable alternative

The concept of niche tourism has emerged in recent years against the concept of mass tourism. This implies a more sophisticated set of practical differentiates and distinguishes tourists. In a world where everything tends towards globalization niche tourism represents diversity and ways to score differences.

Responsible tourism seeks to limit negative impacts on these areas, local

communities and local people of the destination host [10].

For tourist destinations using tourism as a tool for economic development, tourism, niche tourism opportunity more sustainable, less environmentally damaging and can attract tourists who spend more. For tourists, tourism niche provides a more meaningful set of experiences in that their needs and wishes will be met.

Tourism niche is determined by motivation, behavior and experience of both production and consumption. Niche tourism offer addresses a small but steady consumer niche tourism is practiced by a small segment of individuals due to preferences and financial situation.

Tourism, through his work, has a duplicitous nature. On the one hand, countries with a high level of civilization are among the most encouraging environmentalism. On the other hand, tourism itself cause pollution because they use the natural resources of the places visited and often leave behind material for disposal [9].

Social responsibility in tourism is via a symbiotic tourism with physical and social environment, in order to achieve sustainable objectives. Responsible tourism seeks to limit the negative effects of tourism activities on both tourism destinations and the local population.

Because an important social responsibility gets increasingly higher their business, more and more hotel companies (both international chains as well as small business local) have adopted codes of conduct and reporting standards that take into account the results environmental and social, not just financial ones, and joined the various schemes of certification and accreditation. There are many initiatives on certification and accreditation of social responsibility and sustainability in tourism - www.greenglobe.org, www.travelife.eu, www.yourvisit.info, www.blueflag.org, www.eceat.org - Quality Label, www.ceres.org - Green Hotel Initiative, www.ecotelhotels.com, greenleaf.auduboninternational.org, <http://ec.europa.eu/environment/ecolabel> [1]

6. Conclusions

In the global economy at the beginning of the millennium, tourism occupies an important place in both international trade and the national economy of most countries of the world. Contributing to the achievement of world gross product and employment, tourism is among the most important components of the global economy.

Due efficient way to exploit the resources and beneficial effects on economic, social and cultural, governments of many countries give due consideration when determining tourism development programs at macroeconomic level.

Niche tourism concept was born as a reaction to mass tourism that differs by the quality of tourists, supporting sustainable development of tourism objectives, funding by local communities. This form of tourism is produced and consumed simultaneously satisfy consumer desires.

Responsible tourism would help to reduce the negative effects of tourism activities and to stimulate local community to realize that protecting the environment and its objectives must be achieved first in their interest, then, in the background, in the interest of tourists.

Abstract

The increase of the production factors’ mobility, given the facts of the economic and financial globalization, brought again into focus the attractiveness of different states at the world level.

This study is focused on the analysis of conceptual term of fiscal competition, from traditional approach such as Tiebout’s theory, up to spatial approach of fiscal competition, and also on the linkage between production factors’ mobility and fiscal competition.

According to the results, our analysis reflects that while the level of the taxation rates variation represents the only explaining factor of the production factors localization in the traditional approach of the fiscal competition, in opposition the new geographical economics tries to explain the localization decisions of the companies, employees and mobile capital, by taking into consideration all the factors influencing the space distribution in the conditions of the economic integration increase.

Keywords: fiscal policy, factors of production, geographic mobility, economic integration.

J.E.L. Classification: E62, E23, J60, F15.

1. Introduction

The economic integration by building a single internal market in 1992 and subsequently the limited monetary integration, initiated in 1999 with the Eurozone emergence, given the fact that the member states weren’t agreeable to abandon their sovereignty regarding the fiscal policy,

are events which came into notice of experts. The decisions of the member states’ governments to steady the factors of production, given the fact of a fiscal pressure differentiated at the level of the Union member states, were influenced by literature concerning the incidence of fiscal competition and the coordination of fiscal policies.

The fiscal coordination is the solution according to the traditional approach of fiscal competition because otherwise the mobile factors settle in countries with reduced taxation in order to balance the reduced productivity of the factors of production. The delocalization consequences on the departure and implantation countries can be found at the level of the internal and external trade exchanges, the occupancy rate of the work factor, the level of tax collection, and the supply of goods and public services.

2. Traditional approach versus spatial approach of fiscal competition

The analysis of the fiscal competition between the component jurisdictions of a federation elaborated by Tiebout [26] has as reference the arbitrage between taxes and public expenditure, to prove that the public sector can be equally efficient in the supply of public goods as the market. This starts from a series of suppositions according to which simultaneously citizens are perfectly mobile and informed about the collected taxes and the public goods supplied by each jurisdiction, the citizens’ incomes derive only from investments’ incomes, there are no contagion effects and externalities between jurisdictions. According to the “voting with the feet” principle, citizens shall settle their

residence in the jurisdictions which offer the combination of taxes-public goods corresponding to the personal preferences at a minimum cost.

Tiebout ignores the fact that the residence choosing depends on the working places and incomes and the residence place can be different from the place where the capital is established, therefore the principle of equivalence between the paid taxes and the public services the tax-payer is provided with ceases to exist. Setting aside the contagion means the fact of not taking into consideration that, the activities' concentration in a given zone has an impact on other, influencing the citizens' preferences and their welfare, and consequently, Pareto optimum disappears. In conclusion, Tiebout's opinion according to which the citizens' mobility provides a fiscal optimum and therefore a fiscal harmonization is not necessary doesn't correspond to reality.

In the models elaborated by Zodrow and Mieskowski [32] and Wilson [31], the working factor is stationary; the population composing the house sector fully consumes the salary and holds a part of the global capital, which is the only mobile factor. The financing of the public sector, of the jurisdictions perfectly monetary integrated and which are on the same level of administration is made through a tax applied on the capital factor. The increase of the tax on the capital factor, in order to supply more public goods, determines the decrease of the private incomes, the increase of the production cost of the public good per taxpayer, the decrease of the taxable base, as the capital factor performs investments and delocalizes towards jurisdictions where the benefit after taxation is higher. Concomitantly with the increase of the taxable base in the jurisdictions where the tax is lower, the public goods provided by them also increase. Consequently, the fiscal externalities determine the jurisdictions to reduce the taxation rates in order to attract the capital and the public goods are provided to a suboptimal level.

Placing their research to the level of a federation with a small number of member states which have the right to institute taxes, Mintz and Tulkens [20] stated that the different taxation rates of the consume, in the conditions of pure and perfect competition,

determine externalities on the private consumption and on the public expenditure and bring into focus both the possible existence and the optimality of a non-cooperative fiscal equilibrium. In the elaborated model, they depart from the supposition that the optimum level of taxation and the supplied public goods must provide the citizens' welfare and the budgetary equilibrium. In their opinion, the fiscal competition between states determines the alteration of the taxable bases when the rates of the indirect taxes are differentiated because, in accordance with the origin principle, the differentiated level of the rates influences the export or import of economic goods between states. As every states establishes its level of taxation, setting aside the one applied in other state, if a state would reduce the taxation rate, then, the funded public goods would decrease but the welfare loss would be balanced by its increase on the expense of the consumption increase. The states confronted with the loss of taxable base would be forced to reduce the rates to a level to which the fiscal equilibrium wouldn't be optimal any more.

As a result of the performed researches, De Combrugghe and Tulkens [7] stated that when the rates of the consumption taxes are identical in two states there is an optimal non-cooperative fiscal equilibrium, but its improvement can be achieved only by increasing the rates and not by their reduction. Therefore, the increase of the consumption tax rate shall determine the increase of the public expenditure (of the public consumption) in the state exporting private goods and services.

In order to analyze the fiscal competition, authors appealed to:

- urban economics: Von Thünen [28] explained the localization of the agricultural activities by maximizing the net ground rent; Alonso elaborated the monocentric city model; Marshall A. approached the agglomeration phenomena of the companies, the emergence of the industrial districts, the sources of the scale economies; Hoover [12] approached the effects of the agglomeration economies; Henderson [11] elaborated a model in order to explain the company concentration);
- regional science: Weber [29] stated that the minimization of the total transport cost

determined the optimal implantation place for a company; Christaller [6] stated that the transport costs and the economies of scale determined the emergence of certain central places which were assimilated to the urban centres; Lösch [16] explained the concentration through the arbitrage between the reduced transport costs and the increasing benefits generated by specialization and economies of scale; Pred [24] was interested in the dimension and localization of the urban centres;

-space competition: Hotelling [18] stated that anticipations regarding competition according to the selling price influenced the companies' localization strategies by which he explained the agglomeration phenomena.

In the literature referring to space economy, there are a large number of models by which various authors try to analyze the space distribution of the economic activities, departing from different suppositions related to the factors' mobility. Baldwin et al [3] proceeded to a gathering of them in four categories. In the conditions of the working factor immobility, the models based on the supposition of the capital factor mobility stated that the concentration of the economic activities was determined by the profit difference [19]. Given the fact that delocalization is made without costs, at the company level the cost of the working factor is variable depending on the produced quantity, and the cost related to the capital factor is constant. The models with the capital accumulation and depreciation depart from the supposition of the capital and working factors' immobility [2], stating the existence of a process of accumulation in the attractive economic zones and a process of depreciation in the peripheral economic zones. Centre – periphery models depart from the supposition of a differentiated mobility of the working factor depending on the training level [8], [14], [22]. The models based on the contractors' mobility depart from the supposition of the contractors/capital owners' mobility, interested in the level of the real incomes when they delocalize and the lack of mobility of the human factor employed [9].

Various authors were concerned with the impact of the fiscal competition from the point of view of the space, analyzing the effects of the capital mobility on the fiscal

collections and stating the necessity of the fiscal harmonization in general and especially the taxation rates. Persson and Tabellini [23] state that, given the fact of the European economic integration, there is a tendency of leveling the income tax downwards, and when the costs of the capital mobility become insignificant we can reach a void tax for the capital incomes. Oates [21] but also Gérard-Varet&Thisse [10] show that the delocalization of the economic activities determined by the increase of the fiscal pressure produce externalities, consisting in the enlargement of the taxation bases in the implantation countries, but also on the fiscal collections in the provenance countries and their passing-by at the supranational level degenerates in a suboptimal allocation of the public goods. For the internalization of externalities, they find for the fiscal harmonization.

Interested in the impact of the fiscal competition on the space distribution of the economic activities, given the fact of the European economic integration and the existence of the agglomeration effects, Ludema and Wooton [17] started from the supposition that the working factor is the one which determines the space distribution. In their opinion, the agglomeration of the economic activities is encouraged by the need of reducing the transport costs and the reaction of the taxable bases to the taxes' modification. When the agglomeration forces are predominant in comparison with the dispersion ones, the economic integration can determine the increase of the taxation rates which shall have as effect the production decrease, imports increase and the consumers shall pay the transport costs related to the imported goods, as well as the working factor migration. The increase of taxes shall be attenuated by the reduction of the transport costs and the final impact shall be found in price, influencing the company competitiveness on the market.

As opposed to Ludema and Wooton who affirm that the regional integration amplifies the agglomeration forces and allows the states to recover their fiscal autonomy, because the delocalization determines the increase of the consumer price index, Rieber [25] states that the integration in an environment with an imperfect competition and increasing benefits has considerable

implications on the distribution of the productive activities, determining the reduction of the costs and prices implicitly, influencing on competitiveness through price.

Keen and Marchand [13] elaborated a model of the fiscal competition taking into consideration the public expenditure which is distributed between an input for the mobile companies and a public good consumed by the stationary workers. They suggest the rebalancing of expenditure for population, as they state that governments support the companies. On his turn, Wildasin [30] stated that together with competition through taxes there is also a competition through public expenditure funded on the expense of the fiscal collections.

The impact of public infrastructures on industries' localization was studied by Martin and Roger [19] who affirm that their level and quality influence the companies' decisions and contribute to the emphasis of the agglomeration forces. On their turn, Justman, Thisse and van Ypersele [15] have affirmed that the public infrastructures influence the companies' transport costs and the mobile workers' localization decisions by means of the utility function differential between different regions.

Anderson and Forslid [1] analyze the impact of public goods and services on the space localization of the mobile factors of production, given the increase of taxes and the existence of the agglomeration effects which lead to the concentration of the economic activities. In order to analyze the taxation impact on space distribution of the activity, they take into consideration various situations in which the taxation rate either coincides or they are different at the level of the two categories of employees and regions. In the opinion of the mentioned authors, the public goods and services funded by means of taxes represent a factor which encourages agglomeration, and the impact on the localization decision depends on the preference to the offered utilities. In order to limit the agglomeration effect and to stabilize the mobile working factor, they suggest the translation of the fiscal obligation towards the stationary factors (the farmers, for instance). However, the performed analysis is restrictive, because they consider that only

the working factor is mobile, setting aside the capital mobility which represents a reality.

Bénassy-Quéré et al. [5] have elaborated a model through which they support the possibility of coexistence of certain regions with high levels of taxation and public expenditure together with regions where these are low. They tried to explain that competition, by taxes and public goods, explains the continuing of certain high rates of taxation in the economic integration conditions.

On his turn, Rieber [25] tried to prove that the localization of the direct investments in the member states is not exclusively influenced by the taxation of profit made by companies, but we must take into consideration the relative importance of whole factors influencing the production costs.

Taking up the topic concerning the supposition of a pure and perfect competition and stating that the market competition is imperfect, Dixit and Stiglitz [8] consider that the factors determining the agglomeration and respectively, the dispersion of the economic activities influence on the space localization of the companies. The size of the working market and its level of training, the scale economies generating increasing benefits, the information exchange between companies, the presence of the professional providers, represent factors which encourage the emergence of an agglomeration effect as a result of the capital factor and working factor concentration in the same economic zone. Instead, the congestion effect, the immobility of the working factor, the available lands, the ground rents and the transport costs determine the dispersion of the economic activities, discouraging their concentration.

Accordingly, the company localization depends on the relationship between the increasing benefits and costs, and the market size and customers' incomes represent determining factors for the emergence of an agglomeration effect. After the agglomeration has attracted new companies and consumers, subsequently, given the market saturation, the competition increase determines the delocalization towards other zones where it is more reduced.

Starting from the supposition according to which public decision-makers try to

maximize the welfare of the stationary factors, Krugman and Venables [14] and Venables [27] have analyzed the relationship between the level of the working factor remuneration and localization, departing from a model based on the fiscal arbitrage between the factors of production which sets aside the costs of the unequal dispersion of the economic activities. In their opinion, given the fact of the European integration, the economic activities centralize in central countries, even if the salaries are higher.

Affirming that the European economic integration hasn't determined the effects envisaged by the theory on fiscal competition, as there are still different noticeable rates of taxation between the developed states (in the centre) and the emergent states (on the periphery) of the Union, Baldwin și Krugman [4] elaborated a model in order to identify the reasons for continuing different rates of taxation, departing from various suppositions: the capital owners are considered the mobile contractors; the working factor is stationary; there is an asymmetry related to the capital distribution which is located at North; the purpose is to analyze the competition between the central states and the peripheral states only by means of the levels of sustainability, removing the influence of transport expenditure on localization, given the fact that the capital flows and the governments' reaction are discontinuous (because the capital can totally delocalize from North to South and backward); -the national richness influence on the supplied public goods and services (which means that in the case of the developed states their provision is made by means of certain higher taxes in comparison with those in which the capital shows a deficit, in the absence of a fiscal competition).

As opposed to the classical theory of fiscal competition, Baldwin and Krugman affirm that capital is centralized in regions where the market size is bigger even if the rate level is high and not in the poorer peripheral regions. The fiscal competition determines the central developed regions to reduce the taxation rates according to the taxation level of the house sector in order to deal with the lower rates used by the less developed peripheral regions. In authors' opinion, the economic integration reduces the

transport expenditure and increases the incomes of the two regions, and the taxes may increase as the rich electorate is agreeable to pay more for taking advantage of public utilities. Consequently, the economic integration provides the capital attraction in the rich regions with a higher level of taxation. Baldwin and Krugman consider that, because of the agglomeration and dispersions forces, the fiscal harmonization determining a single rate doesn't bring a welfare increment for the two regions as the rich region shall reduce the taxation to a level where the capital should not be attracted by the peripheral region. In their opinion, together with the factors operating towards agglomeration or dispersion, which are emphasized by the geographical economics, the fiscal competition can contribute to the concentration or dispersion of the economic activities.

3. Conclusions

Practically, the conclusions of the traditional approach are based on the supposition of certain constant benefits when the competition is pure and perfect. If the level of the taxation rates variation represents the only explaining factor of the production factors localization in the traditional approach of the fiscal competition, in opposition the new geographical economics tries to explain the localization decisions of the companies, employees and mobile capital, by taking into consideration all the factors influencing the space distribution in the conditions of the economic integration increase. This brings into focus the impact of the agglomeration and dispersion forces on the localization of the mobile factors, considering that companies in order to achieve increasing benefits shall direct towards markets of large sizes, where the degree of activity concentration is high. As long as the agglomeration forces are big, the mobile factors shall not delocalize if takes increase.

The CRM a Solution for the Banks Management

Dinculescu Elena –Silvia
Antonescu Mirela Eugenia
Constantin Brancoveanu University of Pitesti
nataliadinculescu@yahoo.com

Abstract

If a few years ago, the banks in Romania didn't put the problem of implementing a management a system of Customer Relationship Management (CMR), today things have changed, the subject learned the agenda of most Romanian banks.

Thus we can say that the market in Romania has kept pace with international trends in this area and, finally, CRM is no longer a taboo subject for the credit institutions operating in our country.

When it comes to market economy, buyers/consumers are free to choose what, when and where to buy a commodity or whether or not to buy a product or service.

Therefore, in order to be successful in attracting customers, the logical starting point for an organization is to identify what is it that customers want and then try to fulfill these requests in a more efficient way than the competition.

Key words: customer relationship management, solution, loyalty, quality

Clasificare J.E.L.: D12, E50, E58, M31

1. Introduction

The banking activity is complex and varied and for this reason it is difficult to define. From an operational point of view „banks are institutions whose current operations consist in granting loans and attracting deposits from the large public”. [1]

The platform of partnership bank-customer is not just a favor, but an objective requirement, a condition of the success for both parties. [2]

K.J. Blois considers that „the service represents any activity that offers benefits without necessarily assuming an exchange of tangible goods”. [3]

The customer is the main instrument of the banking competition in the modern world. The banking system is the most impact to essential mutation of this century – *the change* - namely the customer orientation, component of the change. Therefore, the major objective of banks management is formed by adapting to a change, if we take into consideration the opinion of the great scholar Peter Drucker, who said “change or die!”.

The most initiatives CRM started in 2008-2009, during the economic crisis, which shows that, in fact, CRM has proven to be an attractive solution for the management of banks that have shifted from attracting new customers to retention of existing ones, as a result of the harsh conditions existing on the banking market. [4]

2. General presentation of study on application specific on the solutions Customer Relationship Management (CRM) at the banks of Arges

The study on application specific on the solutions Customer Relationship Management (CRM) at the banks of Arges aimed to analysis the current situation and to identify the future trends CRM in short and medium term.

The study “CRM at the banks of Arges” proved that if a few years ago they didn't talk about CRM in the Romanian banking system, nowadays this is the topic of most of the banks. The Romanian market has kept pace up with international trends in this area and we can say that, in the end, CRM is no longer a foreign issue for banks active in our country. On the contrary, this issue is quite *hot*, the most banks surveyed having already implemented some type of CRM solutions, from the isolated modules and functionality on its own, to highly sophisticated ones.

From the methodological terms, the study was conducted through by face to face interviews, semi-structured addressed to the top management representatives within 10 banks operating in the local market. The interviews took place from October to November 2012.

The purpose of the study is to highlight the main features of CRM implementation in banks of Arges and also to analyze the critical success factors, best practices and likely future trends in this field.

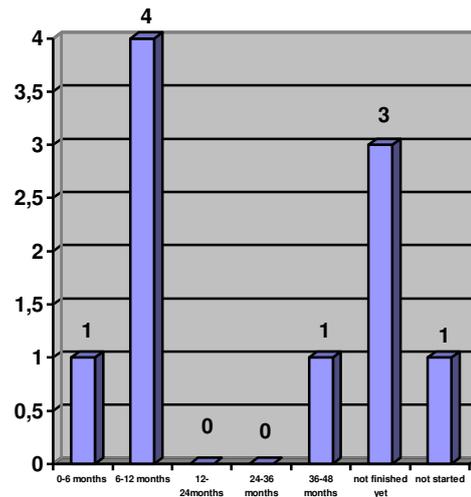

The representativeness of study is measured by two validation keys [5]:

- The aggregated market share of our respondents in terms of net assets (2011). Our respondents cumulated a market share of 78,4%, % as net assets (BCR-19,1%, BRD-14%, Volksbank-6,6%, Alpha Bank-6,4%, CEC Bank-6,3%, Uni Credit Tiriac-6,1%, Raiffeisen Bank-6,1%, Transilvania Bank -5,9%, BancPost-4,5%, ING-3,4%). Given this figure, we can say that the relevance and representativeness are very high research results and trends can be extrapolated to the entire market;
- The aggregate number of retail clients of our respondents (2011). Regarding the total number of retail customers, the banks surveyed have an estimated ~ 16 million clients. Thus, we can say that our research has high relevance and representativeness for the banking system.

3. The analysis and interpretation of results

According to the survey shows that most CRM implementations have a duration of 6-12 months, especially when referring to medium-sized credit institutions and implementation of isolated modules. On the other hand, if we consider the very large banks, on can see that the implementation is longer, up to four years. (Figure1)

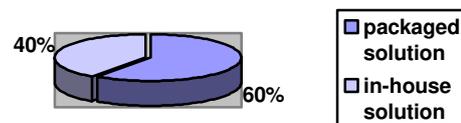

Figure 1. Duration of CRM Solution Implementation

Source: author's data

The data from figure no. 2 shows that many banks have chosen for internally developed solutions, mainly for reasons of cost efficiency. The smaller credit institutions can not support the cost of external CRM software. Most times, they want to implement a few isolated modules and CRM applications. However the largest credit institutions tend a international call providers CRM solutions.

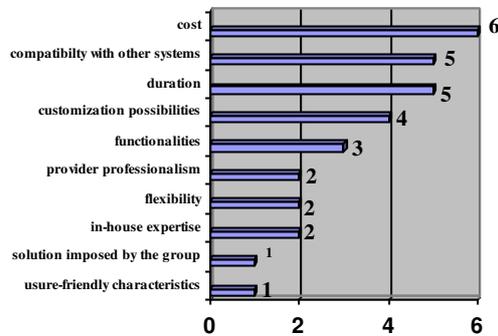

Figure 2. CRM Software Solution

Source: author's data

Regarding the criteria for CRM software providers selection, our respondents indicated: the cost, the compatibility with other systems and the term as the most important in the selection of a supplier. (Figure 3)

Figure 3. Selection Criteria for CRM Providers

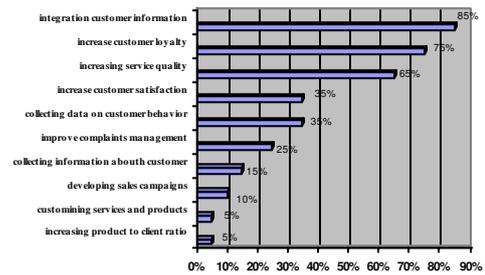

Source: author's data

So far only 60% of respondents recognize the strategic importance of CRM solutions, while the operational relevance is indicated by 40%. Most respondents consider implementations CMR as revenue of increasing opportunities, neglecting the possibility of reducing costs.

Integrating customer information, increased customer loyalty and service quality and these are the major objectives of CRM implementations.

While increasing product to client ratio, services and products and developing sales campaigns enjoys little attention until now. (Figure 4)

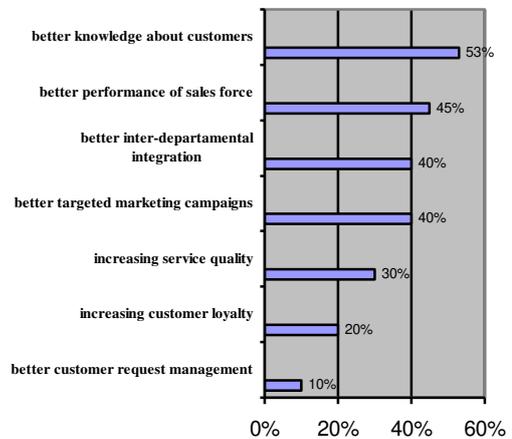

Figure 4. The Main Objectives of CRM Implementations

Source: author's data

Regarding the benefits of CRM implementations, the banks analyzed showed: a better knowledge concerning customers (53%), increasing the number of cross sales (45%), making better targeted marketing campaigns (40%), increase services quality (30%), better performance of customer loyalty (20%) and better customer request management (10%). (Figure 5)

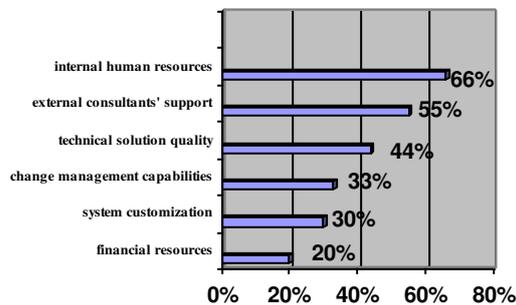

Figure 5. The Benefits of CRM Implementations

Source: author's data

The 10 credit institutions interviewed indicated as critical factors for successful implementation of CRM solutions: internal employees (62%), support external consultants (55%), quality technical solutions (44%), change management capacity (33%), system customization (30%) and financial resources (20%). (Figure 6)

Figure 6. The Key Success Factors in CRM Implementations

Source: author's data

4. Conclusions

In conclusion, we can say, more than ever, that today the ability of banks to maximize customer loyalty is critical to grow their business. Even if the Romanian's bank is still in an incipient phase in terms of CRM, we can predict that this area will see a boom in the coming years.

Banks seem more and more interested to introduce CRM, which allow them to guide their activity according to the customer's request. A customer can be a possible or a real customer, may come in contact which the bank through a multitude of methods, such as [6]:

- Bank's advertising;
- Information requested by phone;
- Information requested in writing;
- Asking at the front office;
- Accessing the bank's of internet.

The more the implementation are, the more visible the results and benefits will become visible to those that are skeptical about the ROI of this investment. This trend is even more striking if we compare with Western markets, the implementation of CRM solutions in the banking sector has been a topic of interest since the beginning of this century [7]

To obtain a stronger customer loyalty, the banks need a better knowledge of this, in order to develop products and deliver services targeted at specific market segments.

This action is a result of better targeting of marketing campaigns, sales and services tactics [8].

The customer loyalty leading to organic growth can only be built through excellent shopping experience and durable. This involves understanding the needs and preferences of each client. One of the biggest challenges banks faced is how can better understand their customers, to offer personalized services, including the application of "Exception Management" adjustable single each client.

The Perspectives of Leisure Tourism in Romania Based on Mountain Tourism Infrastructure and Services

Dridea Catrinel Raluca
Universitatea Româno-Americană
dridea.catrinel.raluca@profesor.rau.ro

Abstract

The negative effects of the economic crises have also affected the international tourism activity. As a result, many destinations have chosen to underline the importance of tourism components like: food and beverage, accommodation, transport and nevertheless leisure.

The leisure services have dramatically changed the notoriety and competitiveness degree of destinations by enlarging the touristic offer, by diversifying it and creating new forms of tourism. The mountain tourism infrastructure and services are considered to be one of the most appealing areas of leisure tourism as major destinations have showed. In consequence, the development of mountain tourism infrastructure can influence in a positive way the revival of Romanian tourism and it's reposition on international touristic map.

Keywords: leisure, infrastructure, mountain tourism, development

J.E.L.: L 83

1. Introduction

Even though many countries are recovering from the negative impact of the economic crisis, the tourism sector is still on the beginning of this process. This is the case of the emerging economies rather than the developed ones.

Many destinations have tried to recover by enhancing their offer by innovation and creating an artificial experience of tourism. But the opportunity of new offer, its variety and novelty are strictly based on the leisure component. Beaches, marinas, cruises, casinos, ski areas, theme parks etc. represent the leisure infrastructure that becomes an

attraction by itself, turning into new forms of tourism for the more experienced and exigent modern tourist. The fruitful experience offered by many countries can establish that the leisure component is more appealing to the modern consumer in regard to the general tourism services. This is why the local and national authorities have reoriented their actions towards the

2. Mountain tourism infrastructure and services

The mountain tourism is strictly depended on the proper infrastructure, being influenced by the degree of its development. The number of ski areas, the slopes and the cable lifts determine the importance of the mountain destination and its attractiveness, especially since the mountain tourists are predominantly skiers. Along with the general leisure equipment, such as: cinemas, malls, clubs, amusement parks etc., the ski areas and their particularity are the central point of the mountain tourism experience.

Therefore, a number of countries have invested in a large amount of modern facilities and a variety of them, which translates into an increase of tourism circulation and destinations' notoriety. More than that, some destinations have grown to be associated with ski practice as a synonym for this activities, for instance: Zell am See – Switzerland, Chamonix – France, Cortina D'Ampezzo – Italy, Kitzbuehel –Austria etc.

A study of mountain tourism presents countries famous for mountain tourism from the point of view of the number and diversity of infrastructure and also, the number of tourists [1].

Table1. Characteristics of major ski areas
Number

Country	Ski areas	Major resorts*	Ski lifts
Austria	254	12	3003
France	325	14	3.731
Germany	510	0	1.827
Italy	349	4	1.948
Switzerland	240	7	1.774
USA	481	7	2.970
China	350	0	800

Source: <http://www.vanat.ch/RM-world-report-2011.pdf>;

* It refers to the dimension of the resort, for instance in Germany are generally small ones;

The countries selected are representative for the impressive number of ski resorts and for the specific infrastructure. More than that, they have oriented the tourism circulation to well positioned market' segments. As far as the mountain tourism, the focus has been on the development of leisure equipment's on one hand, and the general tourism activities one the other hand.

Table2. Major ski areas visitors

Country	Skier visits* thousands	Proportion of foreign skiers %
Austria	52.006	66
France	54.760	28
Germany	13.560	10
Italy	26.820	15
Switzerland	27.550,8	50
USA	58.201	5,6
China	4.640	0,5

Source: <http://www.vanat.ch/RM-world-report-2011.pdf>;

* It refers to an average 5 last seasons or estimated;

Table 2 presents a statistic regarding the number of skier visits and the proportion of foreign visitors, both indicators draw attention to the fact that skiing represents the most important leisure activity for mountain tourism. A brief analyses show that Austria has the biggest number of foreign skiers in comparison to the local ones, but in the same context, the skier visits are ranking on the third position. USA present itself on the first position concerning the number of skier visits, with mainly local tourists (only 5.6% are foreigners).

The figures are sustained by the destinations' notoriety on the international market, especially those related to the Alpes

Mountains. The remarkable result of Compagnie des Alpes – the one that operates the alpine ski area – has determined the importance of ski facilities and ski slopes for the development of mountain tourism. The high number of visit is due to the modern and diversified facilities offered: a large spectrum of chair lifts, increased comfort, such as heated chairs, different types of ski slopes, in concordance with the level of practice and others. In addition, the leisure experience is completed by equipment and services like shopping units, rental ones, food and beverage, animation, entertainment.

Table3. International tourists' arrivals and receipts 2011

Country	Tourists Arrivals Mil	Tourism Receipts Bil. USD
Austria	23,01	19,8
France	79,5	53,8
Germany	28,4	38,8
Italy	46,1	43
Switzerland	8,5	17,5
USA	62,3	116,3
China	57,6	48,5

Source: tourism highlights 2012,

http://dtxqtq4w60xqpw.cloudfront.net/sites/all/files/docpdf/unwtohighlights12enlr_1.pdf;

The majority of countries selected are positioned on the top of charts in regard to the tourist arrivals and receipts, meaning that are perceived to be the most attracting destinations worldwide. This appears as a consequence of the permanent implication in developing the tourism infrastructure and services. Along the others, the mountain tourism has detached itself by becoming a leisure opportunity for ski and après ski activities.

The exigent consumer is attracted to the destinations that provide a more diversified touristic offer, encompassing the benefits of leisure components. The relation between demand and offer is interdependent; for instance the trends in the demand's evolution stimulates the manifestation of future offer and also the new and divers offer has the ability to enhance the addressability degree regarding tourist age, nationality, level of education and others.

Ski practice stimulates increasing tourist circulation to areas that are catering to their needs and wants. As a result, the innovation

turns into more and more ski areas, ski slopes with different difficulty degrees, artificial snow machines, ski schools and so on.

Therefore, mountain tourism destination have searched for innovative methods to decrease the seasonality impact, by investing in specific equipment such as artificial snow machines, or by promoting other forms of ski, like grass ski. Nevertheless, mountain tourism represents a major attraction for all types of consumers that offer a great perspective for general development and competitiveness.

3. Romanian Mountain Tourism

Over time, Romania’s natural potential has exerted an attraction for different types of tourism. Despite the natural environment, the tourism components are inadequate and insufficient and rather poorly harmonized. Nowadays, this is an accurate situation, especially since tourism development didn’t consider the evolution in accommodation, food and beverage and most of all, the leisure one.

Many destinations have invested in accommodation units regardless of the necessity of sustainable tourism, or the inexistence of the entertainment opportunities. This has led to an overflow of tourists in the visited locations, with little or no leisure structures. The lack of these or their obsolete appearance gave birth to a decrease of tourists’ interest in the local destinations; related to the modern expectation of tourists which concentrates on the leisure services and facilities.

In addition, similar countries have acted towards growing reputation in the tourism market. Their initiatives concentrate to promote different forms of tourism and attractions based on the variety of opportunities of entertainment, recreation, development of education level, psychical and psychological toning etc. It consequence, it is imperative that Romanian’ tourism emerge from this incertitude and neglect and reposition the image of an important destination.

As far as mountain tourism, Romania has a great potential, with 27 ski areas and 80 authorized ski slopes [2]. The mountain resorts are permanently visited by a large number of tourists, especially in the winter

season, statistics consistent with market realities. Unfortunately, the ski areas and the specific equipment are rather poorly managed, with little exception; for instance the Prahova Valley hosts the most attractive resorts: Sinania, Predeal, Busteni and others. The large number of tourists corresponds to the public and private investments in tourism infrastructure. As a result, the tourist’s circulation to particular mountain areas tends to increase the seasonality degree with negative impact on destinations and locals.

Regardless of this, the entire mountain tourism infrastructure it position itself at a low level compared to the most important international destinations.

Given that the proportion of Romanian tourism is higher than that of foreign tourists it’s important to analyze the evolution of mountain tourists in comparison to other areas, as it follows:

Table4. Domestic travel by Romanian residents in tourism areas

	Thousands		
	2009	2010	2011
Total	11.165,0	10.796,9	11.985,6
Seaside	1.469,3	1.309,5	1.438,5
Mountain	2.921,7	2.597,6	3.051,4
Spas	290,9	213,5	298,8
Danube Delta	108,1	43,07	42,4
Round Trips	97,1	91,4	86,5
Other areas	6.763,2	6.541,7	7.067,7

Source: adaptation from http://www.insse.ro/cms/files/publicatii\Breviar_turism_2012.pdf; 2011, 2010

It can be seen that, mountain areas play an important part in tourists’ selections of destination. The dynamic records positive oscillation of tourism circulation due to the increased attractiveness of summer and winter sports offers.

The choice of mountain resorts as tourism destinations is explained by the excitement of adventure tourism, extreme sports, and nevertheless ski practice. Even though the leisure opportunities of mountain tourism are at a wide range, the modern consumer is attracted first by the ski facilities and other free time activities are placed on the second option. This ranking stimulates investments

in ski areas and equipment’s rather than non-ski activities.

Related to this are the initiatives of local and national authorities; they have developed a program for mountain tourism development entitled “Ski in Romania „that focuses on 17 ski infrastructure programs: 54 ski slopes, 14 of them with artificial snow and 23 with nocturne facilities accompanied by 2 biathlon tracks, 1 polygon, 1 trampoline, 2 leisure equipment.[3]

The actions were sustained by organizing the event “FOTE” – European Youth Olympic Winter Festival – that required new ski areas, artificial snow, ski lifts and other necessities to cater for them. The European Olympic Committee chose Romania as a proper destination for this event, focusing on the premises that Brasov has invested in the tourism and leisure infrastructure.

The large number of countries participants – 45 – with 910 athletes [4] has led to an increase in Romanian tourism activities. The main problem (regarding the Romanian tourism initiatives) consisted in a little or less promoting actions in order to extend the importance of this event, event that determines benefits for all tourism organizations. Nevertheless, taking part in an international event, developing and organizing it prove that mountain tourism can be an important attraction for a variety of consumers.

4. Perspectives for mountain tourism development

Taking into consideration that some initiative have changed the face of ski areas and therefore mountain tourism and other destination are lacking the necessary funds for tourism development, a series of strategies are considered, such as:

- The attraction of local and foreign investors to specific destinations;
- The strong collaboration between the national, local authorities and the tourism enterprisers;
- The consolidation of accommodation units, food and beverage ones and leisure infrastructure;
- The development of ski areas, ski slopes and all the equipment required in destinations with tourism potential;

- The modernization of slopes descriptive panels, rental equipment centers, protection nets and others;
- The increase of non-ski activities for the segment of non-skier consumer and the large variety of them;
- The extension of ski season by providing artificial snow or developing grass ski as an alternative for winter sports;
- The particularization of ski slopes in regard to the type of sport practiced (ski fond, free ride, free style, telemark)[5]
- The creation of ski and snowboard schools in correspondence with the number of slopes homologated;
- Organizing sport events of national or international notoriety for enlarging the Romanian mountain offer and potential;
- The promotion of accommodation units that include winter and summer sport equipment for all types of ages;
- An intense promoting activities through the mass media and especially through the social networks such as Facebook, Twitter, Google + etc.;
- Creating complex tourism packages similar to all inclusive clubs based on the experience of international leaders, for instance Club Med, or multifunctional tourism centers;
- The development of information centers that provides important and detailed references about the mountain destinations and facilities;
- Identifying initiatives from the countries that are similar to us from tourism point of view and valorizing them etc. These represent a few actions that can stimulate the development of mountain tourism based on the leisure equipment and services.

5. Conclusions

The leisure infrastructure has the ability to change the tourism development and its image in a world ranking. Mountain tourism services represent a major component of leisure and therefore it is a priority to attract investments in valorizing its potential.

Aspects regarding the Romanian tourism suggest that mountain tourism activities and infrastructure are one of the most interesting objectives for the modern tourist; in consequence, the national and local economic agents must collaborate to modernize and promote it for the benefit of all implicated.

A Cultural Explanation for Japan’s Economic Performance, from the view Point of The General Power Theory

Epure Marcel

Alexandru Ioan Cuza University of Iași

Doctoral School of Economics

epure_marcel2000@yahoo.com)

Abstract

There is an ongoing debate over the role of culture in economic institutions, especially those institutions associated with free market, and capitalism. The new theory of General Power is very promising in dealing with all contradictions, and lack of a general view on the role of culture and religion in economic development. Nevertheless there is a particular aspect that is contradicting the general assumptions of this theory in the case of Japan. From the cultural determinates of the preference for wealth and power, Japan should have been an underdeveloped country. This paper tries to eliminate this apparent contradiction.

Key words: Japan, General Power Theory, Mega-goods, Development.

JEL Classification: Z12, B25, E02

Introduction

There are a few theories regarding the role of culture. The oldest is that of Max Weber’s protestant ethics of capitalism. However he doesn’t succeed to fully stand up to criticism. More, critics argue that so called spirit of capitalism isn’t strictly a protestant particularity. Institutionalisms also tries to get a hold on the mechanism of institutional change, recognizes the role of culture, even of religion, but still isn’t able to explain why some institutions persist, why some are bad, and some are stronger than good institutions. Why people tend to ignore rational efficient institution against their obvious interest, in favor of inefficient institutions? The General Power Theory developed by Paul Fudulu offers a new vision, which resolves all these issues, and promises a new understanding of the institutional evolution in developed and underdeveloped counties. [1],[2] As well

formulates a model capable of explaining cultural change, and economic underperformance of culture. However, the model is presenting a concussion that contradicts the facts in the case of Japan.

General Power Theory

In order to provide a good understanding of the issues, we have to present detailed description of the theory. Paul Fudulu starts form the idea of the anti-entropic nature of life: All living beings fight entropic degradation by absorbing low entropy from the surrounding environment. In the case of the humans, this is done by utilizing the available resources in the close vicinity. This amounts to a certain amount of power over an individual’s environment. In other words this capacity to fight physical degradation by engaging at a given time is called General Power.

One can fight the loss of entropy by controlling other members of the human species. In this case the individuals in a society are more interested in gaining positions of power in relation with the members of their community. This promotes an aggressive stance and zero sum games among individuals. The lack of cooperation among individuals is hurting that community ability to maximize on economic relevant opportunities, hence the economic poor performance of such cultures. This preference for power in a culture is called relative power, because its meanings and relevance is defined in relation, or by comparison with other individuals.

People of such cultures to be unequally treated by superiors, teachers, functionaries etc., and they accept that as part of their reality, even from the part of their peers. Everything form economic gains to social conduct and manners are a reflection of the

preference for relative power. For example wealth would be utilized to promote the image of power and superiority among peers, and less wealthy individuals. This preference for power is similar with Geert Hofstede cultural dimension.[5] For example the power distance index describes very well the preference for power in a given community. The findings don't contradict Fudulu's conclusions. Hence cultures with preference for relative power tend to develop centralized institutions, strong market regulation, autarchy and oppressive political institution. Dictatorships and weak human rights ratings are also characteristic. Such countries are plagued by corruption and issues regarding implementation of efficient institutions. Such cultures tend to have more likely quantitative positive trends, then positive quality trends in their economic development indicators.

The second alternative is to control the absolute wealth, without the implication of relative power when referring to this concept, like in the case of hedonistic consumption practices. So the individuals try to control the natural environment. The success in life is measured by the means of one's ability to control his resources, emotions and rationality, in order to acquire wealth. This is not done in order to acquire a position of influence and power. This is indeed unnecessarily, because the acquisition of wealth isn't a factor relative to others people wealth. This is called absolute wealth, because it is not comparable to other people. Such preference for absolute wealth promotes positive games among individuals, and the drive for material possession consistent with the protestant work ethic idea of predestination. Such point of view is often called salvation through acquisition of wealth.

One of the main points for criticism regarding Weber's theory revolves around these issues. One cannot ignore the overall success in economic terms of the Jewish diaspora population, or indeed the economic success of Japan. Max Weber speculates that this is due to the fact that the spirit of capitalism is found in many other cultures, but somehow it wasn't capable of promoting social and economic change in the magnitude of the Protestant Revolution. The main argument for such inconsistencies, not only for Weber, but also for Institutionalism, is a

key cultural effect, described in the General Power model as cultural blindness. From the point of view of western economist, the general premise, from which all economic theory derives, is the desire for material affluence. This is obviously true for all men alive, well most of them. But the way in which this is acquired isn't universally true. If you are culturally programed (culture has been describe by Hofstede as Software of the Mind 1991) to prefer relative power, then all your material gains will reflect this in relation with your peers and superiors. Hence scientists were, with a few exceptions, practically blind to this elusive obvious reality. People in some culture simply prefer positions of power in relation with their peers. This power, in turn, can provide the possibility to acquire wealth, by securing high income; fame, recognition, corruption, wealth redistributions, and extortion form the inferior ranking individuals etc. All their institutions and actions will reflect this preference. This explains very well the persistence of ineffective free market institutions, and lack of sustainable economic development

Relative power and absolute wealth are the only two mega-objectives or mega-goods. It's obviously that one cannot have one hundred percent preference in any one of these two goods, but a mixt in different proportions, much like in microeconomic marginal theory. So the preferences for these two mega-goods can be described in terms of microeconomic theory.

The Problem

All fundamental concepts like rules, institutions and cultures can be defined using these two goods. Each culture would have a predetermined opportunity cost for these goods. This opportunity cost would be inversely related to the preference for a given good. For example if a culture has high opportunity costs for power (because individuals don't accept to be treated unequally) they would prefer absolute wealth instead, hence the community would tend to develop free market institutions and a democratic system. “Institutions are opportunity cost rankings and cultures are preference rankings in terms of the two mega-goods. Each institution, irrespective of

the particular field or sector to which it belongs, consists of a ranking in terms of opportunity costs for the two mega-objectives [1, pp.170]

The consistency with economic performance for a culture requires decoding them in terms of preferences and opportunity costs for the two mega-goods wealth and power. Paul Fudulu classified the criteria of consistency in two sets. The first set consists of criteria which have a direct reference to absolute wealth: (like material prosperity, work related values, prohibition of interest. The second set consists of criteria which contain references to the preference for power. (The means of salvation, type of asceticism, obedience to authorities, the masculinity, and the type of spiritual organization.) These criteria, and the way in which they can be related to opportunity costs for the two mega-good are extensively described by Paul Fudulu. This produces the following general ranking in a descending order: Judaism, Protestantism, Catholicism, Orthodoxy, Islam, Confucianism and Buddhism.[2, pp. 169]

As we can see Buddhism and Confucianism, both important religion in Japan, score the lowest ranking for economic compatibility. Paul Fudulu concludes that economic development in Japan is due to imported economic institutions that were imposed with force by the Japans political elite. Hence the institutional environment resembles a system compatible with the protestant work ethic, but this was imposed with political means.

We argue that, although japan in fact imported foreign economic institutions, their implementation and success is due to some informal institution, which were in place long before Meiji era. Informal institutions are based on cultural particularities and local religion. Somehow Japan manages to have high relative power preference, which is combined with western culture high absolute wealth preference.

Why do Japanese people have a work ethic that puts even then best protestant diligence to shame? There is a particular interpretation of Mahayana Buddhism, particularly the Japanese Zen School of spirituality, which is stressing a work ethic for the believers, that is similar in its ends with Protestantism. Japanese Zen Buddhism

is stressing the belief, that one must devote body and soul to one’s work. Diligence and industriousness were accepted practices among the common people long before Japan was forced to open its gates to the world.

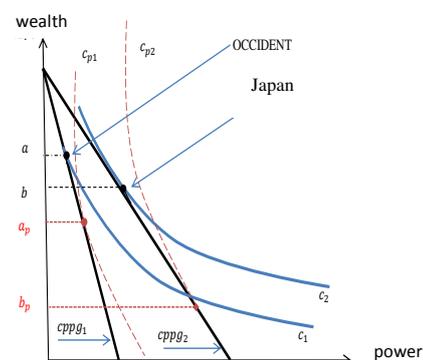

Suzuki Shosan (1579-1655) a buddist zen monk, strongly advocated that sweating at one’s work means the practice of *Buddhism*. *Shosan* preached that: Any samurai, farmer, artisan or a merchant, must exercise diligence in one’s profession:

- 1) *Samurais* must sacrifice themselves for the master with courage,
- 2) Farmers must go out into the fields to work with devotion,
- 3) Artisans must pursue a craft with determination and responsibility
- 4) Merchants must work in the name of heaven, and should engage in trade for the benefit of country and people. [4, pp.12]

In this aspect virtual redemption and end of the cycles of reincarnation is possible for everyone, not only for the monks, that practice an ascetic life impossible for the common people. Hence a huge relative power source for the culture. Now the ascetic way of the monks, can be performed in everyday life. The perfection in accomplishing ones duty to the family, peers, superiors, country emperor, is the way to achieve true illumination, and eventually the end of the cycle.

This is nothing more than what the Protestant preacher demanded form the ordinary believer, and is consistent with low opportunities costs for absolute wealth.

Figure 1 Japans economic institution, from the General Power perspective

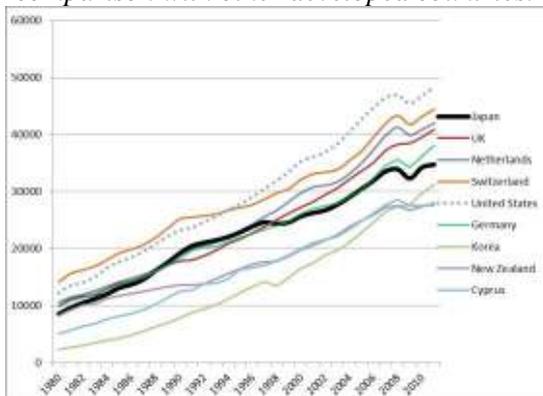

Source: interpretation of the model [1]

Japan has a relatively high preference for relative power based on the cultural influence of Shinto, and Confucianism. This is

confirmed by Hofstede in his cultural dimensions analyses.

In figure no.1 we have the cultural indifference curves c_1 , and c_2 for a high wealth preference culture. For comparison we have also the curves for a high power (in red) cp_1 and cp_2 , In the case of Japan we took in consideration an increase in the preference for power; c_{ppg} (the curve of general power possibilities) represents the combination of general power specific to the institutional system in a developed country; we consider Japan a culture with high preference for absolute wealth, and its c_{ppg2} , is specific for a more controlled economy; is a better institutional alternative for Japan, because it represents a higher position indifference curve c_2 The price is a lower level of economic development ($b < a$), the only difference is that an liberal system like in Occident would produce a slighter higher level of development.(Represented by c_{ppg} 1) The model suggests that Japan should have a lower GDP per capita PPP then most of the western developed countries.

Figure 2 Japan`s GDP per capita PPP evolution between 1980and 2011, in comparison with other developed countries.

Source:[3]

In Figure 2 we can see the evolution of Japan's GDP per capita on PPP. Data suggests that Japan has a development level equal with most of the Western Europe protestant countries. These countries have strong liberal economies, but also with strong regulations and government intervention, but Japan lacks behind more liberal countries like Swiss or USA. The relatively long period of two decades shows that Japan development in qualitative terms is somewhere in the middle range, of developed economies. The empirical data form IMF, and World Bank supports this finding.

Conclusions

The General Power theory does not collide with the Japanese case, and the preference for absolute wealth is based on cultural characteristics of the Japans cultural system.

The Japanese Zen Buddhist work ethic is organically mixed with the collective values of Confucianism and Shintoism. Japan manages to perform an institutional equivalent of a limbo walking, taking advantages form the free market system, but also from the protective, and highly paternalistic culture organization. The price is a relatively lower economic development level, in qualitative terms.

Theoretical Considerations Referring to Law no. 10/1995 Regarding the Quality in Constructions

Gheorghe Lucian,

Ovidius University of Constanta, Faculty of Mechanical Engineering, Industrial and Maritime

gheorghelucian2003@yahoo.com

Abstract

After the year 1989 Romania faced an unprecedented intensification of the legislative activity. But what worries the most is not the great number of normative acts, but their imperfection. Being unsufficiently elaborated, after their coming in operation they were modified and completed by other normative acts, wich in their turn were modified and completed, generating the legislative instability phenomena.

Directly proportional to the multitude and imperfection of the normative acts, appeared both the more ununitary judicial practice, in almost every justice branch.

Keywords: Quality, Buildings, Designer, Certification

Classification J.E.L.: K4 - Legal Procedure, the Legal System, and Illegal Behavior

1. Introduction

Initially, most of the actual form of the Law no. 10/1995 regarding the quality in constructions was elaborated between 1993 – 1994 and approved by the Romanian Government in 1994 by Governmental Order.

Based on the very same law text, diametrically opposite solutions are pronounced. This ununitary judicial practice is emphasized not only between different instances of the same rank, but often between the pannels of judges from the same instance. In this manner it became a fact that some solutions arbitrarily depend on the instance's or the pannel's practice, and not on the law's sense and spirit. These inconveniences wouldn't take place if the elaboration of the normative acts should respect the provisions of the 34th article from Law no. 24/2000 on

the standards of the legislative technique for elaborating normative acts, according to wich „the normative acts should be drawn up in a concised, sober, clear and precise style, wich should exclude any ambiguity, with the strict respecting of grammar and spelling rules”.

At that time, the law consisted in a significant step forward on the way of the transition from a hypercentralised economy to a market economy. The law was the fruit of the work of some of the best specialists in the field, who promoted their best at that time.

The main interest of the Law no. 10/1995 regarding the quality in constructions is that it has regulated for the first time in our contry a unitary system of insuring the quality in this vast field of constructions, settling cryteria according to the European legislation. The regulation for the application of the Law established the method for the abilitated instances to inforce the provisions of the law. It has been institutionalized for the first time in our country the institution of the Projects Verifyers, the Technical Experts and Site Master, settling the responsibilities, the field of action and the degree of responsibility for everyone along with the investor and the constructor. It has been also institutionalized the way of selection and certifying the Verifyers, Experts and Site Masters, so that this activity to contribute effectively to the insurance of the quality in constructions. The subsequent modifications and completions to the law were ment to adapt the law to the new realities of Romania, without operating a structural change of the law as a hole. The new law tried a democratic cosmetization of the intervention measures of the statal authority, taking over some recommendations of the EC Directive regarding the construction products, but without a crytical evaluation in their application to the circumstances of our country.

2. Arguments pleading for a modification of the Law no. 10/1995

Construction law developed in conditions of transition to market economy situation is inadequate and does not provide both biodiversity and prevent environmental pollution and the development of environmental management related to the rational use of natural resources.

In recent centuries, the economic states of the world was achieved mainly on account of damage and simplify capitation natural wastage of natural resources, environmental degradation and health of the human population. The concept of sustainable development requires economic and social development and environmental protection in mutual completion. Judicious management of natural resources can be profitable for both current users and future. Adopt the concept of sustainable development in developing countries can avoid costly problems related to environment and availability of resources for further development. In the 12 years from the publication of the Law no.10/1995, there were major modifications in Romanian political, economic and social life.

The Romanian society was structurally changed, some of the state's functions were profoundly modified and the private property became the main source to increase the IBP.

The civic conscience of the population raised, the professional associations were consolidated in all economy branches, the commercial, cultural and tehnico-scientific changes thoroughed with the most developed countries in the world, the degree of alignment of the Romanian legislation to the European legislation increased.

From the economic point of view, starting with the year 200, the Romanian economy encountered an ascending trend, and on the found of this economic increase the volume of the constructions in our country encountered a great ascendance.

All this factors prove that some laws, standards or normative acts elaborated in other conditions need to be modified, aligned to the actual needs of the economy.

Concerning these ideas, we must admit that the Law no.10/1995 regarding the quality in constructions is a confuse law in the theoretical aspects, not founded on a scientific base, on a logical and viable

concept. The Law no. 10/1995 is an out-of-date law by its spirit proper to the past regime, totalitary and authority, expressed by the total control of the statal authority on all constructions activity, a control wich implied no responsibility from the one in control. The Law no.10/1995 is an out-of-date law by its reference to instances wich no longer exist and to amounts of penalties that became hilarious in the actual circumstances.

In these conditions it is normal to regard the following:

- the necessity to abrogate the Law no. 10/1995 regarding the quality in constructions and to elaborate another law, more comprehensive and adequate to the actual orientation towards the values of the capitalist society, a law capable to include the requests of the constructions activity in such a formulation that the equivocal and taints of the former Law no.8/1977 should be eliminated;

- the necessity to sustain the role of the civil society, the engineering, professional an patronal associations, in wich concerns their active participation to the monitoring of the activities in the constructions field;

- the Law no. 10/1995 regarding the quality in constructions is the continuation of the Law no. 8/1977 regarding the insurance of the duration, safety and security in exploitation, functionality and quality of constructions, wich had and has still the role of subordinating the hole construction activity to the control of the statal authority. It would be more adequate to elaborate a new “Law regarding the activity in constructions”, because by that it could be treated and regulated more important aspects of this activity, the insurance of the quality resulting implicitly from the respectance of its provisions, as it is in other countries.

In fact, even the actual law regarding the quality in constructions regulates also activities explicitly oriented towards quality problems, fact that I wished to emphasize by reformulating its text for a further eventual revision. I considere that the revision of the Law no. 10/1995 or the elaboration of a new law regarding the activity in constructions should be discussed in public, drawing into the debate the professional and patronal associations of the public institutions interested. I appreciate that the following

suggestions should be opportune for a new content of the law:

- First of all the formulation of the title of a new law should be, by example, „Law no.10 regarding the insurance of the quality in constructions”, because it is about regulations referring to human activities and their results, the actual form „Law no. 10 regarding the quality in constructions” not being clear and explicit from the judicial point of view (the grammatical interpretation) of the participants to this actions.

- 1st article could be formulated this way: „The insurance of the quality in constructions is done by a series of activities and measures ment to grant the constructions the capacity to satisfy the requests of the beneficiaries according to their functional destination”, instead of the definition „The quality in construction is the result of their hole performances in exploitation, in order to satisfy, during their period of existence, the exigences of the users and colectivities”. The referring from the 1st art. 2nd align. to technological instalations and equipments can be missing.

- In its actual form, the 2nd art. mentiones : „The provisions of the present law are applied to constructions of any cathegory and their afferent installations – in spite of the form of property or destination – named in the following constructions, and also to their works of modernization, modifying, transformation, consolidation and repair. There are excepted the buildings for dwelling with ground and first floor and the annexes situated in rural environement and in villages that belong to towns, and also the temporary buildings”. I considere that the 2nd art. could be formulated this way: „The provisions of this law are adopted as part of all cathegories of constructions, indifferently of their form of property.” The completion regarding to „works”, as well as the „exceptions from the law” do not have a sense.

- 3rd art. could be more enlightening if formulated like this: „By the present law it is established the system of insuring the quality in constructions wich should lead to the realization of constructions able for exploitation according to their destination and that do not endanger the life and health of people, the integrity of goods and the cleanliness of the environement”.

- 21st art. reffers to investors that finance and realize investments or interventions on the existing constructions from the concieving to projecting, execution and reception. As an obligation and responsibility these investors shoud:

- ◆ Invest only in constructions concieved and projected respecting the conditions of quality imposed by the technical regulations and agreements in operation;
- ◆ The execution should be realized based on a contract wich contains the supplementary quality conditions and the terms of their guarantee, using materials of whom the quality is certified and under the controll of authorized fizical or juridical person;
- ◆ The reception should endorse the finding of respecting the conditions of quality mentioned in contracts and the remedy of deficiency”.

- 22nd art. reffers to designers, who should:

- ◆ Respect the provisions of the technical regulations, of the technical agreements and those of the contract referring to the minimal conditions of quality;
- ◆ Elaborate instructions and projects regarding the monitoring of the constructions;
- ◆ Participate to verifications during the execution and reception of theconstruction, providing the documentation of the project for the technical manual of the construction.“

- Another aspect left uncovered by the Law no 10/1995 regards the certification of the professional qualification. The quality in constructions represents one of the priority objectives at the national level, because Romania’s position in an intense seismic area, with special climatic conditions, leads to the necessity of adopting radical measures for insuring the quality level of constructions, in order to protect people’s lives and goods, the society and the environement. Law no. 10/1995 grants the legislative field wich allows the realization of constructions at the level of requests, still existing a legislative lack in the evaluation of the professional competence of societies, both Romanian and foreign, who participate to the concieving and execution of constructions, regardless of the form of financing.

3. Conclusion

The present article didn't propose an exhaustive analysis of the legislative changes that should be imposed to Law no. 10/1995, but only an introductory presentation of those. I consider that the legislative act analyzed, due to the changes and completions suffered in time and also due to the doctrine and speciality literature, will occasion various analysis and interpretations in practice and juris-prudence.

Juridical Aspects Concerning Fiscality, Work Relations and Professional Training in the Field of Constructions

Gheorghe Lucian,

Ovidius University of Constanta, Faculty of Mechanical Engineering, Industrial and Maritime

gheorghelucian2003@yahoo.com

Abstract

The constructions - a branch that is in close agreement with the overall evolution of Romanian economy - are confronted with the same hardships from a fiscal viewpoint, and not only that, as the whole economic activity from Romania. In the period following the year 1990, the business environment has been subjected to too many changes, which have also negatively influenced the investment activity in Romania. While focusing on the field of activity of constructors, which also involved the collateral industries of construction equipment and materials, we must notice some manifestations which contribute to the negative effects recorded by these.

Keywords: Quality, Buildings, Designer, Certification

Classification J.E.L.: K4 - Legal Procedure, the Legal System, and Illegal Behavior

1. Introduction

European integration is a response to the increasing pressure of globalization in that it is difficult or even impossible to achieve this if the countries do not have the same level of development. Among emerging phenomena which require both theoretical concerns and economic policy, it is noted the phenomenon of international and regional economic integration, which entails, by its nature, a number of consequences of legal, economic, politically and socially. Also, through European integration, it provides enhanced its compliance with the standards of international integration through greater harmonization of policies of local traditional leveling distinctions between policy

instruments, legislative, local and international economic and social. However, these trends are inadequately investigated both at national and at regional and global levels. Sustainable socio-economic system of our country is largely conditioned by the weight and quality of natural capital, the state of the environment and hence the construction sector, which provides optimal ecological balance not only locally and regionally, but also globally. The current phase of post-industrial technological revolution that took place in developed countries, is synchronized with the first confrontation previous environmental hazards and reduction of the influence of eventual exhaustion of resources.

As background and condition of all these processes is the humanization of social life linked to the expansion of the post-industrial values, the heart of which is man's aspirations. Taxation is one of the areas that has passed through the most important changes in recent ten years unfortunately, these changes have occurred either too slow or too fast, so that the fiscal environment often embedded in the consciousness of taxpayers that is an instability factor in the development of Romanian economy.

Businesses recognize the progress in legislative framework for the harmonization with European regulators or the flat tax. however, poor administrative capacity remains the weak link in the Romanian fiscal system.

After 1989, Romania has experienced unprecedented intensification of legislative activity. But what worries most is not so large number of acts, as their imperfection.

Not sufficiently developed, after their entry into force have been amended and supplemented by other regulations, which themselves were amended and supplemented, which led to the phenomenon of legislative

instability. Directly proportional to the multiplicity and imperfection normative acts appeared increasingly inconsistent judicial practice in almost all branches of law.

On the basis of the same legal text gives solutions are diametrically opposed.

This unitary judicial practice is highlighted not only between different instances of the same grade, or between instances of different degree, but often even between panels of the same court.

Thus, it came as some solutions depend on the arbitrary practice court or judge, and not by the letter and spirit of the law. Such inconvenience would occur in drafting laws were complied with art. 34 para. 1 of Law no. 24/2000 regarding the legislative technique for drafting laws, according to which "normative acts must be written in concise, sober, clear and precise to avoid any ambiguity, strict compliance with the rules of grammar and spelling."

The construction sector together with the supporting industries hold a significant place in the structure of the Gross Domestic Product (GDP), and if we take into consideration the demand of investments in infrastructure, civil and industrial constructions etc., then the weight of this sector should become greater, at the normal levels of the process of restructuring which our country's economy is going through.

The experience which was acquired and above all the hardships with which construction units are confronted lead to the conclusion that urgent steps should be taken towards the revitalization of this productive sector of economy and, last, but not least, the increase of the incomes of the state budget.

Furthermore, I will pinpoint the main problems, to which finding a solution is imperative according to me, but also to experienced economic agents. Let me point out that this paper does not discuss all the economic and social problems, it only structures a series of main issues, which affect especially and directly the economic agents from the construction field.

2. Content

At the current level of economic development a major role in contemporary society had unquestionably nature and extent of any construction that were committed

significant human and material resources.

In this context, objectively, it was necessary legal regulations specific to both international and national. These regulations have come, as I show below, different stages of development, from unwritten to the written forms, the regulations scope restricted to regulations affecting the national level.

It should be noted that specific legislation also supported depending on the country's economic development and the nature of the political regime in power, profound changes, but mainly diversification designed to provide solutions to a field as dynamic as that of civil engineering.

I appreciate that, following the documentation that we made, analyzed the current legislation, meet the main requirements of "construction market" and is aligned with the European one. Clearly, significant changes are taking place now, after joining the "European family".

Support this claim, as in the European Union, the legal rules specific to this field so dynamic, are in constant transformation, with an emphasis on both quality standards aimed at material resources used in the construction market and the improvement of working conditions and the protection of people at work. Buildings are designed to provide people the necessary conditions for their material and spiritual activity.

Development of a society in economic and social terms, it reflects on the technical level of construction.

In the current economic context, participation in the public procurement for small companies represent a real opportunity for survival.

Although participation in such procedures can be challenging for operators interested in both the public procurement legislation and the specific legislation for small companies provides a series of levers with which to procedures for the award is facilitated.

The fiscality, unstimulating for the economic development

In Romania, fiscal pressure in the construction activity, and in other activities as well, is very high, reaching over 40%.

This high fiscality does not favour the reinvestment of profit, in exchange it leaves an open way to the development of the "black market". Any investment done in

Romania has a cost of approximately 55%, the rest being covered by taxes.

Establishing the circumstances in which VAT is exigible in obtaining incomes

The current system of collecting VAT is very damaging for construction entrepreneurs, in the event of carrying out construction works financed from public money or from the money of economic agents with integral or majority state-owned capital. Currently, the obligation to pay the VAT arises on the date of making the delivery of goods and chattels, transferring ownership of real estate assets, and providing the services, more specifically at the time of delivering the bill to the client, regardless of whether it has been paid or not. From the moment of delivering the bill to the client, the construction company becomes indebted to the Ministry of Public Finance by the corresponding equivalent value of the VAT.

It is commonly known that in the construction field, between the time of issuing the bill (a bill recognised by the client) and that of collecting (cashing) it more than 60 days pass. During the time in which the construction company did not cash the bills and therefore did not pay the corresponding VAT, it cannot participate to the auctions organised for public investments, since, according to the laws in force, the company being indebted to the state, it becomes ineligible for the auction activity, thus losing important contracts.

The allotment of investment funds uncorrelated with the contracted completion time

At present, a serious problem which construction undertakings are facing is the lack of discipline in contractual relations, especially in the case of investment objectives financed through state budget and local budgets, as well as through the own sources of economic agents with integral or majority state-owned capital. The lack of discipline in contractual relations is visible in the lagging year after year of the dates of release for the works with the increment of the period of completion, as a result of low levels of fund allotment. In such a situation, the construction entrepreneurs' activity results in unfavourable economic effects by

blocking material resources and some worksite means of organisation during long periods of time, blocking the “successful execution guarantee”. Most of the times, the value of unfavourable effects is higher than the level of the profit from the contracts.

Aspects concerning the estimation of the value of the supply contract

If contracts have a period of completion longer than 12 months, then the contracting parties have the right, throughout the completion period of the contract, to arrange for the modification of the clauses regarding its price, for what remains to be completed, by an addendum, only in the event of the occurrence of circumstances which prove to be detrimental to the lawful commercial interests of the parties and which could not be provided upon conclusion of the contract.

The formula for updating the price of the contract, applied in order to ensure protection against inflation, must not result into exceeding the price expressed in euros at the time of making the offer. I feel that a monthly updating of the undertaking contract is advisable, according to the inflation index even in the case of contracts whose period of completion is shorter or equal to 12 months.

Reducing the quantum of the successful execution guarantee

The guarantee should be constituted as a bank deposit, and the updating of the discount price should be done according to the euro - RON exchange rate or to the cumulated inflation index.

A legal framework should be created, by a normative act issued by Parliament, which to allow for the qualification certification of construction companies.

Certification of professional qualification of construction enterprises represent a official recognition to businesses whose activities in construction, by bodies recognized by the regulator in the construction. The existing legislation, Law 10/1995 on the quality of construction ensure at least in theory building performance level requirements. However, it is imperative to introduce ways that technical competence of enterprises to be kept under control.

In most EU countries the construction companies are certified in terms of

professional qualifications, professional associations and / or certification bodies.

Presenting the certificate of professional quality for a particular area may replace eligibility file, the file is requested in the current procurement procedures.

To decide, by statute, on a better cooperation between the professional associations in the construction field and the technical and construction universities towards finding and undertaking valuable research works/projects, useful for the construction companies. Also, it would be opportune to carry out an analysis (with the participation of specialists from the field of education and constructions) concerning the state of education in the field of constructions, with a view to identify possibilities of collaboration for the improvement of study programmes.

Abstract

One of the key indicators of human welfare refers to consumption. Moreover, consumption, along with other component – production, is one of the major themes of EUROSTAT indicators system of sustainable development. In real terms, total consumption expenditure of households in Romania increased in the first eight years of the last decade, growth followed by stagnation and even by a decline during the global financial crisis that hit our country.

The present paper performs a multi-criteria ranking of Romanian development regions, applying two ranking methods: the Relative distances ranking method and the Real ranks method.

Keywords: consumption expenditure, household income, multi-criteria ranking method, relative distance, real ranks

J.E.L. classification: C30, D10, R10.

1. Introduction

European Sustainable Development Strategy supports the idea of sustainable consumption and production, the basis for an improved quality of life [7]. Sustainable patterns of production and consumption means a reduction in the negative impact of human activity on the environment. The first part of the paper includes an analysis of consumption expenditure and income of households at national level, followed by an analysis at regional level.

2. Analysis of consumption expenditure of households at national level.

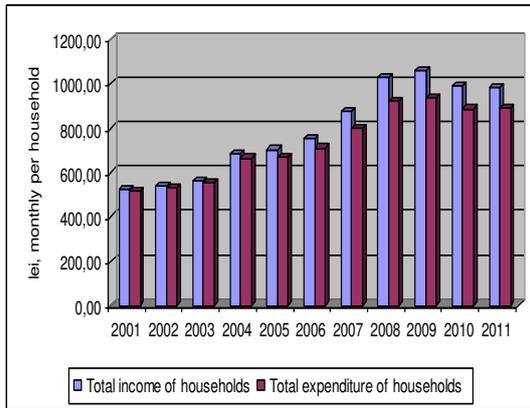

In 2001-2011 period the total monthly income of households, expressed in lei per household has doubled from 521,79 lei to 982,71 lei (real values, comparable to the level of 2001) [1]. Monthly expenses had a similar pattern with the revenues, increasing until 2008 and then decreasing after this year.

Table 1. Total income and total expenditure of households - real values (2001 level) (lei, monthly per household)

Year	Total income of households (lei, monthly per household, real values – 2001 level)	Total expenditure of households (lei, monthly per household, real values – 2001 level)
2001	521,79	516,52
2002	537,56	531,97
2003	562,94	553,28
2004	686,99	664,31
2005	703,65	667,17
2006	755,16	710,68
2007	876,41	801,18
2008	1026,96	922,67
2009	1056,71	934,13
2010	991,00	887,21
2011	982,71	887,78

Figure 1. Total income and total expenditure of households - real values 2001 (lei, monthly per household)

Source: made by the authors, based on data in Romanian Statistical Yearbook, 2012, National Institute of Statistics and www.insse.ro [6] [8]

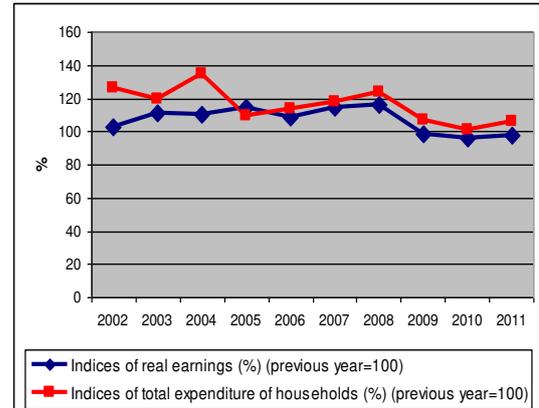

In the first part of the last decade, growth indices of real earnings recorded lower values than those of real expenditure of the population. In the second part of the decade (after 2005) the evolution of the two indicators is similar. Indices have values above unit on almost the entire period, except for the years of financial crisis [2].

Table 2. Indices of real earnings and indices of total expenditure of households (% - previous year=100)

Year	Indices of real earnings (%) (previous year=100)	Indices of total expenditure of households (%) (previous year=100)
2002	102,4	126,16
2003	110,8	119,92
2004	110,5	134,36
2005	114,3	109,53
2006	109	113,51
2007	114,7	118,19
2008	116,5	124,2
2009	98,5	106,9
2010	96,3	100,76
2011	98,1	105,86

Source: made by the authors, based on data in Romanian Statistical Yearbook, 2012, National Institute of Statistics and www.insse.ro [6] [8]

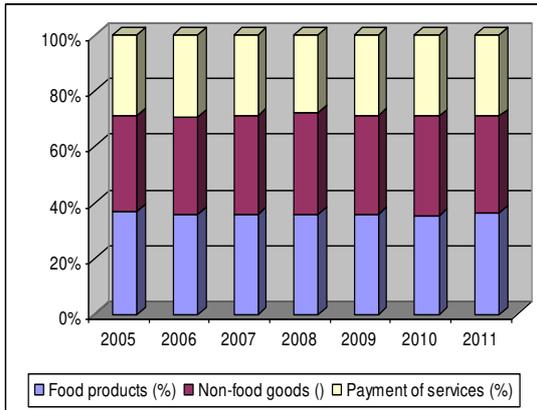

Between 2005 and 2011 in Romania households spend approximately equal weights for the purchase of food products and for the purchase of non-food goods (although the share for the first category of goods is slightly higher). Thus, in 2011 36,1% of money expenditure for consumption was spent for the purchase of food products, 34,8% - for the purchase of non-food goods and the remaining 29,1% - for payment of services.

Table 3. Money expenditure for consumption, 2005-2011

Year	Money expenditure for consumption			
	Total (lei, monthly per household)	of which for:		
		Food products (%)	Non-food goods (%)	Payment of services (%)
2005	720,27	36,7	34,5	28,8
2006	815,46	35,6	35	29,4
2007	946	35,8	35,4	28,8
2008	1185,33	35,9	36,2	27,9
2009	1275,03	35,7	35,7	28,6
2010	1286,29	35,5	35,4	29,1
2011	1320,83	36,1	34,8	29,1

3. Analysis of consumption expenditure of households at regional level.

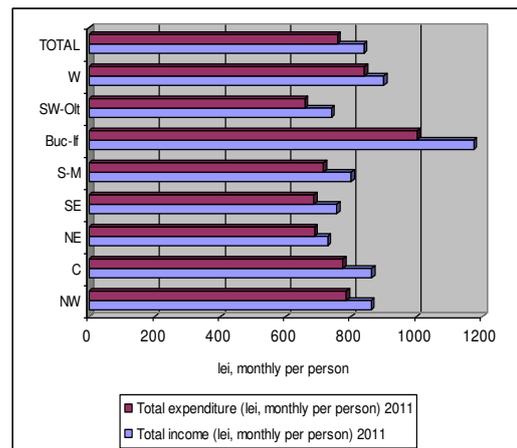

Further, the analysis focuses on the eight development regions of Romania for 2011. The regions with the highest levels of both total income and total expenditure of households are Bucharest-Ilfov (income: 1175,43 lei, monthly per household, expenditure: 1000,72 lei, monthly per household), followed by Western region. In terms of household income, North-Eastern Region ranks on the last place (727,86 lei, monthly per household), preceded by South-West-Oltenia Region (741,24 lei, monthly per household). In terms of households expenditure, the last place belongs to South-West-Oltenia Region (658,94 lei, monthly per household), preceded by South-Eastern Region (687,14 lei, monthly per household).

Table 4. Total expenditure and total income at territorial level, in 2011

Development region	Total income (lei, monthly per person) 2011	Total expenditure (lei, monthly per person) 2011
North-West	861,74	786,7
Center	864,02	774,98
North-East	727,86	688,41
South-East	756,98	687,14
South-Muntenia	800,67	716,12
Bucharest-Ilfov	1175,43	1000,72
South-West-Oltenia	741,24	658,94
West	900,97	841,58
TOTAL	839,53	758,43

Source: Romanian Statistical Yearbook, 2012, National Institute of Statistics and www.insse.ro [6] [8]

Figure 4. Total expenditure and total income at territorial level, in 2011.

Source: made by the authors, based on data in Romanian Statistical Yearbook, 2012, National Institute of Statistics and www.insse.ro

Analyzing the structure of money expenditure for consumption by categories of purchased goods and services, we make the following observations:

- Bucharest-Ilfov Region ranks first in terms of share of money expenditures for all three categories of goods and services: purchasing of consumed food and beverages (24,5%), purchasing of non-food goods (22,6%) and payment of services (22,5%).

- A relatively high share of money expenditure for purchasing food and

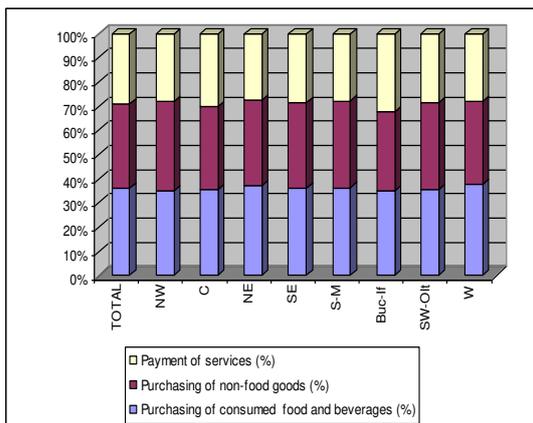

beverages registered in Western Region (24%), followed by South-Eastern Region (22%).

- High share of money expenditure for the purchase of non-food goods were registered in Western Region (21,8%) and in South-Eastern Region (21,6%).

- Besides Bucharest-Ilfov Region, households in Central Region spend more in 2011 for payment of services (18,2%), compared to other regions.

- The lowest shares of the money expenditure for purchasing the three categories of products and services were recorded: in North-Western Region and in South-West-Oltenia Region – for purchasing food products and beverages (20,4%); in North-Eastern Region – for purchasing non-food goods (19,9%) and for payment of services (15,5%).

Figure 5. Structure of money expenditure, by categories of products and services, at territorial level, 2011

Source: made by the authors, based on data in Romanian Statistical Yearbook, 2012, National Institute of Statistics and www.insse.ro [6] [8]

4. Multi-criteria ranking of development regions

The last part of the paper performs a multi-criteria ranking of the eight development regions of Romania, using two methods: the *Relative distances ranking method* and the *Real ranks method* [3] [4]. The criteria considered in the ranking were:

- GDP per inhabitant (lei/inh.) - 1st CRIT.
- ILO Unemployment Rate (%) – 2nd CRIT.

- Total average monthly wages by household (lei – current prices) - 3rd CRIT.
- Absolute poverty rate (%) – 4th CRIT.

Indicators values are for 2010 year, except for GDP per inhabitant, whose values correspond to 2009.

Table 5. Ranking criteria

Development region	1 st CRIT.	2 nd CRIT.	3 rd CRIT.	4 th CRIT.
NW	21297,4	6,8	2307,85	3,9
C	22618,8	10,5	2298,97	5,4
NE	14649,3	5,8	2047,4	7,7
SE	18738,2	8,8	2029,69	6,8
S-M	19913,7	8,3	2369,21	4,4
Buc-If	55079,3	4,6	3039,82	1,1
SW-Olt	17752,8	7,5	2134,13	7
W	25602,4	6	2344,64	3,3

Source: www.insse.ro – Sustainable development indicators at territorial level and Ministry of Labour, Family, Social Protection – Raport privind incluziunea sociala in Romania in anul 2010, 3rd Annex [5] [8]

Applying the *Relative distances ranking method*, first in terms of these criteria ranked Bucharest-Ilfov Region, followed by Western Region (which carried 55% of the maximum performance) and North-Western Region (who made 49 % of maximum performance). The last ranked region was South-Eastern (37% of maximum performance), preceded by the North-Eastern Region (38%).

Table 6. Results of the applying the Relative distances ranking method

Development region	Ranks				Average relative distance	Final rank
	1 st CRIT	2 nd CRIT	3 rd CRIT	4 th CRIT		
NW	0,387	0,676	0,759	0,282	0,486	3
C	0,411	0,438	0,756	0,204	0,408	5
NE	0,266	0,793	0,674	0,143	0,377	7
SE	0,340	0,523	0,668	0,162	0,372	8
S-M	0,362	0,554	0,779	0,250	0,445	4
Buc-If	1,000	1,000	1,000	1,000	1,000	1
SW-Olt	0,322	0,613	0,702	0,157	0,384	6
W	0,465	0,767	0,771	0,333	0,550	2

Source: authors' calculations.

Applying the *Real ranks method* for determining the real average rank, the four ranking criteria have been allocated weights depending on their importance: 1st CRIT. - 45%; 2nd CRIT. - 25%; 3rd CRIT. - 15%; 4th CRIT – 15%. Applying the *Real ranks method* the regions placed in the top two places were Bucharest-Ilfov Region and

Western Region (as in *Relative distance ranking method*). The last two regions, ranked in the hierarchy differ from those resulting from the application of the first method: the 8th rank - Central Region; the 7th rank: the South-Eastern Region. This is explained by the fact that the unemployment criteria recorded the worst value in Central region, and had a fairly significant share in real average final rank.

Table 7. Results of the applying the Real ranks method

Development region	Ranks				Average real rank	Final rank
	1st CRIT	2 nd CRIT	3 rd CRIT	4 th CRIT		
NW	7,836	3,610	7,725	3,970	6,183	3
C	7,803	8,000	7,733	5,561	7,505	8
NE	8,000	2,424	7,982	8,000	6,603	4
SE	7,899	5,983	8,000	7,045	7,307	7
S-M	7,870	5,390	7,664	4,500	6,713	5
Buc-If	7,000	1,000	7,000	1,000	4,600	1
SW-Olt	7,923	4,441	7,897	7,258	6,949	6
W	7,729	2,661	7,688	3,333	5,797	2

Source: authors' calculations

5. Conclusions

Due to its role of reducing the negative impact of human activity on the environment, the sustainable consumption represents a major theme – along with the sustainable production pattern - of the European Sustainable Development Strategy. In real terms, total consumption expenditure of households in Romania increased in the first eight years of the last decade, growth followed by stagnation and even by a decline during the global financial crisis that hit our country. Between 2005 and 2011 in Romania households spend approximately equal weights for purchasing food products and for purchasing non-food goods (although the share for the first category of goods is slightly higher). Thus, in 2011 36,1% of money expenditure for consumption was spent for the purchase of food products, 34,8% - for the purchase of non-food goods and the remaining 29,1% - for payment of services.

In the last part of the paper we had applied two ranking methods: *Relative distances ranking method* and *Real ranks method*. We had used four ranking criteria: GDP per inhabitant, ILO unemployment rate, total average monthly wages by household

and absolute poverty rate. After the appliance of these methods the Bucharest-Ilfov Region was ranked first, the Western Region was ranked the second; the South-Eastern Region and the Central Region were the last ranked regions.

Harmonisation of Excise Duties on Energy Products and Electricity in Central and Eastern European Countries

Maşcu Simona

Doctoral School of the Bucharest University of Economic Studies

mascu_simona@yahoo.com

Burlacu Valentin

Cojocaru Diana

Abstract

The field of excise duty taxes focuses on the use of these economic instruments designed by the European law in the context of protecting the environment and public health and to establish a prudent and rational utilisation of natural resources.

