In the last years, the defintory characteristic of public finances for many countries is that of imbalance, so we cannot state that Romania is an exception. The budget deficits recorded in our country in the periods after the revolution have a character of chronicity, proving the lack of financial means to normally develop the state's activity, but the situation is even more complicated and difficult because, the complexity of the factors which generated and maintain them, but also because of the economic and financial implications which result. The perpetuation of the public financial deficit represents one of the modalities of manifestation of the general economic imbalance, because the balance between the incomes and the public expenses was affected by the imbalance between the request and offer of goods, services and manpower, by the discrepancies between the population's incomes (eroded by inflation) and the population's needs in order to live, by the differences between the necessity of currency resources and the possibilities of raising them. Alongside all these, we can also talk about the influences caused by the companies which produce goods and services where in most cases, there were recorded insignificant profits and even losses. Not in few cases, some economic units are late or even refuse to pay duties, taxes and contributions, they postpone payments to providers generating chain duties among economic agents or they do not respect their obligations of refunding loans even creating difficulties to the banks which credited them. All these behaviours, in a direct or indirect way, sooner or later, negatively affect the balance of public budget and the negative effects which in time spread in an indirect way, bring to the budget balance some prejudices which are more severe than those that are manifested in a direct way. Thus, the obtaining of some reduced profits by economic agents entails the decreasing of tax basis and the reduction of public incomes which have as a source the profit tax. But, on

the other hand, the effects which reverberate over the budget, in a direct or indirect way, are difficult to be foreseen and they cannot be taken into account. Also, the manifestations of some chain reactions reduce the possibility of an unilateral intervention from the budgetary authorities, being in need of long-term actions of the budgetary system, corroborated with those of the fiscal system in real economy. We must not neglect the fact that the economic agents which have losses, besides the fact that they are in impossibility of paying their fiscal liabilities to the public budget, they are also consumers of public financial funds through subventions which lose their quality of actioning like a lever causing disturbances by not carrying out the economic policies in those periods. Beside this, being in impossibility of paying debts to their providers (the so-called arrears), the economic agents create them difficulties in the financial and economic domains. At the same time, the refusal or just the delays of paying debts to banking institutions negatively reverberate over their activities; finding their way out can take place by taking over credits which have no performance on public dept also, affecting the subsequent budgetary exercises. We can add to all these the behaviour of some correct economic agents which suffocated by the fiscal liabilities that they have to pay and demobilized by the discretionary attitude of the public authorities, they start avoiding the payment of fiscal liabilities. If some indirect effects which are chain transmitted can be anticipated, they can no account be quantified. The budget deficit represents the public expenses made on the account of internal and external public loans. Any debt must be paid on term also, including additional expenses related to launching and refunding the credit. If through the budget deficit we cover the expenses meant for the maintenance of an administrative device inappropriate to the economic and social situation of that period or illegitimate expenses from an economic or social point of view, then the budget deficit represents a waste of social effort which will press without any benefits upon the task of the subsequent budget exercises.[4]

4. The efficient management of the budget deficit

The budget deficit is a factor with which modern states confront themselves. So this is dangerous not through its imbalance incomes-expenses but through, the complexity of the elements which generated it and through, the economic and financial implications which result from the deficit. The financial management must not approach the financial balance like a purpose itself because, in certain situations, a justified budgetary imbalance may be more efficient and thus, preferred to an inert budget which reduces the role of the budget to a passive reflection of the report of public incomes-expenses from a certain period. Taking into account this situation, there appears the problem of reorienting the objective from the reduction of budget deficit towards how efficiently the government spends public money and with what effects in the economic and social domains. The efficient management of the budget deficit would lead to a fiscal relaxation taking into account that there should be a connection between the expenses which sustain the public debt and the growth of the financial means of the states in order to pay it. So, the rate of interest at the public debt must have a relative constant weight towards the raise of the global incomes from which it is paid. “Always taking into account a certain overall efficiency of public administration and an intelligent establishing of the state’s attributions, the deficit and the rate of interest should grow in time directly proportional to the general economic development. If the deficit and the rate of interest grow faster, we have to ask if in some way they include certain expenses which do not contribute as they were expected to the economic growth”.

For this, we should take into account the grouping of public expenses made by John K. Galbraith, according to which they are divided into three categories:

- expenses which do not use to a “visible purpose neither in the present no in the future”. In this category there are the expenses made with the excess of personnel which raise in an unjustified way the expenses of the organisational structure and they must be covered from current fiscal incomes. Here there are

included too, the expenses which sustain political and economic interests of some small groups and which do not sustain the needs and aspirations of the broad masses. The role of the financial management is that of controlling and analyzing as objectively as possible this type of expenses in order to rationalize and eliminate those which only reduced segments can benefit of and, which should be covered from current incomes and not from loans which would be paid by the generations of our children; [2]

- expenses which are made in order to sustain current economic and social necessities; in this category there are included public expenses directed towards current activities which support the maintenance of the state, of the government, of the national defence forces, of the justice as well as the expenses made by the government in order to support industry and agriculture. From a financial point of view, these expenses should be carried out only from fiscal incomes and other current incomes, too. Even though, they are useful because they sustain the policy of the state and they are part of the economy; these should be made with consideration and loans should not be got to pay them;
- expenses which serve to future development: the raise of incomes, of production, of future wellness (they represent the growth of future general wellness and of the technical and economic progress). These expenses refer to long-term investments to develop the perspective of economy, for public works which will improve the transport conditions, the public post services, the investments from the public health domain, education, sports; they need high funds which fully motivate loans because their beneficiaries will be the next generations and in the conditions of a stable and functional economy, it is normal to be paid from future fiscal incomes, especially because, the degree of technicity and qualification will grow and so, the future generations will dispose of higher level of wellness and of bigger incomes due to the expenses made nowadays.

If for the last category it is difficult to save money, for the other two categories it is really desirable taking into account that, these costs do not support productive expenses with positive influences in the future. The financial management should preoccupy itself of rationalizing these according to a real policy of savings without affecting the good course of the activity in the public domain.

According to the Keynesian theory (demand-side economics), the public expense may represent a factor of encouraging economic relaunching through the multiplier of budgetary expenses. In this situation, the budget deficit may represent an important source of direct economic growth and stimulation of economic growth in general, in certain economic and financial circumstances. It has been observed that the relaunching policies through budget deficits or through the raise of public expenses have a limited impact sometimes, even contrary to the growth and occupation of labour force. Thus, in order to finance expenses, the state makes loans on the capital market, raising the request of funds which grow the rate of interest. Moreover, it is also produced the phenomenon of eviction of particular investments, which counteract or compensate the impact of public expenses over the global request of goods and services and by creating of money, the monetary system is destabilized and prices grow. Also, if at the same time as the inflation a salary growth takes place, not only that the desired effect of creating employment places is obtained but also, a contrary effect may be produced.

The effect of economic relaunching due to the raise of public expenses may even be cancelled through the amplitude of the effect of eviction of particular expenses by the public ones, irrespective of the source chosen for financing: the growth of taxes, loans or currency issue. Also, even if the public expense is productive as it offers future services and it increases national wealth, the supply of productive assets belonging to the state is continuously degrading.

According to the Keynesian economists, the relaunching through budgetary expenses accelerates the economic activity intensifying the speed of currency circulation and at the same time, the saving; so that, the budget deficit encourages particular expenses. This

reasoning functions in the conditions of the existence of some (important) financial resources which are not used and of some limited instruments of hoarding which clear the way of issuance of government securities through which to finance the budget deficit. In the case of limited financial resources in economy (and a reduced degree of saving), the financing of the budget deficit through treasury securities will reduce the financing means available for the activity of the particular agents. The eviction effect is more emphasized in the periods of rapid growth and more attenuated in the periods of slowing down the economic activity.

Milton Friedman-considered by some economists as being “an Adam Smith of our century”-observed the impact of anticipations in the functioning of economy and especially in the case of the appearance of inflation. In contradiction with the Keynesian vision, he explained that the economic agents do not react in a passive way to the relaunching policies, they modify their behaviours according to the provisions they make in terms of prices and incomes, learning from mistakes. Through the collocation “on the short-term, we are all Keynesian”, M. Friedman admitted the fact that budgetary and fiscal policies may influence on a short-term the economic growth and creating new employment places. The reasoning of M. Friedman was continued by the sustainers of rational anticipations, who sustain that people cannot be cheated in a systematic manner, they obtain very fast and use any information about economic conditions; consequently, they quickly adapt their behaviour to the new information which leads to the situation in which the macro-economic policies to be inoperative on the way of the budget, fiscality and money. The Keynesian orientations had a period of glory when objective factors - reduced inflation, high degree of saving, developed financial market, capacity and reduced speed of information compared with the present period - but also, subjective factors permitted their success and the influence of the relaunching policies over the economic activity and creating new employment places, on short periods of time.[1]

5. Conclusions

It exists the recommendations : to set, to announce and to respect credible objective on a medium and long-term regarding the evolution of the money stock, of fiscality, of public expenses and other market reforms.

A possible success depends on the concrete conditions of the market, on the type of measures and their intensity, on the analyzed country and its economic structures. Also, if the anticipated positive results - economic growth and occupying labour force - have a reduced expansion in time, the negative results - especially inflation - manifest themselves and last on much longer periods.

In other words, it is necessary the limitation of short-term policies as they cannot influence, in a sustainable way, the economic activity and the creation of employment places in the benefit of those on medium-term and long-term, which are stable and predictable.

Abstract

The budgetary politics, regarded as an assembly of state intervention instruments, generated by the forming processes, by taxes and duties, of the budgetary incomes, of budgetary expenses allotment, as well as on ensuring the budgetary equilibriums represent the budgetary politics of the state, directed towards the goals accomplishment, more or less delimited. In this way, the budgetary politics has been dissociated on more components where one of them, meaning the allotment politics or the budgetary politics in the limitary way, generated by the measuring instrument on elements of budgetary expenses, concisely emphasized in this paper. Simultaneously, the allotments of budgetary expenses during 2012-2014, as well as the coordination of economic politics on this time universe and macroeconomic level are illustrated in this paper.

Keywords: politics of budgetary expenses, macroeconomic politics, efficiency, budgetary politics;

JEL Classification: E60, H60, H61, H83

Introduction

The budgetary politics has been defined from many points of view, considering that more acceptances were more often met. Regarded from a limitative vision, the budgetary politics [4] is defined as having specific problems related to the budgetary expenses. It is materialized in the options as

concerns the size and structure of the budgetary expenses, and respectively the assembly of techniques and tools that can be used on establishing the size and financing the doings, carried out into the budgetary expenses. In this limitative approach [2], the budgetary politics seems to be complementary to the fiscal politics, defined in a restrictive way, and which refers to only taxes and duties, since the appertaining to the sphere of public expenses is not in accordance to the budget content that is situated upon basis of the budgetary options.

Regarded from another point of view, the budgetary politics [5] represent the expression of budgetary preferences carried out by a public decision center: local, central or over-national, owning exclusively economic and social finalities, and thus involving the use of public expenses. It is materialized by the decisions as regards the formation, distribution and use of budgetary fund resources, using as main instrument the public budget, the GDP redistribution, as well as in the aim of a lasting influence over the society.

If such politics is regarded as “the budgetary politics of the state”, [8] one might think that this is dissociated on three essential elements, strongly interconnected [7]:

- a. The fiscal politics, generated by the measuring instruments of taxes and duties elements;
- b. The allotment politics, generated by the measuring instruments on budgetary expenses;
- c. The politics of budgetary balance on current account, which aims towards the

financing of deficits and capitalization of budgetary over-plus;

As regards the budgetary politics functions, R. Musgrave affirmed that the public budget carries out some functions, of which significance varies as related to the progress of economic politics in its entire assembly, meaning [1]:

1. The function of macroeconomic conjuncture steadiness;
2. The function of budgetary resources allotment;
3. The function of distribution or redistribution of incomes, with part on maintaining an equilibrated growth under the macroeconomic report.

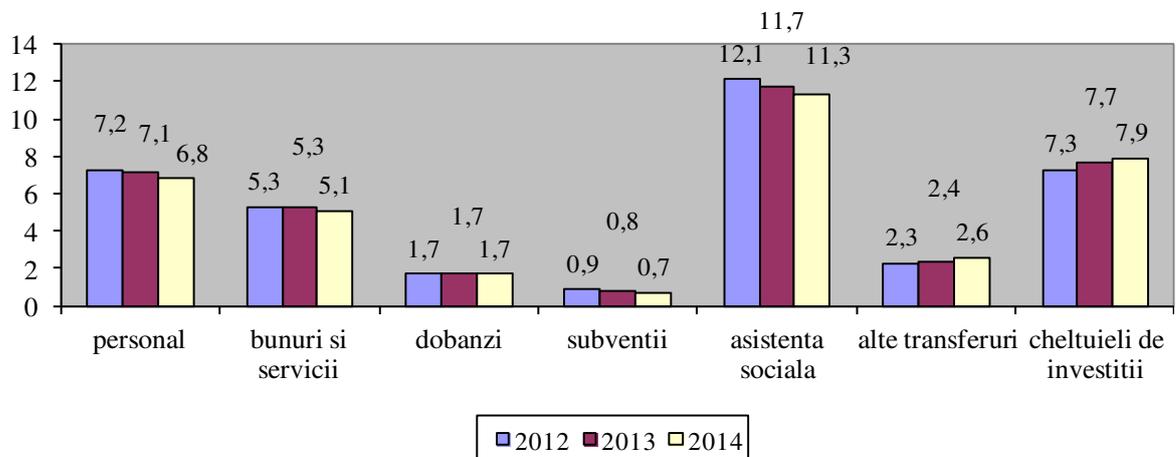

Concerning the mechanisms of budgetary politics [9], one considers that the budget signifies a mean of vivification or deliberate deceleration over the economy, and simultaneously a factor over the economic conjunctures steadiness. The main mechanisms are the following:

- a. The fundamentals of the budgetary actions;
- b. The internal obstacles, amongst which the effect of budgetary politics over the inflation;
- c. The external mechanisms, for instance the internal incidence of the budgetary politics;

By means of combining the mechanism of the budgetary politics, the budgetary functions, the equilibrated allotment and use of the budgetary resources, one can illustrate concisely the expenses politics, as this has been debated and published within “The fiscal budgetary strategy of Romania during 2012-2014”, issued in 2011.

The politics of expenses promoted [10] for 2012-2014 signifies a restrictive, cautious and equilibrated budgetary politics, which was built upon the principle of solid financial management, and which takes into account the turbulences and uncertainties on the international markets, as well as the internal constraints.

Table 1: The progress of main expenses of the general budget established during 2012-2014 – percentages of GDP

Source: The Fiscal-Budgetary Strategy, 2012-2014, 2013-2015

http://discutii.mfinante.ro/static/10/Mfp/strategbug/STRATEGIA_2013_2015revizuita.pdf

The coordination of economic politics is essential for the macroeconomic equilibrium renewal. The correlation of economic politics is necessary [2] for the adhesion objective towards the Economic and Monetary Union, but this should be maintained hereinafter, in conditions where Romania [3] should find the rhythm and resources of development. The public expenses politics should be established in accordance to the development aim, and the strategy of development should

be assumed by all segments of the Romanian society.

The politics of expenses proposed for the interval 2012-2014 signifies a restricted, equilibrated and cautious politics, as this has been formulated by underlying on the principle public money sobriety.

The main challenge [10] consists in ensuring the adjustments continuity, but these will not be as significant and tough as in 2010, taking into account that the economy's

progress foreshadows a sustainable trajectory.

The objectives of budgetary politics:

- Gradual reduction of budgetary deficit to 4.4% of GDP in 2011, 3.0% of GDP in 2011, 3.0% of GDP in 2012 and 2.5% of GDP in 2013, 2.2% of GDP in 2014, being compatible to the elimination of excessive deficit until the end of 2012.

This objective depends upon:

- The elimination of backwards;
- The efforts on maintaining under control the budgetary expenses.

Ensuring an accurate financing of the budgetary deficit on the reference horizon is emphasized by:

- Continuation of adjustments and the restructuring of public expenses system, meaning:
 1. framing of expenses with salaries in 7.2% of GDP for 2012, 7.1% of GDP in 2013 and 6.8% of GDP in 2014;
 2. non-conferment of prizes, bonuses and holiday tickets, launch tickets and compensation of activity carried out outside the normal period of time, exclusively by free hours;
 3. continuation of reducing the number of employees in the public sector, by maintaining the politics of replacement to a single employee out of seven, which leave the system;
- Directing of expenses towards investment projects with part in the economic development:
 1. During 2012 -2014, the expenses with investments represent 7.3– 7.9% of GDP;
 2. The efforts on improving and ranking the capital expenses will be continued depending upon priorities, in order to increase the absorption of European funds, by using the supplementary resources allotted to investments in the first quarter.
 3. In case absorption is increased enough, a higher fiscal space will be created for the investments, starting with the half of 2011.
- The accelerated absorption of structural funds:
 1. Modernization and strengthening of legislative frame, as well as regulation in the public investments

field, and in other fields relevant for the EU funds absorption;

2. Prioritization of investments, in order to ensure the funds necessary for the essential projects;
3. Strengthening of projects evaluation process.

Reform of social insurances labor conscriptions

- Making efficient the social protection will forwards signify a priority, especially in the field of social inspection;
- A new Law of Social Insurances was issued, which will strengthen the categories of labor social conscriptions already existing in a number of nine, and that will get worst the criteria of eligibility;
- The efforts within the sphere of social inspections have had significant results, the number of persons that benefit from heating-up helping being significantly reduced. In total, the measures of reform related to the social labor conscriptions will generate almost 0.8% of the GDP, within the interval 2010-2013.
- The expenses carried out with the social insurances will represent during 2012-2014, 12.1-11.3% of GDP, as result of the measures carried out in this direction.
- The adoption of legislation in order to establish the co-payment system of the medical services is estimated to be carried out in the near future.
- The revision with assistance from the World Bank of the basic services package ensured by the Government, in order to exclude the not-essential medical services, will also be taken into account.

The implementation of laws already approved in the Parliament, which will generate budgetary economies to reach the fiscal sustainability on mean term to fields, such as fiscal budgetary, employment of budgetary staff, of retiring pensions systems or in the education will be highly illustrated within the public politics included in the strategy. The New Code of Labor, which entered into force on 30th of April 2011, proposed to make flexible the labor market, by promoting the labor contracts on fix and

temporary term, by prolongation of the probationary times, and by increasing the flexibility of work schedules.

As regards the Law of social dialogue no. 62/2011, the key elements include [9]:

- majoring the representation limit, for both the syndicates and patronages;
- eliminating the collective contract on national level;
- removing the automatic *erga-omnes* extensions on sectorial level;
- The new legislation will have to respect the European directives and the main EU and OIM conventions.

The effects of expenses politics on the reference horizon 2012-2014

The main effects of the expenses politics are the following [10]:

- Reducing the staff expenses, in collaboration to the decline of assets and services expenses, that will contribute on territory entrance, but negative to the governmental consumption dynamics. In this way, the weight of budgetary expenses will be comprised within 36.9%-36.1% of GDP on the horizon 2012-2014, as comparing to the 38.9%-37.6% of GDP, on the 2009-2011 horizon;
- These adjustments will create the fiscal space on the investments expenses.
- If is integrally implemented, the strengthening reform in the public expenses field will contribute on the sustainability of strengthening effort, that Romania is currently taking, and where the studies indicated that episodes of supported adjustments are especially underlying on the expenses reductions.

Conclusions

Drawing some conclusions, one might confirm that the budgetary politics should ensure the maximum efficiency use of the state financial potential, and should allow the correlation on optimal criteria, as regards the public utilities offer and in relationship to the private utilities offer. In this way, the objectives that should be achieved in the near future consist in the following: ensuring the social equity and social protection, increasing the level of citizens' culture and civilization,

re-launching the stagnant economy being in crisis, restructuring and modernization of the national economy, as well as the growth of living standards.

Abstract

The interest in internal control and its continuous nature is the consequence of the causes which led to the recording of significant losses by some banks.

Therefore, an effective internal control system is a critical component of the management of the banks, which can support the achievement of the objectives of the Bank and to achieve its profitability targets.

Cuvinte cheie: financial crisis, Board of Directors, banking system, corporate governance, Basel.

Clasificare J.E.L.: G21, G32

1. Introduction

The negative impact that the risks they have on the performance of entities from the banking system and the risk management process, have led to major concerns about prudence. Thus, it has become increasingly necessary to introduce a function of measurement, management and control of risks in the system.

In the process of banking risk management involved with internal audit and the other actors: banking prudential supervision, internal controls, management of the credit institution's, statutory audit.

2. Internal control: objectives and elements

For the purposes of the regulations of the Central Bank, internal control is designed as a continuous process involving the Board of Directors, managers and staff of the Bank, to provide reasonable assurance on the

achievement of the objectives of internal control[1]:

- conduct all activities of the Bank, in terms of efficiency and effectiveness;
- the provision of reliable, relevant information, and timely complete structures involved in decision-making within the Bank and external users of information;
- ensuring compliance of the Bank's activities with the legal framework, with its own policies and procedures.

Objectives of internal control within the banks are in full agreement with the recommendations of the Basel Committee on banking supervision.

In accordance with the Basel Committee, the main objectives of the internal control process can be broken down as follows (Figure no.1):

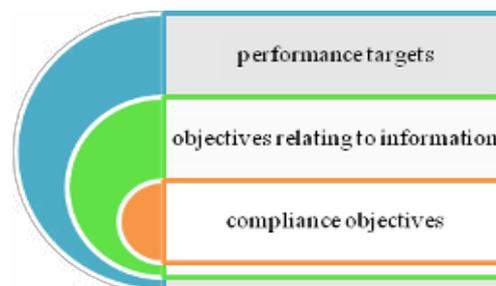

Figure no. 1., "The objectives of internal control"

The **performance targets** of internal control refers to the efficiency of the institution through the use of its assets and other resources at its disposal and its protection against losses. Through the process of internal control aims to ensure that the staff of the institution shall work with efficiency and integrity for the achievement of the objectives of the institution, without excessive cost and without placing other interests before those of the Bank.

The **objectives relating to information** is linked to the operational preparation of relevant and credible reports that would provide the basis for decision-making processes within the credit institution. At the same time, these goals concern financial information, annual financial statements and others, which are intended for members of the Board of Directors, the shareholders, the supervisory bodies, information that requires quality and absolute integrity for the decision-making process.

The **compliance objectives** of ensuring the protection of the reputation and the authorization running through the entire staff of the legal regulations concerning the activity of credit institutions, the requirements of the supervisory authority, the rules and policies

To achieve these objectives, the banks are obliged to organize a system of internal control, which is composed of the following elements in close correlation (figure no. 2):

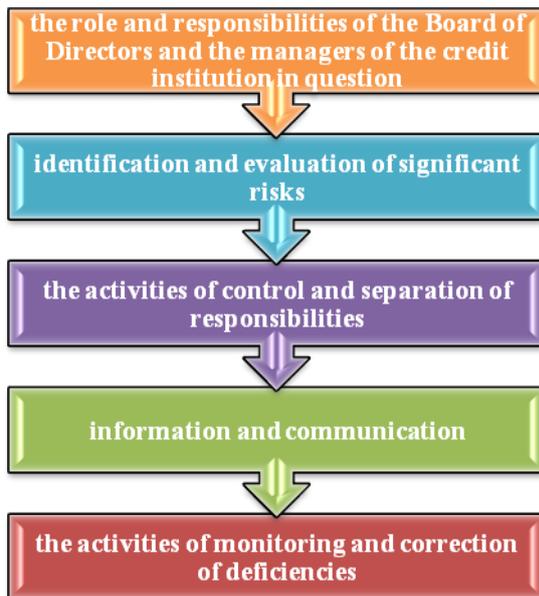

Figure no. 2, „The elements of the system of internal control”

In accordance with the principles of good corporate governance, but also with the legal regulations in force, the responsibility of organizing and maintaining an adequate internal control system and effectively within a Bank, lies with its Board of Directors.

In this regulatory responsibility of the Board of Directors of each of the banks, and

its powers are derived relating to internal control.

Thus, the main tasks incumbent upon the Board of Directors of a Bank, in relation to the organisation of internal control are (figure no.3):

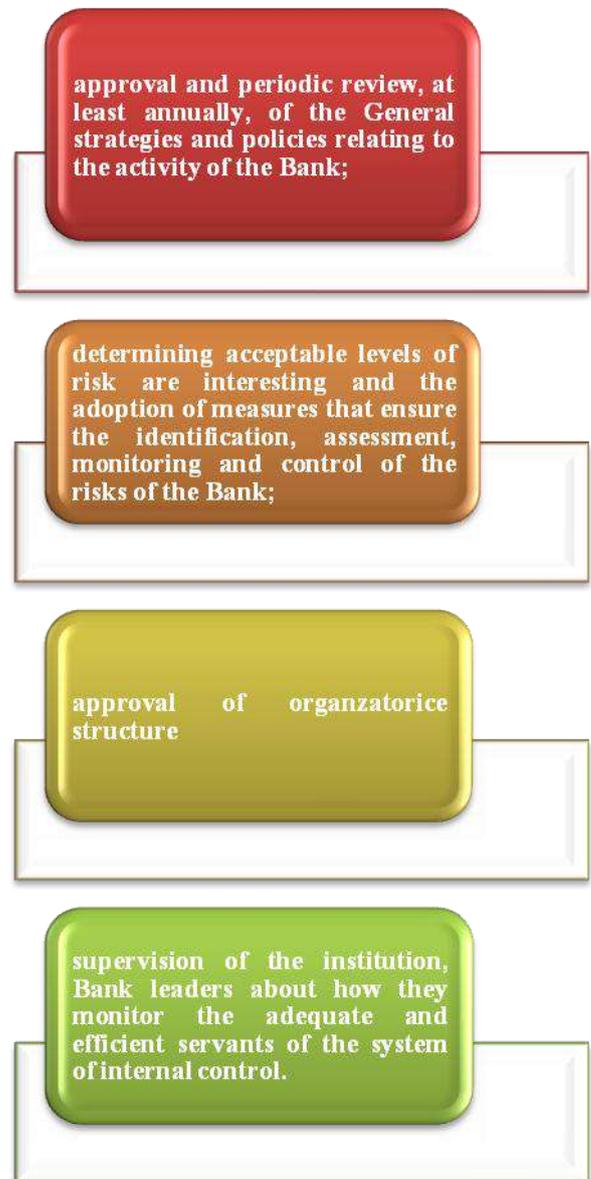

Figure no. 3 „Powers of the Board of Directors in banks relating to internal control ”

In carrying out these duties, the members of the Board of Directors must hold talks with operatively on the effectiveness of the internal control system, periodic assessments of the internal control system of the financial auditor and the National Bank of Romania and to ensure the implementation of the management of the stock recommendations of internal audit, financial auditor and by the Central Bank.

For the performance of its duties relating to the system of internal control, the Board of Directors of the credit institution shall be assisted by a Committee called the Committee on specialized auditing.

The *Audit Committee* established within each of the banks, in line with the recommendations of the Basel Committee on banking supervision, international practices and regulatory requirements, is defined by:

- + set up by each credit institution;
- + is a Standing Committee;
- + it is independent of the management of the institution;
- + it is directly subordinated to the Board of Directors;
- + it has advisory function;
- + it works on the basis of regulations issued by the Central Bank and its own rules approved by the Board of Directors;
- + it is made up of members of the Board of Directors of the credit institution are not and neither had the quality of its leaders;
- + at least the following duties:

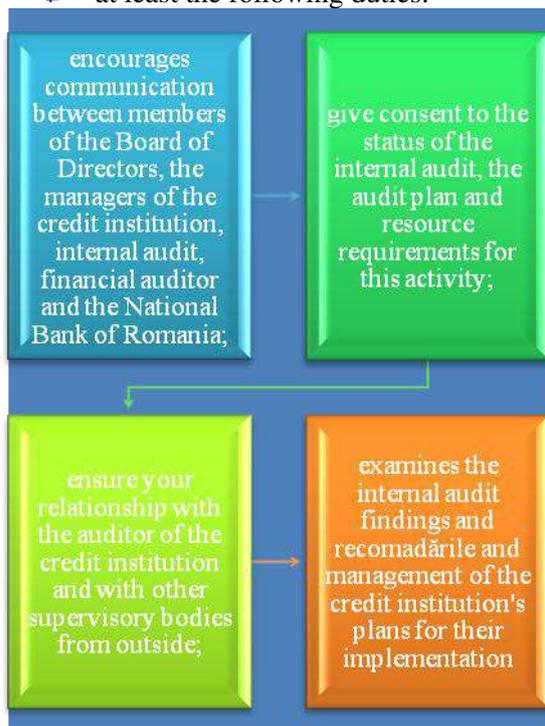

Figure no. 4 „The Audit Committee's duties”

- + access to data or records necessary for carrying out its duties;
- + shall be drawn up regularly;
- + formulated with advice to the Board of Directors relating to the strategy and the Bank's policy in the field of internal control.

3. Functions of the system of internal control

Within the system of internal control of the Bank are [2]:

- ✿ the function of risk management,
- ✿ the compliance function and
- ✿ the internal audit function.

The function of risk management has in the composition of the risk control function on each line.

These functions are independent from the organizational point of view, both each other and towards business lines which it monitors and controls.

Internal control functions are under the control of a manager of the Bank without responsibility on the management of the activities monitored and controlled by them and reporting lines works directly from these three functions, the management structure of the Bank.

The risk management function within the Bank is an important component of the system of internal control. It is organized independently and is under the direct supervision of the management structure of the Bank. Risk control function is part of the risk management function and ensures compliance with the risk policies.

The compliance function: compliance activities within the Bank is assured through Compliance Department, which is responsible for implementing the policy of the Bank. The Line also has the role to track the effectiveness of compliance, to monitor that regulatory requirements are being applied and to report any deviations from them. She is responsible for the communication and representation of the Bank in relation to the competent authorities, supervisory role on issues that fall under its responsibility and cooperate with these authorities to ensure the implementation and interpretation of the Bank of the regulatory framework.

The internal audit function: the internal audit activity's mission is to ensure that the Bank's objectives are being met successfully. In this regard, the Audit Department:

- performing audit assignments for the purpose of forming an opinion on the adequacy and effectiveness of the system of internal control, and the procedures and principles that have been established for risk management and corporate governance;

- evaluate the organisation and functioning of the systems and mechanisms in order to provide the financial and managerial information reliable, complete and timely;
- examine in detail the cases which may affect the interests of the Bank;
- submit proposals to correct any deficiencies identified during the audit missions and improving processes and control mechanisms;
- monitor the implementation and effectiveness of the actions taken to correct deficiencies;
- advise management and the Board of Directors with respect to the fulfilment of the objectives of the internal control system.

4. Corporate governance

For the implementation of an effective corporate governance for managing banking risks, structures of the credit institution, the main tasks the following [3]:

- ◆ IRB approach implementation plan provision (based on internal rating models) the most important categories of exposure;
- ◆ elaboration of methodology for the process of internal risk rating;
- ◆ identifying and assessing events that give rise to risks;
- ◆ monitoring and managing potential sources of conflict of interest;
- ◆ determination of the responsibilities of the unit of risk control and assessment personnel from professional point of view.

5. Conclusion:

The current crisis can be seen as an opportunity for the theory and practice of corporate governance in the banking sector.

Banking corporate governance effective, depending on the business model and the corresponding risk profile is the first step towards successful implementation of Basel III. Internal Auditors also have a very important role because you have to analyze the critical operations and recommend improvements to the internal control framework.

The basic concept of an efficient management is based on the idea that managing risk is for each employee of the credit institution, on each level and

functional line. Bank risk management should become a fundamental part of the culture of the institution, in addition to compliance with the system of values and compliance information.

Recognition and awareness of the necessity of the existence of the corporate governance rules of unitar is a requirement for credit institutions.

The supervisory authority must first evaluate each credit institution depending on the size, structure, complexity and business risk profile, then to resort to corporate governance implementation binding validation.

In terms of internal control, risk assessment involves the identification and evaluation of all external and internal factors that could adversely affect the attainment of the objectives of the information and performance of compliance of the credit institution.

Abstract

The legislative developments at EU level can have a significant direct or indirect impact on private health insurers, although in the EU, member states are responsible for the organisation of their health systems

Insurance Europe supports fair conditions of competition between all health insurance market participants, on the basis of the principle of “same business, same rules”.

This paper is structured as follows: conceptual aspects concerning the health care systems in section 1, section 2 showing the characteristics of private health insurance and estimates the evolution of private health care insurance during the crisis.

Key words: health-care insurance, health-care system.

J.E.L. classification: I1.

1. Introduction

Health systems in the world today are under the sign of diversity – in terms of organization, operation and financing – but are at the same time, seeking to optimize the relationship between the efficacy of the services provided by the system, their fairness and the freedom of the involved stakeholders, amid increasing concerns for financing the system. The main concern is the timing of the pace of the increase in public spending aimed at this sector and the identification of alternative solutions that would support the operation of the system. Developed countries have addressed the issue of the sustainability of financing health expenditures in stages.

In the period 1970-1990 macroeconomic

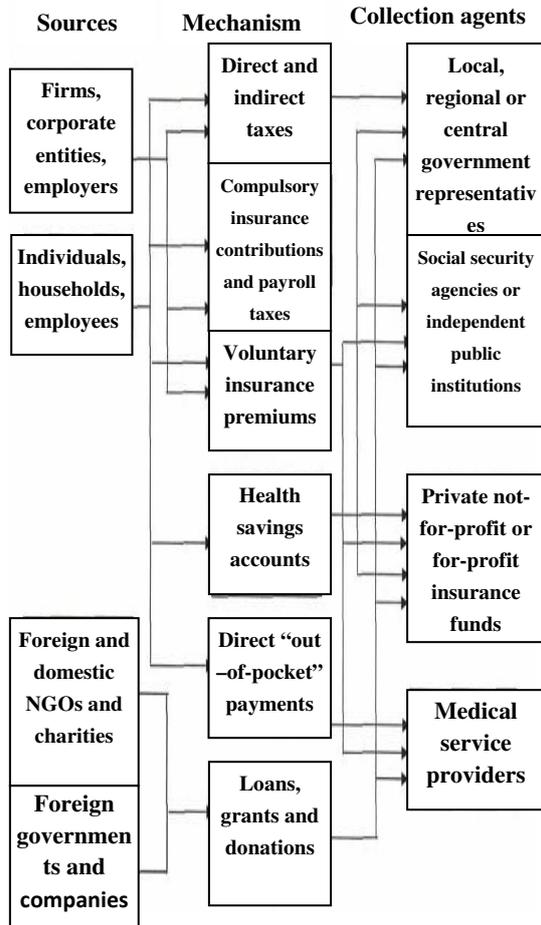

solutions were predominant and through them the funds allocated to the system increased and led to its consolidation and conservation. Under the pressure of the limitation of the possibility to support this growth due to the negative impact on the competitiveness of goods in a strongly internationalised and competitive business environment there was a shift towards preponderantly microeconomic trends by which to limit and control the increase in the public expenditure oriented towards health. For this purpose a number of procedures were promoted in order to encourage the change of the behaviour of stakeholders in the health area.

In a simplified presentation, the defining elements of health financing systems are: 1. the parties between which funds are transferred (which usually are: the government, the health insurance funds, the personnel, the medical units, the beneficiaries) and 2. the payment mechanism (the most used are: the payment per service, the payment per capita and the wages). In the flow of payments, the relationship between the providers and the recipients of health services may be direct or mediated by a third party, such as the Health Insurance Fund. As can be seen in the figure shown below, the healthcare system can be represented in terms of its functional parts: who provides the funding sources, which are the collection mechanisms, and who are the resource collection agents?

The funds come mainly from the public (individuals or corporations), while the collection mechanisms include taxes, social security contributions, private insurance premiums, population savings, payments made directly by patients (“out-of-pocket”), donations, loans, *grants*. The collection agents can be public or private (*for-profit* or

non-for-profit agents), and taxes can be direct (paid individually, by households, firms) or indirect (transactions). Taxes are collected by the government, while the compulsory insurance contributions are collected by an independent or semi-independent agent.

Figure 1. Examples of funding sources, contribution mechanisms and collection agents

The contributions to health social security contributions are paid both by the employer and the employee, and their level usually depends, on the income. Private health insurance premiums are paid either by the insurance holders, by the employer and the employee together or only by the employer. Insurance premiums can be calculated according to the individual risk of disease based on an individual health assessment, or depending on the conditions related to the community or the group to which the individual belongs. Collection agencies, in

this case, are private organizations, *for-profit* or *not-for-profit* insurance companies.

Individual savings for health are accounts where people save money; this money is intended for health-related expenses, for the payment of costs requested to patients for certain types of services. These payments can also be charged as co-payments, additional insurances etc., and the collector agent is the one who provides the service: the doctor, the hospital pharmacist [3].

There are two basic alternatives for the allocation of funds: oriented towards those who provide medical services (in this case the money goes to them, but not necessarily to the beneficiaries too; for example, in rural areas the number of those who provide medical services is low) and oriented towards the beneficiaries (the payment is, in this case, made for the beneficiary himself, so that those who provide the service receive the money if they treated the respective patient, regardless of where the healthcare took place).