Focusing mainly on deriving and explaining economic impacts of the minimum energy taxes rates corresponding to the EU Directive (2003/96/EC) in CEE countries, this article outlines the degree of harmonisation of excise duty on energy products among these countries.

Through this paper, I intended to see whether, for Central and Eastern European countries, there is any significant correlation between energy tax revenues and excise duty levels on energy products and electricity. Therefore, I have drawn two tables [1] including excise duty on motor fuels and heating fuels, such as petrol and gasoline, natural gas, coal and coke levied in Bulgaria, Czech Republic, Estonia, Latvia, Lithuania, Hungary, Poland, Romania, Slovenia, Slovakia.

Key words: excise duty rates, Directive 2003/96/EC, energy taxation, energy tax revenues, green taxes”;

J.E.L. classification: H21, P52, Q40, Q48, K34;

1. Introduction

After the EU accession of the Central and Eastern European countries (The Czech Republic, Estonia, Hungary, Latvia, Lithuania, Poland, Slovenia, Slovakia) in May 2004 and January 2007 (Romania,

Bulgaria), the main objective has been to raise living standards due to harmonizing policies to EU requirements. Hence, they undergone profound and coherent policy reforms in order to ensure better interaction and coordination among EU member countries and to bridge the gap between them and Western European Countries.

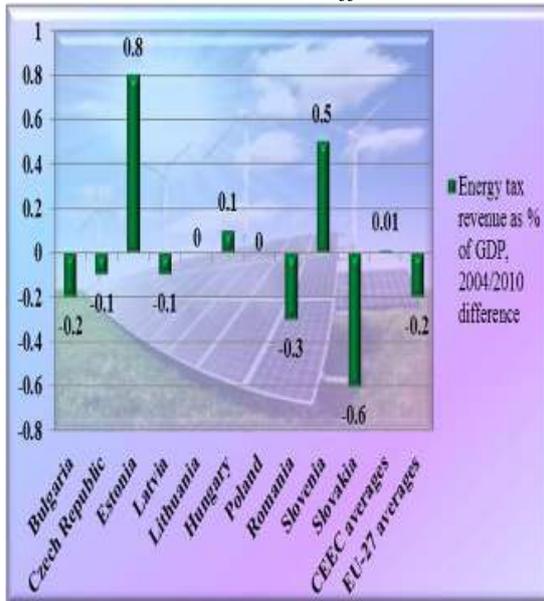

This paper discusses about the evolution of energy tax revenues in the Central and Eastern European Region (CEE), with a focus on excise duty related to the harmonization with the European Energy Taxation Directive (Directive 2003/96/EC) standards [2]. This legislative framework, which was adopted in 2003, aim to restructure the energy policy in European member countries. „It sets out common rules on energy taxes levied on energy products and which exemptions are allowed in order to avoid competitive distortions in the energy sector within the Internal Market”. [3] Energy Taxation enable European Member countries to make the best possible use of energy and, ultimately, support „sustainable growth”..

2. Energy tax revenues in Central and Eastern European Countries

A detailed analyse of energy tax receipts in CEE countries, both as a percentage of GDP and as absolute revenue (millions of Euro), shows differences between countries. The following Graphs were made using most recent data provided by Eurostat, which cover 1995-2010 period.

Between 2004 and 2010, the share of energy taxes in GDP has fallen in EU-27 with 0,2 (%) and in CEEC-10 (ten Central and Eastern European Countries) with 0,6 (%), mainly due to reduced levels of energy tax revenues, as Graph 1.1 shows.

Graph 1.1 Energy tax revenue as % of GDP, 2004/2010 difference

Source: Own processing of Eurostat data

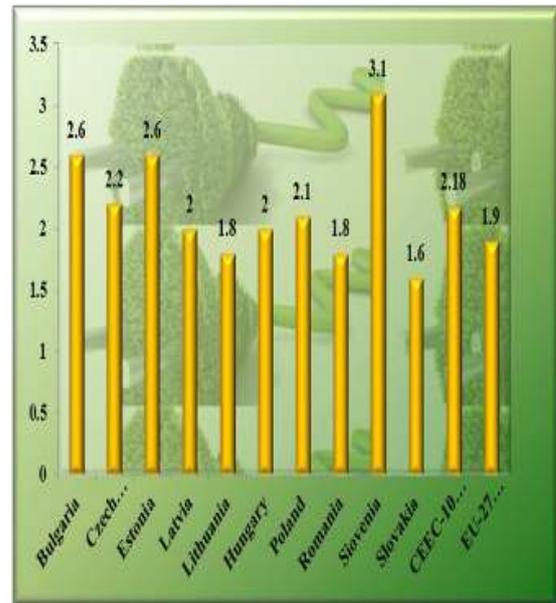

The highest increase in energy taxation took place in Estonia, 0,8 (%) of GDP while other countries with increases were Slovenia and Hungary (Graph 1.1.).

In Slovenia, the ratio of energy tax revenues in GDP is the highest in the CEEC-10 and EU-27, recording 3,1 (%) of GDP. This happened thanks to the Energy Agency, which successfully regulated electricity and natural gas market for a decade. There were adopted new acts related to electricity and the transmission network. Also, extensive work was done in the field of renewable sources and high-efficiency cogeneration.

Customers consumed 3 percents more natural gas than the year before, but still gas is mainly used in industry. [4] Nevertheless, in respect of the absolute revenues, with 1,086 billion of Euro earned in this sector, Slovenia is the fifth highest country in Central and Eastern European Countries, after Poland, Czech Republic, Romania and Hungary.

In comparison with Slovenia, in Estonia and Bulgaria the revenue from energy taxes has formed 2,6 % of GDP in 2010, placing the two countries on the second position.

Graph 1.2 CEEC's energy tax revenues rankings (as % of GDP) in 2010

Source: Own processing of Eurostat data

Estonia is the second lowest in respect of absolute revenues from energy taxation, cashing only 374 million of Euros. It is obvious that the high ratio of energy taxation in GDP is due to low level of nominal GDP, which in 2010 was only 19 billion \$US.

In 2010, the Poland Government received 7,601 billion Euros from energy taxes. Thus, it has ranked first place in Central and Eastern European Countries and the eight place in EU-27.

The five best ranked countries (Poland, Czech Republic, Hungary, Romania, Slovakia) in respect of the amount of revenue from energy tax levied on products and electricity in the analysed year, „met on 28 January 2013 in Budapest to agree on the start of the structured cooperation with a goal to investigate and prepare for the integration of the day-ahead electricity markets of the five countries.”[5]

Energy tax revenue in Romania, at 1,8 (%) of GDP in 2010, lies below the CEEC-10 average (2,18 %) and EU-27 average (1,9 %). The absolute value of energy tax receipts in Romania is the third highest in the EU.

In the current year, the Romanian Government will introduce „a special tax on the revenues of those who exploit natural gas and produce power, revenues derived from the liberalization of the energy price, said secretary of state in the Ministry of Finance Liviu Voinea.” [6]

He also said that these taxes will be implemented as special taxes levied on extra

revenues, only for extraction and production, not to be levied on the distributors, but on the power producers.

3. Excise duty levied on energy products and electricity in CEEC-10

To understand whether the low percentage of GDP derived from energy taxation is caused by a lower taxation, or poor collection capacity, this article presents the situation of excise duties applied to the most important sources of energy in relation to the minimum EU rates on July 2010 and January 2013 in CEEC.

Table 2.1 provides an overview of the excise taxes on energy products and electricity in 2010 and it shows some variation between the countries of the analyzed region. Czech Republic and Slovenia have had the highest tax rates introduced for motor fuels and were above the EU minimum excise tax rates.

Slovakia has imposed the highest taxes both leaded and unleaded petrol. Nevertheless, it has the lowest value in energy tax revenues in the EU-10, which stood at 1.6 % of GDP in 2010. At 505, 11 EUR/1000L for unleaded petrol, taxes are the next highest in Czech Republic. The information presented above reveal that only Bulgaria and Romania had a minimum level and below the minimum of excise duty for unleaded petrol, in 2010.

In Bulgaria, natural gas used in propellant use, commercial/industrial use, heating business use and heating non-business use

processes are fully exempted from energy tax. Also, in Bulgaria the EU minimum excise duty are applied to almost all energy and electricity products. Although, Bulgaria was the country with the highest revenues

from energy taxes in EU-10, and the third highest in EU-27, in 2010, as Graph 1.2 shows.

The highest excise duties on domestic use of natural gas are in Slovenia, Estonia, and Latvia. In Poland LPG, natural gas, coal and coke are exempted from excise duties.

The lowest taxes levied on energy products used in non-business heating can be found in four countries where the ratio of energy tax revenues in GDP is the second highest, the fourth, the sixth, the seventh in the CEEC-10 (Bulgaria, Poland, Latvia, Lithuania). LPG used in non-business is levied only in Romania and Slovenia (Table 2.1).

Taxation of fuels used for heating used in business and non-business district is by far the highest in Slovenia. Taxes levied on gas oil heating – business and non-business use in Romania are the third highest, after Czech Republic and Hungary, and those on natural gas, heavy fuel oil coal and coke are levied at minimum excise duty level, in 2010.

In 2010, Estonia has the highest electricity consumption taxes for households. In Bulgaria, Latvia, Romania, Slovenia the EU minimum tax level for electricity is applied. Only in Slovakia there is no electricity tax at all for households. The EU minimum levels in electricity taxation used in the business sector are applied by two countries, Romania and Lithuania.

This analyse reveals that in 2010, Latvia opted to maintain the lowest possible level of excise duties on energy products; nevertheless the revenue from environmental taxes grew up and was 2.4 % of GDP Graph 1.2).

Table 2.1 Energy products and electricity excise duty in CEEC, July 2010

Minimum excise duty	BG	CZ	EE	LV	LT	HU	PL	RO	SL	SK

4. Energy tax rates increases in 2013 compared to the 2010 level in CEEC

On 13 April 2011, the European Commission put a proposal to review the first Energy Taxation Directive in order to restructure the way energy products are taxed to remove current imbalances and take into account both their CO₂ emissions and energy content. „Existing energy taxes would be split into two components that, taken together, would determine the overall rate at which a product is taxed. One would be based on CO₂ emissions of the energy product and would be fixed at €20 per tonne of CO₂.

The other one would be based on energy

content, i.e. on the actual energy that a product generates measured in Gigajoules (GJ), the minimum tax rate would be fixed at €9.6/GJ for motor fuels, and €0.15/GJ for heating fuels. This will apply to all fuels used for transport and heating. This means that a fuel will be taxed on the basis of the amount of energy that it generates, and greater energy efficiency will automatically be rewarded. The revised Directive, which will enter into force in 2013 aims to restructure the way in which energy is taxed to support the objective of moving to a low-carbon and energy-efficient economy.”[7]

Table 3.1 Tax increase in 2013 compared to the tax rates in 2010

Source: Excise duty tables, July 2010, January 2013, European Commission, Taxation and Customs Union, Indirect Taxation and Tax administration, Environment and other indirect taxes

The increase of excise duty in 2013 on electricity for households in Slovenia stands out for its size (increased by 3,05 (%)). Another significant increase of excise duty in 2013 compared with 2010 levels occurred on natural gas used as propellant, which took place in a Balkan country Bulgaria (0,42), and Slovenia, (0,4). Also, another relatively marked increase of natural gas tax took place in the Czech Republic, over 0,38 increase in 2013 compared to 2010. Hungary, where energy taxes formed 2 % of GDP in 2010,

saw a significant increase of LPG taxes from 2010 to 2013, 0,42. Table 3.1 highlights that the only country where no changes occurred in excise duties on fuels and natural gas, coal and coke, electricity for households is Estonia. This can be explained by the fact that, in 2010, the revenue from energy taxes has formed 2.6 % of GDP in Estonia, placing it on the second position among the CEE countries. As for reductions, the most remarkable case is Hungary, which have cut the excise taxes from 2010 to 2013 on four

energy products: leaded petrol, unleaded petrol, kerosene used as fuel, coal and coke used for households heating and electricity for households. Another country which significantly reduced its excise duty on LPG (-0,3) and natural gas used as propellant (-0,3%) is Slovenia. In Slovenia, the ratio of energy tax revenues in GDP is the highest in the CEEC-10 and EU-27, recording 3,1 (%) of GDP.

5. Conclusions

The tax systems in the ten Central and Eastern European countries that joined the European Union (2004 and 2007) have undergone environmental taxation reforms aiming to reduce greenhouse gas emissions as efficiently as possible. The energy taxation is used in order to stabilize and to enhance the more distortionary existing taxes. A properly designed energy taxation could improve economic efficiency and remove an existing distortion by charging users the true cost of energy products consumption.

This analysis of excise taxes for energy products, which only apply on final energy demand exclusive of the non-energy use, and not on energy production or transformation, in post-communist European member countries, shows some variation between environmental fiscal policy in the countries of the region.

While Slovakia has imposed the highest taxes both leaded and unleaded petrol, it has the lowest value in energy tax revenues in the CEEC-10, which stood at 1.6 % of GDP in 2010. In Bulgaria, the EU minimum excise duty are applied to almost all energy and electricity products. Although, Bulgaria was the country with the highest revenues from energy taxes in 2010, in EU-10, and the third highest in EU-27, as Graph 1.2 shows.

In Romania, energy products and electricity are levied at minimum excise duty level proposed by the European Commission.

Considering that Romania and Bulgaria are the European Union's poorest states, with a per capita gross national income of €6,440 and €4,460, increasing the energy prices in the context of the liberalisation of energy will hurt households.

Abstract

The term "poverty" is gradually replaced with the concept of "social exclusion", the latter involving, more social and economic phenomena, and is the opposite of social integration, which reflects the importance of perceived to be an integral part of society.

The impact of exclusion to social integration can have negative consequences on the personal development, both individually and family because it involves a multitude of psychological problems such as depression, anxiety, low self-esteem.

But, clearly, the goal of economic activity itself is the increase in quality of life and, as far as possible, the reduction of poverty.

Keywords: index, education, innovation, exclusion, inclusion.

J.E.L. Classification: C

1. Introduction

That 80 million Europeans are in poverty (of which 20 million children and 8 percent of the active population), the EU has decided to set up a European Platform to combat poverty and social exclusion. This provides for actions aimed at achieving the European Union's objective of reducing poverty and social exclusion for at least 20 million people by 2020.

In order to avoid the phenomena of poverty and social exclusion, due to the complex and multidimensional nature of the policies of social cohesion to take part and assume the development and raising living standards. How can we do this in an increasingly globalized world if not using the two important factors of progress of civilization: education and innovation?

Together, low rate of unemployment and a high standard of living are paths that lead to one inclusive economy.

The impact of the financial crisis has led to organizations and Governments to change its way of working to be able to "survive", so as to have a trend of increase they must use their best resources in delivering/trying to do new things. As a result, the term "innovation" probably originally appeared as a strategy was subsequently incorporated as a research and development policy. Thus, innovations, especially those of a social nature (taking into account the present theme), could be intelligent solutions for post-crisis Europe.

Much more than a policy, social inclusion is based on a moral position, in which the values are adhered to by every individual/organization. We are now passing thru a moment in which everything is in constant motion, the rapidly evolving education, with schools becoming more modern, they develop abilities and innovative abilities of students, where they are used models and new technologies, and where no account is taken of family of origin, ethnic or cultural backgrounds.

More, inclusion requires responding to the diversity of needs among all learners, through increasing participation in learning, cultures, and communities, and reducing exclusion from and within education. It involves changes in content, approaches, structures, and strategies, driven by a common vision that covers all children and the conviction that it is the responsibility of the regular system to educate all of them [2].

2. Inclusive Economic Analysis Index

As I mentioned above, poverty is an aspect of life, and to measure the level of this phenomenon there is a system of indicators.

This indicates the evolution of poverty in a given country or, to a greater extent, through comparative studies, at the international level. Obviously, this system of indicators is not the only tool used in the process of comparing the stages of economic and social development at the international level, but these index offer a relevant meaning to the studies.

2.1. Global Innovation Index (GII)

The competition between organizations does not exclude forms of cooperation and innovation involves their ability to develop both technical knowledge and practice. Furthermore, I believe that learning and innovation play an important role in the economic development of a country. The present study presents the evolution of the INSEAD [3] reports – Global Innovation Index and includes indicators that go beyond the traditional measures of innovation (such as the level of research and development in a given country).

In the 2012 Edition of the global report by the innovation, it is observed that the developed States have progressed in terms of innovation, but smaller ones have better ranking. If we look at the top 10 Nations noted that only seven are in Europe.

2.2. Human Development Index (HDI)

Human Development Index (HDI) is calculated in order to highlight the evolution of the quality of human life and is a quantitative measure of the degree of a country's success in the ability to be able to develop its human capital. Covers three major landmarks: life expectancy, literacy and GDP per capita. From this point of view, we can approach this three-dimensional and index according to the needs of the study, we will look at that or we can highlight the choose we make. Life expectancy index measures a country's performance in this regard based on the average life expectancy at birth in relation to the minimum level (25 years), and 85 years represents the maximum level.

Literacy index is obtained by calculating the weighted average of two parts: a share of two third part for this index representing adult literacy and a third for coverage of

index in education on the three levels of education.

The index includes gross domestic product GDP per capita expressed in purchasing power parity.

The most important thing is that at the time of data analysis and data correlation does not forget about the hazard of the HDI. Unlike the degree of literacy and educational enrolment are measurable, life expectancy can only be estimated. This is the time of genetic aspects and, clearly, the conditions and the way of life affects the decisive indicator.

In these circumstances, it is possible that life expectancy to be erected in the developed countries but they do carry a relevant progress in terms of innovation, but the most underdeveloped to have a better rank. These aspects can be considered relevant degree milestones of human development of a country.

HDI is calculated as the simple average of these three indicators, its values indicating the degree of development in reverse order.

2.3. Index of cognitive skills and educational attainment

To be able to carry out a comparative analysis of international education systems has developed an Index of cognitive skills and educational attainment. Moreover, taking into account that it compares results from 39 countries and Hong Kong (China), on two categories: cognitive skills education and education level, from the analysis of the index can be a relevant image on the situation of education level in the countries studied.

Of note is the fact that it is becoming increasingly relevant in shaping educational policy at local, national and international.

2.4. Unemployment Rate

The unemployment rate represents the number of unemployed in the active population unemployed, as defined by BIM, are people aged between 15-74 years who meet the following three conditions simultaneously: I don't have a job, I am available to start working within the next two weeks and have been in search of a job at any time during the last four weeks and the active population from the economic point of view

includes all persons who provide labour force available for the production of goods and services during the reference period, including both the occupancy and the long-term unemployed.

A low level of unemployment reflects the ability of a country to supply a perfect balance between request, obviously amid an economy capable of consolidated to provide sustainable jobs and making more smaller the existing labour force.

In the present study is relevant to know that, nationally, in addition to the context witch indicators are used and other categories of indicators that can serve the substantiation process, elaboration, implementation, monitoring and evaluation in the field of employment and vocational training: indicators on access and participation in education and training; indicators of quality and efficiency of vocational education and training; indicators on education system results; results indicators on education and vocational training in the labour market and of labour and quality indicators on participation and investment in Continuing Education/FPC.

3. Data Analysis

The purpose of this chapter is to identify the degree of correlation between the abovementioned indicators as they are reflected on the basis of statistical data and reports from various organizations.

To this end, we have chosen to study the 27 member countries of the European Union witch cover the spectrum of economic development and political and regional developments over the last two decades. The analysis aims, on the one hand, outlining correlations between EU Member States on the same index and, on the other hand, the links between them at some point.

3.1. HDI and GII (2012)

As I mentioned above, the HDI is composed of three components, and in the analysis of the two indices, we will take into account the GDP Index. GII index assesses innovation on the basis of criteria such as institutions, human capital and research, infrastructure, loans, investment, acquisition and dissemination, interconnections,

innovation and creative activity results.

Analyzing and correlating data from Table 1, note: regarding GII, Europe with more innovation – innovation leaders from Northern Europe and the West. Thus, in the context of the estimates, we can consider "innovation leaders" in UE countries with high incomes, such as the Nordic Countries, Switzerland, United Kingdom, Netherlands, Luxembourg, Ireland, Germany, Malta, Estonia, Belgium, France, Slovenia, the Czech Republic and Hungary, which have achieved success in creating innovation ecosystems.

But, by comparison, although the viewpoint of HDI is in the second part of the report GII we can notice that the United Kingdom has a leading position. Explainable, because although allocations for research and development expenditure (% of GDP), GDP fell, the rate for growing has values smaller than 0.3.

From these calculations and observations, we can estimate that there is no explicit dependency relationship between the two indices, which means that you should take into consideration the other factors of influence.

3.2. HDI and Index of cognitive skills and educational attainment (2012)

In the calculation of an Index of cognitive skills and educational attainment data do not exist for the following EU Member States: Cyprus, Estonia, Finland, Latvia, Lithuania, Luxembourg, Malta and Slovenia.

If OECD has dates of from national statistics, depending on the degree of completion of each countries education participant, the data has been checked, then used and analyze where it is considered that they can be comparable. In some cases, there are no data on upper-secondary and/or tertiary graduation rates were not available. In this case, the country has been attributed to the average score for this indicator. A disadvantage for the country to get the average score is that if, in reality, this low average in this, his score boosts Index and vice versa. However, this was considered to be the most fair and transparent. This is true for literacy rate.

Relevant in comparing the two indices is an educational framework of the HDI index

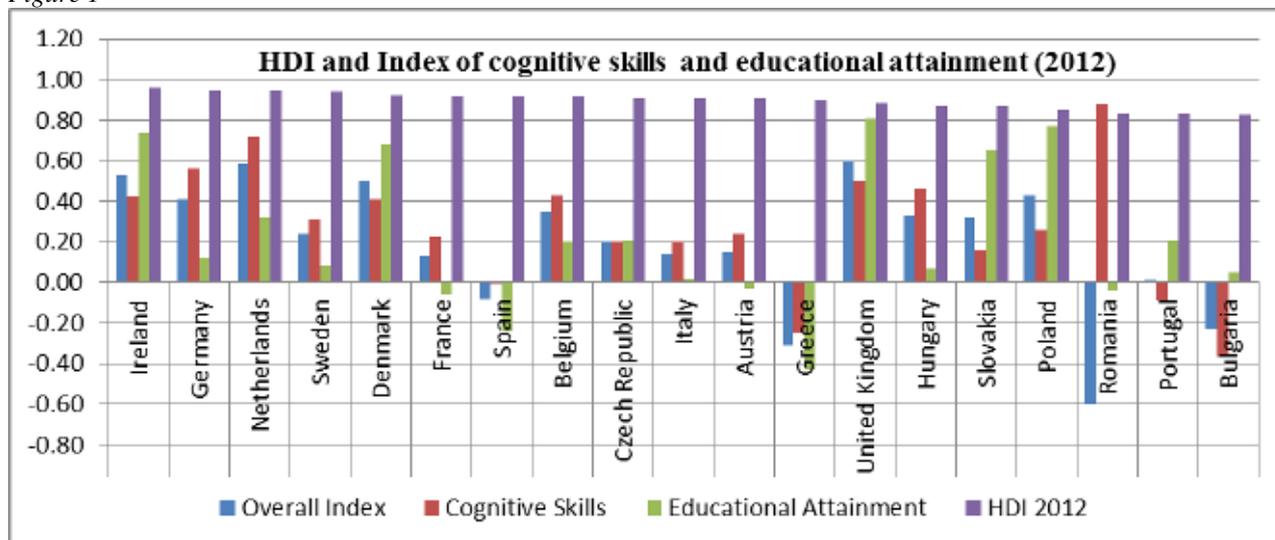

with "z-score" Index of cognitive skills and educational attainment. The latter indicates how many standard deviations an observation is above or below the mean.

To complete the z-score first calculated each indicator's mean and standard deviation

using the data for the countries in the Index, and then the distance of the observation from the mean in terms of standard deviations.

For countries like Ireland, Germany, the Netherlands, we can see clearly the existence of a correlation between the two indices.

Figure 1

Source: <http://hdrstats.undp.org/en/indicators/104706.html>;
<http://thelearningcurve.pearson.com/index/index-ranking>

3.3. HDI and Unemployment Rate (2012)

The lowest rate of participation in the labour market is recorded among people with incomplete secondary education, and studies that assessed in the case of persons with undergraduate and graduate studies. The unemployment rate is highest among people with low levels of education.

Here we can say that the HDI is obviously influenced by Unemployment rates. But a careful analysis of the data shows that regardless of the level of HDI, Unemployment Rates can be as high. If we take the example of the two countries at the opposite pole: Ireland – with the highest HDI in Bulgaria, and the lowest point (both at the level of the year 2012), note that the Unemployment Rate reveal things exactly backwards. Here we can consider that it is related with the HDI hazard component in this framework.

4. Conclusions

From the above relations is evident connection between the four indices. The GDP is higher so we see a better score on the

human development index, and the index of income we can associate with the higher education.

Analysis of the degree of correlation between the HDI and other indicators reveals a number of positive and negative aspects about the way they are designed. Each of the indicators analyzed have strengths and weaknesses in terms of contributing to the formation of an inclusive economy.

Also note the average and high productivity in some countries that there are people with a higher educational level. In other words, we can say that the productivity and, why not, with the development of the latest trends and technologies, and innovation, are directly proportional to the hope of life to more than average school with a clearly superior quality of life and with an unemployment rate as low as.

In conclusion, as the Professor Schleicher said: “It is not a question of if you are rich, you can afford a good education system... . You may need to build a 40-year time gap between investment and economic outcomes, but the causality of the link is established.”

Abstract

The industrial and human activities, in general, are entirely dependent on the existence of the water resource, putting important pressures upon those, both in terms of quantity and quality. The water resources from Constanta County comprise the Seaside water catchment area and the Danube water catchment area.

The measures for improving the quality of surface waters, presented in this paper, are based on a series of studies conducted during the period of my Ph.D. internship, being present in the thesis “Studies concerning the impact of industrial activities on the areas with touristic potential”. In this regard, studies were conducted, in which we treated:

- *The surface water sources;*
- *The sewerage network and the wastewater treatment plants;*
- *The lakes system for pisciculture and irrigations.*

Key words: surface source, wastewater treatment plants, pollution source, wetland technology, protection policies.

J.E.L. classification: Q53, Q56, R11.

1. Introduction

The Seaside water catchment area summarizes 64 river courses with a total length of 834 km and a surface of 5480 km², more important being: Casimcea, Slava, Hamangia, Telița, Taița, Ciucurova, Gura Dobrogei and Nuntași, to which we add the Danube-Black Sea canal with 67 km and Poarta Albă-Midia Năvodari Canal with 27 km.

In Constanta County, establishing the ecological and chemical state for rivers and lakes is realised according to the provisions: of Order 377/2001 concerning the approval of reference objectives for the surface waters quality, of the Government Decision no. 202/2002 for the approval of Technical Norms concerning the surface waters quality that need protection and improvement in order to support the fishery fund and of Order 161/2006 for the approval of the regulation concerning the classification of surface waters. According to the legislation in force, the evaluation of ecological and chemical state of surface waters are based on elements of biological quality, hydro morphological, chemical, physical-chemical indicators and specific pollutants that influence the surface waters state, under which five ecological states have been established for rivers and lakes: very good I, good II, moderate III, weak IV and bad V. The quality standards for biota for rivers and lakes are those provided in the Order 44/2004.

The situation of the quality of the potable water is regulated by the Law 458/2002, supplemented by the Law 311/2004 and the Government Decision no. 100/2002 for the approval of Quality standards that have to be accomplished by the surface wastewater in the process of making potable water – NTPA 013/2002 and the Regulation concerning the methods for sampling and analysing the samples from surface waters meant for producing potable water.

Evacuating wastewater resulted from industrial processes is regulated by the Government Decision no. 188/2002 for the approval of some rules concerning the conditions for discharging wastewater – NTPA - 011 concerning the collection,

treatment and evacuation of urban wastewater, NTPA – 001/2002 that refers to setting limits for loading with pollutants the industrial and urban wastewater, the evacuation in natural water collectors, NTPA – 002/2002 concerning the discharge conditions of wastewater into the towns sewerage networks and directly into the wastewater treatment plants; and the Government Decision no. 100/2002 for the approval of quality standards that have been accomplished by the surface wastewater for the process of making the water potable, in which are included NTPA 013/2002 and NTPA 014/2003.

The purpose

The purpose of conducting this paper is that of bringing to the attention of all competent factors and of those from the industry, the importance of the existence of a modern system for discharging wastewater. Also, the population must be sensitized in order to save and protect potable water sources.

The hypothesis

The hypothesis used refers to “the awareness of all economic agents no matter their size on the necessity of the existence of some personal systems for treating the wastewater”. Through it, we can diminish the danger of polluting the sea water, as a natural water collector, but also the Black Sea coast area.

2. Materials and methods

The realisation of the strategy for improving the water quality is based on many studies, as for example, Studying technological flows at three big industrial agents: CET Palas Constanța, Midia Năvodari Petrochemical Factory and La Farge Medgidia Cement factory. The water pollution sources present in the area of Romanian seaside, or the situation of surface sources, respectively of sewerage network and of wastewater treatment plants.

2.1. The researched material

Galesu catchment is a water source coming from Poarta Albă–Midia Năvodari Canal, with an installed total capacity of 44151/s or 16650 m³/h and a nominal power of 5930 kW, being used for obtaining potable water in the town and in the north area of

Romanian seaside, the water produced being distributed towards Palas.

Galesu catchment, a surface source is important for supplying with potable water the Constanta County (figure 1).

Figure 1 Interconnected system of water supply

Source: Neacșu Gabriela, 2009, [4]

For Galesu catchment, it was determined the pH according to STAS 6325-75 and SR ISO 10523-97, fix waste according to STAS 9187-84, conductivity STAS 7722-84 and SR EN 27888-96, chlorides STAS 3049-88 and SR ISO 9297-98, phosphates STAS 10064-75, chromium STAS 7884-67, SR ISO 9174-98, SR ISO 11083-98, ammonium STAS 6328-85, the chemical oxygen demand for five days STAS 6560-82, lead STAS 6362-85, copper STAS 3224-69, cadmium STAS 1184-78 and SR ISO 5961-93, nickel STAS 10267-89, total ionic iron SR ISO 6332-96, SR 13315-96 and STAS 3086-68, zinc STAS 6327-81, phenols STAS R 7167-92.

The evolution of the indicators tracked for appreciating the quality of potable water has shown that the majority fits into normal limits, some of them even being situated well under the admissibility limit. There are, though, two exceptions, the ammonium quantity which was situated above the admitted limit during the period 2005-2006, going down slowly under the limit in 2007, growing slowly in 2008 and the iron one, which had a growth during 2006, and then

decreased in 2007. Seeing it as a whole, we specify that the occurred overcomes are mainly due to facilities for treating the obsolete and worn out water.

The *treatment* represents the complex process of restraining and neutralizing the dissolved harmful substances, in suspension or in colloidal form present in the industrial wastewater or domestic waters, in wastewater treatment plants [2]. The main purpose is that of improving the quality of these waters in order to be discharged in the emissary without affecting the flora or the fauna. After the water is treated in wastewater treatment plants, it can even be reused in certain fields or technological processes.

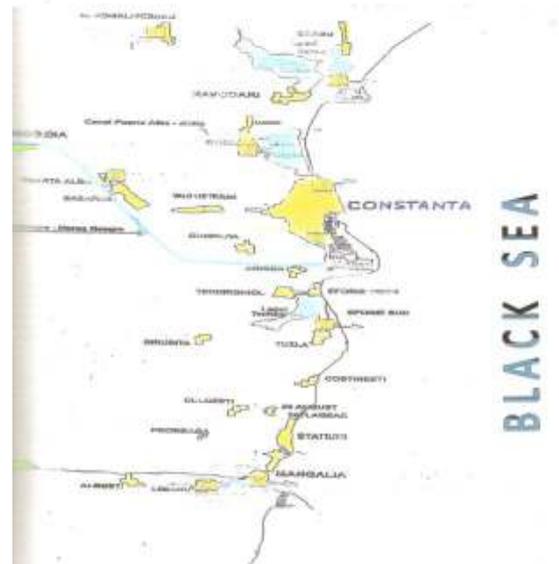

The wastewater treatment, depending on the water characteristics and on the requirements of the evacuation in the emissary, needs mechanical-biological simple wastewater treatment plants or complex wastewater treatment plants. The wastewater with mostly inorganic character will be treated in wastewater treatment plants only through physical and chemical means of restraint and neutralization: sedimentation, neutralization, precipitation, coagulation, flocculation, absorption onto activated carbon, ionic exchange. The wastewater with a mostly organic character is treated in a wastewater treatment plant through physical, chemical and biological procedures.

The waters treatment in wastewater treatment plants is tracked through determinations before and after the entering in the system for: pH reaction; fixed and volatile solid suspensions, BOD₅ – the biochemical oxygen demand for five days, in mg/l, necessary for the biochemical oxidation of organic matters at a temperature of 20° C and in conditions of dark; COD – chemical oxygen demand, in mg/l for the oxidation of oxidised mineral salts and organic substances, based on potassium dichromate or permanganate; the nitrogen presence met under the form of free ammonia, organic nitrogen, nitrates and nitrites; the presence of microorganisms which are of different types, some of them contributing to the treatment process, and others producing diseases and infections to people and animals; their presence leads to the necessity of disinfecting the water when it comes out from the wastewater treatment plant [3].

The wastewater treatment plants present

in figure 2 situated near the economic agents studied in the thesis mentioned above, are: Midia Năvodari-personal system that serves the Petrochemical Factory, CET Midia and Navodari town, Poarta Alba wastewater treatment plant and Constanta North and South wastewater treatment plants.

Figure 2 Wastewater treatment plants
WATER TREATMENT PLANTS

Source: Neacșu Gabriela, 2009, [4]

CET Palas has a sewerage network of approximately 5 km inside the enterprise where the waters are taken by RAJA Constanta, the wastewater quality being of level I (source: Environmental engineer inspector Madalina Munteanu). According to NTPA 002/2002 “for the wastewater evacuated in the towns’ sewerage networks”, we tracked: the hydrogen ions concentration, pH according to SR ISO 10523-97, the matters in suspension STAS 6953-81, the biochemical oxygen demand for five days STAS 6560-82, ammonium nitrogen STAS 8683-70, sulphates STAS 8601-70, lead 8637-79 and cadmium SR ISO 5961-93 [6],[7].

The samples of wastewater discharged into the sewerage system, made during the months: March, July and September in 2009 at CET Palas, have emphasized the fact that in general the matters in suspension and the oxygen chemical content are situated well below the acceptable limit, the ammonium presents oscillations registering peaks in July and September, being situated though under the acceptable limit, as for the rest of the

other indicators, the lead and sulphates content is also very low, the only overcome registered is at cadmium in September.

The waters discharged near the Navodari lock are wastewater that came from the sewerage network of Navodari town, collected both from the economic agents present in the town, others than Midia Petrochemical Factory, and from the population. The sampling took place before the samples were treated in the Midia wastewater treatment plant. The wastewater discharged here come both from Midia port and from Midia power plant. Midia Petrochemical Factory discharge the wastewater in the emissary lake specially created for this purpose that is connected to another lake situated in Chituc sand bank and which is finally linked to the Black Sea.

As a general observation, we can say that we can't establish a connection between the industrial activity and the summer season, within the meaning of diminishing the activities with impact on the Black Sea coast during the summer season.

The lacustrine system Taşaul – Corbu (Gargalâc) in the wide bay found between Midia Cape and Pescariei promontory lie the lakes: Corbu (Gargalâc) and Taşaul. From Midia Cape to Constanta the relief is much flat, three steps being remarked. On the third step which is presented under alluvial, sandy form there are located the territories of Taşaul and Corbu (Gargalâc) lakes, isolated from the sea through well consolidated seaside. Tasaul and Corbu lakes have a reduced underground supply limited to the contribution from the underground and from the patches of limestone.

The samplings are made in the exit sections of Corbu lake, the connection with Tasaul lake and the centre of the lake. The lake Tasaul falls in the category of lakes with brackish water, with the mineralization between 1-24,7 g/l. Corbu lake can be used for fish being exploited by S.C. Pestom S.A. (Corbu arrangement), using annually a volume of 3194 thousand m³ of water, quantity entirely returned. Tasaul lake is exploited by S.C. Pestom S.A. (Kogalniceanu arrangement), which uses 1300 thousand m³ and R.A.I.F. Constanța for irrigations. For example in the case of Tasaul lake, the two lakes Tasaul and Corbu have been provided with a common system of discharge into the

sea, the pumping station being designed to allow when needed an exchange of waters between the two lakes for regulating the levels [1]. Through this common system, the control and the maintenance of the medium level of Tasaul lake became possible, avoiding the unwanted oscillations of level due to flow variations of the main affluent - Casimcea. After 1988 there was a general tendency of alkalisation of Tasaul lake waters, the annual average values of pH registering increases of up to 8,8 and even more in the next years, fact that conferred the lake an alkaline aspect, which situated it to the superior limit of the acceptability for a lake with fishery destination.

2.2. Methods and instruments used

The evolution assessment of the waters pollutants in Constanta County was realized in virtue of sampling conduction, as well as of data provided by: Environmental Protection Agency Constanta, Dobrogea Litoral Water Directorate Constanta, S.C. R.S.J.A S.A. Constanța and National Institute of Marine Research –Development „Grigore Antipa” tracking those water resources that were directly connected to the thesis subject and to the economic agents studied within the thesis.

3. Discussions and results

In the studies conducted on the polluting industries, we permanently considered the importance that the Romanian Black Sea coast has, as a curative and recreational factor for the development of regional and national tourism. In this context, we can highlight that in a relatively young economy, as the one from Constanta County, a balance between the industry and the tourism has to be kept, a symbiosis between the two branches in full development has to be created.

The water is an environmental factor just as important as the air. Therefore, the paper presents a series of measures with protection role, presented in table 1.

The plan elaborated as a guidance guide of the economic agents in view of sustainable development comprises a series of measures that targets the industry agents, whose technological processes affect the

environment.

Table 1 Measures to improve environmental quality water in areas with tourism potential

Pollution sources	Environmental factor upon which we act	Protection policies		Involved factors	The action/the project	Horizon of achievement			Results	
		General	Specific			Short (5ani)	Medium (10 years)	Long (20ani)		
1. Industrial activities generating wastewater whose chemical composition comprises especially: chlorides, nitrates, phosphates, sulphates, benzene, phenols, heavy metals	W A T E R	1. Preliminary processing of wastewater before being discharged into sewerage systems or natural water collectors	1. Using systems of "active mud" type through which harmful chemical compounds to be neutralised	1. Economic agents; 2. Environmental protection agencies; 3. Local authorities; 4. Specialised enterprises	1. Project concerning the fundraising for supporting small and medium economic agents in order to fit them out with treatment plants for industrial waters		x		1. Increasing the quality of industrial wastewater discharged by all industrial agents and protecting the continental waters, bathing waters and underground waters	
		2. The obligation of small and medium economic agents, classified according to the discharged wastewater quantity to purchase (under environmental investments form) individual systems for wastewater treatment;								
		3. Permanent monitoring of industrial wastewater for all economic agents no matter their size;	2. Purchasing wastewater treatment plants for each personal economic unity		2. Increasing the number of enterprises specialised in monitoring the wastewater resulted from industrial activity at prices that make possible the periodic monitoring of small and medium economic agents;	x				
		4. Use of wetland technologies, extended there where the relief and the position of the industrial objective allow it	3. European fundraising from environmental protection field that is used in order to create wetlands	1. Environmental protection agencies; 2. Economic agents; 3. Local authorities; 4. Specialised enterprises; 5. City halls; 6. City planning Department; 7. Department of structural funds within city halls	3. Project concerning the study of the location of great industrial operators in order to apply the wetland technology by naturally or artificially creating such arrangements.		x		2. Mapping the territory in order to establish the parameters for the location of new economic unities, the improvement of discharged wastewater quality, the extension of wetland systems;	
			4. Initiating intercessions of economic agents in order to purchase the lands necessary for locating the wetlands							
		5. Protecting the biodiversity of the Black Sea	5. Feasibility study concerning the opportunity of building a treatment plant	1. Local authorities; 2. Environmental protection agency; 3. Audit companies; 4. Consulting firms;	5. Project concerning the building of a treatment plant in Costinesti area	6. Project concerning the implementation of the technologies based on modern techniques of treatment and recycling of water discharged into the Black Sea, so that they enter in the production cycle.			x	3. Avoiding the overworking of pumping stations caused by the extension of living areas
			6. Feasibility studies concerning the location of new treatment plants or the transformation of those that already exist							
		6. Permanent monitoring of chemical composition of recycled waters designed for agriculture								4. Stimulating the scientific research in general and especially in small and medium enterprises 5. Rehabilitating the irrigations systems and extending the irrigated cultures; 6. Protecting the Black Sea, using waters for other activities; irrigations, industrial water, maintenance of green spaces. 7. Saving industrial water consumption;

Source: Neacșu Gabriela, 2009, [4]

But the lack of financial funds that are to be invested in the environment protection, and the rare check from the Environmental Protection Agency determine that most of economic agents cumulatively pollute (especially if they are concentrated in the same area, as in Constanta case) almost as big economic agents do [5].

4. Conclusions

An action that would especially concern the economic agents with financial power

would be that related to applying investments programs that refer to the implementation of clean technologies, for examples wetlands extension, that are often used in the world, but very little known in our country, although Petromidia has such a system for 25 years, the emissary from Corbu village. Initiating some actions that lead to forming such lakes (we would rather recommend the artificial ones) would have as effect the territory mapping in order to track down the appropriate situations where they could be located (as close as possible to the economic

agent).

An important project is that of recycling the wastewater after its treatment. It was noticed on the basis of the studies conducted that the water treated in the tracked stations, doesn't always fit into NTPA 002/2002 regulations. Therefore, equipping treatment plants with modern installations and moreover researching the possibilities for recycling treated waters and reintroducing them in the production cycle or towards another destination, would be a good thing especially for the Black Sea (as a main natural water collector), but also for the Romanian tourism (being known that 4-5 years ago the most polluted sea area from Mamaia resort was at Parc – the entrance in the resort).

In this study we realised a ranking of factors responsibilities involved in protecting the environment. Therefore, the desire of realising a less pollutant activity must belong above all to economic agents, no matter their measure, who have to be aware of the importance of realising this desire, especially in a touristic area, such as Constanta County, thereby they were given a percentage of 80 %, in respect of their involvement in the industrial sustainable development.

Just as important in implementing the measures plan are the Environmental Protection Agencies (75 % weight) which have responsibilities in what concerns the economic agents' permanent monitoring, including the small and medium ones. Their activity has to develop based on a solid legislation (maybe a little different according to the type and quantity of discharged harmful substances), without discrimination, adopting right measures from case to case. A source good to be exploited, will always be represented by external structural funds, national development funds and personal funds created for the economic agents' sustainable development.

A problem that was tangentially analysed at the beginning was that of small and medium economic agents that raise as many problems as big economic agents do, because of the cumulative effect that they produce on

the environment through their coexistence in the same area. Therefore, we considered necessary the control extension even at small and medium economic agents at short periods of time, in order to monitor them. Regular assessment of the quantities of harmful substances discharged into the air and water, spilled on the soil and subsoil could permit the forming of an overview on the pollution produced by these (known being the fact that great polluters of seaside area have made investments in modern installations that could protect the environment also because of the often checks made by the Environmental Protection Agency), but it could also permit the creation of a database that contains information about the concentrations of polluters discharged into air, water, soil and subsoil.

Tourism in Maramureş, between Desire and Reality

Sabou Simona

*Economic Sciences and Physics Department, Faculty of Science, North University Center
of Baia Mare, Technical University of Cluj-Napoca*

simona.sabou@gmail.com

Abstract

Maramureş County is regarded as having the greatest potential for tourism, according to the study "Data about the cultural and tourism potential of localities in Romania", conducted by the Center for Research and Consultancy in the Field of Culture in Bucharest. So, approaching this theme is logical.

This paper presents the main tourism attractions of the county, its tourism infrastructure, the number of tourists, tourism investments. In this respect the latest information from the National Institute of Statistics shall be used.

Keywords: Maramureş, tourism, North – West Region.

J.E.L. classification: L83, R10.

1. Introduction

Maramureş County is regarded as having the greatest potential for tourism, according to the study "Data about the cultural and tourism potential of localities in Romania", conducted by the Center for Research and Consultancy in the Field of Culture in Bucharest. So, approaching this theme is logical.

Maramureş (MM) is part of the North - West (NW) Region, with Bihor (BH), Bistriţa-Năsăud (BN), Cluj (CJ), Satu Mare (SM) and Sălaj (SJ). After 1989, Maramureş, as well as the entire North - West Region, underwent major changes. Mining, metal processing (other than iron) entered into a continuous decline, which culminated in the closure of all mines in the county. The automotive industry, unfortunately, follows the same trend. Agriculture in the county is also part of the national trend of decline, the yields obtained per hectare being lower than

the regional average, and the fleet of agricultural machines is inadequate. In these circumstances, the county's economic development perspectives are tied to the service sector, mainly tourism.

2. Tourism in Maramureş

Maramureş county's tourism attractions are a reality; we mention some of them [1]:

- wooden churches;
- monasteries;
- Merry Cemetery in Săpânţa;
- the Mocăniţa on the Vaser Valley;
- museums;
- mountain resorts;
- natural spas;
- protected areas.

Maramureş has 38 protected areas, namely:

- 3 scientific reserves;
- 1 national park - Rodna Mountains National Park;
- 17 natural monuments;
- 13 nature reserves;
- 1 natural park - Maramureş Mountains Natural Park;
- 3 protected areas of local interest.

Maramureş County ranks 2nd, nationally, in terms of protected areas.

Taking into account all these tourism attractions, Maramureş is hypothetically suitable for practicing various forms of travel:

- mountain tourism;
- cultural tourism;
- rural tourism;
- sports tourism;
- ecological tourism;
- spa tourism;
- business tourism;
- scientific tourism.

The services sector, which includes

tourism, has been constantly growing in recent years.

In 2010, in Maramureş, 2.37% of the total number of employees in the county were employed in 'Hotels and restaurants', according to data from the National Institute of Statistics [2]. The trend is towards increase, but the pay is low compared to other fields of activity.

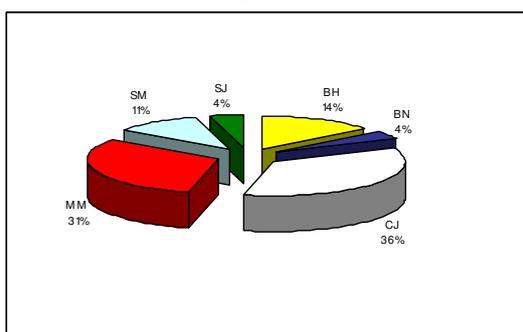

In terms of tourism infrastructure, there is 1 Tourist Information Centre in Maramureş. There are 5 such centers in the NW Region, the rest being in Cluj (3) and Bihor (1). There is also an association that promotes tourism in Maramureş.

The number of existing tourism agencies in the North – West Region in 2012 was 322, of which 39 were in Maramureş County. Most of these agencies have operated in Cluj (171) and Bihor (58), Maramureş being on the 3rd position.

In the North-West Region, in 2008, there were 585 tourist accommodation structures, according to data from the Cluj Regional Department of Statistics [3]. Of these, the majority were in Cluj (206) and Maramureş (183).

In terms of percentage, their distribution between the counties of the NW Region is shown in Figure 1 [3].

Figure 1: Percentage distribution of tourist accommodation structures for the counties of the NW Region in 2008

Source: Cluj Regional Department of Statistics (2013), *Regional Statistics*, [Online], Available: <http://www.cluj.insse.ro/cmscluj/rw/pages/statReg.ro.do> [March 31, 2013].

Tourist accommodation structures in Maramureş County had an upwards trend. For example, in 2006, 146 such units were registered, while in 2008 that number grew to

183. So, this year, tourists accommodation structures in Maramureş represented 31% of the total existing in the North – West Region.

Of the 183 tourism units most fall into the category farmhouses (110), followed by urban and rural tourist guesthouses (35), hotels and motels (27), as shown in Table 1[3].

Table 1: Structures of tourist accommodation in the North - West and Maramureş in 2008

Tourist accommodation	NW Region	MM
Hotels and motels	141	27
Inns	1	0
Chalets	20	4
Camping and cottage type units	12	0
Villas and bungalows	89	4
Camps for students and preschool	19	3
Urban and rural guesthouses	67	35
Holiday villages	0	0
Farmhouses	225	110
Hotels for young people	3	0
Hostels	5	2
Tourist stops	3	0
Sea accommodation	0	0
Total	585	183

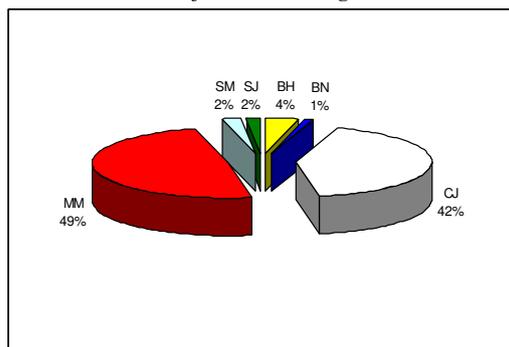

Source: Cluj Regional Department of Statistics (2013), *Regional Statistics*, [Online], Available: <http://www.cluj.insse.ro/cmscluj/rw/pages/statReg.ro.do> [March 31, 2013].

The structure existing in Maramureş follows the regional trend. At regional level, also, most tourist facilities are farmhouses, which account for 38% of all tourist accommodation structures in the Region. However, in Maramureş, farmhouses represent a much higher percentage, i.e. 60% of all tourism facilities.

The number of farmhouses increased from year to year. For example, in 2006, there were 87 registered farmhouses in Maramureş County; in 2008 the number increased to a total of 110 [3].

Figure 2 shows the distribution of the 225 farmhouses existing in the NW Region, for the 6 counties [3].

Figure 2: Distribution of farmhouses in the six counties of the NW Region in 2008

Source: Cluj Regional Department of Statistics (2013), *Regional Statistics*, [Online], Available: <http://www.cluj.insse.ro/cmscluj/rw/pages/statReg.ro.do> [March 31, 2013].

The overwhelming weight of Maramureș, with 49%, and Cluj, with a percentage of 42% of farmhouses, is obvious.

Also, in terms of urban or rural tourist guesthouses, Maramureș holds first place with a total of 35 guesthouses, from a total of 67 in the NW Region in 2008 [3].

The next representative item, namely "Hotels and motels" registers a number of 27 tourist units in Maramureș, 19% of the Region total, ranking 3rd after Cluj (51) and Bihor (36).

Also, it should be noted that Maramureș has null values for the following categories:

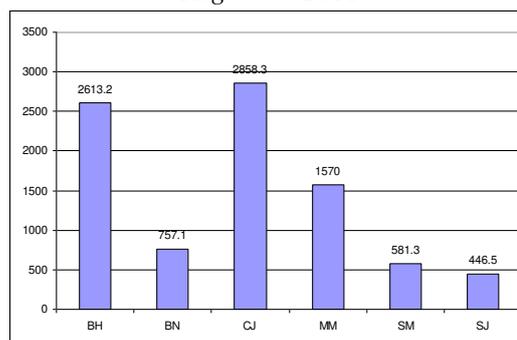

- inns;
- camping and cottage type units;
- holiday villages;
- youth hotels;
- tourist stops;
- accommodation on ships.

Regarding the existing accommodation capacity (number of accommodations), there has been a decrease in the NW Region. Thus, in 2006, the existing accommodation capacity was 26,816, reaching 26,484 in 2008. In contrast, in Maramureș, the existing accommodation capacity grew from 3,363 in 2006 to 3,995 in 2008 [3]. The indicator showed an increased in Bistrița-Năsăud and Satu Mare as well.

Accommodation capacity in operation (number of rooms - days) has increased in the NW Region in recent years. Thus, in 2006, the value recorded was 7.371 thousand - days, reaching 7,760.5 thousand - days in 2008, and 8,826.3 thousand in 2011.

Maramureș is part of the same trend, the value recorded in 2006 being 1.199 thousand - days, 1,454.8 thousand - days in 2008 and 1567.0 thousand in 2011. The values recorded for each county in the North - West Region in 2011 are shown in Figure 3 [3].

Figure 3: Accommodation capacity in operation expressed in a thousand people - days for each county in the North - West Region in 2011

Source: Cluj Regional Department of Statistics (2013), *Regional Statistics*, [Online], Available: <http://www.cluj.insse.ro/cmscluj/rw/pages/statReg.ro.do> [March 31, 2013] and the North - West Regional Development Agency - *North - West Region Development Plan 2014 - 2020*, [Online], Available: <http://www.nord-vest.ro/SERVICIIPentru-Dezvoltare-Regionala/PLANIFICARE-REGIONALA/Planul-de-dezvoltare-regionala-2014-2020.html>, [April 04, 2013].

Maramureș is ranked 3rd in the Region after Bihor and Cluj.

The number of tourists arriving in the NW Region increased from year to year, except during 2009 and 2010. In 2000, there were 559,600 tourist arrivals, in 2006 the number grew to 781,000 tourist arrivals, in 2008 it reached a total of 908,100 tourists arrived, and finally 779,300 in 2011 [4].

Of the total tourist arrivals in Maramureș in 2011 (107,095 tourists), about 81% were Romanian and only 19% foreign (20,020 foreign tourists). The evolution of the number of tourists arriving in Maramureș is linear. It is shown in Table 2 [3][4].

Table 2: Evolution of the number of people arriving in Maramureş County from 2000 to 2011

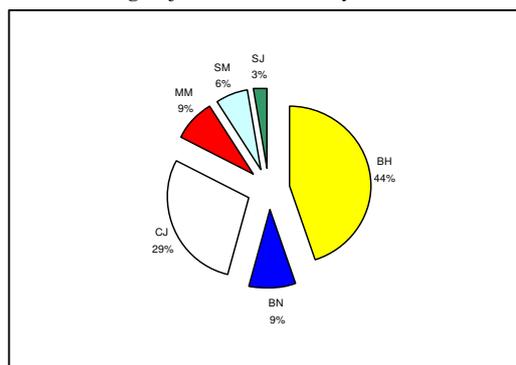

Year	Number of arrivals in Maramureş - thousand tourists -
2000	74.4
2001	93.8
2002	89.4
2003	86.0
2004	79.0
2005	91.4
2007	97.0
2007	108.8
2008	106.1
2009	91.5
2010	92.5
2011	107.1

Source: Cluj Regional Department of Statistics (2013), *Regional Statistics*, [Online], Available: <http://www.cluj.insse.ro/cmscluj/rw/pages/statReg.ro.do> [March 31, 2013] and the North - West Regional Development Agency - *North - West Region Development Plan 2014 – 2020*, [Online], Available: <http://www.nord-vest.ro/SERVICIIPentru-Dezvoltare-Regionala/PLANIFICARE-REGIONALA/Planul-de-dezvoltare-regionala-2014-2020.html>, [April 04, 2013].

In 2011, the number of tourists arriving in Maramureş was 107,100 persons, 32,700 persons more than in 2000 [4]. The highest value was recorded in 2007, when 108,800 tourists arrived in Maramureş. However, the values recorded in 2000 are lower than the ones recorded in 1995, when 123,200 tourists arrived in the county.

The number of overnight stays also increased in the North – West Region, reaching 2,536.9 thousand tourists in 2008, while the value recorded in 2000 was 1,960.8 thousand tourists. The values mentioned are still lower than the value recorded in 1995, i.e. 2,542.2 thousand. Tourists who spent the night in the North – West Region in 2008 chose Bihor as their destination, as can be seen in Figure 4 [3].

Figure 4: Overnights in the NW Region - weight for each county in 2008

Source: Cluj Regional Department of Statistics (2013), *Regional Statistics*, [Online], Available: <http://www.cluj.insse.ro/cmscluj/rw/pages/statReg.ro.do> [March 31, 2013].

The evolution of the number of people who stayed overnight in Maramureş is shown in Table 3 [3].

Table 3: Evolution of the number of people who stayed overnight in Maramureş from 2000 to 2008

Year	Number of people who spent the night in Maramureş - Thousand tourists -
2000	185.1
2001	216.3
2002	192.8
2003	191.0
2004	186.0
2005	208.7
2007	211.0
2007	229.0
2008	215.9

Source: Cluj Regional Department of Statistics (2013), *Regional Statistics*, [Online], Available: <http://www.cluj.insse.ro/cmscluj/rw/pages/statReg.ro.do> [March 31, 2013]

The number of tourists who stayed overnight in Maramureş was 215,900 tourists in 2008, a value higher to that recorded in 2000, 185,100 tourists. During this period the highest value was recorded in 2007.

Regarding the of net use index of accommodation capacity in operation (number of overnight stays compared to the accommodation capacity in operation), it had a fluctuating evolution in recent years in the

North – West Region. In the county of Maramureş, this index had a downward trend. In 2008, it recorded the lowest value in the region, 14.8%, placing the county in the last position, while the other counties had values between 36.8% (Satu Mare) and 29.2% (Bihor and Bistriţa – Năsăud).

The evolution of this indicator in Maramureş County is presented in Table 4 [3].

Table 4: Evolution of net use index of accommodation capacity in operation in Maramureş from 2000 to 2008

Year	Net use index of accommodation capacity in operation - % -
2000	27.8
2001	32.0
2002	31.5
2003	29.2
2004	27.7
2005	21.4
2007	17.6
2007	17.4
2008	14.8

Source: Cluj Regional Department of Statistics (2013), *Regional Statistics*, [Online], Available: <http://www.cluj.insse.ro/cmscluj/rw/pages/staReg.ro.do> [March 31, 2013]

The low value of this index in the county of Maramureş is explained by the fact that guesthouses, present in large numbers, have a low net use index of accommodation capacity, much lower than hotels. And tourists prefer hotels as accommodation structures.

In terms of gross investments in the hotels and restaurants sector, the highest values were recorded in Cluj and Bihor, followed by Maramureş at great distance, as shown in Table 5 [5].

Table 5: Value of gross investments in tourism in the counties of the NW Region in 2008-2010 – million lei

3. Conclusions

Maramureş County's tourism potential is certain due to its numerous tourist attractions. Existing protected areas in Maramureş offer numerous trails for hiking lovers. The county has potential in terms of cultural tourism due to existing monuments. Rural tourism is supported by the large number of rural farmhouses.

The existing material base can support the development of tourism, given its modernization. However, the county's infrastructure is underdeveloped and requires major investment.

Thus, in terms of tourism potential, the strengths of Maramureş are:

- cultural heritage - rich and valuable history;
- attractive landscapes, diverse landforms;
- uniqueness of wooden churches;
- preserved traditions, especially in rural areas;
- road, rail or air access;
- the existence of border crossing points with the Ukraine;
- existence of craftsmen that pass on their knowledge to young people;
- traditional methods used to cultivate land;
- development of agricultural tourism as a valve to absorb labor force in urban areas.

Its weaknesses are:

- underdeveloped tourism services;
- poorly diversified agro services;
- poor access to sightseeing;
- reduced number of foreign tourists;
- fluctuation of workforce in tourism, explained by a reduced salary level;
- tourism products that are poorly promoted by travel agencies;
- underdeveloped transport infrastructure.

Tourism in Maramureş is far from being exploited to its potential, the difference between reality and desire being obvious to anyone.

There are many things to be done before tourism will represent a significant percentage of the county's GDP. The downward trend in the net use index of accommodation capacity in operation shows

a regression of tourism in Maramureş in recent years.

For tourism to be able to develop and fulfill its potential, it must be supported by:

- improving accessibility in the county by upgrading and rehabilitating existing transport infrastructure and improving access to modern communication systems;
- development of rural areas by preserving cultural and historical values;
- helping the economic environment in order to improve the quality of tourism services and make investments, especially in hotels and restaurants that are preferred both by Romanian and foreign tourists;
- increasing service quality in farmhouses;
- training tourism personnel in order to improve the quality of services provided;
- development of human potential in order to increase capacity of design and implementation of projects carried out with outstanding funds.

We believe it is crucial to increase the quality of tourism services in Maramureş. Quality is the safest way to attract tourists.

Abstract

The education of the People’s Republic of China is in constant growth, development and change. Characterized by its size, throughout the country there are over 2,000 universities and colleges that sum up over 6 million graduates every year. Having originally supported ideas and principles of Confucianism universities impose an organized, focused towards performance, but at the same time aimed at providing equal opportunities for people wishing to attend the courses of higher education institutes. Directly influenced by developments in global education, the Chinese University system has to adapt and evolve to meet the requirements and the needs of market economy and hence to be able to directly compete with the major universities of the world.

Key words: analyses, public finances, perspective, quality

J.E.L. classification: H52, H75, I21, I23

1. Introduction

Although China's University system has a long history, traditions and it is principle-based, with the passage of time it has undergone significant changes mainly due to Western influences.

The first of the higher education system could be dated by experts from 771-221 B.c. Until the years 618-907 there have developed a whole series of institutions of higher

education as well as school for sons of the emperor or lifelong learning schools of Confucianism. In addition there were also professional schools of law, medicine, mathematics, literature, calligraphy and dentistry. However, these institutions were organized more in the form of libraries that have subsequently become academies and research institutions. The modern history of higher education in China is relatively young compared with the education in Europe or the Middle East [1].

Although aristocratic families have benefited of higher education from the earliest times, higher education for all population classes has become accessible only from the last years of the 19th century. The first University established in modern China, Tiajin University, created in 1895, plays an important role in the development of the education system of Chinese higher education.

2. Chinese higher education in the last century

Soviet influence in the 1950 played a crucial role in the development of the Chinese University System. During this period, all higher education institutions have passed under the control of the Government, they clearly distinguished between the research and the teaching programs and a national curriculum of study was adopted.

Another shock suffered by the higher education in China occurred during the Cultural Revolution, in the period between 1967- 1976, the number of high school

graduates has fallen dramatically, from 674400 students to 47800. This had a major impact on universities, the decline being profound. The reforms introduced after this period managed to stabilize and revitalize the system. Structural reforms have been initiated in respect of the management of the institutions, investment, labor recruitment or management measures between institutions [2]. These measures were designed to give universities greater autonomy and a greater opportunity to respond to the needs of students.

One of the largest structural changes to the higher education system occurred in 1985 when the Government launched the so-called "3D" and "3C" reforms [3].

The Reform of the "3D" included depolitization, decentralization and diversity in the University System. Once this reform implemented, the control of the University has returned to local administrations in order to obtain a much better cooperation between education institutions at the local level and the needs of the communities. Educational institutions were given greater autonomy with respect to organizational management. The phenomenon of depolitization held more at the curriculum level and in terms of diversity, it was felt primarily through the establishment of private universities. With the implementation of this reform amounts allocated from the State budget to finance the universities began to fall, which has forced the management of the educational institutions to obtain additional sources of funding from research contracts, tuition fees or donations.

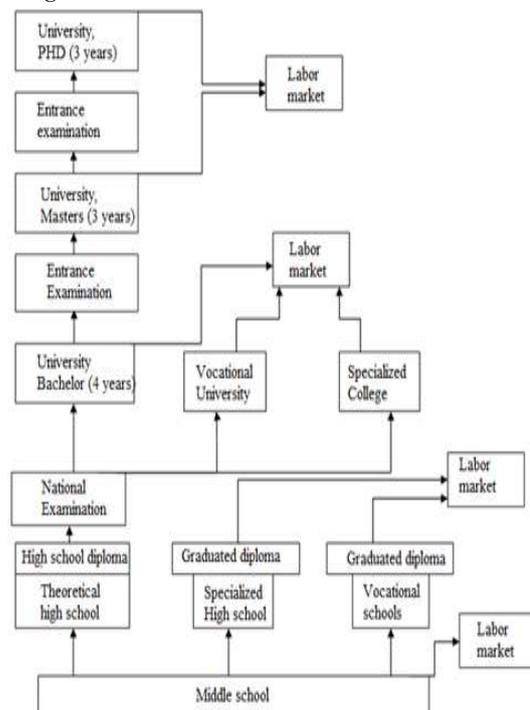

The second part of the reform, entitled "3C", is referring to commercialization, competition and cooperation. The first term, commercialization, refers to the acceptance of the idea of imposing tuition fees and the ability to provide market research and development services. When it comes to competitiveness, this refers not only to the competitiveness of institutions but also to the one between students, employees or researchers. With regard to cooperation, it is necessary to establish partnerships both at institutional level as well as between universities and public or private environment.

These reforms had the desired effect and also revived the Chinese higher education

system. However, in 1993, the idea of a new reform appeared on the Government's agenda, intended to optimize University system and trying to make it compatible with the economic situation. The process was long; the first steps were taken in 1998 aiming to achieve economies of scale. Once this reform implemented, the administration of universities has returned almost entirely to local administrations. But perhaps the most important measure has been that the education institutions were brought together. Thus, by 2002, 637 universities were merged to create 270 new institutions of higher education. In addition, 317 universities have signed contracts of cooperation for the formation of 270 conglomerates.

In 2010 the Chinese higher education system was formed by 797 institutions which offer only postgraduate programs (research centers), 2358 institutions of higher education, 368 centers offering undergraduate adults and 836 private institutions (there establishment was approved in 1980). The programs offered are divided into classes of license, master and PhD programs and are available both to national students and foreigners.

Figure 1 The Chinese educational structure

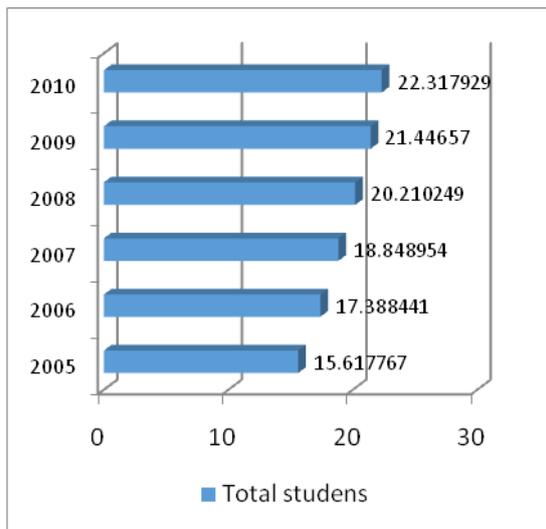

Source: authors' processing based on the date presented by Finnish National Board of Education

It can be seen that the Chinese education system has a complex structure which gives

students the opportunity to follow the most advantageous type of preparation. At the end of high school, those who wish to attend the courses of a higher education institution must take a national exam for admission. This system is maintained since 1977 when, for the first time, it was introduced such a review because, the number of high school graduates was very large compared to the much smaller number of places in universities.

Graph 1. The evolution of students in China, 2005-2010 (millions persons)

Source: authors' processing based on the data presented by the Education Ministry from China

The number of those who attended the courses of higher education institutions is growing from one year to another. In 2010 more than 20 million students were enrolled in the different programs of study. Compared to 2005, their number increased by over 40%.

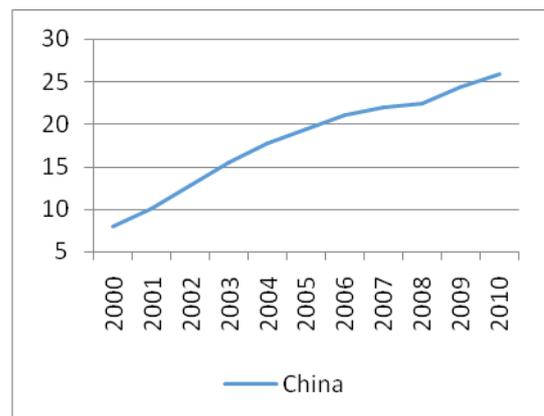

Admission to higher education turns out to be demanding and difficult. To prepare for this exam, students have special preparation courses for almost a year before the exam. Due to the large number of students currently enrolled in high school, more than 100 million, the government allows those who want to study at home to do so. Thus, with 11 million people who study individually they were considering to support the admission Examination.

Between 1999 and 2003 the number of those who have completed higher education has grown from 1.6 million students to 3.82. This trend has been maintained in the years that followed. The number of graduates is currently rising to over 6.3 million. This increasing trend has been seen also among

international students. In 2011 the number of those who decided to travel to China to study for the first time has exceeded the threshold of 290,000 students, their number increased over 10% compared to 2010. Students desiring to go to China to study come from countries like Korea, Japan, Thailand, South America, and Russia. From European countries, most students come from France and Germany.

This high interest that students from all corners of the world provided to the educational system in China may be placed and on behalf of international prestige that this system offers. In the Academic ranking of World Universities-man Chinese education system consists of 28 universities, of which four are in the top 200. The most well-established institution is Peking University followed by the Jiao Tong University and Tsinghua University.

Graphic 2. The share of higher education graduates of total population in China, 2000-2010 (%)

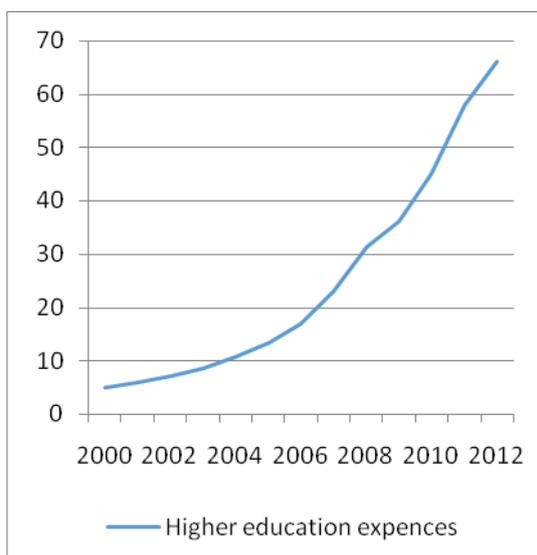

Source: authors' calculation based on World Bank data

The reforms implemented at national level in China motivated citizens to participate more extensively in academic life. This can be observed on the basis of the increase in the weight of population who attended higher education in total population in the last 10 years. If in 2000, less than 10% of the population, i.e. approximately 95 million people, were graduated from university programs, in 2010 this percentage increased considerably exceeding the threshold of 25%, about 335 million inhabitants. These figures indicate that over the past 10 years the number of higher education graduates increased over three times.

3. Chinese higher education at present

Such an educational system, mammoth from all points of view, requires a consistent financial effort. Reforms in education were meant to give a series of freedoms for universities in particular especially to be able to attract new funds. Even if initially it was proposed that by the end of year 2000, the total amounts allocated to education to be increased from 2% to 4% of GDP, this could not be achieved until now. Authorities estimated that this percentage will be attained by the end of 2013. Although this percentage has been increasing in recent years, the share of government spending with the University system has remained steady, in some years with even some decreases [4]. Chinese statistical institutions do not provide an accurate statement about the funds allocated from the State budget in order to finance higher education institutions, but according to UNESCO data, this value is around 20% of total expenditure on education.

Graph 3. The evolution of public expenditure with tertiary education 2000-2012 (bln. Dollars, current prices)

Source: authors’ calculation based on IMF and UNESCO data

Even though, as we could see, the public spending on higher education in the total expenditure on education has remained constant, due to the sharp increase in gross domestic product of China, in nominal values, the amounts have increased considerably. If we take as a reference the year 2010, when the higher education system in China accounted for more than 20 million

students, for each of the student’s government spent from the State budget just over 2,000 dollars.

The analysis carried out shows that the Chinese central authorities provides greater attention to pre-universities studies where, funding has increased from one year to another. These results are due to the reforms implemented in the last period, reforms intended to give the University system a certain autonomy and hence the ability to attract funding from other sources

Table 1 The share of funds allocated for universities (%)

Period	State based funds	Tuition fees
1996	80.3	13.7
1997	78.3	14.8
1998	65	13.3
1999	62.5	17
2000	58.2	21.1
2001	54.2	24.2
2002	50.6	26.3
2003	47.9	28.8
2004	45.5	30.4
2005	42.8	31.1
2006	42.9	29.2
2007	44	33.7
2008	47.6	33.7

Source: authors’ calculation based on data released by the National Bureau of Statistics from China

From the above we can see the dramatic fall of the share of funds from the State budget in the incomes to the universities. In just 5 years, these funds have been reduced from 80% to 50%. This decline has been felt heavily by higher education institutions, since this has not been matched by a proportional increase in tuition fees. Thus, in 1996, over 94% of the funds were coming from fees and funds from the State, budgets of universities being covered by only 78% of these sources of income at present. To cover the shortfall, universities had to be creative in the process to acquire the necessary funds from the private sector.

Even though tuition fees have increased considerably in recent years, they are far below the average in the developed countries, these varying depending upon the program of study and the educational institution. For example, Peking University, the Chinese University rated at international level,

requires a tuition fee of up to \$ 2,000 for a bachelor degree and between 2,000 and 4,000 dollars for a Masters program. Even if these amounts do not seem to be very high, for a Chinese citizen they may represent the whole income for one year.

In order to be helpful for the students with limited financial possibilities, the State initiated a support program, through which over 5 billion dollars are spent annually in various forms of grants, loans and tax exemptions. These measures come especially to help students from rural areas, where the standard of living is very low. In 2009, students have benefited from 622000 aid programs. However, this number is very small compared to the total number of students, 5.27 millions, coming from poor families [5].

Benefits in the form of scholarships are awarded to students and foreigners. In 2011 the number of those who have benefited from a program with over 25,000 has exceeded 14% more than the previous year [6]. Many of these funds are allocated in the form of loans, which students must pay back after graduation. In daily life this can become a burden in light of the fact that only one percent of the 63% of graduates are able to find a job [7].

To be able to still have an educational system, the Chinese State has approved an action plan for the period 2010-2020 which aims on one hand to increase the quality of the education system and on the other hand to extend the population's access to education. Thus, by the year 2020 it is desirable that at least 20% of the working-age population to acquire higher education, aiming to a doubling of the percentage recorded in the year 2009. It is also desirable that by the end of this period the structure of higher education to become more balanced across regions, to promote and to recognize the talents, to focus on research and increased social services adjacent to the educational process.[8]

4. Conclusions

The higher education system in China is characterized by permanent structural changes. These changes can be put on one side at the expense of international pressure to which the country is conducted by the

need to open up to the world economy, and on the other hand changes in socioeconomic conditions nationally.

With a growing population, an educational system that gathers hundreds of millions of people annually, the financial effort in the national budget is consistent. In order to increase the competitiveness and the quality of the reforms implemented that meant to boost both educational institutions and students to become more competitive both nationally and internationally. Reduction of funds assigned to universities and increase of direct or indirect support to students represents a form of long-term investment in human resources.

We cannot take into account, when conducting this analysis, without talking about a country that is based on a centralized system. Although officially a decentralization of the education system was imposed, it is important that, through the measures, China would not intervene in the institutional management and it would allow universities to adopt policies in line with the requirements and needs of the market.

China, the second world economic power, must obey to the economic systems imposed by the international economy. In order to maintain this level, it must possess a competitive advantage also in terms of education. This can be achieved only through the creation of a system of educational quality, giving the economy the experts it needs. Investment in research and development cannot be neglected either. The allocation of funds in order to create innovative products and services can generate results that will maintain China among the most powerful countries in the world.

Economic Aspects of the Aging Population. Case Study on the Czech Republic

Smrcka Lubos

University of Economics, Prague, Czech Republic

smrckal@vse.cz

Colibasanu Oana – Antonia

Academy of Economic Studies, Bucharest, Romania

oana_antonia_colibasanu@yahoo.com

Abstract

This study on the basis of data from the environment of the Czech Republic examines the future impacts of a generally ageing population connected with low natality (which does not even secure the mere reproduction of the population) on the economy. The issue of the pension system is basically left aside as this is a partial problem which has in the majority of developed countries been solved over the past several decades on the basis of political agreements. On the contrary, the study focuses primarily on solving the impact of changes in the structure of the population in key areas of the economy, on its ability to innovate, on impact in the area of creative industries and the influence on the future composition of economic activities. Furthermore, attention is drawn to several other facts connected with the process of the ageing population, i.e. on the issue of intergenerational transfer of experience. Also examined are issues surrounding the development of general added value in the economy as this datum is influenced by household consumption at a time when significant shifts in the structure of the population are expected.

Key words: demography, gross domestic product, creative industries, fertility, population, labour forces

J.E.L. classification: J11

1. Introduction

The ageing of the population in developed countries, connected with long-term natality

well below the level of mere reproduction of the population, is the most underestimated economic problem of the present. Although this has been heavily occupying sociologists, psychologists and to a significant extent politicians as well as doctors and philosophers, the economic impact of these processes is dealt with only in the relatively narrow context of pension systems. The direct economic impacts of the ageing population are not analysed whatsoever.

At the same time, it is immediately evident that these impacts will be significant and very demanding on the economy. This does not even refer to difficulties with financing pension systems and or even quite neglected problems such as the future financing of healthcare systems. These will in fact grow to enormous dimensions over the next few years, which will force developed countries to reform the manner of financing healthcare similarly to the way these countries are being forced to gradually change pension systems in spite of the constant aversion to such measures on the part of the population.

However, the main difficulty caused by the ageing of the population in the next decades will be the lack of qualified and highly qualified manpower, the reduction of the innovative abilities of the economy, the weakening of creative industries, disturbance of systems for intergenerational transfer of experience – in other words, the dismantling of the functional systems which are the main movers of the competitive edge of developed economies and are the creators of high added value.

To summarise this problem succinctly, it could be said that the ageing of the population, together with a long term fertility

rate below the level of simple reproduction of the population brings collateral problems from the angles of both public budget expenditure and income.

As far as expenditure is concerned, we are speaking primarily of the above-mentioned pension systems [19] and of healthcare expenditures. We should, however, also remember the pressure on other social expenditures which will appear especially in connection with the growth of the population in the 80+ age group.

As regards income, this concerns primarily a decrease in the general gross domestic product or other similar aggregated data expressing the entire economic volume of a given country. This will also be connected with a decrease in tax revenues – on the one hand, influenced by a general decrease of economic volume; on the other hand, insofar as the amount of taxed persons will diminish, as will income from taxed businesses. Whether this will occur as a result of their decreased profit or transfer of production to other countries not affected by these demographic complications is irrelevant.

Economic systems of developed countries which have been referred to over the past twenty years as new economies or knowledge economies and which place their hopes in the development of creative industries will, instead of assumed economic growth, arrive at a historically unknown situation (at least unknown in peacetime), to which we will refer as the “old-age trap” for want of a better expression.

2. The “old-age trap” in the Czech Republic from the angle of expenditure

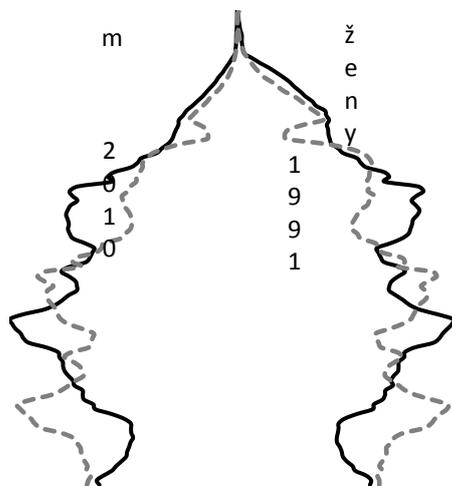

As a departure point, let us use the premise that the demographic development of developed countries is basically similar, which is in very approximate terms a true notion confirmed also by data (UN 1982, 1999, 2002, 2010, World Bank 1994). In reality, however, this development varies quite considerably in individual countries. From our point of view, the most important issue is direction, and in this regard we can assert that it is truly very similar, regardless of the above-mentioned differences in numerous details. If we do not include the United States, the demographic development

of which is somewhat better than that of European countries, the differences between developed countries lies more in the extent to which they have become caught in the problem. For instance, at any time in the past, the population group aged 0 to 14 years was always more numerous than the 65+ population group. This means that there were always more children than pensioners (expressed in today’s language). At the beginning of the second decade of the 21st century this ratio, however, reversed in numerous states. We can name Italy, Germany, Spain, Portugal or Greece. Over a small number of years the remainder of Europe will find itself in the same situation. In the Czech Republic, this will evidently come to pass in 2014 or 2015; in 2020 society will comprise of approximately 16.2 percent children, whereas the ratio of people over 65 years old will be almost 17.2 percent. In 2050 this will be approximately 14.3 percent children to 29 percent of people aged 65+ years.

We basically see two highly significant phenomena: Firstly, a deceleration in the global dimension of population growth (International data Base, 2011); secondly, the precise opposite of catastrophic predictions regarding the complete overpopulation of our planet is taking place [8]. We can with a pinch of salt say that if our planet is indeed threatened with overpopulation, this will be an overpopulation of “pensioners” in a best case scenario, in which these people have and will have created sufficient reserves for their old age. A more likely scenario, however, shows a population of people past productive age, whose prolonged lives will be financially secured only in the most inadequate way [10].

If we examine this demographic development more closely, this shift can adequately be shown by the so-called demographic tree. In the first picture we can observe the shift between 1991 and 2010 and, as we can see, the tree has substantially narrowed in the lower section of the youngest population groups, although the change in the other age groups are not yet marked.

Figure 1: The age structure of the population in 1991 and 2010 (on 1. January)

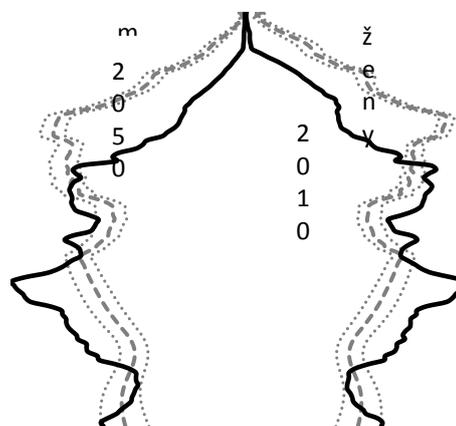

Source: CSA (1992, 2010)

The second image shows the outlook on the basis of data known in 2010. As we can see, dramatic changes will arise according to these views. The narrowing of the tree in the lower section of the estimated state in 2050 is not so significant – besides, fewer children than in the second half of the nineties and the first decade of the new century could not be born. In certain years of the above-mentioned timeframe, fertility (the number of children born alive to one woman in fertile age) decreased to a level slightly higher than 1.1 children. Simple reproduction, however, is achieved at a level of 2.1 (sometimes 2.14 children per woman of fertile age is given). If we look again at the second image, it is necessary to carefully observe the view of the age group from fifteen to forty years. Here, the decrease in population numbers in this age group is plain to see. To serve as an example – approximately sixty thousand men will celebrate their thirty-fifth birthdays in 2050. In 2010 the number was roughly 98 thousand. Or we can also express it thus wise: in 2050 there will be 300 thousand less men and the same numbers of women in the 30 to 40 year bracket in the population living in the territory of the Czech Republic than there were in 2010. Thus, in 2050, there will be roughly 600 thousand fewer workers in productive age between thirty and forty than was the case in 2010. There will be a decrease of about 500 thousand potential workers in the innovative age group between

twenty and thirty years. The reason for this is simple: If fertility does not reach the level of 2.1 children per woman of fertile age, but around 1.1 to 1.5 children, then each successive generation will decrease by a quarter or even a half.

In the groups above seventy, eighty and ninety years, the development will be exactly the opposite. The higher the age, the more distinct the multiple assumed by this view on the development of inhabitants in the Czech Republic as regards the number of given age group representatives in comparison to the present state.

Figure 2: Age structure of the population in 2010 and its estimated level for 2050 in the lower, medium and high variants

Source: CSA (2009, 2010)

The age composition of the inhabitants in the Czech Republic according to the view of 2050, one cannot fail to observe the dramatic growth in the amount of people in the 80+ age group. If this group composed 2.5 percent of the inhabitants in 1990, this figure will be over four times as high in 2050 – somewhat more than ten percent of the inhabitants. This is a known fact and the Czech government regularly negotiates material concerned with the concept of active old age. Nevertheless, these are documents concerned with areas such as lifelong learning, which is certainly a significant aspect, but which in fact does not solve economic questions connected with this “old-age trap”. Entirely missing is a notion as to how to choose a concept of financing healthcare at a time when healthcare expenditure is unsustainable even now and the sector is being burdened by persistent

cash flow problems and, most importantly, is financially unstable. Moreover, costs for healthcare dramatically grow with the progression of age.

Another aspect is the prolonging of time over which the older generation will draw higher expenses for healthcare due to serious or relatively serious illness. Let us note that in certain countries – e.g. in Hungary or in Germany – the average citizen will clearly fall ill or will face significant health problems as early as ten years before he becomes entitled to old-age pension.

Generally, we can summarise these observations into a contention that demographic development will exert considerable and systematic pressure on state budgets, whereas this pressure cannot be estimated at the given time and we have no method at our disposal that can quantify it. This pressure will arise from two highly sensitive political areas – from the need to finance the pension system and the need to finance healthcare for the population. European countries arrived at a complicated state of affairs at an early stage when (while developing the concept of the social state) they took it for granted that the government is responsible for the pensions of the inhabitants and also that the population were to be provided with healthcare which we could deem as state-of-the-art in the world context. As we know, reforms of the pension system are in progress and are primarily moving in the direction of responsibility for individual living standards being transferred to individuals because countries are gradually declaring that only basic and rather low pensions will be paid from public resources. It naturally took over twenty years before the European public grew accustomed to this idea, yet this still does not mean that it has fully accepted it. Problems with healthcare are not being discussed for the time being – aside from occasional observations from the economic field that the present concept of highest possible standards paid by state-organised insurance is unsustainable.

Thus, as far as estimates regarding the growth of state health expenditure are concerned we can expect that the retention of the present system and standards will in the next two decades double the costs for this system; they will, however, probably triple (not including inflation). Let us consider it

absolutely certain that among developed countries there is one which could afford to do this without transferring a significant portion of the expenses to the population – for instance, by means of increasing so-called health insurance or, more likely, by means of a significant reduction of the guaranteed level of healthcare.

But here we are moving beyond the limits of our reflection as expressed in the introduction of the text.

3. The “old-age trap” of the Czech Republic from the angle of income

The problem of the “old-age trap” from the angle of future income of the public budget and thus from the angle of creating the gross domestic product is analysed far less than the problem of future expenditures. It is known that capital does not suffer from over exaggerated sentiment, so it cannot really be assumed that it will remain in countries that will in the coming decades begin to be simultaneously confronted by several kinds of negative pressure as a result of their demographic parameters. It is necessary to properly understand that this strain (from the angle of capital) will begin to transform into significant risks with the passage of time. We can summarise these as follows:

Strain on the expenditure side of the budget (the pension and healthcare system) will transform into risks of increased labour costs and into risks of higher taxation which affected countries could resort to as a reaction to the unsustainable state of public finances burdened by forced payments in the context of the pension and healthcare system.

The lack of manpower in the area of creative workers will lead to a growth of salaries in these fields, the same development will occur among manual labourers also, especially among those who need high qualifications to perform their duties.

Demographically exhausted countries with a small proportion of young inhabitants will not provide sufficient innovatory potential.

The entire field of creative industries will on the one hand suffer a lack of creative forces. On the other hand, it will be especially drastically affected by a reduction of domestic demand as the increased ratio of

inhabitants 65+ to the population as a whole cannot be an assumption for stable demand in these fields. Creative industries are based on new methods, new experiences, constant change and development. Age groups falling into the general appellation of 65+ will not be the natural consumers of products from the creative industry.

The entire area of domestic demand will undergo significant changes and will be transformed in the direction of demand for other merchandise and services than those that have been in demand until the present. There will be a substantially greater demand for pharmaceutical products, dietary supplements, services of a social character. On the contrary, there will be a reduced demand for services and products consumed more by the younger generation. This natural reform of domestic demand (whereas we are in the context of the term *domestic demand* now thinking of demand in developed countries as a whole) will be costly for entrepreneurial subjects and will also be accompanied by complications in the area of buying power of the growing numbers of the 65+ age group. These will be caused primarily by problems with the securing of the pension system and by a marked growth of costs among these consumers in terms of securing their own health as a top priority.

4. Conclusions

A significant drop in available manpower will manifest itself in the whole economy; the impact on individual fields will vary. From the angle of gross domestic product, the processing industry is the most substantial in the Czech Republic (1.242 million employees) and commerce (0.631 million employees), followed by construction (0.497 million employees) and transportation (0.331 million employees), whereas the total number of those employed in the entire national economy was 4.934 million people (2009). At the same time 0.352 million people were unemployed (in the sense that they were registered at the appropriate employment bureaus) of which over two thirds were people without education or only with secondary education without matriculation. As regards qualification assumptions, the most marked were the processing industry, which requires several

specific qualifications and the ratio of posts for the unskilled or uneducated is not at all marked.

High recruitment of workers from abroad between 2005 and 2008 showed that, as far as the education structure and measure of qualification is concerned, the Czech Republic is not in a position to attract highly qualified workers. It is probably not possible to expect an improvement from this direction. Thus, during the time of the greatest economic growth, 290 thousand people worked in the country legally (in the second half of 2008), their numbers dropped sharply during the crisis. Roughly seventy percent of these legal (but temporary) workers were employed in blue-collar professions, and in this context in less skilled professions. This is not to say that many of them were uneducated. Often well educated people were in question, though their true qualification is completely different and mostly unusable outside of their countries of origin (the classical example is teachers of national languages).

On the other hand, qualified employees came almost exclusively from the Slovak Republic. But because the Slovak economy has been growing faster than the Czech economy for several years, whereas the demographic development in the Slovak Republic is similar to that of the Czech Republic, a further influx of workers from this region can probably not be expected.

The change in the demographic structure of the population and the general drop in the number of inhabitants – even if these phenomena are partially alleviated by a positive migration balance – will lead to extensive changes in the structure and performance efficiency of the economy in the Czech Republic. This shift can be expected in the imminent twenty years, that is, until 2032, whereas pressure for changes and especially the depth of these will steadily grow stronger.

Local Government and Sustainable Economic Development

Stignei Veronica Paşa
“Spiru Haret” University Constanta
veronica_stignei@yahoo.com

Abstract

In the current conditions of Romania, the public sector needs to rethink its role as economic hub, to contribute together with the private sector to sustainable economic growth, and not least in the resumption of investment process. Administration is one of the most useful human activity, being found in any area and at all levels of government, in the complexity of all social life.

Keywords: local government, sustainable development, strategy

JEL classification: O40, Q57, R11

1. Introduction

Investment activity in economic zone have a central place, being the factors that influence demand and offer simultaneously, whatever the sector of activity is implemented. The role of investment in the company is known worldwide as the permanence of investment activity across all socio-economic structures, including local government.

This paper examines the need to involve local authorities in services and public investment to achieve sustainable regional development. News of this theme is accentuated by the fact that in perspective, investment process from our country, both at central and local level will increase, so that the Romanian economy be able to cope the current economic crisis that manifests as intense in all areas.

2. The necessity of state intervention

At the community level, the investments are based on social needs and refer to those needs felt by citizens and that cannot be met by individual action, but only through the

efforts of all its members. In many papers have discussed these 'social needs', differing mainly those related to ensuring community defense against invaders and domestic law enforcement. Subsequently, strengthening the organization determined the increase empowering and strengthening of leader and the financial power of the state.

Over time, the state has evolved since diversification collective needs of its members, thus becoming the modern state and executive decision-making power required to achieve public goods necessary to meet those needs. Once accepted the presence of the public sector is trying his intervention efficiency by finding the best answers on areas of intervention, extent or volume of work and modalities of public action. The meaning of the public service activity is the activity organized by the village, town, city or county authority, designed to meet general interest, under the legal regime of public law. If the private sector is characteristic ensuring competition, stimulate interest and increase the quality of goods and services distributed to public sector provision of goods and services has the main advantage that it allows control of the distribution of government policy, and their normal fair. If the private sector is not possible subsidies for poor communities government can subsidize some of the costs of public services.

The state was faced with the difficult choice between freedom and control from the moment of its emergence to the present. The difficulty arises when the choice to opt for modern society or self determination. Inability of successive governments since 1990 to the present, the institutions involved, to developed and implements strategies, policies and programs consistent and realistic economic severely damaged the interests of Romania and on sustainable development. It is an undisputed fact that, macroeconomic policies developed exerts a profound impact

on investment activity and hence locally and on meeting the priorities set out in the general interest of citizens (combating poverty, improving living conditions)[1]. Consequently, the administrative choice is influenced by political factors and this element is the substantive difference between public and private investment.

With foundation for the rule of law, that the separation of powers, decentralization of public services and local autonomy, organizational and functional structures of government are located both at the state (central government and state territorial administration) and in the communities local (local government). Local government is what form of organization best suited to the idea of autonomy, being associated with it, through the principle of decentralization unlike state administration of the territory, which has little autonomy, through the decentralization principle that characterizes it. We can say that the basic function of local government is the needs of the communities of administrative units, always having a continuing relationship of proximity with citizens.

3. Conceptual approaches regarding local administration

Administration is one of the most useful human activities are found in any area and at all levels of government, in all its complexity of social life

Etymologically speaking, the term "administration" comes from Latin and is composed of the prefix "add" which means "to" or "to" and "ministry" which means "servant", "help" or "caretaker"[2]. The word "administer" means a state of inferiority execution of one or even help tool, tool.

Explanatory Dictionary of the Romanian Language provides for the verb "manage" explanation "drive", "to rule" or "to administer an enterprise or institution" and the term "administration" means all of a state administrative organs [3] . Romanian administrative system comprises 41 counties and in Bucharest, 320 cities in 103 municipalities, 2,860 or 12,951 villages common [4]. The large number of common and there are three levels of local government in our country meets the requirements for the organization of local government in the

implementation of decentralization for local autonomy.

Local authorities are becoming more involved in the development of local public investment to improve the quality of life of that community. This is based on the tendency in many countries registered decentralization, which involves giving greater responsibilities to local and regional authorities. They know best as interest in the areas they control and will do everything possible to achieve local development objectives.

Local autonomy in the administrative territorial structure is achieved by regulation and decision (council) and the operating structure (town hall). It can be said that the government is self because local autonomy is actually an expression of the principle of administrative decentralization. This independent regional and micro regional administration assumes an organization of communities and local structures complementary central government organization. In the "European Charter: local autonomous exercise of power", adopted by the European Council on 15 October 1985, the essence of this principle is found linked to local communities both local (communes, districts and departments) and in regional communities (regions) [5].

Networking relations between central and local authorities, and also inside of local authorities, have been changed by the revision in 2003 of the fundamental law of the state, emphasizing the two concepts in line with the developments of European Member: local autonomy and decentralization of public services. Relations between structures representing local level (institution mayor and council) and local representatives of the central system (prefects) are subject to the principle of local autonomy.

Local autonomy attributes symbolizing the existence of local political structures and debt capacity to solve problems in the community interest. In fact, it made the transfer of powers from the central administrative authorities operating at the level of municipalities; there are a number of problems with providing limited support necessary to fulfill their material (material resources, logistics, human resources and providing financial resources).

Many time local government actors have expressed concern about the limited capacity of financial autonomy, and the criticism regarding central government decisions have shown that the application of decentralization is not possible without financial resources because is maintained dependent to the central authority.

4. The involvement of local authorities in sustainable development

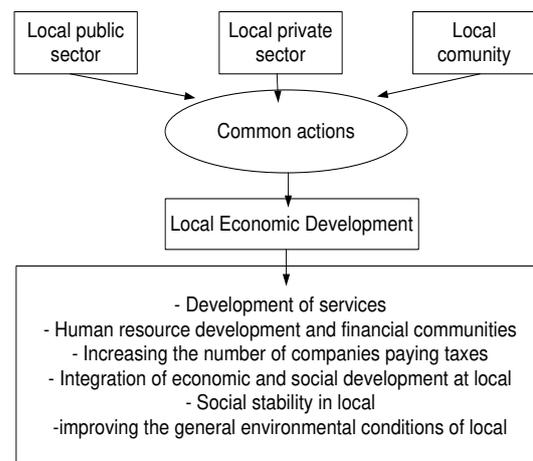

The National Strategy for Sustainable Development of Romania Horizons 2013-2020-2030, our country's authorities have as specific indicators of this type of development to be within the EU average by 2030 by taking the preliminary two stages: 2013 - principles and practices specific to 2020 - framing main indicators specific environments within the EU.

Economic growth, based on a sustainable development strategy must take into account the following aspects [6]:

- economic growth with preserving and safeguarding natural resources;
- integrative perspective on growth and energy needs of mankind when strict preservation and environmental protection;
- work-related needs, food, energy, water, shelter and medical care for humanity;
- actions-new levels of growth;
- controlling the pace of growth of population, conservation and where possible increase the reserves of natural resources and energy;
- technological reorganization and keeping under control the potential risks.

The process by which local and community managing existing resources and enter into a commitment to partnership with the private sector to create jobs and stimulate economic activity in a well defined area is economic development aspect shown in Figure 1.

Figure 1. Local economic development agencies

Source: processing after Porojan D., Iftimoaie C. „Dezvoltare locală durabilă în contextul globalizării”, Editura Irecson, București 2008, p. 27;

The role of local involved in local development is particularly important infrastructure projects, attracting investors in Romanian / foreign by providing various facilities etc. Speaking of benefits occurring in the community through local development, these are: the possibility of other jobs, a positive promotion of the city, increasing the standard of living for residents, strengthening cooperation between local authorities and the private sector.

Each local development actors plays an important role in improving living conditions for the entire population in the area, but it must be understood concretely the concept of sustainable development while mutations involved in all areas (economic, social and political).

If the economy of past centuries was dominated by the classical type of development, nowadays must think of a new kind of economic growth that is sustainable, which is required to use Earth's natural resources, conventional and unconventional forms of energy, while with protecting and preserving our environment, so as to ensure an appropriate level of welfare, not only short or medium term, but long term. So development is sustainable if it responds to current needs, identified of society.

Event concerns about sustainable development, referred to the vast majority of

today's professionals, took place in the early 1970s after the feeling of shock due to energy crisis. Significant is the first use of "sustainable development" by the Prime Minister Gro Harlem Brundtland in 1987 in the report regarding the future of mankind but the imposition concept materialized with the United Nations Conference on Environment and Development held in Rio that VUT de Janeiro in 1992. The specialized literature covered by someone can give meaning endorsed as sustainable development: meeting the current needs of society must be made without compromising the ability of future generations to meet their needs [7].

Synthesizing and many approaches to achieving sustainable development concept early on, we can say that natural resource belongs to a generation within cause and effect, that any social unit should not be more debt than it can pay to her during life. In other words, sustainability is a property set to operate in a perpetuum mobile, i.e. indefinitely without exhausting resources to major. Solving this problem requires the involvement of all stakeholders; it is a burden multisectorial and multiple stakes. Meanwhile, her approach should be a cooperative manner with holistic methods.

Sustainable development is actually at the moment emergency doctrine that economic development should not be seen only in the short term but have a time constant taken to infinity. Green jelly should be well respected by all communities, their actions should not be above the biosphere, the laws of physics and chemistry that have made our life on earth. Lately were debated and adopted international convention that applies scale on biological environmental restoration, so basically the sustainable future development. Main negative effects produced by previous economic activity that must be addressed by future developments are biodiversity conservation, protection of forests and limiting the use of certain chemicals.

Although they seem antagonistic concepts, economic development and environmental protection should be consolidated and seen together so adversely affected the environment in a given time and space to be always followed by an adjustment measure. Another element that has a negative role on sustainable

development is given the explosive growth of population. Specialists are very worried because although developments in food production and population are both progressive, one has an arithmetic progression while the other geometric. In this context, the overall amount of food will always be less than the demand for the planet's population.

The existence and perpetuation of sustainable development is possible where environmental characteristics overlap with the culture and spirituality of the community that is also part of the ecosystem, where people take care of the surrounding nature. What you need to do a community concerned with the future is to have long-term policies and very long interconnected and integrated, taking into account both economic and social issues as well as environmental ones. In light of this reality is an abundance of natural resources does not always ensure a positive development of the economy, not to talk about environmental damage compensation provided. Inability to achieve a positive effect by exploiting plentiful biological resources is determined either by mismanagement of resources, either by inefficient management. The inefficiency may be allocative or productive, that meaning do not exist a proportional allocation between different establishments or there do not consistent combination of production units.

All concepts of development in our country must be affiliated to restore and maintain the ecological balance in the short, medium and long term. Therefore, the resources must be the energy, but in an amount and over a period to ensure the restoration of values. In conclusion, sustainable development must satisfy two conflicting goals: ensuring the standard of living of the population without affecting the standard of living of the biosystem. As can be inferred and the present role of public investment in solving problems such as environmental protection, restoration of ecological balance where it was broken, etc. The natural consequence is that in almost all areas of life will make drastic changes and managers of administrative units will require excellent managerial skills to be able to translate the legal and practical paths to this goal and achieve desired results society.

They both consumer habits have changed and people's conception about the economy, society and politics. When we, Romanians, need a steady transformation of mentality, permanent and active participation in local life in all its aspects, cancellation excessive bureaucracy and secrecy at a constant awareness of our actions and the impact on the present life and future. For sustainable growth, we all need to think unselfishly if we could achieve our personal interests would coincide perfectly with the interests of the community, so that it will reach a modernizing democracy.

Local government is the body itself from the administrative point of view and one that manages the welfare of the community he leads by actions leading to economic growth of the area. It is the guarantee of a positive development of the unit by creating opportunities for local economic stimulus initiatives in the particular system: policy development on which to create new businesses or develop existing ones, ensuring local fiscal policy to encourage businesses in the area, achieving optimal urban plan that meets the needs of development, sale or entry into concession - based on the favorable situation for the community, land or services. Thus, actions that contribute to the welfare of the population are [8]:

- a. the study of the economy of the area and making a complex and interrelated political development of the region;
- b. coordination of economic development in the area, so as to achieve interoperability between public and private in the whole economic resources;
- c. as coordinator of local economic development, local authorities establish plans and strategies in the short, medium and long;
- d. project management, the foundation of local economic development programs and policies (for proper strategic planning, local budget instruments and financial management are critical);
- e. providing local public services (water supply, transport, sanitation, public lighting and fire prevention, protection and security of citizens, health care, etc.);

- f. provide attractive area increases as the quality of local public services;
- g. promoting public welfare and local economic units by maintaining a favorable local climate.

Achieving the ultimate goal of sustainable development of the area can be obtained by proper exploitation official use and development policies. Like any political action, it is an attribute of the authorities, this local time and are represented by the following factors: human resources; transport infrastructure; financial resource, Real estate assets; intake and division management duties; environment and lifestyle; organizational capacity.

Within the European Union, the objective of sustainable development is pursued in the regions because they can mobilize energies and resources. The core problem remains the establishment of competence in accordance with the principle of subsidiary, but that does not create problems of administrative structures, not anime ideas separation on ethnic solidarity and not touch.

5. Conclusions

Throughout this paper, we have presented concepts related to the management of local authorities in sustainable development of the area. Also considered important to involve local authorities in improving the quality of life of its citizens after making public investments in areas of general interest to the local community. I believe that local governments are better able to discern and to interconnect a whole puzzle consists of private economic structures of the area. Local government is the body itself from the administrative point of view and one that manages the welfare of the community, he leads by actions leading to economic growth of the area.

The effectiveness of the sustainable development takes place only if the local government and community consensus given the existing resources and enter into a commitment to partnership with the private sector to create jobs and stimulate economic activity in an economic area defined. In order to assess and manage potential situations of crisis management is recommended to prevent and combat insurance crisis in the administrative structures of logistics for the

prevention, management and mitigation of effects of a Romanian specialists interconnection networks by integrating community management experts Crisis and design, making plans, crisis situations and scenarios and options to address them.

Mathematical Analysis Model of the Incidence of Local Government Investments on Economic Growth in the Constanta County

Stignei Veronica Paşa
“Spiru Haret” University Constanta
veronica_stignei@yahoo.com

Abstract

In the current conditions from Romania, the public sector must think at least for the near future subsequent investment requirements and their performance and not chaotic prosecution of this. As such, one can develop mathematical models on which it comes to shaping the future scenarios of the evolution of public investment and investment impact on the welfare of the community.

Keywords: unifactorial type model, public investment, economical growth.

JEL Classification: C25, C67, H54, H70

1. Introduction

In the substantiation of any local initiated public investment is necessary to take into account both the immediate and direct effects and the future, which acts on the community (by changing the level of education, health status, comfort, income, unemployment, etc). All these effects are difficult to identify and quantify the social and territorial. The approach we tried to estimate correlation at the county level consists of local public investment and GDP per capita welfare indicator and analytical modeling I used unifactorial type.

2. Starting dates of the mathematical model

Local government investments in areas of interest to communities of Constanta default condition and increase their standard of living, which in my opinion implicitly affects GDP growth / capita. Statistical information from national and regional sources are not homogeneous for the period under review (2006-2011). If a business model is built on

false data or affected by measurement errors, it will get these shortcomings compromise the operational aspect. Analyzed period covers a period of growth trends revealed by the indicators between 2006-2007, the national economic crisis began in late 2008 and 2009, with a delay of about 1 year to global economic developments and stabilization in recent years You interval. The year 2006 is considered as the reference year because it ended most economic restructurings.

Given the weight estimating the effects of public investments implemented due to their specificity, in the county of Constanta, we chose the period of discussion during 2006-2011. During this period, Constanta County Council conducted public investment in different proportions in infrastructure (roads, utilities), tourism, environment, health, welfare, education, agriculture and therefore, in my opinion, I appreciate that they have had an influence concrete on the living standards of the community. Vast majority of specialists believes that local investments have the effect of economic growth and are included in income to the following realization, i.e. macro indicators GDP /capita [1].

Building a suitable model of the relationship of interdependence between public investment made and their effect on the macro indicator is relevant, but should consider the default memory side of social and environmental ethics.

Local public investments often lead to imperceptible effects on growth may occur because during off factors that hinder direct and obvious implications. If we look at studies undertaken on increasing, per capita incomes find certain conclusions on the occurrence of growth processes in the course of public investment in the current period.

Other schools of thought refer to late manifestations of achieving public

investment leads to increases in per capita income. I think that in our county, local government investments characteristics specific current first because they are manifested in all areas (infrastructure, tourism, education, health, etc.) and are made in terms of split funding and timetable. So the investment made concrete takes place during a calendar year effects on living standards experienced by the community.

Social utility of public investment projects gives us goals that question is not really recover invested funds but create a revenue stream to allow the administration to maintain the objective of providing community benefits. When referring to the highway such as Constanta -Medgidia, after the project has made it possible for road transport in the area to be faster and cheaper. I think it is important to know the amounts invested in the local government to get the most relevant results in terms of welfare experienced by the population.

3. Develop of mathematical models unifactorial type and their utility

The analytical model involves primarily a function of output Y as the dependent variable that accounts for the impact of independent variables X and associated parameters [2]. How to materialize these items when forecasting the evolution of GDP / capita in Constanta County determines the type of model to be used.

Linear regression by the method of least squares modeling method is most often used. Initial assumptions are:

1. Array of experiences, observations in variable p is fixed: $X_{n \times p}$ is stochastic and $n > p$. In other words, the data obtained correctly (without systematic errors of observation) are sufficiently large, so that solutions to provide stability.

2. X is of rank p (columns are linearly independent - form a basis of a vector space p - dimensional).

3. Value of residual variable are independent (not correlated). Residual variable has a spread (dispersion) for

various segments of equal value x_i . Disturbance vector u consists of n random variable with average 0 and below, even asymptotically, a normal distribution.

Based on the above, I limited the study with the basic unifactorial mathematic model type selecting independent variable as local public investments in Constanta and the dependent variable we considered relevant GDP / capita in Constanta.

In determining equations, we used the software package EXCEL and MS Office 10 applications listed in: Data Analysis and Regression command.

Will be introduced for each regression following:

Entry X - vector of public investment Constanta County Council, the independent variable;

Outputs Y - vector GDP / capita Constanta, i.e. the dependent variable.

Regression function must have a correlation coefficient as close to the value 0.95 to be considered representative. In the present model, we used a regression prediction error (α) of 5%. In studying the relationship between independent and dependent variables. However, in order to test hypotheses using F test and t test of global significance (Student) to verify hypotheses on simple averages to compensate for lack theoretical dispersions.

To study the interdependence of local public investments in Constanta and GDP / capita in Constanta County will use the simple regression:

$$Y_t = a_0 + a_1 X_{1t}$$

4. Unifactorial type model regarding incidence of public investments in welfare of citizens

For choosing mathematical function $f(x)$ recourse to the graphical representation of the two rows of values presented in Table 1.

Table 1. Input data and model output
GDP / capita in Constanta

Nr crt	Years	X		Y	
		PI CCC	GDP/capita	Y estimated	GDP/capita
		mii lei (RON)	lei (RON)	lei (RON)	lei (RON)
1.	2006	23434,906	20449	22599,49	23791,12
2.	2007	52135,308	22637	23791,12	24772,04
3.	2008	75760,832	28630	24772,04	27203,00
4.	2009	134310,466	27649	27203,00	28111,45
5.	2010	156190,612	28245	28111,45	31245,91
6.	2011	231684,044	30113	31245,91	32940,40
7.	2012*	275961,057		32940,40

Note: * - estimated

PI CCG – public investment made by Constanta County Council

GDP / capita - GDP / capita for the county of Constanta

To achieve this you can use Microsoft Excel inserting the diagram by dots. By choosing the trend line that best approximates the function can identify the equation.

Figure 1. Diagram by-point correlation between the investment made by the County Council and GDP / capita in Constanta.

Source: data processing from Microsoft Excel

If open dialogue Data Analysis, Analysis Tools, Regression (Excel), the analysis of the resulting regression function determined in the following form:

To check the correlation between the two variables y and x have linear correlation coefficient R (0.8336) that the more close to 1, the relationship between the two variables is stronger. Coefficient of determination (R^2) is 0.6949 (close to 1).

Table 2. Correlation coefficient of the regression function

Regression Statistics	
Multiple R	0,833600002
R Square	0,694888963
Adjusted R Square	0,618611203
Standard Error	2363,296466
Observations	6

Where:

Multiple R - multiple correlation coefficient. **R Square** - coefficient of determination (is equal to the square of multiple correlation coefficients). It may be thought, expressed in percentage, as the proportion of the variance of the dependent variable explained by the variation of independent variables: in our model the variable x explains 69.5% of the variation in y.

Adjusted R Square - the corrected coefficient of determination. Is introduced to offset (partially) the effect of mechanical growth of R^2 together with the increasing number of independent variables..

Standard Error - standard error of the estimate. It is calculated as the standard deviation of residues (for the number of degrees of freedom used ANOVA will see picture, below) and standard deviation error estimate u.

Table 3. Analysis of variance - ANOVA

	Regression	Residual	Total
df	1	4	5
SS	50880796,09	22340680,74	73221476,83
MS	50880796,09	5585170,186	
F	9,109981		
Significance F	0,039229718		

Source: data processing in Microsoft Excel

To test the hypotheses will interpret table analysis of variance (ANOVA). Columns of this table have common meanings in a painting ANOVA:

Source of variation - total variance decomposition shows the variation explained by regression and residual (unexplained)

df - number of degrees of freedom;

SS - sums of squares under decomposition;

MS - average sums of squares: SS divided by the number of degrees of freedom respectively.

Value on the second line (Residual) is the estimation error variance for the distribution and squared standard error of estimate;

F - value statistics Fisher-Snedecor F test; Significance F - is unilateral critical probability.

The first test used regression analysis - Test F - is a global test of significance of all coefficients (except the constant term). The two hypotheses are: $H_0: a_1 = 0$; $H_1 : (\exists) i$ thereby $a \neq 0$.

Number of degrees of freedom (df) attached to each sum of squares (SS) help us identify the value of F (Fisher-Snedecor table value, according to annex. 1). Thus, $p - 1 = 1$, $n - p = 4$, $n-1 = 5$;

Where: p - plus free term variable x (1 +1) and n - number of observations (6).

The calculated value of F is 9,11, which is higher than the table value $F_{0,05;1;4} = 5,625$, which rejects the null hypothesis. Rejection of null hypothesis would lead to the conclusion that the observed data does not identify a valid linear model, thus regression is not appropriate for forecasting, originally proposed.

As well the value of Significance F – 0,039 (unilateral critical probability) should be less, and it is, as good as significance step of 0,05, rejecting, thus, the null hypothesis in favor of the alternative hypothesis.

Given the situation - the null hypothesis is rejected, it is accepted that the regression equation is globally significant, indicating that it may be that some coefficients are not significant. Thus, the second test that each coefficient t test the hypotheses: $H_0 : a,b = 0$ and $H_1 : a,b \neq 0$.

Table 4. Estimate of model coefficients and statistics needed to verify assumptions

	Intercept	X Variable 1
<i>Coefficients</i>	21626,4768	0,041519626
<i>Standard Error</i>	1820,791756	0,01375608
<i>t Stat</i>	11,87751248	3,018274561
<i>P-value</i>	0,000288	0,03923
<i>Lower 95%</i>	16571,14844	0,003326625
<i>Upper 95%</i>	26681,81	0,079713

Source : data processing in Microsoft Excel

Table columns refer to variables in the model, including the constant term. The table columns are: (first column) - existing names are displayed in the data panel or automatically created for independent variables involved.

Intercept is the name for the constant term (constant) model, *t State* - T statistics;

P-value - the probability of critical bilateral t test with the assumptions set out in t State; *Coefficients* - contains estimates of the coefficients. The distributional assumptions of the linear model, the calculated values of the coefficients from normal distributions, making possible statistical verification of coefficients.

Standard Error - Standard deviation of the distribution coefficient

Lower 95% Upper 95% - lower and upper limits of the confidence interval for the parameter. The 0.05 threshold limits are calculated automatically, regardless of the initialization procedure Regression.

From Table 4 it follows aspects:

- Value of *t Stat* calculated in table - 3,018, to exogenous variable and the constant term is above value $t_{0,05;4} = 2,134$ (theoretical value of t for n-p degrees of freedom and a significance level of 0,05), which rejects each time the null hypothesis, the model variables are significant;

- Critical probability bilateral t test with the assumptions set out in t state (P-value) is below the materiality threshold of 0,05 rejecting the hypothesis of nullity.

5. Conclusions

Modeling as a means of substantiating scientific economic policy decisions, it is useful and applicable when targeting a timeframe that does not produce major changes in the evolution of economic phenomena studied.

With the data available for the period 2006 - 2011 on the development of local public investment, the GDP / capita and the number of firms in Constanta and using them unifactorial econometric model, we set the value of the dependent variable by the County Council budget projection Constance in 2012. Comparing with the data provided by the National Prognosis Commission,

which has a multitude of indicators and monitoring and vast experience in this field, we see a GDP / capita in 2012 to 35,501 Constanta lei, close to the result of modeling study. This entitles me to say that specialist's county council may appeal to this type of modeling for the coming years, not forgetting to analyze the impact on the citizens of the village, as managerial practice proves that performance evaluation is still one of the weak links in public institutions [3].

National Competitiveness and Its Measuring

Ulman Simona-Roxana
Alexandru-Iona Cuza University, SDEAA, Iasi
simonaulman@yahoo.com

Abstract

The global economy faces significant and interconnected challenges, being characterized of economic uncertainty. Policymakers ask for ways to manage the current economic challenges and to establish the fundamentals that underpin economic growth for the long term. All the countries should correctly identify their real sources of competitiveness and minimize the negative consequences on the economic development in certain contexts. For this, the first step is to know what really means national competitiveness and the way it is measured. The main objectives of the paper are to outline and discuss the relevant issues and challenges from a theoretical viewpoint related with the concept of national competitiveness and to show how it is measured by one of the most important institutes among those which realize it, contributing to a better understanding of the key factors that determine a high standard of living.

Key words: national competitiveness, stage of country development, measuring of national competitiveness, key economic pillars.

J.E.L. classification: E00, E01, O11.

1. Introduction

One of the main concerns of the society, in general, but especially of the economy, is the limitation of the resources. In this context, the concept of opportunity cost always is put into discussion because the decisions must be taken so that the resources to be spent as efficiently as possible to maximize the standard of living and the economic wellness. So, the countries should correctly identify their real sources of competitiveness and minimize the negative

consequences on the economic development in certain contexts. The national competitiveness is related in most studies to productivity and the capacity to sell the national products on the international markets. National competitiveness indicators and its determinant factors haven't been widely analyzed and the necessity of these concepts studying and compression is accentuated by another present reality: the present is defined by the correlation between the scientific knowledge, the new economy and the globalization, correlation which complicates the national economic sphere, so, a high level of national competitiveness is more and more difficult to achieve. Also, the global economy is forced to face one of the biggest challenges till now, the greatest global recession. In this context, the economic environment imposes the condition to not neglect the fundamental aspects of national competitiveness, prioritizing the short term urgencies. As Krugman advocates, competitiveness has all the necessary characteristics to be in research and debates center from the public area, but, also, from the business zone [4]. The concept tries to explore and to measure the level of every country's economic wellness using a construction which makes possible the comparison between nations with the main objective to evidence separately the success level obtained by every nation.

2. National competitiveness

The extension of globalization process has as direct consequence the increase of the competitiveness between countries. Although the process of competitiveness is not new, the actual context and the sources which nurture it are different. According to this idea, the concept was redefined to cover the new requirements, but still no standard definition exists and the authors hire the concept between different limits.

„The World Economic Forum’s Annual Global Competitiveness Reports have studied and benchmarked the many factors underpinning national competitiveness” [15]. In this report, the competitiveness is defined as „the set of institutions, policies, and factors that determine the level of productivity of a country”. Instead, the productivity fixes the level of prosperity and the rates of return obtained by investments in an economy. The definition reveals the significance of the national environment for the process of doing business; environment which is determined by the conduct of the institutions and the policies established by them. In this way, to be competitive means to be able to have positive satisfactory results at the macroeconomic level.

Porter tried to integrate all the theories about the concept of competitiveness and to create the *Diamond Model* which was compound by four important factors of competitiveness and the relations between them: factor’s conditions, demand’s conditions, the supported and connected industries and the strategy, structure and rivalry of a company, creating, in this way, the environment in which the companies appear and learn to be competitive [13]. Macerinski and Sakhanova consider that, in this model, competitiveness is defined as the capability of a nation to create the environment which helps companies to innovate faster than the foreign competitors, assessing the extension of the productivity as being the most important national strategy [5]. In addition, Onsel and Ulengin underline that although many authors consider that competitiveness is equal to productivity, these two related concepts are different one by another. Productivity represents a feature of the state and competitiveness refers to the position of a country compared with others [7]. Stateskeviciute and Tamosiuniene identify a list of nine national competitiveness determinants, underlying that a country is competitive when it has a high standard of living, high rate of employment, high productivity, commercial equilibrium, high national attractiveness, high ability of objective implementation, healthy politics, high flexibility and ability of sustaining growth [14]. All these determinants reveal different aspects of macroeconomic performance and, according

to this idea, Balkyte and Tvaronnaciene, also, sustain that the notion of national competitiveness refers to the economic performance of a nation measured as the ability to offer to its citizens high standards of living built on a strong and solid basement on the long term and a high possibility of choosing the work places for those who want to work [2]. Another competitiveness definition is given by Subarna and Rajib, who consider that national competitiveness represents the ability of a nation to create and maintain an environment which offers plus value for its companies and more prosperity for its citizens [12].

Economic literature identified a consistent list of important factors influencing the national competitiveness. The social infrastructure, including education, health, public assurance and politic institutions, including monetary and fiscal policies which the institutions promote define the wide context in which the productive economic activity evolves [3]. Also, national resources, geographical position, country size and national culture are important determinants which make a country to be more competitive than another [11].

Different from these perspectives, Porter sustains that national competitiveness doesn’t depend only of politic, legal, social, macroeconomic conditions, because these are necessary, but not sufficient to generate opportunities for wealth creation. This is created at the microeconomic level, on the basis of operational strategies and advanced practices of the companies, underlying, in this way, the importance of the microeconomic level [10].

3. The measure of national competitiveness realized by World Economic Forum

It was observed that different points of view exist from the perspective of understanding the concept of competitiveness. This lack of idea uniformity is also met when the specialists want to measure it. The existent models select and group different competitiveness factors and include them into a general system. So, the results can vary depending on the used model of measurement.

Different international organizations calculate competitiveness indexes and,

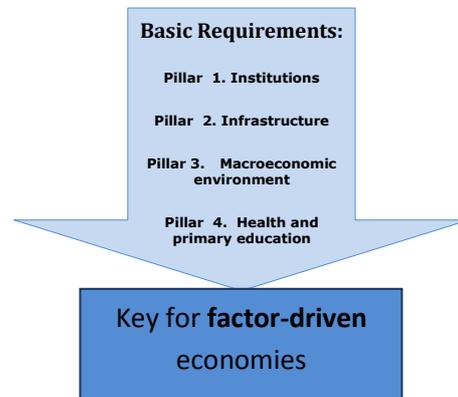

among them, *World Economic Forum* publishes *The Global Competitiveness Report* every year. It is based on the Porter’s approach, professor at Harvard Business School, which is the basis for the *Global Competitiveness Index (GCI)* construction. Since 2005, the *World Economic Forum* has based its competitiveness evaluation on this GCI, „a comprehensive tool that measures the microeconomic and macroeconomic foundations of national competitiveness” [15]. It has many different components, involving static and dynamic perspectives, reflecting aspects of competitiveness and being grouped in twelve pillars of competitiveness: *First pillar: Institutions; Second pillar: Infrastructure; Third pillar: Macroeconomic environment; Fourth pillar: Health and primary education; Fifth pillar: Higher education and training; Sixth pillar: Goods market efficiency; Seventh pillar: Labor market efficiency; Eighth pillar: Financial market development; Ninth pillar: Technological readiness; Tenth pillar: Market size; Eleventh pillar: Business sophistication and Twelfth pillar: Innovation.* The pillars are aggregated into a single index, but they are also presented separately, providing a sense of the specific area where a country needs to improve. It is underlined the interrelation between these pillars: although the results are reported separately for each pillar, they are not independent, tending to reinforce each other [15].

All of the pillars matter for all economies, but they affect national economic environment in different ways. It depends on the stage of development of the analyzed country. The *Global Competitiveness Report* classify countries in 5 groups – 3 concrete stages - *Stage 1: Factor-driven; Stage 2: Efficiency-driven; Stage 3: Innovation-driven* and 2 transition stages – *Transition from stage 1 to stage 2* and *Transition from stage 2 to stage 3*. For this classification, there are used two criteria: *the level of GDP per capita at market exchange rate* as a proxy for wages and *the share of exports of mineral goods in total exports*, assuming that countries that export more than 70% of mineral products are to a large extent factor-driven.

The importance given to different criteria in measure is different from country to country depending on the national stage of development. Onsel and Ulegin consider that

although the evaluation was tried to be corrected in this way, the weight of this importance is subjectively determined [7].

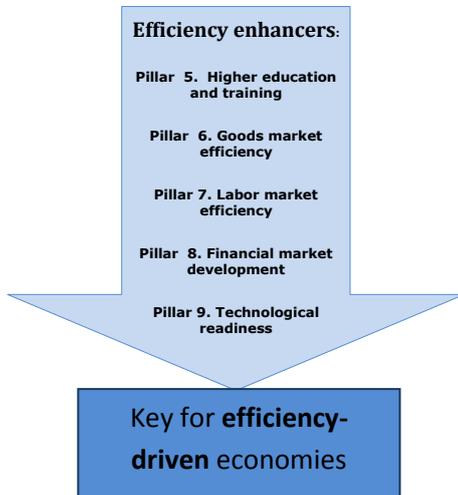

Figure 1. The key pillars for factor-driven economies

First pillar analyses institutions on two levels: public and private. On the level of public institutions, it wants to find out what is the situation in every country referring to property rights, ethics, undue influence, government efficiency, security. For private institutions, there are underlined two aspects: corporate ethics and accountability. So, it also takes into consideration the microeconomic level, using microeconomic indexes to evaluate national macroeconomic contexts. In the second pillar, the infrastructure is studied from the transport infrastructure point of view – quality of roads, of overall infrastructure, of port infrastructure, available airline seat kilometers, etc., and from the electricity and telephony infrastructure point of view – quality of electricity supply, mobile telephone and fixed telephone lines. The third pillar is about macroeconomic environment, underlying the importance of government budget balance, Gross national savings, inflation, government debt, country credit rating. The fourth pillar explores the subject about *Health and primary education*, wanting to find out the impact of malaria, tuberculosis, HIV/AIDS, infant mortality, life expectancy on business and the quality and enrollment rate of primary education. This first four pillars are named as being basic requirements for a competitive country and they have the greatest weight for the evaluation of the countries in the factor-driven stage (60%), 30% for the efficiency-

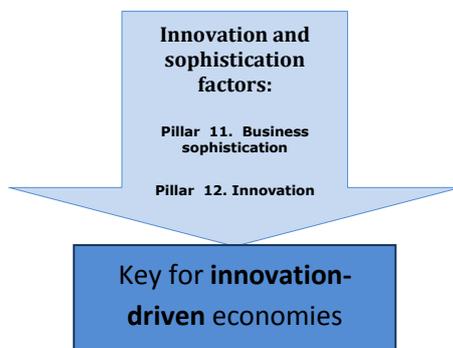

driven stage and 20% for the innovation-driven stage.

Figure 2. The key pillars for efficiency-driven economies

The next six pillars are called efficiency enhancers and they have only 35% weight from the total GCI in the factor-driven stage, 50% for the efficiency-driven stage and 50% for the last stage – innovation-driven stage. *Higher education and training* treats the quantity of education, the quality of education and the training from the job; *Goods market efficiency* analyzes the domestic and foreign competition and the quality of demand conditions; *Labor market efficiency* explores the flexibility and the efficient use of talent; *Financial market development* treats technological adoption and ICT use; domestic and foreign labor size are analyzed in the *Tenth pillar: Market size*.

Figure 3. The key pillars for innovation-driven economies

With a weight of 5% in the first stage of development, 10% in the second and 30% in

the innovation-driven stage, the *Eleventh pillar: Business sophistication* and the *Twelfth pillar: R&D Innovation* try to find out the quantity and the quality of the local supplier, the nature of competitive advantage, the value of chain breadth, the extent of marketing, etc. and the capacity of innovation, quality of scientific research institutions, intellectual property protection, etc.

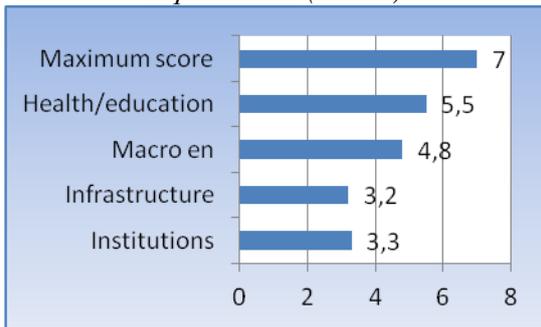

To achieve the measurement in an objective way, there are used statistical data such as enrollment rates, government debt, budget deficit, life expectancy, obtained from the United Nations Educational, Scientific and Cultural Organization (UNESCO), the IMF, The World Health Organization (WHO). There are also used data from the World Economic Forum’s annual Executive Opinion Survey.

4. The case of Romania

Romania is also included in the list of analyzed countries. With a population of 22.1 millions of people and 189.8 US\$ billions as GDP, our country is on the 78th place on the national competitiveness aspect among 144 countries included in the research. It has a 4.1 score that means a little up than the medium in the situation that scores are between 1 and 7. Its rank declined with one position than the last year and with eleven positions than the rank from 2010-2011.

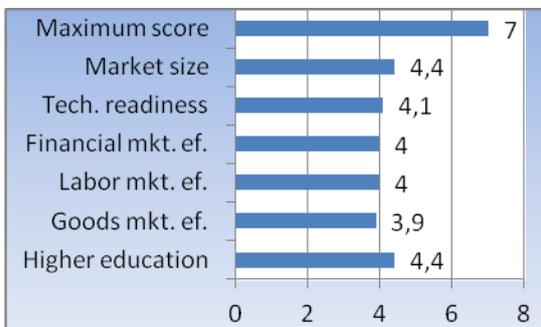

Romania is included in *The Global Competitiveness Report 2012-2013* in the Efficiency-driven stage of development. For the Basic requirements, its rank is 90 and the score is 4.2, underlying that on the first pillar – Institutions, it is between the latest countries on the list, being on the 116th place. This means that diversion of public funds is very common (2.5); that public trust in politicians is very low (1.8); that irregular payments and bribes are common, but not very (3.7); that decisions of government officials almost always show favoritism (2.4); that government spending is wasteful (2.5); that legal framework in settling disputes is inefficient (2.6); that the obtaining of information about changes in government policies and regulations affecting business activities is almost impossible (with a 3.3 score and a 136 rank), etc.

Figure 4. The scores for Basic requirements (40.0%)

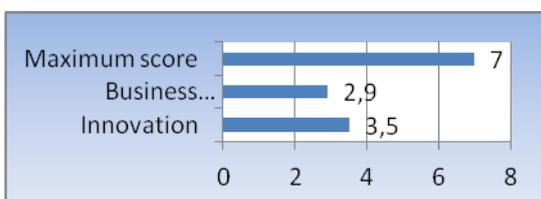

Speaking about the key for efficiency-driven economies, efficiency enhancers (50.0%), Romania is placed on the 64th position and the most problematic aspect at this discussion level is the *labor market efficiency* with a score of 3.9 and a rank of 113. The situation is presented on the next figure. The most problematic factors for doing business are corruption, tax rates, inefficient government bureaucracy and access to financing among other twelve identified factors.

Figure 5. The scores for Efficiency enhancers (50.0%)

At the level of *innovation and sophistication factors* (10.0%), Romania is almost on the latest positions, ranking 110 for *business sophistication* and 102 for *innovation*.

Figure 6. The scores for Innovation and sophistication factors (10.0%)

5. Conclusion

Many determinants drive competitiveness. Understanding the factors behind this process is of crucial interest because, as it was shown in this paper, competitiveness means a high standard of living, a high rate of employment, high productivity, commercial equilibrium, high national attractiveness, high ability of objective implementation, healthy politics, high flexibility and ability of sustaining growth.

National competitiveness is created and developed by the actions of institutions, policies and public investments which direct the evolution of the total economy. In this way, it is observed the major role of the public institutions in the competitiveness process. Unfortunately, Romania has a lot of work to do for improving its national competitiveness scores and to be placed on a better position. For this, as the results show, first it has to improve its Institutions. In actual economies, the public goods multiply and their importance in the economic environment amplifies. The local, national and global programs for the illness control, against the pollution and violence, the judicial, monetary and for the environment protection regulations, good quality governance, the individual and collective security, the actions for influencing competitiveness (legislation, context-conditions, economic politics) represent significant categories of public goods. Without these elements, the market isn't able to function and to generate and regulate them. The unity between public goods and the market is organic, but those who produce such goods aren't always selected taking into consideration the rigor and the qualities of the market criteria. The regulatory market functions acts in correlation with those of different organizations: companies, civil society structures, professional and public administration associations. The public institutions model the market using the norms from the basis of its function, watch to the conformation of the economic actors to these norms and correct the functional market mechanism. When the self-interest is over the social interest, these functions degenerate and income inequality, illegitimate economic biases, disadvantageous conjunctures

generating negative externalities inevitably appear. The conclusion is that it is very important how these institutions develop their activities, the equity of these actions being crucially for the economic wellness.

Aspects of Romanian Education during 1990-2011, by the Principal Component Analysis

Aivaz Kamer Ainur

OVIDIUS University of Constanta, Romania, Faculty of Economical Sciences

kamer_aivaz@yahoo.com

Abstract

Education has been the object of appreciation and research since ancient times, statesmen, great scholars, philosophers, men of culture and art, school people carefully investigating this area with profound implications for the development of present and future society.

Regarded as a cultural, social or civilization factor, the importance of education is widely recognized in the intellectual and moral training and development of people and society, in general. Education begins in childhood and, in terms of contemporary society, it becomes a permanent activity.

Given the importance of this area, in this paper I have proposed an analysis of the situation of the education in Romania during 1990-2011, using representative indicators such as: the number of educational institutions, the school population, the number of pupils, the number of students, the number of teaching staff and the birth rate. For this study, I have used the principal component analysis method and, for the statistical data processing, I have used the SPSS software.

Keywords: multifactorial analysis, principal component analysis, education, correlations

JEL classification: C38, I21, C81

1. Introduction

The principal component analysis (PCA) is a descriptive method of multidimensional analysis which is applied in the study of numerical variables.[6] The Euclidean distance is used in order to calculate the distance between two points in PCA.[2]

The PCA method is one of the most used methods for multidimensional factor

analysis, for quantitative variables. The application of PCA illustrates the statistical relations (correlations) between the variables considered, and it highlights and explains the similarities and the differences between the statistical units taken into consideration.[3]

If the original variables are expressed in different units, their standardization is needed; by means of this operation, there are no longer shown the differences in size between the values of variables but only the value deviations recorded by a statistical unit in relation to the average level. The fact that a unit records the lowest values for both variables, unlike another unit that records the highest values, will be viewed through a graphic representation where the position of the point represented by the first unit will be found at the greatest distance from the position of the point represented by the second unit.[5]

2. Methodology

Based on the p variables studied, the PCA method highlights the p hierarchized lines, called factorial axes or principal components, whereon the individuals and the variables will be projected, depending on the degree of difference between them. These axes, which are linear combinations of the original variables, have the advantage of not being interrelated unlike the variables analyzed. In other words, considering that the origin in an area with "n" dimensions is the centroid defined by the points whose coordinates are represented by the average values, each point moves away from the centre in a particular direction so that we obtain a point cloud centred to "0". The direction of the line where this cloud moves away the most from the centroid highlights the dominant feature of the analyzed phenomenon. This line is the first factorial axis.

In PCA data analysis, each factorial axis is associated with some of the information contained in the original data table. This part is called inertia or variance explained. Each of these axes can be also interpreted in terms of the correlation with the original variables. The factorial axes (F_j) determined by the PCA are ranked in descending order, according to their discriminatory “power”. Thus, F_1 differentiates most of the individuals between them, F_2 does it less etc. Data analysis will be limited to the first factorial axes which concentrate most of the initial information, thus obtaining a simplified representation of the original table, easy to read. In order to analyze the statistical units, it is necessary to consider the similarities, the distance between them. Thus, two units are similar to each other if they have similar values for all the variables considered. In order to calculate the distance between two statistical units in PCA, there is used the Euclidean distance defined by:

$$d^2(a,b) = \sum_{j=1}^P \frac{(x_{aj} - x_{bj})^2}{\sigma_j^2}, \text{ where: } d^2(a,b) \text{ is the}$$

distance between the statistical units a and b ; X_{aj} is the value of variable X_j , regarding individual a ; X_{bj} is the value of variable X_j , regarding individual b ; σ_j^2 is the variance of variable X_j . [4] [6]

In order to analyze the relationship between the two variables (X_i, X_j), there is calculated the correlation coefficient between them, as it follows:

$$r_{X_i X_j} = \frac{\text{cov}(X_i, X_j)}{\sigma_i \cdot \sigma_j}, \text{ where:}$$

$\text{cov}(X_i, X_j)$ is the covariance between variables X_i and X_j ; σ_i, σ_j are the standard deviations of variables X_i and X_j . [1]

Each statistical unit can be represented as a point in the vector space of dimension j . All statistical units form the point cloud whose centroid (G) is the origin of axes. In this space, the distance between the two units is the Euclidean distance. The units that resemble most are those for which the distance between them is minimal. The point cloud shape analysis involves finding the maximum elongation direction of the cloud, and it defines the first factorial axis.

It is impossible to visualize the representation of the cloud of statistical units in an area of more than three dimensions (for a number of more than three variables).

PCA involves highlighting certain factorial axes (principal components), which represent a linear combination of those variables that are correlated with each other. The first factorial axis corresponds to the line situated the closest in relation to all the points of the cloud, using the least squares criterion. It is defined by the component that distinguishes most individuals between them. In order to determine it, it is necessary to calculate the distance between a point and a line. The method used in order to determine this distance is the method of least squares. The axis situated closest to all points simultaneously is, according to this method, the one for which the sum of squares of the deviations from the point distances in connection to this line is minimal. We add that, in PCA, there is used the orthogonal projection of a point on a line.

The variance or the inertia explained by the first principal component (factorial axis) represents the highest eigenvalue of the correlation matrix. The eigenvalues are ordered downwards and their sum is equal to the number of the original variables. This amount indicates the total variance of the point cloud. The principal vectors corresponding to the factorial axes are the eigenvectors of the correlation matrix associated to the eigenvalues λ_k . These vectors are unitary (the sum of the squares of its components is equal to 1) and orthogonal (the sum of the products of the same rank components of the two vectors is null).

The eigenvector associated to the largest eigenvalue of the correlation matrix is the vector that defines the direction of the maximum elongation of the point cloud, or the first factorial axis. This vector is a new variable which is a linear combination of the original variables. The coordinates of this eigenvector represent the coefficients associated to each variable considered in the equation defined by the first factorial axis.

3. Data and results

The analyzed indicators are: the number of educational institutions, the school population, the number of pupils, the number

of students, the number of teaching staff and the birth rate. They are annual indicators, drawn from the official statistics provided by the National Institute of Statistics, for the period 1990-2011. [10]

After processing the data in SPSS, there are obtained the following results regarding the statistical variables: the correlation matrix, the calculated value of statistics χ^2 and of the KMO statistics, the variance in variables, the eigenvalues and the variance explained by each factorial axis, the variable coordinates on the factorial axes, the contributions of variables to the inertia of factorial axes and graphics. [7]

a. *The correlation matrix* shows the values of correlation coefficients between the variables, considered two by two. It is a square matrix, symmetrical towards the main diagonal. The correlation matrix form is as follows:

Table no.1 Correlation Matrix

	Unit	PSchool pop	No.of pup.	No.of stud.	Teachin g staff	Birth rate
Units	1.000	.832	.942	-.917	.687	.437
School pop	.832	1.000	.951	-.799	.469	.717
No.of pup.	.942	.951	1.000	-.937	.528	.674
No.of stud.	-.917	-.799	-.937	1.000	-.414	-.649
Teaching staff	.687	.469	.528	-.414	1.000	-.162
Birth rate	.437	.717	.674	-.649	-.162	1.000

The analysis of correlation matrix coefficients allows the assessment of the possibility of applying the principal component analysis: the high values of these coefficients (higher than +0.5 and lower than -0.5) show that there are statistically significant connections between the variables considered. In this case, the principal component analysis can be applied. The low values of these coefficients show that there is no correlation between the statistical variables and, therefore, the principal component analysis cannot be applied.

A feature of the correlation matrix is that the number of correlation coefficients increases significantly when the number of the variables included in the analysis increases, regardless of the size of the statistical community. This significant increase in correlation coefficients shows the impossibility of interpreting the connections between the variables only by analyzing the values presented in the *Correlation Matrix*.

b. In order to test the hypothesis of the independence between the statistical

variables, I have used the χ^2 test statistic (*KMO and Bartlett's Test* output). To that effect, the following statistical hypotheses have been made:

H₀: the independence hypothesis (the correlation matrix is a unit matrix);

H₁: the dependence hypothesis.[8]

In order to test these hypotheses, SPSS provides the calculated value of the test statistics ($\chi^2_{\text{calculat}}=219,734$) and the probability value associated to the calculated test statistics (*Sig.*).

Table no. 2 KMO and Bartlett's Test

Kaiser-Meyer-Olkin Measure of Sampling Adequacy.		.681
Bartlett's Test of Sphericity	Approx. Chi-Square	219.734
	df	15
	Sig.	.000

A *Sig.*<0,05 value associated with the calculated value of χ^2 test statistics shows that the hypothesis H₀ is rejected and the hypothesis H₁ is accepted. It can thus guarantee (with a probability of 0.95) that there are statistically significant connections between the statistical variables, and the correlation matrix is not a matrix unit. The calculated value of the χ^2 test statistic is sensitive to the sample size: when *n* increases, the chance of rejecting the null hypothesis is very high. However, this does not guarantee that there are statistically significant connections between variables.

The simultaneous analysis of the results obtained from testing the independence hypothesis using the χ^2 test statistics and the correlation matrix determinant value allows identifying the properties of this matrix which present an interest to the PCA. [9]

Identifying the existence of the connections between variables is facilitated by the calculation statistics Kaiser-Meyer-Olkin (KMO), measure of sampling adequacy. The KMO statistic can take values in the interval [0,1]. A value greater than 0.5 indicates that there are statistically significant connections between the statistical variables and, therefore, the PCA can be applied. In our case, a value of 0.681 shows that the solution obtained from the application of PCA is a good one.

c. The variance of variables (*Communalities* output)

The standardization of variables leads to new zero average variables and to variance 1. The variances of the statistic variables are

presented in the *Communalities* output:

Table no.3 Correlation Matrix

	Initial	Extraction
Units	1.000	.963
School population	1.000	.900
No. of pupils	1.000	.995
No. of students	1.000	.891
Teaching staff	1.000	.952
Birth rate	1.000	.958

The variance of values after extracting the factors is calculated on the basis of the *Component matrix* output. For example, for the variable *Number of students*, there is obtained:

$\sigma_4^2 = 0,941^2 + 0,079^2 = 0,891722$. The low values of the variable variance after factor extraction (Extraction column) show that these variables can be eliminated from the analysis itself because they are not correlated with the factorial axes.

d. The eigenvalues λ_k associated to each factorial axis and the variance explained by each factorial axis (*Total Variance Explained* output)

The eigenvalues of the correlation matrix are presented in the *Total Variance Explained* output, in the Eigenvalues column.

Table no.4 Total Variance Explained

Component	Initial Eigenvalues			Extraction Sums of Squared Loadings		
	Total	% of Var	Cum. %	Total	% of Var	um. %
1	4.426	73.773	73.7	4.42	73.7	773.7
2	1.233	20.553	94.3	1.23	20.5	494.3
3	.251	4.188	98.5			
4	.071	1.184	99.6			
5	.016	.274	99.9			
6	.002	.029	100.0			

In the output above, the eigenvalues of the correlation matrix are: $\lambda_1=4,426$; $\lambda_2=1,233$; $\lambda_3=0,251$; $\lambda_4=0,071$; $\lambda_5=0,016$; $\lambda_6=0,002$. The eigenvalues correspond to the inertias explained by the factorial axes. Their sum represent the inertia of the point cloud equal to the number of statistical variables in the original data table, i.e. with the sum of the main diagonal elements of the correlation matrix: $\sum_{k=1}^n \lambda_k = I_n$,

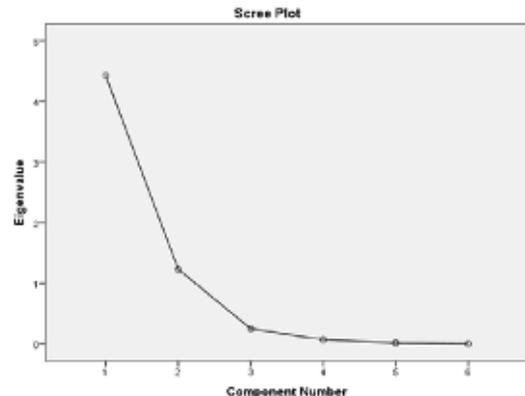

where I_n is the total inertia of the point cloud. Considering the values in the *Total Variance Explained* table, we get: $\sum_{k=1}^n \lambda_k = 5,999$.

SPSS displays these values as absolute (*Total* column) or relative (*% of Variance*

column), i.e. as a percentage of the total inertia and as relative cumulated dimensions (*Cumulative%* column). As it concerns our data, the first factorial axis explains 73.773% of the total variance of the point cloud and the first two axes together explain 94.326% of the total variance. The number of the factorial axes which is going to be interpreted in the PCA is chosen according to several criteria:

- The Kaiser criterion, which involves choosing that number of the factorial axes for which the corresponding eigenvalues are higher than one; for our data, according to this criterion, there are selected 2 axes $\lambda_1=4,426$; $\lambda_2=1,233$;
- The Cattell criterion, which involves the graphical representation of the eigenvalues (*Scree Plot* chart) and the tracking of the sudden "fall" of the inertia explained by them. There are chosen the axes prior to this sudden change of the eigenvalues slope graphic.

Figure no.1 The number of the factorial axes interpreted in PCA

The diagram in figure above shows that the number of the factorial axes interpreted in PCA is two. It is noted that there are significant differences in size between the first two and the last three values.

- The Benzecri criterion, which involves choosing the number of axes explaining over 70% of the total variance of the point cloud.
- e. The eigenvectors associated to the eigenvalues of the correlation matrix allow obtaining the coefficients of the variables in the linear equation of the main axes. The eigenvectors coordinates do not appear in the PCA results but serve to calculate the coordinates of factorial axis variables.
- f. The coordinate of variables x_j on the factorial axis k (*Component matrix* output)

shows the position of the variables on the factorial axis.

Table no.5 Component Matrix

	Component	
	1	2
Units	.951	.241
School population	.943	-.104
No. of pupils	.997	-.025
No. of students	-.941	.079
Teaching staff	.556	.802
Birth rate	.666	-.717

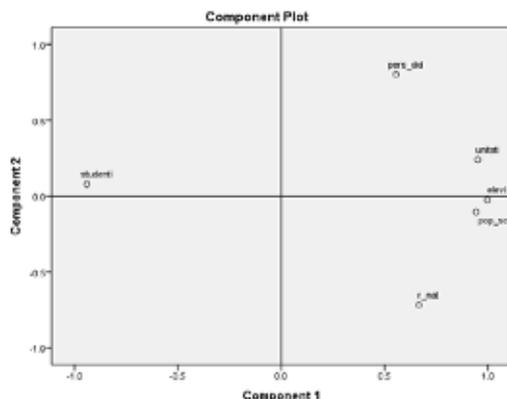

For example, the variable *Number of units* has a highly positive coordinate on the first factorial axis (0.951) and a low positive coordinate on the second factorial axis (0.241). The variable *School population* has a highly positive coordinate on the first factorial axis (0.943) and a negative coordinate on the second factorial axis (-0.104). This indicates that the variable will be graphically represented in the positive values quadrant of the first factorial axis in the negative values quadrant of the second factorial axis.

The high values of the coordinate of the variables on the factorial axes show that those variables are strongly correlated with the respective factorial axis.

For example, the variables *School population*, *Number of pupils*, *Number of students* and *Number of educational units* are strongly correlated with the first factorial axis, revealing that these variables significantly explain the differences between the statistical units (i.e., there are significant differences between the statistical units in terms of the values recorded for these variables).

The graphical representation of these two points in the system of the first two factorial axes is as follows:

Graph no.2 The first two factorial axes

The position of the variables in this diagram shows that there is a direct and strong connection between the variables *School population*, *Number of pupils* and *Number of educational units* and that there is a strong inverse correlation between the variables *Number of students*, on the one hand, and *School population*, *Number of pupils* and *Number of educational units*, on the other hand. The coordinates of the variables on the factorial axis represent the linear equation coefficients of the connections between variables. In our case, the first factorial axis is a new variable defined by the linear combination of the original variables of the form:

$$F_1 = 0,951 \text{Units} + 0,943 \text{ School population} + 0,997 \text{ Number of pupils} - 0,941 \text{ Number of students} + 0,556 \text{ Teaching staff} + 0,666 \text{ Birth rate.}$$

In order to identify the variables explaining the second factorial axis, there are chosen the values in the column *Component 2*. [7]

g. The contribution of variable X_j to the inertia of axis k (*Component Score Matrix* output).

The high values of contributions show the importance of the respective variable in differentiating the statistical units considered.

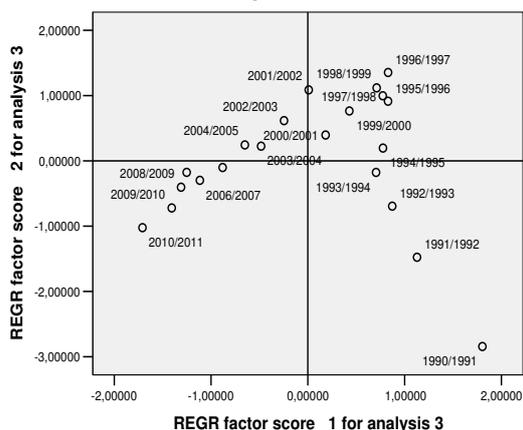

In our case, all variables contribute to the formation of the first factorial axis, while for the second axis the only variables which are contributing are *Teaching staff* and *Birth rate*.

Table no.6 Component Score Coefficient Matrix

	Component	
	1	2
Units	.215	.195
School population	.213	-.084
No. of pupils	.225	-.020
No. of students	-.213	.064
Teaching staff	.126	.650
Birth rate	.151	-.582

The interpretation of the position of the statistical units on the factorial axis has two main study directions: analyzing the closeness and the remoteness between the statistical units and explaining the position of the statistic units by integrating the variables within the analysis. [7]

Graph no.3 The position of the statistical units on the factorial axis

4. Conclusions

The educational system is the main subsystem of education, which refers to the institutional organization of education.

The European integration does not imply only the Romanian partners' access to databases and education policy documents of the European Union member states, but also the access of relevant European authorities (central institutions or specialized bodies, experts and decision makers etc.) to data banks and to any source of information on the education in Romania.

Unfortunately, Romania is labelled by many states as a weakly economically and socially developed country. The value of demographic indicators (population growth, total population) is decreasing, while the economic indicators (unemployment, inflation) reach one of the highest thresholds among the EU countries.

The first factorial axis, which explains the key differences, records a value of 73,77% of the total variance and shows two periods in the evolution of the main indicators of education: the first period consists of the 90's, respectively from 1990 to 1999, and the second period consists of the years 2006-2011.

The first period is a time when the number of educational units, teaching staff, number of pupils and of students were high,

situation due to a high birth rate (the birth rate in 1990 was 13,6%; it reached 10,4% in 1999). However, in the 90's, the number of students was very low (192,110 students).

The second period is characterized by an important decrease in the number of educational units, the number of pupils and of the teaching staff and by an increase in the number of students. At the level of the school year 2007-2008, there have been recorded 907,353 students.

The drastic reduction in the birth rate after the 90's has led to a significant decrease in the school population and in the number of pupils. The economic crisis that broke out in 2008 and the reforms initiated in the educational system have significantly left their mark on all the analyzed indicators, which recorded significant decreases.

filosofieologica@gmail.com

Abstract

The cosmological model is one of the elements of general knowledge. Nowadays, two of these models are dominant. The first model is the one which is generally accepted by the scientific international community, and the second model is the Biblical one. Each model is characterized by several principal aspects.

The aim of this article is to estimate the opinion of the students regarding the two cosmological models. For this, the correlation and association coefficients were used between the principal aspects of the two models

Keywords: cosmological model, association coefficients, correlation coefficients, contingency coefficients

JEL classification: C14, C40, C80, C88

1. Introduction

The first intersection of the religion with the modern science happened in the 17th century, being a friendly one, and most of the founders of the scientific revolution were Christians which were convinced that their activity studies the work of the Creator. In the following century, numerous researchers believed in a God that was the maker of the universe, but they did not consider Him a divine person that actively intervenes in the world and in the life of the human beings. In the 19th century, most of the researchers were hostile towards the religion, even though Darwin himself was a deist (considering that the species have evolved, but accepting the existence of the Creator). In

the 21st century, the interaction between science and religion gained multiple forms, the new scientific discoveries debating again the classic religious ideas. In response, some authors defended the traditional doctrines, whereas others abandoned the tradition, and others reformulated in the light of the science old conceptions that were long supported. Entering the new millennium, this problem arises the interest of the researchers, theologians, journalists and the general public as well. Among the most debated topics today, in this article we are going to focus on certain significant problems: the origin of the universe and its age, the order of the apparition of the Sun and of the Earth.[1]

The two interrogation manners, from the religious and scientific points of view, offer us complementary perspectives about the world, without having a conflict between them. It can be stated that the science is the one that questions itself regarding the causality relations between the events, whereas the religion is the one that seeks to know the meaning and the purpose of our lives. Starting from these two approaches, the one of the international scientific community and the religious one through the Biblical model, the aim of this paper is to investigate the opinion of the students from two different departments of the „Ovidius” University of Constanta – The Faculty of Economic Sciences and The Faculty of Theology regarding the above mentioned issues.

2. Methodology

In order to answer within the best conditions to the objectives of the research, the data collection was done through a questionnaire that was undertaken by the

interview operators without mentioning the purpose of the research so as not to influence the opinions of the respondents.

The statistic interviewed collectivity is represented by the students from the „Ovidius” University of Constanta, the sample containing 474 students, 397 of them studying at the Faculty of Economic Sciences, and 77 of them studying at the Faculty of Theology, which determines a guarantee probability of the results of 95%, with an error margin of 5%.

In order to assure the representativeness of the sample, a random multistage sampling scheme was used and on its base the studied collectivity was divided, respecting the proportions that are occupied by the groups, considering 4 criteria: the sex of the interviewed, the age, the specialization and the faculty. It is the best method for obtaining the representativeness of the sample. The used procedures for determining these segments were calculated starting from the edited data from the site of the „Ovidius” University regarding the statistic situation of the students.

The editing of the data with the view of the centralization and systematization of the information, the calculus of the indicators that describe the intensity of the connections, as well as the testing of their significance was done with the help of the SPSS informatics product.[4]

The bonds between the variables were estimated through the Pearson correlation coefficient and the nonparametric correlation coefficients (ϕ , Q and the Cramer contingency coefficient).[5]

The correlation coefficient, used in the case of the simple linear connection standardizes the average of the product deviations. A value close to zero shows the lack of the linear connection between the variables.

The nonparametric methods are especially used for the study of the association between the quality variables.[6]

The ϕ and Q coefficients are calculated on the basis of the following frequency table:

Table no. 1 The frequency table

The ϕ coefficient has the following formula:

$$\phi = \frac{n_{11}n_{22} - n_{21}n_{12}}{\sqrt{n_{1.}n_{2.}n_{.1}n_{.2}}}$$

The Q coefficient (the Yule coefficient) has the following formula:

$$Q = \frac{n_{11}n_{22} - n_{21}n_{12}}{n_{11}n_{22} + n_{21}n_{12}} \quad [11]$$

These two association coefficients take values near to zero for the variables that do not depend on each other; a value close to +1 or to -1 shows a dependency between the variables.[7]

The Cramer contingency coefficient is calculated on the basis of a frequency table with „r” lines and „c” columns. If there is a dependency between the variables, this coefficient has values close to zero.[12]

3. Data and results

The following interpretations use the hypothesis that students have seriously dealt with the questionnaire, meaning that they did not give random or intentionally contradictory answers.

The first question in the questionnaire refers itself to the beginning of the universe, namely whether the universe has a beginning or not.

Table no.2 Does the Universe have a beginning?

Does the Universe have a beginning?	Frequency	%	Cumulative %
It does	400	84.4	84.4
It does not	65	13.7	98.1
I do not know	9	1.9	100.0
Total	474	100.0	

Out of the students that completed the questionnaire, 84,4% consider that the universe has a beginning. This conception is in accord with the modern scientific theories and it can indicate that the students are aware of these theories.

Moreover, it is also in accord with the orthodox Dogmatic, and the clarification of the situation is done through the second question of the questionnaire. Only 13,7% consider that the universe does not have a beginning. This response may be a consequence of an older conception, which is

	Y ₁	Y ₂	Total
X ₁	n ₁₁	n ₁₂	n _{1.}
X ₂	n ₂₁	n ₂₂	n _{2.}
Total	n _{.1}	n _{.2}	n

still present in some older textbooks, according to which „the matter is eternal; it cannot be created, nor destroyed”. [3] 1,9% of the students (9 individuals) answered with „I do not know”, which shows that the students are either unaware of the above mentioned options, or that they did not adhere to any of them.

The answer to the first question must be correlated with the answer to the second one, which refers itself to the manner in which the universe emerged. [8]

Table no. 3 How did the universe appear?

How did the universe appear?	Frequency	%
Through the Big Bang	133	28.1
It was created by God out of nothing	246	51.9
It was created by God out of raw materials	56	11.8
It did not appear because it does not have a beginning	32	6.8
I do not know	7	1.5
Total	474	100.0

After processing the answers, we drew the following conclusions:

- 51,9% of the students consider that the universe was created by God out of nothing. This conception is according to the orthodox dogmatic.
- 28,1% of the students consider that the universe appeared through the Big Bang, according to the modern scientific theories.
- 11,8% of the students consider that the universe was created by God out of raw materials. This conception is not accepted by the orthodox Dogmatic.
- 6,8% of the students consider that the universe did not appear, in the sense that it does not have a beginning in time.
- 1,5% of the students (7 individuals) answered „I do not know”. It is interesting to note the fact that 7 students said that they do not know the manner in which the universe emerged, considering the fact that 9 students stated that they do not know if the universe has or does not have a beginning.

Therefore, the 2 students that affirm that they do not know if the universe has or does not have a beginning adhere to one of the following possibilities:

- the universe was created by God out of nothing (therefore it does have a beginning);
- the universe appeared through the Big Bang (therefore it does have a beginning);

- the universe was created by God out of raw materials (therefore it does have a beginning);
- the universe did not appear, in the sense that it does not have a beginning in time.

Apparently, the contradiction can be avoided if the creation of the universe out of time is accepted, but, in this situation, its entrance in time can be considered as a beginning. As a result, this interpretation leads to the fact that the universe does have a beginning in time.

Another interesting aspect is the fact that 65 students answered at the first question that the universe does not have a beginning, whereas at the second question, 32 students stated that the universe did not appear, in the sense that it does not have a beginning in time. Consequently, there are at least 33 students that consider that the universe does not have a beginning, but they adhere to one of the following possibilities: Big Bang, creation of out nothing, creation out of raw materials, or „I do not know”. This inconsistency shows that the notions are not clear for those individuals.

In this sample there are 302 students (63,71%) that accept the fact that the universe was created by God and 133 students (28,05%) that consider that the universe appeared through the Big Bang. Both variants imply the fact that the universe has a beginning in time.

As a result, there must be $302+133=435$ students that clearly affirmed that the universe has a beginning. However, only 400 students clearly stated that the universe has a beginning. The discrepancy can be explained in the same manner as in the previous case.

Out of 474 students, 397 students study Economic Sciences, and 77 study Orthodox Theology.

Table no. 4 Crosstabulation: The material Universe/ Faculty

The material universe	Faculty		Total
	Economic Sciences	Theology	
It has a beginning	337	63	400
It does not have a beginning	54	11	65
I do not know	6	3	9
Total	397	77	474

Out of the students that study Economic Sciences, 337 (84,88%) consider that the universe has a beginning, and 54 (13,60%)

consider that the universe does not have a beginning.

As a result, as a percentage, there are more students that study Theology that accept the version of the universe without a beginning, version which is rejected by the orthodox Dogmatic. However, the difference is quite small (0,68%).

Based on the 14,28% percentage, it can be affirmed that there is an influence of the conception according to which the matter is eternal, it cannot be created, nor destroyed, conception that is used in Chemistry, Physics and Astronomy.

This principle dominates the scientific Romanian world before 1989, as it can be seen in the following paragraph: „The matter is eternal. Taken as a whole, the matter is eternal and infinite through time and space; it does not have a beginning or an end”. [9]

At *the second question form the questionnaire*, the Big Bang Theory is accepted by 132 (33,24%) students from Economic Sciences and by a single (1,29%) student from Theology, which can be explained by the fact that the students from Theology accept the creation of the world by God. Furthermore, we are going to study through comparisons the answers to the first two questions.

For the manner in which the universe appeared, we are going to consider 2 variants: the universe appeared through the Big Bang and the universe created by God (out of nothing or out of pre-existent matter).

Table no. 5 How did the Universe appear?

How did the Universe appear?	The Faculty	
	Economic Sciences	Theology
Through the Big Bang	132	1
It was created by God out of nothing	180	66
It was created by God out of raw materials	49	7
It did not appear because it does not have a beginning	30	2
I do not know	6	1
Total	Total	77

Furthermore, we are going to study through comparison the answers to the first two questions of the questionnaire.

For the manner in which the universe appeared, we are going to take into consideration two alternatives: the universe that appeared through the Big Bang and the

universe that was created by God (out of nothing or out of a pre-existent material).

Table no.6 Symmetric Measures

	Value	Approx. Sig.	Exact Sig.
Phi	-.005	.918	1.000
Cramer's V	.005	.918	1.000
Contingency Coefficient	.005	.918	1.000
N of Valid Cases	429		

The association coefficient is $\phi = -0,005$, which shows the lack of association.

It can be observed that 13 students consider that the universe does not have a beginning, affirming that it appeared through the Big Bang, and 28 students state that the universe does not have a beginning, but it was created by God.

The third question from the questionnaire refers itself to the age of the universe.

After the centralization of the recorded answers, the following results were obtained:

- 67,1% students consider that the age of the universe is higher than 16 billion years;
- 15,2% students consider that the age of the universe is lower than 16 billion years;
- 12,2% students consider that the age of the universe is 16 billion years;
- 5,5% students answered with „I do not know”.

Table no. 7 Correlation between How did the universe appear and the age of the Universe

How did the universe appear	The age of the universe			
	16 billion years	>16 billion years	< 16 billion years	I do not know
Through the Big Bang	27	90	14	2
It was created by God out of nothing	23	163	43	17
It was created by God out of raw materials	6	37	10	3
It did not appear because it does not have a beginning	2	25	5	0
I do not know	0	3	0	4
Total	58	318	72	26

It can be observed that 79,3% students consider that the age of the universe is higher or lower than 16 billion years, according to some textbooks.

In order to study through comparisons the answers to the second and third questions, we are going to consider the following variants:

- for the manner in which the universe appeared: either through the Big Bang, or by God out of nothing;
- for the age of the universe: <16 billion years and >16 billion years.

Table no. 8 Symmetric Measures

	Value	Approx. Sig.	Exact Sig.
Phi	.107	.043	.051
Cramer's V	.107	.043	.051
Contingency Coefficient	.106	.043	.051
N of Valid Cases	360		

The association coefficient is $\phi = -0,107$ and the Yule coefficient is $Q = -0,106$. Even though the value of the association coefficients is quite small, we observe the fact that out of 57 students that consider that the age of the universe is lower than 16 billion years, 43 consider that the universe was created by God out of nothing and only 14 consider that the universe appeared through the Big Bang.

As a result, 75,43% out of the students that said that the age of the universe is lower than 16 billion years consider that the universe was created by God out of nothing, which is according to the orthodox teaching, not only in regards to the age of the universe, but also in regards to the manner in which the universe appeared.

Out of the Theology students, 64,93% consider that the age of the universe is higher or equal to 16 billion years. Out of the students from Economic Sciences, 82,11% consider that the age of the universe is higher or equal to 16 billion years. It can be considered that this difference comes from the knowledge of the orthodox teaching, conclusion that is strengthening by the previous observation as well.

The fourth question from the questionnaire refers itself to the chronologic order of the formation of the Sun and of the Earth.

Table no. 9 The order of the formation

The order of the formation	Frequency	%
The sun is older than the earth	357	75.3
The earth is older than the sun	105	22.2
I do not know	12	2.5
Total	474	100.0

The systematization of the data shows that 75,3% of the students consider that the sun is older than the earth (according to the current cosmologic model) and 22,2% of the students

consider that the earth is older than the sun (according to the Biblical model).

In order to study though comparisons the conceptions regarding to the manner in which the universe appeared and the conception regarding the chronological formation order of the Sun and of the Earth, the following data must be considered:

- 28,1% of the students consider that the universe appeared through the Big Bang, according to the current scientific theories. However, regarding the chronological formation order of the Sun and of the Earth, 75,3% of the students answer according to this theory.

- 63,7% of the students consider that the universe was created by God, but only 22,2% consider that the Earth is older than the Sun, according to the Biblical model.

The faith in God can be considered as being most influential in accepting the fact that the universe was created by God. In the same time, we can observe that many people that have this conception are diverging from the Biblical model, considering that the Sun is older than the Earth. The cause of this divergence must be looked for in the textbooks and in the science shows that present the accepted model in most of the current scientific community.

Out of 397 students from Economic Sciences, 318 (80,10%) consider that the Sun is older than the Earth; out of the 77 students from Theology, 39 (50,64%) consider that the Sun is older than the Earth.

The fifth question from the questionnaire refers itself to the chronologic order of two important moments: the formation of the sun and the apparition of the vegetation. The two models are conflicting again.

The first model is the Biblical and Patristic one according to which the vegetation was created in the third day, and the Sun in the fourth day. Saint Ioan Hrisostom comments as follows: „This is why it shows you, before the creation of the sun, the earth covered with everything, so as not to assign the sun the perfection of the fruit, but to the Creator of the universe” [10]

The second model is the one accepted by the current scientific community; according to this model, the sun is older than the earth, so the vegetation appeared after the formation of the sun.

Table no. 10 The apparition of the vegetation and of the sun

The apparition of the vegetation and of the sun	Frequency	%
the vegetation appeared before the sun	13	2,7
The sun appeared before the vegetation	452	95,4
I do not know	9	1,9
Total	474	100,0

An interesting point is the fact that 95,4% students consider that the sun appeared before the vegetation on earth; only 75,3% consider that the sun is older than the earth.

The explanation must be looked for in the intuitive character of these aspects. [2]

Some individuals that consider that the Earth is older than the Sun cannot accept the fact the vegetation appeared before the sun, due to the fact that they have in mind the photosynthesis process that requires light and they cannot understand any other source of light, except for the Sun.