If there is an intermediary who is responsible for funding services for a certain population category, it is necessary to develop certain rules on the allocation of funds. Usually, in the European countries such rules are set taking into account both the free market principles and the technocratic principles; the latter are meant to reduce the unwanted consequences generated by the market or by social or regional inequalities. It is also important to avoid losing control of the expenses in the private space, caused by market imperfections (limiting the information given to patients, incentives, moral hazard, etc.). The financial support may depend on whether the health system provides value for the (public and private) money spent and whether the financing system does not generate budget deficits and/or becomes a burden on household budgets. Resource allocation oriented towards beneficiaries can be done taking into account several factors, according to which we obtain the following typology [5]:

- Financial allocation based on the population needs.
- Financial allocation based on efficiency.
- Financial allocation based on public priorities.

No state funds its health services exclusively through a single mechanism, but

one of the mechanisms is predominant at a certain time namely: government funding based on taxes, whether national or local, private health insurance and social security insurance or direct payments by the patients. There are differences in almost all European countries concerning the organization of public health services and how the insurance system is managed. Public health services in Belgium, France, Germany and Sweden are similar to those in the UK.

Table 1. Public health system in several countries in Europe

Country	P1	P2	P3
Belgium	10,2%	3,55	3,8
France	11%	between 22 and 25% of the gross salary goes to social security	
Germany	10,4%	14.5% split between employee and employer	
Italy	8,7%	The national health system is financed from the income tax	
Spain	8,5%	The health insurance is included in the health insurance contributions	
Sweden	9,1%	0	8,78
Great Britain	8,4%	The national health service is funded from the income tax	

Key: P1-The percentage allocated to health from the GDP; P2- The percentage paid for health by the employee; P3 - The percentage paid for health by the employer.

Source: Kaiser Permanente International 2010 (American health organization).

From the perspective of the expense financing source, there is a revival of the financing through private or mutual insurance, which process is more obvious in countries such as the Netherlands, Poland, the Czech Republic, but less significant for France, Denmark, USA. OECD countries have acted to limit public expenditure by applying the co-payment system in parallel with the operation of structural changes in the healthcare system. The increase in the health expenses preponderantly supported from public sources raises concern because it can lead to a loss of growth potential from the perspective of the tax theory or of the optimal increase. The increase in the private

finance contribution with the purpose of covering health expenses creates problems from the perspective of the fairness criterion and can generate exclusion and discrimination. If the private contribution comes from business entities, by means of various types of insurance, then the risk concerning the loss of economic growth potential occurs again.

The direct participation of the patient in health financing system is discussed in contradictory terms: on the basis of the effectiveness principle the patient must contribute to the covering of the healthcare service cost; on the contrary, as a consequence of the right of access to these services the patient must be exempt from paying any financial benefit. The patient's direct financial contribution is viewed as a tool through which the patient is forced not to abuse the facilities of the system and thus to have a responsible attitude towards his own health.

The gratuity or the quasi-gratuity provided by health insurance are the consequence of the fact that there is a solidarity system. The possibilities of this system to cover an increasingly rich offer of medical services that is combined and sometimes even feeds a growing demand for medical supplies are becoming more limited. This led to the idea of establishing a set of procedures to that should act like a filter to the patients' and healthcare professionals' financing applications.

The orientation towards solutions combining free access to some types of medical services with the direct payment system for others is also justified by the perverse effects of a system based exclusively on gratuity. The studies conducted under the aegis of the World Bank highlighted the risk that the low-income population benefit less from these services, because it is more difficult for it to express its demand and to be acknowledged by the health system.

In the EU, each country is responsible for defining its health policy and for the management of its medical services. The Lisbon Treaty calls on the European Union to complement the actions undertaken by Member States, encouraging the cooperation among them and giving them the support they need. In fact, in recent years, the EU has

supported increasingly the actions of the Member States meant to provide the sustainability and efficiency of the medical systems. Health systems in Europe have a number of characteristics (Table 2).

Table 2. Characteristics of health systems in Europe

<i>Type of insurance</i>
Providing health services is the responsibility of the government at various levels
Health services are a social right
The distribution of medical services is integrated (the prevention and the therapy, emphasizing the former)
The general plan of the entire economic and social order plans medical services and resources centrally
The central health and policy authorities make final decisions on the major characteristics of the national healthcare system, the local groups of citizens having the possibility to contribute to the development of the health policy
When the resources are limited, the health system priorities are directed towards children's and industrial workers' needs
The major authority represented by the Ministry of Health and its subdivisions, integrating and managing all the parts composing the health system
Strict regulations are provided to the medical practice and to the ancillary activities
The healthcare activities are based on scientific principles, and non-scientific practices are not allowed
The dissatisfaction related to the quality, the access to healthcare, the lack of freedom to choose the medical act, the dissatisfaction of the staff and of the healthcare service managers are the last point.

Sources: WHO (World Health Organization)

EU is working closely with countries like Portugal and Greece that due to the difficult economic situation they are facing, participate in economic assistance programs. In these programs, the European Commission helps to identify and implement measures to streamline their healthcare systems and bring them to economic recovery. The objectives of the health systems are presented in Table 3.

Table 3. Objectives of the health systems

<i>Objectives</i>
Allowing citizens' easy access to public healthcare
Improving social justice
Adapting the production of the health services to the changes in the demand and supply of health resources
Introduction of improved or medical technology
Implementing new programs to improve the health of the population
Adjusting the volume and time of health services based on epidemiological and demographic changes
Eliminating factors that adversely affect health
Transforming the health system in order to implement the objectives of the national health policy

Sources: WHO (World Health Organization)

According to WHO, any health system must have 28 functions that include 4 categories (Table 4). The functions of a national health system must be set, coordinated and controlled.

Table 4. Functions of national health systems

Development of health resources	<ul style="list-style-type: none"> - training health staff and manpower - organizing the health service facilities - pharmaceutical production: support, provision, distribution - production of health equipment and supplies - scientific research - technology
Delivery of health care	<ul style="list-style-type: none"> - environmental health - health preventive and promotion services worldwide - primary healthcare - secondary healthcare - tertiary healthcare - individual healthcare (populations with special needs) - healthcare for people with special health problems - organizing personal healthcare

Developing the economic support mechanisms	<ul style="list-style-type: none"> - allocating funds for health - mobilizing financial resources
Activity management	<ul style="list-style-type: none"> - Healthcare problem management - Health policy formulation and planning - Information flow - Coordination within health systems - Community involvement - Adjustment of human resources - Adjustment of material resources - Regulation of health services - International cooperation

Sources: WHO (World Health Organization)

Despite the financial crisis and the alarm signals, the performance of the European health systems continues to improve, with few exceptions. Public health gradually begins to bring higher quality and wider access for patients in Europe (Health Consumer Powerhouse - Euro Health Consumer Index (EHCI) is a standard indicator on health systems in Europe, including 34 countries, based on 42 indicators, on five fields of activity, very important for the population's health: patients' rights and their information, accessibility to treatments (waiting time), medical results, availability of the supplied services and pharmaceutical products. The index includes a combination of public statistics, patient surveys and independent research conducted by the foundation.). The first place is held by Holland, with 872 points out of the possible 1,000. The Netherlands is followed by Denmark, Iceland, Luxembourg and Belgium, at the top. From the previous report (2009) scores have increased, but there are also warning signs, authors say. There is a growing gap between the countries at the top and at the bottom of the deck, the economically "strong" and the "weak" ones. The Netherlands should be the standard aimed by the European Countries, in terms of health system reform, being is an example worth following. Patients' rights are improving in many countries, a lot of information meant to help the patients in their choices, to prevent certain diseases and

for correct choices in the healthcare system is increasing, and the access to it is becoming easier, for example, e-prescriptions and online schedules for examinations are implemented. From this point of view, health systems improved their performance.

Moreover, the “power” gap between doctors/nurses and patients is reduced, for the first time we can see new tools being used effectively: requesting a second professional opinion, recording and keeping medical records, and making informed decisions, together with the patient in most countries.

Europe is divided concerning the health system: un a highly developed group, influenced by consumers in the countries in North-West Europe (the Netherlands, Belgium and the Nordic countries); another group of countries making big progress (Czech Republic, Slovakia, Croatia, Lithuania and Estonia); o another category of developed countries that have clear problems in keeping up with others (Germany, Austria, Italy and Spain); and, finally, a group of always under-performing states (for economic, cultural or political reasons), with no real impediment. The countries with the best systems have shown openness to the private insurance system. Romania received 489 points, which placed it on the 32nd position among the 34 countries the position has not changed from the EHCI 2009), while the last places were occupied by Bulgaria and Serbia respectively.

2. The evolution of private health insurance

Today, and especially because of the global crisis, the optional health insurance system, the private insurance, are gaining more ground and that is not because Romanians can afford private insurance, but simply because they felt the negative effects of the budgetary crisis at the level of the insured patients who could no longer benefit from the discounts made by insurance funds due to the lack of public funds.

Private health insurance is a niche market, their development depending on the reform of the social health system and on the implementation of fiscal incentives. After a decrease in 2009 by 16.4%, the first signs of recovery appeared in 2010, accompanied by an increase in the in gross written premiums

(GWP) by 3.7% (Insurance Supervisory Commission, 2010). However, this market remains small and continues to be based on retail and to be dependent on the corporate sector. Even though health insurance seems to have experienced a slowdown in growth in 2011, it remains the second largest non-life business line in Europe, accounting for a quarter of the total. After a 6% upturn in 2010, a modest rise of 2% (at constant exchange rates) is expected in 2011, with health premiums amounting to €111bn.

The health insurance sector in Europe is mainly driven by the Netherlands and Germany, which respectively represent 36% and 31% of the market. Early estimates show that both markets reported a slowdown in growth in 2011, whereas France, the third largest market (9% market share), experienced a 1% decline, owing to a change in its tax regime on 1 January 2011.

*European health insurance and growth –
2009 – 2011 (€bn)*

1. Total gross written premiums		
2009		101
2010		108
2011		111
2. Nominal growth (at current exchange rates)	2009/10	7%
	2010/11	3%
3. Nominal growth (at current exchange rates) (at constant exchange rates)	2009/10	6%
	2010/11	2%

3. Conclusion

Private medical insurance improves consumers’ access to healthcare either directly or by filling the ever growing gaps in coverage left by public systems [1]:

- Consumers are free to choose their private medical insurer according to their needs, unlike a public healthcare system.
- Each PMI product is tailored, ie, it offers cover that is highly adapted to the needs of individual consumers.
- Through PMI, consumers can choose the healthcare providers they want, as well as the time and place of treatment (eg, hospital or private clinic). They have quicker access to healthcare (PMI reduces waiting lists) and receive better quality care. The sooner treatment is provided, the faster the patient recovers, reducing

healthcare costs. PMI therefore offers a healthier outcome for the patient.

- PMI offers financial security to patients through a wider scope of reimbursement (eg, co-payments¹ of public healthcare insurance schemes can be at least partially covered).
- PMI can insure against the costs of new and better medical treatments, as well as more efficient drugs.
- Private medical insurers operate in a competitive market, which results in lower medical costs and improved quality and efficiency of healthcare, to the advantage of all consumers.
- Private medical insurers aim for greater efficiency and quality through network management, patient mobility (PMI has, in most cases, pan-European cover within the frame of the EU’s Third Non-life Directive) and cost control. PMI manages the risks of medical costs over time and between policyholders.
- New EU member states that are transforming their national healthcare systems (eg, Slovakia) use PMI as an element of their reform to ease the pressure on the public healthcare system.

Abstract

This paper intends to investigate determinants of demand for renewal or not renewal of CASCO insurance policies for a class of individuals. Using a logistic regression model, we estimated the probability a certain person will not buy a new voluntary insurance policy providing full protection against damages, with data from a non-life insurance from Romania. Also we analyzed the direction in which covariates like the age of the policy holder, the insured amount, gender, auto use age, engine capacity influence the probability of not renewing a CASCO insurance. Due to data availability and confidentiality specified by law, we analyzed separately the dependency between the amount of compensations and the gross written premiums and the number of claims.

Keywords: automobile insurance policies, CASCO, logistic regression.

JEL Classification: G22, C14.

1. Introduction

CASCO (Casualty and Collision) insurance is a facultative vehicle insurance policy whereby car owners can protect themselves against financial consequences arising from the occurrence of insured events. CASCO covers losses caused by: traffic accidents, low-quality road surfacing, vehicle theft or burglary, deliberate damage by a third party, fire, natural disasters, glass breakage, damage caused by falling objects, damage caused by animals.

In Romania, according to the latest published annual report for 2011 [7] of the Insurance Supervisory Commission, for general insurance, the structure of classes of insurance gross written premiums, the largest share, i.e. 84.48%, was cumulatively held by: Class III - Insurance for land vehicles other than railway class (CASCO) for 32.72%, class X - third party liability insurance for vehicles for 32.39%, and Class VIII - Insurance against fire and other natural disasters for 19.36%.

For CASCO policies, the subscribed gross premiums amounted for a volume of 1,990,961,515 lei, which represents a decrease by 28% in real terms with respect to the previous year, 2010. Subscriptions on this class of insurance developed (entered on) a downward trend since 2008, with the financial and economic crisis, the decline in leasing, significant reduction of car loans granted by commercial banks, and the declining purchasing power of the population.

In [4], it is examined the effect of price, income, and perceived risk on the demand for automobile insurance. In [6] proposed the use of the multinomial logit and nested logit models to identify variables related to the selection of bundled automobile insurance policies, for a database of a non-life insurance company in Taiwan. Another paper [5] focused on the new car owners' behaviors on physical damage coverage (high-premium non-compulsory auto insurance policies in Taiwan. The regression model estimates revealed that owner's age, vehicle brand and engine capacity are significant factors for the new car owners' repurchase behaviors on physical damage coverage policies in the

subsequent years.

This paper intends to investigate determinants of not renewing CASCO insurance policies for a class of individuals in Romania. Using a logistic regression model, we estimate the probability a certain person will not buy a new voluntary insurance policy providing full protection against damages. Also we analyze the direction in which covariates like the age of the policy holder, the insured amount, gender, auto use age, engine capacity influence the probability of renewal a CASCO insurance.

2. Data and methodology

The empirical data consists of 8118 insured records from a non-life insurance company in Romania in 2011. Due to data availability and confidentiality specified by law, the characteristics we could use for the purpose of this paper were: the age of the car user, gender, insured amount (Eur) of the vehicle, engine capacity, the use age of the automobile, the distribution channel of purchasing an insurance policy, renewal status of a policy. Table 1 presents the sample distribution of some of the variables.

Table 1. Distribution of the policy holders according to some characteristics.

Characteristics		Share of the insured people
Gender	male	66.6%
	female	33.4%
Age group	18-23	1.07%
	24-28	9.41%
	29-30	6.63%
	31-40	31.29%
	41-58	39.56%
	59-70	12.05%
Insured value (amount), in Eur	≤4000	10.4%
	4001-8000	35.1%
	8001-10000	16.1%
	10001-15000	21.3%
	15001-20000	8.3%
	≥20001	8.8%
Auto use age, years	0-1	15.4%
	2-3	27.7%
	4-6	43%
	>=7	13.9%
Renewal status	Yes	34%
	No	66%

Distribution channel	Brokers	78.5%
	Direct sales	11.8%
	Other	9.7%

The dependent variable is a binary variable, denoted Y . The two outcomes are: a casco policy holder buys a new insurance policy or not. The outcome that he does not renews the insurance policy is the outcome of interest.

$$y_i = \begin{cases} 0, & \text{policy holder } i \text{ renews} \\ 1, & \text{policy holder } i \text{ doesn't renew} \end{cases}$$

Let us denote by p_i the probability that the policy holder i does not renew that insurance, $p_i = P(y_i = 1|x_i)$, where x_i is the vector of the policy holder's characteristics or the predictors of the probability:

$$p_i = P(y_i = 1|x_i) = \frac{1}{1 + e^{-(\beta_0 + \beta_1 x_{i1} + \dots + \beta_k x_{ik})}}$$

If we define $\text{logit}(p) = \frac{p}{1-p}$, we will

use a logistic regression model, [2]:

$$\text{logit}(p_i) = \beta_0 + \beta_1 x_{i1} + \dots + \beta_k x_{ik}$$

The k explanatory variables dichotomous and continuous, were chosen such that the model fits the data in a better way.

Table 2. presents the distribution of the dependent variable on some of the characteristics presented previously.

Table 2. Renewal status of an insurance policy, in %, on some characteristics

Characteristics		Renewal status(%) within the class characteristic	
		Yes	No
Gender	male	33.2%	66.8%
	female	35.5%	64.5%
Age group	18-23	15.2%	84.8%
	24-28	20.9%	79.1%
	29-30	30.4%	69.6%
	31-40	34.6%	65.4%
	41-58	35.8%	64.2%
	59-70	39.9%	60.1%
Insured value (amount), in Eur	≤4000	51.1%	48.9%
	4001-8000	40.9%	59.1%
	8001-10000	31.4%	68.6%
	10001-15000	26.4%	73.6%

	15001-20000	20.9%	79.1%
	≥20001	21.2%	78.8%
Auto use age, years	0-1	16.0%	84.0%
	2-3	32.8%	67.2%
	4-6	39.1%	60.9%
	>=7	40.1%	59.9%

In the data the insurance company first offered to us there was no information on the premiums chashed, the number of claims or the amount of the paid claims for each policy holder. However, this information was provided to us in another file, but we could not merge the two files, so these data will be analyzed usig a linear multiple regression model.

Table 3. Descriptive statistics for the variables in the linear regression model: X_1 - Gross written premiums, in Eur, X_2 - number of claims, and DV – the dependent variable represents the amount of the compensation, in Eur.

	X_1	DV	X_2
Mean	884.2	700.8	.79
Median	629.7	.00	.00
Mode	400	0	0
Std. Deviation	892.9	1575.9	1.249
Skewness	3.7	4.5	2.441
Kurtosis	25.2	28.5	11.480
Range	13371	18896	18

	60	792	142.9
	70	1004.3	518.2
	75	1131.3	760.8
	80	1292	1056.2
90	1815.1	2116.4	

Figure 1. The distribution of insurance policies on the gross written premiums (Eur).

3. Results and comments

The estimated linear regression model is:

$$\text{Predicted Compensation} = -33.12 + 714.96 \times \text{Number of claims} + 0.19 \times \text{Premium}$$

both explanatory variables having statistically significant coefficients (p -value < 0.05) and overall the model is correctly specified, as $Significance F < 0.05$. The value of the Multiple R coefficient, 0.610, shows a coderately strong relation between the dependent and the predictor variables; only 37.2% of the total variation of the amount of compensations is explained by the variation of the gross written premiums and the number of claims.

Table 4 presents the estimates of the logistic regression model, as well as the p-values and the odds ratios, for the different sets of predictors.

Table 4. Estimates of the logistic regression model.

	B	Sig.	Exp(B)
Step 1 ^a			
Auto use age	-.144	.000	.866
Constant	1.258	.000	3.518

 e. Variable entered on step 5: Gender.

The final estimated model is

$$\begin{aligned} \text{Predicted logit of (no renew)} &= 0.871 \\ &- 0.012 \times \text{User age} - 0.168 \times \text{Auto use age} \\ &+ 0.079 \times \text{Gender} + 0.001 \times \text{Engine capacity} \\ &+ 0.000 \times \text{Insured value}. \end{aligned}$$

The variables ‘User age’ and ‘Auto use age’ are negatively correlated to ‘Renewal status of a casco insurance policy’, while the other variables (‘Gender’, ‘Engine capacity’, ‘Insured value’) are positively correlated to the dependent variable. If the policy holder is one year older, the odds ratio (OR) of achieving ‘not renewing’ decreased with 1.2% (= 100x(1 – 0.988)%), keeping constant all the other variables. For each year increase in the auto use age, the odds ratio of ‘not renewing’ declined with 15.5% (= 100x(1 – 0.845)%). Women are more likely not to buy a new insurance, the odds of this group being 1.083 times greater than the odds of men, one possible explanation being the fact that women drive carefully with respect to men, so they can spend the money needed to buy insurance on another direction of consumption. If the insured value of the automobile becomes 1000 Eur higher, then odds of ‘not purchasing’ the casco insurance policy will increase by 2.71 times, mainly due to the corresponding augmented premium.

The statistical significance of individual regression coefficients is tested using the Wald chi-square statistic. According to Table

4, all independent variables were significant predictors of ‘not renewing the Motor Hull insurance’. However, the estimated value of the parameter associated to ‘Insured value’ is quite close to 0, making its interpretation difficult. Nagelkerke R square coefficient of 0.35 indicated a moderately relationship between predictors and the prediction of grouping policy holder in the two classes of possible outcomes.

In this study, 94.7% insured were correctly classified for ‘not renewing’ and 9.8% for ‘renewing’ the voluntary vehicle insurance policy. Overall 65.9% of the policy holder were correctly classified. This is an improvement on the 55% correct classification with the constant model, so the proposed model with predictors is a significantly better model. Overall, the logistic model fits the data.

The Impact of the Global Financial Crisis on the Romanian Banking System

Dandara Daniela

Bucharest University of Economic Studies, PhD Student

daniela_dandara_25@yahoo.com

Abstract

Starting the year of 2007, global economies had to face a large financial crisis with direct effects on economic growth and welfare. The underestimating of risk caused large imbalances and at a later date a sovereign debt crisis.

The Romanian financial system and its component, the banking system, was as well affected. The economic recovery is directly linked to the revaluation of risk and ensuring a stable banking system. Macropudential policies have to consider the connections between the financial system and real economy.

An efficient supervision and regulation are eminent. Ensuring comfortable prudential levels of capital and liquidity may result in a more stable banking system, capable of facing external shocks and efficiently performing financial intermediation, conducting to a healthier financial system that will sustain economic growth.

Key-words: financial crisis, banking system, regulation, economy, subprime crediting

JEL classification: G21

1. Introduction

The economic and financial crisis with origins in the United States subprime lending along with sovereign debt crisis had a significant effect on economies worldwide. An interdependent global economy caused concerns about the financial crisis impact on the Romanian banking system. During 2012 the economic environment and international finance have become more tense, marked by the sovereign debt crisis and concerns about the quality of balance sheets and (re)financing banking systems, especially in

the euro area and representing a source of growing challenges and concerns for the financial stability Romania.

2. The definition of a financial crisis

Laeven and Valencia [1] characterise a systemic banking crisis as events in which a country's corporate and financial sectors experience a large number of defaults and financial institutions and corporations face great difficulties repaying contracts on time. As a result, non-performing loans increase sharply and all or most of the aggregate banking system capital is exhausted. This situation may be accompanied by depressed asset prices ... sharp increases in real interest rates, and a slowdown or reversal in capital flows. In some cases, the crisis is triggered by depositor runs on banks, though in most cases it is a general realization that systematically important financial institutions are in distress.

Bordo et. al. [2] define a banking crisis as a period of “financial stress resulting in the erosion of most or all of aggregate banking system capital”.

Reinhart and Rogoff [3] define a crisis to be “one of two types of events: (i) bank runs that lead to closure, merger or takeover by the public sector of one or more financial institutions, (ii) in the absence of runs, closure, merger, takeover or large scale government assistance of an important financial institution (or group of institutions) that marks the start of a string of similar outcomes for other financial institutions”.

Georgescu [4] considers that the current economic crisis has no single cause but is the result of a set of factors acting simultaneously, the perfect storm. Two important factors mentioned by the author are the accumulation of balance of payments imbalances in many countries and an increased volume of loans that were

excessive in relation to the dynamics of the real economy.

3. Review of causes

The *subprime* crediting was named after the debtor's risk profile and took off in the United States following the 2000 year but its origin can be found in the particularities of the banking system of about 15 – 20 years ago. A *subprime* credit is a type of mortgage that is normally made out to borrowers with lower credit ratings. The higher risk associated with the debtor will determine lending institutions to charge a higher interest rate on this type of mortgages than it does on conventional mortgages in order to compensate themselves for carrying more risk. Many of the *subprime* mortgages have had adjustable interest rates that increase at a certain period. The increase in demand of mortgages from clients with high risk profile was superior to the increase in the demand of mortgages from standard clients, as a result of specific demographic evolution, aggressive marketing and consumer orientation mainly towards crediting and consumption to the detriment of saving, as identified by Danila et. al. [5]. During the 2000 – 2005 years the real estate prices grew at an average of 9% per annum. Starting with 2006, the prices growth rate decreased and on some segments prices reduced but in the same time the interest rates on *subprime* mortgages increased. Many of the clients couldn't take another loan at a low interest rate to refinance the old one with an associated increased interest rate as the accepted loan warranty had reduced in value.

An important aspect of the *subprime* crediting is that the main concern of the lending institutions was not the level of risk but the way it could be transferred to other financial institutions through sophisticated financial instruments and a cost surcharge. The transfer of risk was facilitated by the fact that the financial institutions that first accepted high risk debtors had high ratings due to increased performance and high profits, their counterparties that were buying financial instruments derived from *subprime* mortgages couldn't ever directly evaluate the performance of the debtors of these loans and therefore the credit risk to which they were exposed.

These sophisticated financial instruments have been exported to Europe which had a high level of saving. Financial institutions throughout Europe started investing their surplus of financial resources into *subprime* derived instruments but with the highest rating. As documented by Acharya and Schnabl [6] and Bernanke et al. [7] European banks were major purchasers of these instruments. Mostly, these financial institutions also obtained dollar funding in the United States money markets as mentioned by Shin [8]. For this reason, the role of European banks in enabling the expansion of the United States *subprime* derived instruments did not jump out of the balance of payments data, although the implicit risk exposure of European parent banks grew in line with these United States activities.

4. The financial crisis effects on the Romanian banking crisis

The increased availability of liquidity in the international market was attracted by the high yields offered within the Romanian financial system (as an interest rate differential, while the central bank was required to maintain a relatively high interest rate to counter inflation).

The inflows from abroad were reflected in a stronger appreciation of the leu. This appreciation has become stronger after the full liberalization of the capital account in 2006. Thus, the course has reached levels that did not reflect economic fundamentals and inducted the illusion of wealth.

The access of the large financial groups have subsidiaries in Romania to money market cheap funds in the euro area has reduced tightening credit conditions applied by banks in Romania. This led to the duplication of government credit as a percentage of GDP between 2004 and 2007, 17% in 2004 compared to 36% in 2007 [9].

The financial intermediation in Romania was low and its development was predictable, but its increase between 2004 and 2007 was much faster than economic fundamentals allowed it. This became evident when the access to liquidity and low credit risk became transparent. The rapid lending growth resulted in external imbalances. The easy and rapid access to

these sources of income has increased the domestic demand that had to be met by imports, thereby increasing to unsustainable levels of current account deficit. Although inflation would have to notify the imbalance between supply and demand, this was not visible to the exchange rate appreciation has helped to keep inflation at a low level.

The net wealth of population grew rapidly until 2007, mainly due to tripling the value of non-financial assets [9]. This was spent on the rise in incomes and easy access to credit and also increased the risk in Romanian economy.

The loss of credibility in the Romanian economy due to unsustainable current account deficit made it necessary to resort on external financing. Adjusting economy dimensions financing possible to obtain led to economic contraction and therefore reduction of imports, and hence bringing the current account deficit to its normal limits. The economic downturn meant first the decline in consumption, which led to a decreasing demand for credit. Moreover, it led to lower domestic asset prices. The two developments were reflected in the decline in households' net wealth.

In combining the micro-and macro-prudential policies should be taken into account the so-called concept "fallacy of composition" it is considered that the financial system and within it the banking system is secure and stable in its entirety if each component, each bank, is safe and stable.

When adopting macro-prudential policies it is required to take into account the actual links between the financial system and the real economy. Any inconsistencies between the two major elements can be reconciled through a mix of policies to include on one hand the changes in the regulation and supervision of the financial sector and macroeconomic changes and to address imbalances in the financial sector.

The main risk that a commercial bank might incur is a credit default of its debtors. The significant increase in doubtful and outstanding loans from 2007 to 2010 shows that banks failed performing a fair estimation of credit risk.

Nonperforming loans, the dominant risk to financial stability, have continued to grow both both in volume and in rate (from 14.3 %

in December 2011 to 16.8% in the June 2012), but in with significantly lower growth rate compared to previous years (in 2011 the increase was 2.5% compared to 4% growth rate in 2010 and 5% growth rate in 2009). The sustainable evolution of the last year reflects, in part, the adjustments required by IFRS (recognition in the balance sheet of non-performing loans previously recorded in off-balance sheet accounts) and assessment of restructured loans in previous years.

Danila [10] identifies that the behavior of banks, as revealed by a non-performing loans analysis, seems to have been driven by the idea of economies of scale, meaning that the expansive growth of the volume of lending would have allowed the acceptance of losses from bad loans. Romanian financial institutions have expanded their activity taking a higher risk, not fully taking account of the particularities of the Romanian economy and with strategies and targets ranging mainly by volume (loans growth, number of customers, value of assets) and less on qualitative aspects (customer solvency, cash flow projection analysis, domestic and international economic environment).

Given the 81.2% share in total banking assets of foreign capital it is important to pay attention to the specific conditions faced by parent banks in their country of origin, requiring a careful risk assessment. In spite of the international financial pressure, the financing from parent-banks increased by 2% in June 2012 compared to June 2011 and as a result did not great liquidity problems for the Romanian financial institutions. The maturity structure of the resources received from parent-entities, shows that approximately 70% of them are long-term resources.

In the context of deleveraging measures adopted by major European banks, which are yet to be implemented, the parent banks' exposures in subsidiaries in Romania had a comfortable evolution, without affecting significantly crediting conditions. Assuming a mass withdrawal of foreign aid, analyzes and stress tests indicates good resistance of the Romanian banking system with challenges related to transforming resources from RON to EUR, sale of some assets and ensure lending to the real sector.

Regarding the situation of the Greek-owned banks, these credit institutions can

withstand a liquidity shock relatively well due to appropriate capital and liquidity ratios that meet prudential risk requirements [9].

Despite the positive developments observed at the macroeconomic level, the Romanian banking sector recorded a deterioration in financial results as at 31 December 2011, considered to be negative negative as in the previous year. The aggregated financial result recorded a loss of RON 777.3 million in 2011 and RON 192 million in the first half of 2012. In general, positive financial results were obtained by large financial institutions that have costs associated with relatively low credit risk and improved operational profitability. Operating income showed a negative dynamic throughout 2011 and the first half of 2012, driven by adverse developments net interest income. Provisioning costs have continued to be in 2011 and the first part of 2012 the largest expenditure category of credit institutions.

At an aggregated level, financial institutions are capable to withstand the macro level shocks. However, there are a small number of credit institutions with increasing vulnerabilities shown in reduced net interest income as a result of higher financing costs (increase capital requirements that made long-term financing more expensive) and increased lower provisioning as a result of the deterioration of the market value of collaterals and an overall loan portfolio quality deterioration. In an adverse scenario characterized by a strong depreciation of the national currency and recession, the decrease of the solvency ratio of the Romanian banking system is estimated to be about 2.4% giving a solvency ratio of 12.3% [9]. This is a comfortable level, still above the required solvency ratio of 8% according to the implemented banking regulation.

As the Romanian banking system is well capitalized and it proved being capable to respond to external shocks, a stable evolution could be expected, yet it is needed to carefully monitor international and domestic developments and ensure the maintenance of adequate liquidity levels in the system, aiming at the same time at maintaining adequate levels of provisioning and solvency.

5. Conclusions

The 2007 economic and financial crisis with origins along with sovereign debt crisis had a significant effect on economies worldwide. The current economic crisis has no single cause but is the result of a set of factors: the overall volume of loans that was excessive in relation to the dynamics of the real economy - massive phenomenon achieved by relaxing the standards of creditworthiness of borrowers, the appearance of some imbalances of the balance of payments – the increasing level of wages was not caused by an increase in the productivity of labor.

The financial crisis had its trigger in the subprime crediting in the United States. Derivative financial instruments based on subprime mortgages were sold to largest financial institutions worldwide as such facilitating the propagation of a credit risk that the owners of these sophisticated instruments could not evaluate or measure. The Romanian financial system did not have such exposures but had been affected by the 2007 global crisis through the channel of real economy. The main characteristics of our financial system before the start of the crisis was the easy loans given to population and high consumption. As a result one of the main concern of the banking supervision authority was to monitor the quality of the financial institutions loan portfolios. Another concern was the foreign capital exposure that could result in massive withdrawals from parent-entities from the Romanian subsidiaries to their home countries in order to solve eventual capital and liquidity problems in their home countries.

Although the volume of doubtful and outstanding loans has increased during the past years, the level of provisions is comfortable due to the implementation of increased requirements. The parent-entities continue to maintain their exposures on the Romanian banking system, foreign financing consisting mostly of long term resources. Due to increased capital and liquidity requirements, the Romanian banking system continues to have an adequate level of the prudential indicators.

Accounting Normalisation Instruments and Sources

Dima Florin-Constantin

“Constantin Brâncoveanu” University of Pitești
dimaflorin_constantin@yahoo.com

Abstract:

The current economic crisis that troubles the world economy makes the harmonisation of the accounting rules more necessary than ever before. Therefore, in our approach we have attempted to capture the main aspects of accounting normalisation instruments, as well as the main sources of accounting normalisation.

Keywords: normalisation, harmonisation, accounting rule, normalisation instruments, normalisation sources

J.E.L. classification: M41

information drawn from the financial statements. In other words, harmonisation aims at reducing the disparities between the accounting regulations of various states.

The source of accounting normalisation represents the set of terms and instruments that an accounting normalisation or regulatory body recommends to or requires from those exercising the accounting profession and who may be familiar with their beneficiaries.

The accounting normalisation instruments are the object of accounting harmonisation and they are known as regulatory instruments.

2. Accounting normalisation instruments

An important issue of accounting normalisation is the normalising concept. Depending on it, the normalisation object is defined. From this point of view we distinguish two concepts: one based on the general accounting plan, the other based on the conceptual accounting framework.

The concept based on the general accounting plan is particular to a part of continental European countries, its promoter being France. The beginning of this concept was based on the absence or diversity of rules and regulations for registration and submission of financial statements and its purpose is the adoption of accounting principles and rules, general chart of accounts, registration procedures, as well as the form and format of financial statements.

Although in a more modern view, the general accounting plan, as a whole, is in itself a rule, there have been pros and cons regarding a normalisation based on a normative theory that will include the objectives of accounting and of accounting normalisation, as well as the accounting information users and their needs.

The general accounting plan, as a means of accounting normalisation, may be recommended

1. Introduction

Nowadays accounting is more or less the universal language of business. For this to have the same meaning all over the world it is necessary for accounting normalisation to use similar accounting rules worldwide.

Accounting normalisation is the process which has at its core the elaboration of accounting rules. The accounting rule is a rule or a set of rules that constitute themselves as a reference system for drafting the financial statements.

To meet the goal of becoming the universal language of business widely accepted, accounting must go through an extensive and difficult process of harmonising the accounting rules and the normalisation instruments. In this respect, an important role is played by the sources and instruments of accounting normalisation, but also by the accounting normalisation bodies.

International accounting harmonisation is the process aimed at improving and reducing the differences between the national accounting practices and regulations. The harmonisation process aims at developing general principles and accounting rules, leading to the comparability of the

or required, depending on the type of accounting normalisation. This differentiates regarding the characteristics and components from one country to another depending on the concept adopted for the accounting organisation (monist or dualist), on the objectives of normalisation, determined in their turn by the supply and demand of accounting information, by the culture and accounting traditions of the respective country and by other factors.

Regardless of the characteristics, in order for a general accounting plan to meet its goals of accounting theory or doctrine, it must have an appropriate content, which is essentially given by the following components [1]:

- a set of accounting principles and rules;
- a list of accounts and rules for their use;
- an accounting vocabulary (accounting terminology);
- methods and procedures for organising accounting;
- components of the annual financial statements, including their form and format;

In a twofold analysis, of conceptual framework and instrument of national accounting normalisation, the question arises regarding to what extent it has a correspondent within the conceptual accounting framework, on the one hand, and in the international accounting standards, on the other hand.

Seen in terms of a country's economy, we believe that the general accounting plan can be regarded as a national accounting conceptual framework.

The general conceptual framework, and here we refer only to the one developed by the IASB, is an instrument of accounting normalisation including fundamental concepts and principles underlying the preparation and presentation of financial statements for external users. The general conceptual framework is a reference system for the elaboration of accounting standards and a consistency instrument of the accounting standards, regulations and procedures.

The general conceptual framework developed by the IASB is not an international accounting standard; it does not define the standards on the assessment or presentation of the information in the

financial statements and it does not prevail over the specific international accounting standards.

In the situation in which there are cases of conflicts between the provisions of the General conceptual framework and the provisions of IFRS, the requirements within the Standard prevail over those from the General conceptual framework.

The general conceptual framework elaborated by the IASB addresses the following [2]:

- the objective of the financial reporting;
- the qualitative characteristics of the useful financial information;
- definition, recognition and assessment of the structures based on which the financial statements are prepared;
- The concepts of capital and of capital maintenance.