Table no. 11 Symmetric Measures

	Value	Approx. Sig.	Exact Sig.
Phi	-.021	.669	.763
Cramer's V	.021	.669	.763
Contingency Coefficient	.021	.669	.763
N of Valid Cases	428		

The small values of these coefficients shows that there is no bond between the conception regarding the order of the apparition of the Sun and of the vegetation and the conception regarding the manner in which the universe appeared (through Big Bang or creation).

4. Conclusions

In general, the answers to these five questions are grouped into two categories. The first category is the one determined by the Biblical and patristic model.

The second category is determined by the accepted model in the current scientific community.

The individuals that completed that questionnaire did not give answers from the same category, being influenced, in some conceptions, by the Biblical model, and in other conceptions by the current cosmological model.

Abstract

Corporations expanded with no longer being controlled. The failure of multinational companies has become a topic of high interest. Good corporate governance is not only desirable but also a vital business practice. The purpose of this study is to analyse the architectural structure of corporate governance, the problems it faces and how information systems can solve these problems. The question is to what extent modern accounting, integrated in an information system based on current processing and prediction techniques (such as data mining, cloud computing, game theory, business intelligence) may lead to solving these problems in a timely and successful implementation of the best strategies and organizational structures to make a more competitive entity.

Keywords: Corporate governance, information system.

J.E.L. Classification: M14, M15.

1. Introduction

Deep crisis of capitalism is caused by the failure of multinational companies that have grabbed the global economic power, creating monopolies and their own laws that are different from those of the states [37]. The root cause of the recent turmoil is the failure of the dominant economic paradigm - global

corporate capitalism. Corporations expanded with no longer being controlled. According to an AlterNet analysis [6], the invisible forces that acted behind them were caused by the failure of their dominant economic principle - global corporate capitalism.

2. Purpose

The purpose of this study is to analyse the architectural structure of corporate governance, the problems it faces and how information systems can solve these problems. A corporate information system is very complex, involving many stakeholders and transactional processes, technologies, procedures and codes of practice. Another problem is bureaucracy. Large corporations have created monopolies, which brought a huge bureaucracy, becoming inflexible and difficult to manage.

3. Question

The question is to what extent modern accounting, integrated in an information system based on current processing and prediction techniques (such as data mining, cloud computing, game theory, business intelligence) may lead to solving these problems in a timely and successful implementation of the best strategies and organizational structures to make a more competitive entity. Business intelligence has proven to be a valuable information system within the firm's strategy and data mining

technology can improve the operation of the business [9]. To ensure efficiency and effectiveness of corporate governance, in order to increase company performance and strengthen its position in the capital market, it is necessary to analyse the contribution of information technology in this field.

There are three key research questions that can be asked in relation to of IT:

- Are information systems able to solve the problems of corporate governance and how is this done?
- To what extent managers and board members are aware of the potential benefits of applying information technologies, such as creating value for the company?
- Are they well informed for good IT equipment in line with the company strategy?

4. General theory framework

Discussions on *corporate governance* (CG) and its importance began in the 1930s in the American academic world, while in Europe it began at least 10 years later [7]. The term *corporate governance*, or as defined in ISO FDIS 26000, *organizational governance* (OG) is the system by which an organization adopts and implements the decisions necessary to achieve goals. In other words, the term "governance" means the process of decision-making and the procedures by which they are implemented [8]. So the concept of governance includes how an organization is run. In accordance with corporate governance principles of the Organization for Economic Cooperation and Development (OECD), corporate governance involves a set of "relationship between the managers and shareholders of corporations, as well as stakeholders like employees and creditors" and can be defined as a system that provides a fair and reasonable treatment for investors or more broadly, for the whole society [30]. Also, corporate governance can be defined as a structure used to determine the responsibility and authority of the various groups involved in the functioning of the organization [7].

Broad corporate governance is the set of rules and control mechanisms applied in order to protect and harmonize interests in many cases contradictory of all categories of

economic actors (stakeholders) developed within firms. In good corporate governance is expected to pay attention to all stakeholders 'interests including those of employees, creditors, customers, suppliers and local communities [28]. The World Bank defines corporate governance as a combination of laws, regulations and codes of conduct adopted voluntarily and providing companies greater access to financing, lower cost of capital, better firm performance, and more favourable treatment of all stakeholders. Thus, World Bank client countries have initiated legal, regulatory and institutional corporate governance reform projects [36].

Information System can be defined as a collection of components that work together to provide information to management. It enables them to make decision which ensures the control of the organization [3].

Business Information System is a group of interrelated components that work collectively to carry out input, processing, storage and control actions in order to convert data into information products. This information is used to support the activities in an organization [27].

5. Research approach

A recent study on Corporate Governance in 14 emerging markets, found wide variations in performance among companies that apply different levels of governance. Generally, organizations' corporate governance was proportionally as strong or weak as their country's legal system [14]. Corporate governance refers to promoting fairness, transparency and accountability at the company level [5]. A greater focus on corporate governance is largely to answer the collapse of Enron [15], WorldCom, Anderson, Xerox, Merrill Lynch, Allied Irish Bank, Alder Hey, Sellafield, Maxwell, BCCI (Bank of Credit and Commerce International) which led to the subsequent adoption of legislation governing the form of the U.S. Sarbanes-Oxley Act in 2002.

Competitive success of an organization is determined to a large extent on the quality of management and in particular, the organizational, decisive, informational and last but not least by the methodical-methodological subsystems [13]. These subsystems involves the implementation of

appropriate tools and techniques to help diagnose problems with organization and to develop an appropriate strategy [24]. Literature associates theory agent with the notion of corporate governance (Agent theory) [12], first developed by Jensen and Meckling (1976), and the Fama and Miller (1972), which integrates modes of organizing complex decision-making process within the company and with signal theory (Signalling theory) [2], which analyses the impact of economic and financial information asymmetry on entity [7]. The Administrator theory describes management leadership role in maintaining and developing the organization's value [19]. Other theories underpinning corporate governance: stakeholder theory and business policy. In the interests of good governance, a company has to draw his own way, taking into account the purpose and objectives [21]. Other theories associated with the notion of corporate governance range from the agency theory and expanded into stewardship theory, stakeholder theory, resource dependency theory, transaction cost theory, political theory and ethics related theories [1].

Continuous development of new IT technologies was followed by a rapid integration of their organizational level. IT has become an essential element in the strategic development and growth performance of any organization. Corporate governance extends in IT area. Therefore we can speak of IT governance as prerequisite for good corporate governance [18]. In this way, IT governance has become an important part of corporate governance [26].

Information Technology (IT) is an integral part of the business. Also, IT Governance (ITG) is an integral component of corporate governance. Especially after Sarbanes-Oxley (SOX) was passed in the U.S. in 2002, followed by similar regulations in many countries, corporate governance and ITG have become more and more connected as the IT control plan is integrated into the overall enterprise plan [28].

One of the problems facing corporations is the complexity of the information system. We live in the age of giant corporations. According to the classification [10], the largest is JP Morgan Chase, which has assets of \$ 2,300 billion, i.e. triple gold and foreign reserves held by the European Union,

240,000 employees and offices in 100 countries. Inadequate information and the inability of understanding foreign cultures may cause the failure of a business. Thus, it is important a comprehensive information of value systems, norms of behaviour and to accept the existence of cultural diversity. The current economy has two main characteristics: abundance and complexity of data and speed of change, and thus of decision-making [23]. Information is regarded as one of the most valuable assets of a corporation [34]. Today, instant messaging, email, electronic documents have increased the flow of business [29]. In this context, the question is not whether the Board should take decisions on IT governance, but rather on how they should do so [28].

For years, great amount of data coupled with much insignificant and poor information have been known issues by the leaders of large corporations. The expression "elephant in the room" is relevant. But now, corporate governance and regulatory compliance have made the room smaller and more exposed the elephant bigger and much more noisy [11]. Whether working on a simpler architecture or other more complicated (matrix, conglomerates, strategic alliances), global corporations raises complex management problem - of their activities and the external environment, and this cannot be solved only through effective exploitation of interconnections . In this sense, information system is regarded as the backbone of modern business, playing an important role for a well governed company [20]. Such systems characterized by flexibility and adaptability to changes environmental, concern the poorly structured or unstructured problems that managers must deal [5].

According to recent studies, the implementation of IT governance / CG in corporate structures and corporate governance practices supported adoption of IT in governance leads to creating value for the organization [14]. As a result, many top executives of companies consider their business information technology priorities [20]. IT management has evolved now to include IT Governance (ITG). Thus, IT Governance (ITG) has now become a part of corporate governance [17]. An appropriate

information system must be able to establish a balance between the interests of all parties involved in the firm [28]. It involves a management system appropriate to company requirements [33].

In the interests of good corporate governance (CG), corporate information technology (IT corporate) are aligned with the information needs of members of the Board, in order to provide relevant and timely [31]. For good corporate governance (CG), corporate information technology (IT corporate) is aligned with the needs of the Board members, in order to provide relevant and timely information.

The recent economic turmoil forced firms to recognize that, even in good economic conditions, growth does not preclude the need for tangible, accurate data and reliable, transparent analytic processes. Data has the potential of enhancing the IQ of an organization, enabling greater agility and enhanced performance [31].

Thus, IT governance can be seen as an integral part of corporate governance and therefore requires special attention from the top management of the company. Integration of the two forms of government is desirable because it has been shown that both factors have a significant impact on good management [26]. According to a survey [22], 188 corporate executives in Canada indicates that IT plays an important role in ensuring good governance. Firms with integrated IT structure seem to obtain significantly greater profits, up to 20%, than those companies with similar business strategies, but without an integrated IT structure [14].

IT governance implementation may require organizations to rethink the governance structure and the people involved to revive the roles and relationships within the company [26]. IT solutions become more complex and powerful (outsourcing, third party contracts, networking, etc.), among others, due to the inclusion of a broader range of stakeholders [25]. IT solutions in accordance to its strategic objectives, provides flexibility in two ways: adaptation to each specific business environment and openness to change permanent, resulting in value creation for the company [28]. Government decisions usually involve several stakeholders who have conflicting

claims, and they can be classified as potential stakeholders, permanent, active and uninterested [16]. Information system can effectively achieve these stakeholders to prioritize and classify them according to importance and role is the objectives of the entity [32].

In addition to the large amount of time spent collecting and analysing data gathered from different departments, business units within large companies are forced to communicate to higher hierarchical levels, an activity which is time consuming, inefficient and bears significant costs. It is also affected accuracy [25]. According to The Banker [35] there are many problems associated with reference data: poor data quality, missing standards, delays in data delivery, bad data coverage and high costs. Many of the challenges technology improve governance requirements imposed on companies and facilitate their application by the company [5]. Automated information flow helps business performance through standardization, automation, simplification and management processes across the enterprise and by providing better internal controls [9]. It would lead to a decrease of information asymmetry and would increase the transparency of all decision-making processes [4].

Information systems contribute to the ability of a corporation to successfully manage many governance requirements. Without the facilities offered by the new technologies available today, more staff and longer time would be required for database management. In addition to the time spent, the accuracy of the data would likely be questionable [25].

IT system is able to understand, in a complete and complex manner, information from production, accounting department, purchasing and sales, inventories, fixed assets. It can also to put together all these parts of the business and make them work together, eliminating incomplete or irrelevant information for the business. Business Intelligence is the key differentiation for business today. Business intelligence, analytics and performance management are top areas for a good management [38]. Database mismanagement may lead to contradictory results, distorting the truth, or a complete lack of information on important

areas of business [11].

Regarding the reference data, problems can be many: poor quality of their lack of standardization, delays in data delivery, coverage and high cost of processing data, the growth of data, the desire to improve risk management and compliance with regulatory requirements. Reducing errors and processing costs are often cited as key factors automation reference data within companies [6].

6. Conclusions

A corporate information system is very complex, involving many stakeholders and transactional processes, technologies, procedures and codes of practice. A major concern of managers is the investigation and analysis systems that lead to rapid and accurate diagnosis of the current situation, highlighting the negative phenomena that occur, and appropriate measures and decisions in order to increase companies' performance and to maintain a constant state of competitiveness.

In this context, Information Technology (IT) has become an integral part of the business, a key element in the strategic development and growth performance of any organization. IT system is able to understand in a complete and complex manner. It can put together all the components of a business and make them work, eliminating incomplete or irrelevant information.

So information systems are able to solve all these problems by modern methods of processing, storage, and retrieval and transmission databases. While executives and board members are aware of the potential benefits of applying information technologies, they are often not informed enough for good IT equipment in accordance the requirements of a good corporate governance.

Globalization

Andrușcă Maria Carmen
“TOMIS” University Constanța
info@brancrew.ro

Abstract

The field of globalization has highlighted an interdependence implied by a more harmonious understanding determined by the daily interaction between nations through the inducement of peace and the management of streamlining and the effectiveness of the global economy. For the functioning of the globalization, the developing countries that can be helped by the developed ones must be involved. The international community can contribute to the institution of the development environment of the globalization offering resources, on the one hand, and opportunities, on the other hand, its advantages being further for everybody's benefit.

Key words: Globalization, streamlining, effectiveness

J.E.L. classification: F01

1. Introduction

The term globalization was used for the first time in the 80s to characterize the changes incurred in the national economies of the countries by the significant development of the international capital flows. The phenomenon highlighted the main discrepancies between the developed countries and those less developed, respectively the increasing power of the multinational companies related to the national authorities. The power of the globalization process has been given mainly by the contribution of multinational organisations which, in a constant and complex manner, have participated to the elaboration of the national policies, based on the experience and competence held.

The rapid technological developments incurred in the last decades in certain strategic industries (biomedicine,

telecommunications, information technologies etc.), the permanent development of the third sector services, as well as the change of the global economical relations, constituted the determinant factors for a relatively recent process, namely that of the relocation of the activities of the productive companies. The main support of these processes has been related to the promotion of direct investments of the companies from the developed countries in countries with developing economies, the process being beneficial for both parties involved; the first category of organisations can reach their objectives of a more efficient achievement of some production/assembly processes, and the host countries can exploit better their natural, human or anthropic resources available.

The intensification of the international trade and the considerable increase in costs and risks associated to the product logistics also constituted intensification factors for the “invasion” of powerful companies towards emergent economies with a considerable development rate and availability of resources.

On the ground of the structural transformations of the national economies, the globalization process implied the performance of some complex actions related mainly to the limitation of industrial production in relation to the available workforce. This process has been favoured by the integration of information and communication technology in the current practice of the organisations. Similar mutations have also been highlighted on the workforce market by the increase in the mobility of human resources, both from the professional point of view, as well as regarding the practical experience in industrial fields with orientation towards research – development or the information technology. The areas with resource availability have transformed from

independent locations in regions or networks economically – socially interconnected, and the strategies of complex integration of the transnational organisations have materialized in the development of certain international integrated production systems.

The power centre of these systems has partially moved from the field of material and natural resources to that of intensive technologies based on knowledge, professional competences, flexibility and organisational suitability [1].

2. The mechanisms of globalization

It is easy to understand why the multinational corporations play such an important role in globalization: the coverage of the entire planet, bringing the markets, the technology and the capital of the developed countries to the same level with the production capacities of the developing countries require the existence of certain very large organisations [2].

The British economist Adam Smith, the founder of the modern economy, was a powerful advocate of both free markets and the free trade, and his arguments are very convincing: the free trade allows the countries to take advantage of it, because each of them specializes in the field it excels. The great commercial areas allow the companies and individuals to specialize themselves further and to become more competent in what they do. Imagine yourself a small village where there is only one baker, and then imagine a big village which might have two or three bakers. In a bigger town there could exist more bakers of which some of them would make only bread and others only cakes. In a bigger town there could be only bakers which make bread or cakes – its bakers would have so many clients so as he would specialize more and more, producing a large variety of very good cakes and bread specialties. Greater markets increase the effectiveness of each producer and amplify the possibilities of choices available for the consumers.

In the lack of a free trade, the capital and the workforce shall record different profits in different countries. In a country which has no capital, such as equipments and technology, the workforce shall be less productive and the wages lower. If the workforce migrates

from a country in which the productivity and the wages are low to a country where they are high, the production shall be huge, and the global economy shall develop. The free trade removes the necessity to shift. The inhabitants of the developed countries can stay at home and they can buy cheap products from the Asian countries, where the workforce is cheap. In their turn, the Asian workers can stay within their countries and can have access to United States high-tech products, a country with a much more advanced technology, with a very specialized workforce and with high capital investments. Theoretically, this means that the demand for the Asian products increases with the demand for their unqualified workforce, and, finally, the wages of the unqualified workers within these countries shall increase. [2].

3. The improvement of globalization and democratization

The globalization itself is neither “bad” nor “good”; it simply exists. But, undoubtedly, the globalization must be governed.

Globalization is a phenomenon which implies risks and, as it is well known, the risks imply both opportunities and hazards. The good governance maximizes the exploitation of opportunity windows opened by globalization and abates the hazards which might have impact on certain categories of people from certain world areas.

The role of catalyser of the globally really free competition is, according to Antonio di Pietro, the key element for the understanding of which concrete policies must we put into practice and which action lines must we promote, in our quality of “global political class”, in order to get a net benefit, at a global level, from this extraordinary process.

More shortly, Antonio di Pietro centralizes his analysis on the following preliminaries:

- The globalization must go hand in hand with democracy; otherwise, we cannot reach the free economical competition;
- This competition cannot be achieved if the fiscal paradises and the enclaves of money laundering are tolerated.

Even if the term “democracy” can be defined in many ways, we can assume that the level of democracy is given by the “amalgam” of moral imperatives spread within the society and by the way the social and political processes are organized [3].

The democratization is part of a distinct set of changes within the global order. It is particularly related to the establishment of a really global politic economy, to the occurrence of the institutions of global governance and to the establishment of a global communication network.

Strang considers the democratization a consequence of the establishment of the global political economy:

“Most of the recent changes of the global policy, regardless the level of their apparent despair, have mostly common roots in the global politic economy. We can see the same forces of the structural change responsible for the release of the Central Europe, the disintegration of the Soviet Union [...] and the radical changes of many governments of the developing countries, from the military or authoritarian governments towards democracy, and from protectionism and industrialization based on substitution of imports, towards the opening of boundaries and the promotion of export.”

The establishment of the global political economy has its roots mainly in the globalization of production, trade and finances. The specialists agree that the current extension of the trade is higher than in any other point in human history and that we assist to the apparition of some finance and production markets that are really global. The globalization process is both the cause and the consequence of a seismic transformation at the level of the national economic policies and of the global movements towards economic deregulation and global integration. The development cannot take place anymore between pressurized or insulated national boundaries. This is the case of developed societies, but it can be even truer in the case of developing societies which do not benefit of enough capital, know-how technology and trust. Thus, globalization is an irregular process which affects the countries differentially. It has the greatest impact on vulnerable and weak countries, where the countries are less capable to moderate its effects.

The establishment of the global political economy is related to the democratization in various ways. First, it strengthens the authority of occidental capitalist centres over the developing world, reducing the political and economical options made available for the developing countries. The developing countries and the post communist ones have repeated and regular contacts with the agents or governments of the capitalist nucleus. This is a result of the support governments which are based on political conditioning, of the development of some humanitarian intervention programs in the former Yugoslavia or in Somalia, for example, as well as of the apparition of regionalized commercial blocks which started to dissolve the previously well-established boundaries which distinguished the North from the South and the West from the East. At present, the south countries or the post communist ones discover that they are “fixed” in a certain development model which depends of the formal democracy and of an open economy. They are caught in a series of political relations with the developed countries which includes a bond to the liberal democratic model of development [4].

The general meetings of the Club of Rome which took place in the last years continued to centralize on the problematics, globally considered, of learning, as one of the essential issues in the process of social development. The ignorance – synonymous to the absence of permanent learning in the contemporary period – was invariably identified as a serious major impediment both for the extension of the knowledge era, for the social development, as well as for the global abatement of poverty.

But the knowledge and globalization era continue to be current premises for the theses of the Club of Rome; as a matter of fact, knowledge has an undisputed role in all contemporary theories on globalization.

Within the meeting from October 2005, the Club of Rome brought into attention the central idea – the long term global thinking which must centre on the preoccupation for the future generations – in other words, the Club suggested that a new type of thinking is necessary (essentially global, long term, interdisciplinary), otherwise the social development and the eradication of major global problems (among which the poverty

and the conflicts) being impossible to be achieved. The educational issue came back powerfully in the fore within this meeting: to the question “What tendencies must the globalization define so as the human societies be progressively characterized by the economical and social development, and, at the same time, by the ecological balance?” the response given was that the key-role is held by education [5].

4. Conclusions:

The effectiveness requires transformations of the globalization and of the democracy which are reflected in the free market, being a fundamental characteristic of the political and social life. The territories are a key element of globalization in the economic exchange and in the market structure, encouraging the exchange, facilitating the communication which carries along complementary activities as natural or material resources, the labour market and the commercial market which are influenced by territorial factors.

Through a correct streamlining of the globalization for some areas of the world, the advantages are even higher in what concerns the economy and the development of the

standard of living of the population, so as it functions not only for those that are rich and strong, but also for all humans, including those from the poorest countries.

Abstract

In the global competition for markets, the chances of economic success of a country or of a region are based on the offer specialization and on focusing the development efforts to key fields where there already exists competitive advantages, resources and skills. In this context, the clusters represent the ingredient for success because it offers a combination of entrepreneurial dynamism, strong relationship between institutions and companies which have the “know-how” and pro-active synergies between the leading actors of innovation. Clusters’ formation and their development are currently seen as the primordial pillars of the local development. The paper proposes to present a brief image about the process of creation clusters and competitiveness poles in Romania and to analyse and evaluate the chances of success of clusters/competitiveness clusters for increasing romanian economic growth.

Key words: clusters, competitiveness, competitiveness poles, economy

J.E.L. Classification: M21, O16

1. Introduction

The clusters represent a successful solution experienced in Europe in the last decade and have currently become the primordial pillars of the local development. The members of the cluster can keep their independence but in the same time can act in partnership to apply a common strategy of development created around some innovative projects that help the association in its whole and offer all the members tangible benefits.

The first economist who described the clusters from the “chain of suppliers” perspective was Alfred Marshall who analyzing the industrial agglomerations in England found out that these geographical concentrations of enterprises from a specific sector create involuntary positive economic effects. The essence of the cluster concept has its roots in work on what Marshall, as far back as 1890, called ‘externalities of specialised industrial locations’ [1].

Somewhat paradoxically in the current context of increasingly globalised markets, firm location and interdependence are significant explanations of their competitive performance according to cluster theory. At the beginning of the 20th century, two Swedish researchers Ohlin and Hecksher argue that the difference between countries is given by the production factors, and the products are different because of the production factors incorporated. According to the model (Ohlin – Hecksher factor proportion theory), a country holds a comparative advantage and thus will export the product that incorporates the abundant production factors in the respective country. Thus, the more abundant a production factor is, the cheaper it becomes. So, the difference in the production factors is given by the difference in their prices, generating the competitive advantage. In Romania there are many analyses and studies that aimed the identification of economic competitive agglomerations cluster type/ poles of competitiveness, even in an incipient form. But all these analyses, except for the last one, have merely identified the clusters and generated general recommendations regarding the development of a national cluster policy.

2. A brief history about the process of creation clusters and competitiveness clusters in Romania

So, in Romania the analyses didn't follow the advantages generated by these formations and the role they may have in the economic development, in the way we can find in other European states and not only.

In 1998, the Economic Development Institute of the World Bank ordered a study done by the International Center for Entrepreneurial Studies [2] regarding economic competitive agglomerations cluster type in Romania. The study, based on Porter's diamond competitiveness theory was focused on the Romanian economic sector competitiveness and was done on a panel of enterprises of all sizes from all of the 8th regions of development and identified three clusters in the incipient phase in the wood industry, shipping and software production.

In 1999, Marco Riccardo Ferrari, assistant researcher at the Department of Economics of Bocconi University in Milan, published a study focused particularly on small enterprises and on the data analysis based on regional and county level. The study identifies three so-called "proto-districts", but this time, in the wood industry, textiles and ceramics industry[3].

Valentin Ionescu [4] argues the existence of "proto-clusters" or "emerging cluster" and sustains his view by explaining different levels of development and knowledge of industrial agglomerations identified. Research finding confirms the presence of two "proto-clusters" in ceramics at Alba-Iulia and software industries in Bucharest. In addition, he underlines the differences in the methodological criteria applied in the other studies and the vagueness of the clusters' definitions.

The VICLI3 project, developed within the European program INTERREG II C - CADSES4, between 1999 and 2001, tried to identify and support cluster development through regional exchange of know-how. This report identifies four potential clusters appeared in Harghita County (Harghita was the pilot area in the project) in woodwork, pottery, printing and switchgear industry. The emergence of these sectors is clearly related to the area's natural resources.

Between 2000-2006, the INCLUD5 project funded under the Interreg III B CADSES, European Initiative for European Regional Development Fund aimed at an analysis of existing clusters of potential partner countries in Central and Eastern Europe and then assisting these countries in developing such clusters, using the experience and know-how in Italy and Austria. Some potential clusters were identified in the textiles industry in North-East, in particular, Bacau County and West Region, particularly Timis, in the software industry in Timis, Cluj and Bucharest, in wood, steel and metal components industry in the Central Region.

From 2001 to 2004 the WEID8 Project financed by the European Commission in the 5th Framework Programme - FP5 on a period of 3 years investigated the relationships between clusters at European level using the study cases. The project involved partners from 7 European countries – Germany, Italy, Great Britain, Czech Republic, Poland, Slovenia and Romania - and 2 of the 15 study cases were related to Romania in the sports equipment industry, respectively, in the shoe industry. The results of the researches in the WEID8 Project reveal the existence of a more intense spatial agglomeration for the firms in the west and north-west of the country, areas (especially Timis and Arad) where there was also identified a high level of Italian investments that brought the Italian model of clustering.

Due to the distortion of the socialist system under the auspices of which the Romanian economy was developed until 1990, the current orientation towards cooperative structures, public - private partnership and collaboration between industry and universities still suffer now being treated with suspicion and not very much confidence [5].

Michael Porter's economic theory was the starting point in the implementation of the cluster and regional competitiveness pole concept, namely that "a cluster" is an economic concentration of enterprises, small and medium sized enterprises especially, on a given geographical area, interconnected with its own nuclei (centers) of research, professional training centers, specialized suppliers, in a certain field, that are in competition with one another but also in

relations of cooperation and a competitive pole is a regional innovative cluster with national (an elite cluster) and international vocation or a cluster network (6). The economic reality in Romania required the presence of catalytic institutions (entities specialized in the innovation and technological transfer, consulting firms, chambers of commerce etc.) within the pattern called “the Four Clover” [7].

At the end of this studies survey, regarding the economic competitive agglomerations cluster type developed in Romania, we should also mention the most recent initiative in this field which consists in the process of “cluster mapping” (fig. 1) launched by the Ministry of Economy, Trade and Business Environment (MECMA) with the declared purpose of identifying the existing and the potential clusters in Romania. The project, launched in 2009, in the framework of the mutual agreement between the German (represented by GTZ) and the Romanian government (represented by the Ministry of Economy) was held during 8 months (June 2009-January 2010) [8]. There were identified, based on the course of 8 regional workshops (held in București, Iași, Timișoara, Râmnicu Vâlcea, Mioveni, Bistrița, Sfântu Gheorghe and Constanța), whose results were validated by analyzing the questionnaires completed by the most important regional actors and in conjunction with regional development plans and regional development strategies developed by RDAs.

3. The Current Analyze of the Romanian Cluster Process. A Real Success?

The "Triple Helix" - a model that fits well cluster structures in many other European countries and in which the three actors (universities and research institutes, industries and public authorities) cooperate voluntarily very well, must be adapted to work in the Romanian realities. This way emerged The "Four Clover" model where, in addition to the three actors listed above has occurred a fourth actor whose role is to facilitate the cooperation of the other three, the fourth actor is the institution catalysts: specialized service providers, technology transfer centers, chambers of commerce, consulting services in the field of cluster

management, etc.. This new model is applied to the emerging innovative cluster in the woodworking and furniture industry created in the region Brasov - Covasna by FP7 project "Pro Wood".

In the policy of clusters, poles of competitiveness, Romania is interested in the following:

- Attracting foreign investment and investment funds in clusters / poles of competitiveness in Romania;
- Exchange experience with entities which develop cluster policies and strategies;
- The development in partnership of Benchmarking;
- Exchange of experience and best practices with other clusters both in business and economic cooperation;
 - Romanian clusters include transnational and cross-border networks;
 - Preparation of cluster managers and study visits, trade missions, etc..;
 - Supporting the participation of Romanian clusters in Innovation Tours, international fairs and exhibitions to promote regional brands;
 - International cooperation (public-private) in creating theme parks like Technopolis, Copernicus and so on;
 - The Participation of Romanian innovative clusters in projects of the Danube Strategy, of the South East Europe Transnational Programme, INTERREG IV C etc..

The clusters that form will represent the nuclei of competence which will contribute in future to increase the competitiveness of regional business environment and further development of some initiatives, benefiting from the support of local public authorities, universities and other business support structures and research as well.

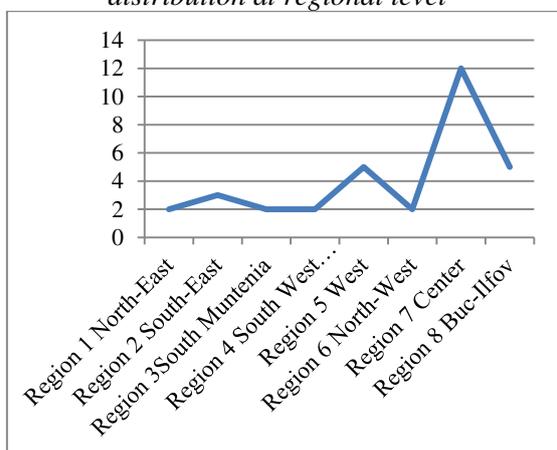

In the year 2012 in Romania were identified 33 clusters / poles of competitiveness which are largely functional since 2011, so we can say that this phenomenon is at the beginning, we take the previous experiences of countries with a tradition already in this phenomenon of creating clusters / poles of competitiveness.

Doing an analysis of clusters / poles of competitiveness on domains it is noted a concentration of 50% of these clusters in automotive, green energy, textiles and tourism. It is also argued that the

concentration is given by our country's tradition in these fields but one thing is certain, namely that the number of clusters / poles of competitiveness is under regional potential available to Romania.

If you were to analyze the regions where clusters are present or competitiveness poles are noted fig. 3 that region 7 Center has the highest concentration of economic agglomerations, respectively 12 (36%), in Region 5 West and Region 8 Bucharest-Ilfov were identified 5 (15%) each, while the North-East, South-East South Muntenia, South West and North-West Oltenia are the least represented in this sense, they have 2-3 clusters at regional level (6-9%).

Figure 1 Competitiveness poles/clusters distribution at regional level

Some of these clusters do not work, agreements are concluded between cluster members and some of them are applicants due to the call on projects within the Sectoral Operational Program - Increase in Economic Competitiveness - Operation "Poles of competitiveness". Most clusters are functional from 2011 and unfortunately we cannot speak of their development because we do not have a record of them.

4. Conclusions

Romania, during the 23 years after the 1989 Revolution tried to catch up, adapt and implement models of European economy at local level, often successfully, other times not because in terms of national policies and strategies of development the imported European models are not adapted to the Romanian economy. This is also the case of

competitiveness poles model "Fabrique en France" (we consider it to be the most sophisticated model of economic concentration), taken by the Ministry of Economy, Trade and Business Environment and implemented with EU funds through the Sectoral Operational Program the Increase of Economic Competitiveness.

It is a concept developed successfully by France, indeed after 25 years of experience in which they went from the local production systems in 1987 to clusters and from clusters to poles of competitiveness since 2005 and this transition was based on a strong intervention of the French Government that allocated inter-ministerial funds for C-D projects, funds from the local authorities, regional directorates of industries, research and the environment, European funds. French clusters are smaller concentration of competitiveness poles, their funding is entirely private in comparison to the pole that is mixed and where the share of public funds exceeds 40%.

Romania is not ready to implement the concept of competitiveness pole as long as more than half of the identified clusters are not functional and are currently funded exclusively from European funds so the question which arises is what will happen after their exhaustion as long as there is no funding from MECMA or from the local authorities? In our country the job/profession of cluster manager does not exist, there is no culture of the cluster brand, and most importantly there is no public funding for innovative projects in the clusters, the clusters that are functional are financed by members' own efforts and other European funds if they applied to SOP IEC - "Operation Competitiveness Poles" according to the selection results.

We consider that the sophisticated French model of competitiveness poles is not functional in the Romanian Economy so it is not suitable for the Romanian economy; we believe that more appropriate would have been any other European cluster model that should be supported, developed, financed and implemented successfully.

Keynesian Realism and the Present State of Economic Science

Asăvoaei Alexandru
Alexandru Ioan Cuza University of Iași
Doctoral School of Economics
alexasavoaei@yahoo.com

Abstract

The aim of this paper is to illustrate a few aspects related to the shortcomings of the mainstream economics, and its unrealistic theoretic assumptions, as it completely failed to anticipate the current economic crisis. In the same time we intend to highlight the much more realistic theories provided by the Keynesian doctrine, which offer much more coherent and precise explanations about the economic mechanisms that cause deep economic recessions, like the one we are going through nowadays. The most important objective of this article is to emphasize the essential role of the psychological factors regarding the macroeconomic cyclical evolution. In the final part of the paper we provide a few scientific pieces of evidence that undoubtedly confirm the Keynesian hypotheses.

Key words: Keynes, economic crisis, animal spirits, uncertainty, behavioral economics.

JEL Classification: D84, D87, E12, G12.

1. Introduction

Since 2007 the world economy is facing one of the deepest economic crisis in history, comparable perhaps only with the Great Depression from 1929 – 1933. As we know now, its origins are related with the collapse of the speculative bubble on the American real estate market. And although the economists and the policy makers from around the world have tried different methods in order to restore the economic prosperity as quickly as possible, the economic situation is still very difficult in most countries. More exactly, the living standard has decreased substantially, the financial sector is still almost paralyzed and the unemployment rates are still very high.

Though, in spite of these already huge problems, the economists have one more thing to worry about, and that is the present state of the economic science. This is because the dominant economic doctrine of the moment proved to be unable to predict the present crisis, let alone to explain it. On the contrary, during the time period that preceded the actual crisis the majority of the economists seemed convinced that many years of economic growth will follow. More than that, when the crisis came, they were taken completely by surprise and could not provide a satisfactory explanation.

From our point of view, this discordance between the optimism of those economists and the real situation of the economy was due to the fact that they were thinking according to the neoclassical theories that are very much “in vogue” nowadays.

2. A quick analysis of the neoclassical theories

As we have stated above, the dominant vision in economics nowadays is based on the assumptions of “perfect rationality” and “perfect competition” suggested by the neoclassical school of thought. According to this economic doctrine based on assumptions, like the “rational expectation hypothesis”, the “real business cycle theory” or the “efficient market theory”, the current crises should have never occurred.

To be more specific, the essence of these theories is that every economic agent present on the market has unrestricted access to every piece of information he needs, for the economic decisions he has to make. In other words everyone is perfectly informed, and as a consequence, the future is completely predictable. Thus, every event that might occur can be easily anticipated by using certain mathematical tools and probabilistic calculations. More than that, the neoclassical

theories argue that the markets will always have the tendency to self-correct almost instantly, every time minor and conjectural imbalances will occur. Therefore there would be impossible for an economic crisis, especially one of this magnitude, to take place. The historian Robert Skidelsky, accurately and appropriately summarize the substance of these theories, as follows: “by means of rational expectation and real business cycle theory economists came to believe that the future was certain, the unemployment was voluntary and the numbers could substitute common sense.”[8]

Just by reading the point of view presented above, everyone should realize that the neoclassical assumptions are unrealistic, and that is the main reason which has determined, in our opinion, a crisis of the economic science itself. In the real world things happen in a different way and the economic science cannot afford to farther ignore the reality.

3. A Keynesian perspective on the causes of the current economic crises

The Keynesian school of thought offer, on the other hand, an entirely different perspective on the causes of major macroeconomic fluctuations like the one we are experiencing nowadays. In his works, John Maynard Keynes explicitly contradicted the assumptions of perfect rationality that were also highly appreciated in the time period that preceded the Great Depression. The lack of realism that characterize the neoclassical theories is best emphasized by Keynes in the following fragment: “The orthodox theory assumes that we have a knowledge of the future of a kind quite different from that which we actually possess... The hypothesis of a calculable future leads to a wrong interpretation of the principles of behavior which the need for action compels us to adopt, and to an underestimation of the concealed factors of utter doubt, precariousness, hope and fear.”[5]

Thus, Keynes introduced in the economic vocabulary and analysis, notions like “animal spirits” or “uncertainty”. He argues that people in general, and especially the economic agents, possess different levels of knowledge, and thus, most of the times they

do not act fully rational. Because the information is “asymmetrical”, most of the times, the economic agents are compelled to rely rather on instinct or intuition, in order to adopt economic decisions, than on probabilistic calculations.

One could ask what is the connection between these new concepts and the deep economic crisis that started in 2007 and that still appears to be far from over. The answer to that question is that, this economic crisis, like many other crises from the past, occurred precisely because of the instinctive behavior that are adopted, especially by the participants on those markets characterized by very high volatility, like the financial markets. And we know that these markets have played a big part on the development of this crisis. The best example is that of the speculative transactions made with those “toxic” financial derivatives, issued by the many powerful financial institutions, like the American investment banks.

The prices of certain asset categories, like the well-known CDOs, seemed, for a while, to increase constantly and rapidly. As a result, many people perceived these price increases as a golden chance to become rich, in a very short period of time. Everyone wanted to buy this kind of assets and nobody seemed to realize that the price increases were not going to last indefinitely. This kind of behavior reveals at least two aspects, which are closely related to the Keynesian concepts of “uncertainty” and “animal spirits”. First of all we can see that nobody really knew about the real value of the assets they were buying and secondly, that nobody seem to care about it. We know now that these assets were based, in a large proportion at least, on potentially non performing mortgages, but in those days the buyers were deliberately ignoring this possibility, in the same manner as “a healthy man puts aside the expectation of death.”[4]

The increases in prices of both, the real estate assets and financial assets were not caused by “pure rational” behaviors, but rather by that kind of “naive optimism” that Keynes had spoken about in his masterpiece – “The general theory of employment, interest and money” published in 1936.

Another aspect that perfectly illustrates the irrational behavior of the economic agents in the period that preceded the current

economic crises is represented by the ease with which the financial institutions granted loans even to the very risky customers. But, in spite of the fact that some bank managers have anticipated the difficulties that might arise when those customers would not be able to repay the loans, they continued to “play this dangerous game” arguing that it was the only solution to maintain the competitiveness on the financial markets, of the institutions they represented. More than that, even if they wanted to adopt different and more prudent strategies, they would not have been able to control the actions of every broker that worked there; the asymmetry of information would have prevented that. In conclusion, they had no choice but to do what everybody else was doing, hoping that the “judgment day” will arrive as late as possible.

This type of behavior has also been described by Keynes in his works. He named it – “herd behavior”, and compared it with the game of “musical chairs”, a game where everybody has to dance while the music is still playing. In a similar way, both the managers and the brokers had to “follow the crowd” if they wanted to keep their jobs. Otherwise they would have been fired or forced to resign. More than that, the situation of the financial system wouldn’t have improved, because others would have taken their place instantly, and would have continued to lend carelessly.

In the recent years, the Keynesian concept of “animal spirits” has been developed by other influential economists, like Robert Shiller or the Nobel Prize laureate – George Akerlof. They divided this concept, which Keynes has defined as “a spontaneous urge to action rather than inaction”[4] into five subcomponents, namely: confidence, fairness, corruption, money illusion and stories.[1] They have also emphasized the role which each of these components has played during the present economic crises. For instance, a key role in the price increases that facilitated the formation of the real estate speculative bubble from the US market was played by “stories”. More exactly, when the dot-com bubble exploded in March 2000, many investors have shifted towards the real estate market. This caused an initial price increase of this category of assets, which, in time, gave birth to the idea that owning a house or a piece of land was the best business

one could dream about. Many journal articles and even books reinforced this idea, and the results were spectacular. Not only the experienced investors, but common people also, rushed to buy real estate properties. Moreover, this phenomenon extended on other countries as well. All over the world the real estate prices increased substantially, as well as the buyers’ confidence.

Money illusion have also played an essential role in the “price explosion” that occurred on the real estate markets. That is because, buying or selling a house represent a transaction that most people only make once in a lifetime, and people tend to remember the nominal acquisition price. Thus, if someone had bought a house twenty or thirty years ago, the actual market value of that house would seem much higher. This creates the impression of an extraordinary investment. But this appearance is deceiving because in the given time interval, all the other prices had increased proportionally.

Even the “fairness” has played an important role in the development of this crisis, at least in the United States. That is because of the political pressures made by the leaders of the Afro-American community, in order to obtain less restrictive conditions regarding the access at mortgages, for its members. These advantages were obtained. The American government allowed certain public institutions, like Fannie Mae or Freddy Mac, to reduce the lending standards for the members of this community. However, the price that the Americans paid for that decision was rather high. That is because the private financial institutions were encouraged to adopt less restrictive credit terms for their customers, as well. After that we all know what followed...

A special form of corruption could be identified in another crucial moment of the crisis. That is the moment when the rating agencies were given the opportunity to evaluate the financial derivatives issued by the financial institutions. In spite of the fact that they were aware of the unorthodox methods used by the financial institutions to create these products, they preferred to look the other way and to give favorable ratings to almost everything. Of course they received consistent fees in exchange of their “generosity”. In these circumstances we believe that it is safe to say that the rating

agencies and their corrupt behavior have played a crucial role in the outburst of the current economic crisis.

4. Experimental evidence that confirm the Keynesian theories

In the previous sections of this paper we emphasized a few aspects related to the way that people act in the real world, and that are not taken into account by the neoclassical doctrine. In this section we intend to provide additional evidence that those types of behavior which we described in the above pages are indeed permanent characteristics of the human actions. In order to do so we will present the conclusions of a few experiments made by certain researchers in one of the newest fields of economics, namely behavioral economy.

The first example is not exactly an experiment but an “everyday situation” that Robert Shiller illustrates in one of his books, titled “Irrational Exuberance”, in order to emphasize the Keynesian concept of “herd behavior”. Professor Shiller presents the image of a person that has to choose between two similar restaurants that are situated close to each other. The only information that our hero has got about the two restaurants come from other people. He hears only good things about the first one, while about the other he receive mixed evaluations. Thus he decides to enter the first one, because it is more appreciated by the people. However when he approaches them he observes that the one he was going to enter is almost empty while the other one is crowded with people. Seeing that, he changes his decision and enters the one that he intended to avoid. In other words, he ignores the information he posses and decides to “follow the crowd”. [7]

A set of experiments illustrating “money illusion” are presented by the economists Eldar Shafir, Peter Diamond and Amos Tversky, in an article published in 1997. One of these experiments considers two individuals – Ann and Barbara – who have similar jobs. Both are receiving the same salary of 30.000 dollars, but while Ann receives a raise of 2% in the absence of inflation, Barbara receives a raise of 5% in the condition of a 4% inflation. In nominal terms Ann gets 600 dollars while Barbara receives 1500 dollars. When asked about who

do they think was doing better in economic terms, 71% of 150 respondents “voted” for Ann. However the situation changed dramatically when the same respondents were asked who they think it was happier. To that question 64% voted for Barbara. More than that, to the question of who is more likely to leave her job earlier, 65% of 139 respondents thought that Ann is more likely to take such a decision first. [6]

The money illusion is also clearly emphasized by Keynes in his “General Theory”, when he writes about the workers rigidity to nominal wages cuts.

There is also experimental evidence that people care about fairness, in the same time they suffer from money illusion. One of these experiments presents the situation of a small firm that has few employees and makes little profit. To the question about the fairness of reducing the wages with 7% in the absence of inflation, 62% of 125 respondents appreciated that such an action would be profoundly unfair. However 78% of the same respondents appreciated that a wage increment of 5% in the condition of an inflation of 12% would be acceptable. [2]

Another example we will present in this paper that illustrates the fact that people do not act fully rational is given by Keynes himself in his book titled “A treatise on probability” and published in 1921. Here Keynes presents the following situation: there are two urns each of them containing white balls and black balls. Certain people that are asked to extract, for example, white balls from the two urns know that in one of them there are white balls and black balls in the same proportion. About the other urn they know that it also contain white balls and black balls, but do not know anything about the proportion. If they would act in a perfect rational way, they would not care from which urn they extract. The probability to extract a white ball is exactly the same, namely 50%. However, in reality, the great majority of people would prefer the urn that contains an equal number of white balls and black balls. [3] Keynes explains this attitude by the fact that people “suffer” from what modern psychology calls “the ambiguity aversion”.

Another recently established economic sector, namely neuroeconomics, provides us with even more experimental evidence about the “irrational side” of the real people. Tests

conducted by the experts in this field have shown that people use different parts of their brain in order to make different economic decisions. When there is the possibility of an immediate gain, the brain area that responds to stimuli is that corresponding to the center of emotions. On the other hand, when we have to make a decision that could bring us a financial reward, but only after a longer period of time, the brain area that responds is the reasoning center.

A classical neuroeconomic experiment has revealed different behavior by potential investors when they were presented with the same question but which was differently formulated. Thus, they were inclined to invest when were told about an investment with 60% chance of winning, and to hoar the money when they were told that the chance of losing their money would be of 40%.

5. Conclusions

The economic history has showed us many times that the recession periods are a part of the economic evolution. They could not be avoided so far, and, in our opinion, this the situation won't change in the future either. The reason is that the economic crises are caused by the emotional component of the human behavior, as Keynes anticipated almost a hundred years ago. But maybe the major crises can be at list anticipated, or even “sweetened” as much as possible. However, in order to make that possible, the economists need to let go of the old habits. They need to renounce at using mathematical tools for analyzing a world composed by real people, who are not fully rational most of the times.

On the other hand, a better analysis of the psychological factors that decisively influence the human behavior, by using the appropriate tools, will determine the real progress of our science. John Maynard Keynes has taken the first steps towards a “healthier” scientific approach on the realities of the economic life. Moreover, the researchers of the newest economic branches have confirmed his theories. Now, all that remains to be done is to adjust the dominant economic theories according to the findings of the great British economist, and thus, to make them more realistic. Let us hope that the necessary adjustments will be finished until the next major economic crisis arrives.

The Balance between Flexibility and Security in the Labor Market in Romania

Avram Costin Daniel

Faculty of Economics and Business Administration, University of Craiova

avramcostindaniel@yahoo.com

Abstract

Balance between flexibility and security in the labor market is essential for the achievement of performance criteria both employer and employee. In Romania populism characteristic of the period of transition to market economy and found an unfortunate reflection Labor Code - Law 53/2003, which established settlement in legal obvious imbalance between the interests of unions, very strong at that time, and the interests of employers represented employers' associations without a definite decision making power. Almost paradoxically triggered by the global financial crisis in 2008, accompanied by accelerating the privatization process led to the change of forces which allowed a number of amendments to the new Labour Code adopted by Law 53/2011. This study aims to identify the elements of balance between flexibility and safety in Romania and if we talk about adopting flexicurity work righteousness, as being implemented in developed countries in the European Union.

Keywords: flexibility, security, contract labor, continuous training.

JEL Classification: D04, J24.

1. Introduction

Flexible use of labor in Romania is manifested primarily in the length of the working day, so in Romania in terms of employment with:

- full time during an average working week is 41.1 hours, while the EU 27 average duration is 40.4 hours and the euro area the average length of the working week is 39.9 hours;
- part - time, the average length of

working week is 9.7 hours, while the EU 27 the average is 18.5 hours and the euro area countries the average working week is 19.9 hours.

Under the law 53/2011 - Labour Code, working time shall mean any period during which the employee performs the work, is available to the employer and shall perform the duties and tasks, according to the individual employment contract, collective agreement applicable to his / or legislation. For full-time employees during the normal working time is 8 hours per day and 40 hours a week. For young people aged up to 18 years working time is 6 hours per day and 30 hours a week. Distribution of working time in the week is usually uniform, 8 hours per day for 5 days, two days of rest. Depending on the specific business or work done, you can opt for an unequal distribution of working time, subject to the normal working hours of 40 hours a week.

The new Labour Code [12] brings an increase in labor market flexibility by introducing the individual part-time employment and work at home.

2. Individual employment contract part-time

In accordance with the individual work part time, "part-time employee is the employee whose normal working hours number, calculated weekly or monthly average is less than the number of normal working hours of employee time comparable full". The employer may fall part-time employees with individual contracts of indefinite duration or on fixed-called individual contracts of part-time employment.

An individual employment contract shall be concluded only part time in writing. Comparable employee is full-time employee in the same establishment having the same

type of employment contract, providing the same or a similar activity to that of the employee's employment contract employee with part-time, taking into account other considerations, such as seniority and qualifications or professional skills. When there is no comparable employee in the same unit, have regard to the provisions of the collective agreement applicable or relevant legal regulations.

The individual part-time employment includes, besides the items in the individual employment contract for full time:

- hours of work and allocation of working hours;
- conditions that may change work program;
- ban on overtime except in cases of force majeure or for other urgent works to prevent accidents or eliminate its consequences..

3. Work at home and teleworking

Under current regulations are considered \ "work at home employees to those employees who, at their home, the specific responsibilities of the position they hold. In carrying out their respective duties, employees set their own work at home program work \ ". The employer has the right to verify employees work at home job, as determined by the individual employment contract.

Individual employment contract ends mandatory home in writing and contain the elements laid out by individual employment contract full time:

- to provide explicitly that the employee works at home;
- program under which the employer has the right to monitor employee activity and practical way of achieving control;
- the employer's obligation to provide transportation to and from the employee's residence, as appropriate, raw materials and materials that are used in business, and the finished products they carry.

Work at home employees enjoy all rights recognized by law and by collective bargaining agreements applicable to employees whose job is at the employer. By collective agreements or individual employment contracts may establish other

specific conditions on home work in accordance with the law. What customizes contract work is the work at home is not the employer, but the employee's residence. ILO Convention no. 177/1996, whose ratification was held in 1998, the European Commission recommended Member States of the European Union since its provisions establish that the work place is not only home employee but any other place chosen by the employee. Employer control over the activities of his employees is manifested by making periodic visits to work. If the employee does not allow representatives of employers, workplace, he commits a disciplinary offense.

Current regulations to reduce parental leave from two years to one year requires flexible working hours greater compliance with the conditions of balancing parenting responsibilities with career training. When negotiating union confederations current labor laws to ensure safety at work of employees, insisted to conclude fixed-term contracts only in exceptional circumstances nature. Most EU Member States widely used fixed-term contracts, their conclusion is left to employers and employees in relation to their specific needs.

Teleworking is a new and flexible at the same time the organization of work, job duties are performed by using information technologies. Teleworking is an unusual way of organizing work. Between employers and unions with European representation ended at European level, an agreement - Frame on teleworking. The EU member countries are widely used on-call contract (upon request) contract that provides greater flexibility of employment contracts, but still unenforceable under any labor law in Romania.

4. Continuous professional training

New technologies change job content and status of the profession and the institutional changes require ongoing vocational training through lifelong learning throughout life. In Romania, the reform of the education system was established by Ordinance 36/1997 National Council for Continuing Education and Training no.129/2000 Government Ordinance, as amended and supplemented, the regulated activity CVT law practice to ensure compatibility between Romania and

the European Union.

Professional bodies: The Body of Expert Accountants and Licensed Accountants of Romania, Chamber of Financial Auditors of Romania, Chamber of Tax Consultants, National Union of Evaluators in Romania, National Union of Insolvency Practitioners of Romania through continuous training programs provide training of professionals in various fields as a result of compliance with national regulations in the field with EU regulations. There is a strong correlation between continuous professional training and macroeconomic performance if we consider that Romania and Bulgaria ranks last in the European Union in the GDP / capita but also to lifelong learning. Neither 1.5% of people aged 25-64 years in the two countries did not participate in a program of continuous training, while in the Nordic countries average more than 30% of the same age segment.

Correction of deficiencies in the system of education and training throughout life may influence expanding and strengthening the principles of flexicurity labor market in Romania. To achieve this required implementing the following measures:

- involvement of universities in non-formal education;
- involvement of social partners in the education and continuous training;
- the involvement of professional bodies in the education and continuous training;
- tax incentives for companies that invest in raising qualifications of employees;
- increasing role of different forms of formal, non-formal and informal learning in creating and developing professional skills and work habits. Achieving that goal requires fostering a culture of lifelong learning since the period of initial training and awareness by individuals of the benefits of such an approach;
- adoption of a coherent legislative framework on the functioning of the education and training opportunities;
- preparation of studies on medium and long term impact on the effectiveness of different forms of adult education and continuing vocational training in particular;
- correlation of program education and training trends of technological change;
- stimulating the development of adult education services in rural areas and small towns;
- increasing role of information technology in learning throughout life;
- increase the professional competence of trainers involved in processes adult education;
- increase skills levels of employees and finding ways to recover costs under continuous training flexibility.

Objectives of the Europe 2020 agenda on economic policy and social dialogue on flexicurity is asked to answer a number of objectives such as:

- a real flexible contractual relations in the labor market by removing restrictions on fixed-term employment, collective redundancies and other contractual agreement of the parties;
- guaranteed minimum gross salary payment to help overcome poverty line as it is defined by international bodies;
- unemployment benefits be linked to employee and employer contribution and to participate in its level to reduce the number of people affected by poverty;

Encourage young people who want to continue and to complete university, and at the same time to engage in employed part-time, including by promoting a system of training vouchers.

5. Conclusions

After 2020, it is possible for Romania to join the euro area should continue the liberalization of the labor market and especially will be corrected social security long term, under the impact of pension withdrawal demographic peak in July of last century decade (between years 2032 to 2036). Lifelong training should not remain only in the texts of the Labour Code, but must contribute to improving performance in the interests of the employee and the employer. Provisions of collective and individual employment contracts must contain elements of flexibility in terms of working hours. Alignment is necessary not only to European legislation and best practice but in the sense that the majority of EU Member States widely used fixed-term contracts, their conclusion is left to employers and employees in relation to their

specific needs. Balance between flexibility and job security is dynamic and it reflects the balance of power between employers' associations and trade unions, progress towards social dialogue and ultimately lead to the modernization of the labor market. For increasing social dialogue would be useful to consider the following conditions:

- union leaders do not hold equities / shares in the capital of economic entities, have no interests in companies in which an employee, and not political enrolled;
- Government representatives not to hold shares / shares in the share capital economic entities, are not represented on boards and committees of auditors, audit committees,
- representatives of employers will not be in conflict situations provided by law.

It is expected that in the next period social dialogue to build the legal framework already established in the interest of all institutional actors. For it must be observed basic rules of dialogue, namely, the ability to listen and understand the positions of dialogue partners, especially the science of compromise in accordance with their best interests. Economic dialogue between the management entities or employers and employees on improving labor must consider the periodic evaluation of the impact of new technologies and innovations have on labor employed in the unit.

Abstract

This paper presents several issues of the management of IT services and their evolution, with focus on ITSM methodology. It includes a short description of the methodology, together with the costs and benefits it brings, as well as several strategies aimed to increase IT organization performance.

Key words: IT Service Management, Knowledge Management, Information Professionalys

JEL Classification: L10, L21, L25, L86

1. Introduction

IT service management has become increasingly more complex for IT managers. Outsourcing and modularization of IT services have led to new developments in the field of IT services such as IT services „on demand”. The current trend of the management of companies is to use the services of an external partner, thus IT managers are forced to work in partnerships.

Service Management enables the service providers to better manage and understand both the usefulness of services offered by them and the costs and risks associated with these services.

„Service management can be defined as a set of specialized organizational capabilities for providing value to the customers in the form of services. These capabilities are actually processes, methods, functions, roles and activities that enable a service provider

to deliver a specific service” [1]. The aim of IT Service Management (ITSM) is to support the business targets of the companies taking into account the life cycle of services and its continual improvement.

The concept of IT Service Management appeared in a project carried out by the Government of the United Kingdom in the mid-1980’s, during a serious economic downturn. The British Government was compelled to reduce the costs and better manage IT service delivery.

So the Government has established the British Central Computer and Telecommunications Agency (CCTA) in charge of a project to develop innovative ways to improve IT service efficiency.

The CCTA knew it could quickly increase efficiency by focusing on improving IT processes. The team was drawn the consultants, suppliers, and users to fix a set of best practice-based IT processes, using a common glossary of terms. Then these were published in an integrated series of 40 books. This series has recently been updated. It was edited in seven books and is now called the IT Infrastructure Library (ITIL).

ITIL is the most complete documentation for the organizations wanting to implement IT Service Management. The companies and governments worldwide have adopted ITIL [2,3].

There are the organizations such as the IT Service Management Forum (ITSMF), an independent, international ITIL users group, which help to share ITIL best practices.

The organizations can be assessed and certified with regard to the quality of IT

Service Management on the basis of some standards.

The following public frameworks and standards [1] are noteworthy regarding the quality of IT Service Management:

- ISO/IEC 20000: IT Service Management
- ISO/IEC 27001: Information Security Management (ISO/IEC 17799 is corresponding Code of Practice)
- Capability Maturity Model Integration (CMMI[®])
- Control Objectives for Information and related Technology (COBIT[®])
- Projects in Controlled Environments (PRINCE2[®])
- Project Management Body of Knowledge (PMBOK[®])
- Management of Risk (M_o_R[®])
- eSourcing Capability Model for Service Providers (eSCM-SP[™])
- Telecom Operations Map (eTOM[®])
- Six Sigma[™].

2. Main components of ITSM and their functions

IT Service Management [4] contains two main elements: Service Support (day to day operation) and Service Delivery (long-term planning, improvements).

The functions of the Service Support are the following: Service Desk, Incident Management (provided by Service Desk), Problem Management, Configuration Management, Change Management, Release Management.

The client requests are taken by the Service Desk which offers first-line support. Also, it has end-to-end task for Incident Management and provides the informations to the end-user domain.

The Problem Management takes the requests which cannot be solved at the first-line, identifies the weaknesses and negative trend of the IT infrastructure trying to correct them according to the quality management system for ISO 900 IT services, and establishes the areas of interest in service support processes.

The Change Management controls that changes taking place in IT Infrastructure have no negative impact on services.

The application of changes is ensured by the Release Management function.

The Configuration Management with its

associated database supports every function of the Service Support.

Also, the Service Delivery contains the following functions: Service Level Management, Financial Management for IT Services, IT Service Continuity Management, Capacity Management, Availability Management.

The Service Level Management assures continuous monitoring of the Service Level Agreements (SLAs) so as the parts of agreements be satisfied.

The role of the Financial Management is to determine and control the service costs.

Ensuring adequate IT Infrastructure and planning the acquisition of software and hardware to provide convenient service levels is the task of Capacity Management.

3. Costs and benefits of ITSM

The main costs related to IT Service Management are [5]:

a. Staff expenditure: The implementation of ITSM can lead to the creation of new work places in IT Department to do various tasks. Usually, in large organizations specialized personnel is necessary while in small organizations, the existing staff is sufficient. Although the staff expenditures are high, however, by increasing the efficiency generated by the Service Management functions, in the end, the total costs are reduced.

b. Expenditure on training: The training costs of the staff involved in the ITSM are inevitable.

c. Consultancy costs: Sometimes the specialist consultancy is needed to implement one or more functions of the ITSM.

d. Costs of tools and equipment: Different equipment and tools are required for the Service Management activities.

e. Cultural change expenditure: Costs on senior managers are required as a result of the ITSM implementation.

Implementation of the IT Service Management leads to the following benefits [5]:

a. High efficiency: The IT resources must be guided so as to improve the performances of services which are most beneficial for the customers.

b. Higher quality IT services: Spare components are included to insure a lower

risk of failure and a faster restoration to the normal service levels, in case of failure.

c. Services are better matched to customers needs.

d. Better management information and metrics: A key requirement for effective work processes is to continue the collection of informations regarding the service management.

e. Cost savings: An appropriate management involves final lower costs with an optimal use of IT resources.

4. Strategies to increase organizational performance

An IT organization must know the strengths and weaknesses. Otherwise it will not be able to establish what services must have priority on the market and what have to be removed.

Usually, IT respectable organizations call the *benchmarking* [6] for their services in order to:

- Compare the services of the IT organization with the services of one or more IT organizations, identified as reference.
- Establish the prices of services in relation to those of alternative providers considered leaders in the field.
- Bring in IT organizations the best practices that lead to performance using the successful experiences of the alternative service providers.

Service –based benchmarking is different from traditional benchmarking.

Traditional benchmarking uses average data and classification of existing firms working in the same field, and so realizing a number of comparisons in order to improve the productivity, efficiency and costs.

Service-based benchmarking performs comparison with the alternative service providers. It uses the bottom-line costs, meaning all contributions that lead to greater productivity and added value.

Of great value to service-based benchmarking is the specification and assessment with accuracy and comprehensiveness of the services and prices of other service providers.

Service-based benchmarking requires significant effort, thus, the IT organizations need to use it only when there is an

alternative supply for services and when there are serious problems at the level of the provision of services related to the added value.

The services that an IT organizations provide, do not have the same degree of importance, so it is necessary to establish priorities.

Prioritizing services [6] depends on the characteristic of the company and of its purpose. So, IT organization can focus on its strategies in order to meet the expectation of clients. However, this classification does not give information about how the services of external providers may be used. In this situation a service provider – customer matrix, a practical tool to help IT organizations in making decisions, is built.

Due to the present economic crisis, IT organizations are restricted to accomplish as much as possible with few resources.

So, IT organizations must focus, as their principal objective, on identifying the services that give the highest value to business.

5. Role of information professionals in ITSM

Nowadays the IT systems provide broad opportunities to develop information services (IS) in different economic and social domains. The efficiency of these services, both for provider and user/beneficiary, is strongly dependent on the management of all the phases of their construction: IS and its infrastructure design, support development, service implementation to the user and maintenance [7]. The management of IS development and maintenance requires qualified peoples and infrastructure. The key professionals involved in IS management programs are the *information professionals* and the human resource managers. Generally, the information professionals are traditionally recognized as good managers of explicit knowledge [8].

An information professional is a person involved in recording, processing, managing and distributing information. He/she is skilled in the information storage and retrieval of recorded knowledge.

The information professional establish the connections between those who have information, and those who need it [9].

He/she must be well prepared in meeting the challenges of the current and the future information environments. Some necessary abilities for the information professionals are:

- to have knowledge and skills in various areas of information services like: knowledge management and technological systems;
- to integrate information services with the needs of business;
- to provide a wide range of services in different areas;
- to provide valuable information to customers rather than just data;
- to participate to a continuous training in order to improve their professional skills and competencies;
- to have the required knowledge, skills and competencies in order to manage information services effectively [8].

Today the traditional market for information skills and services is continuously changing, as *new skills and services are being developed*. Due to this market dynamics the information environment must be open to new and challenging opportunities. The changing nature of the current information environment calls for new skills and competencies on the part of information professionals [9]. They must be well grounded in ICT related competencies such as core hardware and software skills, web design, internet searching and evaluation of electronic information.

Also, the information professionals have to be well trained in new related fields, as: information society, knowledge management, internet based technology, digital world, globalized information access, networked resources, new learning and research systems and the high demands of the user communities, knowledge about information strategy [7]. Also they must be in the same time facilitators, advisors and consultants for IS users. They must help users to find solutions and answers to their problems and teach them how to use the information product [7-9].

It is important for these people:

- to provide the right information to the right user at the right time;
- to develop relationships with users ;

- to engage in strategies that bring on market information products and services to the audience;
- to resolve customer complaints and win their satisfaction and loyalty;
- to use the complaints to improve their services and customer relations;
- to focus on a core group of products and services which is essential to the organization;
- to become an expert in the tasks that are valued and expand those products and services that are critical by assisting the organization in becoming more competitive [8];
- to direct all their energy to better and focused information services based on customer needs and satisfaction and continuous improvement;
- to respond as quickly as possible to user needs and demands;
- to improve professional competence;
- to bring new products to market, and reducing cost of business operations;
- to meet the information needs and support improvements in information transfer services;
- to understand socio-technical systems, resolve conflict over and negotiate plans, and to communicate effectively.

The crucial role of information professionals is to ensure proper management of information services, which is the tool connecting the information systems and the information managers. They must face challenging information environment in terms of demand, user expectations and technological innovations. Also, they need to stay competitive in any information-intensive and highly dynamic market. *In conclusion they must be agents of change and progress in information accumulation, assessment, assortment and access*[8-9].

6. Conclusions

- The recent development of IT infrastructure and IT related services resulted in an increased demand to effectively manage this sector in order to provide high performance products.
- An important guide in the management of IT services is the IT infrastructure library (ITIL), developed in Great Britain.

- This represents a set of principle to be followed in order to effectively develop and run an IT organization.
- Today the information professionals have an increasingly important role in IT Service Management.
- The continuous technological developments, raised important challenges for information professionals, involving significant efforts to enhance their abilities to learn, adapt and change by acquiring new skills and competencies.

Supply Chain Metrics

Brinza Georgiana

The Bucharest University of Economic Studies
georgiana.brinza@gmail.com

Abstract

Over the last few years having a strong and well defined metrics system has earned an increased importance in supply chain management. Supply chain metrics serve for defining and quantifying supply chain's performance, so that a well-designed metrics system helps in addressing supply chain risks and ensures a valid and accurate basis for making management decisions. In the same time, there is known aspect that supply chain metrics systems help organizations to achieve higher profitability levels by improving their operations as an effect to what metrics highlight: supply chains can align their operations among different actors in the chain, or can adopt strategies like cost reductions or product differentiation, thus gaining advantages. In this research paper we will address supply chain metrics in regards to the new requirements, we will then present some steps in creating a valid metrics framework and in the end the SCOR model will be detailed.

Key words: supply chain metrics, SCOR, performance

J.E.L. Classification: D39, L14, M2

1. Introduction

When a supply chain company wants to improve its operations and performance it has to take into account many obstacles raised by the actual global markets in which it operates. The trend of becoming more and more globalized comes up not only with opportunities, but also with a baggage of risks, complexity and uncertainty – most of them determined by the increased probability of disruptions and their effects on supply chain – like natural disasters.

In order to face these new challenges and to cope with the possible risks a supply chain

needs to have a clear view over its own performance and the supply chain's performance. This so called visibility can be established by using the right set of metrics which give an accurate snapshot of the opportunities and threats that the company is facing.

While a good metrics system helps companies to achieve superior performance levels, not having defined such metrics at all drives supply chains to failures in meeting their objectives: customer satisfaction and operational excellence. There are quite a few factors that impede the design of supply chain metrics like: lack of visibility and orientation, difficulty of defining metrics and collecting data, complexity of supply chains, adversity of some partners in sharing information etc.

2. Supply chain metrics new requirements

The research studies done so far are focusing mainly on a single company's performance addressed through metrics and not on the entire supply chain performance. Although there are researchers who understand this need, they don't give a general framework for designing such metrics, so they don't find those areas/processes that drive performance through the entire supply chain. The recent findings deal with questions like what should be measured, when, how, by whom, which are reasonable questions that will conduct the research to addressing supply chain as one entity. Here is where difficulties appear. The metrics systems need to provide a good overview of the entire supply chain [1] so that managers would see what sectors of the chain is performing bad or is very sensitive to risks and disruptions and would improve it in order to increase its overall efficiency and effectiveness [2].

There are many conditions under which new metrics requirements arise:

- Increased complexity of SC;
- Increased focus on sharing information in order to meet the objectives;
- As we said above – lack of measurement over the entire supply chain;
- SC expansion objectives;
- Product specialization/ differentiation;
- Risk and revenue sharing across partners in supply chain etc.

Performance measures for the full supply chain don't exist yet and the metrics addressing not only the focus company, but also the nearest neighborhoods (tier 1 suppliers and tier 1 customers) in the chain are only at the beginning and still need additional revision in order to cover the full chain. That is why the trend is considered to be towards a complete awareness and assessment of upstream, midstream and downstream partners in supply chain and supply chains will be the core systems.

4. Creating a metrics framework

Supply chain metrics frameworks include metrics for all the operational areas existing in the chain: demand planning, purchasing, manufacturing, inventory management, distribution, customer management. They need to be designed in such a way that managers would use their results in decision making for improvements. When designing the framework one should consider the supply chain area to which the metrics will serve and should align them to the overall supply chain objective.

First step would be to create the set of valid and useful metrics. One should incorporate in the set of metrics the following vital characteristics [3]:

- **Validity** – it applies to a specific concept in a specific business environment;
- **Reliability** – metric's results are consistent for a specific area of interest, as long as the external parameters don't change;
- **Accessibility** – metrics should be accessed in an easy manner and with fewer resources needed.
- **Relevancy** – the metric's definition and calculation should be in line with

its objective and with the area addressed so that its results will provide valid information for managers in taking strategic decisions.

The second step would be to relate the set of metrics with the core objective of the supply chain. For doing this one must first determine which are the core objectives of the supply chain and then, for every objective, a sub-set of relevant metrics must be created on several layers – beginning with the overall purpose and going down until the operation based metrics.

In Table 1 a detailed representation of metrics is presented, highlighting the core supply chain objective they serve, their category and their definitions:

Table 1. Metrics categories

Metric Name	Metric category	Supply Chain core objective
Perfect order	Strategic	Customer Satisfaction
Manufacturing Schedule Adherence	Tactical	Customer Satisfaction
Machine Downtime	Operational	Customer Satisfaction
Supplier delivery schedule adherence	Operational	Customer Satisfaction
Cash-to-cash cycle time	Strategic	Operational Excellence
Total Supply Chain cost	Strategic	Operational Excellence

Source: Adapted after F. Tejas and K. Srikanth, "Building and Leveraging a Metrics Framework to Drive Supply Chain Performance," Infosys Limited 2011. Available: <http://www.infosys.com>.

When having this set of valid metrics liaised with the supply chain objectives the next and last step in creating the metrics framework would be to detail the metrics and their interrelations (what metrics are further influenced and what metrics influence them). For a better understanding one can take the *Inventory Carrying Costs* metric [3] and analyze it:

- Definition: $\text{inventory level (units)} * \text{unit cost}$;
- Frequency: monthly;
- Category: tactical metric;
- Characteristic: cost;
- It influences the total SC costs.
- It is impacted by the inventory level and unit cost.

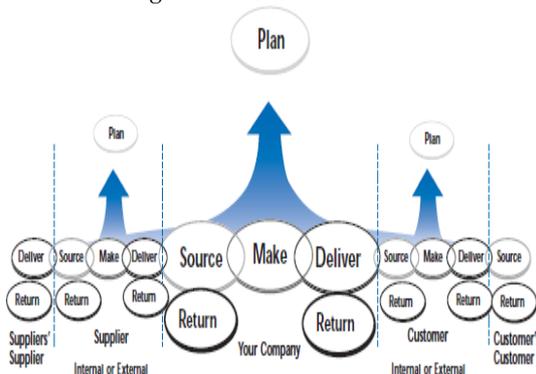

5. SCOR Metrics/ Model

Besides the advantages of having metrics systems mentioned above, the core characteristic of these systems is that they provide frameworks where everybody “talks the same language” – they offer standardized terms, processes and procedures to facilitate quantifying performance. Nevertheless, the value add comes from how the metrics results are interpreted, controlled and leveraged by supply chains to support good and strategic decisions.

There are many methods and models used in practice to assess a supply chain’s performance through metrics, but probably the most used, complete and appreciated is the SCOR (Supply Chain Operations Reference) model.

Supply Chain Operations Reference Model was founded on 5 processes: Plan, Source, Make, Deliver and Return (Figure 1). It is intended to offer a framework with metrics addressing the key processes in a supply chain. SCOR was built on the concepts of business process reengineering, benchmarking and process measurement by integrating their techniques into a cross-functional framework that addresses management issues at the enterprise rather than at the functional level [4].

Figure 1. SCOR architecture

Source: Supply Chain Council, 1

SCOR has 4 levels. At level 1 SCOR model’s objective and content is established. At this level organizations define their performance objectives in respect to their competing nature. The metrics used at this level are primarily metrics that can cross multiple SCOR processes, not only a specific one (i.e. order fulfillment, supply chain management costs, costs of goods sold etc.).

At level 2 every generic process from level 1 is further described and detailed using approximately 30 core process types. Level 3 further details every process type using specific process elements, data inputs and outputs, metrics and best practices. This is the level where organizations revise their objectives and strategies and define management approaches. At level 4 every process is described using process decomposition, in a hierarchical method.

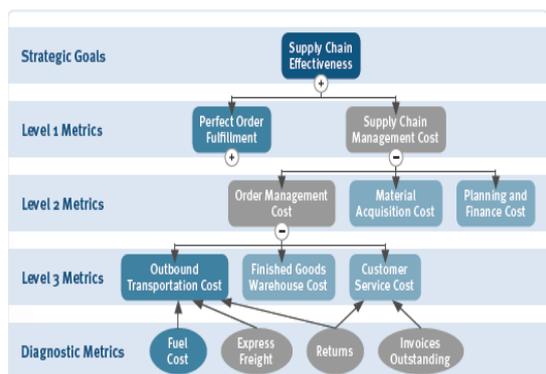

Besides offering a clear view over the performance of a company, SCOR model also signals possible risk sources, identifies opportunities and evaluates tradeoffs. For example, it makes little sense to set an objective of cutting supply chain costs by 6% if these same costs would have to increase to meet the corporate objective of increasing market share. But simply shifting the focus to revenue growth without regard to cost, risk, or strategic impact would also be incomplete.

SCOR model provides to companies the means to:

- Have an end-to-end view over all supply chain processes.
- Highlight the relations between metrics and how they are influenced by each other.
- Identify possible disruption on both short and long term and to address them in advance.

Defining the valid set of metrics (framework) as an important step of supply chain management means that organizations can break down company level objectives - order fulfillment, forecast accuracy, material costs – into department-level metrics - on-time delivery, plant utilization, or order processing time. Every company can establish and control those metrics that are really important for it, as can be seen in Figure 2:

Figure 2. Metrics break-down

Source: Supply Chain Council, <http://www.supply-chain.org>

As the metrics framework gives a though visual representation of the actual performance of a company, this was used to further transform metrics into good business insight, conducting to increased visibility and future performance. Many organizations (like HP or Dell) have implemented with success metrics in their operations, reaching high supply chain performance and driving ongoing improvement. The main result of using the SCOR model lies in the ability of companies to deal in a better way with the supply chain environment in a continuous transformation.

6. Conclusions

For a supply chain (company) in our globalized network, having good, valid and accurate metrics is essential and staying on the market and gaining competitive advantage. As highlighted in this paper, metrics are capturing vital information about the company's performance and not having a metrics framework in place most certainly would cause valuable information about own business and potential opportunities to be lost. Metrics provide the right support for taking management decisions on improving performance and increasing business' profitability.

It has never been so important for supply chain managers to have metrics in place in order to define action plans for straightening the processes which don't perform at the desired level.

Using a metrics framework and comparing the results to what has been identified in research studies and in real life as benchmark, managers will easily and more effectively:

- Combine supply chain performance with shareholder value.
- Discover which are the most important metrics for meeting the supply chain objectives.
- Redesign operations for dealing with improvement initiatives in a more effective and efficient approach.

Optimization Techniques in Project Controlling

Carstea Claudia

„George Baritiu” University of Brasov, Romania
15claudiacarstea@gmail.com

Abstract

This paper explains how to build an adaptive enterprise that establishes a tight partnership between business and IT, and in turn delivers greater business agility. This paper highlights leadership in the areas of infrastructure technology, management software, and IT services and solutions—and spells out the role of independent software vendors and system integrators at each level of the enterprise. In addition, the paper explores the sourcing options available to enterprises for introducing these new technologies and best practices into existing IT environments without causing disruption to the business.

Key words: challenge, management project, information system

J.E.L.Classification: C

1. Introduction

In the everyday course of business, decisions and changes—potentially thousands each day—trigger a series of IT events that ripple throughout the enterprise. Whether the change is expected or unexpected, infrequent or constant, small or large, the success of your enterprise depends on how well your infrastructure [10, 9 and 11] helps you capitalize on change.

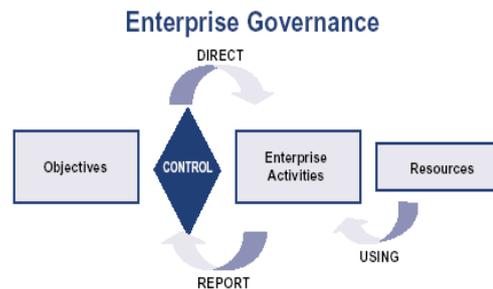

Every business decision triggers a series of IT events. In that sense, and especially in this business climate, an adaptive IT can actually enable agility. However, many IT infrastructures cannot keep up with the pace of change—much less turn these changes into an advantage.

2. The challenge with a vertical approach to IT

When rapid change is imposed on an IT infrastructure that is not designed to handle it, the only choices are costly redeployment of existing assets or, worse, adding yet another silo of incompatible IT. In such an environment, every change makes the business less agile (Fig.1).

System complexity slows down change—especially at scale—and increases the burden on management and maintenance. In fact, the cost of change is the fastest-growing component of infrastructure total cost of ownership (TCO), according to META Group’s July 2002 report “How Do I Minimize Infrastructure TCO by Cutting the Cost of Change?” By any measure, the traditional organization and management of IT is incompatible with business agility. A new way of looking at IT assets is required for enterprise success.

Fig.1 Enterprise governance

Black F., Derman E. and Toy, A One factor Model of Interest Rates and its Application to Treasury Bond Options, Financial Analysts Journal, Jan-Feb 1990

3. Evolving toward a horizontal approach to IT infrastructure

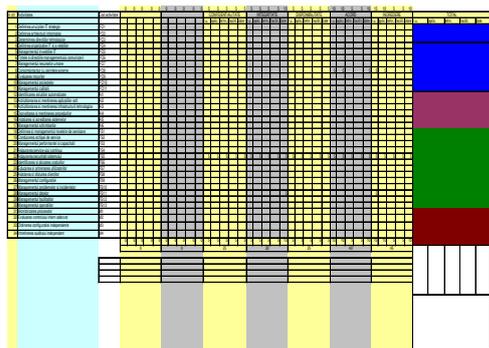

Infrastructure must now evolve from silos of technology to virtualized resource pools. Rather than focusing on supporting discrete applications, used by specific business functions or groups, the infrastructure must be organized to support the needs of multiple groups and

business needs across the enterprise, subsequently reducing the effort associated with administrating specific business processes and infrastructures. As the infrastructure becomes more adaptive, the enterprise becomes more responsive to change, and a new model is created that enables real-time information delivery that is less application-specific, more context-specific. Information is no longer confined to the perimeter of the enterprise, but can now easily extend to customers, partners and suppliers.[5]

4. What is an adaptive GES?

An adaptive GES is one in which business demand is constantly matched by IT supply. It operates on a consumption-based model—the business uses what it needs, then pays only for what it uses. In an adaptive enterprise, every cost is variable, resulting in an optimal use of the enterprise’s assets. Ultimately, this serves the business well: it frees the CIO from focusing on the delivery mechanisms of information, to focusing on more business-strategic applications of the information itself. (Fig.2).

Fig.2 Form evaluation

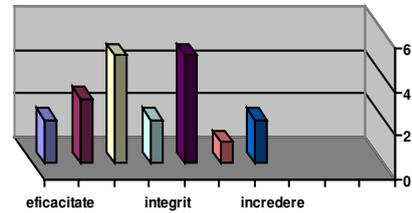

Cobit Standard

To support this kind of agility, the adaptive enterprise must meet three requirements:

- IT resources must be delivered in the form of services. Web services are moving the industry to a service-delivery model. In this model, infrastructure and IT

services—including applications—are delivered, allocated and paid for when and where required (Fig.3).

Fig.3 GES report

Cobit Standard

- Resources must be virtualized. Virtualization means the management and control of physical servers, storage and networks to create virtual resources—computing, information and communications.

Virtualization dramatically reduces adaptation time, advancing it from the purchasing or redeployment time frame to the millisecond world of intelligent management software.[1,3,9]

- The end-to-end environment must become business-process-based. Success today depends of the ability of the IT environment to respond and adapt intelligently to changing business conditions. This is a new and crucial requirement that is at the core of adaptiveness - the continuous analysis of business needs and intelligent delivery of managed resources to optimize business capability and flexibility.

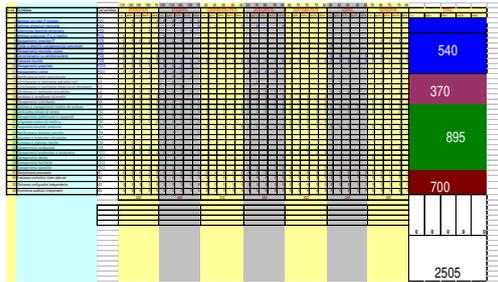

5. The key components of the GES

Adaptiveness is built in through consistent simplification, standardization, integration and modularity of the elements and aspects of the feedback loop.

Business processes are the day-to-day functions that keep the enterprise running. From human resources to accounting to supply-chain functions, the ability of the business to meet its customers’ needs is the driving force against which the IT environment must

deliver. The business processes collectively and continually set and adjust levels of IT resources to meet changing demands. While the priorities for allocating resources to each business process are in constant flux, the supply of resources available to the business must always meet the demand. This is core to creating an adaptive enterprise (Fig.4). [2,5]

Fig.4 Activities control

Cobit Standard

Infrastructure services deliver the secure, continuous computing power and storage capacity applications require. In the past, resources were delivered by assigning servers directly to applications. But low utilization and high cost from “one application, one server” policies compel organizations toward shared, virtualized and on-demand solutions that make better use of processor and storage capacity (Fig.5). The GES adaptive infrastructure technologies and solutions accept requirements from and deliver infrastructure services to applications through open industry interfaces and web services.

Fig.5 Evaluation report

Cobit Standard

Virtualized resources provide the foundation for the adaptive GES, with computing power, information and communications delivered as services

abstracted from their underlying physical servers, storage and network infrastructures. Sharing or pooling of IT resources helps eliminate overdeployed and underutilized technology components, reducing costs for hardware and software, and further reducing management complexity (Fig.6). Sharing IT resources across business functions also helps to increase business agility, enabling the rapid provisioning of new services or resources and scaling of established services. [7]

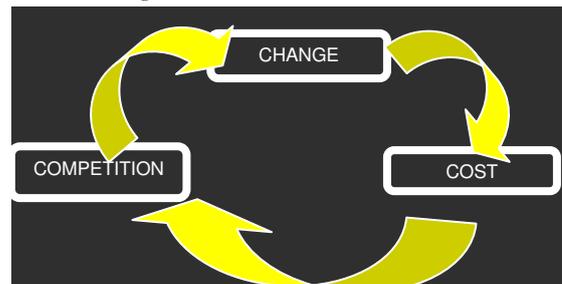

Fig.6 Cobit Standard

Cobit Standard

Business agility is realized when shared resources are dynamically allocated as needed by business procedures [10, 11 and 3]. The creation of this dynamic link between business and IT is aided by a clear assessment and measurement of the agility from the transformation of the underlying IT infrastructure. Management software analyzes demand signals from every part of the organization—from the infrastructure through the extended enterprise—delivering business insight while managing and optimizing the user experience in a secure, continuous infrastructure (Fig.7). [8]

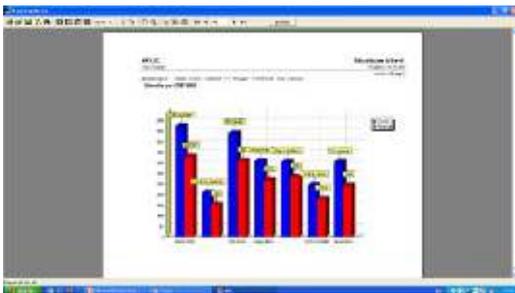

Fig.7 Business environment

Cobit Standard

Coordination and orchestration of infrastructure depends on moment-to-moment inventory and monitoring, planning, provisioning and maintenance. All management and control processes are driven by demands at the IT element level and the IT service and business levels, and are communicated according to open standards. By synchronizing infrastructure, application services and processes with business processes through automated and intelligent management and provisioning, HP enables enterprises to reduce the cost of change, reduce the total cost of ownership, simplify management complexity and provide the enterprise with the ability to rapidly implement the solutions that provide the corporation with a competitive advantage (Fig.8 and 9).

Fig.8 Efficiency report

Cobit Standard

Fig.9 Form report

Cobit Standard

The key to successfully building an adaptive GES is the ability to specifically measure how well the current infrastructure is able to respond to business change—and then diagnose the real barriers to agility. While every enterprise wants to achieve the ultimate state of business fitness, each is unique—

differing by industry, business model, strategy, competitive landscape and existing IT environment (Fig.10). There is no “one-size-fits-all” solution to improving agility. [8,11,12]

Fig.10 Risk monitoring

Cobit Standard

However, there is a common approach that can be followed in building an adaptive enterprise to ensure the optimal level of agility. Running an effective adaptive enterprise requires both operational prowess—the ability to stick to IT fundamentals and run IT like a business—and technology expertise. HP delivers both to the enterprise through our fundamental design principles and processes.[6,2,7]

6. Conclusions

The time needed to implement or react to a business environment change Range—the range of implementation across geographies, business processes or operating units Ease—the breadth and scope of change that the infrastructure can support

These three measures are used to identify technology barriers within an enterprise that are limiting the ability of the business to respond to change. In particular, they must determine whether IT is supporting agility in their business, or holding it back.

Complexity—multiple, independent architectures each with its own requirements—is a barrier to adaptiveness. A complete replacement of existing assets is not usually appropriate or sensible. Simplifying existing

infrastructure through management and control reduces the risks of expanding or replacing current resources. When adding new elements, selecting assets with built-in physical and logical simplicity simultaneously builds added capability and adaptivity.

One approach to simplification is consolidation: underutilized, underpowered and overdeployed resources are identified and streamlined into an updated infrastructure. This infrastructure then contains fewer elements—making it easier to manage—and delivers results with improved speed and ease when executing changes.

The Real Problems of Mergers and Acquisitions

Cherbeleată Iuliana

Academy of Economic Studies Bucharest

Iulia.cherbeleata@yahoo.com

Gogoncea Ramona

Academy of Economic Studies Bucharest

Ramona.gogoncea@gmail.com

Abstract

A world dominated by a long difficult economic period is likely to have deeper negative effects on all business aspects.

Mergers and acquisitions sector is one of the sectors affected by crisis and the problems that will occur during

2013 are expected to be bigger and to represent a great challenge for this market.

The purpose of this paper is to identify the real problems that the merger and acquisition market will face this year and also to analyze the reason of unsuccessful mergers.

Representing a complete overview of the problems that the companies involved in

M & A encountered and the one that are estimated to occur, the paper will bring new knowledge in term of real life problems of transactions market.

Key words: Mergers and Acquisitions, Economic crisis, financial instruments.

J.E.L. classification: G34, G30, H.

1. Introduction

The business environment worldwide is facing a period in which a bad decision on a transaction can lead to substantial losses for the companies involved. That is why the players need analysis on which they can base the decisions. They have to know whether or not those mergers and acquisitions will bring value or the contrary. The question is available both for the company which wants to sell and also for the one wishing to purchase.

Two of the problems which caused decrease in 2012 were the uncertainty and economic stress. Those two aspects will be

for sure visible also this year and will represent slowdown of the M&A sector.

2. Identified problems in M&A market 2013

There are many issues that can occur during this year and that can affect mergers and acquisitions market and cause the transactions failure.

Deloitte presented at the beginning of this year 10 big problems identified for the M&A market, problems that can cause a lack in evolution also this year. We will present those causes further on. [1]

Uncertainty and economic stress represented for the last years a slowdown factor for the companies, which refused to take the risk for transactions. 2013 started with positive expectations at least in some parts of the world, as US or emerging markets, which should lead to improvement in this sector worldwide. However, the economic slowdown affecting the emerging markets made expansion for the western companies difficult and tough. In addition, the Eurozone downturn conducted to a progressive decrease of the interest rates, following the US model. The natural response is a dissuading of investments in the area.

Transactions of high complexity are carrying a higher degree of uncertainty and of course, risk, that make the transactions impossible or are lagging the transaction. The solution may be hire of an external consultant to perform an independent due diligences that can short the time for decision making (analyze, negotiate, implement, etc.)

The private equity companies have increased activity due to the lower price and attractiveness of the cash flow achieved. This may be seen as speculations of M&A sector

that can cause market exit of some traditional companies with problems due to crisis. The historically cash-rich companies from developed markets may find opportunities for growth via horizontal acquisition (in other countries) or developing via vertical acquisition (integration of suppliers or customers from existing market).

The financial crisis made the regulatory entities around the world to pay more attention to complex instruments used by companies to achieve growth – financial or transactional. The consequence in M&A sector was a strengthening of control on capital requirements, which will limit the transactions freedom.

The valuation is still made under the old-standards, at least in the insurance M&A transactions. The opportunities that may occur in 2013 should not be missed; on contrary the valuation of the targets should be exceeded.

Alternative use of capital can be also issues that the decision factors of M&A should assess. If they judge that the capital should be used for other purposes, for example shares buying, the M&A transactions can be still declining. However, companies become more reluctant to invest in financial instruments, especially derivatives which carry a higher risk.

Emerging markets are an opportunity for bigger assets and new business. The problems that can occur from focus on emerging markets are related to the regulations for those areas on long term, as the economical evolution of those parts of the world is not known.

For insurance M&A activity, catastrophes are issues taken into considerations because their enormous impact on economic life.

Tax reform can also affect the M&A market, of course depending on the sector involved.

Last, but not least, the human factor is of high importance, as the talents from M&A sector should be discovered and of course encouraged. The specialists and also consultant’s expertise should be used by decision takers.

Deloitte study shaped the configuration of 2013 M&A market under the most important real issues that may occur for different situations.

Furthermore, those issues are conducted also by the fear of failure of the transactions. This means that unsuccessful mergers and acquisitions history, energy and resources consuming, represents a cause of excessive precaution. Some studies demonstrate that approximately two thirds of the companies involved into transactions fails and the M&A result is a divesture afterward (Schweiger, 2003). [2]

The knowledge of the reasons of this lack of success represents a lesson that the decision makers should learn, or the consultants should teach.

3. Causes and studies of unsuccessful M&A

The importance of the information in this field of interest is known and the literature about the factors which caused the failure of the mergers and acquisitions is substantial.

3.1. Factors that determine failure

The most important root causes of M&A failures are the following:

- a. Strategy - buying the wrong company
- b. Price - buying to high
- c. Implementation - execution of the transaction was improperly made
- d. Unknown factor - everything done adequate, but unknown factor occurred

Those factors should be analyzed before the transaction decision is made by the decision makers:

a. The target strategy represents the strategy of an acquirer to buy a target. This should be done taking into consideration the compatibility between the two companies in terms of field of operations, finance and demands, the long term goals of the acquirer

b. The price strategy, overpayment, has bad consequences as the high price leads to forecast of high synergy. This leads to additional pressure on the higher profitability, even if it is not possible.

c. Implementation strategy is also a phase that should be analyzed and planned before the transaction is closed. Of course all the operational terms should be planned, from

communication to business ethics. If all those compatibilities are checked from the planning phase, then the premises of un-failing M&A are met.

d. Unknown factor - as mentioned in the first part of the paper, even if everything is done properly and really well planned, unexpected can occur and can lead to failure of the transactions. For example, a catastrophe appears unexpected, and is a cause of a huge slowdown worldwide.

The value for the acquirer is given by the synergy created, which is usually as economy of scale or scope. The economies of scale are obtained in horizontal mergers (transactions between companies in the same industry or similar domains), while economies of scope in vertical mergers (transactions between companies in different stage of production's activity).

3.2. Studies of unsuccessful M&A

In literature, there were some studies created to analyze the value and the performance made by the transaction. The event studies examine the abnormal results around the time of announcement of transaction. This means the difference between the change of share price and a given index. All of those studies demonstrated a negative or below expectations evolution, related to the period of time analyzed. For example, the study of Jensen and Ruback, from 1983,[3] based on a 1 year analysis, revealed a return average of -5.5%, while the studies of Magenheim& Mueller, from 1987,[4] for a long-term 3 years show a return of -16%. From the literature studies it can be said that the return shares are oscillating.

Around the time of announcement those are positive, but the long term analyze shows that the acquiring firm shares declines even for a long period of years. The study of Andrade, Mitchell and Stafford, from 2001, goes further on, and examines the share of the shareholders of both target and acquired company. [5] The conclusions are surprising, as the performance of targeted company have in short term a positive growth, bigger than the acquirer company shares on long term.

Other papers go on, and verify if the performances depends on the method of financing the merger or acquisition. For example, the one of Loughran and Vjih, [6] from 1997 demonstrates that if the transaction is cash financed, the results are better than the same situation but stock financed.

Another type of performance studies, the accounting one, compares the financial statements of the acquiring company before and after the transaction. Goughan, in 2007, verified using this method if the acquirer performed better than the non-acquirers. [7]

All the study from literature, even for UK market (Meeks, 1977 and Dickerson, 1997), US (Ravenscraft and Scherer, 1987) or Indian market (Kumar, 2009) demonstrated that after the mergers or acquisitions, the profitability did not grow, just slightly improved for few cases.

The third type of the studies, the executive surveys, based on questionnaires completed by the managers of the companies involved in transactions, offered a different result. This may be, in opinion of the authors of the studies, for example Bruner, a cause of CEO's ego.

Another type of analysis, which revealed better results and insights, are the interviews with the managers involved in transactions, called clinical studies. Many studies were realized and found the causes of success and failure of the transactions. For example, Bruner in 2001 found that one merger failed because of disbelief in merger synergies and transfer control of the two parts, while another study had three clear conclusions: the objectives of the management team is not the wealth of shareholders, hubris (overconfidence of the managerial team) and ignorance of the information available.

This hubris is also the reason of high premiums. The companies acquired with this high hubris of the executive management usually do not reach the synergy projected.

Usually, hubris transactions ignore the information provided by due diligence process, as Hill paper demonstrated in 2001. So, the management team uses all the usual analysis but do not take it in the consideration compared to the self-confidence.

3.3. Solution for failed M&A

A hard decision about a merger or an acquisition that failed is inevitable. Extension of the period of time is just extended agony, as all the real life example demonstrated that sooner the decision is made, sooner the losses decreased.

The solutions can be divestitures or Liquidations.

Divestitures occurs when the organization decide to sell a business unit to another company. This division can be “spun off”, and this mean the creation of a new business organization with the tracking of the initial issues. One example is the case of divesture is Daimler-Chrysler, when Chrysler assets were divested, with losses compared to the payment made to acquire Chrysler.

Usually this decision must be taken by the same CEO and this can represent a psychological decision. Hitt, in his paper from 2005, found that the acquired companies which are afterward divested have some common points, as low performance, desire to maintain the acquisition is low, the acquired company is young and small, or the acquirer has a lot of experience in divesture. [8]

Another solution is closing, or liquidations, when a division is shut down, assets are sold and the personnel are fired.

4. Conclusions

This paper represents an overview of the causes that lead to failure of merger and acquisitions. The economic literature considers that only 40% of the transactions are successful while for the others, the results are under the planned level of synergy or profitability.

The study presents actual reasons of failure, from the business environment to personnel point of view.

Presenting a range of studies on these subjects, we lead to the conclusion that the most important results were brought by the clinical studies. Those studies, combined with accounting studies can be a base for decision makers’ managers in order to proceed or not to a transaction.

2013 will be a year where real life will have to face also big issues, and that is why

decisions based on analysis are likely to be more successful.

Abstract

People’s aging has represented the consequence of a complex of factors, amongst which: the low living standards, the moral pressure on satisfying the biological needs, the stress caused by non-fulfillments and the non-contentedness, on which the crisis related to Romanian economy of the last years is added, fact that brought towards the lowering of funds allotted on protecting the people’s health and health state. The correlation of GDP on inhabitant by the weight allotted on sanitary sector from the public budget and the life expectancy have been significant. As result, after evaluating the effects related to the demographic phenomenon over people’s aging, one might establish that this has been accompanied by the fertility diminution and general death increase.

In such conditions, the massive growth of old people will be firstly reflected towards the diminution of active labor force, having an immediate effect over the economic growth.

Keywords: demographic phenomenon, aging, fertility diminution, demographic politics, infant mortality

J.E.L. classification: A13, D60, E24, I15, J11.

1. Introduction

The old people’s wisdom was so appreciated long before, since a wise-word became well-known, saying that: “Who has no elderly people, should buy”. This saying seemed to be quite wise, since the elderly

people’s advices had the value of “a golden ball”, for people that were willing to hear and take into account such advices. Some thinkers mentioned that aging doesn’t signify a simple phenomenon, but a very complex one, which includes a set of both positive and negative aspects, as well.

On the other hand, the aging has brought away a high level of experience, thus offering the possibility of a rich volume of advices. Simultaneously, the elderly people can offer high precious information, about all kinds of events that were not registered anywhere or that were not known by many people, such as the following: family events, various labor places events, of the childhood community or places where they lived, and the elderly people can talk about all kind of experiences or happenings from the nation’s past.

Elderly people have been able to maintain the traditions, as well as transmitting them to younger generations. On the other hand, as an old saying was mentioning, the aging has “weighty coats”, and meets various tough situations. Elderly people have started to lose their physical strength, their intellectual abilities being reduced, as well as their flourishing aspect that they had when they were young; thus, they lost the chance of being hired and lost a part of their incomings, as well. Many elderly people have been always ill, poor, being isolated by other members of the family or friends, and thus they have been gradually demoralized. Some others are getting old in totally opposite conditions, since they dispose of good physical, psychic and financial conditions and maintain strong relationships with family or friends, being always in a good mood and happy.

The two images of old-age have actually proven that the process of aging has taken

into account two different issues: a social aspect and a persona aspect. Philip J. Lonmen, known researcher at New American Foundation-Washington D.C., affirmed into a report as regards the world economic situation and the people’s progress that “the world of today is getting older and older”.

The demographic prognosis accomplished by various specialty institutions of more countries have confirmed the people’s progress of the world registered up to the half of this century; in this way, the progress analysis as regards the people’s aging process has been simultaneously emphasized (see Table 1).

Table 1- The people’s growth prognosis related to different continents between 2010 and 2050 (Millions of inhabitants)

Year	People’s all-out on world level	Africa	North America	South America	Asia	Europe	Oceania and Australia
2010	6.843	1.007	346	599	4.130	726	35
2015	7.219	1.115	361	634	4.351	721	37
2020	7.578	1.228	375	667	4.554	715	39
2025	7.905	1.344	388	697	4.728	707	41
2030	8.199	1.463	401	722	4.872	698	43
2035	8.463	1.584	411	744	4.992	688	44
2040	8.701	1.705	421	761	5.092	677	45
2045	8.907	1.823	429	774	5.168	666	47
2050	9.076	1.937	438	783	5.217	653	48

Source: World Urbanization Prospects, Revision in 2005

As can be noticed on the wide-world, people is going to grow in numbers, fact reflected into the existence of over nine milliards of inhabitants registered at the half of this century. The increase rhythms of people have been varying from one continent to another. While Africa’s people will be doubled in numbers in the next forty years (for instance, from 1.007 million to over 1.900 million), the Asia’s people will know an increase of about 12.6%, as the North America’s population. The South America will know an increase of over 13%, while the old European continent will be the only one affected by a diminution of people with over 9%. Many demographers have considered the diminution of European people as being determined by the birthrate reduction, as well as being accompanied by a fast aging of people.

2. Demographic issues of Romania

The demographic issues of Romania, related to people’s number diminution, can signify the result of various cumulative factors: a negative external migration, to which the natural diminution was added, diminution achieved after the occurrence of general mortality recrudescence, the massive stroke of birthrate, as well as the temporary external migration, not statistically registered, the demographic politics or the

changes coming from the last history century, and so on (therefore, as regards Romania, while reducing the youth people determined the pyramid’s basis straitening, the increase of old people weight determined the burying of pyramid’s pin).

The consequences of reducing the birthrate on short and mean terms will be neutral, as regards the demographic impact, and preponderantly positive, as regards the economic point of view. These represent an introduction to the future demographic and economic development, which can be extremely complex and underlying negative. The predictable consequences of this situation cannot be stopped by means of setting up the growth of “immediate” fertility; such issue will have the effect taken into account in the second half of the century.

In order to repair such situation, applying a strategy in Romania has become necessary, as regards the measures of straightening of the birthrate. On improving the people’s health state, as well as the people’s demographic recovery, the governmental politics of the last decade have played a part (at all significant), foreseeing:

- ✓ the children’s growth allowance, within a period of two years, after the children’s birth;
- ✓ the motherhood allowance paid;
- ✓ introducing the parenthood allowance, which allows women to follow a career,

in order to compensate the family's incomings;

- ✓ Exemption from some taxes.

The access to the private medical services, owning a high quality and professionalism level, has contributed on maintaining and increasing the health's state of some people. One might mention that mother's mortality has continued to register a high level of occurrence, as comparing to the European standards (According to some recently studies, provided by the World Health Organization (WHO) , Romania has the highest rate of abortions in Europe - 520 pregnancy abortions at each 1000 live born, over the average double value in European Union.).

Though knowing some exceptions, a conception is taken into account, according to which the individuals best placed as regards the economic and social point of view might simultaneously enjoy of a better state of health. Such thing results from many studies and analysis that were carried out all over the time, proving that there is a strong connection between the social-economic status and the mortality rate [1].

The incomings disparities between the rich and poor countries, as well as between the individuals of the same nation, have confirmed that the first mentioned category of people pays a higher attention to health. In the same time, the existence of an inverse relationship between the GDP and the mortality rate is also confirmed, the last one being higher for the countries in progress of development, meaning countries of low revenues.

The countries having higher economies will always allot significant resources in order to finance the health sector, as a premise to a sustainable development on long term. As result, the evaluation of people's health state for nations will be emphasized by three indicators [2]:

- ✓life expectancy on birth;
- ✓infantile mortality (under one year old);
- ✓Mortality, under five years old.

These indicators have been influenced by the social-economic, cultural, behavior or sanitary factors and so forth, factors that are underlying the demographic trends that have been registered especially since the nineties and up to present. One might see that for the countries in progress of development, as

Africa, the life expectancy is extremely low (people of 52 years old), and the infantile mortality and deaths within children of up to five years old will be relatively high (42.67 and respectively, 57 at 1000 live born children); in the developed European countries, such situation is much more improved (the life expectancy of over 80 years old, 13 deaths for children under 1 year old and 14 deaths for children under 5 years old, as regards 1000 live born children)[3].

Concerning Romania, the life expectancy on birth is of 73.5 (since 1970 and up to present, the average life expectancy increased from 67.33 years old up to 73.47 years old. As result, in the last 41 years, the average life expectancy was increased with 74 months, meaning being majored with an average of 7 weeks per year in the last 41 years.) [4] years old, though it is amongst the lowest countries in Europe, where the main causes are the infantile mortality, the youth mortality or the adults up to 65 years old mortality, as well as the down of birthrates. As comparing to the developed countries, the percentage of young people (15-34 years old) is low, and of adult and age people (35-65 years old) seems to be quite high in Romania.

Within the European Union, Romania is placed amongst the countries with the lowest levels of life expectancy on birth, although this has been continuously improved in the last decade, similar to the progress of European Union member states, thus remaining to a lower value of almost 6 years, as comparing to the EU-27 average.

The increase of life expectancy on birth signifies an important issue, as regards the life quality growth, and implicitly the economic growth of the country or region of the world, issue also confirmed by the studies elaborated all over the time. In this way, in 1997, Barro reached to the conclusion that an increase of life expectancy by 10% will determine an increase of the economic growth, from 4% up to 10% (Evaluation illustrated in paper of Richard M. Scheffer) [5]. Such influence has been emphasized by a report of the European Committee, entitled *Macroeconomics and health: investing in health for economic development*, specific to the macroeconomics and health fields, and coordinated by Jeffrey D. Sachs (2001). In this report, it is mentioned that an increase of life expectancy on birth by 10% will

determine an improvement of the economic growth, by at least 0.3-0.4% yearly; this occurs in case the other factors of growth will remain constant [6].

Regarded from the reverse way, a bad health state generated by various infectious diseases, as malaria and HIV/AIDS, will act as a real fracture on the society's level, thus reducing the economic growth and the human development. As result, the growth rate is two or three times lower as comparing to that registered, if the infectious diseases wouldn't have existed. Therefore, one might talk about the health state, regarded as a result of the development level, and depending upon the expenditures allotted to the sanitary system; it results that countries with a high level of the revenue per inhabitant allot in generally a higher weight of GDP to the health caring field, as comparing to the poor countries. The decisions as regards the resources allotment on the health field signify a major topic on national governments, and will remain a subject opened to debates and political research.

The specificity of this situation has his starting point, as according to Jean Claude Chesnais [7], to the demographic transition, which is manifesting y passing from a traditional regime of demographic equilibrium, with high levels of fertility and mortality, to another type of equilibrium, but with a low level of fertility and mortality. The transition starts by the mortality diminution, followed by the fertility reduction.

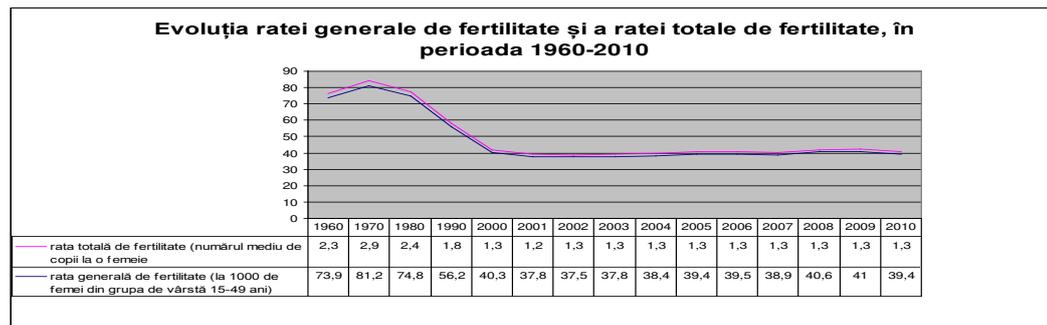

Making a particularization of these concepts for Romania, one might see that the demographic transition has proven specific features, also presented in studies of some well-known Romanian demographers, as V. Trebici, V. Ghetau, G. Retegan-Serbu, M. Balaci or C. Popescu. According to the authors, the transition in Romania has been carried out on a period of 120 years, and the recovering of fertility will signify for now, the only option that is able to bring towards the improvement of the country's

demographic situation, and potentially, towards stopping the future demographic down.

A low level of fertility (Graphic 1 illustrates this indicator for Romania and some European countries) will also emphasize the phenomenon of demographic aging. One might see a diminution of the women generations of fertile age, and the level of conjuncture index of fertility is of 1.3 children per woman. The prognosis issued also emphasize that stagnation of fertility at this level will determine a strict diminution of active people (20-64 years old), which will be reduced at 9 million people in 2050. As regards the people unable to work, with age of over 65 years old, this will reach the numbers of 5 million in 2050.

Making an evaluation of Romania's people fertility in the last decades, one might see a trend of continuous diminution of this (started in the first years after the Second World War), with small oscillations (as result of straight politics applied as regards the birthrate field), but without the possibility of improving the already existing situation. The statistical data available for the interval 1960-2010 will offer the possibility of drawing up the graphic of the general fertility rate progress (at 1000 women included in the age group of 15-49 years old), and of the total fertility rate (the average number of children per woman). In the graphic below illustrated, one might see a comparison between the two indicators of Romania, meaning the general fertility rate as comparing to the total one, during the period 1960-2010. The result will confirm a trend, as regards the fertility diminution, from the level of 73.9 live born children to 1000 women of 15-49 years old (in 1960) up to 39.4 live born children to 1000 women of 15-49 years old (nowadays). As result, the fertility level registered in 2010 signifies almost a third from the fertility level in 1960, and the total rate of fertility was reduced in the same period of time, from 2.3 children to a woman, up to 1.3 children per women.

Graphic 1. Progress of the general fertility rate and the total fertility rate during 1960-2010

Source: *Statistical Year-Book, INS, Bucharest, 1980, 2000, 2011*

As regards the infantile mortality rate related to residence environments, this is maintained as being higher in the rural environment (12.6‰, with 1.268 deaths in 2009), as comparing to the urban environment (8.1‰, with 982 deaths in 2009). The difference became obvious to death people of over one month old (6‰ – 604 deaths in the rural environment and 3.1‰ – 376 deaths in the urban environment) and lower to death people of under one month old (6.6‰, respectively 664 deaths in the rural environment and 5.0‰, respectively 606 deaths in the urban environment). As comparing to the year 2000, one might see a reduction of 45 - 46%, and as comparing to year 1990, the diminution has the value of about 63%.

The above mentioned situation has been explained by the lack of sanitary education, as well as the inaccurate information of people, by a poor sanitary assistance in the

rural environment, and not lastly, by the level of schooling or occupation that is reduced to mothers (homely mothers).

One considers that improving such indicator cannot only be solved on medical level, but an interaction amongst the factors previously emphasized might be essential.

As result to all these illustrated, maintaining low values of the birthrates and fertility rates, as well as aging of generations, will gradually bring towards a changing of structure, on age classes related to Romania's people. Table 2 illustrates the people's structure of Romania, on age classes, the current situation, as well as the strict conclusions that result from extremely pertinent prognosis, as concerns the demographic progress of Romania in 2050 (underlying especially on the prognosis of author V. Ghetau).

Table 2. *Romania's people structured on age classes -thousands of people-*

Age class (years)	2010*		2011**		2050**	
	Number	Weight (%)	Number	Weight (%)	Number	Weight (%)
Total	21400	100,0	19043	100,0	14849	100,0
0-19	3200	15	4076	21,40	2459	16,57
20-64	13800	64,4	11918	62,60	8280	55,76
≥ 65	4400	20,5	3049	16,00	4110	27,67

Source: * INS, *Romania în cifre, 2010*; ** INS, *România în cifre, 2011*; Vasile Ghețău, *Drama noastră demografică. Populația României la recensământul din octombrie 2011. Reprofesionalizarea României IV*, Institute of Projects on Innovation and Development, 2012, p. 47

The development of the dependency report of elderly people in Romania seems to be starting in 2027, when the generations born after 1996 will enter into the old people class (over 60 years old). The prognosis for the next decades have been quite concerning, since they manifest an emphasized trend on reducing the youth weights (0-19 years old), and the increase of elderly people (over 65

years old). Until 2050, Romania will reach the first three countries with elderly population, since the dependency rate of seniorities will become three times higher in value.

3. Conclusions

Improving the people's health state, increasing the efficiency of using the resources and improving the quality of medical assistance given to people, have been prior when establishing the reform of the health system. In this way, the additional complementary investments in those regions that gave impact over the poorness reduction should become the essential condition of politics on economic and social development. In the same time, one cannot ignore issues, as: the transparency in financial resources allotment, organizing if services in accordance to the health needs, the access to quality medical services for the entire people, eliminating the inequalities as regards health, accomplishing comparative analysis between the European Union member states and regions inside them, in order to identify the possibilities of reducing the already existing disparities etc.

Data underlying the above mentioned analysis will make an emphasis over the following idea: elderly people should be ensured by the new generations able to work, as well as by the new employment positions. If a country owns a population with a high percentage of elderly people, the risk of wars launching will be surely lower, by such issue will not ever solve the problems directly connected to the life and its quality, as regards the elderly people.

Taking care of people and ensuring accurate living standards will emphasize a society at a high level of civilization and social progress. The way a society takes care of children, which signify the future, in the same way the elderly people should be looked after, since they represent the society's past. For any other nations, the past should be appreciated as emphasizing the future's protection, a foundation on which the future is built and developed, resulting that “this past” should not be neglected.

Abstract

Prediction is very important in business planning. The ability to accurately predict the future is fundamental to many decision activities in sales, marketing, production, inventory control, personnel, and many other functional areas of business. Time series modeling approach is one of the major techniques widely used in practice. In general, there are two approaches to modeling and forecasting time series: linear approach and nonlinear approach. Linear models [2] were used for a long time and are still very useful, but linearity assumptions underlying these models may be too restrictive. A nonlinear model more flexible is Artificial Neural Networks (ANN), which have received attention recently [19]. The major advantage of neural networks is that they are data driven and does not require restrictive assumptions about the form of the basic model. In this paper emphasize the strengths and weaknesses of neural networks.

Key words: Time Series, Prediction, Nonlinear models, Artificial Intelligence, Neural Networks.

J.E.L. classification: C 45, C53, C 63.

1. Introduction

In the past several years, information technology and the World Wide Web have created lots of innovations in the area of business. More businesses and organizations are collecting high quality data on a large scale. The huge amount of data can be a gold mine for business management [5]. It is therefore increasingly important to analyze the data. However, timely and accurately processing tremendous data analysis in

traditional methods is a difficult task. The ability to analyze and utilize massive data lags far behind the capability of gathering and storing it. This gives rise to new challenges for businesses and researchers in the extraction of useful information [17].

Increasing accuracy of forecasting can save millions for a company and is a major motivation for using formal methods of forecasting and systematic investigation of new methods and better prognosis [18].

Approach to modeling nonlinear time series is probably more adequate for most real-world problems. The world is rather nonlinear and complex than linear because there are so many possible nonlinear relationships or structures. Most nonlinear models developed during the last two decades are likely parameters. To use these models, the model must be specified first. Therefore, these models cannot be used if the data characteristics do not fit the model assumptions involved. The parametric approach is quite suitable for nonlinear problems with complex structures, but there is a lack of theories to suggest a specific form of the structure.

Artificial neural networks are algorithms and techniques that can be used to perform nonlinear statistical modeling and provide a new alternative to logistic regression, the most commonly used method for developing predictive models. Neural networks offer a number of advantages, including requiring less formal statistical training, ability to implicitly detect complex nonlinear relationships between dependent and independent variables, ability to detect all possible interactions between predictor variables, and the availability of multiple training algorithms.

Disadvantages include its "black box" nature, greater computational burden,

proneness to overfitting, and the empirical nature of model development. An overview of the features of neural networks is presented, and the advantages and disadvantages of using this modeling technique are discussed.

2. Neural networks definitions and brief history

An Artificial Neural Network (ANN), or simple Neural Network (NN), is an information processing paradigm that is inspired by the way biological nervous systems, such as the brain, process information. The key element of this paradigm is the novel structure of the information processing system. It is composed of a large number of highly interconnected processing elements (neurons) working in unison to solve specific problems. ANNs, like people, learn by example. An ANN is configured for a specific application, such as pattern recognition or data classification, through a learning process. Learning in biological systems involves adjustments to the synaptic connections that exist between the neurons. This is true of ANNs as well.

A Neural Network is a parallel computing system of several interconnected processor nodes. The input to individual network nodes is restricted to numeric values falling in the closed range [0,1]. Because of this, categorical data must be transformed prior to network training [14].

Another definition is given by Haykin [9]: A neural network is a massively parallel distributed processor that has a natural propensity for storing experiential knowledge and making it available for use. It resembles the brain in two respects:

- Knowledge is acquired by the network through a learning process.
- Interneuron connection strengths known as synaptic weights are used to store the knowledge.

In 1982, John Hopfield published a paper [11] showing how neural networks could be used for computational purposes. In 1984, Teuvo Kohonen [13] introduced a new algorithm he called an organizing feature map, which allowed for a process of using neural networks for unsupervised learning. This opened a new branch of neural network

research where no correct answer is required to learn or train a network. In 1986 Rumelhart, Hinton and Williams wrote a paper [15] on the back-propagation method, which opened up a flurry of activity in the late 1980s and 1990s.

Neural networks are used extensively in the business world as predictive models. In particular, the financial services industry widely uses neural networks to model fraud in credit cards and monetary transactions [8].

Some of the well known types of neural networks are: Competitive Learning [6, 16], the Boltzmann Machine [10], the Hopfield Network [11], the Kohonen network [12], the Adaptive Resonance Theory (ART) [7], and back propagation neural networks [15]. Although there are many other variations of neural networks, the back propagation network and its variants, as a subset of multilayer feed forward networks, are currently the most widely used networks in applications.

3. Elements of a neural network

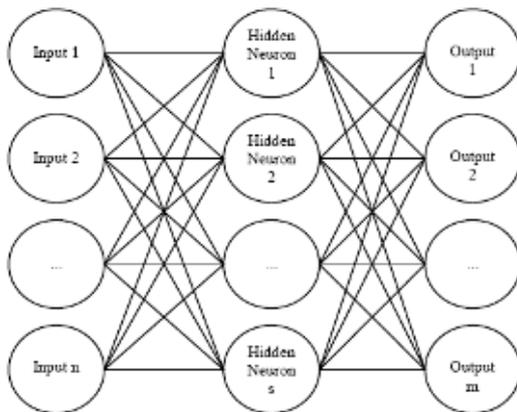

Neural networks attempt to mimic a neuron in a human brain, with each link described as a processing unit. Neural networks learn from experience and are useful in detecting unknown relationships between a set of input data and an outcome. Like other approaches, neural networks detect patterns in data, generalize relationships found in the data, and predict outcomes. Neural networks have been especially noted for their ability to predict complex processes.

Processing elements, or processing units are linked to inputs and outputs. The process of training a network involves modifying the strength, or weight, of connections from the inputs to the output. Increase or decreases in the strength of a connection is based on its importance for producing the proper outcome. A connection's strength depends on a weight it receives during a trial-and-error process. This process uses a mathematical model for adjusting the weights, and is called a learning rule.

Training continues until a neural network produces outcome values that match the known outcome values within a specified accuracy level, or until it satisfies some other stopping criteria.

Figure 1 demonstrates a neural network. Each of the processing units takes many inputs and generates an output that is a nonlinear function of the weighted sum of the inputs. The weights assigned to each of the inputs are obtained during a training process (often back-propagation) in which outputs generated by the nets are compared with target outputs. The answers you want the network to produce are compared with generated outputs, and the deviation between them is used as feedback to adjust weights.

Figure 1. A Neural Network model.

The process of readjusting weights is important to increasing a model's accuracy. Notice there are also hidden nodes, or middle layer nodes, in Figure 1. These hidden nodes are associated with the weighting process. The number of hidden nodes can be adjusted and there can be multiple levels of hidden nodes. The number of inputs, hidden nodes, outputs, and the weighting algorithms for the connections between nodes determine the complexity of a neural network, its accuracy, and the time it takes to create the neural network model. Because the configuration of hidden nodes and weights is so critical to neural networks, there are many approaches for finding the right number of hidden nodes and readjusting weights [8].

Network Design Parameters: Employing a neural network requires an understanding of a number of network design options. Be advised that there are no definite rules for choosing the settings of these parameters a priori. Since the solution space associated with each problem is not known, an number of different network runs must be undertaken before the user can determine

with relative confidence a suitable combination.

Number of Input Nodes: These are the independent variables which must be adjusted to fall into a range of 0 to 1. The number of nodes is fixed by the number of inputs. Inputs must not be nominal scale, but can be binary or better ordinal. Such inputs can be accommodated by providing a separate input node for each category which is associated with a binary (0 or 1) input.

Number of Output Nodes: The number of output nodes depends on the purposes of the research and they are also adjusted to fall within the range of 0-1.

Number of middle or hidden layers: The hidden layers allow a number of potentially different combinations of inputs that might results in high (or low) outputs. Each successive hidden layer represents the possibility of recognizing the importance of combinations of combinations

Number of Hidden Layers: The more nodes there are the greater the number of different input combinations that the network is able to recognize.

Number of Nodes Per Hidden Layer: Generally all nodes of any one layer are connected to all nodes of the previous and the following layers. This can be modified at the discretion of the user however.

Initial Connection Weights: The weights on the input links are initialized to some random potential solution. Because the training of the network depends on the initial starting solution, it can be important to train the network several times using different starting points. Some users may have reason to start the training with some particular set of link weights. It is possible, for example to find a particularly promising starting point using a genetic algorithm approach to weight initialization.

Initial Node Biases: Node bias values impart a significance of the input combinations feeding into that node. In general node biases are allowed to be modified during training, but can be set to particular values at network initialization time. Modification of the node biases can be also allowed or disallowed.

Learning Rate: At each training step the network computes the direction in which each bias and link value can be changed to calculate a more correct output. The rate of

improvement at that solution state is also known. A learning rate is user-designated in order to determine how much the link weights and node biases can be modified based on the change direction and change rate. The higher the learning rate (max. of 1.0) the faster the network is trained. However, the network has a better chance of being trained to a local minimum solution. A local minimum is a point at which the network stabilizes on a solution which is not the most optimal global solution.

Momentum Rate: To help avoid settling into a local minimum, a momentum rate allows the network to potentially skip through local minima. A history of change rate and direction are maintained and used, in part, to push the solution past local minima. A momentum rate set at the maximum of 1.0 may result in training which is highly unstable and thus may not achieve even a local minimum, or the network may take an inordinate amount of training time. If set at a low of 0.0, momentum is not considered and the network is more likely to settle into a local minimum. A process of "simulated annealing" is performed if the momentum rate starts high and is slowly shifted to 0 over a training session. Like other statistical and mathematical solutions, back propagation networks can be over-parameterized. This leads to the ability of the statistics to find parameters which can accurately compute the desired output at the expense of the system's ability to interpolate and compute appropriate output for different inputs. To ensure that a back propagation neural network is not over-parameterized, the training data must be split into a training and a testing set. It is the performance of the trained network on the data reserved for testing that is the most important measure of training success.

4. Strengths and weaknesses of neural networks

Neural networks, with their remarkable ability to derive meaning from complicated or imprecise data, can be used to extract patterns and detect trends that are too complex to be noticed by either humans or other computer techniques.

Other advantages include:

- **Adaptive learning:** An ability to learn how to do tasks based on the data given for training or initial experience.
- **Self-Organization:** An ANN can create its own organization or representation of the information it receives during learning time.
- **Real Time Operation:** ANN computations may be carried out in parallel, and special hardware devices are being designed and manufactured which take advantage of this capability.
- **Fault Tolerance via Redundant Information Coding:** Partial destruction of a network leads to the corresponding degradation of performance. However, some network capabilities may be retained even with major network damage.

Neural networks are universal approximators, and they work best if the system you are using them to model has a high tolerance to error. However they work very well for:

- capturing associations or discovering regularities within a set of patterns;
- where the volume, number of variables or diversity of the data is very great;
- the relationships between variables are vaguely understood;
- the relationships are difficult to describe adequately with conventional approaches.

The greatest strength of neural networks is their ability to accurately predict outcomes of complex problems. In accuracy tests against other approaches, neural networks are always able to score very high [1].

There are some downfalls to neural networks.

First, they have been criticized as being useful for prediction, but not always in understanding a model. It is true that early implementations of neural networks were criticized as “black box” prediction engines; however, with the new tools on the market today, this criticism is debatable.

Secondly, neural networks are susceptible to over-training. If a network with a large capacity for learning is trained using too few data examples to support that capacity, the network first sets about learning the general trends of the data. This is desirable, but then the network continues to learn very specific features of the training data, which is usually

undesirable. Such networks are said to have memorized their training data, and lack the ability to generalize. Commercial-grade neural networks today have effectively eliminated overtraining through "bootstrapping holdout (test) samples", and by monitoring test versus training errors [8].

The mathematical theories used to guarantee the performance of an applied neural network are still under development. The solution for the time being may be to train and test these intelligent systems much as we do for humans. Also there are some more practical problems like:

- the operational problem encountered when attempting to simulate the parallelism of neural networks. Since the majority of neural networks are simulated on sequential machines, giving rise to a very rapid increase in processing time requirements as size of the problem expands. One solution to this problem is to implement neural networks directly in hardware, but these need a lot of development still.
- instability to explain any results that they obtain. Networks function as "black boxes" whose rules of operation are completely unknown.

5. Conclusions

Neural networks have broad applicability to real world business problems. In fact, they have already been successfully applied in many industries [3].

Some more specific examples of using ANN are the following paradigms: recognition of speakers in communications; diagnosis of hepatitis; recovery of telecommunications from faulty software; interpretation of multimeaning Chinese words; undersea mine detection; texture analysis; three-dimensional object recognition; handwritten word recognition; and facial recognition.

Depending on the nature of the application and the strength of the internal data patterns you can generally expect a network to train quite well. This applies to problems where the relationships may be quite dynamic or non-linear. ANNs provide an analytical alternative to conventional techniques which are often limited by strict assumptions of normality, linearity, variable

independence etc. Because an ANN can capture many kinds of relationships it allows the user to quickly and relatively easily model phenomena which may have been very difficult or impossible to explain otherwise [4].

Combining multiple models to improve forecast accuracy has been extensively studied in the literature. The literature is vast and growing. The idea of association models is the assumption that the basic structure of real data is difficult or impossible to model by an exact model and the fact that different models can play a complementary role in capturing different data models. Effectiveness of combined forecasts was determined both theoretically and empirically.

Abstract

It can be said that quality assurance of education has become a major concern of those in charge of educational institutions, but also those responsible for quality assurance of education within the competent ministry (especially in higher education) since the 80s, but especially after 1990.

Accreditation and certification have become major objectives of all universities, no matter where they operate, the number of teachers and support staff, students and respectively graduates, geographical location and so on, especially after 1990.

Both the Academy of Economic Studies of Bucharest and "Ovidius" University of Constanta were institutionally accredited by ARACIS with "high confidence".

As teachers involved in teaching and also in the quality of education, not only in this abode of science and culture, we intend to present in this paper some of the most important issues concerning quality assurance, accreditation and certification of this university, the problems we encountered, but mainly the benefits of this complex process.

Key words: accreditation, certification, quality management, education

J.E.L. Classification: I20, I21, I23, I28.

1. Introduction

Education quality assurance, accreditation and respectively academic certification is among the top management the priorities of and not only from any university, college, department and / or division within an institution of higher education in the world.

According to the Government Emergency Ordinance no. 75/2005, Article 3, "the quality of education is a set of characteristics of a study program and its provider, through which the beneficiaries' expectations and quality standards are met. Education quality assessment consist of the multicriterial examination of the extent to which an education provider and its program meet the standards and benchmarks. "Regarding the quality assurance of education in the same document it is stated that "it is achieved through a set of actions to develop the institutional capacity development, the planning and implementation of programs of study, which formed the trust of the beneficiaries that education provider meets the standards of quality" [4].

Many quality assurance specialists believe that the starting point for improving the performance of an university should be to represent the implementation of a quality management system according to ISO 9000, by which it can ensure the premises to achieve performance excellence through the implementation of Total Quality Management [7].

2. Quality assurance in education. Concept. Statutory acts

In general, according to ISO 9000 [2], quality assurance refers to "that part of quality management focused on providing confidence that quality requirements will be met" other components of quality management are: quality planning, quality control and or improve.

According to CNCSIS, "quality assurance is achieved through procedures and tools for the description of qualifications in higher education, to promote some new skills and monitoring tools and procedures, periodic evaluation and updating of CNCSIS" [9].

On the basis of ensuring the quality of education, particularly Romanian higher education, are numerous acts (in our country in the period 2005-2011 were issued only about 25 legislative measures for evaluation - accreditation of universities), including [5]:

- *Standards and Guidelines for Quality Assurance in the European Higher Education Area, Bergen, third edition, 2009;*
- *Emergency Ordinance no. 75/14.09.2011 for the amendment of Ordinance 75/2005 on quality assurance in education;*
- *MER Ordinance 3928/2005 on the quality educational services in higher education institutions;*
- *Law no. 87 of 10.04.2006 for the approval of Emergency Ordinance on education quality assurance no. 75/12.07.2005;*
- *External evaluation methodology, standards, benchmarks and performance indicators list of ARACIS, 2006;*
- *ARACIS Guidelines for assessing: institutional, daily and at a distance bachelor programs, masters, periodic certification and accreditation requirements, 2006;*
- *ISO 9001:2008 - Quality management systems. requirements;*
- *IWA 2:2007 - Quality Management Systems - Guidelines for application of ISO 9001:2000 in education (adopted as Romanian standard in 2006);*
- *ISO 9004:2010 - Managing for the sustained success of an organization. An approach in terms of quality management;*
- *Criteria of some National Award for Quality: Education Criteria for*

Performance Excellence, Baldrige National Quality Program.

If we talk about quality assurance through the ISO 9000 family of standards, we can say that this process focuses on continuous improvement of organizational processes through preventive action. Its components refers to the quality defined from the perspective of the client and the regulatory requirements, and the actions are aimed at increasing customer satisfaction and the continuous improvement in performance.

ISO IWA 2:2009 Standard. Quality management systems. Guidelines for the application of ISO 9001:2000 in education comes to assist in a clearer understanding of the requirements of ISO 9001:2008 and ISO 9004:2000 standards and how to apply them in education. IWA 2:2009 does not add, replace and does not change the requirements of ISO 9001:2008, also is not for use in contracts for conformity assessment and certification [1, 3].

3. Accreditation of universities in Romania

In the opinion of a group of teachers from the "A. I. Cuza" University of Iasi and respectively ASE [8], accreditation is defined as "the process by the concerned unit / educational institution / organization, based on external evaluation, acquires the right to organize admission, conduct of the educational process for organizing the graduation examinations and issue recognized diplomas and certificates. "However, it can be said that it is "the process of evaluation leading to a formal and independent decision about the extent to which an educational program complies with the quality standards" or another point of view, "that method of quality assurance, through which is certified the compliance with predetermined standards for the establishment and functioning of the education institutions and their study programs; this is part of quality assurance" [9].

In our country, the accreditation of universities is carried out by a non-governmental institution, external to the university, created specifically for this purpose, namely ARACIS - Romanian

Agency for Quality Assurance in Higher Education.

The results of the accreditation process are made public, so that it can be known by all stakeholders, including: students, prospective students, teachers, partners of education etc..

If we talk about the role of university accreditation, it can be said that there are four aspects, namely [5, 8]:

- Quality assurance - a university that has the status of accredited university offers its customers and partners confidence in the sense that the institution meets the standards in force in this area on the act of education itself, related services for students, services from the library etc..
- Allows access to state funds - according to the legislation specific to the education sector, only accredited universities receive funding from the state budget, based on the results of the accreditation / reaccreditation.
- Builds and strengthens public and private sector confidence in the institution of higher education - academic accreditation means that the educational curriculum standards are met, the organizing of courses and seminars / practical assignments, organization of specialty practice, continuous training of teachers, etc.. All this leads employers / potential employers to be confident that the graduates of these universities are prepared (at least theoretically), have the necessary skills to handle a job in the field they were studying.
- Facilitates the transfer and mobility of students from one university to another - the transfer of students from one university to another is possible only if the universities involved in this process are accredited. An undergraduate student may take the exam / dissertation only at the an accredited higher education institution in the field.

Most of the time, in Europe, including Romania, entities exercise one of mixed systems of evaluation - accreditation of universities, namely:

- *Authorization - Accreditation - regular assessment of a study program* (with the possibility that the institution can make some

changes in the program after the authorization / accreditation, subject to the regulations in force).

- *Authorization - Accreditation - regular assessment of the university.*

- *Other external evaluation* on the institution's research capacity, capability of teachers, doctoral supervisors - for example, rating EUA (European University Association).

The accreditation process involves three steps of specific activities (usually), namely [10]:

- The running of a self-assessment process, coordinated by the lead faculty / institution, and other members of the academic body or the departments in the the structure of the faculty / university. This stage ends with the development of a self-evaluation report in which reference is made to the criteria / standards imposed by the accrediting agency;
- The assessment visit, for the accreditation, to the faculty to which belongs the program submitted for the accreditation / reaccreditation. The evaluation commission members are selected by the accrediting institution so as to be compatible with the program evaluated. In the field, the evaluation team visits the locations specified in the self-assessment, evaluates the evidence in the particular file, interviews academic and administrative staff; based on the findings, the evaluation team prepares an assessment report which contains some recommendations to the accreditation committee at the level of the certifying institution.
- The accreditation commission's review of the evidence and respectively of the recommendations issued by the members of the evaluation commission which was in the field, based on a set of criteria on the quality of university education. This stage ends with the issuance of the decision on the accreditation of the academic program in question, a decision which is communicated to the institution subject to accreditation and, if applicable, all stakeholders in this regard.

3. Certification. General aspects

Broadly, "the certification is a procedure for attesting the conformity of a product,

service or quality management system of an organization in relation to a referential default (standard, technical specification)". [6]

"The process by which an association or an agency acknowledges the achievement of established quality standards and usually grants certain privileges to the target individual (student or teacher)". [10]

The quality management system certification involves a procedure to certify that the quality management system implemented in an organization (in our case, the university) complies with referential within the ISO 9000 standards standards or other normative documents which consider an appropriate quality system standards.

The certification body should be neutral and accredited by national bodies; it has the power to issue and respectively revoke a certificate.

Analyzing, in particular, the quality management system certification implemented at the level of an institution of higher education, we can say that among the benefits brought to the university by this process we find [6, 9]:

- Improving the image and hence the university's position on the market.
- Providing trust to the partners, especially students and employers, regarding the realization, constantly of services of high quality and respectively of sending well trained graduates on the labor market.
- Attracting as many candidates as possible to the entrance exams organized at the university and, in many cases, significantly increasing the number of students at both undergraduate and masters.
- Becoming a preferred education / graduates service provider.
- Mitigate the effects of competitive pressure.
- Alignment to international standards.
- Providing confidence to the top management that all activities / actions / processes of the university are controlled and operate at constant quality level.
- Greater involvement of employees (teachers, support staff, etc..) by constantly and continuously being aware of the improved quality.

4. Conclusions

The educational organization should strive to continually improve the effectiveness of its quality management and educational processes, allowing the entire staff to identify and establish improvement projects in its areas of activity [4].

Currently, academic credentials and respectively the certification are heavily regulated in our country, in accordance with recommendations of the ECB.

Analyzing the industry standards, we can say that the main objectives pursued by the Romanian higher education quality assurance are [1, 4, 5]:

- To maintaining and at the same time continuously improving academic standards;
- Accountability at all levels to create favorable conditions to achieve, maintain and improve quality;
- Developing a true institutional culture of quality in education;
- Demonstrating a high level of quality of the programs (bachelor, master, training, etc..) in all faculties within the university structure;
- Full information on the functioning of the Romanian educational system, including the results achieved, and possible ways to improve them.

Events and Macros in Microsoft Access 2013

Cosma Emil

"Ovidius" University of Constanta, Faculty of Economic Sciences
ecosma@univ-ovidius.ro

Abstract

With interface macros you can perform actions such as opening another view, applying a filter, or creating a new record. There are two kinds: "embedded" UI macros, which attach directly to user interface objects such as command buttons, combo boxes, or the Action Bar button object, and "standalone" UI macros, contained in macro objects.

To avoid duplicating code, reuse standalone UI macros by calling them from other macros. You can see the standalone UI macros in the Navigation Pane, under Macros, but you can't run them directly from there. Use the Run Macro action to run a standalone UI macro from an embedded UI macro.

Key words: macro, event, database, form, report.

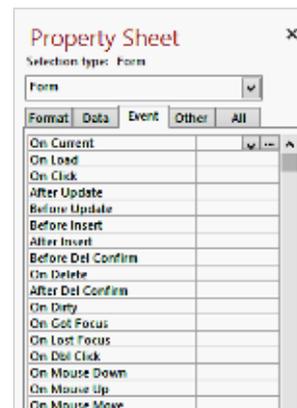

J.E.L. classification: C88.

1. Introduction

An event is the result of initiating an action on an object (**control**). Action can be done with the *mouse* (position even without clicking, left click, right click, double click, drag, drive wheel) or using the *keyboard* (pressing a key or a function key).

When an action is performed on a control, **the control must send a message to the operating system**, allowing it to know what happened. The operating system must then decide what to do, whether to respond to the message or send the message to another object. Obviously, for a message to accomplish its purpose, it must carry some information. Because there are different types of objects and there are various types of actions that can be performed on them, there are also various types of messages.

Microsoft Access provides friendly means to resolve events. The associating of events with a control from a *Form* or *Report* is made in *Design View*. In the Property Sheet window, Event tab, are displayed events that may be associated with the selected controls from a form or a report. The names of most events start with **On**, which means, "**at the time this is done**". In some cases, something must be done before applying the effective action (**Before**) and after the action was applied (**After**):

2. Events Categories

Some events are general and they are shared by most objects. For example, almost all objects can be clicked. Some events are based on objects category, such as only objects that can receive text. Some other events are very restricted because their object needs particular functionality.

➤ **Click Events.** Probably the most common event fires when an object is clicked. The event is called **On Click**. This event does not carry information about the source (not identify that was using the *mouse* or *keyboard*). Another common event of controls is fired when an object is *double-clicked*. This event is represented as **On Dbl Click**

➤ **Focus Events.** A user can place the cursor on a control with the *mouse* or by

pressing the *Tab* key (on *keyboard*) several times (without running *click*). In both cases, when a control receives focus, it fires an event named **On Got Focus**. These controls can generate events, for example, pressing *Enter* - **On Enter**. Controls may be focused successively using the *Tab* key. You can finally run events such as focus - **On Exit**, **On Lost Focus**.

➤ **Mouse Events.** *Mouse* and *keyboard* are working devices most commonly used. In fact, some applications can be completely used with the mouse only. *The mouse* is responsible for at least three events (**Down**, **Up**, **Move**). If the user positions the mouse on top of a control but doesn't *click*, the control fires an event named **On Mouse Move**. In connection with moving *the mouse* should be taken into account several elements: buttons, keys (**Ctrl**, **Alt**, **Shift**), cursor coordinates.

➤ **Keyboard Events.** There are several ways to use *the keyboard*. The user can press *Tab* to move focus from one control to another. A user can also *click* a text-based control and start typing. After pressing the key, when the user releases or depresses it, the control fires an event named **On Key Up**. The message of this event carries the same types of information as the **On Key Down** event. When the user presses a key, if you are interested only on the key that was pressed and not on any combination of keys, use the **On Key Press** event.

➤ **Form Events.** To use a form, the user must open it, either from the *Navigation Pane* or from another object you provide them. When the form is being opened, it fires an event named **On Open**. As the form is opening, it must occupy memory. As this is happening, the form fires an event named **On Load**.

To make itself known to the operating system and to other applications on the same computer, the form must draw its border. When this is being done, the form fires the **On Resize** event.

If the form was already opened more objects (forms, reports, tables), if the user wants to bring it to the front, she must click either its title bar or an area of the form. When this is done, the operating system must paint its title bar with a bright color. Either case, when a form comes to the front of other windows, it fires an event named **On Activate**.

Once a form has been loaded is currently the active form, the user can use it. After using the form the user can close (the user can either use the system close button or you must provide other means of closing the form). As this starts, the form must lose focus. If the form was the only object opened in *Microsoft Access*, the body of the application is emptied. If there are other objects, the form would be closed and another object would become active. As this is done, the form fires the **On Deactivate** event.

When the form is being closed, it must be removed from memory to release the resources it was using (so that those resources can be used by other applications). While this is being done, the form fires the **On Unload** event. Once the form has been removed from memory, it (the form) fires an event called **On Close**.

➤ **Text Box Events.** As you know already, to use a *text box* or a *combo box*, the user can *click* the control and start typing. If the control already contained some text, the user can edit it using keys. When the text is being entered or edited, the control fires the **On Change** event.

➤ **Combo Box Events.** A *combo box* (*drop down list*) is a control that holds a list of items. To use it, the user can *click* the arrow of the control to display the list and select an item. Some versions of the *combo box* allow a user to *click the text box* part of the control and start typing. The control would then try to find an item that matches what the user is typing or has typed. Sometimes, after the user has finished typing (and press *Enter* or *Tab* to move focus), *Microsoft Access* (the database engine) may not find a match and would display an error. This means that the text the user typed did not match any of the items of the *combo box*. In this case, the control would fire an event named **On Not List**.

➤ **Records-Related Events.** Because *Microsoft Access* is a database application, it provides some event that, are particular to records and their fields on a form or report.

To create a new record, the user must move to an empty record on a form. The user can click a control such as a text box and start typing. When this happens, the form fires an event named **Before Insert**. If a record exists already, the user can open or access, *click*

one of its fields and start typing or editing. When at least one value in the record has been changed, the form fires the **On Dirty event**. After a record has been changed and submitted to the database, the form would fire an event named **Before Update**. It also might follow the situation after creating a new record (**After Insert** event). If a table contains more than one record, after the user has opened its corresponding form, the user can navigate from one record to another. When the user moves from record to record, the form fires an event named **On Current**. We know that, to delete a record, a user can *click* the record and press *Delete*. This would display a warning message. Before that message comes up, the form fires the **Before Del Confirm** event. After the user has clicked one of the buttons on the message box, the form fires an **After Del Confirm** event. If the user decides to delete a record, before the record is actually deleted, the form fired an **On Delete** event.

3. Macros

A **macro** is an (automatic) action that must be performed on an object of a database. *Microsoft Access* provides an easy and visual mechanism to create and manage macros.

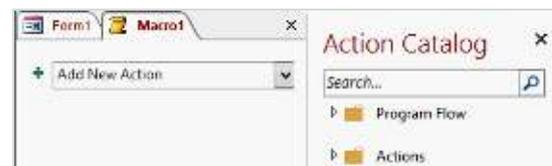

Macros in *Microsoft Access* have nothing to do with macros in other *Microsoft Office* applications. In fact, it should be fair to state that they are completely different. For example, macros in *Microsoft Excel* and *Microsoft Word* directly lead to actual *Visual Basic* programming. Macros in *Microsoft Access* don't write real (VBA) code: they are actions you create and the database engine executes them behind the scenes at the right time. If you want, you can convert *Microsoft Access* to VBA but then, they become code and not real macros anymore.

To create a macro in *Microsoft Access*, you can use an intuitive dialog box that allows you to select the action to be performed and the options the action needs. In reality, when you create a macro, *Microsoft Access* creates a type of script that contains names, expressions, and operations for the action, sparing the details. Still, if you know what is necessary for the macro, you can "**manually**" create it.

To create a macro, *click* the **Macro button** in the **Marros & Code** section. Macro created is given a name and will appear in the list on the **Navigation Pane**:

Two windows would display and they are separated by a split bar. To give more room to one of the window, position the mouse between them, click and drag in the desired direction. The left window presents a tab or a title bar labeled **Macro1**. By default, that window displays a *combo box*. The right window displays buttons with \triangleright . This means that they are nodes. To expand a node, *click* its \triangleright button. When you do, the node would display its items:

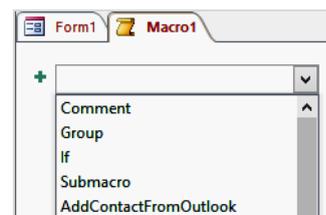

The **Program Flow** node allows you to create a condition.

The **Actions** node holds most of the actions you will create for your macros. If expand it, you will see that it organizes its actions in categories, each represented by a node.

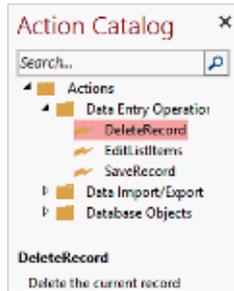

3.1. Creating a Macro

To create a macro from the left window, click the arrow of the *combo box* to display the available actions. The left window would display the objects (controls) needed for the options of the action you selected. The objects in that window depend on the action you selected:

To create an action using the right window, expand the node(s). Many names of actions are explicit or can be interfered

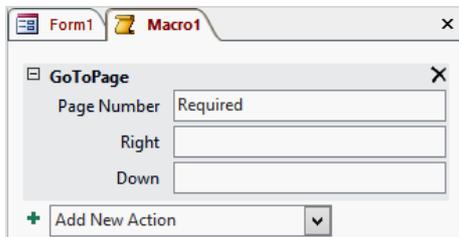

logically. Otherwise, you can *click* an action. The bottom section would show a description of the action:

If you see the action you want, *click and drag* it to the left window. In both cases, if you selected an action you don't want anymore, you can *click* the **Delete** button.

3.2. The Actions of a Macro

To actions its action(s), a macro may need some additional information. This information is referred to as the argument of a macro. The argument can be made of one or more values. The argument(s) depend(s) on the (type of) macro (can be **0**, **1**, **2** or more arguments):

An argument is said to be required if it must always be provided, otherwise the action cannot be performed. If you select a macro that takes a required argument, an empty text field would appear and you must type the necessary values. An argument is referred to as optional if it can be omitted, in which case the macro would use a **default value**. When an action takes more than one argument, some arguments can be **required** while some others are **optional**.

3.3. Using a Macro

After creating a macro, you can use it. This is usually done by assigning it to an event of a form, a report or a control. To assign a macro to an object, access the

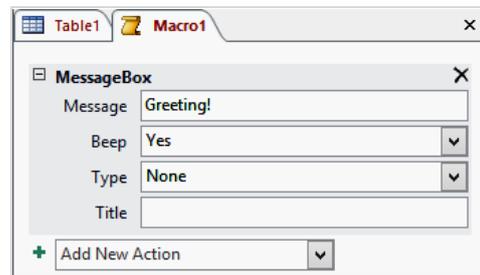

Property Sheet for the object and access the Event.

Instead of first creating a macro before assigning it to command button, as another technique (in the **Design View** of the form) you can *right-click* the object and *click* **Build Events**. In the **Choose Builder** dialog box, you can *click* **Macro Builder** and *click* OK. The new macro would be automatically assigned to the control.

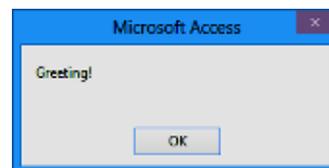

4. Examples

4.1. Creating and using a macro (the database object).

1. *Start Microsoft Access.*
2. On the *Ribbon*, click **Create**.
3. In the **Macros & Code** section, *click* **Macro**.
4. In the **Macro1** window, *click* the arrow of the *combo box* and select **MessageBox**.
5. Complement the text “**Greeting!**” in **MessageBox** action:

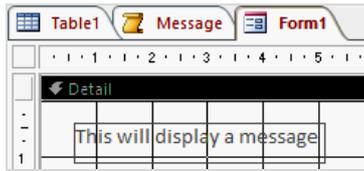

6. *Click* button to run **macro** - when asked whether you want to save, click *Yes* (this **Message**). Macro can be found in the list of objects, in **Navigation Pane**. It will display a message box:

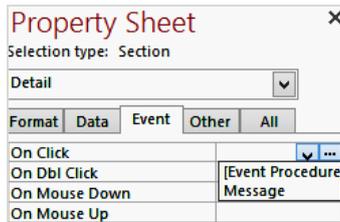

Next: assign **macro Message** to a control on a form.

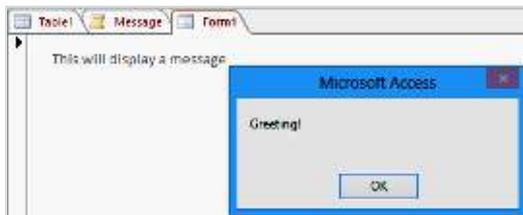

7. *Click* button (**Form Design**) from the **Create** tab, *Forms* group. Insert the form controls **Aa** - *Label* with text “**This will display the text of the message**”:

8. On Click property of the label (the Property Sheet) choose the combination of macro-Message:

9. In Form View, click the text This Will display a message:

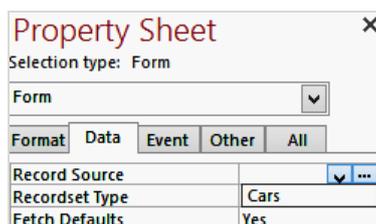

4.2. Creating Macros associated with the controls on a form.

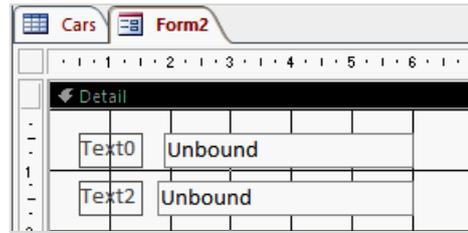

1. Cars table is created:

Model	Price
Opel	11500
Suzuki	8700
Ford	12100

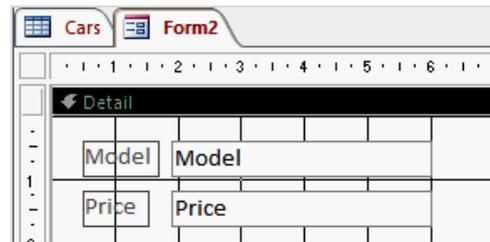

2. It creates a form with button (Form Design).
3. Data source of the form: Cars table (the Property Sheet, Record Source):

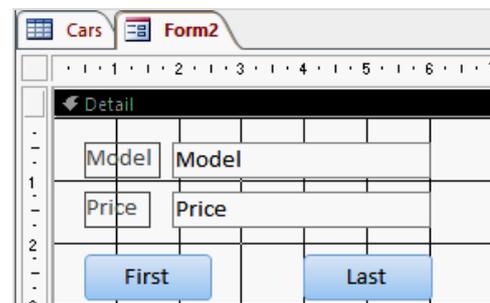

4. Placed on the form, two Text Boxes (with ab button, tab Design):

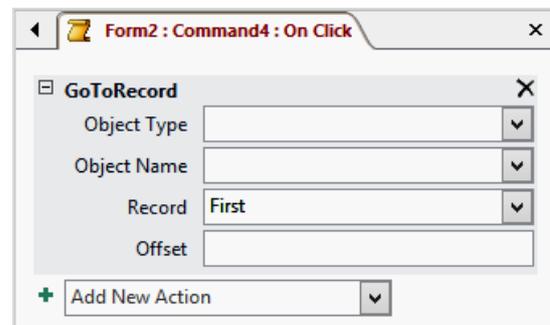

5. Change the labels and is fix the source - Source Control (Model, Price):

6. Placed on the form, two user buttons (with XXXX button, Design tab) - Cancel the Command Button Wizard window. Change Caption properties of the two buttons:

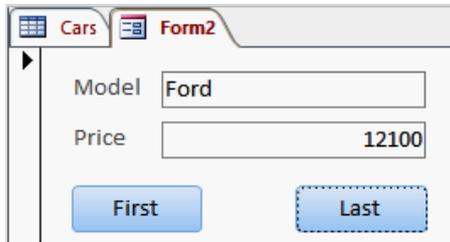

7. Run right-click the first button and choose Build Event, Macro Builder. Enable thereby editor macros (Macro Builder). Select the action to be associated with the first button (GoToRecord - Record box: First):

8. Macro Builder window is closed by pressing the button (macro is saved).

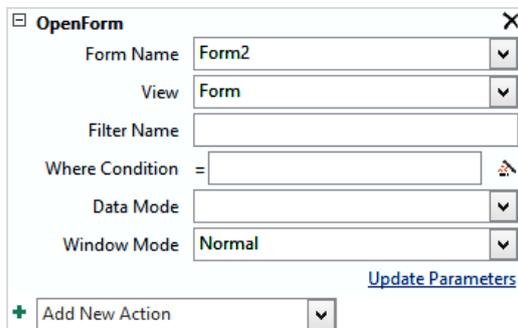

9. Proceed similarly for the second button. Actions these are **GoToRecord** (Box Record: **Last**) and **Beep**. Close the **Macro Builder** window for the button.
10. It displays the form in *Form View*, and finding its operation by pressing buttons **First** and **Last**:

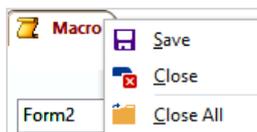

4.3. Creating an AutoExec macro

AutoExec macro is a macro that executes automatically when a database is open. For a database that contains several components, is often preferred activation from the beginning of one of these components. For example, you may want to display a specific form when the database is open.

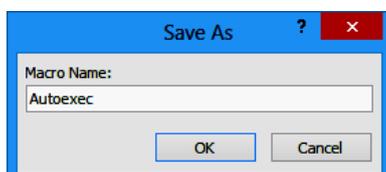

1. **Macro** button in the **Create** tab. Select **OpenForm** action:

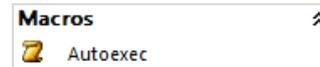

2. *Right-click* the macro's name to initiate a rescue:

3. In the **Save As** window insert (**mandatory!**) the name **AutoExec**:

4. **Macro** created will appear in the **Navigation Pane**:

5. Editor *Microsoft Access 2013* closes (when closing the database is saved under a name that is meaningful, because in the next section will reopen).
6. Reopen previously created database and found activation in the **Form2** home:

Weber and Mises: Views on Bureaucracy

Cosma Sorinel

„Ovidius” University Constanta
sorinelcosma@yahoo.fr

Abstract

Bureaucracy is not a recent phenomenon. Its beginnings go a long way back in history. Looking into the issue of bureaucracy is a good starting point for the study of two social systems – capitalism and socialism. Such an analysis must be built onto the comparison between profit based management and bureaucratic management.

Weber and Mises are two important names to mention when talking about bureaucracy. They both authored studies on bureaucracy, (Weber – Economy and Society in 1922, and Mises – Bureaucracy in 1944 and 1962). However, they each approached the topic from completely different angles and reached completely different conclusions regarding the nature and consequences of bureaucracy.

Key words: bureaucracy, bureaucratic management, profit based management, socialism, capitalism.

J.E.L. Classification: B10, B20, B25.

1. Introduction

Bureaucracy and bureaucratic methods have existed since ancient times. They have been associated to any government whose suzerainty covered large areas. Such was the case of Mesopotamia, Ancient Egypt, the Incas and the Aztecs, the Roman Empire, or China (the Han Dynasty). Medieval feudalism attempted to govern large areas without bureaucrats but the result was the disintegration of political unity which led to total chaos. The church and religious orders are another historical example of large scale administrative mechanisms. But it will take some time until bureaucracy per se emerges and spreads. The French Revolution made the law supreme in administration and made bureaucratic management legal and

constitutional. The French model was taken over by other countries, including Prussia but not by England. The English common law was therefore very different from anything else. Bureaucracy carried on, it survived through the Second World War, it was later renewed and became much more flexible. [7]

The term bureaucracy itself was originated by Vincent de Gournay and had a huge success all through the 19th century.

Bureaucracy (the division of labor applied to administration) comes from the French word *bureau*, meaning desk, or by extension, an office; thus, bureaucracy is rule through a desk or office, that is, a form of organization built on the preparation and dispatch of written documents. In contrast to the commonly held view of bureaucracies, they do not rule in their own right but are the means by which a monarchy, aristocracy, democracy, or other form of authority, rules. [3]

Nowadays, the words bureaucracy and bureaucrat have a rather derogatory meaning or a negative connotation. They always imply criticism or even contempt towards the people, the institutions, and the procedures that are described as bureaucratic. It is usually translated into inefficient and inflexible administration and a more or less parasite social group. But this springs mainly from the fact that very few are able to give a clear definition of these terms.

Progressive critics of bureaucracy aim their criticism towards large corporations. In the past, when companies were relatively small, the entrepreneur was able to supervise all aspects of the business and to make all important decisions. Being the sole owner of company's capital, he was vitally interested in the success of the business. To this very end, he would use his abilities the best he could to avoid any waste and to get the highest results. But nowadays, large corporations are dominant. The owners – the shareholders – have no say in the

management of the company. Given their size, these corporations are divided into departments, divisions, and this brings about a rigid bureaucratic administration in the absence of a creative leadership meant to adapt and adjust production and distribution to the changes in offer and demand.

But the fact is that no profit seeking company, no matter how large it might be, is susceptible of becoming bureaucratic unless the government interferes with its management. [4]

We can say that looking into the issue of bureaucracy is a good starting point for the study of two social systems – capitalism (free enterprise, private property) and socialism. [6] And the analysis must be built onto the comparison between profit based management and bureaucratic management.

2. Weber’s Theory on Bureaucracy

German sociologist, political economist and administrative scholar, **Max Weber** is considered to be the pioneer of the classic social scientific analysis of bureaucracy. His critical study of the bureaucratization of society is one of the most enduring parts of his work. He began the studies of bureaucracy and his works led to the popularization of the term. In 1922 he wrote a book titled *Economy and Society* in which he showed that, in a modern society with a specialized and highly complex division of labor, bureaucracy ensures collective social goals being attained and obstacles to economic development, social advancement and political stability being removed. In other words, it solves many of the shortcomings of the traditional system.

The powerful, centralized nation-states, business corporations and labor unions predominant in the industrialized world of the 20th century were direct creations of the bureaucratic organizational techniques.

Weber lived and wrote in a period when more and more people got desk jobs in large companies which were more of economic cartels. Germany at that time had the most advanced type of bureaucracy in all Europe. Weber drew the conclusion that bureaucracy was not specific only to Germany, but the entire modern society, springing from the extensive administrative needs of the modern state and of the capitalist business. The three

– bureaucracy, the modern state, and the capitalist economy – were linked to one another in their evolution. As an administrative system, bureaucracy was to Weber a social entity both indispensable and rooted into the most prominent characteristics of modern society and a formidable structure of the power, able to control large scale actions, continuous in its manifestation, socially and morally cohesive through its expertise and control of information.

Observing the changes that were taking place during the industrial revolution, Max Weber saw capitalism as the rational way to organize activities: all decisions could be based on the calculation of their likely return to the enterprise. Weber's ideal bureaucracy was therefore devoted to the principle of efficiency: maximizing output while minimizing input. It was characterized by impersonality, efficiency and rationality. Also, it is a system based on discipline.

According to Weber, bureaucracy is a particular type of administrative structure developed through rational-legal authority. His rationale described it as being the ideal way of organizing government agencies.

Weber noted several **major principles or features of bureaucracy**:

- A formal hierarchical structure – in which each level controls the level below and, in turn, is controlled by the level above – is the very basis of central planning and centralized decision making. Subordinates follow orders or superiors, but have right of appeal (in contrast to more diffuse structure in traditional authority).
- Management or control by rules allows decisions made at high levels to be executed consistently by all lower levels.
- Very precise, inertial and abstract rules govern decisions and actions. These rules are stable, exhaustive, and can be learned, and decisions are recorded in permanent files.
- The specialists in the structure do the work being organized according to their skills and the type of work they perform.
- The organization aims at serving either the stockholders, the board or the agency (in which case it is said to be “up-focused”) or the organization itself (then it is said to be “in-focused”).

- Employees and customers are to be treated equally. No differences are to be made whatsoever.
- Employees are hired on the basis of their technical qualifications, appointed not elected, compensated by salary, not fired arbitrarily and given the chance to a life-long career. [1]

Weber made a clear distinction between administrative personnel and the organization that empowers them. A voluntary group – nation, union, political party, company – elects some sort of government to manage its businesses. The government, in turn, employs administrative personnel to carry out its policies. And this administrative staff, once constituted according to the principles above mentioned, will be known as bureaucracy.

One of **Weber's concerns** was how society would maintain control over expanding state bureaucracies. He felt the most serious problem was the increased power of public officials and ultimately the shift in power from the leaders of society to the bureaucrats.

He saw this expansion as a threat to liberal values on several levels. Firstly, he saw it as a threat to individual freedom. Secondly he questioned the ability of the leaders of an organization to set its goals. Thirdly, he called for a pluralism of bureaucratic institutions to avoid any monopoly. Also, the power of bureaucrats must be subjected to a coherent leadership and to an efficient control.

Over the years, there have been numerous **criticisms of Weber's bureaucracy theories**, especially his claim that bureaucratic organizations based on rational-legal authority are the most efficient. There were voices who pointed out the fact that when Weber insisted on the superiority of bureaucracy, he only had old administration forms as elements for his comparison. Another aspect that was pointed out is the fact that, for Weber, the efficiency of bureaucracy was not a unique feature of the system, but a series of features to satisfy the wide and complex needs of an industrial society. Each feature of bureaucracy leads in fact to meeting an efficiency criterion.

Others have shown that, in practice, obeying bureaucratic rules and norms can limit efficiency as well as favor it. This is so because the principles of bureaucracy are

much more ambiguous than Weber envisaged them and they can produce multiple dysfunctions: obeying rules can lead to inflexibility and formalism, impersonality can generate indifference and insensitivity, hierarchy can discourage responsibility and initiative. So, Weber is said to not have been able to seize the ambivalence of bureaucracy, having been influenced by the mechanical discipline examples of the Prussian army and by Taylor's scientific management system. Weber disregarded all aspects related to individual personalities, personal needs and hopes of those who are supposed to work together efficiently. Plus, Weber did not treat separately two types of authorities within the organization – the bureaucratic authority given by the position held within the hierarchy, and the authority given by the experience of the individual, regardless of his or her position.

3. Ludwig von Mises – free market bureaucracy versus statist bureaucracy

Originally published by Yale University Press in 1944, *Bureaucracy* is a classic fundamental examination of the nature of bureaucracies and free markets in juxtaposition to various political systems. Bureaucracy contrasts the two forms of economic management—that of a free market economy and that of a bureaucracy. In the market economy entrepreneurs are driven to serve consumers by their desire to earn profits and to avoid losses. In a bureaucracy, the managers must comply with orders issued by the legislative body under which they operate; they may not spend without authorization and they may not deviate from the path prescribed by law. Writing in an age of exuberant socialism, Ludwig von Mises here lucidly demonstrates how the efficiencies of private ownership and control of public good production ultimately trump the guesswork of publicly administered “planning” through codes and “officialdom.” Although Mises aptly critiques bureaucracy and expounds thoroughly upon the immense power of law-like codes of commissions and administrations, he does not condemn nor dismiss bureaucracy but rather frames its proper bounds within constitutional democratic governments. [8]

In the foreword of the 1962 edition of his *Bureaucracy*, Mises stated that the objective of his work is neither to accuse nor to criticize bureaucracy, but rather to explain what is meant by bureaucratic management and profit management and the differences between these two ways of handling operations in a company or ways in which people work together.

In his view, the bureaucratic process is a symptom of a condition, the effect of socializing, nationalizing and market reduction (profit based management).

In his 1920 article “*Die Wirtschaftsrechnung im sozialistischen Gemeinwesen*”, Ludwig von Mises proved that economic calculation is impossible in a socialist planned economy. The central idea in his article is that monetary calculation is the indispensable mental tool in selecting the optimum production plan within a system of social labor division. A society without monetary calculation is a society without an economic system. Therefore, socialism means eradicating rationality from economy. [6]

Bureaucratic management

Since a leader cannot be omnipresent, he will appoint some sort of deputy, governor, or administrator and will delegate some of his power to them but in order to limit the power and freedom of action of his governors, the leader will issue instructions, directives, rules and regulations showing them how to act when various problems arise. The governors’ management will be affected by these rules – they will no longer do their best to solve a problem, but they will be mainly concerned with complying with these rules. They will become bureaucrats.

There were voices who claimed that bureaucratic management on the one hand and democratic government and institutions on the other hand are incompatible. But Mises claims this is not true: the two pillars of democracy are the supremacy of the law and the budget, and bureaucratic management is management in accordance with the law and the budget.

Bureaucracy, in its essence is neither good nor bad. It is a method of government that can be applied to different fields of human activity.

Any organization would fall to pieces for lack of restrictions.

The bureaucrat is limited by rules and regulations in his actions.

The objectives of the public administration cannot be translated into monetary terms and cannot be checked through accounting methods. In public administration there is no connection between income and expenses. Public services spend money. The little income they produce is absolutely accidental. Their source is the law and not the activity of the employees. Within public administration there are no prices and therefore results cannot be assessed.

So, all in all, bureaucratic management can be defined as the management method used in administrative businesses that have results with no market price (they are not sold or bought on the market) and cannot be subjected to economic calculation. We must not confuse price with value here – the successful management of public businesses does not have a price, but it does have value and importance.

The basis of bureaucratic management

Ordinary people consider bureaucratic management to be inefficient, slow, and formal. But what they identify as flaws and mistakes are in fact the very features of bureaucratic management. It is wrong to compare work within a governmental department (the aim is to obey rules and regulations) and work within a company which carries out its activity under the influence of the market (the aim is to make a profit).

Bureaucratic management of personnel

A bureaucrat works in a field in which his efforts cannot be assessed. Money is spent on his or her salary, on offices and what is used in them (materials, equipment), but the results of their work cannot be expressed in a sum of money.

When employed, the candidates have to have a certain age and certain degrees and they must pass certain examinations. Promotion (and higher pay) is received mainly on the basis of number of years in service plus further examinations. Competence is not always a criterion. The department heads are generally elder people with only a couple of years to go before retirement. Having spent most of their lives in subordinate positions, they have lost their

energy and spirit of initiative, so they tend to avoid what is modern and innovative.

Bureaucratic management of public companies

The objective of a public company is to provide useful services to the community. But who is to decide if and when a service is useful? How can we tell whether services cost more than their results? A deficit cannot be read as a failure and the manager is not blamed for it.

Any service, no matter how good it might be, can still be enhanced. But this is done by the manager out of public funds and according to a strict code of instructions from the government or the local authorities.

When profit is a company's sole objective, the company will never fall under bureaucratic management practices. No matter how large it is, the company will be ruled by the spirit of capitalism.

But the government can use different methods in its attempt to limit the profit of a free acting company: imposing a limit on profit (the excess profit is to be given to authorities, or shared among employees), imposing the price or a limit on the price of the company's goods or services, or setting high rates of taxes on the company's profit. What comes out of these situations is the fact that the company is no longer interested in increasing its profit, in cutting down costs and improving efficiency. [6]

Any interference of the government in the business of a company translates into disastrous consequences – they paralyze initiative and give way to bureaucracy.