The aim of the General conceptual framework is:

- to assist the Board in developing new IFRSs and review the existing IFRSs;
- to assist the Board in promoting harmonisation of regulations, of accounting standards and of procedures for the representation of the financial statements by providing a basis for reducing the number of the alternatives of accounting treatments allowed by the IFRSs;
- to assist the normalisation bodies in developing national standards;
- to assist those who prepare the financial statements in applying the IFRSs and in dealing with issues that are not yet the object of an IFRS;
- to assist auditors in forming an opinion on the compliance of the financial statements with the IFRS;
- to assist the users of the financial statements in interpreting the information contained in the financial statements prepared in compliance with the IFRSs;
- to provide those interested in the IASB activity information on the approach related to formulating the IFRSs;

3. Accounting normalisation sources

Regarded in terms of scope, the accounting normalisation sources can be analysed on three levels: international, regional and national.

At international level, accounting normalisation is required by a number of factors of which the most important ones are represented by the phenomena of globalization and financialisation of savings.

The instrument for performing the accounting normalisation at this level is represented by the International Financial Reporting Standards issued by the International Accounting Standards Board.

The International Accounting Standards Board has developed a body of international accounting rules that can be structured as follows:

- General Conceptual Framework;
- Proper rules which are currently differentiated into:
 - International Accounting Standards (IAS)
 - International Financial Reporting Standards (IFRS)
- Interpretations of the rules and namely
 - Interpretations of the International Accounting Standards (IAS)
 - Interpretations given by the International Financial Reporting Committee (IFRIC)

The International Accounting Standards Board (IASB) is a body specialised in developing accounting rules, but which does not have any attribution regarding the enforcement of the rules elaborated by it and it neither has coercive means to enforce these rules.

Regionally, normalisation is a development of the accounting normalisation dimension at the level of groups of countries, driven by their economic, financial and social objectives. The most illustrative case is the one of accounting normalisation at EU level performed through the European accounting directives.

At EU level accounting normalisation is performed by the European Commission which has developed and changed over time the accounting directives, but also other regulations in the field of accounting. Accounting

normalisation in the European Union is mainly represented by the two accounting directives:

- Fourth Directive, which refers to the structure, content and presentation of the financial statements;
- Seventh Directive which refers to the consolidated accounts.

The European Commission performs accounting normalisation at EU level through the following two organisations: Accounting Regulatory Committee (ARC) and the European Financial Reporting Advisory Group (EFRAG).

Besides the European Union accounting normalisation has to be analysed also at the U.S. level because the regulatory setter in this country has a strong influence on the international accounting standards elaborated by the international regulatory setter.

In the U.S. there are three bodies which contribute to setting the means for establishing and publishing the financial statements:

- Securities and Exchange Commission (SEC): represents the committee that regulates the stock market;
- Financial Accounting Standards Board (FASB): represents the independent body making accounting rules, which is the main source and authority of the accounting doctrine, being recognised as such by the SEC. FASB publishes Statements of Financial Accounting Standards (FAS) and their interpretations.
- American Institute of Chartered Public Accountants (AICPA): represents the highest American authority in the accounting field. AICPA publishes General Accepted Accounting Principles (GAAP), which represent the generally accepted standards in accounting, as well as a professional code of ethics. The accounting standards are developed under FASB, in cooperation with SEC and the AICPA members, within a laborious process, after which they are promulgated as GAAPs.

The main dimension of accounting normalisation is manifested nationally. In Romania it is performed, for the time being, through the normalisation instrument represented by the general accounting plan.

Accounting normalisation in Romania is state-like and it is administered by the government through the Ministry of Finance.

4. Conclusions

International accounting normalisation and harmonisation represent a necessary and complex process, but hard to accomplish. It is likely that when the standards developed by the IASB gain supremacy in the battle between them and those developed by the FASB, in particular, but also with those developed by national regulatory setters, the general conceptual framework remains the main instrument of accounting normalisation or even the only one. In such a sense, IASB would practically produce the accounting rules, and the other regulatory setters would implement them.

Measurement and Evaluation in Financial Accounting

Dima Florin-Constantin

“Constantin Brâncoveanu” University of Pitești
dimaflorin_constantin@yahoo.com

Abstract:

The paper aims to identify and analyze the fundamentals, the principles, the criteria and the evaluation bases used in preparing the financial statements. The paper also captures moments of evaluation and the evaluation of the structures in the financial statements according to their origin.

The approach is important because the accuracy of the information in the financial statements largely depends on the evaluation of the elements contained in the structure of the financial statements.

Keywords: evaluation, historical cost, fair value, utility value, realizable value.

J.E.L. classification: M41

1. Introduction

In contemporary society accounting can not be conceived without evaluation. The term of value is a very subjective one which, generally, is the result of a monetary expression applicable to a specific asset, to a group of assets, to some rendered services or to an entity.

In economics the term comes from the depths of their historical value, but in accounting the term has a later and shy appearance. The term should not be confused with the cost, although, frequently, it is measured by it.

In accounting, the value is expressed in monetary units to conduct current records and centralize and generate data, which requires evaluation as a process of the accounting method.

Evaluation consists in quantifying and measuring the value expression of the material means, claims, liabilities, costs, revenues, financial results and of each economic operation using the monetary units to express value.

In terms of accounting, the term of value is closely related to the cost and price. One can say this on the assumption that the price observed during a transaction in a market is an expression of value or, conversely, that the value of an asset is based on its price.

In terms of cost, this is the financial effort measured by the price paid to acquire or produce goods and services.

2. Principles of evaluation in accounting

If the evaluation needs to provide a picture closer to the reality of the entity's financial position and performance, the elements presented in the annual financial statements are evaluated, as a rule, based on the cost of acquisition or production cost.

The evaluation of the elements in the structures of the statements is subject to the principles of evaluation:

- the principle of historical cost: requires registration in accounting of the elements at the cost of input recorded in the documents;
- the principle of prudence: envisages that the evaluation of the elements should always be made on a prudent basis, meaning that:
 - only the profit registered at the date of the balance sheet may be included in the result of the exercise;
 - one must take into account all debts incurred during the current financial year or a previous year, even if they become apparent only between the date of the balance sheet and the date when it was set up;
 - one must take into account all foreseeable debts and potential losses arising in the current financial year or of a previous financial year, even if they become obvious only between the date of

the balance sheet and the date when it was set up;

- one must take into account all depreciation, whether the result of the financial year is a loss or profit.
- the principle of continuity: states that it must presume that the entity operates on the principle of continuity. This principle implies that the entity normally continues its operation, without going into liquidation or significant reduction of activity. If the administrators of an entity are aware of some elements of uncertainty related to certain events that can lead to inability to continue its activity, these elements should be presented in the explaining notes. If the annual financial statements are not prepared on the principle of continuity, this information must be submitted together with an explanation of how to prepare them and the reasons behind the decision that the entity can no longer continue its activity.
- the principle of consistency: takes into consideration the fact that the methods of evaluation must be consistently applied from one financial year to another;
- the principle of separate evaluation of the elements of assets and liabilities: according to its components of the assets and liabilities must be valued separately.

Starting from the evaluation principles, in the theory and the practice of accounting the following criteria have emerged regarding the evaluation of assets, liabilities, expenses and income [1]:

- utility value;
- fair value;
- market value;
- time.

The utility value represents the “cost” or “sacrifice” agreed to acquire a certain asset or what it could bring it if it was used in the entity or sold on the market. In the case of debts, the utility value represents the amounts accepted to be paid in the account of the obligations.

The fair value is the amount at which an asset can be traded or a liability can be settled between the parties concerned in a

transaction developed in objective conditions.

The market value is the estimated amount for which an asset could be exchanged between a seller and a buyer, both committed and knowledgeable when none of them works by force.

In terms of time, it regards the moment of placing the evaluation in the past, present or future.

3. Evaluation bases

Starting from the evaluation criteria, the literature and empirical research have found the following measurement bases:

- historical cost;
- current cost;
- realizable value (of settlement);
- updated value.

The historical cost represents the real value of the entry of assets and debts, a value recorded in the documents. The elements of the assets are recorded at the amount of cash or paid cash equivalents or the fair value of the service provided to acquire them at the time of the purchase. The liabilities are recorded at the value of the cash obtained in exchange of the obligation or the amount expected to be paid in cash or the cash equivalents to end liabilities during the normal course of the business.

The current cost is the cost or the sacrifice that the entity agrees to acquire, at the level of the actual value, an asset similar to the defined one as an object of evaluation.

In the case of assets, it represents the cash or the cash equivalents that should be paid for the same asset or for a similar product if it was purchased or produced in the present. The current cost of debts is the outdated sum of cash or cash equivalents currently required to end the obligation.

The realizable value (of settlement) represents the amount that the entity would currently receive if they sell an asset or would give it in case of paying the debts. The assets are recorded at the amount of cash or cash equivalents that could currently be obtained by normally selling them. Debts are registered at their settlement value, i.e. the outdated amounts of cash or cash equivalents expected to be paid to settle liabilities in the normal course of the business.

The updated value can be presented, in a plastic way, as a present value determined by the future. Thus, the assets are recorded at the present value of the future net cash inflows to be generated in the normal course of the business and the liabilities are recorded at the present value of the future net cash outflows to be required to settle the liabilities in the normal course of the activity.

The most common evaluation basis used by entities in preparing the financial statements is the historical cost.

4. General evaluation rules

Depending on its timing and purpose we can identify the following moments of evaluation:

- evaluation at the entry in the entity;
- evaluation during the inventory;
- evaluation at the end of the financial year;
- evaluation on leaving the entity.

At the date of the entry into entity, the assets are evaluated and recorded in accounting at their input value, also known as accounting entry value, which can be represented:

- for the goods purchased against payment, the cost of acquisition;
- for the goods produced within the entity, the cost of production;
- for the assets contributed to the share capital, the share value;
- for the assets obtained free of charge, the fair value.

The acquisition cost of the goods purchased against payment includes the purchase price, the import duties and other taxes that can not be recuperated, transportation and other costs directly attributable to the acquisition of the respective goods, of which commercial discounts granted by the provider should be deducted.

The production cost of an asset comprises the purchase cost of raw materials and consumables, the other direct production costs and a reasonable proportion of indirect costs that are attributable to the asset, to the extent that they relate to achieving the asset and the period in which it is accomplished. A number of such expenses like the ones of general administration, sales and financial

costs usually are not usually included in the cost of production.

The input value of the assets contributing to the social capital is determined after the evaluation by licensed evaluators and it represents their value registered in accounting.

In the case of the goods obtained for free, the fair value is the amount for which that asset could be exchanged freely between the parties involved in a transaction with the price objectively determined on an active market.

Inventory evaluation is made at present value also called the value of inventory.

The present value is determined by the utility of the asset in the entity's economy and by the market price. The utility value of the assets and the liabilities is determined by their expected value, receivable or payable, determined according to the terms of the contract. The need to evaluate the assets and liabilities at their inventory value is based on the reality that the input value based on the original cost has only historical value. Any significant change, after the entry, of the real value of goods tends to make the original cost become misleading in the decision making process.

At the end of the financial year, the assets and the debts are evaluated and reflected in the annual financial statements at the input value reconciled with the inventory results.

In these conditions, for the asset elements, the differences going upwards between the inventory value and the accounting value is not registered in accounting, and the differences going downwards on account of additional depreciation, in the case of depreciable assets for which depreciation is irreversible or an adjustment for depreciation or loss of value is reversible, these elements maintaining also their input value.

For elements of liabilities, the minus differences between the inventory value and the accounting value are not registered in accounting, and the surplus differences are registered in accounting based on the corresponding elements of debts.

At the time of leaving the entity or going for consumption, the goods are evaluated and deducted from the inventory at their input value.

From another approach, the forms of evaluation presented above may be grouped as follows [2]:

- the current evaluation, it includes the evaluation at the input and the output of the entity;
- the periodic evaluation, it includes the evaluation at inventory and evaluation at the end of the financial year, as well as revaluations.

5. Conclusions

The evaluation of the elements in the structures of the financial statements has a significant importance so that the image generated by the financial statements can be true and accurate.

However, none of the evaluation bases has general applicability and is not absolutely satisfying, hence a matter of choice. You also need mention that, although fair value is not among the bases of evaluation, it began to be used more frequently and on a larger scale in recent years as an alternative evaluation for the historical cost.

edobre2010@gmail.com

Abstract

Nowadays, even if financial instruments have a bad reputation in the context of financial crisis, they represented a way to control risks. So, we can't ignore it especially because now, attention is played on innovative signals. Advantage for derivatives is the value changes in response to changes in a underlying, little or no initial investment is required, and settlement takes place at a future date. Weather derivatives can be used by organizations or individuals as part of a risk management risk management strategy to reduce risk associated with adverse or unexpected weather conditions. This paper explains the mechanism of such a derivatives use to the hedging of weather risks. The research methodology is the past experience and case study research cause its importance in the field of business and risk management. Results would be useful to managers in agriculture, tourism or assurance industry, and also to finance programs students.

Cuvinte cheie: financial instruments, derivatives, hedging, weather derivatives,
Clasificare J.E.L.: G32

Introduction

After years of intense economic downturn, we still find ourselves in a world of a relative uncertainty where most of our corporate leaders are focused on measures to alleviate the effects of crisis and to ensure the survival entities. Nowadays, attention is played on innovative signals and financial instruments have a good and in the same time, a bad reputation in this field, so, we can't ignore it. A major early pioneer in

weather derivatives was Enron Corporation, through its Enron Online unit. Nevertheless, financial instruments economic utility was proved. Financial instruments generally denote any form of funding medium - mostly those used for borrowing in money markets, e. g. bills of exchange, bonds, stock exchange, etc. Advantage for derivatives is the value changes in response to changes in a underlying, little or no initial investment is required, and settlement takes place at a future date. For this reasons, we believe that a new approach utilization of financial instrument would be useful for Romanian economic and financial environment. This new approach may be knowledge of past experience and adapting at specific local conditions. In this sense, we find an adequate research methodology the past experience and case study research. The case study research is too important in the field of business and management studies to be left to the hazard approaches [6]. The interim and final results of this study would be useful to managers in agriculture, tourism or assurance industry, and also we really hope to finance programs students.

Financial Instruments and Risk Management

In economics, as an problem is uncovered, financial solutions appear. So, in finance we have always changes and challenges. Rightfully, they are called *innovative*. For example, as firms trade more and more internationally, the need to protect sales against undesirable currency fluctuations becomes increasingly important. To deal this problem, currency options were developed [5]. In response to the volatile interest rates, commodity prices, and exchanges rates of the late of the late of

1970s and early 1980s financial managers turned to the futures and options markets for relief. This new financial instruments provided corporations with a low-cost means of hedging away many types of risks associated with possible price fluctuations [5]. Using derivatives like hedging financial instrument are based on managers risks concerning [3]. The cross border companies face risks day by day operating in different economic environments. By result, they should ensure the market risks and maximize cash-flows and stock market value [3]. The point is determining investment goals. To develop own road map for financial success, we need to know what our assets and liabilities are: how much money available to work? how much risk can take with how much money? what debts or moral obligations we have?[4]. Financial instruments can be a very risky good investment. We can categorize them by form: cash instruments or derivative. Cash instruments are financial instruments whose value is determined directly by markets. They can be divided into securities, which are readily transferable, and other *cash* instruments such as loans and deposits, where both borrower and lender have to agree on a transfer. Derivatives instruments are financial instruments which derive their value from some other financial instrument or variable. They can be divided into exchange-traded derivatives and over the counter derivatives. Alternatively, financial instruments can be categorized by "asset class" depending on whether they are equity based (reflecting ownership of the issuing entity) or debt based (reflecting a loan the investor has made to the issuing entity). If it is debt, it can be further categorized into short term (less than one year) or long term. Foreign Exchange instruments and transactions are neither debt nor equity based and belong in their own category. In accordance with International Financial Reporting Standards -IAS 32, IAS 39, IFRS 7 and IFRS 9 [10], a financial instrument is any contract that gives rise to both a financial asset of one entity and a financial liability or equity instrument of another entity. A financial asset is cash, a contractual right to receive cash or another financial asset from another entity, a contractual right to exchange financial instruments with another

entity on term that are potentially favourable, or an equity instrument of another entity. A financial liability is an obligation to deliver cash or another financial asset or obligation to exchange financial instruments with another entity on terms that are potentially unfavourable. An equity instrument is any contract that evidences a residual interest in the assets of an entity after deducting all of its liabilities. According IAS 39 the categories of financial assets are follows: (i) Originated Loans and Receivables; (ii) Held-to-maturity investments; (iii) Available for sale financial assets; (iv) Financial assets held for trading. A derivative is a financial instrument or other contract, for which: (i) The value changes in response to changes in a underlying interest rate, exchange rate, commodity price, security price or credit rating, and so on; (ii) Little or no initial investment is required; (iv) Settlement takes place at a future date. Common examples of financial instruments include: a) Cash. b) Commercial paper; c) Demand and time deposits; d) Accounts, notes, and loans receivable and payable; e) Debt and equity securities. These are financial instruments from the perspectives of both the holder and the issuer. This category includes investments in subsidiaries, associate and joint ventures; f) Asset backed securities such as collateralized mortgage obligation, repurchase agreements, and securities packages of receivables; g) Derivatives financial instruments, including options, rights, warrants, futures contracts, futures and forward, interest rate swaps and currency swaps; h) Leases; i) Rights and obligations with insurance risk under insurance contract; j) Employers' rights and obligations under pension contracts. Hedge accounting rules include fair value hedge, cash-flow hedge and hedge of net investment in foreign entity [7]. Hedging relations, hedging items and hedged items makes the content of hedging accounting [2]. There are many types of hedging and many patterns of hedging accounting in American firms experience: rolling hedging, imperfect hedging, economics hedging, portfolios hedging [2]. Hedging efficiency recommended is between 80-125% (according paragraph 146 IAS 39) but the assessment method it's up to risk management strategy of each firm. However,

firms risks to be in a under hedged or in a over hedged situation.

How Works the Hedging by a Derivative?

Hedging, insuring and diversifying is an real concerning in corporate finance. These are tree ways of transferring risk to others. We hedge a risk when reducing one's exposure to a loss entails giving up the possibility of a gain [1]. Thus, farmers who sell their future crops at a fixed price in order to eliminate the risk of a low price at the harvest time give up the possibility of profiting from higher prices is option and below we present their basics [at the harvest time. A financial instrument used in hedging 12]. *Buying a put option* means the payoffs and profits are generated by a *put* option as seen by the *buyer* of the option. A lower stock price means a higher profit. Eventually, the price of the underlying security will be low enough to fully compensate for the price of the option. *Writing a put option* means the payoffs and profits are generated by a *put* option as seen by the *writer* of the option. Profit is maximized when the price of the underlying security exceeds the strike price, because the option expires worthless and the writer keeps the premium. To buy a Put means the buyer thinks price of a stock will decrease. Pay a premium which buyer will never get back. The buyer has the right to sell the stock at strike price. To write a Put means the writer receives a premium. If buyer exercises the option, writer will buy the stock at strike price. If buyer does not exercise the option, writer's profit is premium. A *put option* is a financial contract between two parties, the seller and the writer (buyer) of the option. The put allows the seller the *right but not the obligation* to sell a commodity or financial instrument (the underlying instrument) to the writer (buyer) of the option at a certain time for a certain price (the strike price). The writer (buyer) has the obligation to purchase the underlying asset at that strike price, if the seller exercises the option. In the case of weather derivatives, the underlying instrument is weather with heating degrees or cooling degrees. *Buying a call option* means the payoffs and profits generated by a *call* option from the *buyer*'s perspective. The higher the stock price the higher the profit. Eventually, the price of the

underlying security would become high enough to fully compensate for the price of the option. *Writing a call option* means the payoffs and profits generated by a *call* option from the *writer*'s perspective of the option. Profit is maximized when the strike price exceeds the price of the underlying security, because the option expires worthless and the writer keeps the premium. To buy a Call means the buyer expects that the price may go up. The buyer pays a premium that he will never get back. He has the right to exercise the option at the strike price. To write a Call means the writer receives the premium. If the buyer decides to exercise the option, then the writer has to sell the stock at the strike price. If the buyer does not exercise the option, then the writer profits the premium. A *call option* is a financial contract between two parties, the buyer and the seller of this type of option. The buyer of the option has the *right, but not the obligation* to buy an agreed quantity of a particular commodity or financial instrument (the underlying instrument) from the seller of the option at a certain time (the expiration date) for a certain price (the strike price). The seller (or "writer") is obligated to sell the commodity or financial instrument should the buyer so decide. The buyer pays a fee (called a premium) for this right. In the case of weather derivatives, the underlying instrument is weather with heating degrees or cooling degrees.

Innovative Financial Instruments-Weather Derivatives

Weather derivatives are financial instruments that can be used by organizations or individuals as part of a risk management strategy to reduce risk associated with adverse or unexpected weather conditions [12]. The difference from other derivatives is that the underlying asset (rain, temperature, snow) has no direct value to price the weather derivative. Farmers can use weather derivatives to hedge against poor harvests caused by drought or frost; theme parks may want to insure against rainy weekends during peak summer seasons; and gas and power companies may use *heating degree days* (HDD) or *cooling degree days* (CDD) contracts to smooth earnings.

The term *hedge* is derived from the phrase "*hedging your bets*" used in gambling games such as roulette. The term gradually moved into common usage within English-speaking cultures and today covers a broad range of risk-reduction activities or conditions. For such activities, weather is the most important because their specific elements or because many locations are in open space, in plain air. For example, *amusement park* is the generic term for entertainment attractions assembled for the purpose of entertaining a large group of people. An amusement park is more elaborate than a simple city park or playground, usually providing attractions meant to cater to adults and teenagers. A theme park is a type of amusement park which has been built around one or more themes, such as an American West theme, or Atlantis. Amusement parks evolved in Europe from fairs and pleasure gardens which were created for people's recreations. The oldest amusement park of the world (opened 1583) is Bakken, at Klampenborg, north of Copenhagen, Denmark [11]. Heating degree days (HDD) are one of the most innovative types of weather derivative in United States of America experience. Typical terms for an HDD contract could be: for the November to March period, for each day where the temperature falls below 18 degrees Celsius keep a cumulative count of the difference between 18 degrees and the average daily temperature. Depending upon whether the option is a put option or a call option, pay out a set amount per heating degree day that the actual count differs from the strike.

Heating degree day (HDD) and cooling degree day (CDD) are quantitative indices designed to reflect the demand for energy needed to heat or cool a home or business. These indices are derived from daily temperature observations, and the heating (or cooling) requirements for a given structure at a specific location are considered to be directly proportional to the number of heating degree days at that location. More specifically, the number of heating degrees in a day is defined as the difference between a reference value of 65°F (18°C) and the average outside temperature for that day. The value of 65°F is taken as a reference point because experience shows that if the outside temperature is this value then no heating or

cooling is normally required. Occupants and equipment within a building usually add enough heat to bring the temperature up to a more comfortable level. Suppose, for example, that the average temperature for a given day is 55°F. Since this value is ten degrees lower than the reference point of 65 °F then one would say this is a ten degree-day. The outside temperature is not always constant, so one needs a method to determine the average temperature. Heating and cooling degree days can be added over periods of time to provide a rough estimate of seasonal heating and cooling requirements. In the course of a year, for example, the number of heating degree-days for New York City is around 5000 whereas that for Barrow, Alaska is over 20,000. Thus, one can say that, for a given home of similar structure and insulation, four times the energy would be required to heat that home in Barrow than in New York. The degree-day system has several problems. Heat requirements are not linear with temperature, and heavily insulated buildings have a lower "balance point". Some will need heating in temperatures above 65°F, but others will not need any heating until the temperature is much lower. Solar gain reduces the need for heating on sunny days (but not cloudy days), and wind increases it (by an amount that depends on how tightly the building is constructed). People also differ in their opinions about what constitutes a comfortable indoor temperature.

Weather Derivatives Utilization

The first weather derivative deal was in July 1996 in United States of America [11], when Aquila Energy structured a dual-commodity hedge for Consolidated Edison Co. The transaction involved Consolidated Edison's purchase of electric power from Aquila for the month of August. The price of the power was agreed to, but a weather clause was embedded into the contract. This clause stipulated that Aquila would pay to Consolidated Edison a rebate if August turned out to be cooler than expected. The measurement of this was referenced to Cooling Degree Days (CDD) measured at New York City's Central Park weather station. If total CDDs were from 0 to 10% below the expected 320, the company

received no discount to the power price, but if total CDDs were 11 to 20% below normal, Consolidated Edison would receive a \$16,000 discount. Other discounted levels were worked in for even greater departures from normal. After that humble beginning, weather derivatives slowly began trading over-the-counter in 1997. As the market for these products grew, the Chicago Mercantile Exchange (CME) introduced the first exchange-traded weather futures contracts (and corresponding options), in 1999 [11]. The CME currently trades weather derivative contracts for 18 cities in the United States, nine in Europe, six in Canada and two in Japan. A major early pioneer in weather derivatives was Enron Corporation, through its Enron Online unit [11]. Investment bank UBS-AG, a financial services company, headquartered in Switzerland, was trying (before actual financial crisis) to change weather investing by launching the first Global Warming Index (GWI), which provides a simple way to take a view on a wide range of weather variables [13]. While initially linked to the temperature of several US cities, there were plans to add European and Asian ones soon. In fact, as UBS notes, there is no limit in principle to the number of cities to be included as references. In this sense, the UBS index would truly capture global phenomena in one stroke. Thanks to this pioneering development, it is now possible to bet on whether Global Warming is true or false. If people believe the direst predictions will hold true and a persistent upward trend in global (or, at least for now, US) temperatures will become the norm, an investor would buy the Index (which goes up with the underlying temperature). If people think that is an alarmist sensationalist roomer, the same investor would sell the Index. Another innovative securities based on weather is *weather bill*- an electronic commerce website launched in January 2007 [8] that allows companies to buy contracts based on future weather events as a hedge against weather-based business risks.

The data information disclosures by the company are follows:

Table 1. Characteristics of company WeatherBill, Inc

Type of capital company	Private
Founded	2006

Founder	David Friedberg
Headquarters	San Francisco, California, USA
Key people	David Friedberg, Founder; Siraj Khaliq, Founder
Industry	Financial services
Slogan	Weather is unpredictable. Your bottom line doesn't have to be.

Source: www.weatherbill.com

Another example, Tech Crunch [9] mentions golf course owners may buy a contract by which they will receive \$1,000 per day of rain, thereby shielding the course against losses due to bad weather. Tech Crunch sells image advertisements for US \$ 10,000 per month with a minimum purchase of 2 months. The company also markets contracts to commodity traders, who may use them to hedge investments they have made in future crops or other goods whose value is affected by the weather. Weather Bill's pricing is based on weather statistics and computer modeling of future weather forecasts and trends. One of the company's early clients is an Arizona ski resort that uses Weather Bill to hedge against losses from a refund it offers season ticket holders should there be inadequate snowfall during the season. According to the company's website, United States contracts are legal and regulated by the Commodity Futures Trading Commission. Due to limitations imposed by the Commodity Exchange Act, contracts in the United States are only sold to buyers who meet certain eligibility requirements. As of October 17, 2007 the company also offered contracts in the United Kingdom, Germany, Netherlands, Spain, and Norway [8].

Conclusions

In finance we have always changes and challenges. The inventive capacity in the field of financial instruments was more and more increasing before actual crisis. At the moment of downturn, we need to turn of the risk in opportunity. But for this, every investor and every company using these new derivatives would know the general concepts and mechanisms of financial instruments, and particularly, concepts and mechanisms of derivatives. Nowadays, these new derivatives

may become a real instrument for companies or individuals to hedge against the physical risks (temperature, rain, snow, tornados or earthquakes) or financial risks (price, liquidity or counterparty). On the other hand, everybody knows that securities took a bad reputation after 2007 when financial crisis arise. Now, the optimistic scenario is to use newer and newer hedging financial instruments to save and create new opportunities. For Romanian economy, such sensitive hedging instruments would be use in agriculture, tourism and assurance industry. Anyway, financial instruments remain ever innovative in a risk environment.

Abstract

The purpose of this paper is to present the perspectives of using XBRL (eXtensible Business Reporting Language) as a tool for financial auditors considering the increasing coverage of this language for financial reporting.

We performed an extensive literature review concerning XBRL utilisation in Europe and in the US and identified several key areas where this technology may be extended in order to facilitate the planning phase of a financial audit. We propose adding several XML tags to the standard taxonomies that would include information which is useful for auditors. This information may be account-specific (such as significant risks affecting an account or classes of transactions affecting the account) or may relate to the audited entity as a whole.

Our conclusion is that XBRL may be successfully extended in order to contain data that may aid auditors in the planning phase of their engagements.

Key words: XBRL, financial audit, risk based approach.

J.E.L Classification: M41, M40

1. Introduction

XBRL (eXtensible Business Reporting Language) is an extension of XML (eXtensible Markup Language) which was developed with the purpose of providing a common method for presenting, transferring

and analysing financial reporting data on the internet. [1]

Its history starts in 1998 when Charles Hoffman proposed to the AICPA (American Institute of Certified Public Accountants) to create a team that would study the possibility of using XML for structuring financial reporting information [2]. The first version of XBRL was launched in 2000, containing around 1900 financial reporting items as per the US GAAP (Generally Accepted Accounting Principles). Since then, several milestones in the development of XBRL were reached, including [3]:

- fully aligning the XBRL standard to the format recommended by W3C (World Wide Web Consortium), which is the organisation in charge of supervising the evolution of XML - 2001;
- the Shanghai Stock Exchange adopted the XBRL format for financial reporting for all listed companies (the first official utilisation of XBRL) - 2004;
- the US SEC (Securities and Exchange Commission) started a pilot program for financial reporting using XBRL (listed companies were encouraged to adopt the new standard) - 2006;
- starting with 2009 listed companies which were supervised by US SEC were required to present their financial statements using XBRL;
- in 2011 the European Commission proposed replacing the two Accounting Directives (78/660/EEC and 83/349/EEC) with a single Directive that would harmonize the financial reporting process starting with 2018 [4].

XBRL is promoted worldwide by XBRL

International, Inc. (more commonly referred to as “XII”), which is a non-profit consortium of around 600 companies, professional associations and government institutions with the purpose of developing a harmonized financial reporting language over the internet [5].

Versatility and large use of XML language led to its adoption as a start point for developing the XBRL standard. XML was created to transfer, process and store data from internet (with focus on defining data) opposed to HTML which was developed for displaying data.(with focus on aspect).[6]

The idea behind XBRL was to add to the financial information XML labels (tags) that contain details on the interpretation and processing by software.

Classic presentation of financial statements on the internet in HTML or PDF formats do not allow automated analysis of that information by the software. The software programs do not know how to interpret values and concepts included in the financial statements analyzed.

If a user needs to obtain a particularly important information from financial statements, will have to go through the entire file and manually extract that information. In situations such as comparing the information obtained from other companies of a similar nature, obtaining average values for a particular industry or trend analyzes financial indicators of a company for a certain period, manual data processing is not feasible, because the time required to obtain information is too large.

If this is added the complexity of the information presented (many financial reporting standards, presentation of financial statements and specific terms of certain economic sectors or industries) can understand why simple sequence of elements of financial statements in text or in a table does not ensure comparability of information when you want automatic processing or transfer them from one application to another, given that most of the times, applications store data in incompatible formats.

The main objectives of XBRL are to [7]:

- Automatically obtain quick and well-defined certain information in the financial statements available on the Internet by ordinary users (those for

which the only source of information about a company's financial statements is from the Internet);

- Development of complex financial analysis tools, such as those used by financial analysts and professionals in auditing and consulting companies that process financial statements presented on the Internet in XBRL format and are accessible to regular users of financial information;

Improving financial reporting for companies who choose the standard (for example, financial statements presented in XBRL format can automatically perform complex processing such consolidation group or other restatement under financial reporting standards).

2. XBRL basics

Eliminate manual processing of financial information when they are transferred from one application to another established the need to standardize the names of items in the financial statements, and the relationship between them so that the information to be singers in the same manner by any application can process data in XML format.[8]

This objective was achieved with the following standards recommended by the W3C (World Wide Web Consortium), an organization which has among its duties and supervision of XML development:

- XML Schema – files containing specifications of the structure and content of the XML files that are used to verify that items are properly defined XML [9]
- XML Namespaces – used to ensure uniqueness of name elements in XML files [10]
- XLink – standard for creating hyperlinks in XML [11]
- XPath – standard used to traverse the elements and attributes of an XML file [12]

Using these standards, XBRL International has begun the process of performing electronic dictionaries (called taxonomy) of elements that define financial information as well as specified relationships between these various financial reporting standards (e.g. IFRS or U.S. GAAP).

Information in the financial statements are divided into two components: XBRL instances and taxonomies. Instances contain data that is reported and taxonomies contain information on how to interpret the data. [13]

Taxonomies can provide semantic modeling XBRL elements presented in court, which is expandable. Thus, an item can be added to information on what kind of value can take (money, fraction, percentage, etc.) on how to calculate it or on how to present this information in the financial statements.

3. Presentation of the risk based approach in financial audits

This approach has been promoted by large audit companies (the so called “Big 6/5/4”) since the beginning of the 1990s with the declared purpose of improving audit quality. This objective would be achieved by focusing on the business risks that might cause material misstatements in the financial statements being audited [14].

At the same time, audit standards such as ISA 315 or SAS 109 required auditors to understand how business risk may lead to material misstatements in the financial statements that are being audited.

According to ISA 200 [15], the risk of material misstatement (RMM) as the risk that financial statements are materially misstated prior to audit. This consists of two components, described as follows:

- Inherent risk – The susceptibility of an assertion about a class of transaction, account balance or disclosure to a misstatement that could be material, either individually or when aggregated with other misstatements, before consideration of any related controls.
- Control risk – The risk that a misstatement that could occur in an assertion about a class of transaction, account balance or disclosure and that could be material, either individually or when aggregated with other misstatements, will not be prevented, or detected and corrected, on a timely basis by the entity’s internal control.

According to ISA 315 [16] business risks result from significant conditions, events, circumstances, actions or inactions that could adversely affect an entity's ability to achieve its objectives and execute its strategies, or

from the setting of inappropriate objectives and strategies.

According to ISA 315 and ISA 320 [16], [17], the risk based approach requires auditors to perform several key steps during the planning of their audits:

- perform risk assessment procedures in order to determine business risks which are relevant to the financial reporting process and other significant risks (risks of material misstatements that require special audit consideration)
- determine significant accounts and disclosures and the classes of transactions that generate them
- consider the relevant assertion (e.g. existence, completeness, valuation, etc.) for each significant class of transactions
- identify the applications that are relevant to significant classes of transactions
- grouping all the potential errors (“what could go wrong”) at the assertion level for classes of transactions, account balances and disclosures

Based on the assessment of the risk of material misstatement, auditors determine what is the acceptable level for the detection risk at assertion level for classes of transactions, account balances and disclosures

Depending on the determined value for detection risk, auditors choose the audit strategy (substantive procedures or control based approach) at assertion level for classes of transactions, account balances and disclosures

It is important to notice the iterative nature of the risk assessment process. Following the execution of tests of controls and substantive procedures, the entire audit strategy may be reevaluated..

4. Extending XBRL for financial audit using a risk based approach

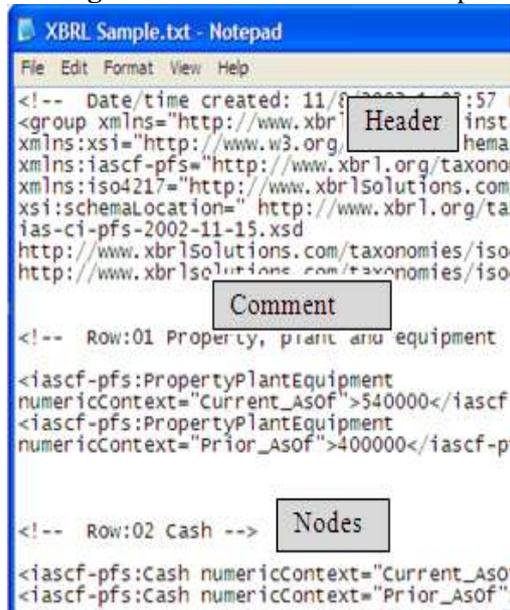

A typical XBRL document looks like the one in Figure 1.

Please notice there are two main sections of the document:

- The header contains general technical data regarding XML namespaces, schemas and taxonomies
- The body of the document contains XML nodes for each item in the financial

statements. Each node may have several attributes containing account specific information.

Figure 1: XBRL document example

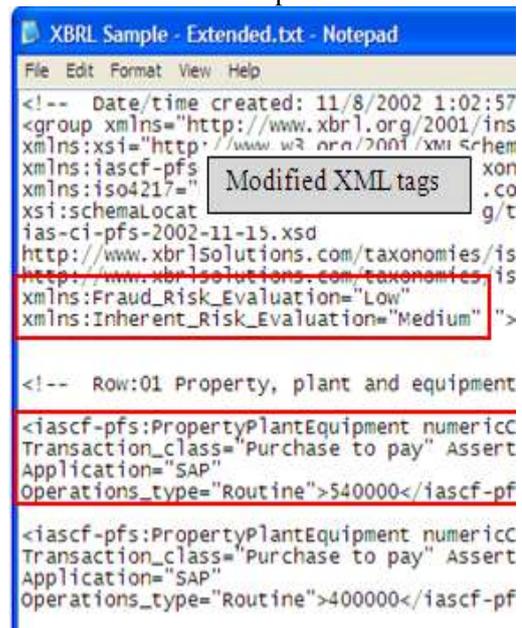

Source: <http://www.xbrl.org/taxonomy> [18] modified by authors

The example from Figure 1 contains information for two accounts: Property, plant and equipment and Cash (for both the current period and the previous period).

Considering the increased usage of XBRL in the past decade and the potential this technology has for growth, the authors propose expanding XBRL documents containing financial statements data in order to include information that can be used by auditors in the planning phase of their audits. This information can be related to the audited entity (e.g. Inherent Risks, Specific Business Environment Conditions, etc.) or to certain accounts (e.g. relevant assertions, classess of transactions, applications). The authors also consider that such information should be included in XBRL instances of financial statements due to the fact that it can be used from one audit period to another, independent on who performs the audit or on what audit methodology is applied (e.g. the Completeness of the Cash account will always be a relevant assertion and the Cash account will always be linked to the Purchase to pay class of transactions).

Please refer to Figure 2 for an example of XBRL extension that might be used for helping auditors in the planning phase.

Figure 2: Extended XBRL document example

Source: <http://www.xbrl.org/taxonomy> [18] - modified by authors

The following Entity-specific information was added:

- Fraud risk evaluation - this indicates whether the management of the audited company created a working environment that discourages fraud;
- Business risk evaluation - this indicator may be helpful for assessing the audited entity's ability of meeting its objectives;

The Entity-specific information can be used for assessing risk for all accounts in the financial statements.

The following Account-specific information was added:

- Classes of transactions that impact the account
- Relevant assertions for the account
- Applications used for processing information reflected in the account
- Type of operations included in the account (routine / judgemental)

Please refer to Figure 2 for the extended example of the XBRL document..

5. Conclusion

Using XBRL can enhance quality audit and decrease execution time of the audit. Besides these issues, XBRL can enable researchers to analyze information in financial statements without the need for a

data collection time high. As up to this point, the company's privacy policy may impose restrictions on the disclosure of such information. That limit research to identify lack of access to financial information reported applying XBRL. We intend in the future to contribute to develop some research on XBRL to determine opportunities, and limits imposed by the implementation of this standard. The economic crisis has generated numerous complaints of how current financial reporting. The main reason is the lack of transparency, which can be improved by using standard XBRL.

Abstract

The rapid development of financial audit and its applicability can be an important factor for the development of a company. The explication is that the financial auditors are not require to account for the company's transactions, but they have to check the elements from their financial statements taking into account principles, postulates and the criteria for reporting and recording them. Considering that the checking process is based on financial information analysis, we can conclude that presenting some consideration about the development of audit is necessary in order to reveal the audit evolution. Moreover, some recommendations were pointed out in order to improve the credibility of the audit process.

Key words: history, audit, accounting, financial reporting.

J.E.L. Classification.: M41, M40

1. Introduction

The diversity and complexity of financial audit can be found from the idea that there are not general accepted techniques for carrying it. The explication comes from the fact that no universal rules could be applied in order to encounter all the situations that an auditor has to consider. The assumptions used by auditors are based on standard rules, but the decisions that the auditors are taken belongs to them as they have to adapt to extremely different situations.

As a fact, we consider that the professional judgment should prevail, when an audit operation is realized.

Even though in the past, the audit was based on checking the accounting information, not it means not only checking it, but also to assure the disclosure presented in the financial statements.

As a fact, considering the audit evolution, five significant periods can be identified: the period before 1840, the period between 1840 - 1920, the period between 1920 - 1960, the period from 1960 to 1990, and the period from 1990 till now.

2. The period before 1840

The audit evolution is strong correlated with the development of accounting and the principles on which it is drawn up. As a fact, we have to consider the accounting on-going process due to economic and social development needs. The establish of rules and of the accounting principles was influenced by the evolution of the accounting and audit practices from the past (Previts, G,J, Parker, L, D, Coffan, E, N – 2000[1]).

Lee, T(1994)[2], points out that a history of audit in this period cannot be properly realized.

It is considered that ancient civilizations had realized audit processes even before the appearance of writing. Some authors (Capron, M. [3], Baxter. W. T -1989 [4]) consider that evidence of the accounting existence was detected 20000 ago.

Same idea is pointed out by Power, M. (1997) [5] who consider that the oldest types of writing were in fact the accounting

documents discovered around 8500 B.C. We believe that as human needs have widened, the accounting development was realised in order to meet the current need with the existing resources.

The archaeological proves reveal that the first accounting system was discovered in 8000-7500 B.C, when accounting records were made in order to count and to check the goods from agriculture and form the accumulated production. Mattessich, R. (1998) [6], reveals that the development of accounting techniques was achieved by adapting to the needs of conservation, management and wealth management through clever accounting techniques.

In ancient Egypt, each element was immediately recorded and no element could have been used without the prior existence of a written order. [7]

In ancient Greece, was carried out a full transaction accounting, while in ancient Rome, accounts stands as bilateral and a single currency is used for the accounting operations

Other proves were discovered in Italian towns like Genoa, Florence and Venice, issues that generated the summarizing of the accounting Knowledge by Luca Pacioli in 1494.

Porter, B & all (2005) [8] reveal that before the industrial time, the audit upon companies had no relevance as their activity had not important dimensions. In this period, the audit duties were designed primarily to check the honesty of people who had tasks regarding fiscal responsibility or who were charged with tax collecting. [9].

3. Period from 1840 to 1920

Until the Industrial Revolution, the practice of audit was not properly implemented. The operations that lead to significant industrial revolution were due to the legal form of the companies [10]. The increase of companies dimension and the development of technology have generated the development of the middle class. In order to protect small investors, the development of audit was performed.

As a fact, in 1844, The Great Britain adopted the “Joint Stock Companies Act”, through which the auditors had to check the accounting recorded of companies. The audit

has received a mandatory character only from 1900.

After that, some certified bodies were created that looked at the activities realised by the accounting profession. As a fact, the Chartered Accountants, the Chartered Accountants of Ontario, the Canadian Institute of Chartered Accountants and the Certified General Accountants Association of Canada can be mentioned.

Once these bodies were formed, the mandatory of the audit transactions could not be postponed.

As a fact, the Canadian Law imposed the need for audit report through the Ontario Corporations Act (1907) and through Federal reserved act (1917). We consider that the Ontario Corporations Act from 1907 laid the modern financial reporting foundations, and thus the basis of the modern audit. Through this, it was requested for the public companies to present an audited balance sheet at the end of the year. Moreover, the law stipulates that realising a simple comparison of the values from the balance sheet with the values from accounting records, is not enough to ensure the quality of audit

Even though the audit was based on exhaustive checking, starting with 1910, an audit techniques commonly used in the UK has become the use of survey [11]. We consider that placing the identifying of financial fraud into the background, was due to the fact that as companies became larger, the costs and the time allocated for achieving a comprehensive check became higher. Some attributions correlated with financial fraud detection were placed within the manager's duties and through the act from 1929; the financial fraud detection was not any more a request for the auditors.

The use of the sample validation was done considering the tendency for uniformity and standardization of audit practices which were implemented in 1917. As a fact, the chartered accounts from America recommended what were the elements that an audit mission should focus on.

Generally, the auditors from this period were shareholders of a company which generated less credibility for audit activities as the auditors should prepare financial statements and should achieve total transaction checking.

The auditors' duties were also influenced by the court decisions [2]. The auditor functions were to identify the elements that can contribute to financial fraud or to technical or financial errors.

As a fact, we consider that the auditor activity was mainly based in revealing the elements necessary for company sustainability.

4. Period from 1920 to 1960

In this period, it is considered that a migration of audit from UK to USA had been realised. As a fact, at the beginning there was a high development of companies, that was followed by the great Depression in 1929. After the great Depression, the investments in companies increased a lot. As a fact, the development of the capital market was realised. Due to this, it was impossible to divide the management attribution by the administration's one. As a fact, in order to ensure further development of the companies, granting of guarantees of financial statements has become increasingly necessary. We consider that the audit represented the operation though with the credibility of financial statements reported by managers to shareholders was ensured. As a fact, the auditors attributions were defined from another point of view: it was considered that they should focus upon financial statements, and not upon the detection of financial fraud..

Moreover, the concept based on the evidence collection and the use of sampling units was used. Due to the increasing of the number of transaction, these techniques developed quickly.

Not only was the adoption of these elements essential, but also the information provided by the internal control was taken into consideration. As a fact, this information contributes to the development and research in the audit field.

The principles through which the audit focuses on were the observation and the evaluation of physical assets, of inventories and of the amount of the available funds and the external use of them. Realizing the audit operation at some companies (e.g. Royal Mail) pointed out that the auditing process to the profit and loss account was also necessary. These elements were only made mandatory in 1934 in USA when the

Securities and Exchange Commission Act was adopted and in 1948, in UK when Companies Act was implemented.

In 1933, the SEC Act was adopted through which the companies listed at New York stock Exchange were obligated to submit their financial statements certified by an independent accounting and were forced to attach an independent audit report . In 1946, were issued the accounting standards by Chartered Certified Account from Canada.

As a summary, it can be said that economic and social development has had a significant influence upon the audit practices. We believe that the audit focused on the information provided by the internal control and used the sample unit technique, the audit opinion being underlined both by internal and external information.

Not only the evolution of the balance sheet has been realised, but also the evolution of the profit and loss account, even though the first element was still the benchmark by which the auditor's opinion was based on. Moreover, it has to be reviled that for pointing out a high quality audit opinion, physical items or goods of foreign origin and items that were not in the accounting data recorders were analysed. Due to this, we consider that the credibility of audit has increased a lot compared to the period before 1920.

5. Period from 1960 to 1990

Economic development begun in the previous period continued to expand after 1960. Present period is characterized not only by increasing the size of the company, but also by improving the technological elements and the increasing complexity of operations carried out by companies.

Therefore, auditors contributed to the credibility and truthfulness of financial statements, something that was essential for the development of the capital market operations.

In the literature it is mentioned that the audit has experienced some setbacks and that he treated some criticism during the analysis, although in 1965 it adopted Ontario Securities Act and the Canadian Business Corporations Act.

Thus, there has been progress in transition and analyse transactions recorded in the

application system. This was due to the increase in the number of transactions as a result of the increased size and complexity of corporate activity and the auditor's role is not only to verify transactions. Therefore, in our opinion, within this period, the auditors focused more on internal control. Also, auditors are required to establish and document accounting system with a focus on identifying information flows and internal controls. With the internal control was effective, auditors no longer were centred on thorough presentation of details.

Around 1980, it was found that the costs of internal control are extremely high, so they have shifted to analysing the analytical procedure as Salehi, M (2007) [12] states. During 1985, were developed auditing standard that accepts the existence of risk. This element requires that auditors will focus more on items that have a higher risk. Thus, the approach to risk based audit, we believe that it was necessary for auditors to understand the customer's accounting system, key personnel, the industry in which it operates and the policies adopted by the company. Therefore, risk-based audit involves analysing information from various sources, both internal order and external order given by the audited company. A correlation of these practices can be achieved by way of implementation of modern audit. We can say that modern audit focuses on identifying the risks and the proper analysis of information in the financial statements. In this regard, we recommend that the financial auditor to try to assimilate accounting policies and development company premises, but on the other hand, it must report any ambiguities discovered.

Also during this period, many companies began to use computer systems for financial statements for processing and controlling the operational and administrative processes. In this case, the auditors have given more confidence these elements, while the audit procedure was much easier. In terms of services, not only audit services were performed, and the nature of consultancy services. Thus, it can be stated that in addition to the role that audit we have to verify and validate the financial statements in the period 1960-1990, has formed a new dimension to the audit. From now on, we consider that the audit had financial advisory

role and the role of conferring a degree of assurance as to the reliability of financial statements.

6. Period from 1990 to present

The audit itself underwent major changes since 1990. Nowadays, audit focuses on the company's financial statements, the aim being not only to highlight discrepancies between observed and specified elements, but also to highlight any items which may affect the credibility of provided opinion and may contribute to the worsening of the financial situation of the company. In our opinion, currently, the audit is oriented towards risk disclosure to customers being subject to audit. In this respect, we focus on the idea that the auditor will present a more credible opinion given that it focuses its attention on understanding the risks that an entity is subject to.

Since 1990, the audit began to identify and report elements that may constitute financial fraud. Furthermore it should be noted that doubts and uncertainties arose as to whether an auditor give credibility to audited financial statements, given that corporate governance issues and existing increasingly transparent reports, have become more pronounced.

The credibility of the audit was much affected since the 2002 scandal of Enron and Arthur Anderson, the decrease also being emphasized by the economic crisis of 2007 effects.

Under these circumstances, we believe that the audit should be primarily aimed at providing credibility of financial statements, as well as of financial and non-financial items that managers provided in the annual reports. However, audit firms focused primarily on providing consultancy, reducing therefore the importance of audits.

Due to a sharp criticism of auditors and of the risks to which companies are subject to, the consulting firms were declared independent. Companies adopted more severe auditing standards to ensure the independence and a higher quality of the audit services.

Certain reforms were made at governmental level of the accounting bodies, in the level of the fees charged on the stock exchanges in order to increase confidence in

audit practices. We believe that the independence auditor from the audit client is a key element for ensuring the credibility of the audit opinion and to improve the quality of services provided by the auditors.

Following the collapse of Enron recorded, the U.S. adopted "Sarbanes-Oxley Act". This law provides precise rules on auditor independence, quality control performed by auditors, and on changing the main auditors. In reality, the "Sarbanes-Oxley Act" law extended the attributions the auditors have in the sense that they must emphasize that the results of internal controls are in line with the elements of the financial statements.

In Australia, the "Ramsay report" was adopted. The auditor independence is ensured by means of a statement in the audit process and must be maintained to the board of the audited company. We believe that auditors' independence is strongly correlated with the independence of the Supervisory Committee, while the existence of an audit committee for the non-financial services, for determining fees for the audit operation, is required in order to avoid the occurrence of disagreements between the auditor and the client.

Many reforms were made on audit practices in different countries during this period. In our opinion, we believe that the future role of auditors will converge towards one objective only: it will focus on the pursuit of public interest in redefining the audit relationship, on ensuring the integrity of financial statements and on the separation of non-audit services and consulting ones from the audit ones.

We also believe that the audit methods will return to the basic elements: a focus on the risk to which the company is subject to, detection and identification of the items generating financial fraud, ensuring independence and objectivity of audits.

Currently, auditors are focused not only on the expression of an opinion that the reports should provide financial credibility, but also it is expected from them to provide services that add value to the company by identifying the irregularities, the risks which the company is subject to, as well as by offering tips on how to carry out internal control.

The problems auditors currently face are closely related to loss of credibility of the

users interested in the financial information of the company. As a result, important measures were adopted nationally and internationally, aiming to boost confidence in the financial audit activity.

At European Union level, certain measures that provide strict regulations of the audit were adopted. Thus, improving the quality of audit has been imposed by the European Commission by the adoption of a document entitled "Green Paper" [13]. The implementation of its provisions is based on the social and economic role the audit plays in a society, given that auditors should present a credible opinion on the accuracy of audited financial statements. The document also specifies that the failure of the one "Big 4" company would contribute to a severe distortion of the auditor's credibility. Therefore, large companies should allocate more time to the audit process. The auditor's opinion should be substantiated taking into account the risk that the audited company is subject to, industry or development risks.

We believe that risk avoidance can be achieved by implementing a better communication between internal and external audit.

The European Commission also proposed successive rotations of auditors in order to maintain the independence between them.

As regards the non audit services, they should not be made by the same company since the relationship between the audit committee and the audit client may be distorted. We feel that credibility may be higher or lower depending on restrictions that may arise from legislation.

The developed document focuses mainly on the principles of transparency, which the company performing the audit should follow. Transparency refers to the elements from the financial statements, which are reported by the audited company to the auditors. In this sense, the reduction of the conflict of interest is aimed on one hand, and the presentation of a more detailed report for the audited financial statements that may improve the credibility of the audit, on the other hand. We recommend therefore, a correlation with the development of capital markets given that any information can have a significant influence.

It is considered that there should be no entry barriers and the auditor rotation should

be frequent. Also, international cooperation between states is essential. In this respect, we believe that the development of international auditing reporting means would generate greater confidence in the services provided by auditors, and, in the same time, would ensure the sustainability of the audit profession.

7. Conclusions

We consider that, in order to ensure objectivity, auditors should necessarily be independent of management bodies or of the management of the audit client. We also focus on the idea that auditors should orient towards a more detailed presentation of the financial statements of the audited company. Therefore, we recommend the issuance of a more detailed audit report for both shareholders and other users of financial information. For highlighting a quality report, auditors should consider all elements that affect profitability such as the exchange rate, the industry risk or the evolution of macroeconomic indicators.

Abstract

This article aims to highlight the need for implementation in the European Union Member States of new ways of achieving specific procurement, namely computerization of the public procurement system. The European Union has promoted directives regarding the need to establish electronic platforms in order to promote public administrations acquisition activity having as the final goal the transition from traditional paper acquisitions to electronic acquisition. A first step in this direction is the decision taken by Portugal where public procurement using electronic means became mandatory. In this paper, we aim to identify and analyze the electronic procurement system's specific index's dynamics.

Keywords: public procurement, public administration, electronic procurement system

J.E.L. Classification: H77, H83

1. Introduction

A key component of e-procurement is the use of media and transaction processing for the assignment of public works contracts for the purchase of goods and public services. The ultimate goal is that all phases of public procurement, starting from the notices publication until the billing and payment to be in an electronic version.

The gradual introduction of electronic procurement is part of the ambitious reform initiated by the European Union regarding the public procurement system. Legislative

basis for achieving this goal had been made when the Action Plan for Procurement in was implemented in 2004, and in 2005 when the European Union ministers have drawn Manchester Ministerial Declaration of 2005 where an important point brought in discussion was the use of ICT in the public procurement. The conclusions were based taking into consideration statistics that showed that public procurement represents 15-20% of European GDP and that computerization would lead to a more efficient expenditure reducing costs by 20%.

Therefore, both in the European Union and Romania in particular, the public sector performance will depend "of how government will find motivation and appropriate control mechanisms in the production of goods and services without strict procedures implemented at the level of each public entity" [7].

2. Theoretical background

Electronic public procurement requires connection to a number of sciences starting with the administrative approach, computer science, interfering with economic and ending with European legislative framework in which it finds its germs and substance, so the concept is defined in Article 1.7 of Dir. 2004/18/EC and Art. 1.6 of Dir. 2004/17/EC as "a repetitive process involving an electronic device for the presentation of new prices, revised downwards, and / or new values concerning certain elements of tenders".

European Union should establish a framework for implementing linear concept for the development in some countries at a faster electronic public procurement could lead to the birth of unnecessary barriers to cross-border participation of economic operators from other Member States. Major problems faced by traditional systems in the contracting of public goods and services such as the human factor associated with corruption in the public sector, reducing administrative costs, lack of transparency, limited access of economic operators to procurement documentation will find a solution in computerized acquisition public.

The European Union was built starting from the idea that a conglomeration of peoples with different cultures and practices will create a compact structure governed by European authorities, just as the public procurement system will create a common market acquisitions. Still we currently find the major problem in the way of this project, e-auction, is represented by public authorities and economic operators who believe that classical solution are better alternative than the electronic solutions.

To meet this goal the governments of the Member States of the European Union should attract diverse sources of funding, including partnerships with firms, partners who are willing to fund research and perform simulations on the implementation of a unique procurement system for all Member States. Romania in particular, should benefit from EU Structural and Cohesion Funds for 2014 - 2020 to try to implement the e-auction at national level for all procurement. The main obstacle Romania is confronting in this aspect is the absorption of these funds, registering delays in all the phases of the absorption process of European funds, mostly because of the requirement to assure finances before having the approval for the projects. (Milena Messori's declaration, Head of European Investment Bank Office–Romania). In order to increase the absorption of the Structural and Cohesion Funds it is required not only a strategy adopted by UE but also an adequate strategy adopted nationally that is based on the needs of the potential beneficiaries.

3. Public electronic procurement stage

To achieve the final phase of this plan of computerization of public procurement metaphorically defined as the possibility that any company in the European Union that has a computer and an internet connection can participate to an electronic public procurement, the European Commission financed and sustained several initiatives and practical tools by which to overcome administrative obstacles. Among these, a major importance consists in:

- Pan-European Public Procurement Online (PEPPOL) - development of a system in which EU countries can exchange the documents, billing and order online;
- Open e-PRIOR - development of infrastructure in order for the European Commission to facilitate documentation transfer for a public procurement: electronic catalogs, invoices, electronic bills;
- E-CERTIS - is a platform through which suppliers receive more information about the various certifications required for participation in public procurement;

European Union Member States have supported and implemented more and more electronic platform for public procurement phases conducting some for the entire process and others only for certain phases of acquisition. Despite efforts taken by the European Commission, the level of electronic procurement does not exceed 5% of the total as there are countries that have moved to electronic acquisition exclusive mandatory, like Portugal, others made only certain phases of the procedure such as Cyprus, Belgium and the Netherlands.

There are also countries that have achieved significant savings by using various electronic platform for public procurement implementation in all its phases: publishing ads, providing documentation, submission, evaluation, assignment, order, billing and payment – the best example in this case is the Austrian federal agency that reported savings of 178 million euros for a volume of 830 million euros.

Romania benefits from one of the most commended electronic public procurement (Electronic System for Public Procurement). This system publish notices and tender

documents, thus ensuring of transparency and public procedures that exceed the threshold value provided by GEO no. 34/2006.

Table no.1 The dynamics of specific indicators of the National Public Procurement in 2007-2011

Number of contracting authorities and economic operators enrolled in the ESPP Procurement market players	2007	2008	2009	2010	2011
Number of contracting authorities enrolled in the ESPP	9.256	11.187	11.551	12.272	12.903
Number of economic operators enrolled in the ESPP	9.433	13.140	21.978	30.751	37.892

Source: Activity Report for 2011 of the National Authority for Regulating and Monitoring Public Procurement

From this table, we can observe that although Romania is an EU member since 2007 it had understood the opportunities and offers of the ESPP, by facing with a multitude of Structural and Cohesion Funds absorbed between 2007-2013.

3.1. Advantages and disadvantages of implementing electronic procurement system

Implementing and developing the concept of electronic procurement for the entire European area has some advantages in the operation of public administration:

- Easier access to suppliers interested in accessing it;
- Lack of transparency can be outgunned by openness of this electronic system;
- Reducing administrative costs related to the crisis facing the European Union;
- Creating a single European market to increase competition and where the demand showed by the authorities will meet the suppliers offer the national barriers will have broken;

- Improvement of human resources involved in developing various phases of public procurement;
Transition to electronic public procurement is not an easy process, and it faces some problems as follows:

- High level of technical costs to support various electronic platforms may become true financial obstacles for some state facing economic problems;
- Introduction of electronic signatures for economic providers could lead to a fraud acquisition processes if a standard certification is not required;
- Equality offered to economic actors on the unique public procurement market should not be directly proportional to the differences between Member States;
Institutional framework, economic stability and legal-system are directly impacting factors in the evolution of the concept of electronic procurement.

3.2. European objectives regarding the justification of european acquisition

The analysis of European electronic procurement system should be viewed in light of the objectives proposed by the European Commission and their implementation status. The point of departure in this approach is the way they set up the proper functioning of the internal market procurement. To achieve this goal there have been established the limits within the legislative framework, the reforming of the legal instruments by removing barriers that could negatively influence the development of electronic acquisition

Although the procurement system is an institutional system, the approach should be taken in magnitude of the process by standardizing the documentation and the evolution phases of the acquisition in all Member States. In this respect, there have been promoted a series of measures to support achieving the final goal, achieving a single market for public procurement that is moving from paper to electronic purchasing procurement: an european legislation, electronic platform to support electronic signatures for economic operators, introducing a common procurement vocabulary. Therefore, the core set of measures taken by the European Commission

is interdependent by the variable factors starting from the social and political context of Europe and ending with the present economic reality in the Euro Zone.

4. Conclusions

Procurement should no longer be seen in terms as project, or as an alternative to the classic paper, they must be understood as necessities for achieving a common market in application of public procurement to meet multiple offer coming from a variety of economic operators. Common practice in many states that have implemented electronic solution has demonstrated an spending decline in terms of economic crisis.

It requires leadership at all levels of government (including the European Union) to maintain and accelerate the transition to e-procurement. If they are given freedom of choice, contracting authorities will be satisfied with tried and trusted procedures (paper) instead to invest in these promising new options and use them.

From the Accounting Treatment Required by the Accounting Regulations Corresponding with European Directives to the Accounting Treatment Required by IFRS - Legislative Steps Taken by Romanian Credit Institutions

Doroş Alexandra

"Drăgan" European University of Lugoj, Faculty of Economic Sciences, Romania,
alexandra2doros@yahoo.com

Abstract

Legislative stages in accordance with IFRS accounting treatment began to OMF no. 907/2005- approving categories of entities applying accounting rules in accordance with International Financial Reporting Standards, accounting regulations that comply with European directives, as amended, continued with NBR Order no. 13/2008, NBR Order no. 15/2009, NBR Order no. 9/2010 and ends with NBR Order No. 27/16.12.2010 - for approval of Accounting Regulations in accordance with International Financial Reporting Standards applicable to credit institutions.

Keywords: Accounting; Financial; IFRS; Normalization; Harmonization
J.E.L. Clasification: M 41

1. Introducing

Due to globalization, and the global spreading of economical phenomena, of the countiuous development of in between states economico-political relations, of the complexity of relation between investors, of the harmonization of legislations on regional and international level, we are assisting at a considerable increase of the importance of accounting information.

In our country the financial statements of credit institutions come together in a document synthesis made by the Ministry of Public Finances, approved by the National Bank of Romania, and contains the following elements:

- the statement of financial position;
- the statement of profit and loss;

- the statement of changes in equity;
- the statement of cash flows for the period;
- notes, comprising a summary of significant accounting policies and other explanatory information [3].

The accounting of credit institutions in Romania has witnessed, in the last two decades, multiple transformations. In this context, the process of normalization and harmonization of accounting credit institutions, has come a long way, with numerous legislative changes and adaptations to the directives of the European Community, first, continuing the harmonization and compliance with IFRS accounting regulations.

2. Legislative steps taken by Romanian credit institutions

Current accounting regulations corresponding with international financial reporting standards, accounting regulations that comply with European directives define as credit institutions in our country, the following entities [1]:

- banks, Romanian legal persons
- credit cooperative organisations;
- savings and loans banks for housing;
- mortgage loan banks;
- branches in Romania of foreign credit institutions;
- foreign branches of credit institutions Romanian legal persons.

In 2005 the Ministry of Public Finance issued an Order of the Minister of Public Finance no. 907/2005, approving the categories of legal persons applying accounting rules in accordance with International Financial Reporting Standards,

accounting regulations [7] that comply with European directives.

Through the Government Emergency Ordinance no. 99/2006 - on credit institutions and capital adequacy [6], approved with amendments by Law no. 227/2007, as amended and supplemented, shall be regulated:

- conditions of access to banking services in Romania;
- prudential supervision of credit
- institutions and investment services firms;
- oversight of payment and discount
- systems for financial instruments
- operations.

Considering the Accounting Law no. 82/1991 [4], republished, the M.F.O. nr.907/2005 - approving the categories of entities to apply accounting rules in accordance with International Financial Reporting Standards, accounting regulations that comply with European directives, as amended, the Government Emergency Ordinance no. 99/2006 - on credit institutions and capital adequacy, approved with amendments by Law no. 227/2007, as amended and supplemented and the Law 312/2004 [5] - the National Bank of Romania, NBR issues:

Order no. 15/22.12.2009 – regarding the drawing up by credit institutions, for information, of individual annual financial statements in accordance with IFRS come into force on 24.dec.2009, which in Article 1, paragraph (1) stipulated the following "for the financial years 2009, 2010 and 2011, credit institutions shall prepare, for information, a set of individual annual financial statements in accordance with adopted IFRS stipulated in Art. 6, paragraph 2 of Regulation (EC) no. 1.606/2002 of the European Parliament and the Council of 19 July 2002 on the application of international accounting standards (IFRS), obtained by restating the information presented in annual financial statements prepared under the accounting records kept under accounting regulations in accordance with European directives applicable to credit institutions, on-bank financial institutions and the Deposit Guarantee Fund in the banking system, approved by the NBR order no. 13/2008 [8], further on called Accounting Regulations in accordance with European directives." [9]

One can notice that the start of Regulations in accordance with International Financial Reporting Standards (IFRS) is given by EC Regulation nr.1.606/2002 the European Parliament and ruled by the NBR by Order nr. 15/2009.

By this Order, NBR asks for information purposes only "a single set of annual financial statements" [9] in accordance with IFRS for financial years 2009, 2010 and 2011 of credit institutions in our country.

In order to stress the differences between the accounting treatment in accordance with the accounting regulations harmonized with European directives and the treatment required by IFRS, the NBR Order no. 15/2009 specified in Art. 3. Paragraph (1) that "Credit institutions shall prepare a statement to reflect differences between the accounting regulations harmonized with European directives and treatment stipulated by IFRS for each item in the format of the statement of financial position and the statement of profit and loss.

Order no. 9/16.iul.2010 - "on the application of International Financial Reporting Standards by credit institutions ..." [10], applicable since July 30, 2010, stipulates in Article 1, paragraph (1) that "as of January 1, 2012, credit institutions shall keep records in accordance with the treatment under International Financial Reporting Standards adopted according to the procedure stipulated in Art. 6, paragraph 2 of Regulation (EC) no. 1.606/2002 of the European Parliament and the Council of 19 July 2002 on the application of international accounting standards, further on referred to as IFRS."

Credit institutions in Romania were advised, since the end of July 2010, about the applicability of IFRSs, with express mention in Article 1, paragraph (2) that accounting organization and lead shall "follow the Accounting Law no. 82/1991, republished, of IFRS, of the regulations issued by the National Bank of Romania for the implementation of this Order, as well as other applicable legal provisions." [2]

One can clearly observe Romanian accounting normalizer's care to make available to credit institutions in our country, accounting procedural rules, both in accordance with International Financial Reporting Standards (IFRS) and for their

better understanding, comparability and applicability.

Order No. 27/16.12.2010 - for approval of Accounting Regulations in accordance with International Financial Reporting Standards applicable to credit institutions [11], published in the Official Gazette, Part I - nr. 890 of 30 December 2010.

This Order approves the Regulations in accordance with International Financial Reporting Standards applicable to credit institutions in our country, as of January 1, 2012. To ensure a high degree of transparency and comparability of financial statements, the regulations in Article 1, paragraph (1) of Order No. 27/16.12.2010 apply with:

- Accounting Law no. 82/1991 republished;
- International Financial Reporting Standards;
- Other legislation applicable to credit institutions.
- NBR Order No. 27/16.12.2010 includes two Annexes, namely:
- Appendix 1 - Settlement of 16/2010 entitled " Accounting Regulation in accordance with International Financial Reporting Standards applicable to credit institutions";
- Appendix 2 - Annex since 16/2010 on consistencies between accounts in the chart of accounts prescribed by regulations in accordance with International Financial Reporting Standards applicable to credit institutions and appropriate accounts under the regulations in accordance with European Directives".

Legislative stages in accordance with IFRS accounting treatment [1], began to OMF no. 907/2005- approving categories of entities applying accounting rules in accordance with International Financial Reporting Standards, accounting regulations that comply with European directives, as amended, continued with NBR Order no. 13/2008, NBR Order no. 15/2009, NBR Order no. 9/2010 and ends with NBR Order no. 27/16.12.2010 - for approval of Accounting Regulations in accordance with International Financial Reporting Standards.

3. The impact of legislative changes in accordance with IFRS on the accounting of the Romanian credit institutions

The main changes brought by NBR Order no. 27 / 16.12.2010 - Accounting Regulations for approval in accordance with International Financial Reporting Standards applicable to credit institutions, refers specifically to the General Accounting Plan used by credit institutions.

Accounts under the Plan accounts are ranked according to asset liquidity, liability for debt and equity nature in conjunction with the rules underlying the financial statements in accordance with International Financial Reporting Standards.

In the Annex of the NBR Order No. 27/16.12.2010 - on consistencies between accounts in the chart of accounts prescribed by regulations in accordance with International Financial Reporting Standards applicable to credit institutions and appropriate accounts under the regulations in accordance with European directives, there are significant changes made in the General Accounting Plan. [2]

4. Conclusion

Romanian credit institutions have aligned to the International Financial Reporting Standards (IFRS)'s requirements after a long process of harmonization but the beginnings of Accounting Regulations in accordance with International Financial Reporting Standards (IFRS) is given by EC Regulation No. 1.606/2002 of the European Parliament and stated by NBR Order nr.15/2009.

Operational Techniques and Methods Used in the Internal Control Process

Ducu Corina Maria

“Constantin Brancoveanu” University - Pitești, Faculty of Finance – Accounting
corina_ducu@yahoo.com

Abstract

The existence of a wide range of actual or potential threats with effective impact on the business entities is a certainty, as well as their influence on the results of the entity (often negative). In this context, increasing economic performance and conducting effective activities are strictly related to implementing a system of internal control. With the possessed tools and techniques, internal control evaluates the activities accomplished by the entity and identifies the risks that it faces.

Therefore, presenting a fair view of the entity requires the implementation and development of internal control processes.

Key words: internal control, instruments, composing elements, entity, performance.

Classification J.E.L.: M4

1. Introduction

In Romania, the legal basis regarding the organization and conduct of internal control is contained in Section 11 of the Accounting Regulations in accordance with Directive IV of the EEC, part of the Accounting Regulations of the European Directives, approved by OMPF 3055/2009. According to them, internal control is “an activity designed, implemented and maintained by the entity management and staff in order to provide reasonable assurance related to the increase of efficiency and effectiveness of its operations, achievement of objectives, credibility of financial statements and providing a true and fair view”.

Moreover, the internal control is a dynamic process that constantly needs to be adapted to the changes that occur within the economic and social environment by adapting specific tools and techniques, it is

designed to eliminate or minimize the risks of the business and the specific activities conducted by staff from all entity’s departments and at all hierarchical levels.

To achieve a more detailed exposure of the internal control process, it is necessary to present the elements of internal control, i.e. the tools used by it, all reflected in its functionality.

2. Elements of internal control

The main elements of internal control are:

a) The control environment includes all actions, policies and procedures elaborated by the responsible persons within the entity (directors, board of administration, directorate members) regarding the need to conduct internal control and the awareness of the importance of the entity’s objectives.

The detailed elements that contribute to the understanding and the evaluation of the control environment are:

- the ethical values and competence criteria promoted by the entity in the process of employment, promotion and motivation;

- the importance given by administrators, board members, members of the audit committees regarding the evaluation of the efficient operation of internal control and the clear signals that the executive management give to the entity’s employees related to the categorical attitude to apply the internal procedures and their own adopted policies;

- the permanent monitoring of the way in which the functional, operational and managerial aspects of the entity are achieved through its organizational structure, respectively ensuring that the organization clearly defines each entity hierarchical levels of authority and responsibility;

- establishing clear responsibilities in job descriptions for all employees of the entity

and the existence of policies and procedures regarding the activities in which they engage;

- understanding and assuming that the most important aspect to be considered in their expectations related to the solidity of the internal control within an entity regards the staff professionalism, competence, honesty and its proper motivation.

Therefore, the control environment represents the means by which the employees of the entity are evaluated, trained, promoted and rewarded so that the objectives of the entity could be carried out successfully

The proper functioning of the internal control environment is influenced by several factors, such as [1]: “functioning of the management structures, management policy and its operating style, organizational structure of the entity, the way to determine responsibilities, management control system which includes the internal audit function; personnel procedures and policies, segregation of duties”.

The control environment is considered to be one of the important and necessary elements in organizing the internal control system. An appropriate control environment is an environment in which employees comply tasks, policies, procedures, regulations, and existing laws precisely because the activities in the entity need to be mastered and performed efficiently.

b) The risk evaluation procedure aims to identify and analyze risks for a correct financial reporting without significant distortion.

Responsibility for risk evaluation lies with both those charged with corporate governance (directors, directorate members) and executive management according to the field of activity (accounting, marketing, etc.).

For a correct evaluation, it is necessary to start with the analysis of the organization and the internal control, the accounting strategies, procedures and policies and then to continue to evaluate other risks arising from a series of internal or external sources with which the entity gets in contact.

Today, an increased attention is paid to risks, their evaluation is both for internal and external auditors during the auditing mission.

The main objectives of the internal control process are:

- operational objectives, considering the efficient use of the economic assets held by the entity, and reducing losses;

- informational objectives, regarding the accuracy of the information held in pursuit of relevant reports and implement the most appropriate decisions;

- compliance objectives, which ensure the coordination between internal policies/ internal procedures and the applicable law.