In the 19th century, for example, in the heyday of European liberalism, the boards of directors used to include pairs, former ministries and generals, government officials, secretaries of state and councilors, politicians, or relatives of theirs, who had no business skills or experience but who ensured a smooth relationship with the government and with political parties. They had no concern about the prosperity of the company and, being used to bureaucratic management, they altered the company's management. They were not interested in producing better quality and cheaper goods, but rather in getting government contracts and other favors as well as tax protection in exchange for contributions to the political parties' funds and for positions given to persons

favoured by authorities. This kind of situation lasted for quite some time before efficient experts starting to manage companies. [2]

With the exception of Mises, economists had no or little interest in bureaucratic behavior prior to the 60s. It was only later that the internal mechanism of bureaucracy was properly studied especially in relation to political leadership.

4. Conclusions

Weber and Mises both authored studies on bureaucracy. They each approached bureaucracy from completely different angles and reached completely different conclusions regarding the nature and consequences of bureaucracy. Weber's theories are formal and typological, while Mises' theories are axiomatic. Both of them viewed bureaucracy as destructive to society (it reduces innovation and creativity, deepens compliance and obedience, destroys consumer-producer communication, and leads to waste as a result of resources misallocation), yet continually expanding. Though throughout his *Bureaucracy* there is no reference to Max Weber, Mises' discussion complements Weber's and improves upon it.

Léon Walras and Social Justice

Cosma Sorinel

„Ovidius” University Constanta
sorinelcosma@yahoo.fr

Abstract

*Mainly known as a pioneer of the general equilibrium theory, French economist Leon Walras was also a thinker on human nature, mores, scientific inquiry and knowledge and a great defender of human freedoms and social justice. His normative economic ideas on the distribution of social wealth were developed in his works *L'Économie politique et de la justice* (1860) and *Études d'économie sociale* (1896). He dealt with property, land, and taxes, wealth and poverty, freedom and equality, justice and equity and built a social system around the individual, the state and the society by referring to general social conditions and particular personal positions.*

Key words: social wealth, freedom, justice, nationalization, taxation.

J.E.L. Classification: B 13

1. Introduction

Hailed by Joseph Schumpeter as "the greatest of all economists", French mathematical economist **Marie Esprit Leon Walras** (1834 - 1910) is well-known for having formulated the marginal theory of value (independently of but almost simultaneously with William Stanley Jevons and Carl Menger) and for having pioneered the development of the general equilibrium theory. As one of the founding fathers of the neoclassical model, he constructed a general equilibrium theory for the first time in the history of economics. For him, general equilibrium means that demand and supply are equilibrated in all markets (market equilibrium) and that all economic agents maximize their satisfaction under given incomes (subjective equilibrium). [1]

But he was also a great defender of **human freedoms** and **social justice**. For him

liberty was the source of both society and morality. His **rule of equality** states that if every man is a free person, then all men in their capacity as free persons are equal in society (but only in a free, just and stable society). Still, men are unequal from the points of view such as the development of their faculties, merit and demerit. But this natural inequality based on equity does not pose any social problems. [2]

In his letter of application for the position of chair of political economy at the University of Lausanne, Walras made the following division:

- The study of natural laws of exchange value and of exchange or the theory of social wealth.
- The study of the most favorable conditions of agriculture, industry, trade, bank loans or the theory of wealth production, also called applied political economy.
- The study of the best conditions for property and taxes or the theory of wealth repartition, also called social economics.

Applied political economy is nothing but applied theory of industry and abundant production proportional to social wealth. Social economy is nothing but applied moral theory of property or of the equitable repartition of social wealth. Pure economy is the theory of exchange value or of social wealth. It is the science that studies social wealth by trying to determine the laws that rule it. As far as his pure political economy is concerned, it studies purely and simply the fact of the determination of price or the proportions of ex-change under a hypothetical regime of absolute free competition. [6]

Leon Walras decided, under the influence of his father, to devote itself to the political and social economy. His great interest and ambition was to develop the economic science on the same rational foundation as the natural sciences.

Walras originally intended also to write comprehensive treatises on social economics and on applied economics, but lack of time and bad health stood in the way of that plan. He presented instead two collections of his main publications on the subjects under the titles *Études d'économie sociale* (1896) and *Études d'économie politique appliquée* (1898).

In his *Études d'économie sociale* (1896), in which he applied economic theory to real problems, he presented the essence of his normative economic ideas and revealed himself to have also been a great thinker on human nature, justice, mores, and the structure of scientific inquiry and knowledge. *Études d'économie sociale* deals primarily with distribution considered from a normative standpoint.

Walras started his career as an economist in 1860, by publishing *L'Économie politique et de la justice* (*The Political Economy and Justice*). He was only 26 years old at that time. This book was intended to criticize Proudhon and to show his own plan of scientific socialism by showing how the theory of property and that of exchange are related, which suggests the future definition of his pure and social economics.

He brought forth a number of social questions related to wealth and poverty in society. For him, poverty does logically results from laziness, stupidity or the reverse of good luck. There does not exist any other sort of wealth than that legitimately acquired by work, talent or success and proportional to these causes.

As Anghel Rugină pointed out, he drew a clear distinction between involuntary poverty produced by the social system and poverty produced by individual deficiency. In the spirit of social justice, Walras made a distinction between property legitimately acquired by work, talent or success, and illegitimate property acquired by deception, fraud, chance or corruption. [5]

In this book, Walras cited his father's conclusive remarks in *De la nature de la richesse* (1831) on the inequality caused by the increase in rent and land price in a progressive society. Based on this idea, Léon Walras showed more clearly his plan for the nationalization of land when he participated in a congress on taxation held in Lausanne in July 1860.

For Walras, the justification for **social economics** lies with the interest towards the study fields – economic agents, state, market, money. [4]

2. The individual, the state and society

In building his social system, Walras identified **four elements**: the individual, the state, the general social conditions, and the particular personal positions. He also identifies a series of questions: when does the individual have to act by himself and when does he or she act as part of the state? When and how can it be determined if the gain is individual or belongs to everybody? Should the forest belong to the most skilled hunter or to the entire tribe, community, or group? The answer to the first question lies with the conciliation between the **individual's freedom** and the **authority of the state**. The answer to the second question lies with the juxtaposition of equity between **conditions inside society** and between **individual positions**.

As Rugină noted, the social order envisioned by Walras theoretically represents a synthesis between the rights and obligations of the individual on the one side and of the state on the other side, with respect to economic and social matters. In any civilized society one cannot exist without the other. [5]

The starting point in Walras' analysis is the fact that nature has given the land to all of us and personal skills to each one. In terms of **natural rights**, personal skills and abilities (those we are born with and also those we develop by training and education) are the natural right of the individual, whereas land is the natural right of the state. Being the owner of his personal skills and abilities, the individual will also be the owner of his work, wages and the goods bought with his money. He will work when and how he will please and will have a standard of living according to his income and to his saving habits. Also, let us not forget that the ability to make efforts is unequally distributed among individuals. Since the individual is the sole owner of his skills and abilities (acquired by birth or by personal efforts) and of what these skills and abilities can produce, for Weber, taxes on wages are unjust. [8]

The distinction between **individual moral** and **social moral** springs from the distinction

between the individual action of the human being and the social conditions within which his activity unfolds. Individual action belongs to the economic sphere in which a positive economic freedom defined in terms of rights and not obligations. And this individual freedom is fully expressed through exchanges of goods between economic agents under restrictive conditions that are specific to the environment in which man lives: the society. These conditions are referred to as the social issue by Walras.

Individual moral rests on everyone's inherent responsibility to fulfill its goals, to properly use the necessary means to do so and finally accomplish their destiny. Everyone's role is to fully establish their particular personal position in accordance with their ambitions. **Social moral** insures equal chances for individuals and protects personal interests. Thus, Walras defines the role of the state: to build the environment for the accomplishment of individual destinies, to insure inner and outer security, to issue and apply laws and organize the conditions for the success of society.

Society exists independently of the generations that come and go. If we consider society as a simple aggregation of agents, it is difficult to give it its own authority and its autonomous existence. Such a holistic approach in which society is the acting element strips the individual of all responsibility for his or her actions.

Walras said that if each moral person is an essential element of society, than society is an essential element of each moral person. Each person lives and breathes surrounded by the conditions of moral society, the conditions of property and taxes, family and government. In other words, general social conditions can be defined as all the cultural, theological, moral and juridical rules common to all of us. Rules and regulations insure harmony amongst agents and represent the basis for commutative justice for which the state is responsible.

For Walras, the individual and the state are two equivalent social types, with the same value, based on a common ground – social wealth, both of them politically and economically independent. The state gets its revenue from the rent on its lands thus being able to function and to develop.

3. Freedom

The essence of justice in liberal thought is that each is free to accomplish their destiny. For Walras, freedom translates into individual responsibility. [8] Therefore, the state does not have the right to interfere in order to ease the misery of an individual who has not got insurance and has fallen ill and has no income. Neither does the state have the right to do anything for the individual's children since the sole responsible people for them are their parents. Thus Walras excludes the concept of public assistance. He only accepts private charity, which is, of course, optional. Walras believes that the state should stay loyal to its sole mission – to insure the general social conditions for the benefit of all people, the principle being that the state should offer the exact same services to everybody. He only agrees with a tax on land for everybody, both for the rich and for the poor. Since all citizens have the same advantages from the public services provided by the state, they should by consequence equally contribute to the expenses generated by these services. Freedom would be nothing but a mere word without the means to put it into practice.

Inequities are therefore just in the context of the justice of the market. Given the fact that the conditions of a fair competition are observed, the income of an economic agent is proportional with the services he offered: the more these services are appreciated, the more they are in demand and the income they produce is greater. There is no injustice as long as nobody is compelled to buy the services in question. The levels of consumption and the levels of income are indeed unequal, but no one is directly affected. [7]

One of the consequences of such a theory is the well-established distinction between freedom and the conditions for its manifestation. Freedom without obstacle is the best guarantee for efficiency. Man is a moral person only in and through society.

Walras draws the rights and obligations of the state both in the economic field and in the social field. Among his original ideas, he had valuable revolutionary propositions for reform in the field of education. He considered that **education**, both general and professional, was a condition for freedom.

4. Social Justice

At the core of Leon Walras's conception of the world lie the concepts of **justice and equity in exchanges**. He establishes a relationship between the terms freedom, society and equality. Free individuals are equal among themselves through their actions in society, and not necessarily through their talent. They have the right to set objectives, to attempt to accomplish their expectations, to use their abilities to reach their goals.

When Walras speaks of equality among individuals he does not mean identical and interchangeable positions among individuals, but rather positions to insure them fair and equal chances to succeed.

As far as justice is concerned, Walras defines **commutative justice** and **distributive justice**. Commutative justice (symbolized by a pair of scales) establishes that all competitors in a race start the race from the same point of departure. Distributive justice (symbolized by a victory wreath) establishes the order in which competitors reach the finish. Commutative justice has to do with the fact that all individuals are born equal. Distributive justice is founded upon the difference in skills, talent, perseverance and industry. Each and every individual enjoys his or her own success and is responsible for his or her failure.

Justice as seen by Walras legitimizes the status and position differences in society through each individual's free action, as an ex-post result of his or her own calculations. The fact that not all individuals enjoy the same general social conditions in society goes against commutative justice. The fact that individuals do not enjoy particular personal positions according to their merits and are not responsible for their fate goes against distributive justice. [8]

At first, the state has to be strong, independent and to have a certain and legitimate authority to impose the points of departure in the race. Then it has to become discrete in order not to interfere with anyone's free action to accomplish themselves. Inequity, if allowed, it is not a fact of society, it results from each and everyone's efforts to reach their goals. In other words, inequity cannot be but the result

of the confrontation between individual ambitions and means used according to their aims or rather the result of natural and physiological inequities. Society is nothing but the place where individual fates express themselves in their temporal existence.

As long as each individual enjoys the same social potentialities, inequity can only arise from individual physical or moral weakness. Social potentialities refer to the methods employed by the state to give agents equivalent means to accomplish themselves as individuals.

Léon Walras strongly believed that without an **equitable distribution of wealth** there could be no **social justice**. Leon Walras defines social wealth as being all material and immaterial things that are rare, which on the one hand are useful, but on the other hand are available in limited quantities.

He defended the right of private property, yet he considered that land was a special case and that it belonged to the community as a whole. He called for the nationalization of land, the abolition of taxation on wages, the curbing of monopoly power, and the promotion of a strong cooperative movement. He insisted that the only way the working class could regain their freedom was by becoming property owners.

5. Nationalization of Land and Taxation

We have to emphasize that the Walrasian proposal is one of **nationalization of land** but not collectivization of agriculture or society. As Rugină said, landowners would receive proper indemnization, so they would not sustain a loss. This land would be offered by the government to private entrepreneurs who would bid highest price as rent and it would be used as the needs of the people required for food and other purposes. The rent previously collected by private landowners would now go to the state.

As Rugină noted, Walras' nationalization of land is not an expropriation in the communist sense, but rather a repurchase by the government of all land in private hands and paid for by a special issue of public obligations maturing over a certain period of time and carrying the current rate of interest. For Walras, the nationalization of land and **taxes** go hand in hand and insure the state's financial autonomy. [5]

By the nationalization of land and the abolition of taxes Walras believed that his ultimate goal – the realization of his double concept of justice of equality and inequality by preserving complete individual freedoms – would be achieved.

The starting point for his ideas was his view on private property: a person’s property on a good gives the person the right to use that good to satisfy a need, even if it means consuming the good. Therefore, the owner of the good also owns the service provided by that good and the price generated by the good. As far as land is concerned, all people are moral persons and have to equally profit from the natural resources that are available. And this is applicable in the benefit of the state, in the name of commutative justice. An equitable division of land among the members of the society would not be a right solution as it would be detrimental to future generations. Land must be collectively owned by society in a stable and continuous manner. He goes even further and speaks of optimal allocation in dividing and using the land. And this comes as a response to considerations related to justice. But how does the state become the owner of the land? By simply taking away the land from its owners? This would be totally against the liberal principles. Or by repaying the owners? This would bring no advantage to the state whatsoever.

Once the state becomes owner of the land, it must not administer/manage it.

Walras questioned the legitimacy of **taxes**, both proportional and progressive taxes. They go against the principle of justice, they deprive individuals of part of their revenues and prevent them from reaching their ideal. Walras was totally against income tax, which he thought violates both social interest and social justice. [5]

The third stage or step, beside nationalization of lands and removal of taxes, would be to let the economy function by itself under the superior rule of competition as soon as the land has been nationalized and taxation has been abolished. [3]

6. Conclusions

Walrasian social economics are built around the individual, the state and the

society. Leon Walras depicted a social system based on liberty, freedom, justice, and equity. In the distribution of social wealth, he stated that there must be a part made available to the community at the same time as a part made available to private ownership. In his theory of property, Walras assigned land and rent to the state after assigning personal faculties and wages to the individual.

He also made it clear that there is a social morality which is distinct from individual morality. As a consequence, to Walras, society cannot be viewed as the sum of individuals motivated solely by economic rationality.

For Walras, the state is a legitimate part of society. This inclusion in society should be rewarded by land ownership and land-rent should be its only source of income. In his view, government expenditure could be entirely financed by land rent, which translates into land owned by the society and not by individuals. And, if land rent is the sole source of state revenue, it may also replace taxation. Therefore, Walras called for tax reform. Taxes are unjust in the sense that they are a consequence of the opposition between the state and the market.

Abstract

The external migration of people is not limited only to geographic movement; it is also a much more complex process, which brings up for discussion more items.

The changes caused by migration in its various forms (internal and external) impact on the economic, political, social and cultural life.

They occur both at the place of origin, from where the potential migrants would leave, as well as at the destination, where they finally settle.

Key words: emigrant, economic costs, identity, migration

J.E.L.Classification:F22–International migration

1. Introduction

In a vast specialty literature, migration is treated as a movement, more or less organized, of a group of persons, moving on a certain territory or area of a country. This extremely controversial issue, the intensity of the migration’s phenomenon, has become, in my opinion, in the last decades, a „delicate” issue, being often treated superficially or theoretically.

The main economic and social causes of this phenomenon are often debated, as well as the positive or negative impact on the countries involved. On the other side, the financial and social costs that leverage on the immigrants in the destination country are rarely discussed.

2. Migration – between present and future.

For as long as Homo sapiens have existed, the members of this species have migrated in search of food, shelter, or to run from disasters or conflicts. Population movements were a frequent phenomenon during each historic period, all of them having in common the migration’s phenomenon. All these movements were related to searching for a better way of life, or to conquering new territories – the barbarian invasions in the middle Ages. [1]

Roberto Merlo in his work „Italian literature of Romanian migration – guideline and analysis” considers that „migration, by nature, goes beyond the political, cultural, linguistic and national barrier, and the literature of migration is written in a national language, which is not always free of difficulty and misunderstanding, if we relate to national literatures and their languages. ” [2]

Through the years, the migration phenomenon came to the attention of not only the economists, but especially the sociologists, which have studied the problem of migration. The foreign immigrant, in Antonio Perotti’s opinion, may be defined through his past, present and future. The author thinks that the immigrant may identify himself to his past, present and future. [3]

Antonio Perotti considers that the immigrant, through his past, feels like he has no „roots”, arriving in a new country, facing a new culture. At this step he feels like a stranger in a new world, having a past of his own, a stranger in his adoptive country.

In this situation, the reasons and main causes (economic, political, and social) that determined his migrations play a secondary role.

Through his present, „he is newly-settled”, resident for a certain period of time in a new country. In this phase, his interests come first and competes with the ones of the host-population, having common and even similar interests with the local community from which he is now part of, even sharing the same interests with other foreign immigrants living in the same country as he does.

Through his future, his „temporary” situation will gradually change in time, so that, in the end, he will be totally integrated in the new population, as a consequence of socializing and cultural and linguistic integration. In this phase, his personality changes radically, taking on fully and completely customs from the host country. For some immigrants, this phase is similar to ignoring their own and their parents’ origin.

Migration leads to a good living for the people taking this decision, being preceded by the need of adventure and the curiosity of the young people, eager to discover new horizons and new parts of the world. This may be considered to be a reason for mobility: the mobility of human resources as a part of the development of the human capital [4].

3. The determinant factors of the external migration

One of the most important factors triggering the migration process is the economic and global context, meaning the economic crisis and the economic recession many countries are going through.

The economic cause gives migration a real, current meaning, also the most important at the base of the migration decision.

From the political, social, xenophobic and religious point of view, people leave an area where they feel oppressed or unsafe.

At macro economical level, migration leads in time to the destabilization of the labor force market, either through creating a surplus of supply in some areas in the host country, and also a deficit in some sectors

and areas in the origin country of the emigrant.

The over saturation of the labor force market in a certain sector, well developed and with a real economic potential, may be seen as an aggressive phenomenon by the native population of the origin country of the immigrant.

At individual level, there are positive phenomenons that lead, in time, to an increase in the living conditions of contempt and the feeling of certainty regarding the workplace, but, at the same time, there are a series of negative phenomena regarding the relation of the immigrant with the group in the host country.

Dudley Baines tries to find an explanation for the dimension of the migration’s phenomenon, and reaches to the conclusion that emigrants choose to migrate taking into consideration certain characteristics of their country. The author considers that we may talk about a so called selection of the migration’s phenomenon, which takes place and forms according to the age and gender of the migrants. [5]

Regardless of the age or gender of the migrant, now, as it was 200 years ago, the main causes at the base of the migrating decision are economic and social in the host country.

The status of the immigrant when he takes the decision to migrate is unclear. By the nature and dimension of the phenomenon, the migrant is faced with, maybe, the biggest and the most important experience in his life.

4. The Romanian emigrant in the current global context – „Finding the identity, again”

If people migrate under serious political and economical constraints, such as the refugee emigrant, the migration would be, for the possible migrant, an option known as „the worst one”, which may involve a real decrease in the good-being and the capacities of the pre-refugee. [6]

The main determinant factors worldwide generating the migration are: economic climate, together with the population increase in the migrant’s country, and sometimes, with armed conflicts, religious persecution and xenophobic attacks.

The intention to migrate or to stay home is influenced by a series of factors: language, cultural barriers, personal opinions of the potential emigrant on changing the location, leaving the family and friends, changing the country and birth place.

Trans nationalization of the „migrants’ life” led to the identification of models for the assimilation of migrants. It is more and more difficult to determine a clear distinction between the two already traditional terms in the specialty literature: „origin” and „destination”, or between other terms, highly used: „temporary”, „permanent” and „returning”, because the migrants’ life is characterized by circulation and simultaneous commitment between two or more societies (communities) they are part of [7]

Romania, after 1989 lived the migration’s phenomenon in various phases and forms, our country being a supplier of cheap labor force for the countries in Southern Europe: Italy, Spain, Portugal and Greece.

Because of the fact that many Romanians transited these countries in the last twenty years, we may say that the Romanian migrant, once arrived in the destination country, „takes on” many profiles or personalities, depending on the destination place.

Sociological studies on groups of migrants showed that there is a migration culture, in which communication between the undecided, the ones staying at home, and the group of migrants is very important.

In time, the undecided will become more determined to migrate to other countries, this proving that the simple contact between the one staying home and the migrant returning home is sometimes vital in taking some decisions regarding the future of the potential migrant and his family.

Romania is not just a gate from East to West (such as Portugal, Spain and Italy – gates for South-North), our country being considered a heterogeneous labor market, which needs qualified workers, and maybe less qualified in various domains.

Romania is more prone to migrating than other countries in the EU, considering the defective labor force market, significant discrepancies in wages, several shortcomings and a rather high unemployment in certain regions of the country.

The Romanian citizen has a strong motivation for migration: poverty in certain areas of the country, low income, the lack of real professional opportunities, low living conditions for some part of the population; all these lead to the intensification of migration.

Most of the Romanians left the country in order to significantly improve the financial situation of the persons left behind at home, and the same time, to have a decent living.

The choice of remaining in the Western countries in full economic recession or to return home to increase the number of unemployed becomes a real issue for the Romanian migrant, who is now hopeless, in a completely foreign country.

Working abroad is most of the times a temporary strategy, many Romanians, as well as other migrants, not having any other choice. They have to take on such a strategy – compromise, for themselves and their families.

Many of the Romanians that leave to work and cross the border for the first time, and who bring with them the children, relatives, friends, start „colonies”, which turn into diasporas, causing a real clash of civilizations and assimilation of a new culture, traditions and customs.

The countries in Western Europe have become so far a multi-ethnic environment, having important communities of non-European immigrants.

Never the less, EU was the promoter of such an „experiment”, being a multicultural and multi-religious entity, from the very beginning.

Furthermore, the idea of „citizenship” and „national identity” are renegotiated in the mutual language of the actors involved in the migration process, as a normal reaction to the contemporary models of migration.

5. Expenses of the migrant abroad

The socio-economical determinants generate a series of factors that contribute to increasing the labor force mobility.

The most important are: labor force market segmentation, the need for much higher salaries, regional (country, continent) demographic changes, liberalization of the economic and labor force market, the development of multinational companies and

foreign investors which generate jobs, and last but not least, the development of the commercial exchanges between states and regional infrastructure.

On the other hand, the financial and social costs cannot be overlooked, these costs being paid by the main actors of this process: the foreign migrants arriving from different corners of the world, in much more attractive countries, from an economic and social point of view, hoping for a better life.

The financial costs paid by the migrants include: decrease of the migrants' savings, taking a job completely out of their study range, some migrants are forced to constantly move from one place to another, since they don't find a job in a certain region, this generating extra costs and additional expenses, immigrants are paid much less than the normal wage for the job, most of the time, employers take advantage of their migrant status and give them much lower wages than the official level of the market, foreign migrants are often forced to pay taxes, higher than the ones paid by the local population, most of the times the migrant work without legal forms in the host country.

The social costs paid by the migrants are also considerable: the feeling of frustration, of not being able to fulfill their goals in their own country and to be forced to work in a domain completely different than the one they specialized in. Making friends within the local population is hard.

This thing is mainly generated by the negative image that the local population has about immigrants, from local and international media.

In time, many migrants who are away from their families and their loved ones fall sick with certain diseases, depression, mental or heart illness being some of the most common ones. Many migrants feel discriminated at their job, and so do their children studying in the schools in the destination country.

The racism and xenophobia accentuate the personality of the migrant changes in time, along with his perception on his family or his own country. Most of the times, because of the significant income in the destination country, migrants are often seen by the communities at home as being snob, new-money people.

All these lead to the increase of the social discrepancies between the ones that stay at home and the ones that leave.

According to Costea Moarcăș Claudia, the intensity of the migration's phenomenon is seen as a result, a main feature, but also as a necessity of globalization, talking mainly about „different languages between developed countries – developing countries – poor countries”, about a true „exchange or globalization of competences” for the mobility of employees in the developed countries, because of the rather similar high economic level, the desire to migrate in order to earn more doesn't exist. There is a replacing flow, consisting of foreign migrants. [8].

There is also a real „exodus or export of competences”, specific for a long term or permanent migration, without any compensation by comeback, to earn much more and to balance the national budget, training human resources (specific for developing countries.) [9]

The economic crisis in the latest years has affected all the EU member states, having political, economical financial and social consequences, but especially on labor force migration between countries.

It is well known and proved that during economic growth, migration has also positive effects, for both the origin and host countries. But either we are in a new economic crisis or in strong recession, the Romanian is still willing to leave to work abroad, being ready to leave home the „Romanian dream” and to embrace „the European dream”

The Romanian is willing to „reluctantly leave at home the family, relatives, children, but, at the same time, he leaves behind a much darker social aspect: poverty, unemployment, corruption, red tape, and his own inability to perform, all these things do nothing but determine the fate of the Romanian migrant.

„The migrant is a man between worlds, he has needs and life strategies he strives to achieve by working abroad, and at the same time he is a man that tries to keep or increase his quality and name.” [10]

6. Conclusions

Migration abroad, regardless the origin country brings up for discussion different

opinions shared by the migrant's family members or by the persons that do not have anybody working abroad, creating two groups, for and against migrating.

According to the two sides: migration contributes to a certain development of the origin country, it helps the ones abroad achieve experience and broaden their horizons, but at the same time, migration breaks the families left a home, make the migrants more interested in money, accentuating the discrepancies between rich and poor, and many "outsiders" are seen as „snobs" by the ones not having relatives working abroad.

The persons involved must not be analyzed through the group they are a part of. They must be seen as individuals. People are different by nature, have different behavior, and have their own ideas, opinions. As a consequence, the motivations and causes of a certain behavior are different.

The migration of persons everywhere must be analyzed differently. Maybe, something that for someone is a choice or a life decision for another one may be something harmful.

Our choices are, most of the times, different, may they be subjective ones, or based on tradition. This differentiates us from the other members of the community we are part of.

Controlling the Influence of Globalization on the Firm

Dimitriu Mihail

Centre for Financial and Monetary Research – Victor Slăvescu, Romanian Academy
dimitriu689@gmail.com

Abstract

Currently, the companies are obvious changes in activity mode of organization, type of development, behaviour towards the environment. There are different views about the causes of these changes, but all the authors mentioned globalization as one of the causes.

Focused on the relationship between globalization and method of organization and control at the micro level, this study develops the concept of interface and presents a working model of it.

Key words: microeconomics, globalization, interface, internal structuring, internal control, interface,

J.E.L. classification: D00, F60, F61, M10

1. Introduction

Current conditions in which must operate a business made it necessary to solve new kinds of problems. Currently, the company is developing more than ever linked to the conduct of the transformation of resources into sustainable results for clients. Undesirable effects of globalization, the crisis of raw materials, personal crisis and financial crisis are just sides of the same process: the erosion of quality and level of resources used at the micro level. Moreover, from the source of raw materials, energy, labour, business information and resources that transform society outputs required supply shocks occurred (in the broadest sense) to the firm adjusts in various ways. There might be problems in the future that may lead to profound changes in society. Nicholas Georgescu - Roegen said "Every human life born now are down in the future" which means that any change in the current structure leads to a more profound change in

the future and ultimately to hasten the disappearance company!

Any form of adaptation is threatened by the interaction of the company in the short term, with its environment. To be consistent with the objectives of adaptation in the short term adjustment, we believe it would be useful following:

- Identify possible effects of globalization (as a specific form of manifestation of the external environment) on firm

- Analyze general trends of development of society, due to advances in science and technology

- Changes in the leadership change at the microeconomic level, using new tools for control.

2. Identifying the effects of globalization on firms

Globalization is a relatively vague concept of semantically because of its use in political contexts rather than journalistic or scientific contexts. Therefore, an assessment of the impact of globalization (that said, the impact of globalization) requires, first, a definition of the process. For this purpose, we use the definition of globalization proposed by a team of researchers from the Centre for Financial and Monetary Research - Victor Slăvescu led by PhD. Emil Dinga (project "Mix adjustment policies towards achieving sustainable Romania's economic convergence with the European Union" - CNCISIS - UEFISCSU, no. 821/2008 PN II - IDEI 600/2008): all type phenomena necessary, structural, and spatial-oriented fractal nature that occur in a horizon of time at a planetary level.

In this context, globalization, as a process, is generated by the action of all the phenomena of globalization taking place on the time horizon considered. So, there may be many phenomena of globalization, "contemporary" with each other, which

means that at every moment of the analysis, we have a certain "profile" of the globalization process as a whole given the composition profile of the process phenomena (for example, nowadays, global warming phenomenon is specific to contemporary globalization, while in the 18th century, the phenomenon of industrialization was the most visible and effective globalization). Also can be no question of globalization (or a limited number) which satisfies the lead in the overall process of globalization.

Among the effects of globalization most often mentioned in the literature mentions the following:

- The particular challenges of global economic governance, "Interdependence would cause when des-integration, that competing and conflicting regulatory agencies at different levels. Such a conflict would weaken on global efficiency of public governance." [17]

- From multinationals to transnational companies: "The company will not rely on a single major national location (as in the case of multinationals), but will serve global markets through global operations. Unlike multinational, transnational companies will no longer be controlled or constrained by national policies of certain states. Rather, it will be subject only international regulatory standards imposed and agreed. National governments could no longer take any effective regulation against these standards" [17].

- Continued decline in political influence and economic bargaining power of organized labour;

- Increasing multipolarity in the international political system: "A number of organizations, international non-profit agencies to transnational companies will gain more power at the expense of national governments and using the global markets and the media could call and obtain legitimacy consumers / citizens. In this way distinct powers of national states will decline, even if the majority of their citizens, especially in advanced countries will remain attached nationally. In such a world national power would be less efficient and will not be able to be used to achieve economic objectives". [17]

Generally, it speaks about the seven sins of globalization and, in addition, about the globalization of economy. They are:

- Alienation. Leaders of the third world believe that their destinies are determined by the forces of globalization and tsunamis hope this turns into a beneficial force for reconstruction and development, not destruction and destabilizing force threatening. Experience Africa seems to be the most frustrating, because it continues to be the most favoured part of the world due to lack of economic cooperation within globalization.

- Selective action. Developing countries say NO selective globalization, i.e. liberalization of trade, investment and financial flows was done in an accelerated benefit only developed countries, while the momentum was reflected in a much weaker intensity for products imported from developing countries.

- Marginalization. Most developing countries consider that the only visible consequence of globalization is their own marginalization. Marginalization is the situation that best describes countries outside the "current". Countries that can not keep up with the rapid integration beg special attention not to fall back into the abyss of poverty and decay.

- Return to colonialism. Interests of developing countries are confronted by a series of international sanctions perceived as a return to colonialism. Colonialism returns as IMF, World Bank, other financial institutions and economic cartels and when necessary even military alliances. Globalization reinforces economic dependence, political and cultural.

- Imposition. Multiple options were completed and globalization brings dogma "one size fits all forms." The Cold War and the triumph of one party completely eliminated tensions, but broke the balance, and now the world's countries will have to choose one option. It will be an economic and political system, the drawing of one dominant system.

- Loss of national sovereignty. Shook the foundation's sovereignty and not due to objective reasons, but "due to the widespread arbitrariness in international relations". It produces an erosion of sovereignty with economic consequences, but also a reduction

in the viability of institutions and social stability.

- Loss of identity. New cultural values of globalization come with the system based on irrational consumption in rich countries. Globalization seems to cultural diversity "something old-fashioned." Globalization could lead to a single civilization, standardized according to Western culture. Global world as uniform and the variety will disappear.

- Globalization of economy. In the new era of globalization, the borders were opened, trade barriers were removed, and information flows with unprecedented speed. "Turnover of transnational companies and cross-border criminal organizations explodes. Colossal fortunes are often the result of drug trafficking and arms smuggling, prostitution, money laundering, all under the umbrella of corruption. Their opportunities to exploit the system they have never been so high because the world market was liberalized before creating global institutions needed to control and supervision." [5]

3. Trends in development of firms and knowledge society

The economy of the future, mutations will be much bigger than we can imagine at first glance. New types of electronic communication could be used as a platform for expression for political organizations, social and cultural. In the knowledge economy, the product, many changes will occur:

- Shorten the life of the product. To be competitive, companies are forced to constantly launch new products into the market. This means that the cycle "concept, production, presentation, abandonment" is increasingly restricted. There are clear benefits in attracting companies that can promote new technologies, strong companies that can support complex research programs. The products will be cheaper and more competitive. Their quality will be better, and life will be determined by the design (not the materials used). Limiting the lifetime of the product means abandoning the idea of repairing and replacing it with the concept of reliability. This means that the products will be guaranteed to withstand a certain period of time without repairs (because it is impossible

to maintain a stock of spare parts of dozens of products launched each year). However, products that will have a long life (which is likely to need repair) will be made modular. Thus, they, though they look different, according to fashion that year, will be built on the concept that will be kept for years.

- Valuation of high-tech products will tend to grow at the expense of simple, basic. This means that activities which include technical progress in a lesser degree: as agriculture, animal husbandry, production of metals, energy, fuel, etc. become increasingly less effective.

- More and more products will encompass intelligence technology. Mobile communications systems, micro-computers, multimedia systems will be incorporated into household products, in cars, in toys, etc. Future products will be almost entirely automated, robotic, so that physical work will be slowly replaced. On the other hand, the amount of knowledge necessary for people to be able to function normally in society will increase considerably.

- Latest trend of the information society is the idea of "communication" between different products. Example would be smart house that will automatically create living conditions by human presence.

And the companies will show many changes:

- Due to competition from increasingly powerful conglomerates will form big international companies? They will share the risk identification, production and launching new technologies. Strategic partnerships between these large companies will make to local small firms being disadvantaged against subsidiaries of multinational corporations. Competition will move from the local market at a much higher level landing at the international level. To reduce costs, multinational companies have already begun moving production activities in poor areas, where labour is cheap. They were kept in technologically advanced countries only conception and design activities. In this way they spread their branches in different countries, using local opportunities in terms of information resources, natural, human, and legal, to obtain a competitive advantage.

- In the future, companies will become less and less contoured organization. The organizational structure will change from one

pyramid to one network type. From this point of view, the future will resemble firms increasingly less with the current company. They may have no headquarters, do not possess a certain nationality, and employees do not even know each other. Thanks to the information revolution, most transactions will be conducted on-line, business meetings can be replaced with video conferencing and some employers will even be able to work from their own home at a terminal connected via the Internet to a fixed "virtual" .

- On the other hand, multinational firms will seek to eliminate their structure those activities they become unprofitable. As the passage of time and increased decentralization consortia will become more "brand" than what is now known companies. In other words they will be organizations that will produce goods to "mark" a certain quality, and the vast majority of business activities, from conception, promotion, bringing to market products will be subcontracted.

- The companies will develop more and more electronic commerce (e-commerce) in a virtual space with its own rules of procedures.

- It will develop new types of interfaces between the companies, people and artefacts evolved in society, so that the information is "merchandise" the most important in society.

In this context, we believe that means (at least in the current phase of development of concepts) for changing relationships between companies in a continuously changing environment, it is a special interface, an intelligent membrane included in the organizational structure of the company.

4. The concept of interface - tool control at the micro level

Any input or output is noticed first company interface with its environment. [10] In the context of open systems, the interface transfers made of matter, energy, information between the environment and business components with a role similar to the cell membrane.

In the context of this paper, this "membrane" is all the means, tools, techniques, mechanisms and procedures by which the company can make a transfer

(controlled!) of material, labour, energy and information with the environment.

Any "membrane" defined in this way must be permeable enough to be able to exchange from and to the environment, but only within certain limits.

This includes: - a flow transfer - transfer channel - receiver to be part of the interface (membrane) and the entity receiving direct connection with the transfer channel (external receiver) - a receiver to be part interface (membrane) emitting entity which is directly related to the internal environment of the company (internal receiver) - a transmitter which is also part of the interface (membrane) emitting entity which is directly related to the transfer channel (external transmitter) - a transmitter which is also part of the interface (membrane) emitting entity which is directly related to the company's internal emitters (national broadcaster).

The flow of transfer is carried out continuously or periodically, and with certain amplitude. Transfer channel can be potential or active, its activation is achieved when one of the two ends of the channel and emits a stream at the other end, a receiver interface supports the feed (feed material, energy or informational).

Permeability is the fundamental property of the interface that allows the transfer flows from transmission channel in the internal environment of the company.

It is obvious that if closed systems, the permeability is zero, but if we can say that the open system tends towards a maximum permeability? We think not, because the interface by its mode of organization and operation does not allow maximizing permeability.

If maximum permeability as we have two extreme cases:

- Owned by the company would end up being the same as the emitting entities;

- Destroys the internal structure of the company and the entity receiving it disappears.

In both cases, no longer make a transfer and permeability referential disappears.

In general permeability P can be expressed as:

$$P_m = f(\sum F_t, \sum F_i, N, O, G)$$

where:

- $\sum F_t$ - cost for accepting a flow of a certain frequency transfer

- $\sum F_i$ - the cost of accepting the transfer flow (and the type of feed) for a certain amount of

- N - cost "technology" for the construction or maintenance interface architecture

- A - The cost for providing a predetermined degree of organization of the interface

- G - the cost of providing a pre-absorption capacity of the internal environment of the company.

It is very important for the survival of the firm's internal organization of the interface to allow a transfer so as to ensure the functioning of the parameters set according to company strategy, plans and tactics adopted.

Shock may occur when:

- Transfer flow exceeds the capacity of the channel and then transfer lock can be turned in shock to the issuer;

- Transfer the flow exceeds the capacity of the receiver;

- Transfer flow is changed or turned off during transfer, because the issuer or change channel transfers properties.

- Transfer flow is blocked inside the interface, although it has a utility company's internal environment.

- Transfer flow past the interface and blocks the organizing company's internal environment.

From the point of view of the firm, shocks occur when flows exceed certain predetermined limits transfer of entity sets (or transmitters) and its impact on the organization.

It should be noted that the organization must be seen in two ways:

- The internal organization of the firm in general

- The internal organization of the interface. Usually overlooks the fact that an interface is organized in a certain manner, including items, relationships, actions, processes, mechanisms and right is carried out, but all are more or less noticeable depending on the size of the interface and / or company.

In this vision with shocks occurring on the interface can transfer to the internal environment of the company or be stopped with the interface and have a change in the organization of the interface, and then if the

flow type shock moves forward, there is a change in internal organization of the firm itself.

Transferring a shock through all these "steps" - transmitter, transmission channel, the initial receiver of the company, working with the interface, the transfer to the company's internal environment and changing organizational status is a certain erosion of the "quality" of shock.

This erosion that is carried out in a suitable time frame, the receiving entity may be beneficial for the purposes of proper adjustment.

5. Conclusions

This paper tried to add some views on how certain specific concepts dynamic approach to business firms may alter the methodological level. One of the biggest obstacles reported by several authors [14,32] is the requirement to gather a large amount of data to characterize the dynamic system (as it can be considered a company). Taking them is very often hampered by the lack of appropriate measurement tools for dynamic variables, the excessive prolongation of the duration of the research, the reactions that may occur in some cases the subjects to repeat a task request a number of times (decreased motivation or fatigue, abandonment).

Our research is at the beginning, but what we do believe that efforts in recent years to integrate the concept of interface in economic theory will lead to proper management of firms in an unpredictable future.

Abstract

In this paper we intend to present an overview of the advantages of using R – the most powerful statistical software.

The statements on R are exposed versus SAS and SPSS – actually the most used statistical software in Romania. The study also focuses on comparing strengths and weaknesses of SAS, SPSS and R.

As an example on how R is much more flexible than the other software, we used a statistical analysis.

We will see how dominant R is already in the academia and how it is predicted to be in the commercial. It is time now for open-source powerful software for official statistics as well as for companies and business.

Keywords: R, SAS, SPSS, statistical software, statistical analysis, variable selection

Clasificare J.E.L.: C46, C81, C82, C87

1. Introduction

The use of data analysis tools in companies and especially in official statistics offices has a high inertia to change, often because of the high aversion to change caused by the use of commercial software generally with a predictable cost.

This paper aims to set users wondering more about the different dimensions which can be used to compare statistical software and to compare the strengths and weaknesses of them.

R is the most powerful statistical language created by statisticians for statisticians. In the presented circumstances, it is necessary to reshape the thinking at academia and official statistics level in order to expose R's advantages.

As an extra accreditation for R, it is appreciated the affirmation of Norman Nie, co-founder of SPSS in the 1960's: "R is the most powerful and flexible statistical programming language in the world". Currently, Nie is CEO and president of Revolution Analytics, a company that provides commercial version of R.

2. Literature review

In the last few years, the literature became wide as regards the statistical software; also regarding comparisons between the most commonly used statistical software: SAS, SPSS, R, Stata, Matlab, Statistica.

The technical report "Strategically using General Purpose Statistics Packages: A Look at Stata, SAS and SPSS" [5] draws a parallel between SAS, SPSS and Stata. There is also a section dedicated to R where it is characterized as hard to learn.

A real valuable study is "R for SAS and SPSS users" [8] because it presents in a

comprehensive and captivating way the use of R for users of SPSS and SAS; the book could be a real useful “translator” kit.

Also, for the ones who want to migrate from other statistical software to R and need further assistance, there is a special website [17]. Anyway, R stands in a continuous develop and release at academic level, growing list of print books and e-books.

3. The advantages of R

While SAS and SPSS have many things in common, R is different. It is a software with personality.

First of all, it is open-source, the cost of using it being related only with the training of users. Also, its numerous GUIs, IDEs and packages are freeware. R is working on various operating systems: Windows, Linux, Mac OSX and it is easy to install and configure.

The fantastic useRs community grows continuously. The users of R have a very enthusiastic behaviour and they consider the knowledge exchange a real challenge. The user support is based on a very active mailing list, blogs and dedicated forums.

R is used for statistical analysis, data manipulation, visualization and exciting applications in various fields like: statistics, economy, financial, business, genetics, engineering, biology and many more.

One of its big advantages is the linkage with the way statisticians think and work (e.g.: keeping the track of missing values).

It bears Excel integration via RExcel; SPSS has not this issue available. Other big easement is the use of mix-and-match models for best results and re-use and reproduce new discovered techniques on analytic operations that the user is going to perform – this is difficult in SAS or SPSS. R functions can nest inside one another, creating nearly infinite combinations of output, in this way it gives the warranty for the best result.

Also, R could be a threat for Geographic Information Systems (GIS) because it has great and competitive tools for a wide variety of map functions and projections. Also, R has interactive motion graphs and charts [11]; SPSS has not this feature available.

R supports connection with the main commercial software, such as: SPSS, SAS, Matlab and Statistica. It is also integrated in

one of the biggest giant of databases: Oracle through Oracle R Enterprise [12].

R offers the freedom to use for teaching real-world examples from outside organizations, which is forbidden to academics by SAS and SPSS licenses (it benefits those organizations, so the vendors say they should have their own software license). R also gives many opportunities to the open-minded people that use it. The contribution users have to R is a real value-added for the software itself as well as for the contributors.

The wide area of use - statistics, journalism, mapping, finance, forecasting, social networking, computational biology and many more – makes R a common language for all the researchers and data analysts.

4. Variable selection for stepwise regression in R

4.1. Conceptual framework

When a multiple regression analysis has a large number of explanatory variables (exploratory studies) it is not feasible to fit all possible models so it is more efficient to use the variable selection method. Hence, if we do not know in advance what variables to be included in the model could be applied two algorithms (regression step): forward stepwise regression and backward stepwise regression.

In case of forward stepwise regression, all the predictor variables are added one by one in the model and are correlated with the variable of interest. The variable that has the highest correlation is introduced first in the equation. The next variable which is introduced into the equation has the highest correlation, after being eliminated earlier variable effect. The process continues until the predictor variables contribution is too small to be considered. At backward stepwise regression, all predictive variables are introduced into the model, being successively removed (in case they do not have a significant contribution).

4.2. Description of dataset and R procedures

We considered a dataset with 18

predictors and one response variable (y). The predictors refer to some socio-demographic characteristics: gender (male, female), age group (gr), activity (active), marital status (marst) and education level (edu).

In the next section we present two procedures developed in R which are able to perform the selection of variables from regression models.

The first one is included in MASS library that could be uploaded in R environment. The method used for the variables selection is **stepwise regression**.

The stepwise selection (forward, backward, both) can be performed using the stepAIC() function from the MASS package[10]. stepAIC() performs stepwise model selection by exact AIC.

```
>library(MASS)
>fit<-
lm(y~male+female+edu_inf+edu_med+edu_
sup+marst1+marst2+marst34+activ1+activ2+
activ3+activ4+activ5+gr_1+gr_2+gr_3+gr_4
+gr_5,data=mydata)
> step <- stepAIC(fit, direction="both")
Start: AIC=-2592455
y ~ male + female + edu_inf + edu_med +
edu_sup + marst1 + marst2 + marst34 +
activ1 + activ2 + activ3 + activ4 + activ5 +
gr_1 + gr_2 + gr_3 + gr_4 + gr_5
```

Table 1. The variables selected in the final model

	Sum of Sq	RSS	AIC
<none>		8379.9	-2592455
- edu_med	0.21	8380.1	-2592442
- gr_4	0.22	8380.1	-2592441
- gr_2	1.37	8381.2	-2592358
- edu_inf	5.66	8385.5	-2592048
- marst1	7.36	8387.2	-2591926
- gr_3	9.33	8389.2	-2591783
- female	18.47	8398.3	-2591124

Source: R output

The RSS represents the residual sum of squares. Akaike information criterion (AIC) is a measure of the relative goodness of fit of a statistical model:

$$AIC = 2k - 2\ln(L)$$

where:

k=the number of parameters

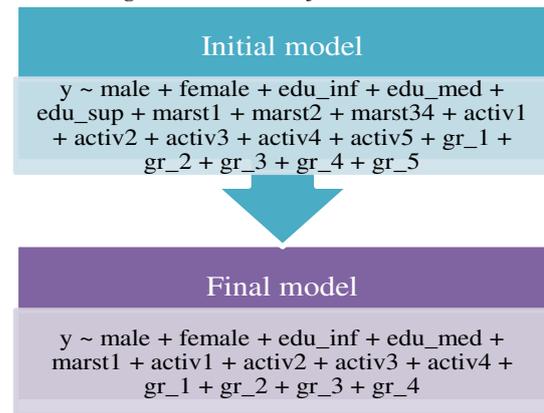

L=the maximized value of the likelihood function

The AIC is compared for every step in the regression and in the final will be considered the optimal model.

Hereinafter it is performed an ANOVA test in order to establish which is the final model. The command line and the output for ANOVA test are presented below.

```
> step$anova
```

Figure 1. Result of ANOVA test

Source: R output

The eliminated variables (gr_5, activ5, marst34, marst2 and edu_sup) are described also in the output of ANOVA test. They are out of the final model because the Akaike criterion is not satisfactory.

Alternatively it can be performed **all-subsets regression** using the leaps() function from the leaps package – which is more complex. In the following code the argument nbest indicates the number of subsets of each size to report. In this example, the ten best models will be reported for each subset size.

```
>library(leaps)
>leaps<-
regsubsets(y~male+female+edu_inf+edu_me
d+edu_sup+marst1+marst2+marst34+activ1+
activ2+activ3+activ4+activ5+gr_1+gr_2+gr_
3+gr_4+gr_5, data=mydata, nbest=10)
> summary(leaps)
```

Subset selection object

```
Call: regsubsets.formula(y ~ male + female +
edu_inf + edu_med + edu_sup + marst1 +
marst2 + marst34 + activ1 + activ2 + activ3
+ activ4 + activ5 + gr_1 + gr_2 + gr_3 +
gr_4 + gr_5, data = amigo, nbest = 10)
```

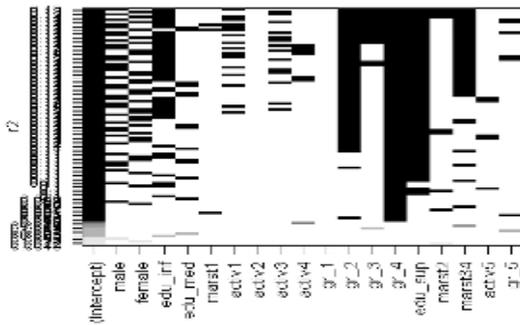

In this stage of the analysis 10 subsets of each size up to 9 are computed by an

exhaustive selection algorithm concerning the statistical significance of each variable. Below it is performed a plotting of a table of models showing variables in each model. The models are ordered by the selection statistic.

```
> plot(leaps,scale="r2")
```

It gives rise to the output in the Figure 2.

Figure 2. Plot table of models showing variables in each model

Source: Processing of the authors based on dataset

The black in the plot indicates that a variable is included in the model, while white indicates that they are not. It is considered R-squared criteria. Other possible criteria that can be used are adjusted R-squared criteria and BIC, respectively, it can be typed:

```
> plot(leaps, scale="adjr2")  
> plot(leaps, scale="bic")
```

5. Present and future of R development

Currently R is still a controversial software. Many people are still sceptic on it. Even so, R enjoys a great popularity among academia and companies. Some companies and organizations that are using it are the following: Google, Facebook, World Bank, Pfizer, Mozilla, Johnson&Johnson, Shell, The Economist and The New York Times. Also, R is used by some official statistic offices like: Austria, Australia, Italy, Netherlands and Canada.

In commercial companies R is in a similar position now to how it was in academia a few years ago.

According to the previsions of Patrick Burns [1], in 2020 R will be a dominant force in business similar to how it currently dominates in academia.

The Language Popularity Index [13] currently ranks R onward SAS.

Currently fighting with the three giants of the statistical computing – SAS, SPSS and Stata, R is in a continuous release and upgrade of its components. Some experts [7] have already forecasted that year 2015 will be the beginning of the end for SAS and SPSS. According to the latest data [6], there are 6,275 R packages in all major repositories, 4,315 of which at CRAN.

6. Conclusions

The selection of a subset of predictor variables from a larger set is a controversial topic. In this study the most efficient two methods are presented: stepwise regression and all-subsets regression.

R offers flexibility and has many cutting edge features. Those who are able to access its power would be able to access tools that may not be found in other software. This might come with a serious investment of time to sufficiently use R.

Externalities, Public Goods and Natural Monopoly as Market Failures and Their Implications for the Consumer

Abstract

The reality of daily life gives us sufficient examples of situations in which individual decisions within free market do not automatically and warranted lead to a global economic optimum. Such a situation is denominated as “market failure”, both understood as “the failure of a more or less idealized system of price-market institutions to sustain “desirable” activities or to stop “undesirable” activities” [1], but also as any performance of the market which is considered less better than the best performance possible [2].

Specialized economic literature generally distinguishes four categories of market failures, namely: externalities, public goods, natural monopoly and information asymmetries.

The present paper will focused on the first three of these, both from the point of view of generating causes and the effects involved on the consumers, and from the point of view of the possible solutions for rectifying them.

Key words: market failure, consumer, externalities, public goods, natural monopoly

J.E.L. classification: D11, D49, D62, H41

1. Introduction

Rational decision theory produced, in time, decisive demonstrations of individual rationality insufficiencies, the best known being *prisoner’s dilemma*, constructed by starting from a simple mental experiment, based on the idea of a game in which two prisoners under suspicion of committing a crime together participate and who are

separately investigated by police authorities, without being offered the possibility of communicating with each other.

They are suggested the following deal: if they betray their accomplice, the one who betrays will receive a gentler sanction, and the other the maximum penalty. If both betray, they will receive half of the maximum sanction, and if both choose to remain silent, they will be convicted for a minor crime. As the two suspects can not communicate, they must adopt the most rational decisions individually, respectively more advantageous for each one of them. In fact, paradox intervenes, consisting in the fact that each of the two prisoners will make statements in order to obtain individual acquittal, but a maximum penalty for the accomplice, by following the maximum of individual benefit. The final result will be that both will make simultaneous statements, thus reaching not to the optimum solution, but, on the contrary, to an equal punishment.

So, the two suspects will adopt the most rational decision from the individual point of view, but which finally proves not to contribute at all to getting the most rational, respectively the most advantageous result for none of the prisoners, following the aggregation of the two decisions.

2. Externalities

This mental experiment can be very well translated into free market perimeter, within which rational economic agents may influence by their actions the activity of the other participants in the market by following their own interests for maximizing the benefits, without desiring to do that

intentionally. Within this context, we deal with the so-called *externalities* or *external effects*, which designate the consequences which consumption activity or that of producing a good by an economic agent can have on other economic agents, without reflecting these interdependences in the market price system.

Such situations in which consumers can also be enlisted may appear when a consumer's individual satisfaction depends not only on the quantities of products and services they consume, but also on other consumers' satisfaction (for example, the complaints formulated by dissatisfied consumers with regard to a specific product or service may attract the supplier's reaction of improving the offer or provided services, by which other consumers will also profit, who have not confronted such a dissatisfaction yet) or when a consumer's satisfaction may be influenced by producers' activities not only through offered products or services which he consumes effectively, but also through other modalities (for example, third persons may suffer prejudices as a result of vicious products offered by a specific supplier and effectively consumed by other consumers) – situations denominated by Tibor Scitovsky “the interdependence of consumers' satisfaction”, the first case, or “producer's indirect influence on personal satisfaction”, the second case.[3] But in both situations, the issuing agent of such an external effect will not take into consideration in his calculations the relation cost-advantage and the beneficial effects (in case of a *positive externality*) or the damaging ones (in case of a *negative externality*) his behavior can have upon the other participants in the market, so that the social value of the undertaken activity will differ from its particular.

The restorative action in the situation of putting forth the externalities consists in their internalization, by assuming by the initiator the costs or marginal benefits generated by it. The way in which the initiator of a negative externality can be made responsible, depends on the number of affected parties, as a rule. Thus, if their number is small, the most accessible solution is found within the market itself, by the agency of the negotiations that can be developed, in a particular plan, between the involved parties in order to

establish a voluntary agreement of compensation or of “bribery” for the damaging external effects produced by the developed activity.

The classic example in supporting this point of view is offered by Steven N. S. Cheung, who analyzed the situation of reciprocal external externalities which arise between bee-masters and the owners of apple orchards in Washington state (apple growers offer valuable services to bee-masters by means of apple flowers which constitute a major source of food for bees, and bee-masters supply services to the former by the help of the bees which pollen naturally the apple flowers). The system of contractual relations developed between them, on the basis of voluntary agreements concerning the allotment of hives and honey flows, approximate rather well the functioning in optimum parameters of a free market in which resources are allotted efficiently.[4]

Following the same example, consumers may address with complaints to the producers in order to find an amiable solution to such a disagreement, which becomes possible through bilateral negotiations or by appealing to a third independent party, a mediator, who offers a solution to this effect.

In case of failure concerning the reaching to a reciprocally advantageous agreement, a different alternative that looms is represented by the legal system, that is constituted in an institutional mechanism of correcting externality problems, by dictating and applying some clear regulatory laws of civil and penal responsibility by law courts, if need be, for the committed crimes (negative externalities are especially considered). For example, strict norms can be adopted by which producer's responsibility in relation to the prejudices caused by defective products offered to third persons, others than the so-called consumers for whom those products were destined, should be provided.

When all these solutions fail and especially in the situation in which the number of affected parties is big, “the salvation” comes from outside the market, and public intervention is justified – either by direct regulation of the activities which cause externalities, or by tax assessment or subsidy of that activity.

Direct regulation supposes in this case the establishment of some standards that must be

fulfilled by the activities inclined to generate negative or positive externalities, on purpose to prevent the production of eventual imbalances within the market, starting from the principle “it is better to prevent than to repair”. Such an example would be safety conditions in consumption that a specific product must fulfill in order to receive marketing authorization.

This approach, also known by the name of *demand and control*, however involves certain deficiencies, such as: the impossibility of taking into consideration the entire variety of situations with which economic agents directly involved may confront, and especially those who can be indirectly involved; excessively high costs generated by the political process which intervenes in the establishment of the respective regulations; low adjustment rhythm of regulation process to the rapidity of the innovation one which determines the permanent occurrence of new technologies. Consequently, it is estimated that a much better technology of encouraging the behaviors society wants is represented by the adjustment of particular costs in order to take into account social costs, too, by levying taxes in the case of negative externalities and subsidizing in the case of positive externalities. Even this alternative is not without problems, a clear identification being difficult and especially the exact measurability of externalities in order to establish correctly the tax level, respectively the subsidy level which must not generate a new imbalance within the market by levying it.

3. Public goods

A particular case of a positive externality which generates an imbalance within the market is represented by *public goods*. To this effect they can be defined, in opposition to “public goods” – “public evils”, which generate negative externalities instead of positive ones (for example the pollution or the corruption of political class).

In Paul A. Samuelson’s classic approach [5] and Richard A. Musgrave’s [6], *public goods* diverge from the particular ones by being *non-rival*, in the sense that they cannot be distributed to each one of them, being communal, and *non-excludable*, because if

they are assured to some of them, they are assured to all and no one can be excluded from using them.

However, these concepts involve a profoundly theoretical characteristic and, as James M. Buchanan also observed [7], while in daily life the characterization of some goods as purely private is obvious, the identification of some goods as purely public is difficult, if not impossible to fulfill. More exactly, in practice we find only the situation of some public goods so-called “impure” or „mixed”, these satisfying only one of the pure public goods, to which effect there can be made a distinction between *club goods* - which, although non-rival, their access can be reserved only to certain categories of consumers (the case of television or radio broadcasting available only by means of a decoder for the decryption of TV and radio signals and without which anyone can be excluded from providing those broadcasts) and *common goods* - which, although characterized by non-excludability, may be divided to a certain extent (the case of communal natural resources, the most frequent examples to this effect being sea and ocean water, fishy resources etc.).

Coming back to the idea that the problem raised by public goods can be assimilated to the one which is characteristic to externalities from the theoretical point of view, economists also applied in this situation game theory, a different *paradox* unfolding to them, that of the “*free riders*”, which appears as a consequence of non-excludability characteristic of public goods. Thus, there will always be individuals who will prefer to profit by the respective goods freely, without contributing proportionally to social effort (tax payment, the compliance with certain limitations, the abstention from certain actions) necessary to assure them. Although morally (and sometimes even legally) condemnable, the “free rider” alternative is the most rational, from the individual point of view, because it maximizes the initiator’s advantages. Paradoxically, if it is adopted by several or each one of the members of a community, this alternative leads to a non-rational solution (disadvantageous) for all.

Starting from this paradox of clandestine passenger, the bases of the theory advanced by Mancur Olson with regard to *the logic*

collective action were laid, which comes to refute the presumption according to which persons with collective interests would voluntarily act together, so that to promote this type of interests. What Olson puts forth is the fact that, on the contrary, “unless the number of individuals in a group is quite small, or unless there is coercion on some other special device to make individuals act in their common interest, rational, *self-interested individuals will not act to achieve their common or group interests*” [author’s underline].[8] In the argumentation of this point of view, Olson starts from the prerequisite that the person who cannot be divested of the benefits supplied by a collective good, once it was produced, is divested of the motivation of willingly involving in the production of the respective good.

An eloquent example to this effect is represented by the collective action of a group of consumers, as it is the case of consumers’ independent associations, as a response to certain incorrect practices a producer commits, an initiative in which certain consumers may decide not to participate in, for example by means of some annual contributions paid to the respective associations and by the agency of which these can finance such actions, but by whose results they can profit without being excluded.

Maybe the most important concern with regard to public goods is connected to who should be in charge with their production and provision, a debate on which no unanimously accepted point of view has been reached either in academic environments or in the political ones. For example, in the situation in which rational consumers, in search of maximizing their own interests, come to degrade the used commons, a situation defined by the collocation “the tragedy of the commons”[9], there are opinions which indicate public authority as the best control alternative on the majority of natural resources, in order to impede their destruction.[10]

At the counter pole we find opinions which underline the necessity of ending the joint ownership system, by starting a privatization process of resource exploitation [11,12], although, many times, the production and provision of public goods by

private sector becomes if not disarmingly ineffective, being very expensive, even impossible.

Practical experience pointed out that, worldwide, neither the state nor the market managed always to allow individuals the maintenance of a long term productive use of public goods.[13,14] The solutions which functioned best were different from case to case, for the most part even the institutions in charge with such categories of goods represented complex mixtures of institutions analogous to the private and public ones.

4. Natural monopoly

Bound up with the discussion with regard to public goods is the one concerning *natural monopoly*, respectively that situation in which a producer can realize a specific series of goods and services to the lowest cost, in comparison with any other economic agent, as a result of some scale economies. The producer who lies in this situation has the “natural”, innate power to eliminate the competition and control sale price within the market, which he will try to raise in order to scale up profit. It is easy to understand that, under these conditions, those who suffer most are the consumers, whose choices are fundamentally affected, the alternative at their disposal being an expensive one and, in most cases, even a dissatisfactory one from the qualitative point of view.

Therefore, another market failure is produced, which, in order to be rectified, the strict supervision by governmental authorities of economic operators’ activity who lie in such a situation and the exercise of a specific control on their price policy were invoked towards protecting consumers’ interests. On the contrary, when the best modality for recovering the allotment inefficiency lost by monopoly prices is represented by the competition, governmental intervention is required by deregulating the activities which are characteristic to such natural monopolies, in the sense of guaranteeing market access for other competitors, which meet consumers’ demands with more diversified offers, and also better, both as to price, and as to quality.

A particular discussion on these lines covers the so-called public services or the services of general economic interest –

respectively those services provided under market conditions and in whose provision certain required obligations must be complied with in order to guarantee the indiscriminating access of all consumers to certain essential services, by a specific quality and to accessible prices – whose representative business segments are naturally monopolized because they constitute the infrastructure of national economy, and regard activities as: gas and electricity input, post, telecommunication and transport services. These segments, initially situated exclusively in public property and having monopolist dimension, were progressively subordinated, in market economy, to an ample liberalization process, a generator of beneficial effects in terms of productivity amelioration, exploitation cost reduction and price fall on the benefit of the consumers.

5. Conclusions

The liberal apology of free market operation assigns to the rational consumer absolute sovereignty on the producer, the economic success of the latter being conditioned by the best possible satisfaction of “master’s” interests – the consumer. This hypothesis, as attractive as it may appear theoretically, its practical validity seems to be rather menaced following the failure of the “magical power” of free market to exploit always the positive influences and to counteract the negative ones, assuring the equilibrium and economic progress. In such situations, the regulatory or “curative” intervention of public power in economy, although not inerrable, often becomes socially unjustified and really eligible, especially when the problem of rehabilitating consumer’s sovereignty within the market by promoting some efficient measures designed to his protection, is raised.

Information Assymetries as the Main Source of Market Failure Affecting the Consumer

Gheorghiu Gabriela

„Ovidius” University of Constanta, Faculty of Economic Sciences

gabrielag3110@yahoo.com

Abstract

The reality of daily life gives us sufficient examples of situations in which individual decisions within free market do not automatically and warranted lead to a global economic optimum. Such a situation is denominated as “market failure”, both understood as “the failure of a more or less idealized system of price-market institutions to sustain “desirable” activities or to stop “undesirable” activities” [1], but also as any performance of the market which is considered less better than the best performance possible [2].

Specialized economic literature generally distinguishes four categories of market failures, namely: externalities, public goods, natural monopoly and information asymmetries.

The present paper will focused on information asymmetries both from the point of view of generating causes and the effects involved on the consumers, and from the point of view of the possible solutions for rectifying them.

Key words: market failure, consumer, information asymmetries

J.E.L. classification: D11, D49, D82

1. Introduction

Traditional economic analyses start from the supposition that rational individuals dispose of the necessary information in order to adjust the best decisions in their favor. Everybody has all the relevant information; everybody knows that everybody knows that information and so on. But, in order to locate, gather and assimilate the information, anyone needs time, effort and resources especially channeled on these lines; that is precisely why the information is nothing but a

commodity, and those who want to obtain it must decide on the quantity of resources they are willing to give up for the benefit of it. Accordingly, there will be an information market where the price for which information can be sold, respectively bought, is formed, on the basis of a mechanism that is similar to that of forming the price on goods and services market.[3]

Thus, it is not surprising the fact that the occurrence within the market of a difference or irregularity between the information individuals have with regard to a specific article is imminent, these always tending to be concentrated in “the hands” of the person who is most interested in obtaining it and who will profit by controlling the way in which a specific transaction in which he participates may finalize, because, as George J. Stigler estimated, “information is a valuable resource: knowledge is power”[4]. All these *information asymmetries*, basically generated by the fact that different people know different things [5], only create significant discrepancies between the results obtained in practice and those visualized under the conditions of the existence of complete and correct information possessed by all market participants, affecting market equilibrium and generating its failure.

Unfortunately, consumers generally run against such a situation, because traders have most of the information connected to their offer, which they are not always willing to share, at least not entirely or correctly, with their transaction partners.

2. How information asymmetries work

Within the market, the main mechanism of transmitting the information to the consumers with regard to the available offer is represented by *prices*. However, economic reality discloses us that prices may differ not only from one good to another, but also that,

when the same good is targeted, its price may differ, not so much from one period to another, but especially, at the same moment, from one point of sale to another, for various reasons, such as: the situation or localization of the respective point, the transportation cost, the services which accompany the respective good etc. Thus it becomes impossible for only one person to know all the prices, reason for which any consumer willing to obtain the most advantageous price must embark on its searching action, by exploring the market.

Yet, the search of the best consumption alternative supposes specific time and money expenses the consumer does not always have, so that he will adventure in finding the information which concerns him in relation to a specific product or service until, in principle, the marginal cost of the search is equal to the expected marginal benefit.

For the mathematical determination of the expected benefit of search (EB) the value of each possible outcome will be taken into account (V_i), expressed under the form of possible prices the consumer might find, together with the probability that any given outcome would occur or that any given price would be found (P_i), respectively:

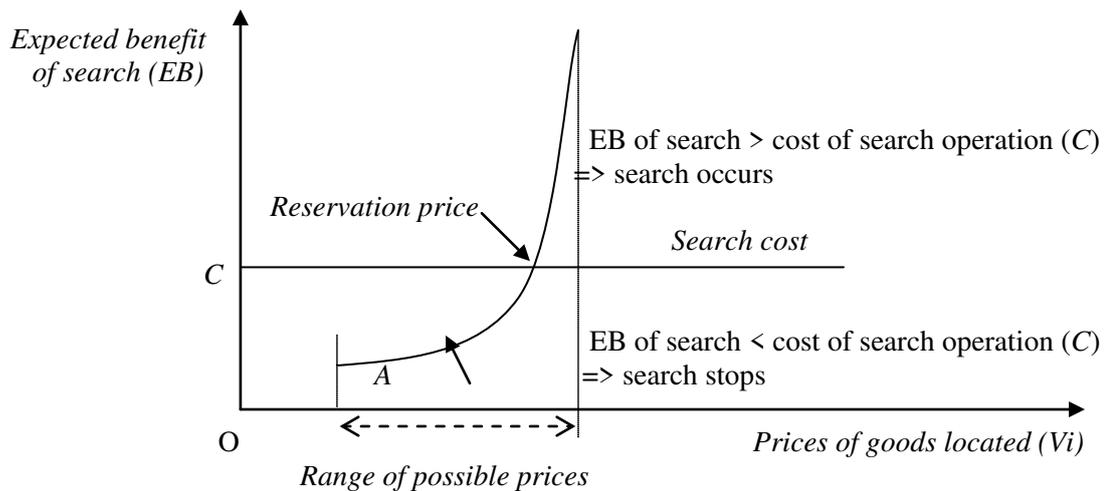

$$EB = \sum_{i=1}^n P_i \times V_i$$

where i - represents the set of possible outcomes, namely the number of prices that can be found by the consumer after searching.

Starting from this mathematical determination of the expected benefit of search, *the consumer's optimal search strategy* (Figure 1) can be graphically described in a system of two orthogonal axes, in which the evolution of the expected benefit of search is pointed out on the vertical axis, and on the horizontal one – the prices of the goods localized by the consumer.

In this graphic representation price is used for making the distinction between the more- and less-preferred outcomes, the expected benefit of search being determined as a difference between any newly located lower price and the price that the consumer had already located. Consequently, in the situation in which he has already located a low price (represented by point A in our chart), the consumer no longer expects much gain generated from the extended search, so the expected benefit of search is low; on the contrary, when he found only high prices, the expected benefit is high.

Figure 1. Consumer's optimal search strategy

Source: D. K. Round, J. Tustin, *Consumers as International Traders: Some Potential Information Issues for Consumer Protection Regulators*, International Trade Law Conference, Attorney-General's Department, Canberra, 23 September 2004, pg. 11

Considering the cost of search operation (C) that must be borne by the consumer, the optimal search strategy will be determined in terms of *reservation price*, corresponding to that level of the benefit expected after the search operation which allows the recovery of the expenses involved. Thus, when even consumer finds a price that is below or equal to the reservation price, he must stop the search and purchase the located good, as the cost of further search outweighs the expected benefit of search, although it is possible that the price of the respective good is not the lowest possible. Similarly, when even consumer finds a higher price than the reservation price, he should continue the search operation, as the expected benefit from further search exceeds its cost.

In practice, the level of the expenses involved by information search process in which the consumer must commit himself in order to adopt the best purchase decision, directly influences the prices established within the market. Thus, prices tend to rise along with the rise of the expenses implied by getting the information, a situation which confers sellers a specific monopoly power, due to consumers' limited mobility in finding better transactions, as to costs. This evolution is explained in that, in proportion as search costs rise, the gain obtained by the person willing to find the lowest price will be more and more reduced, and the extent to which companies will be able to exploit their monopoly position will be larger. Particularly, sellers can exploit the lack of information on the part of the consumers asking them scaled up prices for the offered products.

Consequently, as Stanford J. Grossman and Joseph E. Stiglitz reasoned, since in real economy information costs, prices can not reflect perfectly the information available within the market; or, those who would invest their available resources in order to get that information would not receive any type of compensation, so that the existence of some entirely efficient markets from the informational point of view becomes impossible.[6,7]

In addition to the prices, the transmission of information by the consumers also may take place in the market perimeter through other methods, respectively by means of advertising or the decisions adopted by the

producers and the actions unfolded by them, which disclose information about them, but especially with regard to *the quality of their offer*, which is not always reflected by means of the prices. As a matter of fact, the information regarding the quality of the traded products and services within the market is most difficult to be obtained by consumers, reason for which it represents the main source of informational market failure.

On these lines, two types of asymmetries were developed in economic theory, which start from the pre-requisite according to which one of the participants in a transaction has at least a relevant piece of information in comparison to his partner. To a certain extent, this is inevitable, because any individual normally knows much more things about himself than somebody else. In the model of *adverse selection*, one of the parties involved in the transaction does not have all relevant information in relation to the characteristics of the good or service which is the object of the transaction, while in the model of *moral hazard*, the same party lacks for relevant information concerning the actions the other party may undertake.

- The term of *adverse selection* was initially used in insurances in order to describe the situation in which the persons exposed most to a certain risk are more inclined to sign an insurance contract, since the insurer cannot discriminate against them by reason of the lack of information with regard to the individual risks which are specific for each person. The problem of adverse selection was then generalized by economists to other markets, not only the insurance one, as motor car market, labor force market or capital market.

On these line, George A. Akerlof's remains famous with regard to “market for lemons”[8], where second hand car buyers can not know exactly their quality, respectively if they are good or bad (lemons), so that they will be inclined to pay for them a price that is situated somewhere between the price of a good car and that of a bad one. Owners will sell less good motor cars, being dissatisfied with the very low price received in exchange for them, but they will choose to sell more lemons, being satisfied with the good price they are repaid with. After a specific time, buyers will realize this and will not be inclined to pay the old price asked for

a lemon. Consequently, the price will fall even more, so that more less good cars and more lemons will be offered on the market. Ultimately, good car sellers will be taken out of the market. The conclusion is that *market fails* to keep lemons away because of imperfect information with regard to their true quality, these coming to overlap at the expense of good quality cars.

On such a market, the disposition to sell second hand cars or not at the practiced price reveals information about that car if it is a lemon or not, so that, those willing to sell cars at market price will actually be write-off owners, since they profit by them, unlike the owners of quality cars, who would rather not sell them at all, since they only lose.

Starting from this example, it is logic for us to think that some participants in the market, as lemons' sellers, will not be willing to transmit supplementary information that might jeopardize their image in front of buyers, or their gain diminishes considerably. On the contrary, other participants in the market, as quality car owners, will prefer to transmit information by which the quality of the offer can be perceived, in order to determine the consumers to buy their cars at the expense of lemons.

This imperfection can be rectified by providing the surplus of necessary information in the consumer's benefit in order to adopt the best decision. The undertaking may firstly come on the part of the more informed person, respectively the seller, by emitting signals toward the partner with regard to his credibility and the quality of the offer – a procedure which is known in specialty literature under the name of *signaling* and developed by Michael Spence[9]. Such signals take the form of guarantees; these, the more advantageous they will be, the better quality of the products they will communicate to the clients for two reasons: on one hand, the reduction of the risk of going to supplementary expenses by repairing possible failures, but, especially, on the other hand, the certainty that the seller would not have offered that guarantee if the chances of the product to get out of order had not been small.

Not lastly, an important signaling source on the part of the seller is also represented by advertising, whose main role, estimated in this context, is that of informing the potential

buyers with regard to sellers' identity, the quality and the prices of the products offered by them. But, unfortunately, correct information connected to the offer is not always transmitted by advertising, a discussion on which we will go back immediately.

The initiative of rectifying the informational deficit can come not only from the most informed person, but also from the uninformed one, respectively the consumer, who can undertake search actions of some supplementary details concerning the seller and the quality of his offer, a process named by Joseph E. Stiglitz – *screening* [10]. However this solution involves certain limits which reside in the inherent expenses of previously analyzed search operation.

- A second model of informational asymmetries – *moral hazard*, was delimited by Kenneth Arrow and also exemplified for the first time in the field of insurance services.[11] The informational asymmetries which are the subject of this model are considered, in fact, as a problem connected to *incentives*, because when they are insured against a specific risk, the consumers of such services do not dispose of adequate incentives for undertaking actions that are meant for avoiding the regarded risk. Moreover, insurer's actions are for the most part imperfectly observed or even pass unnoticed by the insurer.

A special case of this model was developed by Stephen A. Ross and became known under the name of *principal-agent problem* [12], which may appear when employing by the consumer an authorized supplier in order to provide him certain specialty services. If their interests are not aligned, the agent will have the tendency to adopt an opportunistic behavior, trying to maximize his own utility, being advantaged also by the principal's impossibility of monitoring him at any step, and especially because of the lack of specialty knowledge, so that he will finally have more information compared to the principal regarding the intentions or the actions he undertakes.

Generally, the problem of incentives degenerates in a market failure when individuals are not gratified for what they do or when they do not have to pay the entire cost of a wrong action. This problem can be solved by the agency of the negotiation

between the interested parties, respectively between the consumer and the service provider, of some contracts in which should be specified very clearly all the conditions for the development of the transaction, especially the obligations which come to each one of the parties in any given situation and the eventual penalties to bear for the breach of contractual terms. However, it is impossible that such a contract comprises all the unexpected situations that may appear during the development of the transaction, and even if it were possible, the parties would lose a lot of time for stipulating them distinctively. Additionally, no matter how complex the contract would be, uncertainties and dispute still may appear, so that this only represents a partial solving of the incentives problem.

Another solution in offering incentives in market economy is constituted by *reputation* [13, 14], which can be gained by a company through reliability and the quality of products, respectively of the offered services. But in order for the reputation to be an efficient mechanism, companies must record losses if it would suffer. Consequently, in the markets where quality is maintained due to a reputation mechanism, price must be superior to marginal production cost (otherwise companies do not have incentives for maintaining their reputation), unlike the hypothesis of competitive markets with perfect information, where competition reduces the prices to the level of marginal cost. In fact, in the markets where reputation is very important, the necessity to establish it acts as a barrier at the market entry and limits the nature of competition; in order to become known, new-comers must offer a sufficiently small price, accompanied, in most cases, by powerful guarantees with regard to the quality of the offered products, conditions under which the access on such a market becomes extremely expensive.

Regardless of the source of origin and the cost of obtaining them, even when the consumer would ideally be in the possession of all the necessary information for adopting the best purchase decision, a different problem intervenes, namely the process of that information, an activity which implies a supplementary effort on his part in order to understand and interpret it. In fact, information process is dependent on several

factors, respectively the time available to the consumer, his education level and the financial income, estimating that, generally, the consumers more educated and prosperous from the financial point of view tend to consult several information sources with regard to the offer, these being separately analyzed by comparison before making the purchase decision.[15]

Moreover, under the conditions of technological developments presently involved in communication filed, especially by extending the use of the internet – which firstly result in the reduction of information search cost, and secondly, the increase of its volume which is at the consumer’s disposal - more and more the problem of informational overload is raised. On these lines, experiential proofs point out the fact that, although consumers feel more satisfied and less confused when they have a surplus of information, the decisions adopted by them are not always the most “inspired” [16,17], a tendency which can be explained by the limited time at his disposal in order to process the available information and which move them toward ignoring certain information sources. Accordingly, the more time and effort are spent, the less remains for processing it on purpose to make a decision, so that consumer’s decisional process involves, in the end, a limited rationality.

3. Conclusions

The internal logic of functioning of market economy, approached from the perspective of the interests and motivations of the consumers in economic activity – producers and consumers, points out the fact that they are in an out of balance proportion, objectively, at the expense of the latter, even if the consumers, with their needs and necessities, should represent the origin and at the same the final point of the production activity. The existence of the “sovereign consumer”, invoked by the supporters of free market, is jeopardized within the context of economic reality, by the failure of the action of spontaneous self-adjustment of the market.

Considering that information asymmetries represent the form of market failure which most often affects the consumers, this situation offers the traders the possibility of influencing their decisions, so that the

choices undertaken by the consumers are no longer guided exclusively by the principle of rationality, but they can be induced by the interests of transaction partners.

Such situations demand the deliberate intervention of public power towards the diminution of this relation which is unfavorable to the consumers up to an acceptable sustainability level.

Economic Issues in the Wind Energy Development at World and European Level

Holban Dana – Elena
Dunarea de Jos University of Galati
dana_marcean@yahoo.com

Abstract

Energy has become increasingly more a commodity we can not replace, a good without which modern life can not exist. Over time, sources of energy have experienced several stages of development. The quantitative involution of energy sources from fossil fuels, leading with climate change and a range of additional costs due to their scarcity, have led scientists to find them a replacement.

Like any large-scale technological innovation, electricity obtained from wind power required huge cost of implementation, turning out to be a real industry. Nowadays, the investment costs are still high, but the need of this type of power to operate, made the results worth the financial efforts of those involved. Increasingly used both in developed countries and in countries with developing economies, wind energy turns out to be not only in line with sustainable development, but also profitable for investors.

Key words: energy, wind, development
J.E.L. Classification: F18, P28, Q42

1. Introduction

Form of renewable energy, along with energy from biomass, solar energy, geothermal energy and water (hydro, tidal, osmotic), wind energy has been used for the first time in human history by the Egyptians as a means of propulsion on the Nile. Wind energy was also used by Christopher Columbus in the late fifteenth century, when he discovered America.[1]

Nowadays, wind energy is increasingly used worldwide, being the energy source that recorded the fastest growth in the last twenty years. Its scale is based on a number of

considerations. Among them, the most important is the idea of sustainable development, based on respecting the environment for future generations, but also taking into account the alarm signals drawn by holding powers of fossil resources about the sharp reduce of their quantity; this fact has determined a reshape in energy production for the purpose of obtaining it from inexhaustible sources.

Along with the purpose of sustainable development, wind energy has created a real market with multiple implications and sides, being involved in the production and commercialization both private enterprises, state and last but not least, the final consumers. The need to implement green energy policy has made this market experience a drastically increase in record time.

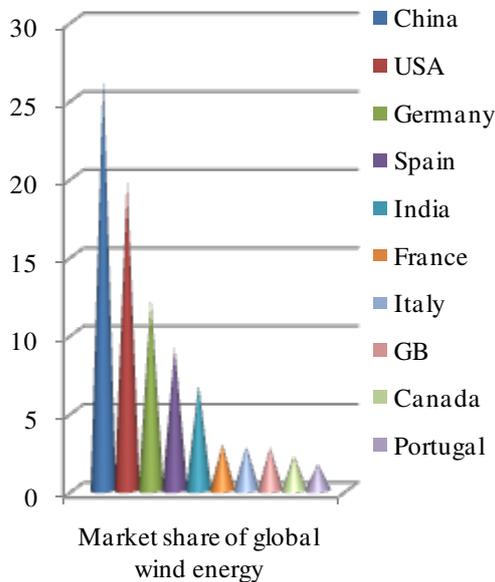

2. The current state of wind energy use

At a worldwide level, the use of wind energy has been conditioned by the existence of primordial energy source, in this case, the wind. The second issue of major importance is the ability of investment required to capitalize commissioning and production of wind energy. These are the reasons why the states that have nowadays the most important role in this sector are China and United States of America, followed by the first representative state of the European Union in this field, Germany.[2]

Germany has always been the pioneer state of the European Union in terms of energy drastic decisions. The decision to eliminate the use of nuclear energy until 2022, and the recent decision to readjust the few coal mines it has until 2018, in order to deter complete pollutive fossil energy production and replace it with a more effective one, determined Germany to invest

heavily in green energy production, this fact being also reflected in production of energy from wind sources.[3]

Figure no. 1: Top 10 market share of global wind energy in 2012

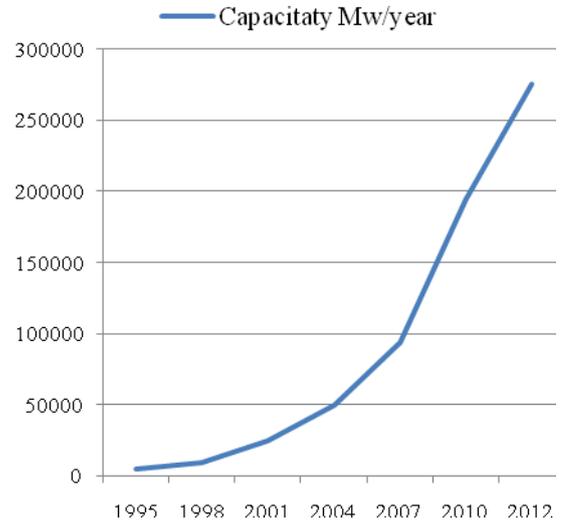

*Source: Own processing of the information in Global Wind Energy Outlook 2012 Report, available at http://www.gwec.net/wp-content/uploads/2012/11/GWEO_2012_lowRes.pdf.