In order to ensure a reasonable level of internal control the following types of verifications are carried out [2]:

- “prevention controls: effectuated to avoid unwanted events;

- detection controls: performed to detect and correct unpleasant events that occurred;

- directive controls: made to produce a desired event;

- administrative controls: aiming the following activities: patrimony inventory, control of cash values etc;

- accounting controls: made by experts while performing the duties of the job;

- physical controls: aim at controlling staff.”

c) The internal control activities generally concern the entity’s policies and procedures relating to:

- the separation of duties to prevent fraud and errors. This separation is intended to ensure the separation of the responsibilities of asset management from those of accounting; the separation of the approval process of an associated operation of asset management; the separation of the operational (operating) activities of an entity from their accounting tasks; the separation of the main functions related to the information technology from the functions of the departments which are the key users of these technologies (in conjunction with the size of the entity);

- the approval for the operations and activities of the entity. In each entity it is required to have clear rules related to the approval of general and specific character for its operations;

- preparation and use of the accounting documents in accordance with the legal requirements;

- protection of the entity’s assets by storing, managing and securing appropriate and adequate physical controls;

- verification made by persons who apply verification procedures that ensure the independence of those responsible from the outside of the entities. For example: the observations regarding the account balances from the bank statements to those of internal records should be made by persons who are not involved in the maintenance of the accounting records; the information systems should include automated and system-integrated internal verification procedures; options for internal and external auditing regard most of the entities as a result of their insurance and independent action

d) The information and communication system refers to: receiving, recording, processing and analysis of all information about the entity. These systems contribute to achieving some reports containing operational, financial and compliance information.

The implementation of the policies and procedures for the proper functioning of the entity is based on relevant, pertinent and reliable information.

e) The process of supervision and monitoring requires a permanent and regular evaluation by those responsible of the correct application of internal controls in order to determine their consistency and to intervene with necessary changes, where this is required. This means that:

- each responsible person must be organized in order to conduct his business as efficiently as possible;
- establish and assign specific and correct tasks to the entity personnel;
- develop and implement methods and work procedures;
- implement a coherent information system of coordinated activities;
- achieve staff supervision of the work covered by the liability of each charge. Each responsible person is required to establish a system of internal control. Directing this task to another person leads to a failure of the control in the entity. But those responsible can turn to specialists to advise and assist them in the design, development and improvement of the internal control mechanism specific to the coordinated field.

3. Internal control specific instruments

The internal control system has its own

toolbox with specific procedures used in achieving its objectives and specific actions as it follows:

a) Tools that regard human resources.

The existence of competent personnel will lead to the increase of effectiveness of internal control. Therefore, internal controls aim at both recruiting and selection, and continuing professional education.

In the process of recruitment and selection, a series of procedures are developed:

- to identify recruitment needs over a period of time;
- to develop and use an interview guide;
- to communicate policies and procedures for recruitment and selection;
- to create a checklist for legal compliance recruitment and selection procedures applicable in the entity.

Professional training is both a compensation of any possible weaknesses in the recruitment and development of staff knowledge.

Until the actual realization of this process, a series of activities need to be carried out, subordinated to the internal control related to:

- the development of a questionnaire to identify staff training needs;
- data analysis related to the training needs among employees;
- prioritizing the identified training needs;
- elaboration of some training policies;
- their clear communication to the workforce;
- setting the checklist for the control of planning and staff training;
- development of procedures for initiating new staff.

Knowing and obeying the rules of the entity's code of ethics by the staff is the prerequisite for the good functioning of internal control.

b) Tools that regard financial resources.

Coordination of the entity's objectives and financial resources available to achieve them requires a lot of internal control activities, as it follows:

- verifying the correctness of setting up the budget of income and expenses;
- performing update operations of the cost of the objectives to be achieved;
- carry out some verification of the documents regarding the expenses incurred by the entity;

- verification of the documents the show a clear record of the entity’s earnings;

- diagnostic analyses related to the economic and financial entity.

c) Tools that regard material resources.

These include: products, services and works held by the entity. As internal control processes, we include:

- analysis of the ways to cover the real needs of the entity with the existing material;

- analysis of the need to procure material resources for the entity;

- application of the checklist to monitor compliance of the procedures regarding the acquisition by the entity of a good or service.

d) Tools that regard information resources.

It represents the totality of procedures, methods, processes used by the entity for the collection, processing, transmission and use of the information within the entity.

The information resources consist of: data, information, databases, information flows, means of information treatment information, information flows and make up the entity’s information system.

Analyzing all the activities, the information system should be established to permit a control over them in order to achieve the objectives. Thus, internal control conducted in this area should focus on:

- the accuracy of the information used;

- the continuous improvement of the system by: technical improvement and diagnostic analysis;

- the system supervision for each domain.

Therefore, the tools used for internal control and the procedures undertaken on each instrument represent effective means contributing to the work of the entity.

The documents used in internal control include:

- the internal control questionnaires elaborated to evaluate the internal control instruments;

- the analytical records that record the conclusions regarding the activities of the persons engaged in internal control activities;

- the synthetic documents elaborated to inform the entity’s management on the actions taken by the persons responsible for internal control;

- the list of risks identified and evaluated for a given activity, aimed at presenting risks as a result of the activities carried out;

- the synthetic evaluation document is

made by those responsible for internal control on each of these activities.

4. Conclusions

The internal control is perceived as a process engaged in: monitoring, verifying, developing procedures, recruiting personnel, improving it, production of documents, identifying risks in order to provide reasonable assurance that the assets are safeguarded and transactions are made in the best conditions.

This is not just a means to implement procedures/internal policies to ensure the achievement of objectives, but also a way of achieving performance for the identification and elimination of risks/hazards which the entity must face.

The Financial and Economic Crisis in Romania and the Possibilities of Recovery

Duduială Popescu Lorena

The University of “Constantin Brâncuși” Tg-Jiu

lorena_ucb@yahoo.com

Abstract

The world economy is currently still facing one of the worst economic and financial crisis since the Second World War. In fact, this crisis has spread worldwide with maximum speed, the economies of all Member States of the European Union encountering serious difficulties, both in the banking system and the real economy.

The purpose of this paper is to highlight what triggered the crisis in the global economy today, why not follow a particular thread and another, all with reference to the area where Romania is that the European Union, hoping to find a cure to the current problems of economic, social and political that we must face.

Keywords: economic crisis financial, economic recession, countercyclical policies, economic recovery

JEL Classification: F15, F41, F62

1. Introduction

If current economic and financial crisis has spread rapidly worldwide, EU Member States economies facing serious difficulties, both within the banking system and the real economy [3].

In fact, the speed and depth of the crisis shows how interconnected our world is. As the crisis unfolded, the importance of the community has become increasingly evident. The single market was the foundation of the EU economic growth over the past 15 years, creating millions of jobs, making Europe more competitive and efficient.

The overall impact of the financial crisis on the real economy is strongly felt, and the economy as a whole is affected by a

slowdown in the development of enterprise and employment.

In late 2012, the number of unemployed in the EU reached 21 million, and in 2013 will reach 25 million.

2. The evolution of the global crisis

To know where they will turn this global financial and economic crisis is carried out an analysis of events. So first there were some news about the U.S. housing market, which suffered a strong devaluation. There was shock at hearing the news that some banks and insurance companies in America went bankrupt and the state had to pay several hundred billion dollars to save them.

Then waves of the financial crisis were spread rapidly and in Europe. Spanish property market has collapsed. Major automobile companies in Germany breathe harder and Opel even suffocated.

Britain facing historic unemployment, with over 3 million people unemployed, Italy fall into recession and Hungary and Ukraine asking for help and emergency financial assistance from the IMF. Alone, France has maintained balance and not yet officially in recession [1].

The Moscow government is struggling to keep the ruble stable and throw billions of dollars in the market. Japan, one of the world's advanced economies symbols, and she surrenders to the recession.

After American banks, carmakers are great crisis overseas. Once the engine of the U.S. economy, three of the largest car manufacturers in the U.S. have sought help from Washington [5].

The crisis in the United States of America is worse than the most pessimistic expectations, even if the public expects of the best news. Thus, if at the end of 2011, optimism had made the U.S. economists to

forecast GDP growth for the last quarter of 2012 by 2.7%, then in May of 2012, for example, growth forecasts economic for the last quarter of 2012 reached only 1.5%.

Measures to stabilize the financial market, the easing of monetary policies and economic recovery plans will allow us to stop damage to the economy and create the conditions for a gradual recovery in the second half of the year. Priority is the effective implementation of those measures: improving credit flow at reasonable prices and timely implementation of fiscal stimulus packages to encourage investment and private consumption.

To increase reliability, it is essential also for Member States to commit explicitly to reverse the deterioration of public finances as soon as you get back to a normal economic situation, to ensure thus, medium and long term sustainability of public finances ", said Joaquín Almunia, Commissioner for economic and Monetary Affairs.

According to the latest projections by the European Commission in 2012 expected a decrease of 4% growth after, in 2011, there was an increase of 0.8%. Almost all EU countries are severely affected by the economic crisis, falling global economic growth and ongoing housing market corrections in some economies [2].

However, it is estimated that fiscal and monetary measures to be implemented will lead to the resumption of growth in 2013 (although the projections for 2013 show an increase of 0.1%). These figures - largely identical throughout the euro area and the EU - are lower than those presented in autumn 2011 and the forecast of January 2012.

In response to the economic crisis more acute facing the EU, the European Commission proposes measures worth 200 billion euros, aimed at increasing purchasing power, generate economic growth and create new jobs. This package of measures, short and long term, is 1.5% of EU GDP. Most of the money 170 billion, come from national budgets. The remaining 30 billion is allocated from the EU budget and the European Investment Bank funds.

The plan aims to protect the population, workers and entrepreneurs who may be affected by the financial crisis as it spreads throughout the economy. Proposes more support for these vulnerable groups, including investment to boost job skills and

help people to remain as long as jobs or find new ones.

EU will accelerate the distribution of social and regional funds - worth 6.3 billion euros - and intends to provide incentives for the hard-hit construction and auto industries to build greener cars and buildings energy efficient.

European Investment Bank, which provides long-term loans could play a greater role in financing major projects. B.E.I. has already prepared a package of loans worth 30 billion euros for small businesses struggling to obtain financing. Plan flexibility allowed under EU rules on national budget deficits, which give governments to temporarily borrow more in times of crisis.

The package is "big enough and bold enough to short-term results, but at the same time it is sufficiently reliable to turn the crisis into an opportunity in the long term," said President Barroso.

Jumpstarting the economy through investments in infrastructure, green technology, energy efficiency and innovation, the package proposed by the Commission plans to accelerate the transition to a knowledge-based society with low carbon. The plan also encourages partnerships between government and business.

Several European countries (including the United Kingdom, France and Germany) have already announced their own stimulus packages. The Commission calls on all nations to follow suit and act under EU auspices. Governments spend money in a way best suited to their own economy as challenges vary from country to country. The Commission will monitor national efforts to ensure that businesses do not confer competitive advantages in their country.

3. Libra financial crisis lean toward recovery

Since the first signs of positive exit for the Member States of Central and Eastern Europe can not speak alike, an economic and financial recovery.

As stated chief economist of the European Bank for Reconstruction and Development (EBRD), Erik Berglof: "In terms of growth, Eastern Europe will lag behind the rest of the world."

On the other hand, Western European countries, more powerful economically, will have to support the countries of Central and Eastern Europe, other countries, with remarkable economic and financial potential.

This leads to the idea of involvement of all member countries for economic recovery of the entire Europe, or, as Barroso said "Europe will become irrelevant."

The worst recession since the Second World War ended in the third quarter of 2012, when it registered a growth of 0.4% in the euro area, after five consecutive quarters of decline, the all the 27 EU countries, GDP growth was 0.2%, but between Member States continue to be significant discrepancies.

So, in Poland there have been considerable economic growth, but it is still concerned about the state of its public finances. The budget deficit this year would be 6% of GDP, peaking up to 7% in 2014.

In Slovakia, which joined the euro in 2012, GDP grew by 1.6% in the third quarter compared to previous three months.

Lithuania has achieved a quarterly increase of 5.1%, but compared with the third quarter of 2011, GDP fell 14.3%. But Latvia is in an even worse situation, with a decrease of 18.3 percent of GDP in one year. Estonia has had in the interval from July to September a negative economic growth of -2.8% compared to the previous quarter.

"Poland, Czech Republic and Slovakia, who have committed fewer mistakes, can look to the future with more optimism" believes Witold Orłowski, expert at PricewaterhouseCoopers.

In Hungary, the economy contracted by 1.8% from the second quarter and 7.2% annual rate, but with relatively low budget deficit in comparison with other EU countries, from 3.9% of GDP. Romania recorded in the third quarter of 2012 GDP decreased by 0.7% compared with the previous three months and 7.1% over the same period of 2008. Bulgaria reported in the third quarter of 2012 decreased by 5.8% of GDP annual growth rate, which is the worst result of the onset of the economic crisis, and analysts expect a recovery in economic growth in 2013

Optimistic signs of recovery were supported by a banking system that, in addition to the reduction in cases of

bankruptcy of financial institutions, leading to lending to the real economy.

Improving economy but takes place in a fast, given unemployment: Unemployment in the European Union (EU) rose in the last year and a half, reaching 9.2% (2.5% more), which is an increase of 6.1% in the number of jobs lost, totaling 22.1 million people.

EU countries most seriously affected are Ireland and Spain, where the unemployment rate has doubled in the past year, and in the Baltic countries even tripled, while Dutch and Austrian unemployment remained visibly decreased.

By applying adjustment measures such as reduced working hours, short-term tasks and temporary closure of jobs, reduce wages instead of firing them, seems to lead to an increase in unemployment. In this mode, Austria, Belgium, Germany, Italy and the Netherlands have focused, reducing productivity rather than downsizing. But an increase in unemployment longer durations of time could have a significant impact, given the reduced possibility of finding a job.

In this way, cyclical unemployment could turn into a structural problem. For example, in the EU, about 45% of the unemployed are left without a job within a year, while in the United States, the number is 10%. For the elderly, the average unemployment extends up to 14.7 months, while for skilled workers, time to find a new job is "only" 8.1 months.

The new strategy of the European Commission in 2020, seen as an exit strategy requires that every head of state and government to "establish a small number of objectives and policies to define appropriate action, to be pursued at EU level and Member States, in partnership". document defines four priorities for 2020: Innovation and knowledge, the fight against exclusion, green growth and digital Europe.

C.E. adopt formulas to adapt to the crisis by reducing redundant ceiling half, including redundancies due to causes other than world trade.

It has shaped an unprecedented interdependence. All Member States conduct more trade with each other than with the rest of the world. The best way to stimulate the economy is to build on this interdependence. Will intensify partnerships to overcome the crisis in a way that protects all citizens of the European Union.

Itself begins to rewrite the economic underpinnings that markets are not self-regulating, but reborn state theory interventionism launched after World War by John Maynard Keynes and implemented and the Great Depression of the '30s.

Contrary to economic theory, the current situation has shown that prices have fallen so much that it took government intervention to direct artificial economy.

On the other hand, the market can not self-regulate, because of the mistakes they committed companies to earn huge mistakes that lead to harm to society.

When we talk about geopolitical state we mean primarily the state, in turn, involves man as the fundamental unit, more complex words, institutionalized political man.

Geopolitics is directed towards expansion states, their relationships, which may be conflicting or congruent. Asymmetries between countries can lead to instability interstate, when the cartel is a first step towards stabilization, states tend to forums and intergovernmental organizations, are clear examples IMF, WTO or the EU.

States qua states to choose between increasing internal operation, external expansion or A combination of them. Revolution is internal limit, the limit is external world.

When are liberal, they are not ontological states, enter into productive logic, societal, edifying, and not subject to geopolitics [4].

4. The ways out of the crisis of Romania

Here are 10 things that Romania could do to stimulate the economy by encouraging consumption and export policy review:

1. Export orientation to markets that had good behavior in crisis, such as China (up 8.7% of GDP in 2012) and India (7.2% GDP growth forecast for 2012), the Asiatic continent, and even Brazil, in South America, would be a solution that might appeal Romania. Some of exports which, traditionally, they headed for the European market could be directed to these markets. Of course, export production should be reformed to be adapted as the standard of living there, much lower than that in Europe.

2. To benefit from the great crisis. If large markets not out of the crisis, then postponed

until such time as government financial support will be withdrawn savings.

3. Avoiding all forms of taxation that can lead to limiting consumption. So I think professionals should avoid increasing the value added tax, entry tax and fast - food, turned into a tax on foods containing additives, so most foods.

4. Further granting certain subsidies. Although they were often blamed by experts, state subsidies for utilities or other products and services managed in 2012 to maintain a high level of consumption in these sectors, as recently mentioned NBR representatives .

5. Additional programs stimulate domestic consumption guarantees. Experience has shown that they are the cheapest ways the public sector can encourage consumption. They do not involve giving money to the state, but only providing guarantees to encourage banks to issue loans. Also proved highly effective programs. Currently, the program provides guarantees to banks in the first house and first silo. Launching new or expanding old ones to new categories of customers, could encourage even more local market consumption, analysts say.

6. Appropriate monetary policy. Further lowering of key interest and maintain the course at a level that would not discourage exports, but let it not be dangerous to the financial stability of Romanians indebted in foreign currency, is the task of the central bank should pay to support consumption growth.

7. Negotiation with the EU agricultural subsidy extension periods, in order to encourage production in the field, may be another solution, even suggested local farmers.

8. Decrease public spending. "If you reduce the budget deficit from 7.3% in 2012 to 5.9% this year (targets negotiated with the IMF) will be made by cutting public spending, the state would not be pressured to substantially increase revenues, raising taxes and thus affecting the economy, "said representatives of ING Bank Romania.

9. Public sector financing from foreign markets. Unlike 2012, when the state does not allow outsiders to access loans because of the high costs this year costs have fallen more credits to Romania. The state could thus choose to provide the necessary funding,

especially foreign markets, not local banks (as happened last year). Such banks would have the necessary liquidity for lending to the economy.

10. Encouraging foreign investments, which are one of the main engines of economic growth. Low cost of labor, well qualified is the main advantage enjoyed by Romania in relation to markets in the area, when it comes to attracting foreign investment. To make Romania attractive to investors, but the state must contribute, in turn, the budget deficit to an acceptable level so that investors have confidence that the public sector will not reach raising taxes to get the money

5. Conclusions

After a year 2011 absolutely spectacular in terms of profits, 2012 was a decent year for banks, if one takes into account that demand for loans on the retail side was absolutely anemic, but last year was the perfect client state, providing banking a profit of about 185 million euros according to calculations by Business Standard.

Stands and increased operating profits, which means that if in 2013, provisions that banks will have to make up will be lower than in 2012, profits can increase significantly.

This year there is still profit targets, but provided that the banking system will be less profitable than last year, even if the banks will not ensure a profit as high as 2011. In this regard, there is increasing interest margins between active and passive, which means that this year, banks will earn more in interest differential.

If Romania would export more to China and India, countries that have successfully withstood the crisis and encourage domestic consumption by whatever method, then the economy would be likely to get by, even if major European markets remain in lethargy, experts say.

European foreign markets, with which Romania carried about 70% of trade, not out of the crisis, as was thought. German economy declined in the last quarter of 2012, compared to the previous quarter. France surprised, in turn, caused by excessive deficit last year, indicating that make great efforts to overcome the crisis country.

Therefore, the only solution for Romania to recover seems to be trying to stimulate rather domestic consumption and open trade with other markets more stable than European could make out of the crisis.

Abstract

Starting with the 20th century practitioners and academics have tried to correctly identify the dependency relations between the capital inflows and the macroeconomic equilibrium of an open economy and the intensity of them in order to create better macroeconomic policies capable to ensure the perfect capital mobility. The present paper aims to present and analyse the main contributions to the international capital flows theory focused on the economic growth in an open economy and the financial liberalisation.

Keywords: capital flows, open economy, financial liberalisation, economic growth

JEL Classification: G23

1. Introduction

Economists have, during the last decades, been constantly preoccupied with developing economic growth models, initially for closed economies, and later for open ones. The subject of economic growth in an open economy was approached starting with the relations between two or more countries: international trade and capital, human and technology flows.

After the 1940's, economic growth was traditionally approached through neo-classical models. These models try to explain economic growth as the general trend of the long term growth rate of per capita income.

2. The economic growth models in an open economy

The Harrod-Domar model – during the 40's, economists Row Harrod and Evsey Domar independently developed economic growth models based on the assumption that a constant ratio is maintained between the factors of production used in obtaining a finished good. This model focuses on two essential aspects of the growth process: savings and the efficiency of capital use in investments. This model can supply correct short term forecasts, and was widely used in developing countries to determine the required investment rate for a desired growth rate.

The Harrod-Domar model synthetises several equations in order to obtain the equation showing the calculation of the growth rate of income:

The model therefore shows that a higher savings rate will result in a higher growth rate, as more savings result in more investments and faster income growth. Its limitation consists in the fact that it maintains equilibrium only for a 100% employment rate and full capital utilization, leading to erroneous long term predictions. Additionally, the model disregards technological changes and productivity differences in using the factors of production, which are considered essential for long term economic growth.

Solow's growth model (the neoclassical growth model).

In 1956, Robert Solow created a new growth model, attempting to eliminate the

limitations of the Harrod-Domer model. Solow replaced the fixed coefficients in the production function with a neoclassical production function. The model allows the substitution of factors of production. The neoclassical production function takes the graphical shape of a curve, unlike the L-shaped previous model, as it allows flexibility in using various combinations of the labour and capital factors of production. Solow considers technological change as a cause of productivity growth. The neoclassical production function demonstrates that a capital increase or improved labour skills result in income growth. Solow assumes technological growth to be exogenous to the model, and that it can be accomplished in two ways: physical (in the case of capital assets) and human (improvements in education, health, labourer skills). Thus, the model identifies population growth and technological change as the determinants of economic growth, and these factors drive the incomes of rich and poor countries towards convergent long term trends. "The surprising implication of the Solow model was that the savings rate is not as significant to growth rate as under the Harrod-Domar model".

The Solow-Swan economic growth model was the inspiration for the first generation of growth models associated with exogenous factors of economic growth, also known as exogenous growth models. The focus on these models diminished after the 70's, when the issue of economic growth in open economies directed researchers toward other aspects: inflation, unemployment, petrol crises, increasing volatility of financial markets resulting from widespread use of variable exchange rates. Economists were thus preoccupied with creating macroeconomic policies that would tackle these new problems [1].

The second generation of economic growth models, dubbed endogenous models, appeared in the 80's – 90's with Romer's work.

Paul Romer's (1990) paper "Endogenous Technological Change"[2] signalled the birth of a new theory of economic growth. One of Romer's important contributions to economic theory is that on technological change. Of this, he says it is an economic good unlike any other and the driving force behind

economic growth, a result of the reaction of the human factor to market challenges.

The new generation of economic growth models targets several issues: deeper explanations of differences in international economic growth rates, more important roles for the accumulation of knowledge and monetary policy instruments in explaining the economic growth process [1].

An important characteristic of this new generation of economic growth models is the international perspective. The contributions for the past 20 years to economic growth theory have shown that an economy's openness has a positive effect on economic growth, when it is considered not only as international transactions of goods and services, but also as capital mobility[3], [4],[5], [6]. In reality, in some countries economic growth is possible only when they receive capital inputs that partly finance productive investments [7].

Bailliu (2000)[8] investigated the link between economic growth and private capital flows, concluding that three economic growth stimulation channels exist: capital flows can promote economic growth by raising the domestic investment rate, by investments with indirect positive effects on the economy, and/or by increasing domestic financial brokerage.

Most studies researching open economies growth models also identified proofs of a convergence process, by which poor countries tend to achieve faster economic growth, compared to rich countries ([5], p 103).

Reviewing economic growth models, we can conclude that the neoclassical theory assumes that capital flows will move from rich countries toward poor countries, since it states that investment yields are higher in developing countries, stimulating north-south flows. Starting with the assumption that different countries produce the same goods, generating the same income by using capital and labour as factors of production, and then per capita income differences will reflect per capita capital differences. Thus, if free capital flows were allowed, new investments would only be made in poorer countries, which would remain true until investment yields are equalized across all countries [9].

3. Modern approaches to the international capital flows theory

As we have shown earlier, the economic theory, whether it relates to the macroeconomic equilibrium whether brings into discussion the economic growth has developed models proving that achieving the economic growth is easier in the context of an open economy to international flows of capital, labour and goods.

This situation will increase the complexity of the issue of macroeconomic equilibrium because only theoretically the markets are efficient and guided only by supply and demand, in reality there are only imperfect markets that will not allow a perfect capital mobility so that both the actors in financial markets and goods and services markets and the macroeconomic policy decision makers will be forced to take into account that the information in the real markets is asymmetric which leads to the presence of phenomena such as moral hazard, adverse selection, market manipulation.

These phenomena adversely affect the efficiency of the resource allocation through the free movement of capital leading to inefficiency at best and in some cases triggering regional or global crises.

However, in the 60s 70s, while phasing out the regime of fixed exchange rates, the emerging economies have decided the liberalization of the national financial markets by opening the capital account in the hope of achieving an economic development driven by the efficient allocation of resources between economies.

According to the neoclassical theory of economic growth the liberalisation would have had to have the effect of an increase in the capital flows from the developed economies to developing economies.

In the literature, one of the theories coming to question the neoclassical theory is the so-called "paradox of Lucas". Lucas (1990) proves in "Why Does not Capital Flow from Rich to Poor Countries"[10] that, contrary to the predictions made by the neoclassical theory, the capital flows have no general direction from the developed countries to developing countries.

Lucas demonstrates this fact by comparing the U.S. with India at the level of 1988 and showing that, if the assumptions of

the neoclassical theory were true then India would have a marginal rate of capital of about 58 times higher than the U.S. and therefore the capital flows would be fully oriented in the direction of India which did not happen in practice.

Therefore Lucas questions the neoclassical theory conditions and also puts the issue that would be correct assumptions to support the direction of capital flows existing in reality.

Alfaro și Volosovych Kalemli-Ozcan ([9] p2) realise a synthesis of the literature and finds that the Lucas paradox triggered a lively debate, several researchers including Lucas showing that changes in the standard the neoclassical theory makes this so-called paradox disappears.

The theoretical explanations for this paradox can be grouped into two categories: one category includes the differences between the fundamental features of the economies that affect the structure of the production - technological differences, lack of inputs, government policies and institutional structure and a second category that focuses on the international capital market imperfections mainly the sovereign risk and the asymmetric information.

Another so-called enigma of the international capital flows is the "Feldstein-Horioka puzzle" and is considered one of the 6 puzzles of the international macroeconomic theory as it summarizes Obstfeld and Rogo in 2000. The intertemporal theory of the current account if we consider the possibility that an investor can invest in any economy (perfect mobility of the capital), then he chooses to invest in those countries where the yield per unit of investment is higher leading to the prices increase until the yield per unit of investment in different countries become identical showing no relationship between savings and investments in the sense that the determinants of investments and savings are different.

Therefore the countries should borrow or lend out when they want to invest or disinvest regardless of the saving decisions taken internally. Feldstein and Horioka (1980)[11] prove that this assumption is not valid for the OCDE countries where the rates of the domestic savings and the investment rates are highly correlated.

In the years in which the savings are high

so are the investments. They believe that the results show a low mobility of capital among OCDE countries. In the years that followed the publication of the results of Feldstein Horioka study the capital mobility among OECD countries continued to grow but the correlation between savings and investments has decreased very little [12].

The capital account liberalization in the developing countries in South America and Asia and the transition to the variable exchange rates in the 60s-70s has created a wave of enthusiasm in terms of the capital mobility as a catalyst for development and economic growth. Unfortunately, the crises that have affected the economies at regional or even global level resulted in an aberrant evolution in the dynamics of the capital flows.

Phenomena such as: the capital flows reversal, the sudden stop of the capital inflows, the abundant capital inflows followed by large capital outflows are studied by the recent literature under the imperative of seeking solutions to the risks and the disadvantages of a national financial system liberalization, subject to the financial contagion as the factor that determined the entry of most national economies into a deep contraction in the 2008-2012 period.

4. Conclusions

Practitioners and academics alike have tried to correctly identify the dependency relations between the capital inflows and the macroeconomic equilibrium of an open economy and the intensity of them and to create models, as noted above, but the practical utility of these models has proved limited or non-existent.

The enthusiasm that marked the decades 70-80 with regard of the globalization process and the liberalization of financial markets has moderated significantly in the early 90s when the former communist bloc economies have experienced major macroeconomic imbalances at the time of opening borders to the foreign investors and proved that the expected benefits than can be quickly cancelled by the risks that arise in an economy ruled by hyperinflation, with markets where supply and demand are disproportionate and with a weak external competitiveness.

The modern economies, open to the capital inflows, are put in front of a complex reality: the capital inflows due to the capital account liberalization and a high interest rate differential poses a challenge for the monetary policy and equally for the management of the capital outflows that, amid internal and international crisis, can generate imbalances affecting the financial market and the economy as a whole.

Ethical Dilemmas: Are the Accountants Doing Something Good or Something Bad?

Abstract

The question of title is about the ethical dilemmas which are involved into the accountancy profession. There are millions of accountants, who must do their jobs well each day and don't break the law, who have to rigorously apply accounting standards and professional principles in their work and who generally have to do something good, not something bad.

Society needs to have confidence in the quality of the services provided by professional accountants; their services should be highly competent, reliable, and objective. Therefore accountants must not only be well qualified but must also possess a high degree of professional reputation which is one of the most important possessions.

This paper realizes an evaluation of various libraries and electronic data bases, in order to provide radiography for these dilemmas ethically and in order to be able to talk about them.

Key words: ethics, accountant, ethical principles

J.E.L. classification: M 41

1. Introduction

In the past, has been pressure from various business and professional accounting bodies to place greater emphasis on ethics education and this is obvious in academic research and curriculum development.

There are many researches which are

done in accounting ethics field. Thinking about the kinds of ethical competencies that should be the objective of ethical education is quite a complicated and widely debated topic. It is difficult to develop a list of objectives for a course about professional ethics in accountancy.

The paper aims to identify the broad range of ethical issues associated with accounting, issues which are related to a fundamental set of values for accountancy profession.

2. The importance of ethics for accountants

Post Enron, WorldCom and Parmalat, there has been quite a lot of discussion of the ethics of accountants and professional ethics more generally, because the accounting profession is no stranger to these scandals, and also there are many others historical examples of individual accountants who have acted unethically in some particular circumstances. However, despite the massive scale of these debacles, it is surprising how quickly they have been forgotten and how little substantive change they really engendered. These historical and empirical cases present a series of quite fundamental ethical questions, such as: Why people do bad things, in spite to do good things?

In response to this crisis, the primary agenda of professional bodies has been to try to re-establish their credibility and legitimacy. The magnitude of the scandals, combined with the other major social shifts may just have disorientated professional bodies enough to cause them to reflect on

whether the task is simply a matter of re-establishing a relationship of trust, or more fundamentally re-conceptualizing it and making it work within a different cultural context. [1]

Accountants are confronted with broader ethical dilemmas.[4] Unlike the legal profession the obligation of which is primarily to an individual client, accountants, particularly auditors, can be regarded as having the public itself as the ultimate client. Because of the continuing globalization of business and accounting activity, the public will also become more global. Furthermore, the globalization of business activity is seeing a parallel process with accounting firms. Accountants participate in these developments either as employees of multinational firms or through international affiliated accounting firms, thus bringing accounting graduates increasingly into contact with different cultural and ethical values.

The level of political interest in the accounting profession immediately following the Enron scandal indicates that accounting performs a hugely important function within a market-based economic system. Perhaps it is because accounting is perceived to be a technical and fairly specialized subject that it is not exposed to more public debate and discussion. The lack of political debate and public discussion surrounding the role of accounting within contemporary society, however, does not reflect views from within the discipline. Over the past few decades a substantive body of research has given rise to a major school of critical accounting thought that challenges the conventional, technical view of accounting as a politically neutral and amoral practice. Influenced by this alternative perspective on accounting, this more critical school has begun to explore the ethics of accountants, the function and purpose of the accounting profession and the ethics of accounting.

3. Accounting ethics education

Because all mature professions have a well-developed code of ethics it is important for the future professional accountants to find these aspects into the education and training programs.

Research indicates that students

themselves strongly believe that ethics is an important issue in business and accounting, and that a lack of ethics hurts the accounting profession.

The academic community has also made calls for a greater emphasis on ethics education both in course content and accounting text books and various pedagogical techniques for teaching ethics have been put forward together with curriculum recommendations.

The most important problem is how ethics education can be increased or improved within the accounting curriculum.

In the past accounting education tended to be technical in nature and focused on the preparation of students for professional examinations. Coverage of ethics was generally restricted to discussion of professional codes in auditing courses and was not otherwise formalized or systematic.

In contrast, other professions such as law and medicine have had a long tradition of requiring ethics courses as part of their education. In present, the situation with accounting has changed, because ethics education is required as part of an accredited curriculum or professional program in most countries.

Many academics have expressed concern over the ethical predispositions of both accounting students and practitioners. Some studies suggest that accountants seem to exhibit lower levels of moral reasoning than other professional groups, and this possibility has led to a debate about the extent to which accounting education (at both the undergraduate and professional levels) either contributes towards or stultifies accountants' ethical development. Taken in its entirety, the literature presents the somewhat disturbing possibility that conventional accounting education has a more negative than positive impact on students' ethical predispositions.

The current research literature show that accountants appear to exhibit lower levels of moral reasoning than other professional groups and the accounting students become less ethical as they progress through their accounting education. Also, accounting students are less ethically aware than other students and they don't recognize the broader social responsibility issues associated with professionalism. Most accounting students think that accounting is an amoral and

technical activity. [7]

4. Accounting ethics in the new business context

Globalization, financial engineering, cross-cultural issues, the knowledge economy, information technology and cyber-ethics are just some of the characteristics of the new business context against which public concern is emerging. Intangibles, complex financial instruments and pensions are just a few of the associated ethical problems that the accounting profession is struggling to resolve. However, while this increased technical complexity has focused attention on the competence of accountants and the profession's requisite body of knowledge, these issues also problematize the profession's public interest claims. For example, while resolving the issue of how companies account for pensions requires a fairly advanced level of technical competence; the emotive and very civic nature of the issue also problematizes the profession's claim to be acting in the public interest. [1]

However, the increasingly complex and important role that accounting plays within contemporary society extends beyond the comparatively 'developed' economies of the West. The accounting profession is also playing an increasingly important role in development policy in relation to emerging economies through the influence of the likes of the World Bank and the International Monetary Fund.

Business, the traditional site of accounting, is becoming increasingly more complex but there seems to be a lack of public and political engagement with the ethics of accounting. At a time when societal expectations are increasing and business is becoming more complex, the traditional resources that may have provided the grounds for addressing these problems in the past has diminished and there is growing concern that we lack the ethical capacity within the accounting profession to engage seriously with these challenges. Despite its professional claims and its hugely important current socio-political function, many accounting students and practitioners seem to lack not only the competencies in relation to understanding the principles behind a

particular professional code, but more importantly they also seem to lack the ethical skills that would enable them to articulate the current set of rights and values which accounting promotes, critically evaluate this practice in the light of contemporary discourses, for example on corporate social responsibility, human rights and deliberative democracy, and generally participate in a dialogue about the function and the future of accounting.

Studies indicate some level of concern over the ethical maturity of accountants in particular, there appears to be similar unease within other professional bodies over the level of ethical competence of their members, like lawyers or doctors. Also studies show that an accountant as individuals lacks the capacity to recognize what is good behavior and do it and the ability to analyze accounting ethically within its broader organizational and political/economic context.

People are not willing simply to accept what those in authority say anymore. The trend here seems to be a shift away from a reverence for and deference towards the professions, to viewing professionals in some partnership role, a shift that is also part of a broader socio-political movement for greater deliberative democracy.

Accounting ethics education, therefore, should aim to equip students with moral expertise, which may be later evidenced by their ability to make ethical judgments. [5]

A study of ethics could increase their skills for systematic analysis of moral beliefs and attitudes, and their capacity to handle the conflicts in values that can arise between practitioners, clients, and society in actual business settings. More specifically, seven possible goals of teaching ethics in the accounting curriculum have been identified. [8]

They include:

- to relate accounting education to moral issues;
- to recognize issues in accounting that have ethical implication;
- to develop a sense of moral obligation or responsibility;
- to develop the ability to deal with ethical conflicts;
- to learn to deal with uncertainties of the accounting profession;

- to set the stage for a change in ethical behavior; and
- to appreciate and understand the history and composition of all aspects of accounting ethics and their relationship to the general field of ethics.

5. What factors influence the way accountants respond to ethical dilemmas?

There are studies which discussed above how could determine whether one person or profession is more or less ethical than another. It is necessary to imply some objective scale of morality. A considerable number of the comparative studies draw on the work of Lawrence Kohlberg and his model of Cognitive Moral Development (CMD). Kohlberg's model is routinely used to gauge an individual's moral maturity based on their responses to a series of hypothetical dilemmas. [1]

In general, personal characteristics which have impact on ethical behaviour are:

- *Gender* (females are more ethical than males, show the studies, and have different kinds of attitudes towards ethics and codes of ethics, so a good way to resolve ethical problems in large accounting firms is to employ more woman);
- *Age*;
- *Moral maturity*;
- *National culture* (accountants of different nationalities have disparate perceptions of what is and is not ethical, so international differences in ethical values could impede the effectiveness of the IFAC Code of Ethics for Professional Accountants);
- *Organizational culture* (the characteristics and dynamics of the groups to which accountants belong may affect the way in which individual accountants encounter and resolve ethical dilemmas. Individual ethics depend, also, on the position and level an individual occupies within an organization: increase as they attain supervisory levels, but decrease among managers and partners).

Both individual attributes (moral maturity, age, gender, nationality) and structural or contextual characteristics (national and organizational culture, group and role) influence individual

ethics.

6. Conclusion

As evidenced by so many accounting scandals, many of the goals of accounting ethics education have become extremely important today and it is necessary to convey to accounting students the importance of professional responsibility.

Attempts must be made in accounting curriculums to either address ethics issues at the course level similar to the professional responsibility course described in this paper or at the curriculum level throughout the accounting program and an increased exposure to ethical situations is needed in the accounting curriculum.

The future of the accounting profession depends on ethical leadership by accounting professionals and accounting educators. Accounting profession and academics should focus on calling individuals to excellence. By presenting the importance of high ethical standards, by teaching the importance of personal integrity, will be assured current and future of accountants like professionals.

Ethics is apparently a critical issue in accounting practice and, consequently, to accounting education. Colleges and universities have no choice but to take up initiatives to improve ethical standards among future accounting professionals.

Some Considerations on the Fiscal Fraud Resulted from the Assignment of Social Shares

Dumitrescu Serju

Abstract

In our paper we shall try to present two mechanisms of fiscal fraud used when assigning the social shares held by natural persons at limited corporations. The first mechanism of fiscal fraud will refer to the assignment of social shares belonging to a corporation that registers commercial obligations to creditors and suppliers or fiscal obligations to the state institutions. The second mechanism will refer to the assignment of the social shares held by a corporation that has obtained a profit for several years and whose net asset is positive when the sale occurs. The fiscal fraud, empirically researched, will be presented through certain figures in which we will present in detail the operations which appear in both cases. We have to mention that the cash payments from the assignor to the cessionary, in the first case, and from the cessionary to the assignor, in the second case, usually „slip through the fingers” of the fiscal organs as they are not fiscalised although in both cases we identified incomes that should be imposed with a 16% taxation representing the share of income tax.

Keywords: fraud, social shares, assignor, cessionary, assignment

JEL classification: H 26

Introduction

It is well known that there are firms which „manage” to accumulate important debts towards creditors, suppliers and the consolidated state budget along their activity. There are also other firms which are created

in order to „participate” to schemes of frauding the fiscal obligations owed by other economic agents. In both cases in order to „get away” with a huge number of accumulated debts or in order to restrict the research performed by the fiscal organs, the associates assign the social shares held by them in the social capital of the firms. The strategy is quite simple because the persons who are involved in such operations are usually foreign citizens, sick persons, persons with a reduced level of education or people who don't have any income or possess any goods. The reason for involving such people in the operations is easy to understand because it is practically impossible to collect in any way the obligations owed by that particular economic agent. In other cases the purpose is to make it impossible to check the reality and legality of the operations performed in the frauding schemes which have as a consequence the diminution of the fiscal obligations. We have to mention that in the presented cases we will refer to the assignment of the social shares in a general sense and we shall refer to Law no. 31/1990, with further modifications, regarding the commercial societies. It is necessary to mention this because in some situations (see here the warehouse owners who are authorised for operations with excisable products) it is obligatory to inform the fiscal organ with at least 60 days before performing the assignment of social shares. It is required to inform the fiscal organ, in order to perform the fiscal inspection, for the warehouse owners whose authorisations have been canceled, revoked or suspended. In the case of the authorised warehouse owners the operations of assigning the social shares

without informing the fiscal organs can be canceled.[1]

Fiscal fraud resulted from the assignment of the social shares to a commercial society with debts

Most of the times the frauds are based on certain strategies performed by the participants to such operations, strategies which take into account the risks to which the participants are exposed to in case they get caught. In the case of fiscal fraud, some „artificial steps” are introduced to avoid the payment of the owed taxes or the reduction of these obligations. The British lawyer Lord Templeman (2001) stated that: „A tax avoidance scheme includes one or more interlinked steps which have no commercial purpose except for the avoidance of tax otherwise payable, and can conveniently be described as artificial steps. A tax avoidance scheme does not leave the taxpayer any better or worse off but leaves the Revenue worse off”. [2]

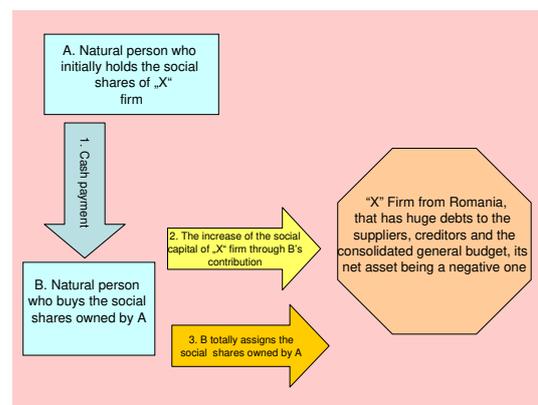

To better understand the phenomenon of avoiding the payment of obligations, in the case of assigning the social shares to a commercial society we have to consider some legislative aspects. If we consider the assignment of the social shares in the case of a limited corporation certain conditions need to be respected: [3]:

- the social shares can be assigned between associates without any restriction;
- if the assignment takes place between persons which do not belong to the commercial society this can be performed only if it has the approval of $\frac{3}{4}$ from the shareholders or the associates who owned social capital;
- if the approval is obtained, the decision of assigning the social shares is to be registered within 15 days to the Office Trade Register in order to be published in the Official Monitor; the same decision has to be communicated through an electronic system by the Office Trade Register to the Finance Ministry and its county representatives;
- starting from the moment when the decision has been published in the Official Monitor any interested person can appeal to Court within 30 days.
- if there is no appeal the assignment of the social shares is to be operated within 30 days from the moment of publishing the

decision in the Official Monitor; if there is an appeal, the assignment takes place in the moment when the rejection decision is communicated.

In order to avoid the appeal (done by any person interested in the assignment of the social shares to other persons who are not associates) there are to be undergone some “intermediate steps” which are to be presented in Figure nr. 1 “The avoidance of opposing the assignment of the social shares”

Figure nr. 1-Avoiding the opposition to the assignment of the social shares

Source: personal interpretation

Here are the intermediate steps undergone to avoid the opposition:

- taking into account that „X” firm registers significant debts to suppliers, creditors and the consolidated general budget, A (the person who initially owns the social shares) tries „to get rid” of them; A decides to perform a cash payment „in black” toward a new B associate who accepts to take over a firm that has losses and debts too; B associate is usually a poor person, or a foreign citizen who is difficult to identify or if he/she is identified it results that he/she doesn’t possess any assets. In this case the supplier, creditor or any fiscal institution can’t recuperate the claims regarding „X” firm.

- Immediately after the B associate has been paid „in black” we identify an increase in the social capital justifying the contribution of the B associate at the social capital of „X” firm (even if this contribution appears just in the documents); after this operation has been performed A associate owns a share of the social capital of the firm

while B associate owns another share according to the papers;

➤ a few days after the increase of the social capital, we can observe the total assignment of the social shares held by A natural person, so that after the operation, B natural person becomes the only associate in the firm.

We observe that „the increase” of the social capital reduces very much the period in which the social shares of a firm can be assigned so that within a few days the suppliers, creditors and the fiscal organs can't recuperate the claims held by that particular commercial society.

In some situations there are also other „operations” taking place when the assignment of the social shares occurs. Here are some of them:

➤ „the production of documents” to attest the fact that the initial associate A transfers everything to the new associate B; everything includes here the archives with all the accountant/bookeeping documents of the X firm for the entire period of time when it has performed an activity, i.e. from the moment when it was founded up to the assignment moment. We can also identify situations when A declares the archives with all the firm's documents as being lost; this happens before the assignment of the social shares from A to B;

➤ in the above mentioned situations the fiscal organs can't prove the reality or legality of the commercial operations performed by the economic agent in the period when the firm was owned by A natural person;

➤ if A natural person is the same person who was responsible with the bookeeping of X firm he will also „declare” as being lost the electronic accountant evidence; This electronic evidence consist of: balance sheet, trial balance, sales journal, purchases journal, register journal, analitical charts for suppliers and clients. We have to mention that according to accountancy Law [4], all the firms that keep their accountancy in an electronic format are obliged to store the data for a period of ten years and to allow the fiscal authorities access them.

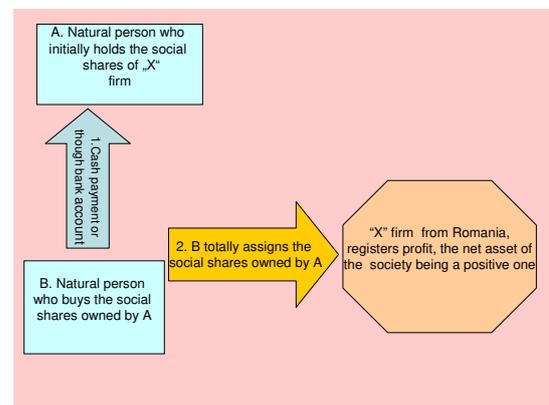

➤ in the given situations the control organs can only rely on few information such as: cross checkings for all the natural and juridical persons who had commercial relations with X firm, the accountant reports

and declarations delivered by X, the declarations performed by other persons in regard with the commercial relations performed with X and other types of documents provided by the banks where X firm opened its bank accountants.

The fiscal fraud resulted from the assignment of the social shares of a commercial society with a positive net asset

The second case we have chosen to analyze will be presented from the perspective of the fiscal organ and it refers to the assignment of the social shares belonging to a limited corporation that doesn't register significant debts to suppliers, creditors or any fiscal obligations to the state general consolidated budget. The net asset at the moment of the assignment is positive what shows us that the economic agent holds assets such as: fixed means, claims, cash in lei or other foreign currency. We mention that these assets exceed the accumulated debts for suppliers, creditors or the fiscal organs up to the assignment moment.

Figure nr. 2 The avoidance of paying the tax on income resulted from investments

Source: personal interpretation

Unlike the Figure nr. 1 "Avoiding the opposition to the assignment of the social shares", when the person who assigned the firm paid "in black" another person to receive the social shares, in Figure nr. 2 "The avoidance of paying the tax on income resulted from investments" we observe that the person who purchases the social shares directly pays the sum of money to the person

who decided to give up his social shares. In order to avoid a 16 % tax, stipulated by the Fiscal Code [5], the tax applied to the difference resulted from the selling value of the social shares and their nominal value there are used different methods:

➤ in the contract signed on the occasion of assigning the social shares, the selling value for a social share is its nominal value obtained from the rate between the firms social capital and the number of social shares issued. Because the selling price for a social share mentioned in the assignment document is equivalent to its nominal value and the tax on the investment income is applied as a percentage on the difference resulted from the selling value and the nominal value of the social shares, we easily deduce that the owed tax is 0. In order to cover the difference between the net value of the social shares at the assignment moment and their nominal value, a cash payment takes place but „in black” from the person who buys the social shares to the one who sells them. The payment from the cessionary to the assignor of the difference resulted from the selling price and the nominal value of the social shares can be performed through bank transfer as an operation between natural persons- for example: loan approval, loan return, cash advance acceptance, cash advance return;

➤ in the assignment contract the selling price of the social share is not mentioned, the only reference being made to the nominal value so that the contract doesn't clearly specify the selling price of the social share.

In the above mention conditions although the fiscal organs are entitled to impose a tax on the difference resulted from the selling value of the social share and its nominal value, they can not do that because they lack the fiscal resources [6].

We consider that right now the Law of the commercial societies is very permissive when it refers to the assignment of social shares and social capital increases.

In order to remedy such deficiencies we suggest the following:

➤ the social capital increases performed by other persons than previous associates or shareholders should be based on evaluation reports drawn up by accountant experts, financial auditors or evaluators, who are credited by the professional organisms they

belong to. Their evaluation reports should reflect the net asset at the moment when the social capital increased. If the net asset, mentioned in the report, is negative the sum of money brought to increase the social capital should be at least similar to the net asset value so that the assignment of the social share could be registered at the National Office of Trade Register. If this condition is not carried out, the social capital increase must be communicated by the National Office of Trade Register to the fiscal organ and the assignment can be performed just by having the fiscal organ's approval.

➤ the total assignment of social shares or other shares to other persons than previous associates or shareholders should be based on evaluation reports out of which we should clearly identify the asset at the assignment moment. If the net asset is positive the selling value of the social shares or other shares enrolled in the assignment contract should be different from the nominal value. The difference between the selling value and the nominal one is to be taxed when considering the tax for income resulted from investments. [6].

Conclusions

In the case of the first presented fiscal fraud mechanism, its effect will be perceived by the creditors and suppliers for the commercial obligations and by the fiscal organ for the fiscal obligations owed by the assigned commercial society. In the second case of fiscal fraud, the assignment of the social shares will affect the fiscal organ because the person who sells the social shares tries to avoid the payment of the 16 % tax on investment income. The phenomenon of tax avoidance should be regarded from two perspectives:

➤ the perspective of the one who has to pay his fiscal obligations to the state;

➤ the perspective of the fiscal organs who have the obligation to watch if the fiscal regulations are obeyed by the tax payers.

From the tax payer's perspective, the fiscal obligation is seen as an act of „giving up your work” in another person's favour, in this case the other person being the state. If the tax payer identifies „the flaws” of the legislative framework and doesn't feel that

the state offers him something in return to his fiscal obligation, in this case the taxpayer takes the risk of using different means to reduce the owed fiscal obligations.

From the perspective of the fiscal organ, the obligation owed by a taxpayer is seen as a vital resource for an appropriate functioning of the state institutions. In this case the state should find the right solutions to reduce the possibilities the taxpayer can use in order to avoid the payment of taxes.

The state has also the obligation to make the mechanisms of fiscal equity work, so that the tax should be perceived by the taxpayer as a part of his work while the state should ensure the proper conditions for the right functioning of his activity [7].

We appreciated that in order to have a solid social and fiscal equity there should be a system to check the correlation between the goods, assets and obligations of a natural person and the income obtained by the same person, the income that has been declared to the fiscal organs by the person itself or by others.

We also mention that according to the last legislative changes, stipulated in the Code of Fiscal Procedure in January 2013[8], any natural person who is under investigation for income tax has the obligation to present a declaration of patrimony and income, as requested by the fiscal organ. The sums enrolled in the income declaration should justify the source for the goods which are mentioned in the patrimony declaration.

Abstract

In this article we aim to present a side of the nonfinancial reporting, which is more and more presented by the companies all over the world: the social reporting. In order to do this, we present a review of the requests included in the Romanian regulations in force regarding this aspect and the way these requests are solved by an ERP system, named here MF ERP, as we consider that the ERP is a strong IT tool which can be used by the accountants for reporting purposes as well.

Key words: nonfinancial reporting, human resources, management control, ERP, regulation

JEL classification: M41

1. Introduction

In the last years, because of the impact of the environmental changes on the quality of the human beings' life the companies involved in more aspects. Their responsibility grew from a financial responsibility to a broader one called “societal.” This new type of responsibility was amplified after 2000 because of the profound changes affecting the world in general (the terrorist attacks, the war in the Middle-East, the world economic crisis) and the business world in particular (the corporate collapses of Enron, Parmalat, Worldcom etc.).

In front of these social changes, a new type of reporting appeared: the “non-financial” one. Thus, more and more companies disclose voluntarily information concerning the social and environmental impact of their activities in order to limit the negative impacts and their performances in this area.

The human being is the most important resource of the company. The profitability of the company is born out of the coordination of the human resources elements. The relationship between the economical performance and human performance at the level of a company is very tight [2]. Even if this relationship cannot be measured directly, there is a range of indicators that can do this.

Our study is conducted in order to present an aspect of the societal disclosure: the social disclosure. The target of this research is to surprise the managerial HR reports presented by a Romanian ERP in the hypothesis of a better understanding of these reports and the reasons of the companies presenting them.

2. Previous studies concerning the HR disclosure

HR is an element of the intellectual capital, intangible in nature that creates substantial value for the company because of its individual and collective

competences developed. Starting from 1960 [10] in USA the concept of Human Resources Accounting was developed. The first company interested in applying it was RG. Barry Corporation. It included the HR as assets items in the company's statement of financial position.

In France at the end of the years 1970 [5] appears the idea of a Social Statement of Financial Position.

Another author [6] presented in his work the objectives and the range of the social management control; the main social indicators, classified in economical and financial, structural, training, payment, attitude and professional risk indicators; the “human” dimensions of the French “tableau de bord”, balanced scorecard and skandia navigator and their recent developments. He concludes that the disclosure of the human management dimension in the performance reports needs an improvement of the existing tools.

Other authors [3] prepared a study supported by an empirical survey performed within 79 companies concerning the level of development of the social responsibility indicators as management control tools. The study showed that the indicators connected to the social responsibility have a low presence among the driving instruments of the company. They are also little connected to the strategical objectives, when they exist. They also show that mainly the companies quoted on the SEC and the industrial companies present the most developed practices for driving the social responsibility.

Another author [9] tried to synthesize the methods of assessment and recognition of the intellectual capital in the financial statements. She presents various opinions regarding the possibility of the recognition of the intellectual capital and the extent to which there is a need to recognize it. The conclusion of the paper is that, the traditional accounting system needs to be extended

to capture the company's value creation potential and to be based on the effectiveness of its response to the stockholder's expectations as well.

Other authors [7] asked themselves which are the axes of intellectual capital disclosure in the annual reports of a recently privatized company and what would be the challenges, risks and benefits involved of such disclosure. They analyzed the financial statements of Petrom Company on a three years period. The study is interesting, as the foreign company that took over the Romanian company brought an important intellectual capital. Their conclusion is that this company presents most detailed information concerning the structural capital and less detailed information concerning the human capital.

In Romania, The National Statistics Institute asks from the companies that fulfill some conditions to present the following items regarding the human resources disclosures: the number of employees at the end of the year, the average number of employees at the end of the month, the time worked in normal time and supplementary hours, the gross amounts paid out of the wages fund; the gross amounts paid out of the net profit; the gross amounts paid out of the other funds; the gross amounts paid out of the social insurances; employees contribution to the health budget; employees contribution to the social insurances budget; employees contribution to the unemployment fund; the wages tax; the average gross wages; employees structure on sexes, occupations and income categories.

Some researchers consider that there is an impact of the information technologies on the management accounting [1], while other studies cannot offer such a certainty and consider that the impact is indirect, through the control system [8]; [4]. In this paper we focus on the impact of the introduction of an ERP as a form of information technology.

3. Research methodology

In order to explore real-world implementation of a management control model, we used the fundamental research (for the literature review). We also aim to present the situation of the Romanian companies concerning the indicators and reports requested by the management regarding HRMC. In order to do this we will present a set of indicators included in the Manager Financiar ERP (**MF ERP**).

4. Indicators provided by MF ERP

Indicators and reports prepared by controllers for managers are in direct relation with the activities that have to be identified by MC. HRMC must be directed towards eight activities:

- i) economical and financial indicators;
- ii) structural indicators;
- iii) planning and recruitment;
- iv) compensation;
- v) training and development;
- vi) performance appraisal;
- vii) climate indicators;
- viii) professional risk indicators.

We will use this classification in order to present the indicators included in **MFERP**.

i) Economical and financial indicators

The indicators that we can suggest and the way the **MFERP** computes them can be presented as follows:

- Productivity: turnover/number of employees; added value/number of employees or gross wages etc.

The program computes these productivity rates because the user can introduce all the elements required, when computing the wages.

- HR expenses: personnel expenses/number of employees; gross wages/turnover etc.

All the components of the HR expenses are presented in **MFERP** because it computes the wages so that it can compute more than the rates on the left (for instance, average net wages, total value of the taxes paid by the company and by the employee etc.).

- Financial rates: human economic value added; human capital value added; human capital return on investment; human capital market value.

All these indicators can be computed in **MFERP**, because all the preliminary data is included in the database. The program can compute any rate because it has a generator, where the user himself can define the rates.

ii) Structural indicators

The structures that we can consider are: productive, administrative or distribution employees; professional equality between women or men; percentage of employees belonging to national minorities; percentage of handicap employees; employees distribution on ages; distribution on average wages.

MFERP includes a set of graphics, among which the structure of the employees by the function of the company. In Production module it also computes the expenses (gross wages and company's taxes) on each function.

iii) Planning and recruitment

Indicators concerning the planning and recruitment activity are: activity total cost; number of employees; employees' salaries; number of interviews; number of recruitments; average cost for recruitment; the degree of the coverage of the necessary personnel; candidates rejection rate etc.

We couldn't find a special function for planning and recruitment activity in **MFERP**. However, some of the reports can be encountered in the software. Among these, we can mention: expenses

concerning the Planning and Recruitment Department, number of persons working in this department, and employee’s history – that presents the activity of the employee within the company and before being hired by the company.

iv) HR compensation

HR compensation indicators considered include: total employees number; employees’ salaries; average salary; average salary for men and women, hierarchical level and geographic area; the evolution of the wages on geographic areas and hierarchical level; average cost per hour; total productive workers expenses; total administrative employees expenses; total distribution employees expenses; degree of the yield/work productivity; supplementary hours/medium cost per supplementary hour.

MFERP includes plenty of indicators concerning the remuneration: gross wages, presenting separately the basic wages and each type of bonus for special conditions, medical leave wages, rest wages, contributions to social security, health, unemployment funds, wages for each department, number of normal and supplementary hours worked, average cost per hour etc. It also presents the way it computes the bonuses, for instance, for the sales agents. Usually, the employees are introduced per department. In this case, indicators concerning the activity of Wages department, for instance, can be selected. However, the program doesn’t compute automatically the rate of the increase in the purchase power, for instance. We consider that the ERP shouldn’t for instance compare the wages within the company with the wages in other companies in the same activity sector.

v) Training and development (T & D)

To realize training and development targets companies often devote ample

resources presented in budgets. These resources are allocated to the employees that have the motivation to stay within the organization. This is why we split the report in two parts:

- Maintenance and motivation of the employees (adapted from [6]): fluctuation rate/ fluctuation costs; cost-benefit-motivation analysis; the time spent by the employees within the organization; the reasons of the personnel for leaving the company etc.

In *MF* the user can compute the time spent by the employees within the organization and can introduce the reasons of the personnel for leaving the company. Yet, more “qualitative” analysis like cost-benefit-motivation analysis cannot be made automatically.

- T & D activity (adapted from [6]): total resources amount; T & D effort: total resources amount/number of employees; actual amounts/budgeted amounts etc.

In order to prepare the budgets or the indicators regarding the T & D actions, the user can introduce into the database the following information: total number of employees, total number of trained employees, number of training programs, number of training days, cost of training, name of the training program, quality obtained at the end of the training program, the time spent by the employees in the organization, the jobs performed by the employees in the organization etc. The software has no special function for assessing the impact of the T & D in saving the resources within the company or the degree of jobs coverage and strategic competences. *MFERP* includes functions for preparing the budgets. The items presented in the budget can be introduced by the users. They can be either quantitative or qualitative indicators.

vi) Performance appraisal

Performance appraisal is a way to evaluate how well employees have met expected levels of accomplishment compared to some standards or goals. Performance appraisal influences HR decisions on such issues as pay, promotion, training and development. The appraisal may focus on outcome measures such as levels of quality, productivity or financial performance. Values and methods in performance appraisal may be presented as follows: direct individuals or direction to the work force; control people and processes; feedback used for ratings, rewards and sanctions; feedback useful for improvement; motivating or demotivating employees.

Indicators concerning the performance appraisal can be found in the previous sections, both as suggested indicators and as indicators encountered in *MF ERP*.

vii) Climate indicators

These indicators can be classified as follows (adapted from [6]):

- Rotation: Number of persons leaving the company during the year/number of employees (this rate can be presented per reason for leaving);

The rate can be presented in *MF*, but not for reasons of leaving.

- Stability rates: Number of persons employed after N months/number of persons recruited N months ago; Time spent by the employees in the company;

The indicators concerning the stability in the left side of this table can be extracted from *MF*'s database.

- Absenteeism: Hours of absents/Theoretical hours; Hours of absents/Number of employees*Theoretical hours etc.

The information regarding the number of absents per person is introduced in *MF* when introducing the working hours of

the employees. However, the absents reasons are not included in the database.

- Conflicts: Frequency; Range: number of persons adopting an attitude; Intensity: number of hours or days of work lost; number of hours or days lost for the strike; Range: number of persons on strike/number of employees during the period.

The indicators regarding the conflicts are not included in the *MF*.

- Other crisis indicators: Number of production incidents (errors etc.); The increase in the number of working accidents; The increase in the documents of complaints.

For example, the number of working accidents is included in the database along with the medical leaves and the all the documents are registered in the software accompanied with a short presentation of their content.

- Personnel satisfaction: Study concerning the personnel satisfaction performed by an independent person.

This is an external report and shouldn't be included in the ERP.

- Personnel involvement: Survey regarding the organizational involvement.

This is an external report and shouldn't be included in the ERP.

- Strategic alignment: Survey concerning the knowledge and acceptance of the strategically focus of the company by the employees.

This is an external report and shouldn't be included in the ERP.

- Suggestions of the employees: number of suggestions taken into consideration by the management etc.

The suggestions of the employees are introduced in the system, as well as the answers received, just like all the other documents.

viii) Professional risk indicators

The professional risk indicators include: frequency rate regarding the permanent working incapacity and importance of the temporary working incapacity.

In this case all the necessary information is presented in *MFERP* in the section concerning the medical leaves: the reason of the medical leave, the nature of the working incapacity, the payer of the medical leave (the company, the social security fund, the health security fund), the duration of the medical leave etc.

Conclusions

The management of the HR is more and more complex. We started this research by presenting human capital concept, because this notion is used to calculate sustainable development indicators. For all the countries it is necessary to value the human capital, but this is a difficult action. The value of human capital is determined based on human resource components for each company.

The economic environment along the social system has to suggest a strategy at the HR level, taking into account the demographic evolution, but also the professional qualification.

The preparation of different reports for managers needs information about expenses, costs, number of employees, types of jobs, types of activities etc. Some information is obtained from HR department (employees, jobs, activities) and often from accounting department (costs, turnover etc). We could see that a part of the information is included in the database of a Romanian ERP that we analyzed in order to see the offer of HR

indicators and reports for the Romanian managers.

Aspects Regarding the Influence of the Governance Structure on the Company’s Performance

Georgescu Cristina Elena
Ovidius University of Constanta
crisrina.georgescu95@gmail.com

Abstract

The corporate governance is one of the key elements for improving economic efficiency, particularly in the current context of financial global crises. This paper discusses the relationship between corporate governance and firm performance. We intend to present the classic and new comings of scientific literature on the topic. Beside the theoretical approaches we also intend to present the practice poin of view, in order to give a complex image over the topic and suggest new progress on the matter.

Key Words: Corporate governance; company’s performance; performance measurement.

JEL Classification: G32, D 23.

1. Introduction

In this era of globalization, competitiveness growth and salience of financial flow mobility, corporate governance has become one of the key elements that have a high impact on companies’ performance and implicitly on national companies. Due to its implications with the efficient allocation of resources on a national scale and economical performances growth, corporate governance has proven to be an essential factor economies.

Corporate Governance is an increasingly complex concept ranging over many fields from business administration, economics, accounting, law and more recently ethics and social sciences.

Corporate governance has managed to attract strong public interest, due to its obvious importance to the economic health of corporations and of the society in general. However, the corporate governance concept is not clearly defined, due to the fact that

there is an array of different phenomena and economic operations encompassed within its scope.

2. The connection between corporate governance and the company’s performance

Performance is situated at the center of the contemporary problem of company governance [7]. The main idea of this issue is rather simple: well elaborated and articulated structure and governance mechanisms that operate in an efficient manner, must lead to a high level of profitability for the entity, generating significant economical performances, which can guarantee a high level of financial performance and an estimable stock value of securities for shareholders.

The connection between the company governance and performance is complex and may, sometimes, even be troublesome. The main leverages for solving the agency and governance issues are monitoring and performance measurement. As regarding monitoring, the basic occurring issues are related to the external and internal bodies that can provide it, as well as their independence. As for performance measurement, it is conditioned by the information entered into the measurement system and the instruments used [14].

3. The company performance concept

In the economic theory there is a variety of opinions concerning the definition of the company performance concept, thereby, there isn’t a generally accepted definition of the company performance term. Therefore, some economists approach performance through the outlook of the company’s target objectives, making reference to the degree of achieving them, others regard it as the

measure of the value created by the company, while a third category see performance in terms of the productivity and efficiency of the company's activity. Consequently, we will carry on by presenting the various acceptations of the performance term, as they have been set out throughout the previous century, leading up to the modern performance approaches.

Starting with the vision of the company as a “group of people carrying out common activities oriented towards the accomplishment of one or several objectives” [12], performance represents „*the degree by which an organization, as a social system, with certain resources and means, accomplishes its objectives*” [16]. By this acceptance, performance involves its analysis in relation to the set out goal, requiring the existence of certain (internal or external) references, to which the reference will be made. This first assessment of performance is, however, heavy with subjectivity, being that it completely depends on the objectives set out by the company. Hence, the companies that have established modest objectives may assess performance as being high, if the degree of objective achievement is high, while other companies might consider the same level of performance as low, in relation to the low level of fulfilling more ambitious objectives. As a result, the same level of performance may be appreciated differently.

Tannenbaum and Shimdt [16] have studied organizational performance by using quantitative measurements. They have described performance of an economical organization by means of its level of reaching objectives and by focusing on “work productivity, net profit, the degree by which the company fulfills its mission and its success lies in maintaining or growing”.

Lavalette and Niculescu [10] suggest a similar definition, by showing that a company's performance follows „*the achievement of organizational objectives, regardless to their nature or diversity*”. As such, in their opinion, performance only depends on the degree of fulfilling objectives, without taking into account the specialty of each company. However, coming back to the meaning of the notion of performance, the same authors describe it as being „*a company's state of competitiveness, reached*

through a level of efficiency that ensures its long-term presence on the market” [13]. Thusly, according to this last definition, a company's performance is the result of the efficient and effective activities carried out by said company. It is, however, in this context, necessary to point out what the notions of efficiency and effectiveness mean. Efficiency, as defined by Drucker [6] means “doing things right”, while effectiveness means “doing the right things”. Hence, in economical terms, efficiency implies either maximizing the obtained results, while having a certain quantity of resources (maximizing value), or minimizing the quantity of resources used with the purpose of obtaining a certain result (minimizing cost).

From this perspective, in the eyes of Philippe Lorino [11], the performance represents „*all, and only all, that contributes to the accomplishment of the strategic objectives*” of the company, as well as „*all, and only all, that contributes to the improvement of the cost-value pair*”. That is to say, that defining performance is no longer amounts to obtaining the results wanted by the company, but is now viewed in terms of the cost-value pair. This definition of performance reveals a new approach, respectively, as a measure of the value created by the company. In this context, the cost-value pair may be improved by diminishing costs, on the one hand, and raising the company's value, on the other, both actions being needed to be executed simultaneously.

The new performance approach, in term of creating value, is based on a generally applicable truth, namely, that companies create value only in the extent in which the capital is remunerated with a profitability rate superior to its cost.

Similarly, Stern, Shiely and Ross [15] show that performance is „*an unstable level of a company's potential, obtained as a result of optimizing the cost-value relation and that makes the company be competitive on certain strategic sectors*.”

In the modern economic theory, „*performance is multi-dimensional, covering aspects related to profitability, innovation, product design, quality and growth*”. Performance is thus the reflection of a

company's entire activity, with multiple implications and valence.

4. The impact of governance on performance

An implicit supposition of corporate governance, of the relations formed between the members of the strategic leadership of a corporation, is that performance depends on the choice of the leaders, on the contractor's options concerning the structure of the governance. A key question being asked refers to the degree by which the leading bodies can implement strategic corrections in order to raise performance. We must not lose sight of the complexity of an organization, which, together with the variety of invested interests, constitutes significant restraints, opposing to change [4].

An important thesis states that the leaders of organizations exert an important influence on processes and results, mainly when the company is faced with a financial crisis [3]. In this kind of situations, the necessity of an efficient leadership can be felt more than ever; here is where the leaders' competence should be tested.

The specialized literature almost entirely agrees on the fact that the most powerful executive position is that of general manager/director (CEO). It exerts a unique influence on processes and results, as several studies indicate. Begley and Boyd [1] show that small company general managers occupy a privileged position, being the control center and decision making bodies.

The contractor/founder is by definition the individual (or one of the individuals) who founded the business. A part of the researchers in this field have concentrated on the direct impact of the founder's status on the company's performance. Comparisons were made between the performances of companies lead by founders and the performances of companies lead by non-founding professionals. For example, Begley [2] found that companies personally managed by the contractors have a return on assets (ROA) higher than the rest of the companies. No significant difference was recorded for the other variables of the performance: the growth rate, the leverage and liquidity.

Relating to the innovation capacity, a study done by Walsh and Anderson [18],

based on a test sample of 113 small enterprises from Ireland, showed that founding members (as compared to other people in the management) are, evidently better innovators and use more efficient methods of solving arising issues. However, no relations were identified between the effectiveness of these methods and the degree of employment, or the company's growth, regardless of the founders' involvement.

Some researchers consider that the *duality* of a CEO (manifested when the general manager occupies the position of president of the board of directors in parallel) significantly disparages the independence of the company's management, offering us a George Patton type model of corporate governance [5]. The principles of the agency theory would suggest that such a centralized management structure, by which the management might “dominate” and control the board of directors, will determine a lower company performance. Alternatively, the organization thereby states that the centralization of authority, as is the case with dual CEO structures, will be accompanied by a higher level of company performance.

By using a test sample of contracting companies, Daily and Dalton [3] have analyzed this phenomenon and could not assess the existence of any statistically valid connection between CEO duality and the financial performance. Authors have measured performance though accounting methods (e.g. ROA, ROE), and used stock methods (e.g. PER) as well. By using the same tools, other authors have not identified any relation between the dual quality of general managers and the under-evaluation of the initial public offers.

Furthermore, considerable efforts were directed toward analyzing the impact of the top management teams' structure, on the financial results of the companies. The comment made by West and Meyer [19] is notable: for a company with a huge potential of growth there is a rather high probability that de disagreements between the members of the top management teams will have a negative impact on performances [19].

Haniffa and Hudaib [8] did an analysis of the relation between the structure of corporate governance and performance, based on a test sample of businesses listed in the stock exchange. Specifically, the authors

have analyzed a number of 347 companies listed in the stock exchange in Malaysia, respectively the Kuala Lumpur Stock Exchange (KLSE), between 1996 and 2000. The results show that the size of the board of directors and the first five shareholdings, of a substantial percentage, are significantly associated with stock and accounting performance.

Corporate governance may reduce agency issues, by adopting mechanisms for monitoring the managers' activity. This should, on the one hand, lead to a higher operational performance, as long as managers are stimulated to invest in projects with a positive current value, and, on the other hand, to a growth of the company's value, as the investors realize that the larger part of the company's cash flows go back to them. In countries where the shareholding structure is traditionally dispersed, as is the case with the United States of America, Great Britain or Japan, the concentration of capital has a positive or negative effect on performance. In contrast, in countries with a predominant, stakeholder-type culture, such as Germany, Italy, France, the concentration of capital seems to have a negative effect on performance [7].

The specialized literature presents an impressive number of studies, lately investigating the relation between corporate governance and the value of the companies or their performance, by identifying mixed results:

- for *emerging countries*, the results indicate that corporate governance lies in a positive and significant correlation with the company's value, but the results are not conclusive for assessing the relation with profitability;

- for *developed countries*, the results are even more controversial. Some authors have identified a poor proof of the correlation between corporate governance and the value of American companies, while other authors argue a strong correlation between governance and the companies' performances.

An essential issue in studying the relation between corporate governance and a company's performance is the causal connection. This connection is not clearly defined as being ex-ante.

5. Conclusions

Performance reflects the company's entire activity, as the sum of the activities of all parties involved, being also influenced by external factors of the company, such as preferences and the clients' expectations, competitiveness, access to information.

We consider that a proper performance measurement system is made up of three interconnected elements: individual indicators that measure the efficiency and effectiveness of the company's actions, a set of indicators combined to measure the global performance of the company, an infrastructure through which information are collected, sorted, analyzed, interpreted and disseminated.

The connection between corporate governance and performance is complex and may sometimes even prove problematic. But, a structure and well elaborated and articulate governance mechanisms that operate effectively, must lead to a higher profitability for the entity, generating significant economic performances, which can guarantee a high level of financial efficiency and a stock value of securities that is estimable for shareholders.

Relevant Performance Indicators in the Analysis of Corporate Governance

Georgescu Cristina Elena
Ovidius University of Constanta
cristina.georgescu95@gmail.com

Abstract

Corporate governance covers all systems and processes in place to manage and control the company, in order to increase performance and value. Organizations must adhere to all the concepts, principles, standards and corporate governance regulations to be assessed and achieve relevant policies and expected performance and corporate governance codes and policies come to be a balance between compliance and performance. This paper presents company performance concept and the main indicators used for measuring the company's performances. We intend to present the classic and new comings of scientific literature on the topic. Beside the theoretical approaches we also intend to present the practice poin of view, in order to give a complex image over the topic and suggest new progress on the matter.