Along with leading members of the wind energy market, a range of other countries with potential wind energy development joins in order to accomplish the target of gradual eliminating the energy produced by fossil fuels, which on the one hand, are of a limited quantity, and on the other hand, they pollute most. All the states that are involved in energy production with wind fuel, made that during 1995-2012 the installed capacity of wind turbines to grow up to 57 times, being a relatively constant trend in rising year by year. As the issue of replacing the classic fuels is more acute, the increased use of renewable fuels is higher. Consequently, the use of wind turbines is expected to see further significant growth.[4]

The European Union sustains this type of energy production with all possible means, assuring legislation and finance for different projects implying green energy. The need of replacing conventional fuel is so stringent that the European Commission established

targets for the 27 states to accomplish and different terms regarding each one of them.

Figure no.2: Evolution of installed capacity of wind power turbines worldwide in 1995-2012

*Source: Own processing of the information available at http://www.thewindpower.net/statistics_world_en.php.

At continental level, the first place in producing electricity from wind power is occupied by Europe, closely followed by Asia. America has the next place and at a long distance, Oceania and Africa. From the technological point of view, the biggest engineering results in elements necessary for these processes were obtained from India.[5]

3. Wind energy between economic considerations and sustainable development

The starting point of using wind turbines for electricity production was the need of mankind to pay attention to becoming more considerate regarding sustainable development in the context of the sharp rise in the number of people in the world and the consequently growth of consumption and needs. These considerations, which were affecting the entire population of the globe, have required increased attention to all aspects that the initialization and development of this energy industry branch assumed and still assumes until reaching a maximum point of development.

Deeply involved in the process, the economic terms have been a priority for private companies that have decided to invest in this sector, but also for the states that subsidize a part of this process and especially for individual users that participate in the development of renewable energy through the green certificates.

At investment level, the boom known in the development of wind farms demonstrate their profitability. At European level, one of the biggest investors in wind energy is the group British Petroleum. Looking strictly at the business part, British Petroleum has invested in wind energy since the beginning of the mass implementation of turbines. Wind energy's extensive development, in states where wind energy really matters in the energetic system, led to the price of MW to fall a lot.

Altogether with this reason, uncertainties in government subsidies, the discovery of new oil and gas fields and their increased profitability, prompted some investors to readjust. Consequently, British Petroleum has decided to give up all the stakes it holds in wind parks completed or almost completed in the U.S.A.. Along with multilateral developed companies, there are companies specialized in the development of wind farms and electricity production, companies constantly worrying about investing in areas of the world in which this business knows a high profitability.[6]

[top ten/top-10-business/the-top-ten-largest-wind-farms-in-the-world](#)

The wind farms are located in areas with maximum and relatively constant wind power. This is why, although China is the main producer in the world, U.S.A. has the largest wind farms, China having several smaller parks. The same issue can be observed for the EU member states – they have large wind farms, but there are many smaller regions of location. It is also noted a sharp increase in households resorting to energy independence, less by installing wind turbines, but through solar panels.[7]

At the individual consumer level, among with increased quality of life through the introduction of environmentally friendly technologies, wind energy brings additional electricity costs. These costs are due to the introduction of green certificates, through which it is provided additional income for investors operating in an environment so risky, but absolutely necessary. It is estimated that half of the revenue from a wind farm is represented by subsidies provided by the state and the green certificates, and half by the price of electricity supplied.

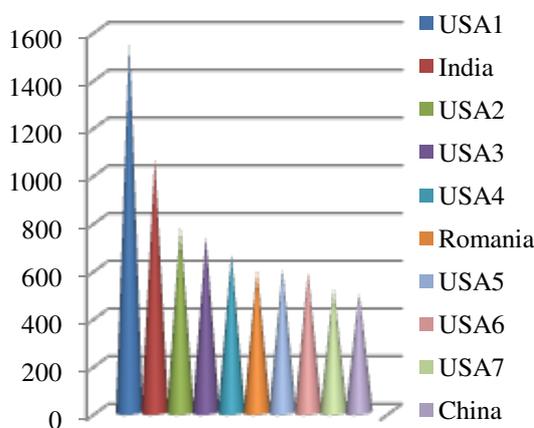

4. Conclusions

The need to develop renewable energy is already a way too debated topic in the literature of specialty. However, the economic funds involved in this process are highly complex and often difficult to quantify. Strategic branch of the national economies of each state, the energy industry suffers permanent changes in „greening” its existence. Since 1980, when there was installed the world's first wind farm in New Hampshire, U.S.A., wind turbines have seen a sharp increase in use, being until now a great opportunity for investors.

Investments in wind power technology were based not only on commissioning as many turbines, but also to optimize them so that the resulting product - electricity - to be in high quantity. To the wind turbines located on land were added offshore turbines.

States that have a real history behind in this field, have managed to get through sustained efforts the cost per MW of wind power similar to a MW of nuclear power.

Fig. No. 3: Top 10 wind farms onshore worldwide (2011)

*Source: Own processing of the information available at <http://www.energydigital.com/>

This has led some investors to readjust their investment in branches with greater profitability rate. However, for states where wind energy is emerging, the cost per MW is double compared to the one produced by nuclear fuel and 50% higher than the one produced by fossil fuel. This is why government subsidies are essential, especially if the European states have to achieve targets set by the European Union.

cusudorinela@yahoo.com

Abstract

In financial terms, firm performance is an overall result of the firm's activities. It consists of the profits generated by sales of the firm. Obviously, consumers play an important role in this sense, as they are responsible for creating demand for goods or services. They base demand on their incomes.

The present study aims to establish the relationship between firm financial performance and consumers' incomes. The research is based on an empirical study on Romanian companies within manufacturing sector. For the purpose of our study, a regression model was used. As a result, we constructed a linear model of regression outlining the impact of income changes over firm financial performance.

Key words: consumer income, consumer behaviour, financial performance, regression model.

J.E.L. Classification: C50.

1. Introduction

At microeconomic level, the consumer income is the essential factor which, by its value, type, dynamics, distribution in time, destination etc., is the material prerequisite of the consumer behaviour and the main restriction imposed to the consumer. The consumers income change obviously affects on the long-term their behaviour towards the goods and services they consume. Thus, a decrease in their income leads to a decrease in the demand for goods and services, with a

negative impact on the financial results of companies producing such goods and services. In the analysis we have made upon, we have intended to see the *influence of the income changes on the financial performance of the companies producing goods and services.*

We think this is a topic of general interest, for we try to answer the economic contradictions emerged. As incomes increase, some economists note that people prefer to buy some new things rather than repairing the old ones, thus leading to increased consumption of certain goods, and consequently to increased business income for the producing companies. A second view shows that some consumers think about the future and even if they earn more, they do not consume for short-term, in order to do once an important investment. Another view is that of the consumption "of snobbery". If people's incomes grow, they buy more even if they do not need to, just to impress their neighbours and friends.

2. Methodology

It is generally accepted that consumption is determined by numerous factors, such as incomes, prices, demography, infrastructure, acces to information, individual preferences, etc.

Firms target profits as the rationale of their existence. Hence, targeting profits means targeting consumers, as they are the main actors influencing firms' incomes. Consequently, we consider that consumption has a significant impact on firms' incomes, as consumer behaviour influences demand for

goods and services. All in all, we assume that consumer behaviour is an important factor influencing firm financial performance.

We define this issue as a simple regression model, of which endogenous variable is the financial performance, measured by a financial indicator, and of which exogenous variable is the consumer's income.

We take into consideration within present study the influence of incomes on consumer behaviour, with great impact on firms' profits - its financial performance. Collected data clasifies consumer incomes into two different groups:

- wage incomes, and
- non-wage incomes (e.g., annuities, dividends, rental incomes, etc.).

The data on the financial results of the investigated companies were obtained from the website of the Ministry of Finance. Financial performance of the selected firms was computed as a profitability indicator - return on sales (ROS). ROS was calculated for a period of 10 consecutive years. The data for the period 2002-2012 were applied transformations, i.e. they were denominated according to the law in force since 2005 by

which the amount of 10,000 lei is 1 RON. The data series were also transformed by deflating, into comparable prices for 2002.

Given the above assumptions, variables considered within our regression model are:

- ✓ Financial performance, represented by ROS - endogenous variable named PERF;
- ✓ Wage incomes of consumers - exogenous variables named WAGE_INCOMES;
- ✓ Non-wage incomes of consumers - exogenous variable named NON-WAGE_INCOMES.

3. Research results

By means of the least squares method, we estimate the parameters of the regression model as $PERF_t = \alpha_1 + \alpha_2 NON-WAGE_INCOMES_t + \alpha_3 WAGE_t + \varepsilon_t$, and, by introducing letter c in the equation, we estimated the regression model by also taking into account the free term α .

Based on the results of the calculations above, the regression model is estimated as follows:

$$PERF = -2.243084214 + 0.2536569766 * NON-WAGE_INCOMES + 0.2175918549 * WAGE_INCOME$$

Table 2 – Estimation of parameters using the Least Squares Method

Dependent Variable: ROS				
Method: Least Squares

Durbin-Watson stat	2.041761	Prob(F-statistic)		0.000000

Source: Authors' processing using SPSS

We used the t-Student test to verify the two hypotheses, the null one and the alternative one. We decided to also test the free term α although it shows the value of the explained characteristic, which is independent of the explanatory characteristic one.

For α_1 we tested:

$$H_0: \alpha_1 = 0$$

$$H_1: \alpha_1 = 1$$

From OLS, we have the following values: $\alpha_1 = -0.243084$, the standard deviation = 0.677498 and the t-Student value = -3.310837. Given the obtained value of the

significance marginal level (p-value) of 0.0107 (<0.05), we reject the hypothesis H_0 and accept the hypothesis H_1 by which α_1 is significantly different from 0.

For α_2 we tested:

$H_0: \alpha_2 = 0$

$H_1: \alpha_2 \neq 0$

According to the parameters estimation by the method of least squares, we have the following values: $\alpha_2 = 0.253657$, the standard deviation = 0.021916 and t-Student value = 11.57426. Since the value of the significance marginal level (p-value) is 0.0000, we accept the hypothesis H_1 , consequently α_2 is significantly different from 0.

For the parameter α_3 we have:

$H_0: \alpha_3 = 0$

$H_1: \alpha_3 \neq 0$

According to the parameters estimation by the method of least squares, we have the following values: $\alpha_3 = 0.217592$, the standard deviation = 0.037888 and t-Student value = 5.743035. Since the value of the significance marginal level (p-value) is 0,0004, we accept the alternative hypothesis H_1 , according to which the parameter α_3 is significantly different from 0.

Also, in the case of the parameters for which we accepted the hypothesis H_1 we have in addition a relatively high value for the F statistics, significantly different from 0 (156.5403), which requires the acceptance of the hypothesis H_1 while rejecting the null hypothesis.

Model-specific hypotheses:

1. The residual variables of the multiple regression are random variables of mean 0; $E(\varepsilon_i) = 0$, for any $i = 1, \dots, n$;

This assumption is permanently valid for the parameters estimated by means of OLS.

2. The residual variables are not correlated: $\text{cov}(\varepsilon_i, \varepsilon_j) = 0$, for any i different from j , namely the errors are independent;

3. The value of the Durbin Watson coefficient calculated in the table is 2.041761, which shows the non correlation of the residual values; but this is not sufficient for the statistics value also depends on the number of exogenous variables, respectively on the length of the data series. We extracted from the table the Durbin-Watson values $d_1 = 0.83$ and $d_2 = 1.52$, according to the significance threshold of 0.5, to the number of exogenous variables $K=2$ and to the number of remarks $n=11$.

Moreover, by comparing the DW value calculated by means of OLS with the values in the table, it resulted: $d_2 < DW < 4 - d_1$, i.e. $1.52 < 2.04 < 3.17$; this relation is verified and, consequently, there is no auto-correlation among the residues.

4. The residual variables variance is invariable. This assumption defines the homoscedasticity in regression;

Using the White test (no cross terms) via the Eviews, we obtain p-value equal to 0, less than the significance threshold of 0.05%, which urges us to affirm that the homoscedasticity hypothesis is satisfied. Moreover, the residue graph confirms that the hypothesis is fulfilled.

5. The residual variables are not correlated with the explanatory variables $\text{cov}(X, \varepsilon) = 0$. Given the fact that X is not random, this condition is satisfied.

6. The regression model is correctly specified (correct choice of explanatory variables, specifying the correct form of the regression function, the correct form of the residual term).

The explanatory variables are correctly selected, a fact proved by the parameters estimation by means of the OLS method and by the descriptive statistics, which have proved that there is direct dependance among the variables.

7. The residual variables are linearly independent; the residual variable is distributed according to a normal distribution.

To check up the normal distribution of the residual variable, we use the Jarque-Bera test with the following hypotheses:

a) $\varepsilon \rightarrow N(0,1)$

b) ε does not follow a distribution $N(0,1)$

Under the null hypothesis of the existence of normal distribution, the Jarque-Bera test is distributed Chi^2 with 2 degrees of freedom. The calculated probability is the probability that the Jarque-Bera test should exceed the absolute value of the null hypothesis (a low probability causes to accept the null hypothesis of the existence of a normal distribution). If we consider a threshold of significance $\alpha = 0.05$ and the calculated probability equal to 0.055, we can admit that the distribution is normal.

8. The resident variable is distributed according to a normal distribution

In the multiple linear regression formula we note that the model linearity depends on

the vector of the parameters α . Consequently, this model defined as $PERF_t = \alpha_1 + \alpha_2 NON-WAGE_INCOME_t + \alpha_3 INCOME_t + \varepsilon_t$ is a form of the linear regression model of which exogenous variables are $NON-WAGE_INCOME$ and $INCOME$.

To test whether, at the level of the linear regression model, there is at least one explanatory variable to justify the behaviour of the explained variables, the F test is used. By estimating the parameters by OLS, the value of the F statistics is 156.5403 with a probability of 0.0000. Thus, the null hypothesis is rejected, which means that the model is correctly specified.

A qualitative indicator of the regression model is the coefficient of determination (R-squared). Values close to 1 of the coefficient of determination shows that the endogenous variable variations are explained by the changes in the exogenous variables. In our case, the coefficient of determination is 0.975084, which shows that this model adjusts better the sample data.

Since the coefficient of determination in this form is very little influenced by the number of explanatory variables of the model, we used another form of it, namely the adjusted coefficient of determination. In the case discussed here, the value of the adjusted coefficient is 0.968855. We note that the two coefficients of determination obtained for this regression model have similar values and we consequently may conclude that the model is validated.

Moreover, the obtained value of the Durbin Watson statistics (DW) indicates that, for the model considered, it does not appear the phenomenon of autocorrelation of errors.

The formulated model is statistically validated; consequently it may be used in forecasting.

4. Conclusions

The regression model being validated, it may be used to make predictions about the evolution of the companies producing goods and services. To verify whether the relationship between the variables of the model is correct for estimating the model parameters in general, it may be also used the method of the maximum verosimilarity or the method of moments.

The described model is validated, this being a linear-type model. The model illustrates the positive effects caused by an increase in the consumer incomes, both the wage-incomes and the non-wage incomes, on the financial performance of the companies in the manufacturing sector.

The value associated to the free term cannot be interpreted in economic terms.

We note that the influence of the non-wage incomes is higher, this being due to the fact that we are talking about non food goods. From their wages, people satisfy their basic needs first, while other incomes may bring more life satisfaction.

Abstract

The present paper aims to reveals the result of a graphical analysis made over the numbers tourists nights spent in the Constanta County area and the evolution of employment and the monthly net average earnings in the same period. The time period was 2006-2012 and the analysis considered the data for every month of that period. The methodology used is graphical analysis considering that the economy was influenced by the financial crisis and any mathematical linear approach wasn't efficient. The analysis showed that, even if the tourist nights spent has a certain influence over the employment and income, it isn't the decisive element of influence for the entire Constanta County area. Also, the economic crisis influenced all three data considered, but with different evolutions.

Keywords: tourism, touristic reception, employment, monthly net average earnings.

Journal of Economic Literature (JEL)

Classification: E24.

1. Introduction

Today tourism has reached, in people and in dollars, the top of the heap. More money, time and equipment are involved in tourism than in any other single business. In major tourism countries (see accompanying list) more than 350 million visitors intermingle annually, bringing billions into these countries while paying for airline, ship, hotel, entertainment and other services and goods.

Even with such massive numbers travelling, tourism remains mainly a business of the wealthier countries although some smaller and poorer countries manage to provide a livelihood for some citizens catering to visitors from richer countries. A recent phenomenon is the rise of a segment of the world population with the largest amount of disposable income - young Japanese women between ages 19 and 34 who, through a strange mix of tradition and the new Asian economic miracle, are far ahead in the new "world order" of tourism[1].

Because of the tourism specificity the Constanta County area is characterized by the sessional employment/unemployment. Thus, it is necessary to overcome the problems raised for population by the sessional earnings, especially in the winter when the unemployment is higher.

So how the tourism influences the local level of living through employment and net average earnings? This is a question that the authors try to answer in this paper, specifically for the Constanta County area.

2. Data

The analyzed data comes from the 2006-2012 (for 2012 only for the first 10 months) time period. The data were collected from the Romanian National Statistical Institute [2] and it states the 2006-2012 situations for the Constanta County area [3]. Also, the data was presented for every month of the considered period.

The data taken into account were, as follows:

1. The tourists spent nights in the

- establishments of touristic reception with functions of touristic accommodation – ARR (in numbers of nights);
2. The Employee numbers (EMP) at the end of every month, for the entire considered period of time (in numbers). The employees’ pool data was considered from the entire Constanta County area.
 3. The monthly net average earnings (EAR) - in RON/person - for the entire employees pool data.

The EMP and EAR were considered for the entire pool data because the authors believe that both their values are influenced by the ARR.

3. Methodology

The methodology consists in graphical analysis of every considered data (ARR, EMP and EAR).

The general tendencies and certain specific evolution will be investigated. The results of this analysis will be followed by conclusion and recommendations for the employers and employees.

4. Graphical representation and analysis

For a better understanding and easier analysis of the evolutions and tendencies of the three data two types of graphical representation were used. First the yearly evolution of each data and second the comparison of monthly data values.

The spending nights of tourists (ARR) are represented in figure 1 and figure 2.

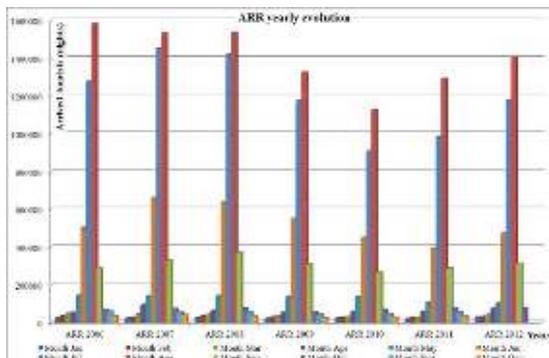

Figure 1. ARR's yearly evolution.

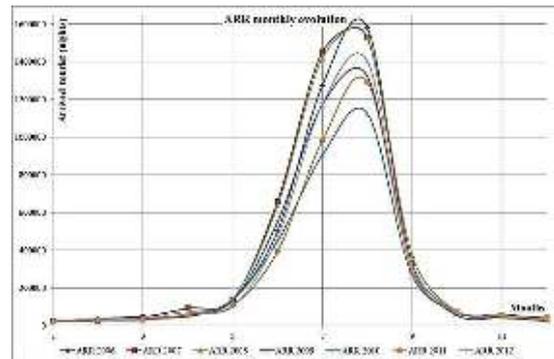

Figure 2. ARR's monthly evolution.

The employee numbers (EMP) are represented in figure 3 and figure 4.

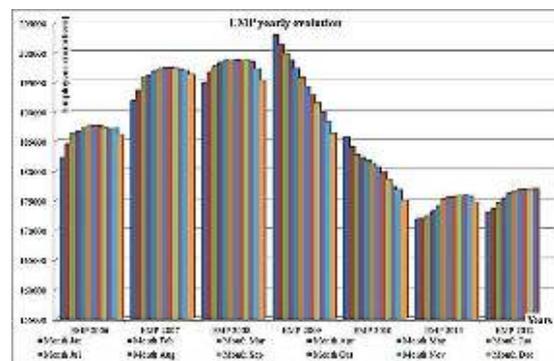

Figure 3. EMP's yearly evolution.

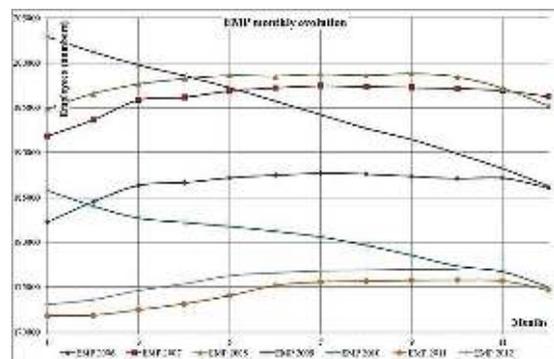

Figure 3. EMP's monthly evolution.

The monthly net average earnings (EAR) are represented in figure 5 and figure 6.

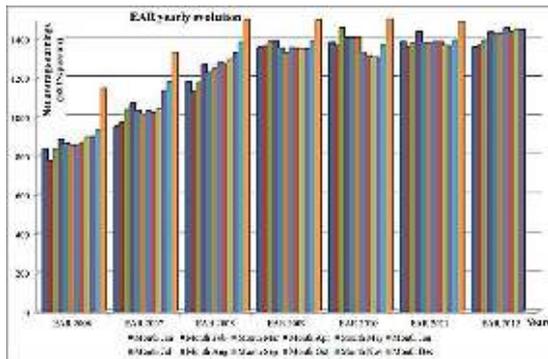

Figure 5. EAR's yearly evolution.

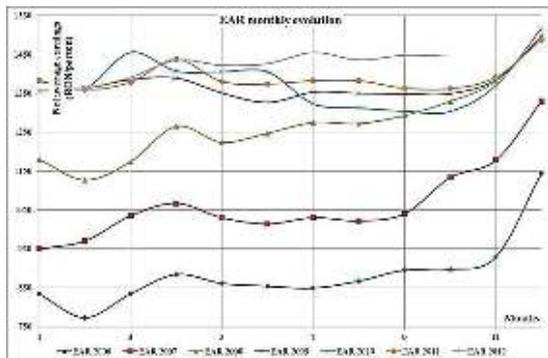

Figure 6. EAR's monthly evolution.

Considering the above figures the following specific conclusions were developed:

For the ARR evolution (figures 1 and 2):

- The year with the biggest number of spending nights was 2007 (4469418 number of nights) followed closely by 2008 (4435702 number of nights) and 2006 (4115909 number of nights);
- The month with the highest number of tourist was august 2006 (1581077 number of nights) and the worst month was January 2011 (19646 number of nights);
- The worst year by tourist numbers was 2010 (3166706 number of nights);
- The months with more than 200000 tourist are: June, July, August and September;

It is obviously that the tourists prefer the summer months (between June to September) to visit Constanta. Thus, the tourists are not interested to visit Constanta County in all others seasons.

The economic crisis influenced the numbers of number of nights by diminishing

it in the years 2009 and 2010 with a small come back from 2011.

For the EMP evolution (figures 3 and 4):

- The month with the highest number of employees was January 2009 (202900 employees) and the worst month was January 2011 (171804 employees);
- The worst year by employees numbers was 2011 (between 171804 and 175783 employees);
- The employees best year was 2008 with an average employment of 197608 persons;
- The months with relative constant numbers of employees were from June to October, excepting years 2009 and 2010;

What most be considered here are the years 2009 and 2010.

First we must highlight the tendency that governance the evolution of yearly employment considering the analyzed figures. It is obvious that the employment is more efficient in the summer and early fall months. Also, the employment is smaller at the beginning of each year than is growing until the end of September, than is falling again. Furthermore, for the considered period the employment looks like it is increasing with each year.

But those conclusions don't apply in the case of economic crisis. This is what happened in the year of 2009 and 2010.

In 2009, the year with the highest employment (in January) the evolution decreases dramatically to levels of 2006. So after an increasing average employment because of economic crisis the numbers of employees decreases sharply to the smallest levels yet. Furthermore, in 2010 the employment still drops. This diminishing stops in February 2011. From this moment the evolution re-enter in the 2006-2008 evolution of growing.

For the EAR evolution (figures 5 and 6):

- The month with the lowest monthly net average earnings was January 2006 (773 RON/person) and the best month for monthly income was December 2010 (1517 RON/person);
- The best year for the net average earnings was 2012, even if we didn't had the

earning for the last two months;

- The worst year for the earnings was 2006;
- The highest level of net average earnings in the year is in December for each analyzed year.

Here it is necessary to mark out that the highest net average earnings were not in summer months when is the highest employment rate, but in December. Also, considering the financial crisis it was expected a decrease of net earnings after the year 2009. But as can be easily seen the amount of money earned each month remained relatively constant. The exception are the 2009 May to October with a slightly decrease and 2010 July to October with a more serious diminish of the net income.

As in the case of the EMP evolution the net average earnings constantly increases from the year 2006 until April 2009 when the economic crisis became perceptible.

5. Conclusions

The authors concluded that even if the nights spent in the Constana County area has a certain influence over the employment value and the monthly net average earnings, but it is not the most important one. In order to determine the evolution of the employment and monthly earnings we must consider others industries like agriculture or manufacturing. Also, the study should be extended to more specific area like the Mamaia resort from Constana seaside.

Consumers' Behavior on the Insurance Market

Iliescu Elena Mihaela
Nicolae Titulescu University Bucharest
mag_mihaela@yahoo.com
Stroe Mihaela Andreea
Nicolae Titulescu University Bucharest
andreea19_stroe@yahoo.com

Abstract

Given that the limitations, the weaknesses of the economic activity in general have been enhanced by the financial crisis, the role of the insurance companies is undeniable.

This because enable households and businesses to manage their risks effectively, ensuring the recovery and even reunification their patrimony. The competitiveness of the insurance sector depends in particular on the knowledge regarding the consumer's behavior especially since the new realities brought about changes in his behavior. Therefore new strategies were imposed that would ensure a balance between the customer's consumption needs and the profitability of the insurance companies.

This is because the consumer has changed in recent years, he became more educated, consumerism behavior, adopted especially between 2006 and 2008, has been transformed into a cautious one, of individual and family protection.

Keywords: insurance, consumer risk, market
Classification J.E.L.: D11, D12, D81, G22

1. Introduction

At the base of Maslow's pyramid, life safety, as a basic need, represents a priority for all citizens. Provided that the risk is a constant of human activity, insurances have now become products destined for covering these needs. But the transformation of the need for insurance into an actual demand, depends greatly on the position, the attitude on the market of the suppliers of such services.

Given the difficult economic conjuncture, the instability of the social, political,

environmental factors and the fluidity of the insurance services offer, namely, the permanent adjustment to the needs of the insurance carriers is an essential condition to ensure the efficiency of the insurance companies.

To this end, the systematic monitoring, the understanding of consumer's behavior as a consequence for knowing the objective and subjective factors that influence the purchasing decision, represent the key to success on the insurance market, and not only.

2. The risk – the premise for insurance emergence

Human activities (government action, corporate or of the current life of the individual) are more or less subject to risk and uncertainty.

It is therefore of importance the distinction between risk and uncertainty. Thus, uncertainty is the result of lack of information and occurs when the consequences of an action are not known and by default, neither the probabilities of their occurrence. If the occurrence probability of an event and also of its consequences can be quantified, the decisions are taken under conditions of risk.

The ideal situation would be the one where future events are certain, the decision maker being able to anticipate in this situation, accurately, the results of his actions. At the opposite pole the situations where there is no information regarding future events, the effects of the decisions made under these conditions being uncertain. In practice, however, most often, decisions are based on the anticipation of certain results that may be obtained with different probabilities.

Under these circumstances, it may be said that nothing is certain, the activities with a high degree of safety are almost non-existent, the concept of risk becoming complementary to that of activity. We live, thus, in a world of risk and, as stated by the physicist Louis de Broglie, we must accept the risk because it represents the condition to all successes.

There are several definitions of risk. Most of the definitions studied see risk as the probability for loss occurrence, due to certain unforeseen and unfavorable events.

The economist Raymond Barre, analyzing the characteristics of the market economy, has highlighted the growth tendency of risks in this organizational system, due to the social transformations economic agents' interdependence and technical progress acceleration.

Globalization also implies new opportunities as well as increased risks, given that all nation states are involved in various foreign relations, which makes them parties, to an greater or lesser extent to the effects of major international events. In this context, the risk has acquired a great importance in all fields of the economic and social life, taking risks becoming a common practice.

The existence of these risks, whose materialization may cause losses led, for that matter, to the emergence of insurance as a distinct activity.

Insurances have therefore become an instrument for risk management, facilitating the elimination or reduction of damage by transferring the risks to insurers.

However, not all risks can be insured (the risk must be of the future, possible, real and uncertain).

The oldest written proof, about the emergence of insurances is dated approximately 6500 years ago, when in the Lower Egypt, the stone workers have constituted, anticipated, an insurance fund, where everybody contributed, in order to compensate the different losses that could affect the members of their community.

Since then, the insurance market registered a continued dynamic. Thus in 1900 there were about 1272 insurance companies worldwide, and by 1969 it reached a number of approximately 9700, widespread in 71 countries.

Our country has a tradition in the insurance field of over 130 years. Although

the insurance companies currently offer a wide variety of products and services that support individuals and organizations exposed to risk, the number of companies operating in the insurance market has dropped in recent years. Therefore, in 2011 an approximate number of 5000 insurance companies was reached, compared to the 5416 that existed back in 2005, for example. [1].

The situation accounted for in the last period of time is due to the challenges the companies have undergone- increasing competition due to globalization, the impact of the global economic crisis, consumers' demands and their continuously changing behaviors.

With a percentage of 36% of the global market, the insurance market in Europe is the largest in the world, followed by North America with a share of 29% and Asia with 28%. [2]

In contrast, the insurance market has increased in Bulgaria by 14%, becoming thus the fourth market in 2011.

All these differences regarding the insurance market, demonstrates that it is a complex market, which interacts with many aspects of people's lives.

Under these circumstances, the competitiveness of the insurance sector depends mostly on the knowledge of the consumer's behavior as a decision maker regarding the acquisition, and on the companies' ability to adapt to the new conditions.

3. Consumer - the engine of the insurance market growth

Consumer behavior represents thus an important vector in the trajectory of the insurance market..

Therefore, knowledge of the consumer's behavior and the repositioning of the products according to it, represent essential variables in the process of organizing and conducting effectively the companies' activities. The various points of view regarding the definition of consumer's behavior support the idea that it should be considered interdisciplinary (economics, law, psychology, sociology, theory of risk and even history).

Synthesizing these approaches led to the

conclusion that both the factors that influence the consumer behavior and consequently, the demand for insurance products can be grouped from this perspective. Thus, the increase / decrease in demand for insurance is determined by economic and financial factors (average standard of living within the specific area, current income, expectations of its evolution, interest rate, liquidity preference), cultural (besides the educational level, we include here religion, ethnicity, nationality), social (social status, group affiliation, family), psychological (beliefs, motivation, self-esteem), personal (age, occupation, life cycle stage, tendency for risk) and incidental.

3.1 The diversification role in ensuring the competitiveness of the insurance market

Considering that, besides the price of the insurance policy, the quantity demanded on this market is influenced by other conditions, objective, but the most part subjective, the insurer must include in his strategy, a permanent diversification of the portfolio, and even a differentiation of products and of distribution channels, with the purpose of providing personalized services depending on the customer needs.

The diversification idea had been formulated ever since 1952, by Harry Markowitz, who has formulated a revolutionary theory at that time for the business world, showing that diversity is gold for any investor or manager. In fact, he won the Nobel Prize for economics in 1990, following his theory from 1952 (Portfolio Selection) - the first notable attempt to quantify risk, showing that there is no gain without risk and that we should not put all our eggs in one basket, as it involves unacceptable risk.

Adopting the customer-centric strategy, the offerer will obtain competitive advantages and thus will achieve his goal - increased profit.

This approach is required because the new realities left their mark, also on the current consumer who is more educated, more informed and therefore more difficult to handle. In this equation should be included also those with a prudent attitude towards new, especially to new technologies. Consequently, the companies need to expand

and optimize the distribution and information channels, combining new technologies (online distribution channels), with the traditional distribution channels, to ensure that they can be contacted by anyone interested.

Nevertheless, traditional distribution channels have retained an important role.

Thus, if bancassurance (introduced in Europe in 1980) is the main distribution channel in many countries, reaching a record of 92% in Malta (France 61%, Austria 63%), in Eastern Europe, the system is still widespread. Distribution is made, still, mostly through the two traditional channels – agents and brokers. In Romania, for example 55% of the insurance market is covered by agents, 21% brokers and only approximately 14% is covered by bancassurance. [3]

In terms of portfolio diversification in relation with the current context is has been imposed for example the growth of insurances with lower loss.

From the demand for insurance bearer, reporting to the same diversification theory, we can say that, purchasing more products represents a solution for risk reduction.

The complementarity idea between different financial products (the combination of banking products and insurances) was highlighted even in the 2009 OECD report.

Complete and correct information is thus a decisive step for establishing the action strategy on this market, both for the insured and the insurer.

However, market failure is felt also of the insurance market segment, in the form of asymmetric information, because each of the two parties hopes that they own more information than the other does, and thus a greater gain.

Thus, the insurer has better information due to the large number of clients and knowledge of its own products and, the customer has control over the information regarding their personal situation being able to provide false information about his health, financial situation, etc .) [4]

This situation reminds us of the classical issue on lemon, present on all free markets under the conditions of asymmetric information. Formulated by George Akerlof, in his article "The market for the Lemons: Quality, Uncertainty and Markey Mechanism", he argues that individual

rationality correlated with asymmetric information undermines the economic efficiency of free markets. He sustains his affirmation with a suggestive example from the used cars market. Because only the sellers know the true value of the automobiles, the prospective buyers assume that all are of average quality and are willing to pay the best price for a car of known average quality.

Of course, those with good quality cars are disadvantaged, and therefore the transactions are blocked. [5]

Considering this aspect, a mutual behavior based on ethical principles would bring benefits for both parties, but it is an aspect very difficult to control.

3.2 Current insurance market issues - comparative analysis

Based on the magnitude and multitude of changes that have occurred on the insurance market, Ernst & Young, along with an independent firm, Ipsos, conducted a study in order to identify, quantify and interpret the factors that have generated these fluctuations. [6]

The study was conducted between August and October 2011, on a sample of 24,000 consumers in seven regions around the world.

Have been observed, as expected, numerous differences in the consumers' behavior, depending on the geographical areas, demographic factors, level of development, competitiveness, but data analysis allows us to formulate the following general conclusions:[6]

- The consumer desires safe, sale purchase process to be simple and transparent in order to understand what they buy.
- Generally in non-life insurance sector, price is the most important variable in the decision making process (in Turkey, Canada price influences the choice up to 60%) but there are also areas where the brand, the reputation are decisive.
- Internet has changed the way people interact with insurers (insurance through internet became possible, including in our country). The transparent environment, rich with information, allows only those interested to make their own analysis, comparing the products and the prices;
- Even if the previous acquisitions were

based on a good research, 70-80% of the respondents claim that they have this intention for the next acquisition;

- In general, in the non-life insurance sector, the price is the most important variable in the decision-making process (in Turkey, Canada the price influences the choice with 60% percent) but, there are also areas where the brand and the reputation are decisive;
- The interpersonal interaction is important in the purchase decision. Regardless of the region, 70-80% of those surveyed claim that, considering the complexity of the products, need the assistance of an expert (in Malaysia 95%). A greater independence is registered in the life insurance sector. Although there are people drawn entirely to the online services, most prefer to complete the information and online services with the information provided by the insurance agents. This idea emphasizes once more the necessity of continuous adaptation of the existing channels to new technologies.
- It is recommended to maintain the relationship with the client eve after the sale was completed, throughout the life cycle of the product, because it has been ascertained that the policyholders expect the insurers to contact them when the contract reaches its maturity or for the renewal of the contract. Most of the times, the buyers prefer to work with well-known companies, with whom they had a positive experience (in China 52% of the respondents have bought a new product from the same supplier, while in Europe 17%).

The resources limited character is in fact the economy's general issue, regardless of the place, time or institutional sector and thus, of the insurance consumers (we are considering both the economic resources and the temporary and cognitive resources). Under these circumstances, the optimum revenue allocation is brought into question. Therefore, the financial behavior influences the attitude towards insurance.

Thus, regardless of the living standard, preference towards liquidity suggest an aversion towards risk and thus a positive effect on the demand in the insurance market.[7]

4. Conclusions

Therefore, the suppliers of insurance products must adapt their strategies, according to the market segments, consumers' patterns because, even though there are common elements, consumer's behavior varies, from one area to another, due to differences regarding the development level, demographic factors, legislation, etc.

For example, in China the insurance market is dominated by state-owned companies, thus offering a limited choice, while in the US, the competition is much greater.

In conclusion, the new realities require new approaches, insurance companies' efficiency, depending on their capacity to manage the changes in their consumers' behavior.

Investor’s Perceptions and Financial Instability in the Emerging Countries

Ionescu Cristian

Academy of Economic Studies

cristian.ionescu@economie.ase.ro

Abstract

Due to the importance of the financial instability and of its negative consequences within the economies, especially in the emerging ones, it is important to study the link between financial instability and investments, as a factor of economic stability. Therefore, the paper aims to analyze the relationship between the risk premium comprises by the financial instruments, the country-specific factors that influence spreads, the factors that influence the general perception of emerging market risk and the risk appetite, both having great influence on the investments level.

Keywords: financial instability, investment, emerging countries, financial instruments

J.E.L. Classification: D53, E22, G23, G32

1. Introduction

Risk perception of currency investments significantly affects the capital flows’ direction, the domestic financial instruments’ yields, and finally, the financial stability. Depending on the size of interest rate and exchange rate exposures, yields’ volatility and the currency exchange rate affects the profitability of the financial intermediaries, determining the financial conditions of households and of the firms. Volatile capital flows, induce by the shifting of the investor sentiment, may endanger the financing of the balance of payments.

Market sentiment about investments is frequently affected by the risk perception regarding the investments, especially across emerging markets, which is illustrated by the size of the required risk premium and by the irregular movements in capital flows (which are usually uncorelated to the domestic fundamentals, being able to periclitate

financial stability in the case of a significant contagion effect.

This paper aims to present a general description of country-specific and external factors related to the market sentiments across emerging countries. It also aims to analyze the perceptions’ role on the emerging country risk and how does it leads to the variation of the risk premium on currency investments. Finally, the paper aims to describe the exposure of financial instruments to contagion.

2. Estimating the risk premium on emerging country financial instruments

If the investors think that the emerging country financial instruments imply higher and more risks than the advanced market instruments, the yields on the emerging country financial instruments contain a risk premium.

The premium on investments that is denominated into the domestic currency, implies two main constituents. The first one is the premium required due to country-specific risk and due to the liquidity risk. The second one is the premium for exchange rate risk that investors demand in order to compensate the unforeseen exchange rate movements (the uncertainty regarding the currency’s future value).

The size of the risk premium that foreign investors require on the financial instruments, issued in the home currency, is given by the difference between the domestic yields to foreign yields differential and the expected nominal depreciation of the exchange rate. But the change of the expected exchange rate cannot be directly observed; thus, the numerical /quantitative definitions of the required risk premium are very uncertain. Yet, it may be possible to directly remark the difference between the spreads of a country’s foreign currency denominated bonds and

other bonds in the same currency and with the same maturity, assuring a proper estimated size of the country-specific and liquidity premia, since there are no exchange rate expectations or other uncertainty components involved[6].

Sovereign bond spreads mainly mirror three types of risk. The first one is the *credit risk or default risk*, which describes the likelihood of the bond issuer to fail or to refuse to service the debt. The second one is the market risk, which is correlated to the variance within the secondary market bond prices.

These two risks are inter-linked, since one of the factors that leads to price changes is represented by the perceived credit risk. In addition, market risk is affected by other factors, such as the willingness of the investors to take risk. The third risk is the *liquidity risk*, which describes the likelihood that investors only sell bonds on the secondary market at a very low price.

Even if foreign currency bond spreads do not encompass any premium for exchange rate risk, it doesn't mean that foreign currency bond spreads shifts do not provide indications regarding the risk premium on financial instruments that are denominated in the home currency. The country risk premium which is reflected in the foreign currency bond spreads and the exchange rate premium are very linked. In the case of currency crises, it is a high probability that the government will do not meet its foreign liabilities; therefore, an exchange rate premium increase is followed by an increase in foreign currency bond spreads. The effects of the changes in the exchange rate on the default risk is often very important for the emerging countries, where there is a large share of market participants' balance sheet liabilities denominated in foreign currency, implicating significant financial losses in the case of the home currency depreciation, raising the foreign currency debt. So, exchange rate shocks imply higher threats to the emerging countries than to the advanced countries, since the unforeseen depreciation in the emerging economies is regularly followed by an economic recession, while across developed economies the economic recession do not appear in this situations[2].

3. Country-specific factors that influence spreads

The emerging countries cannot be considered as homogenous. The average value of the spreads implies very wide gaps of levels.

It has to be verified if this difference in levels is due to the differences in default and liquidity risks, and to study the macroeconomic characteristics of these risks.

It may be helpful to analyze the relationship between credit rating and foreign currency bond spreads. Due to the fact that the countries' external debt rating mirrors the default risk, there is a link between the credit ratings and the spreads. It has been proven that a higher credit rating reflects a lower spread within countries and across countries. But spreads' shifts may only partially be taken into consideration for the difference in ratings.

Macro-economic empirical research has shown that domestic fundamentals that better reflect the default risk are important to the spread evolution, both within and between countries. Liquidity indicators and solvency indicators (for example, the debt ratios, the international reserves, the ratio between the balance of payments and the gross domestic product, the share between the debt service and exports) and payment issues are also significant causes, as well as the gross domestic product growth and per capita gross domestic product. In addition, the issued quantity (an indicator of secondary market liquidity of a certain bond) has also significant effect on spreads.

Regarding the capability of economic fundamentals to predict risk, it has been demonstrated that the influence of fundamentals may be described by their role in predicting the probabilities of the default risk and of liquidity risk: spreads increase more during a currency crisis than is certified by the raise in risk probabilities. Lower credit risk (described by the state of domestic economic fundamentals) leads to lower risk premia, still these properties do not properly take into consideration the spreads' short-term fluctuations, which may be owed to other market factors[4].

4. Factors that influence the general perception of emerging market risk

Co-movement of foreign currency bond spreads underlines the nature of the shocks that affect the emerging economies. A strong correlation between spreads means that the perception of risk within emerging economies is influenced by common shocks, or by shocks that the investors think that the emerging economies have in common.

A weak correlation between the spreads means that the idiosyncratic shocks dominate. External shocks may appear as a spillover effect of a shock that affects a specific country or due to global actors that affect several emerging economies.

Country-specific macroeconomic characteristics often are unable to explain the changes in the risk premia on emerging country financial instruments, particularly during financial crises. Therefore, the analysis will focus on the external factors that may determine the market sentiment co-movement and the risk perception related to emerging economies[5].

5. Risk appetite

One of the causes for the general changes in market sentiment, which is not related to the country-specific fundamentals, is that the fact that there are some events that determines a shift in the risk appetite of the international investors, leading to changes in the risk premia among other separate markets. So, risk appetite affects both the emerging markets and the higher-risk instruments that are traded within developed capital markets. The occurred events within these markets usually are determined by the shifting sentiment regarding the emerging markets.

Risk appetite may lead to confusion. The yields of the risky instruments, relative to yields of risk-free instruments, may be affected by two factors: the beliefs regarding the distribution of expected yields (the perceived risk), and the preferences of investors related to risk-bearing. Risk appetite wrongly refer to the likelihood of preferences changing, which determines the investors to reallocate their portfolios, aiming to diminish the exposure. But the demand change for risky financial instruments

doesn't mean that risk preferences vary in time[1].

The effect of risk appetite over markets is properly reflected by the high correlation between the developed market risk indicators. It has been proved that in the emerging economies the shifts in global risk appetite have been mainly induced by the expectations about global economic growth, which has been affected the credit availability and the export prospects.

There has often been the case that changes in risk appetite, accompanied by growth expectations, have exceeded the measure of risks shifts. One cause for the risk appetite procyclicality is given by the fact that investors try to forecast the future outcomes, taking into consideration recent events, so that the probability of negative outcomes is disproportionately low during economic booms and disproportionately high during economic slowdowns.

6. Changes in reference rates

Regarding the effect of the reference rates on foreign currency bonds on emerging market spreads (with other words, of the developed country interest rates), there is no clear theoretical link. A drop of reference rates will reduce the debt burden of an issuer of foreign currency bonds, diminishing the default risk, so that the spread becomes narrower. But the effect may be different in the situation of the global risk appetite decline, so that the fall in demand for higher-risk instruments is followed by an increase in risk-free instruments demand (for example, the government bonds issued by the developed markets). Developed market rates and emerging market spreads are negative correlated even when the fall in long-term rates illustrates the expectations of a economic slowdown.

Empirical research on the reference rates' effects on the risk perception provide no additional information, so there couldn't have been identified any certain relationship between reference rates and spreads. In addition, the coefficient of developed country rates is either negative either not significantly different from zero, but never positive. There hasn't been proven any correlation between the emerging market spreads and the short-term rates.

7. Contagion

One of the causes the correlated foreign currency bond spreads is the spillover created by financial shocks from a country to other countries. Contagion appears after a shock is propagated, regardless the state of economic fundamentals. The shocks are transmitted through various fundamental channels, which play an important role during financial crises. One shock mechanism is the trade channel, which may lead to the transmission of exchange rate crises. The currency depreciation/devaluation may discredit the competitiveness of trading partners and competitors.

Another shock mechanism is the financial channel, which comprises the international financial intermediation and the financial market links. A financial shock that affects a country and that shifts the market sentiment towards the financial instruments of that country is transmitted to another countries through the channel of international institutional investors, who reallocate their portfolios, and who might face severe losses that determines them to liquidate their investments across other countries.

„Pure contagion” implies the fact that the spread of financial shocks cannot be assigned to the fundamental channels. Related to this, the concept of „herd behavior” refers the tendency of the investors to trace other investors, but without a proper evaluation of fundamentals. Herd behavior does not unavoidably mean that investors behave irrational. If information is costly, to copy others’ behavior may be rational[3].

One explanation for the shock transmission, related to risk appetite, is that a shock that occurs in a country will cause investors to re-evaluate their positions in other countries. Thus, financial crises inform investors to the likelihood of negative outcomes.

Regarding contagion that cannot be explained by the economic fundamentals and by the incentive systems related to investments, an increase in volatility in a country will also raise the credit risk and the market risk in other countries that have faced similar volatility. Thus, shifts in market sentiment towards risk in one country will increase risk premia in other economies.

The trade channel may represent an important factor for trading partners countries or for countries that compete within third markets, while the contagion that has been transmitted via the financial channel mainly endangers the countries having a common creditor. The distinction between different mechanisms is a difficult task, so that empirical studies have been suggested that if contagion is large and widespread, then spillovers occur through more channels, so that the spillover of the risk premia is stronger. A proof of pure contagion is the fact that the correlation between the yields on the financial instruments significantly increase, so that the link between countries is different during financial turbulence than during normal periods.

Regarding the link between foreign currency bonds, intra-temporal changes in co-movement between emerging economies is quantified as the average bilateral correlations between changes in the countries’ spreads. Investors make the distinction between the emerging markets and the events that do not lead to general shifts in market sentiment regarding the emerging markets.

8. Investors’ perception of market risk

The relationship between the investors’ sentiment towards risk and the country-specific fundamentals is illustrated by the correlation between the credit rating and the foreign currency bond spreads. During financial crises, since there is a general worsening in market sentiment about emerging economies, the downward trend in spreads has often been interrupted, leading to an upward shift in the general level.

The intra-temporal shifts of correlation mean that lows value cover irregular co-movements over time, so that country-specific factors may be more important for the investors’ sentiment. It may be the situation when better-than-expected macroeconomic news (regarding the budget deficit and the balance of payments) may severely reduce the bond spreads. Moreover, wider shifts in market sentiment and the risk perception of risk within emerging economies investments affect the spreads.

Despite possible weak average correlation, the exposure to contagion has to

be taken into consideration, since there is no immune emerging country to contagion.

Even if financial contagion may have a limited impact over time, financial stability may be endangered by the shifts in the investors' sentiment regarding emerging markets (due to volatile yields and to excessive exchange rate fluctuations).

The correlation between the movements in the currency interest rate differential and the bonds' unweighted average lead to similar conclusions.

Even countries which have EU membership and which improve the credit rating (leading to a reduction in the impact of financial contagion) are unable to entirely avoid the exposure to these effects, which can be done only by abandoning the domestic currency.

9. Conclusion

Investments have a two-way effect on financial instability. Financial investments often lead to financial problems, which also have repercussions in the real economy. In the same time, (foreign) direct investment have a stabilizing effect in the economy. More important that the stabilizing effect is the long-term involved by this category of investments, compared to the short-term or

even medium-term involved by the financial instruments.

In conclusion, policy makers within emerging countries have to encourage (foreign) direct investments by providing fiscal and financial incentives, a stable political climate and a proper legislation regarding competition and the rules related to the business environment.

Current account deficit and financial instability in the emerging countries in the European Union

Ionescu Cristian

Academy of Economic Studies

cristian.ionescu@economie.ase.ro

Abstract

There is a strong link between current account deficit and financial instability. This paper aims to study this relationship, taking into consideration the following: the short and long-term developments in the current account; the factors that determine the cyclical developments in the current account balance; the finance of the current account deficits; the connectivity between the current account and financial instability, given by the long-term sustainability of the current account deficit.

Keywords: financial instability, current account deficit, emerging countries, crises

J.E.L. Classification: F32, G23

1. Introduction

Economic policy makers in emerging-market countries carefully take into consideration the evolution of the current account balance, due to the fact that financial crises are correlated to large current account deficits.

It has been proven that although a large current account deficit do not almost certainly determines a financial crisis, the costs of sustaining a large current account deficit are very large. There are few countries that are capable to sustain large current account deficits.

Regarding the welfare costs of the inversion of capital flows and the decrease in current account deficit, in most of emerging countries there have been a reduction in the investment and gross domestic product growth. Also, large deficits tend to increase the probability of financial crises.

Excepting some exceptional cases, large current account deficits imply risks.

It is important to clarify the meaning of the concept of “financial crises”, as following: i) a *debt crisis* involves the fact that if the foreign lenders from an emerging country maintain their perceptions regarding the economic and financial developments taking into consideration the current economic fundamentals of the country, then the country will become insolvent. This doesn't mean that there will be bankruptcies, but the economic policy has to consider to undertake austerity measures, in order to prevent bankruptcy; ii) a *currency crisis* takes place if the national currency of an emerging country faces a *speculative attack*. due to this speculative attack, the economic policy has to give up to the existing nominal exchange rate target and to devalue or to depreciate the national currency, since the protection of the currency's value implies very high costs; iii) a *banking crisis* implies the collapses of the domestic financial intermediary system[3].

Debt crises and currency crises are known as “current account crises”, since in types of crises the current account deficit and the foreign capital inflow decline severely.

The link between large current account deficits and debt crises is given by the fact that a durable and large current account deficit determines a raise in the country's debt, leading to the weakening of the investors' confidence in the country's capacity to service its debt. These crises imply high fiscal deficits; the most recommended solution to these crises is the fiscal restrictions and currency devaluation, which aim to diminish the current account deficit and to hinder the build-up of future debts (through savings increase and competitiveness improvement).

But current account crises are not inevitably linked to insolvency. The main

source of currency crises is the fact that investors start to believe that the costs of protecting the currency will be extremely high for the central bank, so they focus on foreign currency; the self-perpetuating process determines costs of defending the currency to increase, so the central bank permits the exchange rate to float.

If a central bank protects a fixed or narrow-band exchange rate regime through interventions, a large current account deficit may severely reduce the reserves of the central bank, so it abandons the exchange rate target.

But a certain exchange rate target has to be protected by both interventions and interest rate increases, even if there is a specific limit to the interest rate increases, due to the likelihood of a very excessive tight monetary policy that is able to lead to recession. Thus, there can be speculative attacks on the market, if the market believes that the macroeconomic costs of protecting the exchange rate will be very high (for instance, if the market believes that the interest rate increases will determine an economic slowdown that the economic policies are unable to manage). In addition, the ones that require the speculative attacks may be given by the self-perpetuating aspects rather than fundamental factors, in which case there may be various causes that may influence the future expectations. One such factor that moves expectations towards inflaming a crisis is the large current account deficit[5].

In addition to the causes of speculative attacks and to the current account crises, there are also other issues that have to be considered; for instance, the effect of crises on the real economy. In developed countries, speculative attacks usually do not affect the performance; in the contrary, a more lax monetary policy, accompanied by currency devaluation, may increase economic activity. But speculative attacks often determine recessions in emerging countries. One of the main causes for this is the fact that capital outflows are followed by a *bank crisis*[2].

There are two causal links between bank crises and currency crises. During a currency crisis, the monetary base diminishes (since the central bank reserves fall down), contracting the credit supply. But if the economy faces a bank crisis, the central bank

will provide supplementary liquidity. But the loosening of monetary policy may compromise the credibility of the exchange rate targets and may cause speculative attacks.

2. Short and long-term developments in the current account

One factor that may influence the evolution of the current account balance on the long term is the fact that the ratio of per capita physical and human capital is lower in emerging economies than in the developed economies. Thus, the return on capital is higher, stimulating investors from developed countries to invest in the emerging economies. This induces a current account deficit.

In a utopia economy, without any uncertainties, where information is perfect and symmetric, the equilibration of returns on capital would entirely reflect the path of current account balance. But in reality the current account deficit is lower than the ideal one, since lenders do not permit to an emerging country's debt to increase above a specific level, due to uncertain and fragmented information. Depending on the circumstances, there is a certain level of debt at which investors believe that the future debt repayment is cannot be assured, so that they will no longer finance the country.

From a debt crises perspective, the long-term evolution in the current account balance is very important. Regarding the country that is able to service its debt, the main factors are the rate of gross domestic product growth and the rate of return on debt. Thus, in order to avoid future debt crises and to maintain the long-term sustainability of the current account balance, it is important to protect the balance of payments. The structure and methods of financing deficits are also important, since they affect the average return on the aggregate debt burden.

Cyclical movements in the current account balance are also important, since the expectations regarding the long-term evolution in the current account balance depends on the short-term balance variations.

Although the deficit size is critical, the method of financing is also relevant, due to the occurrence of currency crises. Regarding the evolution of the currency crises, the

cyclical position of the current account balance has to be studied considering its inter-connection with financing[9].

2.1 Factors determining cyclical developments in the current account balance

The cyclical evolution in the emerging countries' current account balance takes into account several exogenous factors: the evolution in the export demand of the non-residents, the non-residents' goodwill to supply capital, the evolutions in the basic materials prices and the supply shocks. Moreover, the economic policy has a significant influence on the evolutions in the current account balance through government spending and monetary policy. The two components of current account balance developments in the emerging countries may be classified as following: the period before stabilization and the period after the stabilization (characterized by normal economic cycles and political cycles).

The period before stabilization can be described by exogenous shocks: i) the large transitional supply shock, where there is a high level of worthless and useless physical and human capital stock (due to the market economy's conditions); ii) the foreign direct investment inflow that takes place after the market economy institutions consolidation, created by the durable positive productivity shock. Due to the initial negative supply shock and to pessimistic expectations, the investments fall. But due to the positive shock to the foreign direct investment inflow, the ratio between savings and investments increase. Deficit may also increase due to structural causes that may be connected to the transformation crisis. If deficits are due mainly to consumption and no to investment, there may arise sustainability issues[8].

Regarding the factors that may stop boom of the current consumption to lead to an excessive increase in the current account deficit, there have to be underlined the following: i) one long-term consequence of emerging countries joining the EU will be a restrictive fiscal policy, that may have positive influences on the consumption; ii) a prudent and proper-regulated financial intermediary system may adjust the self-ability of the economy (the worsening of the

current account balance, generated by a consumption boom, will raise the foreign funding cost, reducing consumption); if shocks that affect the emerging countries and the European Union are widely synchronized, this may reduce the amplitude of the current account cycle. For example, if the European Union faces a positive productivity shock, it will increase the demand for the emerging country's exports. If the emerging country faces a similar shock, it will increase the country's import demand. Narrower fiscal policy maneuvers may EU and EMU accession will lead to the unification of the monetary policy, so the shocks of other emerging countries capital market will have no significant effect on the emerging country. In addition, the current account balance will be cyclically influenced by consumption and by productivity shocks. The higher the integration of the emerging country into the European economies, the lower the probability of asymmetric productivity shocks.

2.2 Financing current account deficits

So far the paper analyzed the cyclical movements in the balance of savings and investment, and thus the variations in the current account balance. It is also important to analyze factors that influence the financing structure on the side of balance of payments.

There is a strong correlation between the level of economic development and the role of foreign direct investment. The examination may be undertaken two steps: i) measuring the effect of the economic development of a country on the total capital flows; ii) measuring the effect of development on the ratio between foreign direct investment and total capital flows. It has been demonstrated that capital flows are larger among developed countries, followed by the emerging markets, followed by the low-income regions. The more developed a region, the larger the capital flow volume between countries, while the ratio between foreign direct investment and total capital flows is inversely proportional to the development level. One cause for this is the existence of *transaction* costs (costs related to the operations of markets and organizations). So, if the transaction costs are large within a country's financial market (as

in the case of under-developed economies), it is more advantageous for investors to internalize the investment transactions, and not to permit to the market to do that. Since in the developed countries the financial markets are more efficient and imply low transaction costs, it is profitable to invest capital among these countries. Within the less developed countries, it is more indicated to replace the local financial markets and the finance activity with corporate expansions and intra-company capital flows. For example, one common imperfection of emerging countries' financial markets is the concept of “original sin”, which means that incomplete markets are unable to borrow from abroad in the country's national currency and that the domestic borrowing is limited to the short term, leading to difficulties due to the volatility of the exchange rate and due to the maturity mismatch. This situation can be avoided by the foreign investors that can establish and finance a subsidiary in the emerging country, taking financial resources from the mother company that operates in a developed country where the “original sin” is inexistent[1].

There are some main aspects related to financial stability: i) the degree to which foreign direct investments are volatile in comparison to other categories of investments; ii) the stability of the investments' behavior during financial crises. The general opinion is that foreign direct investments are a category of investments included in the physical goods, presenting the impossibility of mobilization during financial distress periods. But in fact there is no notable distinction between foreign direct investments and other foreign investments. This can be demonstrated by the convention used in the foreign direct investments computation: a foreign investment is considered a foreign direct investment if the investor buys at least 10% of the company's shares. The fact that investors do not withdraw their foreign direct investments during a certain period does not mean investors do not withdraw certain amount of capital from the country using other methods. So, the relationship between financial stability and foreign direct investments is very important. For instance, the short-term domestic borrowing undertaken by a foreign

owner of a company and abroad fund-investing is not a withdrawal of foreign direct investments, although the company's owner has withdrawn capital from the country. It has been proved that different categories of foreign direct investment may lead to higher incidence of financial crises: the ratio between foreign direct investments and total investments within developed countries has no significant importance on the probability of financial crises. But, among developing countries, this ration has diminished the probability of financial crises, since foreign direct investments have involved higher stability than other forms of investment.

Therefore, a higher ratio of foreign direct investment means that financial markets are operating improperly. So, foreign direct investments have a significant role for the emerging countries, permitting to increase foreign funds, which are otherwise inaccessible due to improper market coordination. Foreign direct investments behave in a more stable way than other types of investments during financial crises. Foreign direct investments also have a significant role in financing the current account deficit, being a less volatile component of deficit financing.

3. The current account and financial stability. Long-term sustainability of the current account deficit

The relationship between foreign debt as a proportion of gross domestic product and the current account deficit and goods trade surplus is given by the equation:

$$(1 + g)d_t - d_{t-1} = cad_t \\ = -tbs_t + r_{t-1}d_{t-1}$$

where d_t represents the ratio between the country's debt and the gross domestic product, g represents the rate of gross domestic product growth, cad_t represents the ratio between the current account deficit and the gross domestic product, tbs_t represents the ratio between the goods trade surplus and the gross domestic product, r_t represents the return on debt, t represents the time index in years.

The current account deficit is seen as sustainable if it induces a debt level which is

expected to be serviceable, taking into consideration the expected performance of the economy. The debt burden can be computed as follows: it may be assumed a certain ratio between the debt and the gross domestic product that has been stabilized. So, this ratio implies that $d_t - d_{t-1} = 0$, so, taking into consideration the first equation, it results the following relationship: $tbs = (r - g)d$, where the time absence suggests that variables are constant.

The last equation allows defining the future burden on a country's liabilities and foreign debt. It illustrates the measure of the country's goods trade surplus at a certain return rate r and growth rate g , if, at a certain moment, the ratio between the country's foreign debt and the gross domestic product equals d , considering that the liabilities' size is stabilized in the future.

In addition, the last equation illustrates the following: the higher the rate of economic growth and/or the lower the return on debts, the lower the future burden on debt. In order to use this equation, it is necessary to use a proper measure of return r . It can be argued that the interest rate on a risk-free bond is not a proper discount factor, since it doesn't comprise the uncertainties related to the economic growth. One proper measure of return is the long-term average of equity returns, which can be approximated to 8%.

So, the co-ordination of the investors' behavior is important, especially in emerging countries which are not allowed to have a debt-to-gross domestic product ratio higher than 80%. A 8% discount factor, a 4% economic growth implies and a 80% debt-to-gross domestic product ratio means that the debtor country has to meet a 3.2% goods trade surplus. In the case of a private mortgage loan, this is not a large measure. But in a sovereign country, where creditors are not capable of enforcing their rights, they are not willing to allow the debt burden to increase above this measure.

There are two main factors that are able to influence the investors' views regarding the degree to which claims are recoverable favorably, making possible the toleration of the debt-to-gross domestic product ratios above 80%. The first factor is the following: the larger the private companies' debt and the lower the government debt, the larger the capability of repaying the debt, since future

governmental revenues are dependent on the political factors. The second factor is the following: if the debt composition comprises large equity investments, especially foreign direct investments, it is able to favorably influence the investors' behavior, since investors have a higher control over business activities that provide repayment guarantees[6].

4. Conclusion

This paper has analyzed the relationship between the current account deficit and different types of financial crises. A lasting and large current account deficit induces a severe foreign debt, which may lead to a debt crisis. If the central bank aims to maintain a given exchange rate target by allowing a high current account deficit and/or by allowing a reserves fall and/or creating adverse expectations, it may determine the emergence of speculative attacks and, finally, a currency crisis, which may imply negative real economic and welfare losses, especially if it is accompanied by a banking crises.

Speculative attacks on domestic currencies cannot be ruled out, since they are related to both the size of current account deficit and to the financing method. The likelihood of asymmetric shocks that affects a country and leads to a current account deficit and to negative changes within the financing structure is also important, even if a relatively flexible exchange rate mechanism is partially able to avoid this type of situation.

Ways of Classifying Banking Customers Using Fuzzy and Crisp Algorithms

Jeflea Victor Florin

Faculty of Economics, Ovidius University of Constanta

jefleavf@yahoo.com

Abstract

Customer care management has developed, mainly in the last years. The present level was reached as a result of implementing new information technologies. One of the sectors subject to these changes is that of classifying customers. Classifying clients has a fundamental function in communication, campaign development, elaborating new products, awarding existent customers. Having a portfolio of information regarding the customer with socio-demographic data and a history of transactions about each client, companies and banks may develop a new design of transaction profiles. [6],[5].

Keywords: customers, fuzzy classifying, crisp classifying

JEL Classification: D80

1. Introduction

Customer scoring is a new analytic procedure to assign each client a score or metrics on one or more transaction dimensions. Following are some examples of the most common behaviour characteristics: transaction volume, level of commitment and predisposition to respond to campaigns and promotions. These behaviour characteristics have the fundamental function of assessing the risk level of the customer, the profitability and the life value of the customer. [6],[4]. The validity and pertinence of the scoring assigned to the customers are given by the precision of the information and the classifying algorithm used.

2. Decision Support Software

Our purpose is to create a system for credit allowing to customer natural person. This approach consists of carrying out a system which operates with a series of information considered relevant regarding the customer, offering the credit officer a support instrument in taking decisions.

Two types of algorithms will be used:

Fuzzy algorithm In this case each relevant information about the client is fuzzyfied, resulting in a degree of belonging to the referred domain. Throughout the inference system a customer classification will be obtained, the fuzzifying is not net, but the client will belong to different classes, with different degrees of belonging.

This approach consists of carrying out a system which operates with a series of information considered relevant regarding the customer, offering the credit officer a support instrument in taking decisions.

The starting point is the way in which the customers are rated by the banks in order to receive a credit. The method consists of granting a scoring to each customer. In the case of assigning a scoring to a customer for a specific category, the scores will be assigned or not, without have the possibility to refine this choice.

Regarding the fuzzy techniques, each relevant information about the client is fuzzyfied, resulting in a degree of belonging to the referred domain. Throughout the inference system a customer classification will be obtained, the fuzzifying is not net, but the client will belong to different classes, with different degrees of belonging.

To start with the following variables were considered to be fuzzyfied: income and work experience. The other variables were considered as eligibility variables. For

the income 4 linguistic terms (Figure 1) Small, Medium, Large and Extra Large and for work experience 3 linguistic terms (Figure 2): Small, Medium and Large. The rule basis is described in (Figure 3) and in (Figure 5) is described the way of applying the inference. The resulted information is basically a scoring between 25 and 75 (arbitrary limits). The advantage of this method is that it allows a continuous variation of the customer scoring.

Figure 1 Linguistic terms for income

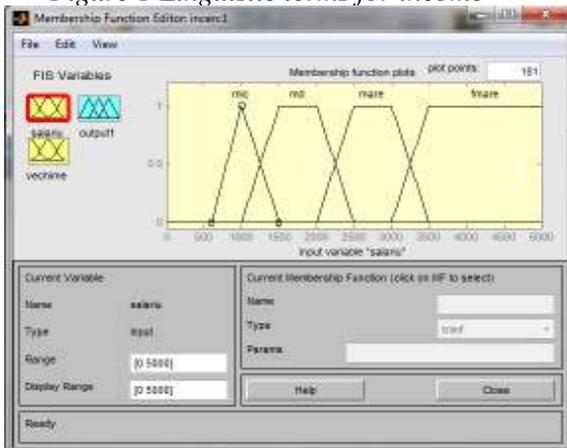

Figure 2 Linguistic terms for work experience

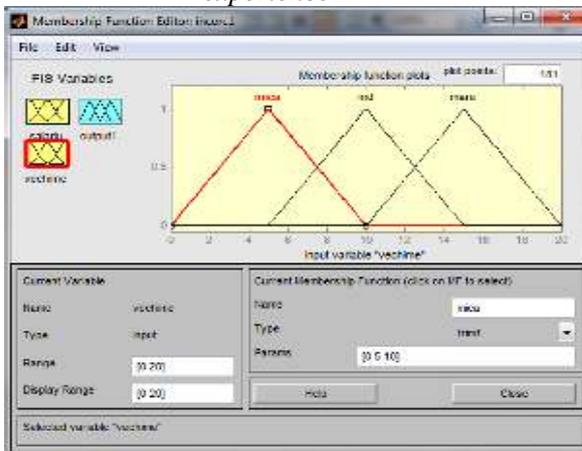

Figure 3 Scoring according to work experience and income

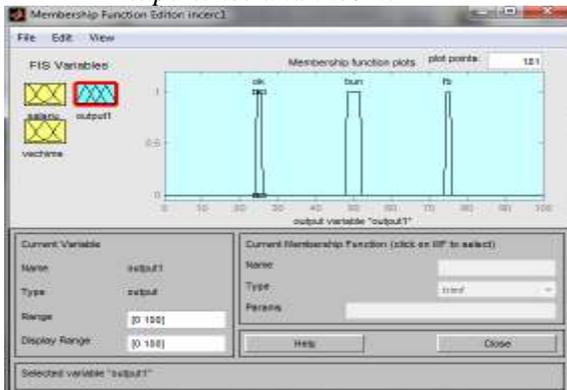

Figure 4 Rule basis

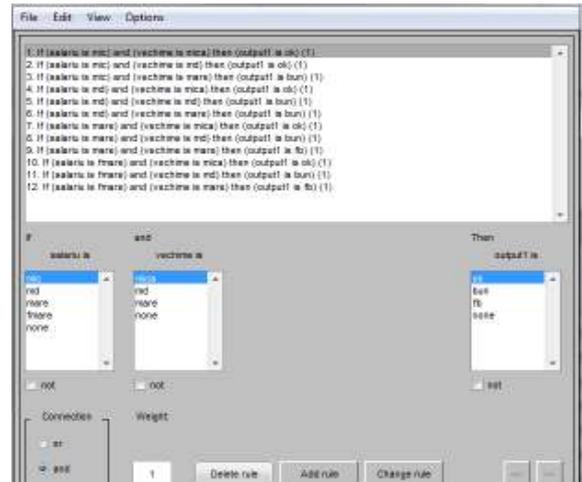

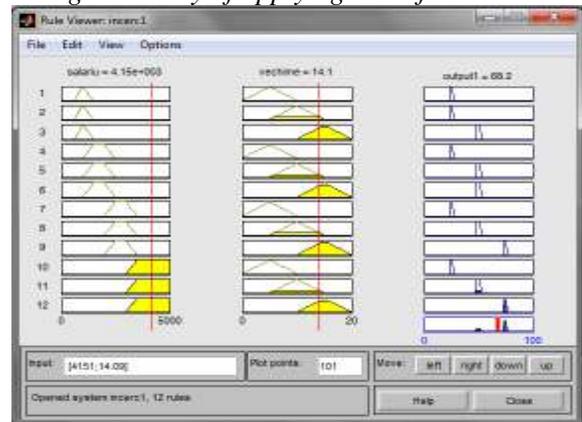

Figure 5 Way of applying the inference

Crisp algorithm In this case we use the approach from the classic sector of system for situation recognition. In this case, the customers will be classified in different classes, determined by relevant information gathered about them. Through data processing, related to class minimum distance, the customer will be included in one of the classes. Following the algorithm for situation recognition is presented and an example for the two-dimensional case, in which we have 2 entry information and 4 classes were considered (for examples with more entries the graphic representation is not possible).

The data processing algorithm is a part of the classic sector of the systems for situation recognition. The phases for implementing the algorithm are:

- normalizing measured variables, meaning bringing them in the domain [0,1]
- characteristics weight based on apriority information regarding their importance: $\tilde{x} = w^T x$ where vector

weight components are included in the $[0,1]$ domain;

- defining some poles, $\mathbf{p}_{ik}, k = \overline{1, m_i}$, which describe each class $S_i, i = \overline{1, p}$, and also some radial functions (potential functions) associated with the

$$K(\tilde{\mathbf{x}}, \mathbf{p}_k) \equiv \varphi_k(\tilde{\mathbf{x}}) = \frac{1}{1 + \alpha d^2(\tilde{\mathbf{x}}, \mathbf{p}_k)} \quad \text{the poles:} \quad (1)$$

- defining discriminant functions of S_i classes:

$$g_i(\tilde{\mathbf{x}}) = \boldsymbol{\gamma}_i^T \boldsymbol{\varphi}(\tilde{\mathbf{x}}) \quad (2)$$

where

$$\boldsymbol{\varphi}(\tilde{\mathbf{x}}) = [\varphi_1(\tilde{\mathbf{x}}) \ \varphi_2(\tilde{\mathbf{x}}) \ \dots \ \varphi_M(\tilde{\mathbf{x}})]^T \quad (3)$$

and

$$\boldsymbol{\gamma}_i = [\gamma_{i1} \ \gamma_{i2} \ \dots \ \gamma_{iM}]^T \quad (4)$$

Is the representative vector of S_i class. Vectors dimension

$$M = \sum_{i=1}^p m_i \quad (5)$$

- the decision rule regarding $\tilde{\mathbf{x}}$ vector belonging to S_i class is

$$\text{Max}_i \{g_i(\tilde{\mathbf{x}})\} = g_s(\tilde{\mathbf{x}}) \Rightarrow \tilde{\mathbf{x}} \in S_s \quad (6)$$

The representative vector (prototype) of a class, e.g. S_i , can be determined in two ways:

- by bringing vector components γ_i to values equal to +1 or -1, depending on the belonging, not belonging of the poles $\mathbf{p}_{ik}, k = \overline{1, M}$ to S_i class. For example, for S_1 class, the prototype vector is:

$$\boldsymbol{\gamma}_1 = [\underbrace{1 \ 1 \ \dots \ 1}_{\text{de } m_1 \text{ ori}} \ \underbrace{-1 \ -1 \ \dots \ -1}_{\text{de } M - m_1 \text{ ori}}]^T \quad (7)$$

- by adjusting in instruction duty the vector $\boldsymbol{\gamma}_i$.

In this case, the prototype vectors are initialized according to the previous mentioned procedure (see example (29)), initially marked with $\boldsymbol{\gamma}_i^0$. Instruction is necessary if, after determining the

prototype vectors, errors appear, that is assigning some $\tilde{\mathbf{x}}$ vectors to classes that are adjacent those they actually belong. To correct the class separation surface, the prototype will be adjusted through an instruction algorithm. In this case should be available, along with the M vectors initially used as classes poles, also a batch of instruction data, formed by vectors with known belonging. Considering N the number of vector from the instruction batch, the common instruction algorithm is:

$$\boldsymbol{\gamma}_i^k = \boldsymbol{\gamma}_i^{k-1} + \beta^k \left(y_i(\tilde{\mathbf{x}}^k) - \boldsymbol{\varphi}^T(\tilde{\mathbf{x}}^k) \boldsymbol{\gamma}_i^{k-1} \right) \boldsymbol{\varphi}(\tilde{\mathbf{x}}^k) \quad k = \overline{1, N} \quad (8)$$

where k is the current step of instruction iteration, β^k determines the instruction degree, and by $y_i(\tilde{\mathbf{x}}^k)$ is defined the $\tilde{\mathbf{x}}^k$ vector belonging, as follows:

$$y_i(\tilde{\mathbf{x}}^k) = \begin{cases} +1 & \text{daca } \tilde{\mathbf{x}}^k \in S_i \\ -1 & \text{daca } \tilde{\mathbf{x}}^k \notin S_i \end{cases} \quad (9)$$

In the case of the most simple version of the algorithm, the instruction degree is constant. In this case, choosing β metric takes into account convergent inconsistent requisites and ensuring stability.

A more efficient solution consists of using β^k as follows

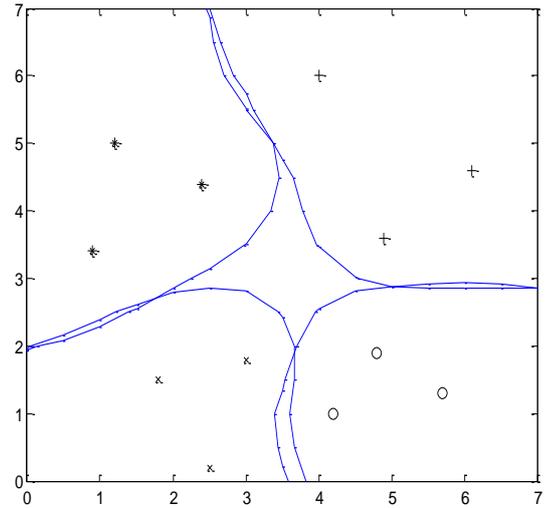

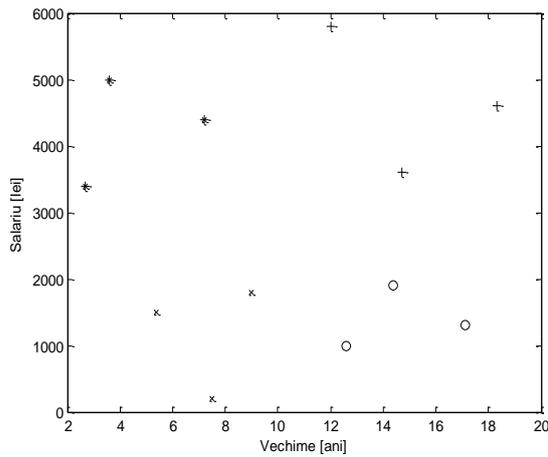

$$\beta^k = \frac{1}{\|\boldsymbol{\varphi}(\tilde{\mathbf{x}}^k)\|^2} \quad (10)$$

which leads to error correction algorithm.

The structure of the situation recognition instructable system correspond with a RBF type neuronal network, emulated of the computer.

In order to use the situation recognition algorithm we will consider the same example used with the fuzzy algorithm. Therefore, two essential information will be considered when classifying the customers, income and work experience, and 4 classes, $C_j, j = \overline{1, 4}$, where the customer can be included. For instruction, the data from (Figure 6) will be considered. Analyzing the figure we can observe a clear demarcation between the 4 classes.

Figure 6 Data used for instruction

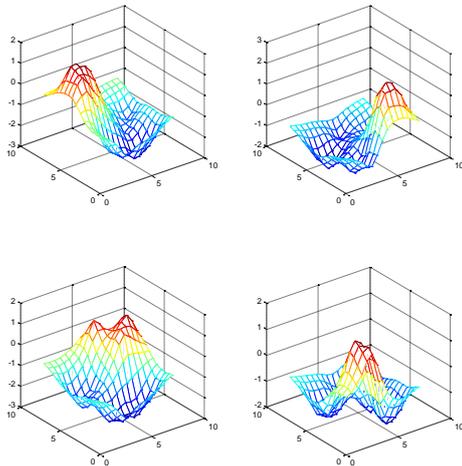

In the instruction procedure the entry vectors, income and work experience, are graded, so as to obtain two vectors having values between [0 7]. Following the instruction it is obtained the belonging of the entry data set to the four classes, as it is represented in (Figure 7), class delimitation being presented in (Figure 8).

In order to verify the recognition algorithm we will consider the following entry data: income with 12 years work experience and 2000lei income. After grading the entry vector is [4 2]. By applying the recognition vector we will have the following class discriminant functions:

- FP1 = -0.6510
- FP2 = -1.9309
- FP3 = -1.6513
- FP4 = 0.5668

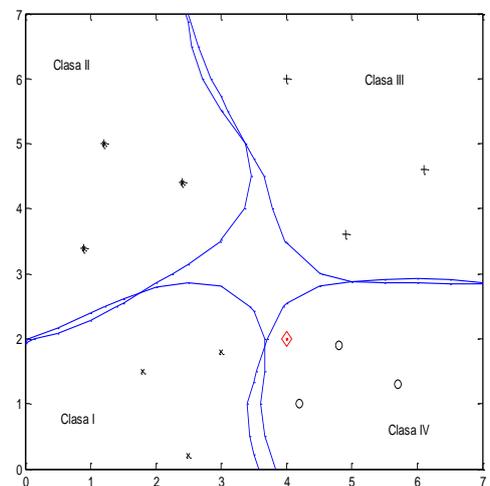

Figure 7 Data set belonging to the four considered classes

These discriminant function values show that the considered vector belongs to Class 4, corresponding to the maximum value of the resulted discriminant function. This situation is represented also in (Figure 9), where the tested vector is represented by the red dot.

Figure 8 Space partition as a result of instruction related with the 4 considered classes

Figure 9 Situation recognition example

3. Conclusions

Our software system is based on two algorithms Fuzzy algorithm and Crisp algorithm. In the first case each relevant information about the client is fuzzyfied, resulting in a degree of belonging to the referred domain. Throughout the inference system a customer classification will be obtained, the fuzzifying is not net, but the client will belong to different classes, with different degrees of belonging. In the second case we use the approach from the classic sector of system for situation recognition. In this case, the customers will be classified in different classes, determined by relevant information gathered about them. Through data processing, related to class minimum distance, the customer will be included in one of the classes. Following the algorithm for situation recognition is presented and an example for the two-dimensional case, in which we have 2 entry information and 4 classes were considered (for examples with more entries the graphic representation is not possible).

Cloud Computing Information System for Attracting Banking Sector Customers

Jeflea Victor Florin

Faculty of Economics, Ovidius University of Constanta

jefleavf@yahoo.com

Abstract

We have brought into effect the design of an application intended for attracting new customers, based on fuzzy algorithms and the integration in Private Cloud. Through customer classification techniques, based on fuzzy algorithms, through it's approach, the application represents a new information system.[4],[5] Basically the persons requesting a credit will replace the troublesome researches for the best lending offer with accessing the application available online and filling some documents.

Keywords: banking customers, cloud computing, information system

JEL Classification: D80

1. Introduction

The decision software used to allow a credit can be transformed into an application that can attract new customers through integration in Private Cloud field. In this manner the owner of the application can use an online interface to attract new customers. Through this application the necessary data to allow credits will be selected from potential clients. Based on the existent algorithm the customer is shaped using fuzzy elements and a scoring is obtained according to the scoring chart[6].

2. Cloud Implementation

Two types of algorithms will be used:

Fuzzy algorithm In this case each relevant information about the client is

fuzzyfied, resulting in a degree of belonging to the referred domain. Throughout the inference system a customer classification will be obtained, the fuzzifying is not net, but the client will belong to different classes, with different degrees of belonging.

This approach consists of carrying out a system which operates with a series of information considered relevant regarding the customer, offering the credit officer a support instrument in taking decisions.

The starting point is the way in which the customers are rated by the banks in order to receive a credit. The method consists of granting a scoring to each customer. In the case of assigning a scoring to a customer for a specific category, the scores will be assigned or not, without have the possibility to refine this choice.

Regarding the fuzzy techniques, each relevant information about the client is fuzzyfied, resulting in a degree of belonging to the referred domain. Throughout the inference system a customer classification will be obtained, the fuzzifying is not net, but the client will belong to different classes, with different degrees of belonging.

Crisp algorithm In this case we use the approach from the classic sector of system for situation recognition. In this case, the customers will be classified in different classes, determined by relevant information gathered about them. Through data processing, related to class minimum distance, the customer will be included in one of the classes. Following the algorithm for situation recognition is presented and an example for the two-dimensional case, in which we have 2 entry information and 4 classes were considered (for examples with more entries the graphic representation is not possible).