Key Words: Economic governance; performance; financial indicator; non-financial indicator.

JEL Classification: G32, D 23.

1. Introduction

Basically, the concept of corporate governance refers to the coordination of interests of various company stakeholders: shareholders, managers, employees, lenders, clients, suppliers, the state, et.al. Within every company an ensemble of particular relations develops, between natural or legal persons, with a stake in the business. In the progress of the entrepreneurial activity, the company's management or governance must take into account the subsistent conflicts, generated by the co-existence of various interests, within the corporation.

As case studies show, the company's performance and value are, concurrently and greatly, influenced, by corporate governance, i.e. by the management and control systems and operations, implemented on a company level.

2. The concept of economic governance

Economic governance concerns the processes that support the economic activity and transactions, by protecting property rights, enforcing contracts and invoking the collective action, with the purpose of offering a proper organizational infrastructure. These processes are realized within the framework of formal and informal institutions. As a research field, economic governance studies and compares the performance of different institutions under various conditions, the evolution of such institutions and the passage from one set of institutions to another.

Specialized literature suggests the need for achieving a conceptual differentiation between “governance” and “governing”. The two concepts are not synonymous, although both terms make reference to intentional behavior, purpose-oriented activities and legal systems. Thus, the idea of governance suggests the fact that activities are supported by a formal authority that ensures the implementation of policies, when and where there is need. On the other hand, the idea of governance refers to activities sustained by a common goal, which may or may not result from legally or formally statuate responsibilities and are not necessarily based on some coercive authority.

Governance targets a device that simultaneously involves institutions, relations, regulations and behaviors, that is to say, more than the structure that the word governance represents.

The term “governance” was first used in Ronald Coase’s article, published in 1937, called *The Nature of the Firm*, and means authority rather and governance [1].

The company’s governance, generally speaking, may be defined as an entity’s coherent ensemble of devices and institutional practices that legitimize the authority functions directly enforced by the leaders and hierarchical delegates. Is a company’s governance system is improper, it may prove inefficient.

3. The company performance concept

In the economic theory there is a variety of opinions concerning the definition of the company performance concept, thereby, there isn’t a generally accepted definition of the company performance term. Therefore, some economists approach performance through the outlook of the company’s target objectives, making reference to the degree of achieving them, others regard it as the measure of the value created by the company, while a third category see performance in terms of the productivity and efficiency of the company’s activity. Consequently, we will carry on by presenting the various acceptations of the performance term, as they have been set out throughout the previous century, leading up to the modern performance approaches.

Starting with the vision of the company as a “group of people carrying out common activities oriented towards the accomplishment of one or several objectives” [7], performance represents *„the degree by which an organization, as a social system, with certain resources and means, accomplishes its objectives”* [10]. By this acceptance, performance involves its analysis in relation to the set out goal, requiring the existence of certain (internal or external) references, to which the reference will be made. This first assessment of performance is, however, heavy with subjectivity, being that it completely depends on the objectives set out by the company. Hence, the companies that have established modest objectives may assess performance as being high, if the degree of objective achievement is high, while other companies might consider the same level of performance as low, in relation to the low level of

fulfilling more ambitious objectives. As a result, the same level of performance may be appreciated differently.

Tannenbaum and Shimdt [10] have studied organizational performance by using quantitative measurements. They have described performance of an economical organization by means of its level of reaching objectives and by focusing on “ work productivity, net profit, the degree by which the company fulfills its mission and its success lies in maintaining or growing”.

Lavalette and Niculescu [5] suggest a similar definition, by showing that a company’s performance follows „the achievement of organizational objectives, regardless to their nature or diversity”. As such, in their opinion, performance only depends on the degree of fulfilling objectives, without taking into account the specialty of each company. However, coming back to the meaning of the notion of performance, the same authors describe it as being *„a company’s state of competitiveness, reached through a level of efficiency that ensures its long-term presence on the market”* [8]. Thusly, according to this last definition, a company’s performance is the result of the efficient and effective activities carried out by said company. It is, however, in this context, necessary to point out what the notions of efficiency and effectiveness mean. Efficiency, as defined by Drucker [2] means “doing things right”, while effectiveness means “doing the right things”. Hence, in economical terms, efficiency implies either maximizing the obtained results, while having a certain quantity of resources (maximizing value), or minimizing the quantity of resources used with the purpose of obtaining a certain result (minimizing cost).

From this perspective, in the eyes of Philippe Lorino [6], the performance represents *„all, and only all, that contributes to the accomplishment of the strategic objectives”* of the company, as well as *„all, and only all, that contributes to the improvement of the cost-value pair”*. That is to say, that defining performance is no longer amounts to obtaining the results wanted by the company, but is now viewed in terms of the cost-value pair. This definition of performance reveals a new approach, respectively, as a measure of the value

created by the company. In this context, the cost-value pair may be improved by diminishing costs, on the one hand, and raising the company's value, on the other, both actions being needed to be executed simultaneously.

The new performance approach, in term of creating value, is based on a generally applicable truth, namely, that companies create value only in the extent in which the capital is remunerated with a profitability rate superior to its cost.

Similarly, Stern, Shiely and Ross [9] show that performance is „*an unstable level of a company's potential, obtained as a result of optimizing the cost-value relation and that makes the company be competitive on certain strategic sectors.*”

In the modern economic theory, „performance is multi-dimensional, covering aspects related to profitability, innovation, product design, quality and growth”. Performance is thus the reflection of a company's entire activity, with multiple implications and valence.

4. Performance indicators in the analysis of corporate governance

In order to appraise a company's performance and its ability to continue producing wealth and value, instruments that require orientation towards the value creating sources and origins must be used. From the shareholder's point of view, a company is efficient if it creates value. Hereinafter, we will try to review the main indicators that can be used to this extent.

4.1. The financial indicators

The financial indicators used for measuring the company's performances are highly diversified. Traditionally, the measurement of the company's performance is achieved through classic indicators. However, throughout the last two decades a more heightened attention was paid to the development and use of modern performance measurement indicators, whereof, at present, special significance is given to value creating indicators, which can contribute to a more real reflection of the company's performances and that can also offer possibilities of improving the respective performances.

The most representative indicators used in financial diagnosis are financial rates. Specialized literature identifies over 150 financial rates.

Aside from these rates, considered to be classics in financial analysis, practice has developed certain modern indicators, the most important of which being: the economic value added (EVA), market value added (MVA), cash value added (CVA), cash flow return on investment (CFROI), total shareholders return (TSR) etc. EVA is an instrument for measuring the value created by the company for its shareholders, calculated subsequently based on the determined data, considered to be an indicator of the company's internal performance. MVA, which represents an indicator for external performance, reflects the additional value brought by managers for the funds entrusted to them by investors, are easy to measure for listed companies, but do not particularly indicate the moment, place or manner in which the company created value or not. EVA may be chosen for the performance analysis of a company, because it is less sensitive to the evolution of stock quotations, as opposed to MVA, and answers to the principle according to which value creation exists only if an investment brings, not only, a positive result to its investors, but also a superior result to that envisioned by investors [4].

By using these indicators for the measurement of the company's performance, the primordial orientation of the company's strategy is value creation for shareholders, the impact on the company's management being crucial, through the development of certain administration and leadership methods, directed towards creating value for shareholders [11].

4.2. The non-financial indicators

The critics brought to the information capacity of the financial indicators are increasing in number and diversity, starting with the quality of the source information and also invoking the lack of practical use for decision making. Thus, a larger number of analysts started using a new type of indicators, respectively non-financial indicators that better characterize the companies' performances seeing as how they directly touch blind spots within the

organization, such as: the quality of the management and of intellectual capital. Of course, those non-financial indicators will not substitute the position held by financial indicators, which continue to keep their privileged spot in substantiating an investment decision. It is, however, considered that non-financial indicators, used by investors for appraising the performances of groups of companies, are strongly linked to corporate governance practices and mechanisms.

According to the study realized by Ernst & Young Center for Business and Innovation (*Measures that matter*, 1997) regarding the use of non-financial indicators, the variables related to the corporate governance system are considered as being among the most important non-financial performance criteria used by investors while evaluating listed companies. In this study, each non-financial criterion was given a score, varying between 1, being the maximum, and 3, being the minimum [3].

Hence, amongst the eight non-financial performance criteria, relevant for investors, half refer to the means of administration and governing of companies: quality of management, corporate culture, the effectiveness of the policies for the remuneration of the executive management and the quality of the system for communicating with shareholders.

1) The quality of the management is defined with the help of variables: the degree of the company's execution strategy (score 1), the quality of the company's strategy (score 3), management experience (score 7), the quality of the organizational vision (score 16), the managers' style of administration (score 24).

2) Corporate culture is assessed with the help of several non-financial variables, such as: the ability to attract and keep talented people (score 5), the quality of the manpower (score 18), the quality of the stimulant assignment system (score 23), the quality of the personnel training programs (score 28), social and environment policies (score 37), the use of team work (score 38).

3) The effectiveness of the policies for the remuneration of the executive management are expressed at the factors concerning the harmonization of the management stimulation policy with the

shareholders interests (score 8), the remuneration policies, based on adequate performance criteria (score 12), the report between the remuneration of the executive management and the remuneration of the manpower (score 39), etc.

4) The fourth non-financial performance criteria referring to the corporate governance system, the quality of the system for communicating with shareholders, is highlighted with the help of certain variables, such as management credibility (score 2), management accessibility (score 26), the efficiency of the shareholders relations department (score 31), the quality of the materials published (score 34) etc.

By analyzing the cores given to the non-financial performance criteria, they may be classified in ascending order, thusly: the degree of the company's execution strategy, management credibility, the quality of the company's strategy, innovation potential, the ability to attract and keep talented people, market quotation, management experience, the harmonization of the management stimulation policy with the shareholders' interests, the quality of the production processes and the research advantage.

The level of the scores given by investors to these non-financial performance criteria prove that most criteria placed by investors among the first ten are related to the quality of the corporate governance system.

The final conclusion of this empirical study by Ernst & Young Center for Business and Innovation, realized in 1997, concerning the use of non-financial indicators, reflects the fact that, on average, 35% of the information used by investors in the process of placing their capital is non-financial. Moreover, the structure and score given to this information demonstrates that half of them refer directly to different aspects of the companies' corporate governance systems.

5. Conclusions

Performance reflects the company's entire activity, as the sum of the activities of all parties involved, being also influenced by external factors of the company, such as preferences and the clients' expectations, competitiveness, access to information. Thus, a correct evaluation of a company's global

performance implies taking into consideration financial indicators, as well as non-financial indicators. However, as we have observed, most of the times, performance is measured through financial indicators, as they are unquestionably necessary in the analysis of the company's performances. By presenting, however, that drawbacks do not offer possibilities of anticipating future performances, but only executes an analysis of past ones, financial indicators have proven insufficient for a pertinent evaluation of performance, by neglecting aspects of the company's activity that cannot be quantified in monetary terms. Non-financial indicators, on the other hand, can supply useful information for the future performance of the company, but they may never be used separately for appraising performances.

A new question nevertheless arises: which are the most proper indicators, specifically non-financial, that must be included in an optimum company performance evaluation system? The sphere of each activity, especially the objectives of each company, enforces various proportions of the indicators within the performance evaluation system, and even the election of different indicators, for each company in particular. Hence, the quality of the indicators used is very important in determining performance. Notwithstanding, the number of indicators taken into consideration should be limited, in order to ensure a clear general image on past and future performances.

This is why, as studies for the identification of an optimum performance evaluation system show, it is necessary to establish a set of indicators, financial, as well as non-financial, which will reflect the company's true performance.

For a pertinent assessment of the companies' performance the existence of a balanced multi-dimensional system is therefore necessary, which would include financial and non-financial indicators, with the purpose of diminishing the limits between the two sets of indicators.

Abstract

In order to maximise profit and to reduce the burden of tax in the jurisdictions with high tax, many of the multinational companies abuse transfer pricing by directing the profit towards subsidiaries which are localised in more favourable jurisdictions from this point of view. The cross-border transactions effectuated, more exactly the mechanisms used to establish the transfer pricing involved in them, vary from the perfectly legal to the illegal ones and very often it is almost impossible for the tax authorities to contest them. The purpose of this paper is to analyse the mechanisms and practices of determining transfer pricing and their effects on the financial flows at the international level. The conclusions emphasize both the role played by transfer pricing in tax optimization and in cross-border tax evasion.

Key words: transfer pricing, tax optimization, tax evasion, multinational companies

J.E.L. classification: F23, H21, H26, M4, O16.

1. Introduction

In the present global context, more and more managers of multinational companies are focusing on transfer pricing because it plays a very important role by having significant influences over the cash flow of the enterprise and its tax debts [3].

Raymond W. Baker [5], the director of Global Financial Integrity and a specialist in

analysing international money laundering, describes the illegal financial flows that are circulated across the border from one country to another instead of being used to develop the economy as being „the ugliest chapter in global economic affairs since slavery”.

The greatest companies in the United States of America as well as others from similarly well-developed countries have subsidiaries in other countries from economic reasons such as sale opportunities, the existence of natural resources, qualified personnel and favourable work conditions as well as tax benefits [21]. These companies always proved to be able to adapt to the continuous changes in the business environment, they constantly developed their mechanisms and they discovered new challenges and opportunities in other tax jurisdictions when they needed to [20]. An important factor which lead to the elimination of barriers in international trade is the rapid development of the internet and e-commerce. Nowadays, enterprises have the possibility to perform trades outside the national borders with providers as well as with clients very easily through the internet. As a consequence, the number of assets, especially the intangible ones, traded through e-commerce or simply through the internet, has faced a huge increase every year and the reaction of the tax authorities in many countries was to issue regulations for determining transfer pricing for the e-commerce area and intangible assets [1].

2. The characteristics of transfer pricing

The notion of transfer pricing refers to the prices used in transactions in which the

parties are affiliated entities, from different tax jurisdictions [12]. Two entities from distinct tax jurisdictions are considered to be affiliated by the Organisation of Economic Co-operation and Development (OECD) [17] when one of them “participates directly or indirectly to the management, control or capital” of the other one. The entities are also considered to be affiliated when the transactions effectuated between them are different from the ones that would have taken place if the entities were independent.

For the groups of enterprises that perform their activity in one country, the function of transfer pricing is that of allocating costs for several activities and of following the intra-group transactions. However, for transnational companies that own subsidiaries in several tax jurisdictions, transfer pricing has more than an internal control and managerial role [6].

Transfer pricing represents a tool utilised on a large scale by multinational companies to maximise their profit through its distribution towards subsidiaries which are localised in a more favourable place from the perspective of tax rates [20], [22]. Most of the time, transfer pricing is established relative to the central headquarters level and it is not based on the economic context or on the needs of the subsidiaries implicated in these transactions [14]. In order to diminish the revenues of the enterprises from countries with high tax and to divert them towards subsidiaries from low tax jurisdictions, the transnational companies perform an incorrect evaluation of transfer pricing by over-invoicing imported goods and services and under-invoicing exported ones [9]. However, in spite of the nature of the effects, the authors David Ledure and Mourad Charar [12] affirm that “transfer pricing may not be automatically assimilated to tax optimisation” because usually, the affiliated entities that belong to the same group must cooperate and carry out transactions between them.

Transfer pricing can determine the outcome of the activities performed by an affiliated entity which can be obtaining profit or having losses, but the issue is more complex and has moral and ethical implications [19]. In this way, the development of cross-border trade and the opportunity for multinational companies to

get rich rapidly by manipulating transfer pricing triggers moral dilemmas for the subsidiaries’ managers because they are asked to choose between being ethical in business and orders from the main headquarters [14]. Also, Hansen, Crosser and Laufer [8] emphasize the ethical perspective of the conflicts that appear between tax reducing mechanisms and the interest of multinational companies for the welfare of the citizens. To solve this dilemma, the authors suggest that the methods of establishing transfer pricing must correspond to the ethical behaviour that should be adopted by the managers of the multinational companies and that the methods of diminishing tax should be in harmony with the ethical conduit of the accounting experts. Kenji Matsui [13] states that the tax authorities must compromise between tax revenues and the welfare of the consumers, while Aid [2] criticizes the companies that adopt an incorrect evaluation of transfer pricing and still consider themselves to be socially responsible.

3. The problem of transfer pricing at a global level

Undoubtedly, transfer pricing have become a major problem at the international level because of the fraud and tax evasion practices which resulted in a fierce battle of the tax authorities against the companies that manipulate transfer pricing in order to distort financial statements and to artificially increase their profit [14]. Baker [5] underlines three main ways of acquiring illicit money which are circulated across borders in the world which are: the acquisition of revenues through criminal activities (such as drug trading, financing terrorism, contraband, blackmail), the acquisition of sums of money by acts of corruption and funds diversion undergone by government officials and the acquisition of funds from commercial transactions carried out through money laundering and tax avoidance procedures. The same author states that the manipulation of transfer pricing constitutes a component of the illicit financial structure, along with tax havens, off-shore secrecy jurisdictions, disguised corporations, anonymous trust accounts and fake foundations.

In the opinion of the authors Nor, Ahmad and Saleh [16], transfer pricing constitute a tool for fraudulent financial reporting, as well as over-evaluating acquisitions, under-evaluating sales, including fake expenditures, or adjusting the incomes. Moreover, Aid [2] emphasizes the problem of manipulating transfer pricing in the case of loans granted between affiliated entities, by over-evaluating or under-evaluating, according to the situation, of interest rates. However, Paz-Vega [19] affirms that the frequent usage of unfair policies regarding transfer pricing is not always beneficial for multinational companies because they may have a negative effect, i.e. the strategic alignment is distorted and is not respected anymore in the relation between the parent company and its subsidiaries. The tax authorities consider an intra-group transaction to be legal if it respects the arm's-length principle but they face a series of problems in developing countries. Because of the relatively low level expertise in the area, and because of the incomplete information regarding the parent company and the local subsidiary, and by taking into account the extremely complex techniques of diverting the profits used by multinational companies, it is rather difficult for the tax authorities to contest the establishment of transfer pricing [2].

Multinational companies are forced to practice mispricing because of the differences between tax rates from different jurisdictions, in order to reduce tax debts which produces a greater tax loss at the global level [4]. A recent study undergone by Global Financial Integrity [11] estimates that the illicit financial flows from developing countries reach the amount of 5860 billion dollars in the 2001-2010 period, out of which 858.8 billion dollars are just from the year 2010. The countries with the largest number of illicit financial flows in the analysed period are China (2740 billion dollars), Mexic (476 billion dollars), Malaysia (285 billion dollars), Saudi Arabia (210 billion dollars), Russia (152 billion dollars), Philippines (138 billion dollars), Nigeria (129 billion dollars), India (123 billion dollars) and Indonesia (109 billion dollars). Romania is among the analysed countries and it is situated on the 55th position in the ranking (8.84 billion dollars) along with Hungary which is on the 42nd position (14.42 billion

dollars) and Bulgaria which is on the 38th position (15.85 billion dollars). The Price of Offshore Revisited, a study made by Tax Justice Network [9] on 139 countries and lead by the researcher James Henry, estimates that the virtual investments made through offshore financial centres in 2010 are between 21,000 and 32,000 billion dollars. These estimations take into account only financial assets which include transactions effectuated both by companies and individuals.

In the case of the United States of America, a report from June 2010 of the Government Accountability Office states that the estimations regarding the total value of international fraud and tax evasion in which American multinational companies are involved is between 10 and 60 billion dollars [7]. For the United Kingdom, Richard Murphy [15] estimates that the tax losses from the offshore operations reach the annual sum of 18.5 billions of pounds, out of which only 7 billion pounds are strictly from tax evasion activities. From this, 8.5 billion pounds represent the losses from individuals, and 3 billion pounds from the big companies, both situations being considered by the author as “legal” tax evasion actions. The results of a study undergone by Kar and Freitas for the Global Financial Integrity [10] show that in Russia, in the period 1994-2011, the financial flows had the value of 782.5 billion dollars, out of which only 211.5 billion dollars constitute just the illicit capital obtained through tax evasion, crime or corruption. A controversial aspect present in this study is the fact that Cyprus, a small country with around 800 thousand citizens and with a Gross Domestic Product of just 23 billion dollars [23], has made foreign direct investments (FDI) between 2009 and 2011 of about 128.8 billion dollars, a fact which makes the legality and legitimacy of the operations developed between these two countries questionable.

4. The OECD methods of establishing transfer pricing

The OECD Transfer Pricing Guidelines for Multinational Enterprises and Tax Administrations [18] classify the methods of establishing transfer pricing as: the traditional transaction methods (comparable

uncontrolled price method, the cost plus method and the resale price method) and the methods regarding the transactional profit (the net margin method and the profit split method).

4.1. The comparable uncontrolled price method

The comparable uncontrolled price method requires that the price of goods and services sold by the multinational companies to the affiliated entities to be established by comparing it to those used in other similar transactions carried out on the market, but between entities which are not controlled [1]. Determining the market price is not a simple procedure, because there is always the possibility of facing several difficulties. The market price can have distinct values from a country to another, can vary in time or it could be distorted by the subtraction of transport costs [3]. Especially, difficulties may appear in the case of intangible assets because open markets rarely exist and the differences regarding the functionality and performance of those assets make this process even more laborious [1].

4.2. The cost plus method

In the event of not being able to identify the market price or of encountering difficulties in identifying it, one could use the cost plus method [3] which is considered to be probably the most efficient method when the subject of the transaction between affiliated entities is service provision or selling semi finished goods as well as when supply agreements exist and they have been settled for long-term [18]. This method is based on incrementing the costs paid by the goods and services supplier in a transaction controlled with a margin of profit [18].

4.3. The resale price method

According to paragraph 2.21 from the OECD Guidelines [18], the resale price method requires decreasing the price for a product bought from an affiliated entity and then resold to an independent entity with an appropriate profit margin. This margin is called “resale price margin” and it represents the value that a reseller would use in his

attempt to cover his sale expenses and to obtain an appropriate profit. In this way, after reducing the gross margin and the other costs of acquiring the product, the value one is left with can be treated as a price at arm’s length for the initial transfer between the affiliated entities.

4.4. The net margin method

The net margin method of transaction, as it is called by the OECD [18], is used to analyse the net profit margin relative to an appropriate basis which is realised by a taxpayer in a transaction where the parties are affiliated and it is somehow similar from this perspective with the resale price method and the cost plus method. In this way, the net profit indicator of the tax payer in a controlled transaction must be established by comparing it with the same indicator but from comparable uncontrolled transactions carried out by the taxpayer mentioned. If this is not possible, it must be used as a reference base for the net margin which would have been obtained by an independent company in a comparable transaction [18].

4.5. The split profit method

The split profit method is used in order to eliminate the effect of „special conditions made or imposed” on the profit in a transaction where the parties are affiliated. This method first identifies the split profit between the affiliated entities in a controlled transaction and then splits the profit between the two parties, using as a reference the way the profit has been split in agreements settled between independent entities [18].

5. Conclusions

The problem posed by transfer pricing is a current controversial one. Ethical behaviour in business, social responsibility and the loyal tax competition are aspects which are often not taken into account in the process of achieving the goals set.

Ever since the commercial barriers have been eliminated, the labour market has become more liberal and the internet has become more versatile, multinational companies have the possibility to encounter favourable conditions for trading in other

jurisdictions than the one they are resident in. This allows them to become certain that their profit will be maximized and their tax debts will be minimized. In this respect, transfer pricing constitute the best weapon in the battle with tax. This led to the existence of an upward trend from year to year in the number of transactions effectuated between affiliated enterprises.

In order to reduce tax debt, some multinational companies decide to manipulate transfer pricing by over-evaluating acquisitions, under-evaluating sales and granting virtual loans between affiliated entities, although transfer pricing must be established according to the arm's length principle. In this way, the financial statements are being distorted and companies manage to avoid paying high taxes. Because of the complexity of determining transfer pricing, tax authorities are often unable to contest the prices set by some companies, especially when the effectuated transactions contain intangible assets, such as intellectual property, for which there is no basis of comparison on the open market.

A solution used in the fight against this world-wide phenomenon would be intensifying the controls effectuated in the transfer pricing area but in order to take this action, tax authorities must possess a high level of expertise because multinational companies seem to always be one step ahead.

The Contracts for Difference – Elements of Financial Innovation on the Romanian Capital Market

Ghiță-Mitrescu Silvia

cristinaduhnea@gmail.com

Abstract

The financial derivatives market in Romania is still at an early stage of development. However, the oldest and, in our opinion, the most important market operator, the Sibiu Stock Exchange (Sibex) always tried to include in its portfolio new types of instruments, providing new opportunities for investors for hedging and arbitrage operations. Among the elements of financial innovation that the investors from the Romanian capital market can benefit we can include and Contracts for Difference (CFDs), introduced in 2009 in the Sibex portfolio.

This paper aims to analyze CFDs in a theoretical manner and their evolution on the capital market in Romania, trying to identify possible motivations of the poor development of this segment of the market.

Key words: contract for difference (CFD), financial derivatives, Sibiu Stock Exchange
J.E.L. classification: G23

1. Introduction

The Romanian derivatives market will soon celebrate 16 years of existence. In this period of time the structure of the products traded at the Sibiu Stock Exchange (the most important derivative market in Romania, in our opinion) evolved and enriched continuously as the market operator tried to respond to the demands of the investors. Thus, if in 1997 the transactions were limited to futures contracts, and a year later options contracts were added, now investors can benefit from the use of two new, more “exotic” types of instruments: contracts for

difference (CFDs) and binary options.

In the following we will try to analyze the impact that the introduction of the Contracts for Difference had on the derivatives market of Romania.

2. A brief presentation and history of CFDs

A contract for difference (or CFD) is a contract between two parties, typically described as “buyer” and “seller”, stipulating that the seller will pay to the buyer the difference between the current value of an asset and its value at contract time. If the difference is negative, then the buyer pays instead to the seller. In effect CFDs are financial derivatives that allow traders to take advantage of prices moving up (long positions) or prices moving down (short positions) on underlying financial instruments and are often used to speculate on those markets.

CFDs were developed in the 1990s in London, their invention being widely credited to Brian Keelan and Jon Wood. [1] The original purpose of the CFDs was to allow hedge funds and institutional traders to hedge their stocks exposure on the London Stock Exchange at a low cost.

In the late 1990s and early 2000, CFDs raised the attention of the retail traders who realized that the real benefit of trading CFDs was, apart from the tax exemption, the ability to leverage any underlying instrument. This was the starting point of a new era for CFDs. Soon the range of underlying instruments expanded to include indices, commodities, bonds and currencies. The index CFDs became the most popular type of CFD traded.

In July 2002 CFDs crossed the UK

borders and were introduced on the Australian capital market. Since then many other national capital markets such as Hong Kong, Poland, Portugal, Germany, The Netherlands, Switzerland, Italy, Canada, France, Ireland, Spain, Japan started using CFDs. The U.S. Securities and Exchange Commission restricted the use of CFDs on the over-the-counter market.

Until 2007 CFDs were traded only on the OTC market. After November 2007 the Australian Securities Exchange listed exchange-traded CFDs on the top 50 Australian stocks, eight currency pairs, key global indices and some commodities.

Since CFDs are traded between individual traders and CFD providers there are no standard contract terms for CFDs, each CFD provider being able to specify their own terms.

Unlike a futures contract a CFD does not have an expiry date or a settlement date so the position is closed when a second reverse trade is done. However, since CFDs are traded on margin and the trader must maintain the minimum margin level at all times, any positions that are not covered will be liquidated by the CFD provider.

For the Romanian market the interest is charged at the end of each day into the account of the buyer by the Romanian Clearing House and it is deposited into the seller's account. The interest rate is established by the Romanian National Bank.

3. Reasons for and against using CFDs in hedging and arbitrage operations

There are many reasons why an investor can be interested in using CFDs as hedging or arbitrage tools. The most important one is, in our opinion, the possibility to have full exposure for the underlying asset by paying only a fraction of its price.

Also, CFDs are more flexible than futures contracts since there is no settlement date and the contract size is smaller making it more accessible to the small investors and pricing is more transparent. The ability to open “short” positions and profit from falling prices and the possibility to gain profit both when the market increases and decreases are other two important advantages of CFDs.

If we add to those said above the reduced counterparty risk due to the fact that all

settlement obligations are cleared and guaranteed by the Romanian Clearing House, we can say that CFDs are an important element of financial innovation that can prove useful for the Romanian capital market.

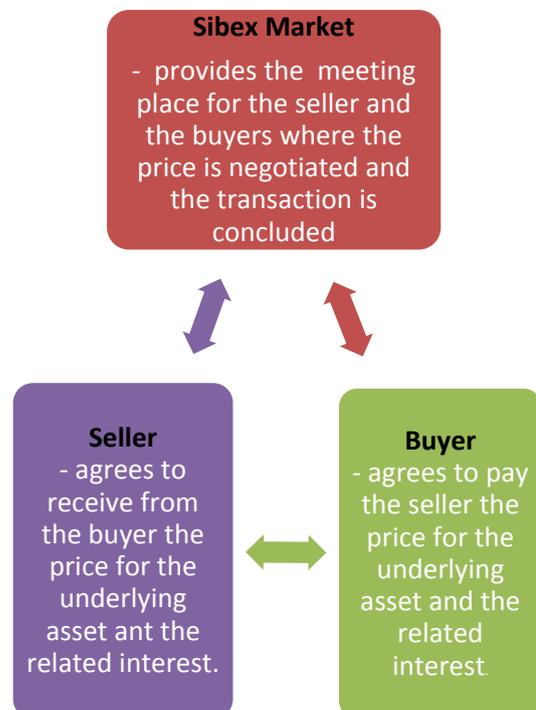

However, there are some disadvantages to be taken under consideration, mainly the leverage effect of CFDs. Some financial commentators argued that trading CFDs is riskier than gambling on horses or going to a casino. [2]

There has also been concern amongst the specialists worldwide that CFDs are little more than gambling implying that most traders lose money trading CFDs [3]. This affirmation is however difficult to prove since most of the CFD traders do not publish information on the average returns from trading.

4. How does a CFD work?

In order to understand how an investor can profit from the use of a CFD we first have to take a look at the mechanism of a CFD transaction:

Figure 1 The mechanism of a CFD transaction at Sibex

Source: adapted after Sibex website

Let's assume that one wishes to speculate the increase in the price of BRD Groupe

Societe Generale shares. Instead of buying 100 shares at the price of 7 lei/share and immobilize 700 lei, the investor can buy one CFD at a margin of between 105 and 140 lei (the margins at Sibex are between 15-20% of the transaction's value) and take advantage of the increase in share price.

On a daily basis, the Romanian Clearing House will charge the account of the buyer with a sum calculated by multiplying the value of the contract with the Romanian National Bank interest rate and will deposit the money in the sellers account.

The position can be maintained as long as the investors wants and can be liquidated by taking a contrary position.

If at liquidation time the price of the BRD shares is 7.5 lei/share the CFD buyer will gain 50 lei, while the seller will lose 50 lei. Therefore a 7% increase in the shares' price leads to a profit of between 35 – 47% of the original investment.

Compared to the spot market, the investors can get the same profit from the fluctuation of the shares' price, but with significantly lower costs, which means that they can get a better net result.

Compared to the futures market, the mechanism of the transactions is the same, but the lack of a settlement date gives the opportunity to maintain an open position for a longer period of time, even for years, without having to pay the costs and to take the risks of “rolling over” a position from one settlement date to another. This is an advantage from which both buyers and sellers can benefit, since CFDs allow the opportunity to open a “short” position (to sell the underlying asset without owning it or without previously assuming a buying position).

Another major resemblance between CFDs and the spot shares market is the possibility for the buyers to cash in dividends for the underlying shares. The sums representing dividends are transferred from the seller's account to the buyer's account in maximum 5 days since the registration date.

However, the CFDs buyers do not have the right to vote in the General Shareholders Assembly as they do not actually own the shares. But there is an upside to not owning the shares: the CFD buyer can get an unlimited exposure to a company's shares without having to disclose information about

this ownership.

Compared to an option contract, a CFD has a much simpler way to establish its price and a smaller range of underlying assets. While for an option the pricing process is complex and the price tends to decrease near the end of the maturity period, for a CFD the price represents the price of the underlying asset.

We can conclude that the CFD market resembles more with the futures and options market, but there are some major differences:

- The lack of an expiry date, which means that the price doesn't decay near the settlement date;
- The minimum contract size is small so the margins are lower;
- CFDs are not available in the USA;
- The contract's price usually mirrors the price of the underlying asset.

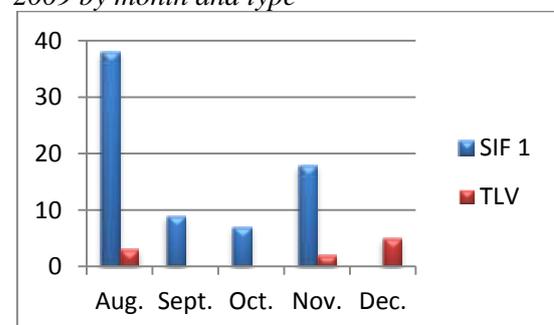

This is, in a brief overview, how a CFD works and the main advantages of buying such a contract. In the next chapter we will try to analyze how the Romanian capital market responded to the introduction of these contracts.

5. The evolution of CFDs on the Romanian market

In Romania, the first CFDs were introduced at SIBEX in August 2009 and had six types of shares as underlying instruments.

Even though the investors seemed interested in this new form of hedging and arbitrage only 82 transactions were carried out in 2009: 72 with the SIF1 CFD and 10 with the Transilvania Bank CFD.

Figure 2 The number of CFDs traded in 2009 by month and type

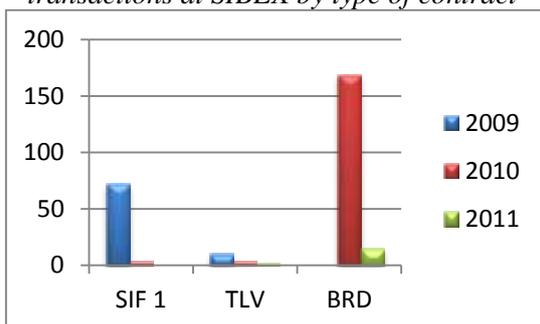

Data source: Sibex annual report

The largest number of contracts traded was reached in the first month of implementation, August, afterwards the

number of traded contracts plummeted.

In 2010 the number of CFDs transactions rose to 175, representing an insignificant fraction of the total transactions of the futures market. While the contracts preferred by the investors in the previous year, SIF 1 and TLV decreased to only 3 trades each, the contract with the shares of the Romanian Development Bank (BRD) as underlying asset totaled 169 transactions.

Figure 3. The evolution of CFDs transactions at SIBEX by type of contract

Data source: Sibex annual reports

In 2011 only 17 contracts were traded, 15 with the BRD shares and 2 with the Transilvania Bank shares. Compared to the previous year, BRD CFD plunged by 91% representing 88% of the market share, while TLV CFD volume decreased by 33%. All 17 contracts were traded in January and September.

In 2012 and the first quarter of 2013 no transactions with CFDs were recorded at SIBEX.

After the review of the evolution of CFDs trades on the capital market in Romania we conclude that despite the benefits of these tools, the illiquidity of the market in general and the lack of investment culture of market participants make this niche area of the Romanian capital market not exploited to its true value.

6. Conclusions

The introduction of CFDs on the Romanian capital market almost 4 years ago was a big step ahead for the market's taxonomy. For the first time, the investors had the opportunity to use an instrument that offered higher advantages than futures contracts or the spot market, but at lower costs.

Although the moment was right from the point of view of the market operator (Sibex) as CFDs offer bigger gains in a time of market rebound, the investors did not react as expected.

The Romanian capital market in general is still struggling with a major lack of liquidity and, more important, with a lack of financial culture from the investors' side.

Therefore, it is our opinion that these instruments will not be used at a bigger scale in the near future unless the entire climate of the capital market changes.

Considerations on Consolidated Financial Statements of the Group

Guni Claudia Nicoleta
Spiru Haret University
borsanclaudia@yahoo.com

Abstract

The consolidated financial statements concern the financial statement presentation and the results of a set of companies as if they form only one company, composed of different departments, divisions or branches. The recognition of the informative role does not allow its reduction to a simple accessory of the annual accounts of the dominant company. The group of companies, by its consolidated synthesis documents, shall provide accounting information that corresponds, in every respect, to its qualitative characteristics.

Key words: the theory of property, the entity theory, the extended theory of the parent company.

JEL Classification: G3; G32; G34

1. Introduction

The consolidated financial statements are the financial statements of a group, presented as those of an independent business. The parent company should introduce consolidated financial statements, which will include statements of all enterprises in the consolidated perimeter established. The parent company will also include in the consolidated financial statements the interests of minorities. In order to prepare the consolidated financial statements, the financial statements of the parent company and those of its subsidiaries, they are combined, one element at a time, adding similar active items, liabilities, equity, income and expenses. In order for the consolidated financial statements to present financial information about the group as a single enterprise, they should follow the following steps:

→the determination of the accounting value of the investment of the main enterprise in each branch and its share of capital;

→ the identification and adjustment, in relation to the group's profit, of the minority's interests in the net income of the consolidated subsidiaries, for the reporting period, for the purpose of reaching the net profit attributable to the owners of the main company;

→ the minority's interests in the net assets of consolidated subsidiaries are identified and presented in the consolidated balance sheet, separate from the liabilities and the shareholders' equity of the parent company;

2. Considerations on consolidated financial statements of the group

Minority's interest is that part of the net results of the operations and of the net asset of a branch, attributable to the participants, which is not owned, directly or indirectly through subsidiaries, by the parent society. The users of financial statements of the main company are usually concerned and should be informed on the financial situation, on the result of the exercise and the changes in the financial situation of the group as a whole. This requirement is satisfied by the consolidated financial statements, which present financial information about the group as a single enterprise.