The obtained scoring will be reported to the customer in real time, afterwards to the banks along with the information gathered. The information will be verified by the banks and used to draw up the credit offer. The banks will contact the customers using the using the information made available to the Private Cloud owner. In order for the application to run adequately, the following types of agreements must exist:

- A first set agreement is between the owner of the Private Cloud and the banks involved in the project. Based on it the banks are obliged to promote the solution Cloud type (the website of the Private Cloud owner), and the Private Cloud owner is obliged to provide the banks with information about the customers[2],[3]. For example, the banks can request that the Cloud supplier would release only information about the customers that have a scoring of 70 points. The banks will draw up the credit offer and send it to potential customers. In addition the banks are obliged to inform the Cloud supplier about the customers that have accepted the credit offer.
- Another mandatory agreement is the one set between the Cloud supplier and potential customers regarding the trueness of the information introduced and sending it to the banks.
- Financial agreements set between the involved banks and the owner of the Private Cloud solution.[2],[3] For example, a commission paid by the bank to the owner of the Cloud for each credited customer will be set

Application description Data insertion Data insertion will be made using four forms (Figure 1, Figure 2, Figure 3, Figure 4)

Tip Angajator: privat, Numar angajati: 1000, Salariu: 1400 RON Contact Angajator: SIDEX Galati	

In contrast with other existent applications, the suggested application has the major advantage that it facilitates the assessment of contractual relation between the customer and different banks in a short period of time. Basically by filling in some forms the potential client, if he/she acquires the scoring, can be contacted by tens of banks having the total freedom of decision. Nowadays, there are online application designed to attract customers, but sadly they can only be considered a bank lending website, for example www.vreacredit.ro.

3. Conclusions

The mentioned example offers the visitors an ensemble of financial-banking information and establishes a relation between the client and the bank throughout a link. The visitor has the possibility to send the necessary information for a credit by filling in forms for each bank. In this manner he is in the situation of obtaining a credit in a classic way.

Modern Tendencies of Information Systems Use in Trade Organizations

Korneenko Olga
okorneenko@gsu.by
Doroshev Dmitry
doroshev@gsu.by

Abstract

This article covers aspects of implementation and use of information technology in retail trade organizations.

Key words: information, technology, systems, implementation, necessity

J.E.L. classification: M15

At present the small and medium-sized retail organizations are under more and more intense pressure of large Belarusian enterprises. To plan the further development is possible only by providing increased business efficiency what is impossible without implementation of multifunctional and reliable information systems that enable to control the retail structure, logistics, variety of goods, prices. Modern information systems provide the ability to treat a large volume of information, to cooperate with enterprises branches, to increase speed and quality of client service.

The purpose of this article is to identify the critical factors required to implement information systems in the management of commercial activities, as well as to analyze the complexity of this process and its privileges relative to facilitation and improvement of operational control of the company.

At this moment the predominant focus is to implement widely the informational and analytical systems to forecast demand, to plan purchases, to manage stocks, to merchandise effectively etc. [1].

In our view, the implementation of information technology (IT) is connected with:

- the technological necessity – when using of IT is dictated by the need to ensure complex manufacturing operations (e.g.

processing of barcode). The same technological needs force the wholesale trade organizations to implement computer programs to print shipping documentation which volume is significant for wholesale trade and without automation is almost unrealized;

- need to have analytical tools to measure the efficiency – if you have a large number of homogenous "production sites" (branches, sales managers, etc.), you need and you should to compare constantly the results of their activities. Thanks to the implementation of information systems, the assessment of enterprises situation, rapid orientation in trade and financial flows, covering all stages of the movement of goods cycle become possible.

There are five main causes explaining why it is difficult to implement information systems and to use them at the Belarusian enterprises of retail trade:

- superficial understanding of the concept by the enterprise managers;
- insufficient development of the IT-infrastructure of the enterprise;
- low qualification of consultants of the enterprise;
- errors while selecting an automated system;
- resistance of the staff of the same trade enterprise [2].

Today the clients self-service software tools are actively developed (self-service terminals, information kiosks, using price-checkers, etc.); IT-support of the clients' loyalty programs, collection and processing of personal data, as well as expansion POS-terminals functionality through program support of their functions. For example, viewing the status of stocks balances, visual identification of the product - ID Imaging, support of RFID- technologies for carrying out the payments, etc. They allow to offer

products that meet in optimal way the needs of customers, to process quickly, to distribute orders and to monitor their execution, to schedule deliveries, to forecast the demand for optimal control of stock resources, for example, using IBS Trade House program and IBS Retail Analytic program.

The enterprises of retail trade show interest in the following areas of information:

- BI - data analysis systems to process more quickly large quantities of information that allow to obtain quickly the summary data on the performance of the whole enterprise (for example, SAP, Microsoft Dynamics AX, Oracle BI systems), to analyze all information available in the trade organization regardless the kind of information system in which it accumulates. This decision is based on a data warehouse that accumulates information from various sources and, thanks to its special structure, allows to generate reports more quickly than ERP-systems. There is no more need to contact programmers to generate reports with the required data from different systems, to unload the data in Excel what greatly improves the speed of the analysis and quality of taken decisions based on it[3];
- customers relationship management – CRM. In the conditions of increasing competition, a growing number of commercial enterprises are interested to know better their customers and to implement effectively policy in the field of assortment, marketing and discounts management. In addition to the various CRM- systems, there are different IT-products to interact with clients via SMS and specialized programs that use bonus cards;
- Stores Commerce Management (SCM) that are asked by trading companies (for example, Visual Pos Manager (VPM) which allows to manage all the cash and discounts of retail chain from a single center, and which integrates with SAP Retail, Microsoft Dynamics AX, 1C, Oracle Retail, etc). Among the evaluation criteria, we can mention the registration of the needs in a specific segment of the retail market, an easy scalability if the organization grows, a use of modern IT development tools, a proven technology of implementation and operation. The competitive advantages: functionality, reliability and proven technology of the implementation, assistance and training of the users;
- working places of cashiers – PosX, equipped with a cash program, as besides standard operations of money acceptance and change giving, it needs to organize the non-cash payments, the discount and bonus cards service;
- "1C: Retail 8" on the platform "1C: Enterprise 8" program supports geographically distributed information bases (DIB). This provides clear separation of documents circulation within shops, and the information on all shopping network is consolidated in the central node of the DIB. As a result, all processes requiring information exchange are realized not only with minimal effort, but also according to the schedule, and the centre gets promptly information necessary for taking management decisions on sales and movement of goods. At the same time, the "1C: Retail 8" already includes the ready plans of exchange. The "1C: Retail 8" automates the entire range of necessary operations within the retail store, new business processes, it generates accounting reports for operational management. The connection of a wide range of commercial equipment of various types is supported– barcode scanners, data collection terminals, fiscal recorders, magnetic cards readers, cash registers, electronic scales, etc.;
- use of Pocket PCs or communicators (PDA), i.e. mobile commerce, RFID system. These devices are used as storage information data on customers, products, accounts and are used to record information about sales. Data are regularly synchronized with the main accounting system of the enterprise. The possibilities: making applications for sale of goods; merchandising; the calculation of the recommended quantity for an order; accounting of cash refunds, mutual settlements of accounts with clients; management of several firms; individual system of discounts; reminders of

promotions, new products and discounts; catalogue of goods photos; planned visits to sales agents, control agents route, GPS support, control of the date and time of visit, etc. The system increases the efficiency of the sales agents and saves their time for direct communication with customers. Collection, processing and analysis of information on time close to real-time allow to adjust quickly the work of the company, as well as to take into account the change of external factors earlier than their competitors [3].

Thus, the application of information technology in retail trade largely determines the success of the development of a trade organization.

The information products are designed to simplify and to improve the monitoring system of operational activities of the company (finance and costs, stocks and warehouse, purchasing and sales, accounts receivable and pricing policy), to manage relationship with customers and suppliers, to control the sales process. If earlier the market offered solutions affordable only by large enterprises, in recent years have appeared the full-fledged mobile trade automation systems available even for small enterprises [4, p. 56-57].

On the modern market, competitive positions can be kept only by those who constantly develop and use new information technologies that results in a reduction of operation costs, obtaining additional revenue due to increased turnover and/or investment attraction of the company.

despina.muhcina@gmail.com

Abstract

The purpose of this paper is to illustrate the importance of cloud computing to an E-Commerce business. This has been done by analyzing both the benefits and the risks implied by this technology, one which has been quickly developing for the past few years.

Firstly, we present the notions involved in this paper. Secondly, we present and detail the benefits and risks of using cloud computing. Lastly, we draw our personal conclusion.

Keywords: Cloud Computing, E-Commerce, Marketing, Business

J.E.L. Classification: M20

1. Introduction

Every year, numerous entrepreneurs come up with different ideas to start a new business. For the majority of them, there are nowadays various technologies and IT solutions that offer entrepreneurs solutions for the infrastructure and the management of a business. Nevertheless, information technology is a domain that is rapidly changing due to the fast-paced technological development, and as a consequence, these solutions can sometimes be replaced by other, more efficient and improved. For the past years, cloud computing has become one of the IT innovations that can improve a company or a business' activity; thereby, it

can also be applied to E-Commerce businesses.

E-Commerce is “a type of industry where buying and selling of product or service is conducted over electronic systems such as the Internet and other computer networks”^[1]. It is associated with notions such as: automated data collection systems, online transaction processing, electronic data interchange and Internet marketing^[1].

Cloud computing refers to “the delivery of computing services over the Internet”^[2] (the “cloud”) and is beneficial especially for small and medium-sized businesses and companies.

The services offered by cloud computing can be applied to areas such as: project management (Paymo), customer relationship management (Salesforce), database (QuickBase, ZeusDB, Amazon SimpleDB), accounting and finance (FreshBooks, Intuit Payroll, QuickBooks), online storage and collaboration (Google Drive, Microsoft SkyDrive, Dropbox), risk management (PureCloud)^[3].

The cloud offers entrepreneurs access to sophisticated technologies without the need of a trained IT specialist. Thus, it is beneficial especially for small and medium-sized businesses that do not have many resources available or specially trained people.

Cloud computing services providers can offer entrepreneurs various marketing solutions, such as: E-mail Marketing, Mobile Marketing, Targeting etc.

These providers of cloud computing services can help marketers to initiate and

develop marketing researches or promotional campaigns, using various promotional tools, such as: advertising and direct marketing, marketing events etc.

In the following paragraphs, we will present and detail the benefits and the risks of cloud computing for small and medium-sized E-Commerce businesses.

2. Benefits

2.1 Reducing Costs

One of the main benefits offered by the cloud technologies for small and medium-sized businesses is represented by the reduced costs. As the cloud provides access to various technologies without the need of trained specialists, staff or consultants, the company will reduce its costs by reducing the number of people needed in the business.

Moreover, using the services provided by the cloud can mean reducing the necessary material resources or licenses for the business. For instance, in some cases, an E-Commerce company may only need as little as a desktop PC, a laptop or even a mobile device (and may not need a specific server, such as a database server). Also, the material resources do not need to be very sophisticated or performant, because they will not support such complex programs anymore.

On the other hand, marketing services providers that are cloud computing customers can promote cloud computing services. This aspect could be beneficial for both parties involved, because they compensate the prices of their services.

However, the cost can be influenced by the chosen cloud infrastructure provider.

In regard to planning the budget of the E-Commerce company, it is important to know that using cloud technologies will mean a transition from capital expenses to operating expenses. Capital expenses of material resources may be replaced by operating expenses for running the system, monthly fees for the cloud providers^[5].

2.2 Flexibility and agility

A key benefit of cloud computing is represented by “the independence from the office”^[4]. Data may not necessarily be kept

in in-house servers, so employees are able to access it from outside the office. As a consequence, work becomes more flexible and problems are easily and quickly solved.

What is more, it is easier to apply changes, test new features or improve the customer experience, as the E-Commerce company is not dependent anymore on a high-cost infrastructure and can revert back to the original system if the changes did not appeal^[4].

In addition to this, updating and synchronizing product databases, for example, is easier and quicker to do and thus, more efficient. Data will be available to customers easier and quicker, which may result in higher revenue for the company. A slower performance of data access due to excessive traffic on the in-house servers is not an issue anymore when using cloud computing^[6].

2.3 Reliability and security

Cloud services can be more reliable, due to the specially trained and experienced personnel and to technical support available, in comparison with an inner-company IT team, for example. Moreover, the cloud provider may have more experience and knowledge in matters of security issues than the staff of the E-Commerce company^[4].

Also, with cloud computing, it is less probable to lose data. In the case of in-house servers, data is more likely to be lost, due to human errors or unfavorable events (local floods, fires etc.). Another advantage is represented by the ease of data recovery. Thus, even in case of such unfavorable situations as above, your data in the cloud cannot be lost^[5]. Moreover, data can be duplicated across various virtual servers, which is also a plus for data recovery^[6]; as an example, an E-Commerce company could store and duplicate its product and customers databases on different virtual servers to gain more stability and security.

3. Risks

3.1 Network dependency

The main disadvantage of cloud computing is the dependency to the network (usually the Internet). Thus, in order to

benefit from the innovations of the cloud, you must have access to the Internet.

Moreover, this implies that the system is prone to interruptions at any given time, without prior notification. For an E-Commerce business, this could mean that during a transaction or an auction, the system can suffer an outage and the action in course can be delayed or even lost. Inconveniences may also appear if the vendor's services or the provider's system goes down^[4].

3.2 Security

Although data may be more secure and easily-recovered in the cloud, there are also some risks implied when storing it online. First of all, the fact that the data is “crossing more borders”^[2] can make it more vulnerable to interception and hacking. Secondly, the company must be aware that the data entrusted to the cloud provider is protected and it is not available to other parties (for example, for advertising purposes)^[2].

Conclusion

Taking everything into consideration, it seems that integrating cloud technologies into small or medium-sized E-Commerce business would bring rather benefits than risks. It is important to note that such a business is characterized by a limited budget or by few people involved.

First of all, an E-Commerce company could store its product and customers databases on a chosen virtual server, and also duplicate them using a different virtual server. Thus, the capital spent on buying expensive in-house servers is replaced with the monthly fee for the service provider (if required). This way, the company not only reduces its costs, but also gains more security over the data handled.

Moreover, the E-Commerce company could use cloud computing for services of project management, customer relationship management, accounting, IT solutions or risk management. Consequently, it would avoid costs associated with program licenses or specially trained personnel. The platform used would be more flexible and it would allow the company to change and update the system easier and quicker. This could be

reflected in the company revenue and could even help attracting more customers.

From the E-commerce and marketing business point of view, a future prospect in cloud computing can be represented by the improvement of databases and marketing approaches, and the development of new marketing techniques, methods and instruments (especially in marketing researches, advertising or distribution policy areas).

The most important risks are related to issues of security and confidentiality of the clients' databases, and the high dependence to the provider's technology, stability and seriousness.

In conclusion, the activity of the E-Commerce company could become simpler and more efficient if the management decides to use cloud computing, this new innovation in technology.

Abstract

The aim of Lisbon Strategy is for European Union to become "the most dynamic and competitive knowledge-based economy in the world capable of sustainable economic growth with more and better jobs and greater social cohesion, and respect for the environment by 2010".

Within this context, as Romania is part of European Union and adhere to the same goals, studying the evolution of the possibilities of knowledge development and the effective use of the environment that favors knowledge, in the past, between 1995 and 2007, to underline the contributions to the accomplishment of European Union's goal, is essential.

There is also of great interest the comparison over time of Romania, other European countries and also the first place country developments towards knowledge-based economy.

Key words: Knowledge-Based Economy, Knowledge Index, Romania

J.E.L classification.: O11, O19

1. Introduction

Within the Lisbon Strategy context, as Romania is part of European Union and adhere to the same goals, studying the evolution of the possibilities of knowledge development and the effective use of the environment that favors knowledge, in the past, between 1995 and 2007, to underline the contributions to the accomplishment of European Union's goal, the is essential.

There is also of great interest the comparison over time of Romania, other European countries, mainly its neighbors, and also the first placed country developments towards knowledge-based economy.

In order to highlight the accomplishments of Romania towards the knowledge-based economy there will be used an interactive instrument provided by World Bank, using a system of 80 variables to order 132 countries under two coordinates: index of knowledge (KI) and index of knowledge economy (KEI).

The World Bank Group methodology for determining the ability of a country to generate, adopt and diffuse knowledge, representing the possibility to develop knowledge of the analyzed country, is materialized into an index of knowledge (KI).

The index of knowledge economy (KEI) is aimed to quantify the effective use of the environment that favors knowledge for economic development of that country.

To have a complete picture of the present state of art in the field of knowledge-based economy regarding Romania, there will be conducted a SWOT analyze, straightening the conclusions drawn after applying the World Bank instrument.

Using this instrument will proof that Romania have registered important changes and important accomplishments towards a knowledge-based economy, proving that even before the accession it was prepared to support the European Union's goal.

2. Knowledge development in Romania

A knowledge-based economy is represented by the sum of firms practicing knowledge management and having been implemented a knowledge management system.

In particular cases, the development of different firms in their demarche for implementing a knowledge management system and thus sustaining the knowledge-based economy, is more or less visible, but as a whole, the development of this new economy, towards the way of using new resources – knowledge – may be estimated and monitored using the methodology and the instrument of World Bank.

Using the interactive instrument of benchmarking offered by World Bank Group [5, 6, 7] there were concluded the following facts, considering that there were used values reported to the number of people from each country for a more accurate relevance.

In 1995 data, Romania occupied the 51 place in the top (KEI = 5.37), compared with the country from the first place – Sweden (KEI = 9.2).

Compared to 1995, Romania obtained, based on most recent data, the 54 place in the top, with a value of 5.37, compared with the first on top, Denmark, with 9.23. Also, in 1995 Romania occupied the place 54 (KI = 5.41) and place 47 based on most recent data (KI = 5.58).

An analyze regarding KEI values over time was also developed in order to compare Romania and its neighbors in their demarche towards knowledge-based economy.

In 1995 Hungary had a KEI value of 6.99, Poland a value of 6.48, and Bulgaria a value of 5.81; according to the most recent data, Hungary has a value of 7.64, Poland a value of 7.24 and Bulgaria a value of 5.86.

The differences between Romania's KEI values and its European neighbors have increased in case of Hungary from 1.66 to 1.78, in case of Poland from 1.15 to 1.38 and have decreased in case of Bulgaria from 0.48 to 0.32.

3. SWOT analyze

The SWOT analyze is aimed to present the most important straights, weaknesses, opportunities and threats that Romania is

facing towards its way to a knowledge-based economy [1, 2, 3, 4].

Romania acceded to membership in the European Union in January 2007. In the past, governments have lacked political will and have backed away from reform at the first sign of popular opposition.

The present weakness is lack of progress in reducing corruption, which had held up Romania's accession to the EU.

However, the EU has targeted corruption in Romania and is working with the government to address the issue in a concerted fashion.

In comparison to its EU Balkan neighbors Romania comes a distant third in terms of the World Bank's Control of Corruption indicator behind Slovenia, Croatia and Bulgaria.

The political weakness is also the state bureaucracy that is slow and cumbersome with the result being that some foreign investors may encounter substantial delays and problems in sorting through red tape.

Another weakness comes from the legal environment, which is unpredictable and there has been considerable legislative change throughout the past years in the lead up and following Romania's accession to the EU in January 2007.

Laws are in place to protect property and contractual rights, including guarantees preventing expropriation, but the enforcement mechanisms are weak.

From the economic point of view, the straight is a favorable attitude towards improving the investment environment and accessing European funds.

From the economic point of view, a threat is that the fiscal policy is understandable but disconcerting.

Most of the increase in planned spending is in public capital infrastructure, public sector wages and subsidies payments.

Projections of revenues net of EU transfers are fairly conservative, with only a small increase budgeted.

The threat is that an expansionary fiscal policy at this stage in the business cycle will only add to already high domestic pressures in the economy and will make very hard work for the NBR to maintain control of inflation.

From the social point of view, the most important threat is that Romania, as well as

other Eastern European countries, has a low level of social capital, as a result of the systemic destruction of the civil society and of private property.

Values and norm such as trust, transparency, reciprocity and participation have been undermined.

This is reflected in people’s passivity, and inability to express adequate demands, inability to understand and accept the differences and to participate at community level in activities of common interest. From the point of view of technological environment, the use of computers telephones and Internet is increasing, this being an opportunity for the development of a knowledge-based economy.

In conclusion, the most important straight are represented by: highly qualified human resources; low cost of human resources; high flexibility of manpower; presence of IT companies from US and Europe.

Also, one must consider: sound software industry base employing over 25,000 people; strategic market location to serve EU; workforce with knowledge of English, French and German; inherent cultural and linguistic ability for rendering IT-enabled services.

In short, weaknesses are represented by the fact that: business environment lacks credibility; high cost of telecommunications infrastructure; lack of credible investment policies keeping foreign investors and companies; insufficient resources for marketing and brand building; lack of understanding of software quality, certification and development methodologies.

The opportunities consists of: Romanian market for e-business, e-governance and the developing knowledge society; fast growing West Europe IT market having cultural similarities.

Also, there has to be considered: large emerging global IT market for off shore development, R&D, IT-enabled services; e-commerce necessitating skilled professionals; IT deployment improving productivity of other sectors.

And the threats for Romania are: lack of a domestic market to enable industry to develop expertise; lack of communication between government and industry. Some other lacks include: lack of support programs

for industry promotion; lack of a coherent industry image; too less employment in IT sector.

4. Conclusions

Romania have registered improvements, translated both through a better and effective use of the environment that favors knowledge (KEI), and through the increased possibility to develop knowledge (KI).Papers are written electronically, using a word-processing application.

Also it has registered important successes compared with its neighbors, also members of EU. But the fact that there is a social capital missing and that the legal environment is so changeable may affect the progress towards a knowledge-based economy.

Romania implemented strategies for using opportunities and eliminating threats, considering the high qualified work force and the interest for IT industry – as IT is an enabler for a knowledge-based economy.

Also, there is a great opportunity for Romania accessing European funds, designed to support the development of knowledge-based economy that it has to use.

Abstract

The paper aims to present an approach in evaluation of knowledge management processes and systems, based on a case study regarding the development of knowledge management processes and knowledge management system within an IT corporation, which goal is to increase the use of knowledge, considering the context of the knowledge-based economy development.

The paper is focused on synthesizing the main aspects of applying a well-known model, McKinsey model, operational made by European Committee for Standardization.

Key words: Knowledge-Based, McKinsey, system

J.E.L clasification.: C00, C81, C83

1. Introduction

Knowledge management is a debatable subject for at least 20 years, some researchers and specialists considering it to be a fad, others a mean of development [3, 4, 7]. Considering the large number of organizations – public or private – that have applied successfully the processes and principles of knowledge management, many of them becoming case studies, we consider that knowledge management is a concept of which application is essential in order to win competitive battle.

Even considering scientific aspect of knowledge management, its development is a boom within last five years, consisting mostly in the interest for the development of instruments to measure the impact of knowledge management processes and knowledge management systems over the firms [10]. Over the years, many known and

recognized organisms have established such instruments [1, 9].

The present paper is aimed to underline the importance of using such instruments in order to eliminate the subjectivism and qualitative feature of knowledge management evaluation. It consists of presenting and applying a quantitative instrument, McKinsey model in order to evaluate the knowledge management processes and knowledge management system for an IT company.

The instrument consists in a questionnaire applied on the employees of the corporation for a representative sample, the questionnaire being proposed by the European Committee for Standardization. The conclusions consist in strengths and weaknesses, at the organization and individual level, regarding the processes of knowledge management.

2. The model of McKinsey

The model was developed by Tom Peters and Robert Waterman, consultants for McKinsey & Co. They have published an article called “Structure Is Not Organization” (1980) [5, 8] and also few chapters in the following books: “The Art of Japanese Management” (1981) [5] and “In Search of Excellence” (1982) [6], all of them regarding this model.

The authors consider that the organizations consists of seven elements, from which, three are called “hard S” and the other four, “soft S”. The “hard S” may be found within the documents of the organization, and the “soft S” are determined mostly by human resource, this meaning that they are much more difficult to be planned or influenced, having a strong impact over the “hard S”.

Hard elements are easy to be identified and consists of structure, strategy and system within the organization, meanwhile soft elements are difficult to be described are represented by skills, style, staff and shared values, their characteristics being presented in table 1.

Regarding the application of this model for evaluation in the knowledge management field of study, the CWA 14924-4 resolution of European Committee for Standardization presents an instrument, a questionnaire that made this model ready to be applied, in order to evaluate the development of the knowledge management processes. The questionnaire consists of 42 questions evaluated by the respondents with a scale between 1 and 5.

In the end, the important aspects are those regarding the questions that have obtained the highest or the lowest score, consisting in strengths and weaknesses in development of a knowledge management system and/or knowledge management processes.

Table1: The McKinsey Model

Hard S	
Strategy	Actions that the organization plan in order to respond or anticipate the changes from external environment
Structure	The basis for specializations and coordination, determined by the strategy and the dimensions of the organization.
System	Formal and informal procedures for making operational the structure and the strategy.
Soft S	
Style	Managerial style: the way in which the manager motivates, coordinates, control and lead the employees.
Skills	Distinctive competencies that determine the success and strategic differentiation of an organization.
Staff	Human resources management: selection process, socialization, integration of new employees, career management.
Shared values	Organizational culture: values, beliefs, development norms

	along with the organization's life.
--	-------------------------------------

Data source: Peters, T., Waterman, R., In search of excellence, New York, London: Harper and Row, 1982, pg.113]

The authors say that the efficient organizations benefice from the capacity to harmonize all the elements, this criteria generating in time the other name of the model: organizational efficiency diagnosis model.

3. The methodology

The questionnaire was applied first in 2009 and then in 2012, for comparative results.

In order to apply the questionnaire, it was first established the size of the representative sample, formed by 384 employees. The sample was established using aleatory and systematic aleatory sampling techniques [2] at the level of the whole population represented by the employees of a big IT company from Romania – the name of the company remains unknown because of the agreement with the organization's management.

Base on the aleatory sampling, the sample was chosen from a list – the list of employees' name, then it was established the length of the interval – of the mechanical step – used for the process of selection. The length calculated was 2, the aleatory, it was chosen a component from the collectivity – the starting point for the others – considering the length of the interval.

The starting point was, in this case, an employee having the surname starting with A, from a division chosen aleatory, then choosing the other elements for the sample from all the 8 divisions of the company. The level of trust was 95%, the accepted error was +/- 5%, the value of z factor was 1.96.

The preliminary check of the questionnaire, the pilot study and the viability of the questionnaire were considered implicit because of the reputation of the Committee that has promoted the questionnaire.

From the total of 384 distributed questionnaires, there were collected 347, the rate of respond being 90%. The responses

were analyzed by using software, SPSS for Windows, the results being the following.

4. The results of the study

After collecting the questionnaires and synthesizing the main results, for each process of knowledge management, it was then calculated the balanced average of the results for each of the variables of the questionnaire.

The results are presented for the general situation of the IT company regarding the general situation and the knowledge management processes, for each of the seven elements of the model and also for other two elements – attitude and performances – in using the processes of knowledge management.

From the point of view of McKinsey model, considering the development and the improvement of the knowledge management processes, the straights were and still are represented by strategy (4.690 and 4.720), skills (4.791 and 4.811) and shared values (4.702 and 4.705).

These figures attest the fact that the organization has a strong strategy regarding knowledge management processes and the organizational culture is favorable to the development of these processes.

Also the distinctive competencies have determined the success of the development of knowledge management processes.

The weaknesses consisted and still consists of staff (3.090 and 3.110), meaning their implication for the development of the processes, which can be correlated with the managerial style (3.740 and 3.114), mainly the neutral perception regarding the stimulants, offered for the employees in order to improve the knowledge management processes.

From the point of view of knowledge management processes, the straights regarded and still regards sharing knowledge (4.448 and 4.449) and creation of knowledge (4.272 and 4.445), the results being justified considering the characteristics of the main processes conducted within the organization, centered on tacit knowledge.

The weakness, more correctly called aspects that need improvement, consisted and still consists of knowledge storage (3.431 and 3.556).

Considering individual level, from the point of view of knowledge management processes, the straights were and are represented by the creation and storage of knowledge (4.040 and 4.112), because of the attitude and the performances of the employees.

Also, the perception regarding the individual performance concerning the development of the processes, namely personal contributions to this development, is favorable (4.178 and 4.558).

5. Conclusions

After applying the McKinsey model, in 2009 and 2012, the conclusions are that the corporation evolves favorably towards the development and improvement of the knowledge management processes at the level of the basic processes.

Organizational aspects, that still necessitate special attention consists of more implication of the employees for the improvement of the attitude for the knowledge management as a phenomena, aiming to the development of storage knowledge.

The general conclusion of the paper is that, by providing a quantitative instrument for evaluating knowledge management processes from the point of view of development and improvement, both the science field and the practice in knowledge management matters is improved, the questionnaire and the model being one of the most used and cited over the literature from now on.

Abstract

Over the last few decades wind energy renewed the interest to its environmental benefits over fossil fuel combustion. The wind has been used as an energy source by people in the past and as long as the wind continues to blow, its power can be used on the large scale. The wind is converted into electricity creating wind energy so that it can be used as a source of power. This paper will try to make an analysis of wind situation in Europe and Romania and to make some forecasts concerning the continent and the region.

Keywords: wind energy, investments dynamic, green investments.

JEL classification: E22, Q01, Q20, Q43

1. Introduction

In the current context, characterized by an alarming increase of pollution from energy production from fossil fuels, it becomes increasingly important to reduce dependence on these fuels. Wind energy has already proven to be a very good solution to the global energy problem. The renewable resources are important not only for the energy production, but their use is offering a new model of development and decentralization of the resources.

Wind energy is a renewable energy source generated from wind power. The kinetic energy [17] of the wind can be used to turn some turbines, which are able to generate electricity. Formation of winds is due to the earth's motion and because the sun does not heat the Earth evenly, which creates air

movement. Use wind to generate electricity was a technique much used in ancient times.

To produce enough electricity for a lot of consumers, power companies build "wind farms" with dozens of huge wind turbines. Wind farms are built in the open plains, where the wind blows at least 14 mph. It is estimated that the global technical potential of wind energy can provide five times more energy than is consumed now. This level of service would require 12.7% of Earth's surface for operation on the assumption that the land would be covered with 6 large wind turbines per square kilometer. These figures do not take into account the continuously improving obtained in turbine efficiency and other technical solutions in practice [17].

2. Literature Review

The green energy field has a large dynamics in the present – this phenomenon began in the last years, precisely in the last decade. The ideas, however, are more ancient but the traditional resources presence did not required a major shift in perspective, though the academia constantly warned the business about the risks of using fossil fuels. Of all these views, we remember some that underpin the form and the content of our article. First, we remember „The Renewable Energy Policy Manual” of John Armstrong and Jan Hamrin in „U.S. Export Council for Renewable Energy”[2]. The authors bring to the fore the strategic capital investment in electricity generating and the global warming demand, a deregulated framework for renewable energy. They are underlying assumptions for a rational and analytical framework, which assumes a potential

objective shared by the governments and the private sectors. This manual seeks to identify those issues that are the most relevant to countries that are seeking to attract private capital for their renewable energy. We complete this rational point of view with Fred Beck and Eric Martinot. In their study „Renewable Energy Policies and Barriers”[4] they noting the explosion of energy policy changes that occurred around the globe during the 1990s. These changes have been driven by economic, environmental, security and social concerns, and have in turn had a profound influence on renewable energy. The article therefore explores the barriers that have traditionally faced renewable energy policies. The barriers to renewable energy are subdivided into three broad categories; first, under costs and pricing, secondly, legal and regulatory factors are explored and finally are considered the factors that influencing the market performance of renewable energy sources.

In this renewable energy market context we remind the Rodney Janssen opinion concerning „The Evolving Renewable Energy Market”[6]. The publication explores the changing status of renewable energy sources and technologies. He discusses about the future development of renewable energy technologies in terms of development of new energy industries and markets and in terms of the energy policies that may facilitate the development of all these. Dr. Keith Kozloff makes an interesting analysis in „Electricity Sector Reform in Developing Countries: Implications for Renewable Energy”[8]. In the face of growing demand for electricity and the increasingly apparent environmental problems associated with carbon emission, energy sector reform in developing countries will need to address the potential of renewable energy sources says Kozloff. The article anticipates a trend towards the abandonment of centrally planned electricity systems in developing countries and explores the impact of electricity sector reforms on markets for renewable energy.

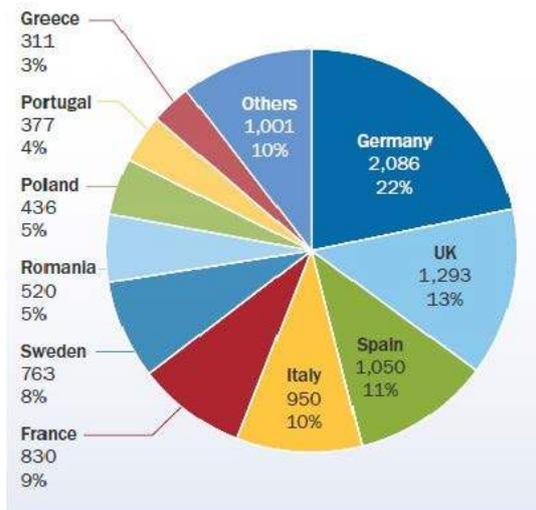

In comparison terms we bring in discussion another two studies. First, the article of Navroz Dubash, „Revisiting Electricity Reform: The Case for a Sustainable Development Approach” [5]. This article explores the recent transformation of the conventional wisdom

on the structure and operation of the electricity sector and the associated trend towards power sector reform. The article focuses specifically on the drivers of electricity reforms in the developing world and on the potential for social and environmental benefits from electricity reform. Secondly, the article of Joanna Lewis, a excellent comparison of wind industry development in three different countries: „A Comparison of Wind Power Industry Development Strategies in Spain, India and China” [9]. The paper compares the manner in which three companies – situated in Spain, India and China – became domestic leaders in the wind industries of their countries. After a brief overview of the global wind industry, the paper presents case studies of India, Spain and China, and concludes with a comparative analysis of the three countries. Each of the case studies explores the policy environment for wind energy and the business practices of the leading wind turbine manufacturer. In the same time we remind the documents of The European Wind Energy Association, Global Wind Energy Council and Romanian Wind Energy Association.

3. Wind energy in EU - market case study

During 2011[11], 10,281 MW wind energy were installed across Europe, including EU countries accounted for 9,616 MW. EU investment in wind farms in 2011 were € 12.6 billion, the sector reached 10.2 billion onshore and offshore at € 2.4 billion. From 10,281 MW of installed capacity in Europe, 9415 MW were installed onshore and 866 MW offshore. This means that in 2011 offshore market fell slightly (by 1.9%) than in 2010, but the prospects are encouraging in terms of preparation for new offshore projects. There are numerous offers for financing, suggesting a strong foundation for future growth. In terms of annual installations, Germany was by far the largest market in 2011, installing 2,086 MW of new capacity.

Figure 1 - EU Member State market shares for new capacity installed during 2011 in MW. Total 9,616 MW

Source: European Wind Energy Association

UK has stabilized in second place with 1293 MW, including 752 MW of offshore capacity, followed by Spain (1050 MW), Italy (950 MW), France (830 MW), Sweden (763 MW) and Romania (520 MW). Among the markets of Central and Eastern Europe, Poland was second after Romania, installing 436 MW. Both countries are still among the top ten European markets for the second consecutive year.

2011 was a record year for new installations for energy production in the European Union with 44.9 GW of new capacity added to the grid, an increase of 3.9% compared to 2010. Wind power accounted for 21.4% of new installations, the third place after solar (46.7%) and gas (21.6%). New coal plants accounted for only 4.8% of the added capacity, oil 1.6%, 1.3% large hydro. Nuclear technologies, biomass, waste, geothermal and ocean are each less than 1% of new plants. In 2011, 235 new offshore wind turbines in nine wind farms were fully commissioned, totaling 866.4 MW, bringing the cumulative offshore capacity in Europe 3813 MW, with 1371 wind turbines in 53 parks, spread across ten European countries.

Meanwhile, 6.3 GW of nuclear capacity was shut down and more than 1 GW of capacity fuel was switched off in 2011. At the same time, a greater capacity of producing energy from renewable sources – 32.1 GW - was installed in the EU than ever before. Renewable energy represents 71.3% of all new installations. Years 2011-2012 are

the fourth and the fifth consecutive year that renewables accounted for more than 50% of the installed capacity of new plants. Since 2000, a total of 302.6 GW of new installed capacity was put into operation in the EU, of which 28.2% was wind power, other renewables 47.8%, 9.8% renewable energy combines with gases.

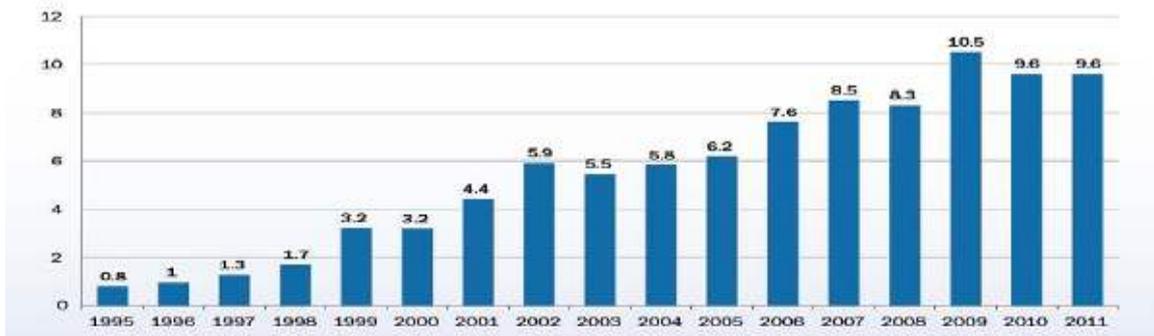

EU reached target of 21% renewable energy in the EU according with Directive 77/2002/EC for the end of 2010. Even more impressive is the fact that if the production of electricity from renewable sources in the EU continues to grow at the same rate as from 2005 to 2010, it would reach the value 36.4% in 2020 and 51.6% of electricity consumed in the EU in 2030.

In autumn 2011, the European Commission published a legislative proposal for multiannual financial framework program for 2014 - 2020. The document includes a proposal for increased budget for research at EU level "Horizon 2020" [16], financed with EUR 7 billion allocated for energy research. European Parliament together with the Council of Ministers adopted it last year. A further € 9.1 billion is anticipated for projects related to energy networks and promote simplification of authorization and licensing for electricity infrastructure through the infrastructure package of the European Commission. The package includes also revised guidelines for trans-European energy infrastructure.

In December 2011, the European Commission presented also energy roadmap [15] aimed at ways to reach the EU target of reducing emissions by 85% in the energy sector by 2050. In each scenario, wind energy is the technology leader in power generation, providing between 32% and 49% of total electricity consumption in the EU by 2050. Roadmap is not legally active, but a debate on renewable energy targets for 2030 and a path to implementation was released, and is expected to be approved before the current Commission's mandate to end in 2014. We can present a balance of European Wind Energy in 2011:

- 9616 MW of wind capacity (amounting to approximately € 12.6 billion) was installed in the EU in 2011.

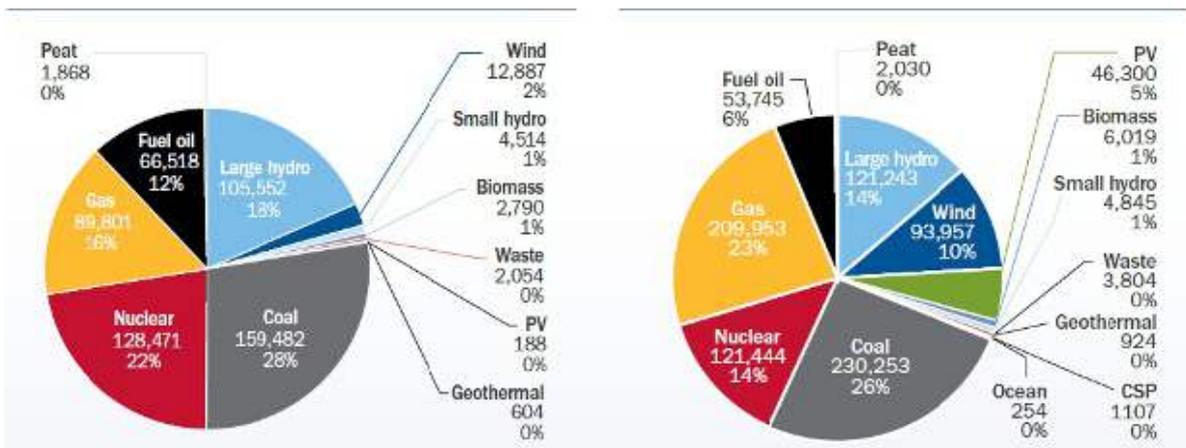

Figure 2 - Annual installed wind capacity (GW)

Source: EWEA

- Wind power accounted for 21.4% of total capacity in 2011 electrical installations;
- Renewable installed capacity accounted for 71.3% of new installations in 2011: 32,043 MW out of a total of 44,939 MW of new capacity installed;
- The capacity installed from renewable sources in 2011 was greater than that of any other year, an increase of 37.7% compared to 2010;
- The largest capacitor installed in 2011 than ever before - an increase of 3.9%, due entirely to renewable energy installations.
- Since 2000, a total of 302.6 GW of new installed capacity was put into operation in the EU, of which 28.2% was wind power, other renewables 47.8%, 90.8% renewable energy combines with gases .

Figure 3 - EU power capacity 2000/2011

Source: EWEA

- For the third time since 1998 the EU energy sector installed more coal than dismantled, highlighting the urgent need for the EU to move to the target of reducing greenhouse gas emissions by 30% by 2020, introduce a standard emissions performance and the decades period of subsidies for coal.
- EU energy sector continues moving away from oil and nuclear energy and, with every technology continues to dismantle more than install;
- Annual installations of wind power have increased steadily over the past 17 years to 814 MW in 1995 to 9,616 MW in 2011, an average annual market growth of 15.6%;
- A total of 93,957 MW is now installed in the European Union, the cumulative installed capacity increased by 11% over the previous year;

- Germany remains the EU country with the largest installed capacity, followed by Spain, France, Italy and the UK;

Increasing onshore installations in Germany and Sweden, and offshore in the UK - with strong performances of continuity in some emerging markets onshore in Eastern Europe compensated more than the decrease of the installation in the mature markets such as France and Spain;

4. Wind Energy in Romania – market case study

Romania [12] has vast wind resources, but wind power accounts only 2% of its national electricity production. Romania is powered predominantly by fossil fuels, which accounted 54% of its generation in 2011, by large hydropower at 25%, and nuclear at 19%. However, wind energy has grown in the past three years. Romania’s 982 MW of operating wind farms are located mainly (97%) in Dobrogea, on the Black Sea coast. Two other regions with an significant potential are Banat and Moldavia.

Romania was the Europe leader concerning the emerging markets in 2011, with an installation of 520 MW. In the same time the country has a significant development pipeline, and soon will be a new european country to pass the 1 GW mark.

CEZ (A Czech investor) dominates the romanian wind market. The company completed 338 MW of its Fantanele-Cogealac project which will be the largest onshore wind farm in Europe once completed at the end of 2012 (600 MW). The two other developers are EDP with three wind farms (238 MW), and Enel Green Power, also with three wind farms, accounting 174 MW.

In this moment, the most important projects of wind energy in Romania are [13]: Fântânele (CEZ, 347,5 MW), Casimcea, Topolog, Dăieni (IMA PARTNERS + Verbund, 532 MW), Tulcea county (ENEL, 174 MW), Moldova and Dobrogea (PNE Wind, 200 MW), Cogealac (CEZ, 252,5 MW), Mihai Viteazu (Iberdrola, 80 MW), Constanța county (ENEL, 118 MW), Cernavodă (Renovatio / EDPR, 138 MW), Galați county (Renovatio / EDPR, 100 MW), Mitoc (IWE, 100 MW), Borșa (Alstrom, 56 MW), Topolog (Land Power, 168 MW) and Casimcea (Martifer, 40 MW).

In November 2012, wind generated electricity will begin to receive two green certificates /MWh, and it is expected that this thing to open the door for investment by commercial banks. In the wind sector Romania has not been seriously impacted by the financial crisis, but the real impact remains to be seen in the future. However, the sector seems now to have a bright future.

In november 2008 was adopted the renewable energy law which is a major step forward for wind development in Romania, introducing a green certificate scheme for renewable electricity, for a 15 years period, as well as the loan guarantees and tax exemptions for renewable energy investments. In 2010, the renewable energy law was amended with another improvements. The amendments introduced a 20% target for 2020. The most important amended law are:

Wind projects before the end of 2016 will receive two green certificates per MWh produced until 2017 and one certificate/MWh for the balance of the 15 years of the scheme, encouraging early deployment.	The value of the green certificates, initially set between EUR 27-55 (USD 35.84-73), will be adjusted annually using the inflation index of the Eurozone. In 2012 the cap is EUR 57.67 (USD 76.54).
The penalties for suppliers for each non-produced certificate increased from EUR 110 (USD 146) to EUR 115.34 (USD 153.08) in 2012.	

On 13 July 2011, the European Commission finalized its review and approved the Romanian RES promotion scheme. The RES implementation started on 1 November 2011.

In Romania, the most important obstacle concerning the wind energy is the grid, especially in Dobrogea county, where the existing grid can only integrate about 400 MW of wind energy. The Romanian energy system could absorb about 3,000 MW of wind power, and this is expected to increase to 5,000 MW. There is currently more than 7,000 MW under contract to be developed. If

grid capacity is not improved, the connections will can not be realized. Stronger investments in transmission links in to the rest of the country are also urgently needed. Only 3.2% of Romania’s electricity demand came from renewable sources, despite the considerable progress made in 2011. The Romanian Wind Energy Association predicts that 3,000-3,500 MW of wind power will be installed by the end of 2013, and at least 5,000 MW by 2016.

5. Conclusions

Use of wind energy in recent years has taken a major amplitude in the European Union. For Romania, a country so generous in terms of wind resources should be that this issue addressed more seriously and even more strongly, especially in terms of the legislative, regulatory framework, wind representing a huge opportunity. If before 1989 the use of non-conventional energy (as they were called then) was a national problem, in the last 15 years, it has been neglected, following an upward trend, especially in the last 5-8 years. Researchers have dealt with this issue have focused mainly on opportunities for energy storage and less on analysis of technical feasibility and economic issues. Romania's integration into the targets established by national and European plans, will require sustained efforts and, above all, political will and administrative capacity. Romania's problem is therefore to build additional infrastructure to support investors in wind energy in creating coherent legislative and fiscal frameworks to reduce bureaucracy, time of application and tax overcrowding.

gabrielasuba@yahoo.com

Abstract

This paper presents a decision support tool used in testing and trial laboratories. It gives an optimum quality control in these types of laboratories.

Key words: Management, Optimization Problem, Laboratory Activity Management

JEL Classification: L20, L23, M54, M11

1. Introduction

The present technological development is based on planning and quality improvement in every activity field. The complexity of activities performed in test and trial laboratories and the need to get accurate results is required by mathematical modeling. In this respect, a model solution is to develop some software able to give an active response to the need of reducing the uncertainty of the results and to eliminate testing errors. Software automatic adaptation to the specific character of various test and trial laboratories having different configurations requires the development of a “flexible” software and this leads to OOP techniques use.

Artificial intelligence techniques used in mathematical modeling in order to process input and output data and to develop automatic models are the optimal solution to any logistics strategy problem [1], [2].

More and more, quality infrastructure organisms are admitting that logistics is not only an operational variable but it has a unique position allowing the coordination of the relationship between the factors influencing both information and asset flow whose final purpose is to carry out the orders.

The flow starts when the customer orders something and it ends when the order is fulfilled and paid.

The strategic use of quality logistics requires a test and trial laboratory to adopt a specific and systematic approach of the market in order to establish some carefully chosen priorities and to strictly assign resources.

To meet international requirements and practices, self diagnosis instruments have to be created, meaning that a flexible software system for quality check up has to be developed.

This system has to be able to adapt itself to any certified test and trial laboratory.

To establish the data and information flows needed to develop this software, data included in the quality manual must be used.

In this paper are presented in detail all the procedures performed to accomplish a test/trial in laboratory. Also, the paper is taking into account the up to date standards.

Going into such details allows quantification of the whole laboratory activity.

The complexity of activity flow within test and trial laboratories is given by the large number of parameters involved in tests and trials as well as by the constraints of the determinations.

Owing to the great costs of the resources involved in the laboratory activity minimization is a must.

Using a software for quality check up as compared to a classical approach (without using this software) the following advantages may be pointed out:

- The uncertainty and the difficulties in a test and trial laboratory are efficiently solved by using accurate tests and multiple planning scenarios for unpredictable situations.

- The program using large scale modeling of integrated systems allows test and trials laboratories to find more profitable solutions than using manual approach.

- The program takes into account any change in test and trial laboratory configuration.

In addition, this software can carry out a more detailed analysis of a situation concerning quality management and make possible a thorough examination of every requirement.

2. Laboratory monitoring

The procedures involved in test and trial operations are decomposed according to the Quality Book into elementary procedures described by a minimum parameters.

Considering the laboratory as a system, the input data are represented by the test/trial orders and by the raw materials supply. In this case the quality book contains the constraints of the system. The system outputs are the values resulting from the test/trial processes.

In order to quantify the elements of the environment (M) in which tests/trials take place, a coordinate system for the locations (L) is established for tests and trials equipment places. Also access constraints for the determination of optimal routes concerning resources flow in the system are taken over.

- For equipment (E) and tools (U) quantification detailed work parameters are given for every equipment and the operating conditions. Figure 1 shows input/output parameters for an equipment considered as a subsystem.

- The quantification of material resources (RM) involved in test and trial processes depends on quantities required by every elementary process involved in test/trial methods. This quantities are given in the Quality Book.

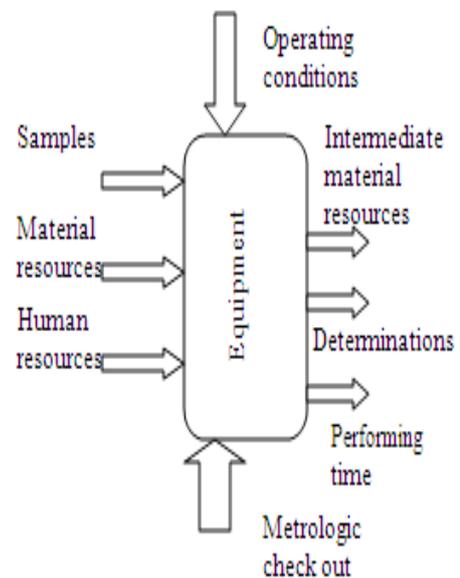

- For the quantification of test and trial procedures (P) these procedures are decomposed in subprocedures (SP). The last level resulting from the decomposition is called elementary procedure level (PE). Each elementary procedure takes data concerning the quantified resources of the laboratory. The elementary procedures are performed in one location (L) and in a well determined

time interval (T1-T2).

- The quantification of metrologic (VM) and nonmetrologic check up needs a complete chain of specific tests and trials. The check up procedures are system constraints. Metrologic check up procedures are different from control procedures because the latest are more important for resource allotment optimization.

- Quantification of human resources (RU) is carried out according to a specific time location and elementary subprocedures.

Figure 1 Model of quantified equipment

Personal source

System decomposition in subsystems is performed down to the level of elementary subprocedure. According to the Quality Book, material and human resources are established for every elementary subprocedure.

To obtain greater flexibility in the assignment of elementary procedures, these are considered equipment dependent and so they can have different performing times depending on the specific equipment. The performing time of an elementary procedure depends also on the skills of human resources (this parameter is also quantified). The various performing times for the same elementary procedure type lead to the increase of the complexity of the decision system used for optimum allotment of all

resources.

The program can determine optimal assignment of staff per procedure and optional assignment of procedures per apparatus. Optimal assignment is carried out using specific optimization techniques. Optimization results in uniform distribution of the staff per functioning apparatus.

The optimization criterion is the minimization of every cost procedure. The optimization problem is to determine some apparatus, tools/accessories and staff combination so that the cost per procedure be minimum under certain time and interdependence constraints between assigned resources.

Optimal assignment can be made both at specific general procedure level and at elementary procedure level [3].

For an optimum assignment of laboratory resources multivariable optimization algorithms based on gradient methods as well as algorithms based on geometrical search are tested and implemented [4].

Multivariable penalization methods are implemented in order to study the possibility of gradient algorithms to be used in explicit and implicit constraint problems.

For the linear case, a Simplex algorithm was implemented. For non-linear problems, a Box algorithm using search by geometrical methods is chosen.

Although the iteration number is large, it has the advantage of high robustness and accuracy.

Gradient algorithms have high convergence speed but the use of penalization method diminishes the computing accuracy and significantly increases the computing time.

To get the criterion function, successive questioning of databases are used. These questioning are imbricate and managed by stack mechanism. By successive calls of imbrications procedures, criterion functions and the constraint system for the organization problem are built.

In conclusion, the chosen algorithms (Box for non-linear problems and Simplex for linear ones) represent a practical solution for a fast determination of optimum resource assignment in test and trial laboratories.

These algorithms are coupled with monitoring questioning and management modules of databases.

3. Software implementation

The present software was developed by using C++ Builder. The core of the system built by software implementing of optimization algorithms consists of dynamically linked libraries. This techniques were adopted with the following intentions:

- To allow better control of the whole program (the possibility of an independent testing of algorithms);
- To include new algorithms in the present software without significantly changing the program;
- To have the possibility for the functions implementing the algorithms to be called by other software programs as well.

The program consists of two executables and includes ten dynamically linked libraries, each one corresponding to a given algorithm type.

To have the possibility to compute in the program any type of function or function combination, a syntactic analyzer was developed which takes over the functions as character strings, replaces X- variables and returns the values of the function.

The syntactic analyzer can be called independently of every program because it is implemented as a library.

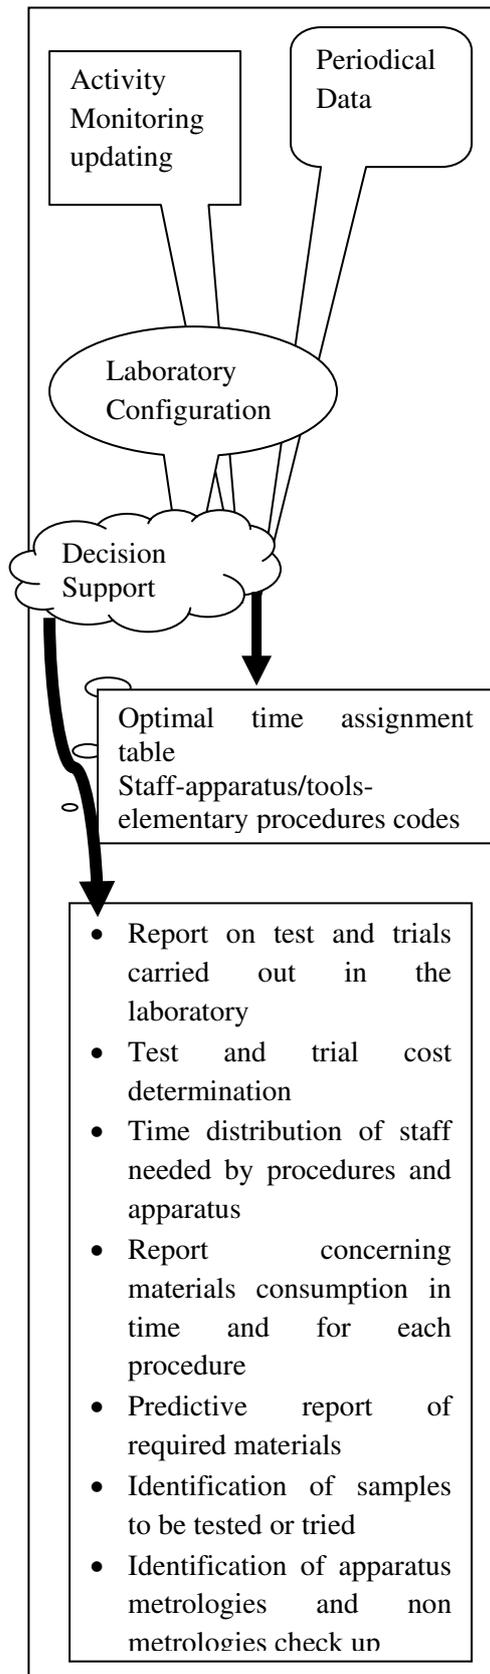

The quantified information is taken over using the procedures of object oriented programming which allows generic take over and easy configuration obtaining every time the procedure is operated. The consequence is software flexibility, meaning it can be used for any certified laboratory.

The process models are taken over by class constructors and the optimization function is implemented as a virtual function at class level. These are input data taken over at the moment the application is configured. The other input data are represented by the orders for tests and trials and by the supply with material resources (periodical inputs).

The software output data are: reports for activity monitoring, check up for conformity with the Quality Book, optimal work parameters (material and human resources assignment in time) so that the time for tests/trials achievement be minimum.

Figure 2 shows the architecture of application configuration module.

Figure 2 Architecture of application configuration module

Personal source

4. Conclusions

Quality standards are the general mandatory framework for the functioning of a tests and trials laboratory. The requirements are a consequence of the fact that every product has to function in such a way as to provide all the functions for which it was developed, maintaining the quality parameters in given ranges.

The repair frequency has to be such as economic efficiency of the product exploitation be not diminished.

On the other hand, the set of standards should be completed with specific standards for the activity field of the tested and tried products because each product has specific parameters for quality evaluation and hence individual specific requirements.

On the basis of specific data and resource flow, an adequate software for optimum time assignment of resources and for monitoring the activity of a certified test and trial laboratory was developed. By using accurate computing techniques, customers' confidence in products conformity with specifications will increase.

Abstract

The effect of fiscal policy on economic growth has been one of the most debated and controversial issues in economics. Some economists consider growth as a result of the accumulation of capital, others believe that technical progress is effective and does not accept that this growth is influenced by factors such as fiscal policy. Macroeconomic relationship between fiscal policy and economic growth long fascinated economists. Unfortunately, the analysis of this relationship has frustrated for too long, the empiricists. A cause of that frustration was represented by the set of indicators which affect this link.

Key words: GDP, fiscal policy, budget deficit

J.E.L. classification: H50, H60, O40

1. Introduction

There is a voluminous empirical literature that has dealt with the relationship between fiscal policy and economic growth. Among the most important contributions are those of Levine and Renelt, Engen and Skinner, Easterly and Robelo, Villanueva, Lin, Körmend and Megu, Landau, Skinner, Ram, Barro[3].

To examine the effects of fiscal policy on economic growth, we must first correctly classified the influencing factors and then examine separately the impact of each factor on growth. These influence tools can be divided into three groups, according to Tanzi and Zee: government spending, taxes, and

general government balance policy, each being able to affect economic growth in several ways[27]. Literature does not systematically favor one indicator of fiscal policy on the other. Furthermore, it was found that none of these indicators is strongly correlated with fiscal growth when they are individually assessed[17].

2. Current state of knowledge

Several studies have been conducted and attempted to analyze the relationship between fiscal policy and growth. Studies have included many countries, different regions and areas.

In order to discover the impact of fiscal policy and monetary policy on economic growth in Iran, a study was conducted during 1960-2006. Study of Khosravi and Karimi found that the impact of the exchange rate and inflation on economic growth was negative, while the study found that government spending has a positive effect on GDP growth[26].

A study was conducted in the European Union, in order to investigate the relationship between fiscal policy and economic growth during the 30 years from 14 European countries, the results showed that the impact of public spending on infrastructure spending and government spending on protecting the rights ownership is positive on economic growth[5].

In an attempt to assess the role of fiscal policy on economic growth in Romania, the study was conducted during the 1992-2013. The years 2012 and 2013 were estimated by the International Monetary Fund. The study found that reducing the budget deficit is positively related to growth as decline deficit

increases growth rates. The study also found that an increase in public revenues and public spending cuts increase economic growth rates[29]. In addition, the study found that reducing the general budget of Romania by 1% lowers economic growth by 2.59%. Thus, the study of Enache in 2009 concluded that fiscal policy has a role in increasing growth rates by increasing the overall efficiency of revenue mechanisms[9].

Ocran in 2009, in a study in South Africa during the period 1990-2004, conducted in order to determine the impact of fiscal policy variables on growth, was found that consumption expenditure, capital formation and tax revenues have a positive impact on economic growth but the extent of the impact of capital formation is less than the impact of government spending.

3. Budget expenditure and economic growth

Literature on the relationship between public spending and growth is quite extensive and can be divided into two main streams: one that supports the Keynesian theory of the positive impact of public expenditure on economic growth and other stream, which public expenditure influence negatively economic growth.

For the first stream relevant works are Holmes & Hutton and Aschauer, who found a strong positive relationship between government spending and economic growth[10][2]. On the other hand, Grier and Tullock, analyzing the relationship between the size of government spending as a percentage of GDP and economic growth in a sample of 113 countries, found a negative impact on economic growth.[12] Similar results were obtained by Barro and Cashin [4][7]. The results of a study by Folster and Henrekson indicate a robust negative relationship between public spending and growth in a sample of rich countries covering the 1970-1995 time period: an increase in the expenditure ratio by 10 percentage points is associated with a decrease in growth rate of 0,7-0,8 percentage points.[11]

Some studies have reached mixed results, growth was strongly affected only by certain types of public expenditure. Public infrastructure, communication and information systems, education funded by the

government, research and development are the most frequently cited examples of public goods provided, which contributes positively to aggregate production. Many studies have divided public spending on productive and unproductive spending. According to Carboni and Medd, productive expenditures include spending on infrastructure, law, education and training, while unproductive expenditures include expenditures on national defense, national parks, social programs.

Devarajan and others argues that studies differ in terms of government spending analysis and studies are classified into three groups. Some economists consider variable as needed to express fiscal policy, but others have found it necessary to adjust this variable into categories and groups, by analyzing these groups individually, to identify the link with growth.[8] The last group stressed the need to share the costs into two parts, the first called capital expenditure, working to stimulate investment and consumption, and two included consumer spending that prevent or restrict growth. But with the development of studies on growth, consumption was divided into government spending allocated for production, including spending on education, health, infrastructure and government spending for non-production.

4. Taxation and economic growth

In terms of public revenues from a general perspective, any tax has a distorted potential or real impact on economic growth because it affects economic choices of individuals (companies and individuals) on the activities they carry (production, investment, consumption or savings). Income tax negatively affects investment incentives and resources companies, income tax from wages negatively affect both consumption and saving, and individual investment in human capital. Consumption taxes affect individual choices between work and leisure according to Milesi-Ferretti and Roubini.[20]

Given these characteristics of tax, Sala-i-Martin grouped public revenues based on their impact on economic growth: distorted public revenues (which have negative effects on economic growth), undistorted government revenue (which are neutral or have an insignificant impact on growth) and

other public revenues (which have an insignificant impact on economic growth).[24]

Table 1 - Classification of public revenues according to their impact on economic growth

Distorted public revenues	undistorted public revenue	Other public revenue
Corporate tax	VAT	Custom duties
Income tax	General sales taxes	Other tax revenues
Social security tax	Excise	Current non-tax revenues
Wealth tax		Income from capital
		Other income

Source: Barro (1990)

Numerous empirical studies have investigated the relationship between taxation and growth. Plosser and Kim and Rebelo suggest that an increase in tax leads to a reduction in growth while Kneller, Levine Renelt (1992) report an insignificant or even positive correlation between the two.[23][25][15] On the other hand, Tosun and Abizadeh found that economic growth as measured by gross domestic product (GDP) per capita, has a significant effect on the tax mix of OECD countries. Mendoza and others concludes that the tax mix has no significant effect on growth.[28][18]

Relationship between fiscal policy and economic growth was also studied by Martin Zagler and Durnecker Georg, and concluded that "taxes on savings, R & D, profits, premiums of capital and labor have a direct impact on the rate of economic growth, while the total tax year rate has indirect effect on economic growth.

Obreja L. Braşoveanu and Braşoveanu V., analyzing the relationship between taxation an grotwh on Romanian economy through "regression technique application for the period 1990-2007 concluded that in Romania distorted and not distorted effects of taxes on economic growth are negative[21].

Numerous empirical studies have investigated the relationship between taxation and growth. Engen and Skinner suggested five possible mechanisms through which taxes affect economic growth[16]:

(1) investment rate can be inhibited by taxes, such as personal and corporate income and capital gains taxes;

(2) Taxes can slow the growth of labor supply by influencing labor-leisure choice for leisure;

(3) Fiscal policy can affect productivity growth by discouraging effect on research and development expenses;

(4) taxes can lead to an outflow of resources to other sectors, which may have lower productivity and

(5) high taxes on labor supply can distort the efficient use of human capital, discouraging workers through higher tax.

Harberger spoke about the relationship between government taxes and growth rates, and found that high tax rates in the economy will limit foreign and local investments and thus affect the growth rates of capital, which will have a negative impact on employment growth and reduce overtime that workers are willing to work, which reduces the marginal productivity of labor and reduce research and development, which will lead to lower growth rates[13].

While some studies find that taxes have long-term effects on growth rate, others find no significant effect. After controlling performed to determine the initial level of GDP through different fiscal measures a study finds that average and marginal tax rates are negatively correlated with economic growth. However, both coefficients tax rates, marginal and average are not statistically significant[6].

Helms examined the effects of increased state and local taxes. He argues that a tax increase can stimulate growth if they are used to finance development costs. Helms found that taxes have a significant negative effect on economic growth, Helms regression coefficient indicating that the tax rate can be positive if production costs and finance charges may be negative if the tax revenues are used to finance social transfers. Redistributive public transfers can negatively affect economic growth[14].

5. Budget deficit and economic growth

Impact of government deficit problem is even more complex. If deficits tend to reduce economic growth, there will be a negative impact on long-term growth. Similarly, if

there is a higher deficit today, there will be further offset by a higher rate of consumption or income tax, the rate of growth will decrease in the long term, according to Peretto. [22]

Begetar deficit could influence economic growth through a transmission channel represented by the interest rate. In the literature, the explanation is that crowding out increases the interest rate and reduce the amount of savings available for private investment. To the extent that deficits are used for investment, total capital may not register a total loss. Moreover, the continuous accumulation of public debt could undermine long-term sustainability of fiscal policy pursued by government authorities, with a negative impact on economic growth.[1]

Ricardian vision is contrary, suggesting that the deficit has no effect on growth. Since the current deficits will be paid with higher taxes in the future, households will save more now than they would pay in the future.

An important dimension in the analysis of fiscal policy and economic growth is the extent to which tax expenditures are financed by distortionary taxation. Distortionary taxation decreases willingness to save and invest by reducing the rate of capital accumulation.

6. Conclusions

Regarding *short-term effects of fiscal policy on economic growth*, there are a number of empirical research, primarily for industrial countries, dedicated to understanding under what fiscal conditions multipliers are small, and even negative according to Alesina and Perotti, Alesina and Ardagna and Perotti. According to Perotti consolidation tends to be expansionary when debt is high or growing fast, while Alesina and Perotti and Alesina and Ardagna notes, that in addition to the size and persistence of momentum fiscal, budget composition matters in explaining the various responses of private sector to fiscal policy (and therefore increase effect)[1].

Potential *long-term effects of fiscal policy on economic growth* generated also substantial attention, according to Tanzi and Zee, 1997. The most recent work in the growing field of endogenous growth suggests that fiscal policy can either promote

or delay growth, investments in physical and human capital - both can be affected by taxation and government spending - can affect balance.

In both directions of the literature, *the effect of fiscal policy on growth may be nonlinear*. This can happen, for example, because the private sector's response to fiscal policy can be nonlinear, which implies a complex relationship between the size, the composition of public expenditure and revenue and growth. According to Giavazzi in industrialized and developing countries, non-linear effects of fiscal policy in economies tend to be associated with large and persistent increase in the primary deficit.

Organisational Learning and Knowledge Management within NGO

Neagu Olimpia

"Vasile Goldis" Western University of Arad

olimpian2005@yahoo.com

Abstract

NGOs are learning as well as knowledge-intensive organisations. They are creating social value in the community where they act as social change agents, by creating, sharing and using knowledge. As components of the new, knowledge-based society, their organisational processes are marked by learning and knowledge.

The paper aims to propose a conceptual model of the link between organisational learning and knowledge management within NGOs

Key words: learning, knowledge management, NGOs

J.E.L Codes: A13, D01, D83

1. Introduction

Non-governmental organizations (NGOs) consist of people unified around a group of common values, ideas and desires, committed to contribute with their knowledge, skills and time resources to the achievement of the organisational goals. Through their non-profit activities, NGOs are creating social value for the community where they act as social change agents. As components of the new, knowledge-based society, their organisational processes are marked by learning and knowledge.

Unfortunately, knowledge management literature has been written mostly with business organisations in mind and has not provided many answers for NGOs regarding the processes of learning and knowledge management.

The present paper tries to conceptualise the link between organisational learning and knowledge management, by explaining firstly why NGOs are learning organisations, secondly why they are knowledge-intensive, then by emphasizing the link between

individual and organisational knowledge and finally, by describing the conceptual content of the two processes: learning and knowledge management.

2. The present nature of NGOs

2.1. NGOs as learning organisations

In the mid to late 1990 NGOs became aware of the concepts of organisational learning and learning organisation from the corporate world [4]. Corporations were a source of methodological and practical frameworks for NGOs, to respond to their learning needs. Today, there is a general recognition that organisational learning is beneficial for the effectiveness of NGOs in the process of social value creation. NGOs have the specific features of learning organisations; learning processes within NGOs occur and are supported by the internal specific processes (facilitated by a flexible organisational structure, human resources policy, social interaction, and an open vision of leaders).

According to Hyvarinen and Wall, an important feature of learning organisations is that they are organised so that learning occurs at five levels. This can be applied to NGOs in the following manner:

1. *Individual learning* – learning that NGOs members experience through involvement in campaign and organisational development;

2. *Team or work group learning* (sharing lessons between individuals working together in permanent work groups or temporary teams) – participation in sub-collective or main collective meetings and project work yields discussion regarding practices and outcomes that is recorded and used to augment future planning and action;

3. *Cross functional learning* (sharing lessons between departments or sections e.g. between fundraising and operational staff) –

meetings occur between coordinators of different areas. This allows the opportunity to streamline organisational processes and the development of knowledge management systems;

4. *Operational organisational learning* (focusing on improving practice, increasing effectiveness and efficiency) – strategic meetings occur whose objective it is to assess organisational practices toward improving effectiveness and efficiency in event planning and management, volunteer coordination, publicity and networking, capacity development of participants and organisational learning and knowledge management.

5. *Strategic organisational learning* (learning to deal with significant changes in the environment which affect the overall strategy of the organisation) – scenario planning occurs within the organisation so that it is equipped to deal with a number of potential environment and organisational changes that may occur.

2.2. NGOs as knowledge intensive organisations. Individual and organisational knowledge

NGOs are also, knowledge-intensive organisations; their knowledge capital is heterogenous, widespreas, rarely formalized and unstable (due to volunteer workers). The creation of a unique corpus of knowledge, formalized and useable by all members is a challenge that the NGOs are facing at present [8].

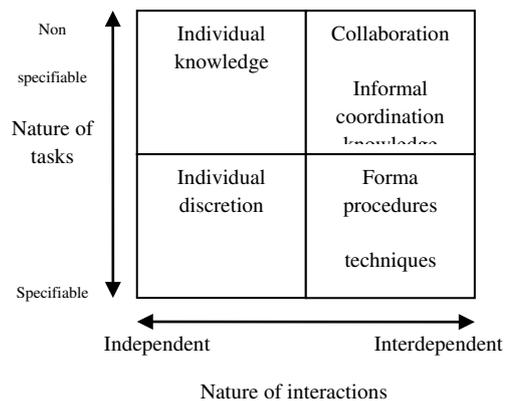

Between individual and organisational knowledge there are conceptual differences. On the one hand, individual knowledge is created based on differences in each person’s cognitive abilities. What one individual learns is different from that of another, because of differences in their respective cognitive skills. On the other hand, learning at the organisational level involves a social dimension. Learning occurs at the organisational level by: interaction between people, sharing of ideas and information; and development of common schemas and language [1],[10].

The knowledge in the organisation represents a consensus or agreement on ideas and information [5]. While employees may have their separate knowledge, what becomes

part of the organization’s knowledge is only what employees have shared and agreed upon. Thus, the knowledge that becomes part of the organisation represents: ideas introduced; agreement on the ideas that reflect the combined individual experiences of these employees; and consensus on how these ideas are interrelated and affect each party’s tasks and responsibilities [9],[14].

According to Bhatt (2002), we can differentiate individual knowledge from organisational knowledge using two criteria: the nature of internal interactions (from low or independent to high or interdependent) and the nature of people tasks (from specifiable to non-specifiable).

Figure 1 The link between individual and organisational knowledge

Source: adaptation from Bhatt, 2002, p.4

In the cell 1, the level of interactions between organisation's members, employees or volunteers is very low and the tasks are specifiables. Organisations are likely to empower their members to be discrete. In the cell 2 the level of interactions is low, but employees or organisation's members who are experts in their field are able to solve non-specifiable tasks. In this group we can include project managers and seniors managers. In the cell 3 the level of interactions is high and the tasks are complex. To deal with these kinds of conditions, employees need to continually share their expertise with others so that they coordinate their tasks in unison [2]. In the cell 4 the level of interactions is high and the

tasks are not very complex. In these conditions, organisations often follow rules and procedures (for instance: communication, administrative or admission procedures).

One of the main constituents of organisational knowledge is "interactions". Within NGOs, the internal interactions are kept at maximum by strengthening the organisational culture. There are several methods to stimulate internal interactions: formal, informal and periodical meetings with members and volunteers, team working, training sessions, e-groups, intranet, internal newsletters. If individual knowledge is not shared with others, it has no influence on the organisational knowledge base. One of the most important task of NGO's management is to stimulate the members interactions so their individual knowledge is amplified and internalized.

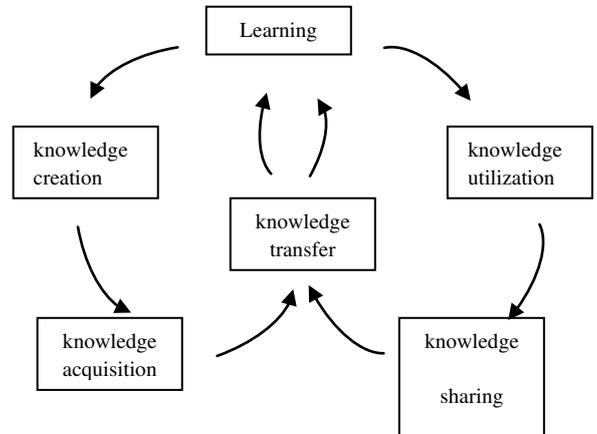

3. Knowledge management in NGOs

Lately trends in knowledge management research show an increasingly psychological view of knowledge management [3],[6],[11],[12],[13]. Knowledge is considered to be that which is embedded within individuals and occurs either as a result of experience, or is generated through thinking or reasoning; otherwise it remains as data or information [3]. From this perspective, knowledge can be seen as an activity and data and information are objects. This perspective is very close to the context of NGOs, where members are committed to give a part of their expertise and time to contribute to the NGO's goals achievement. Within NGOs, the reasoning and social interactions are driven factors of *knowledge creation, acquisition, transfer, utilization and re-utilization*. The communication processes within an NGO facilitate all these knowledge processes. For instance, *knowledge creation* can be driven by curiosity or in a response of an internal or external problem, and refers to the deliberate and purposeful collation of facts and observations to generate new or novel ways of understanding a particular phenomenon. Annual reports, campaigns reports, general assemblies resolutions, findings of brainstorming sessions or workshops, and results of strategic planning processes are some examples of NGOs

documents containing new knowledge. Within NGOs, *knowledge acquisition* is facilitated by the *transfer* of existing knowledge to others. The success of this transfer depends on the effectiveness of communication processes and the learning capacity of NGOs members and employees. The existing knowledge can be *used* and *re-used* by the members and employees through the organisational structure (i.e. networks, hierarchical levels) rules and procedures (i.e. for internal communication, for administrative issues, documents management).

Figure 2 shows how knowledge, as a result of learning process, is created, transferred, used, shared and re-used within NGOs. There are two cycles generated by learning, one for knowledge creation and other for its utilization. The common element of both cycles is the knowledge transfer. This process is amplified in NGOs through a concern for strengthening the organisational culture and for internal interactions stimulations.

Figure 2 Knowledge management cycle within NGOs

Source: author's own view

4. Organisational learning and knowledge management within NGOs

Organizational learning and knowledge management processes are interrelated as it is shown in the Figure 2. Going into details of the content of these processes, we can notice that organisational learning generates knowledge and knowledge underpins organisational learning. Table 1 offers an

overview of differences and similarities between organisational learning and knowledge management. Organisational learning is a process of harmonisation of individual and collective learning processes, focused to increase the satisfaction of NGOs beneficiaries and stakeholders while knowledge management means the processes by which knowledge is acquired, shared, used, stored, used and re-used. Furthermore, organisational learning provides a purpose for the use of knowledge but knowledge management, by its component processes, is a means to enable organisational learning. Unlike organisational learning, knowledge management is context-independent, meaning that the circumstances of knowledge utilisation have no relevance when the knowledge is developed.

Table 1 Link between organisational learning and knowledge management

Organisational learning	Knowledge management
-is the intentional use of collective and individual learning processes to continuously transform organisational behaviour in a direction that is increasingly satisfying to its stakeholders. -provides a purpose for the use of knowledge. -is always context-specific. The purpose of learning is to solve problems or address challenges and knowledge is selected because of its utility in the specific circumstances. -is usually demand led.	-is the systematic processes by which the knowledge required by an organisation is acquired, distilled, shared, stored, retrieved and used. - is a means to enable organisational learning. - can be context-independent. For example, good practices can be developed and disseminated without awareness of the circumstances in which it may be used. - is usually supply driven.

Source: [4], p.8

5. Conclusions

Organisational learning and knowledge management are of key importance for NGOs in the process of social value creation. NGOs which are not able to internalise the learned lessons and to learn from previous experiences achieve a low effectiveness in

offering social added value for their beneficiaries. Managing knowledge within NGOs means first, enabling the organisational learning and second, stimulating the internal interactions between individuals, between and within various groups of members, staff and volunteers.

The Entrepreneurship, an Actual Challenge for the Young Graduates of Higher Education Institutions

Negoescu Gheorghe

“Ovidius” University of Constanța, Faculty of Economic Sciences

negoescugl@yahoo.com

Negoescu Liliana Georgeta

Abstract

Considered from the point of view of the brought challenge, the entrepreneurship is proving an alternative source of income for young graduates, source increasingly attractive in terms of labor market suffocated by oversupply and tough competitive terms influenced by international economic crisis. Various funding programs that run nationally in partnership with the European Union, increase the attractiveness of entrepreneurship. In this paperwork I propose to develop some aspects of new developments in the field, to highlight a few issues currently facing young entrepreneurs and develop a case study of a successful entrepreneurial business.

Cuvinte cheie: entrepreneurship, incomes, costs, magnetic poetry.

Clasificare J.E.L.: M21

1. Introduction

In the XXIst century you cannot live decently than under financial planning. Monthly income requirement for a family of two parents with two children is on average 9,000 euro.

Given Kondratiev's theory of business cycles, for a economic growth of 8 years (2000-2008) following a period of economic decline for 8 years (2008-2016).

The economic revival in Romania could be achieved under a galloping inflation process, in this sense I appreciate that at the end of decline period the leu / euro will be 8 lei / euro in December 2016. You cannot win 9,000 euro per month for a family of two parents with two children only in the quality of employer and investor. Assimilation of

deep financial knowledge while benefiting from management techniques based on solid marketing knowledge and accounting ensures business success.

2. Entrepreneurship in Romania

From the entrepreneurship of a country and its level of economic development there is a direct correlation.

In the economies oriented on factors of production, existing in poorer countries, the average rates of entrepreneurship are higher in the initial stage, which expresses the need to increase the gross domestic product (GDP) by initiating new business. The efficiency-oriented economies, where the values of the GDP / capita are higher in early stage entrepreneurial activity rates are lower, while innovation economies these rates are higher, because of the opportunities for entrepreneurial development and innovation environment economic.

A particular case is that of the countries of Eastern Europe, including Romania is located and who have undergone a period of profound structural change important system while decreasing the population. They generally have fewer entrepreneurs and therefore an insufficient number of new private businesses.

In relation to the overall indicator, Romania has a precarious situation, positioning only on number 53 among the 59 countries assessed. The same position is maintained low country with efficiency-based economy, where Romania ranks 23 out of 24 countries [1].

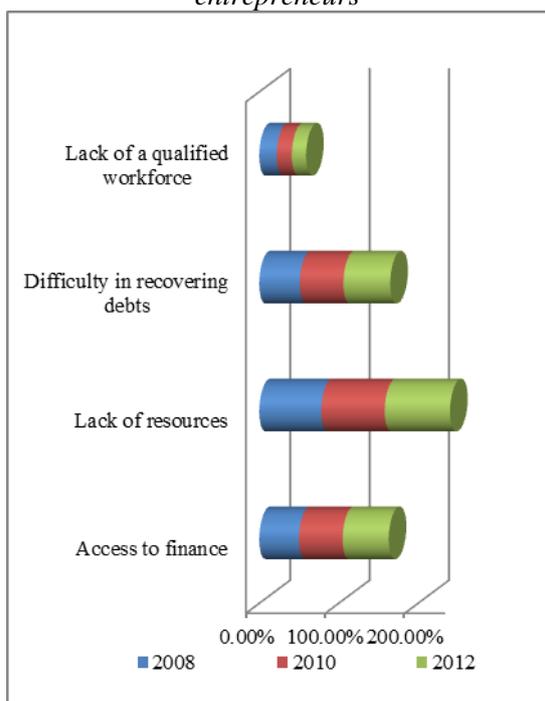

3. The main difficulties faced by Romanian entrepreneurs

Experts say the biggest problem of business is restricted access to credit, and bad

news is that banks will not finance companies resumed in 2010, because it will analyze the situation of companies which will seeking loans on the balance sheet situation of 2009, which "looks disastrous." [2]

Impact of financial crisis on the problems faced by entrepreneurs is given below:

Figure no. 1. The main difficulties faced by Romanian entrepreneurs

Source: Processing from INS 2012 Statistics; Annual Report 2011/2012, the European Commission