The parent society, that presents consolidated financial statements, will enhance all subsidiaries, in the country and abroad, that are in the consolidation perimeter. The consolidated financial statements include all enterprises controlled by the parent company, other than the subsidiaries excluded from consolidation.

It is assumed that there is control if the main company owns, directly or indirectly, through subsidiaries, more than half of the votes of an enterprise. There is control, even

if the main company owns half or less than half of the votes if:

- there is an agreement with other investors so that all together they hold more than half of the voting rights;
- it is established by law or by contract that he has the authority to conduct the financial and operational policies of the enterprise;
- he has the authority to appoint or replace the majority of the governing body of the enterprise;
- has the authority to pass on the majority of votes in general meetings or in the decisions of the Board [4].

A subsidiary cannot be excluded from consolidation because its business activities are different from those of the other companies in the group. On the contrary, by consolidating such subsidiaries, additional information is brought in the consolidated financial statements on the diverse activity of such subsidiaries. A subsidiary may be excluded from consolidation if its inclusion is not significant in giving a true and correct image by the consolidated financial statements; several companies may be excluded only if, taken together, their importance is not significant. The consolidated financial statements should provide information about the financial position, performance and cash flows of a group of enterprises, which is useful to a wide range of users in taking their economic decisions. In order to achieve this goal, the consolidated financial statements should provide information that enables users to make predictions on future cash flows, especially regarding their maturity and probability.

The objective of consolidated financial statements is to provide a structured financial representation of the financial position and the transactions performed by the group. So the information in the consolidated financial statements shall relate to:

- The assets controlled by the group, meaning the resources generating future cash flows;
- The group's debt, foreign liabilities that should be at the basis of payments;
- Equity as residual interest of the properties in the assets controlled by the group, including minority's interests;

- the group's result and its economic performance, played by the reflection of the development in equity (net assets);

- the past cash flows, which can constitute the basis for determining future cash flows.

Based on these data, the users of financial information will be able to assess the ability of the group of companies to pay dividends, interests, rates and, in general, to honor the debts of the due dates stipulated. The financial statements should be clearly identified and separated, both as a whole as well as on each component, by other information presented in the annual report or by any other document, even if these are useful to users, not being customary to standards [1].

The consolidated financial statements include: the consolidated balance sheet, the consolidated profit and loss account and the annexes to these. They form a whole and they are presented comparatively on two financial exercises: previous and current.

It is recommended for these documents to be accompanied by:

- a situation that reflects all changes in equity, as well as those arising from capital transactions with owners and distribution of capital to owners;

- the cash flow statement or the financing panel;

- accounting policies and explanatory notes;

The financial statements should be presented at least annually. In the event that, for some exceptional reasons, the annual financial statements are presented for a period longer or shorter than one year, the management should submit, in addition to the period covered by the financial statements, both the reason for using a different period of the year and the fact that the amounts corresponding to similar elements of the profit and loss account, of the changes in equity statement, of the cash flow table and of the corresponding notes, are not compatible. The usefulness of the financial statements is impaired if they are not available to users in a reasonable period of time, after the balance sheet date. Specific deadlines are presented by law and by the capital market regulations [3].

Regarding the technique of consolidating the accounts, the ownership theory is based on the percentage of interest exercised by the

main company over his branches, as it starts from the premise that the parent company acquires only a part of a subsidiary company and, therefore, only that part should be presented in the consolidated financial statements. Thus, the parent company strictly consolidates its percentage of ownership of the assets and liabilities of the subsidiary company. The commercial fund related to the acquisition, determined as the difference between the acquisition cost and the net fair value of the net assets of the subsidiary company, is entirely attributed to the parent company. Any amendment in the capital of the subsidiary company, of the participation structure that generates, from the parent company's perspective, a purchase or sale of assets and liabilities, leads to an initial consolidation and respectively a deconsolidation. As a result of this consolidation, the consolidated financial statements do not present any information regarding the interests of the minority shareholders in the group, whereas in the balance sheet and in the profit and loss accounts, positions have been taken over only at the level of interest percentage of the group, individually for each subsidiary company.

Regarding the entity theory, the focus is on the group as dominant economic entity, taken as a whole. Therefore, the consolidated financial statements are drawn from a group's perspective. These consolidated financial statements become individual cases at the upper level of the group as an economic entity, its subsidiaries being assimilated to dependent subdivisions. According to the same theory, both parent and daughter companies lose their individuality, the participants' structure in the group being considered irrelevant, not making any difference between the parent company shareholders (the majority) and the minority shareholders [5].

The individual financial statements of subsidiary companies are entirely taken over in the financial statements of the group, being performed the valuation of assets and liabilities at fair value, regardless of the percentage of the majority interest. The reference period to determine the fair value is the moment of acquiring control on the subsidiary. The treatment of the commercial fund is the major difference compared to

other theories. Thus, in entity's theory the recognition of the commercial fund occurs, being related to the acquisition of the subsidiary, not only that acquired by the parent company but also its distribution between the interest of the majority and the minority. In contrast to other theories, some changes in the ownership structure in a subsidiary do not lead to making a first consolidation or deconsolidation. These occur only when a company joins, or leaves the area of consolidation, which usually coincides with the moment when the parent company acquires, respectively loses control over a company's assets and liabilities. Transactions in the same group are entirely eliminated[4].

The financial statements of the group, according to the parent company's theory are drawn from the perspective of the parent company's shareholders. The consolidated financial statements represent, in this case, an extension of the individual financial statements of the parent company. The central idea of this theory would be that the parent company's interest in the subsidiary is of a purely financial nature, the consolidated information being complementary to the information provided by individual financial statements of the parent company.

Contrasting with the theory of property, the financial statements of the subsidiaries are fully taken over in the consolidated financial statements, as it is intended in applying this theory, the presentation in the group's situations, of the entire patrimony under the economic dominant influence of the shareholders, of the parent company and not only of the owned percentage. In the consolidation process, all assets and liabilities of subsidiaries are taken over, valued at the net book value, adding the percentage of interest of the parent company in the difference between the fair value and the net book value. The commercial reported fund is allotted only to the majority's interest of the parent company, being represented only by the commercial fund acquired. Any amending in the participation structure, in the capital of subsidiary companies, that from the perspective of the parent company, generates a purchase or a sale of assets and liabilities, leads to an initial consolidation or deconsolidation.

According to this theory, minority's interests are allotted their share of the assets and liabilities of the subsidiaries in question, valued at net accounting value. Minorities are not assigned the difference in value at the level of percentage of interest between the fair value and the net book value of the net assets and they are not allotted any part of the commercial fund. The reporting of minority interests in the balance sheet is done in the debt's group, as from the perspective of the parent company's shareholders, minority shareholders are considered creditors. The part related to minority's interests as a result is deduced from the result of the group in the consolidated profit and loss account so that it only reports the result corresponding to the majority's interest.

The extensive theory of the parent company - in the case of this theory, the perspective from which, the consolidated financial statements are prepared is still that of the shareholders of the parent company. This aims to reflect, helped by the financial statements of the group, of the entire patrimony under the control of the parent company's shareholders, being taken over within the consolidation, as a whole, the assets and liabilities of the subsidiaries. The first difference from the parent company's theory is the assessment of the net assets of a subsidiary entirely at fair value. Similarly to the theories presented, the reported commercial fund is not measured at its fair value, referring only to the commercial fund acquired, allotted entirely to the parent company. Another difference from the parent company conception, aims the total elimination of intra-group transactions, not only at the level of the majority percentage. The application of this theory assumes for the interests of the minority to get their share of the assets and liabilities of subsidiaries, valued at fair value. Because the commercial fund reported is limited to the purchased one, minorities are not allotted any part of it. The reporting of minority's interests in the balance sheet is carried out, in view of this theory, always between debt and equity. In the consolidated profit and loss account, the part corresponding to minority's interests as a result is deduced from the results of the group so that it only reports the result to corresponding interest shareholders of the parent company[2].

In accordance with IAS 1 "The Presentation of Financial Statements" a complete set of financial statements includes the following components:

- The balance sheet;
- The profit and loss accounts;
- The situation of variation or changes in equity;
- The cash flow panel;
- The accounting policies and explanatory notes;

The enterprises are encouraged to present additional statements such as: environmental reports, statements on the added value, additional information on employees etc.

The presentation of the consolidated balance sheet or the consolidated financial position - traditionally, the financial position of an individual or group entity, finds its representation via the balance sheet which is renamed in the latest version of IAS 1 "the statement of financial position". IASB considers that the new denomination reflects better the function of this situation and it is consistent with the terminology adopted in the Framework of preparation and presentation of financial statements. Some important aspects of the presentation of the balance sheet of an individual entity or group refer to the format, the classification of assets and liabilities and the order of presentation of assets, liabilities and equity.

The structure and content of the balance sheet should realize the distinction between current and non-current items. Each group applying the international referential has to decide, depending on the nature of its business, if it is useful to make the distinction between current and non-current items of its balance sheet, both for debt and for assets. When such a distinction is not performed, the assets and liabilities are classified, basically, depending on the liquidity, respectively on their enforceability [3].

The presentation of the consolidated profit and loss account or of group performance – companies should provide either in the income statement or in the notes thereto, an analysis of expenses using a classification based either on the nature of expenses or on their function within the enterprise. The expense items continue to be classified in order to highlight the area of components of the financial results, which may differ in terms of stability, the potential for gain or

loss and the predictability. This information is classified according to the nature of expenditure, and it is not reassigned on the various functions of the company, or after the expenses function as part of the immobilization cost, distribution or administrative activities.

An enterprise should disclose, either in the profit and loss account, either in the income statement or in the notes, the amount of dividends per share, declared or proposed, for the period covered by the financial statements.

The presentation of the consolidated cash flow statement – the cash flow panel presents the streams of receipts and payments during the period. It shows the origin of liquidities and how these have been spent explaining the causes of their variation. Such a picture provides information that allows the users to evaluate the changes of the net assets of an enterprise, its financial structure and the ability to change values and the cash flows schedules in order to accommodate changed circumstances and opportunities. In terms of presenting the consolidated cash flow statement, the central issue aims the presentation method of cash flows for exploitation activities, differing in international accounting theory and practice, two methods firmly established, namely the direct method and the indirect method.

The presentation of the situation's variation in equity, consolidated - in accordance with IAS 1, such a situation should include the following elements:

- the profit or loss of the period;
- profits and losses, expenses and revenues that have been directly affected in equity as well as the total of these elements;
- the total of incomes and expenses of the period, calculating separately the total amounts attributable to the parent company and to minority's interest;
- for each component of the equity, the effect of changes in accounting policies and the corrections of errors, recognized in accordance with IAS 8.

In terms of submitting this document, the set out format at international level is the matrix, where the lines represent the sources of changes in equity and the columns represent the equity elements, and the totals of related amendments of the owners of the

parent company related to minority's interests and to the whole group[4].

The disclosure of accounting policies and of the consolidated explanatory notes - the information contained in the notes, drawn up at the consolidated financial statements, is particularly important because it allows completing the accounting information presented in the balance sheet and income statement, which sometimes are insufficient. Qualitative information that cannot be captured in the two other synthesis documents allows stating the terms and conditions in which there were carried out the consolidation works. The Explanatory Notes highlight the accounting options retained from a wide range of possibilities, offered by international accounting practices. Whatever the source, the information in the notes meets the principle of good information, which allows a fair assessment of assets, of financial position and of the overall result, consolidated. The Explanatory Notes should include any significant information that allows users of consolidated accounts to make a fair assessment of assets, of the financial position and of the result of an ensemble of companies chosen for consolidation.

3. Conclusions

The financial statements are a structured representation of the financial position and of transactions carried out by an enterprise or group of enterprises that operate as a single enterprise. In this sense, financial statements provide information about the assets, liabilities, equity, income and expenses, including profit and loss as well as cash flows of the company. The financial statements shall fairly present the financial position, the financial performance and cash flows of an enterprise or of the group. In order to prepare consolidated financial statements, the management has to evaluate the business activity of the companies in the consolidation perimeter in terms of the predictable continuity of the activity.

The Role of Corporate Governance within Groups of Companies

Guni Claudia Nicoleta
Spiru Haret University
borsanclaudia@yahoo.com

Abstract

The corporate governance is a new concept in the international economic life. There is no unitary definition of the concept. Some economists consider that corporate governance envisages the mechanisms that assure the investors they will get the expected results of investments in companies others ensure the responsibility of those who take decisions, thereof the owners. The corporate governance specific to the way of distribution of rights and responsibilities among different participants in company's activities, such as The Board of Directors, the managers, shareholders and other persons directly interested, establishes the rules and procedures for taking decisions.

Key Words: the theory of the agency, the theory of administration, the theory of the stakeholder.

JEL Classification: G3; G32; G34

1. Introduction

The concept of corporate governance has emerged in the 70s in the United States amid the Watergate scandal when it was revealed the involvement of American companies in politics by contributions to various political parties. The concept was first used in national institutions, commercial organizations, but also in the management of colonies and occupied territories. Subsequently, the concept of corporate governance has been developed in the private sector and it was taken over and applied in most of the areas of activity, expanding rapidly in recent years, especially in the public sector organizations. Nowadays, all organizations and most countries are concerned about the implementation of corporate governance principles. The governance is a very broad concept that includes a robust and effective

supervision of the way in which something is achieved, managed, controlled or administered, in order to protect the interests of the components of a respective field, organization or institution. According to some authors the concept of corporate governance must be addressed together with the risk management throughout the organization and with the evolution of the financial management system and internal control.

2. The role of corporate governance within Groups of companies

The corporate governance should be seen as a process in which the organization is involved in general and it refers to all internal components working together, that will eventually be integrated into a single recognized management structure. On the other hand, in the 1992 Cadbury Report, Sir Adrian Cadbury defined the corporate governance as the system that guides and controls companies. The Cadbury Code established for the first time the basic rules of running a campaign to achieve efficiency, concomitant with a nondiscriminatory behavior towards shareholders. The Cadbury report series that began in 1992, admitted the need to establish some audit committees, the widespread use of non-executive directors that do not have managerial responsibility within the company[2].

The organizations should adhere to all the concepts, principles, standards and corporate governance regulations in order to be evaluated and achieve expected relevant policies and performance. The corporate governance codes and policies have become a balance between compliance and performance.

There are known to two sides of the corporate governance concept:

- the behavioral one, referring to the way in which interact the managers of a company,

the shareholders, the employees, the creditors, the customers and suppliers, the state and other interest groups within the overall strategy of the company;

- the normative one, referring to the set of regulations that fits these relationships and behaviors, respectively the companies' law, the securities' law and the capital markets, the bankruptcy law, the competition law, the stock exchange listing requirements etc.

The corporate governance regards the interests of both the company's internal components, and the external ones, defined as follows:

→ the internal components are represented by shareholders / partners, board members, directives committee members, managers, employees, creditors, investors and customers;

→ the external components are represented by the legal provisions that govern the relations between the internal components as well as the decision-making activity in the company;

The corporate governance objectives are:

- The effective and continuous communication between the internal components;

- Financial discipline through the internal and external audit of the company;

- The efficiency, the Board of Directors taking optimal decisions;

- The continuous communication to the public of the financial condition and of the company's objectives;

- Ensuring that the company, through its actions, demonstrates responsibility towards community and environment[4].

The corporate governance does not represent a concept applicable only to the individual enterprise level, it also extends to the group of companies, where the complexity of the links between companies and of the activities performed, involves a high degree of responsibility of the managers towards the owners. The corporate governance has its roots in the corporate mechanisms and in the bankruptcy laws in each country, and in the judicial enforcement mechanisms that establish basic rules of the internal relations between various participants in a corporation. The implementation method of the corporate governance varies significantly from country to country and from company to company.

An efficient implementation of the governance allows companies an easy access on the capital markets, access that is required in order to obtain financing, given that growth opportunities can be financed domestically.

The concept of corporate governance has drawn the attention on the business environment, first of all in the main countries, with market economy, on one hand, as a recognition of the fact that large financial institutions have an increasing influence on the companies they finance and, on the other hand in response to notorious financial failures. Moreover, the major financial and bankruptcy scandals have determined the European Union to develop a corporate governance code, which however is not mandatory. There are also two international and two European codes, applicable to European Union companies that come to provide transparency, quality, consistency and comparability of information. The attention for the concept of governance is now focusing on the developing economies because the stock listing crosses borders more intensively. There is a growing preference of investors to seek new markets to place their funds. In these countries, most companies consider adopting corporate governance rules as being complicated, as it involves the modification of the constitutive document of the company.

The changes would aim, among other things, to a sufficient and transparent communication. Last, but not least, the corporate governance assumes a well established control system. The investors become more and more demanding, in terms of data quality and governance standards that they require from the companies and markets where they intend to invest capital[1].

Regarding the consolidated financial statements of the company, they are audited by one or more individuals or legal entities authorized by law. The person or persons responsible for auditing the consolidated annual financial statements, referred to as statutory auditors, also express an opinion on the level of compliance of the consolidated report of the administrators with the consolidated annual financial statements for the same financial exercise.

In recent decades, the corporate governance is the concept that has affected

most of the already developed and developing countries. OECD published in 1999, as an argument, "The Corporate Governance Principles", including the principles referring to the issues where the administrators have a key role: the rights of shareholders, the fair treatment of the shareholders, the role of the shareholders in the corporate governance, the communication of financial information and its transparency, the responsibility of the Board of Directors.

The global corporate governance principles developed by the OECD, are:

- to promote transparency and market efficiency, compliance with rules and laws and the division of responsibilities between different managements, regulations and authorities;
- to protect and facilitate the rights of shareholders;
- to ensure the fair treatment of all shareholders, including the minority and foreign ones, so all shareholders have the opportunity to obtain effective compensation for violation of their rights;
- to recognize the rights of the shareholders, established by law or by approved commitments and to encourage cooperation between organizations and shareholders in creating value, employment and in supporting entities that are financially healthy;
- to ensure a timely and reliable disclosure of information concerning all the aspects of the materials relating to the corporation, including the financial situation, the performance, the ownership and the management of the company;
- to ensure the strategic direction of the company, the effective monitoring of the management by the Board of Directors, as well as the Board of Directors' responsibility towards the shareholders and the company.

The overall objective of any government is to ensure the balance of power between different actors participating, and commissioning these control tools for both shareholders participating in intangible capital and for other participants to this equity. The corporate governance nowadays, assumes treating complex contemporary issues by teamwork where everyone contributes. A strong governance assumes the establishment of some fundamental principles that define the relationships

between different actors, clearly outlines the responsibilities and guarantees the correct function of the decision-making processes. The governance systems actually have two main objectives: ensuring the integrity of management and its orientation to maximize the value created for shareholders or stakeholders[3].

The specific objectives of the corporate governance at the entity level refer to:

- the effective and continuous communication between the internal components (the shareholders, the Board of Directors, the Steering Committee members, the executives);
- financial discipline via internal and external audit in the company;
- ensuring effective protection of shareholders' rights;
- the effectiveness and efficiency of the activities of the organization in achieving management objectives through optimal decisions taken by the Board of Directors;
- continuously informing the public on the company's financial condition and objectives, while respecting commercial confidentiality;
- ensuring that the entity, by means of its actions, demonstrates responsibility towards the community and the environment;

In the Western world, especially in the developed countries, there are faced two patterns of corporate governance: the shareholder and stakeholder pattern.

- The shareholder pattern type is the one found in the Anglo-Saxon countries. The objective to be achieved is the maximization of value for shareholders, namely the profit and the stock market. In these countries, the financial markets are highly developed, and the capital of the enterprises is relatively atomized, in these circumstances the managers are controlled by the general meetings of shareholders.

- The stakeholder pattern type is present in most European countries, except for certain countries in northern Europe and UK. For this pattern, the objective to be achieved is not so much the maximization of the shareholders wealth, but defending the interest of all parties involved, one way or another, within the company (the employees, the business partners, the shareholders, the managers and so on). In the stakeholder pattern type the financial markets are not very developed and the capital of the

enterprises is often controlled by powerful shareholders, that hold a significant part, alone or through several control blocks. France and Germany are examples of this type of governance. It appears clearly the fact that in terms of corporate governance our country should choose a stakeholder pattern type[5].

The different corporate governance practices and structures reflect the interest to reduce the agent's costs and to minimize the conflict between shareholders and managers or principals and agents. Typically, the effectiveness of different systems of corporate governance appreciates based on their capacity to solve various inevitable conflicts that arise between social partners of the enterprise. The ability of the managers and of other decision factors such as the shareholders, the Board of Directors, the auditors, to harmonize and prioritize these interests directly influences the risk and the income generated from the investment in the shares of the company. Thus, the quality and the operational efficiency of corporate governance form, determine the control of variables that have a significant impact on the company's performance. However, the impact of corporate governance is not only about the micro economic sphere, but it has profound and lasting implications at macroeconomic level as well.

At the microeconomic level:

- the managers get a better understanding of the real aspects of the business in their society, with a positive impact on the ability of organizations to form alliances and partnerships and on the transparency in providing information;

- the investors become more concerned, more interested in finding information and more aggressive; a study shows that in Western Europe 56% of investors give equal or additional importance to the information on corporate governance and to the financial one. Therefore increasing the entity's ability to finance rapidly and inexpensively its development;

- the management boards become stronger, more influent. As the councils' responsibility increases, the pursuit for the highest competent managers becomes fierce. The good administrators are more expensive and more difficult to find;

At the macroeconomic level:

- increasing the national economic efficiency by a better allocation of resources;
- increasing the transparency, diminishing the level of corruption and tax evasion;
- developing the capital markets and increasing the attractiveness for investors with financial power;
- mobilizing public savings by organizing an alternative investment - the capital market;
- positive influences are also noticed on the living standards of the population;

Applying the principles of corporate governance has visible benefits on the companies that adopt them, generating competitive economic advantages. Corporate governance is often considered difficult because it involves changing the constitutive document of the company. The governance should also be supported by a well established control system.

Taking into consideration those rules, the corporate governance norms that constitute the theoretical and legal framework of carrying out the mechanism that directs and controls entities, it is worth noting that in the European Union there have been adopted a number of 35 corporate governance codes, each country having at least one code. Most of these codes were issued after 1997, after financial scandals and bankruptcies of British companies listed on the stock market. Approximately one third of the codes, applicable in EU countries, have been elaborated by groups or associations of investors. These codes applicable in the EU are different, due to the purpose they have been issued for and their detailing degree. They address the following issues: fair treatment of all shareholders, whose interests should be a priority; the clear responsibility of the Board of Directors and management; the company's transparency or the accuracy of the financial and non-financial reporting; the responsibility for the minority shareholders' interests and of other social partners, as well as the compliance with the law[4].

The corporate governance codes provide flexibility and they are not compulsory, even in the case when the principle "comply or explain" applies, the companies are free not to follow the recommendations of the codes provided they report and explain their failure. However, the fact that they are not compulsory raises the question of their

effectiveness in practice.

3. Conclusions

The corporate governance may reduce the agency problems by adopting mechanisms to monitor the activity of managers. This should result, on one hand into a higher operational performance, as long as the managers are encouraged to invest in projects with positive current value, and on the other hand, to increase the company's value, as the investors realize that most of the company's cash flows return to them. In the countries where the traditional ownership structure is dispersed, as in the USA, UK or Japan, the concentration of capital has an either positive or negative effect on the performance.

Dynamics and Structure of Domestic Credit in Romania

Gust Marius

„Constantin Brâncoveanu” University Pitești
mariusgust@yahoo.com

Abstract

The crisis that affected the Romanian economy from the last months of 2008 was not without consequences for the banking system of our country. One of its effects was the Romanian banks' lending policies. Changes in lending policy content of Romanian credit institutions can be seen by analyzing the structure and dynamics of domestic credit.

Keywords: Romania, banks, credit, dynamics, structure.

J.E.L. Classification: G21

1. Introduction

One of the functions of banks in a market economy is that of intermediary in the relationship economy - investments, in other words it temporarily collects the amounts available in the economy in the form of deposits and redistributes them to the economy, to those that need financial resources, in the form of loans [1].

This second aspect, granting of loans, is the objective of this work. More specifically, the analysis of the impact of the economic and financial crisis had, which made its presence felt in Romania in the second half of 2008, on the domestic credit in terms of its dynamic and structure.

2. The research method

The research methods used are: classification, synthesis, static and dynamic comparative analysis, methods of induction and deduction, the graphical representation of events and phenomena investigated. Partly were also used a series of mathematical and statistical tools, accompanied by deductive analytical analysis. However, the work is of a qualitative nature, rather it aims for an overview of the instrument and its results not

to validate or criticize the dashboard. Statistic data used are for official nature, being taken from documents or databases of the National Bank of Romania.

3. Dynamics of total domestic credit

Total domestic credit in lei, at the current value, continued to increase during the four years of crisis, increasing its value with about 60 billion lei. However, its dynamic was more modest compared to the period up to 2008, when there were years in which only the annual growth meant doubling it, perfectly understandable situation given that our country had gone from relatively low lending.

Table 1. Domestic credit in Romania.

Year	GDP (billion lei current price)	Average exchange rate (lei/euro)	GDP (billion euro current price)	Total domestic credit (billion lei)	Total domestic credit (billion euro)	GDP rate(%)
2008	514,7	3,68	139,9	224,2	60,9	44
2009	501,2	4,24	118,2	271,1	63,9	54
2010	523,7	4,21	124,4	271,1	64,4	52
2011	556,7	4,24	131,3	265,6	62,6	48
2012	587,5	4,46	131,7	284,7	63,8	48

Source: Authors' calculations based on data from the Monthly Bulletin no. 1/2013, the National Bank of Romania and the information from the database interactive NBR <http://www.bnr.ro/Statistica-87.aspx>

However, for correct assessment of domestic credit growth in the period after 2012 is required to follow its share in gross domestic product (GDP), the latter recorded in comparable values decreases during the first years of crisis and subsequently registered modest or negligible growths. Thus, domestic credit, as rate to GDP experienced a contraction of about 4%, after recording a maximum of 52% in 2009. Domestic credit contraction is a very negative phenomenon for

the Romanian economy, while its value is less than half of the EU average and, on the other hand is about 8% of the maximum value that the indicator reached [2].

Another appreciation can be done converting the whole domestic credit in euro using the average exchange rates for each year. Thus, although higher than the value at the beginning of the crisis, total domestic credit converted into euro, shows at the end of the interval an increase of much less than 5%, while the maximum was reached in 2010.

The conclusion drawn is that in the four years of crisis the intermediary role of banks experienced an acute erosion, their lending capacity maintaining at the values near the beginning of the recession.

4. Domestic credit structure

The main structural change in the total domestic credit is localized at the level of domestic credit. Thus, as absolute value in lei, it has increased of about 5 billion lei, from 99 to 104 billion lei in the four years analyzed, but declined both as a share of GDP by about 1.5%, and as value converted into euro, a decrease of 3.6 billion euro and as a percentage of total credit. In the latter case, the contraction most consistent was of 7.5% [3].

Reasons for the decline must be sought into: (1) the reluctance of banks to invest in loans to people, given that it currently brings most of the bad loans in the banking system, (2) uncertainties of the population in regarding future revenues of this group, (3) and the tightening of granting credit, making few people to still qualify for new loans.

In contrast with lower credits for population in crisis years we have seen a consolidation of loans to the business segment, growth being of about 25 billion lei. However, credit to businesses increases are much lower if you convert the euro and analyze it as a share of GDP and as a share of total credit, has even a slight decrease.

Regardless of previous evolution to note that lending to businesses during the crisis has become the main form of credit, showing a change in their banking policies and a boost in their involvement in the economy. In the four years of crisis we have witnessed: (1) a slight disengagement of banks towards the financial sector, lending to them decreased to negligible values; (2) an increase in government lending

in the early state of crisis, given its ample financial needs and consistent budget deficits. But in recent years government lending fell slightly, the state borrowing cheaper in foreign markets and budgetary pressures and the budget deficit getting smaller; (3) an increase in credit to non-residents.

Table 2. Dynamics and structure of domestic credit in Romania.

Year	Total credit (billion lei)	Of which, granted:				
		households	Public companies	Non-monetary financial institutions	Public administration	Non-residents
billion lei. Absolute values						
2008	224,2	99,2	94,5	4,3	6,2	19,9

5. Credit to population trends

At the credit to population level are observable a number of structural changes.

Thus, foreign currency loans, especially the euro, remain the main type of credit required by the population, given that it costs continued to be below the national currency credit. Interestingly, if declaratively the management of Romanian commercial banks, and the central bank, reiterated the risks of this type of credit and the in the future the wish for it to be reduced in size, in practice it grew [4].

Table 3. Dynamics and structure of the credit for populație in Romania.

Year	Total	Of which:

2011	100	33,6	53,1	13,3	59,4	32,0	8,5
2012	100	32,9	54,6	12,4	55,5	35,5	9,0

Source: Authors' calculations based on data from the Monthly Bulletin no. 1/2013, the National Bank of Romania and the information from the database interactive NBR <http://www.bnr.ro/Statistica-87.aspx>

Loans in exotic currencies (Swiss franc, Australian dollar and so on), but also those in U.S. dollars, although increased slightly in absolute value (normal in the conditions of the leu depreciation of the four years) decreased as a share of GDP or as a share of

total loans, meaning that banks understand credit risks in such currencies, as well as population, credit institutions, in recent years, initiating conversion processes of this type of loan into other currencies.

To the domestic credit in lei contracted by population, the crisis made it more smaller in size, the decreases being ample in size and were observed regardless of the method of measurement. Worth mentioning a figure in the total loans to households it represents more than a third, while in euro it gives about 55%.

Analysis of lending to households by purpose indicates other interesting changes. Firstly there is a contraction of consumer credit, by approx. 16 billion, but as a percentage of total loans to the population decrease is of about 25%, from about 75% to just over 50%. Decrease explanation is that many consumer loans granted before the crisis or its early years, usually with terms of 1 year or between 1 and 5 years, have reached maturity, banks initiating few such new contracts of consumer credit during crisis years, to replace those that have reached maturity.

Secondly, housing loans increased absolute value doubled, the increase being from about 20% to about 35% as a share of total credit to the public. Housing loan usually takes into account long term, for over 10 years and in most cases it is denominated in euro. Thus, explains why it grew, the leu depreciation amplifying its value as decreased consumer credit has increased the housing and, additionally, the state has supported this type of loan, the program "First House" [5].

6. Credit developments for companies

Loans in foreign currency is, as with people, the main form of business lending, nearly 60% of total loans to firms are denominated in other currencies. Obviously, the best placed are loans in euro, the other currencies (dollar, etc..) are much more underrepresented than those granted to population (about 3%).

Euro loans to businesses increased in the four years of crisis with approximately 17 billion lei and those in lei with about 8 billion, the only decrease is recorded in loans in other currencies. However, converted into euro loans to companies seem more stable in volume, only growth seen in the denominated loans in euro, with an increase of approx. 2

billion, the explanation is very strong depreciation of the leu during this period.

Table 4. Dynamics and structure of the credit for companies in Romania.

Years	Total	Of which:					
		By currencies			By terms		
		lei	euro	Other currencies	Up to 1 year	1 - 5 years	over 5 years
billion lei. Absolute values							
2008	94,5	40,9	48,9	4,7	39,6	27,3	27,6
2009	96,2	39,2	53,3	3,7	39,4	26,6	30,1
2010	104,6	40,0	61,0	3,7	39,6	30,1	35,0
2011	115,4	44,6	66,3	4,5	45,2	32,1	38,1
2012	118,7	48,8	65,8	4,1	48,5	32,0	38,3
billion euro							
2008	18,4	7,9	9,5	0,9	7,7	5,3	5,4
2009	19,2	7,8	10,6	0,7	7,9	5,3	6,0
2010	20,0	7,6	11,6	0,7	7,6	5,7	6,7
2011	20,7	8,0	11,9	0,8	8,1	5,8	6,8
2012	20,2	8,3	11,2	0,7	8,2	5,4	6,5
GDP shares - %							
2008	25,7	11,1	13,3	1,3	10,8	7,4	7,5
2009	22,7	9,2	12,6	0,9	9,3	6,3	7,1
2010	24,8	9,5	14,5	0,9	9,4	7,1	8,3
2011	27,2	10,5	15,6	1,1	10,7	7,6	9,0
2012	26,6	10,9	14,8	0,9	10,9	7,2	8,6
structure (% - in credit for companies)							
2008	100	43,2	51,8	5,0	41,9	28,9	29,2
2009	100	40,8	55,4	3,8	41,0	27,7	31,3
2010	100	38,2	58,3	3,5	37,8	28,8	33,4
2011	100	38,7	57,4	3,9	39,1	27,8	33,0
2012	100	41,1	55,5	3,4	40,8	26,9	32,3

Source: Authors' calculations based on data from the Monthly Bulletin no. 1/2013, the National Bank of Romania and the information from the database interactive NBR <http://www.bnr.ro/Statistica-87.aspx>

The same mentions in the case of analysis of lending to firms as a share of GDP, although in this case loans in other currencies seem to decrease more. Regarding the term of granting, which in the case of loans to businesses overlap destinations: the ones on short-term, under one year, being destined to exploitation, the middle term ones, between 1 and 5 years, exploitations of firms with a long activity cycle, but also small-scale investments and long-term over 5 years, large investments, the following changes occur:

- analyzed in terms of absolute value, loans

of up to one year and more than 5 years, grow each with values of about 10 billion, and those of middle term with about 5 billion lei, but converted in euro increased by half a billion, the short-term ones with more than a billion, the long-term ones appear to have stabilized at values of about 5.5 billion the ones of medium term;

- as a percentage of GDP, short-term credit in 2012 returns to its value at the beginning of the crisis, 10.9% of GDP, the medium term one decreases slightly, to 7.2%, the only increase being observed in long term credits, they increased by 1% and reached 8.6%. The same behavior is also found when analyzing the terms for granting credit to business as a share of total [6].

As a conclusion, in the case of business credit, we find that the request is directed, on the one hand, to the loans to finance current exploiting activities, they are trying to overcome liquidity problems generated by the crisis (late collection of deliveries, decrease of sales), and on the other hand, the technical renewal through investments they probably do, trying to offset the loss of competitiveness due to higher costs. Should also be noted the orientation of companies to foreign currency credit, Romanian companies prefer currency risk and avoiding the credit in lei, although it would have generated lower financial expenses. In fact, in the last three years, the depreciation of the leu was below 10%, so it had a much smaller impact on business costs, while interest rates on loans in lei, in relation to the currency, means interest expense is almost double.

7. Government credit developments

In the early years of crisis the credit addressed to the public administration (government) greatly increases. Thus, it almost doubles its value, reaching over 11 billion USD, compared to 6 billion lei, at the beginning of the crisis, amid lower state revenues, maintaining the level of public spending and increasing the budget deficit. In the last two years, it compresses and government resolves some budgetary problems, under Agreement with the EU, IMF and so on or preferring to borrow cheaper on foreign markets.

It should also be noted that the government loan converted into euro has

modest value, just over 2 billion, while the total external debt of Romania was close to 100 billion euro and external public debt was on 31 January 2013 almost 30 billion euro.

As a share of GDP, government credit is 1.7%, and total domestic credit under 4%, values that do not have a negative impact too important. Sure, that does not mean that this type of loan does not lead to resources reorientation to finance the real economy to financing unproductive expenditures, which are the prerogative of the state. However, the mere existence of government credit means higher state costs with interest.

Table 5. Dynamic and structures of government credit in Romania.

Years	Loans granted to public administration	Of which for the administration		Loans granted to public administration	Of which for the administration	
		central	local		central	local
	billion lei.			billion euro		
2008	6,2	2,3	3,9	1,7	0,6	1,1
2009	11,3	6,3	5,0	2,7	1,5	1,2
2010	11,2	5,3	6,0	2,7	1,3	1,4
2011	10,8	3,7	7,1	2,5	0,9	1,7
2012	9,9	1,2	8,6	2,2	0,3	1,9
	GDP rates - %			Rates-% in total credit		
2008	1,2	0,5	0,8	2,8	1,0	1,7
2009	2,3	1,3	1,0	4,2	2,3	1,8
2010	2,1	1,0	1,1	4,1	1,9	2,2
2011	1,9	0,7	1,3	4,1	1,4	2,7
2012	1,7	0,2	1,5	3,5	0,4	3,0

Source: Authors' calculations based on data from the Monthly Bulletin no. 1/2013, the National Bank of Romania and the information from the database interactive NBR <http://www.bnr.ro/Statistica-87.aspx>

I would also like to note that for credit institutions, government credit meant that keeping their interest income, which is partially offset lower interest generated revenues more modest increases in credit to the public, the latter generating up to the crisis the bulk of banking revenues.

More important is the structure of government credit. Thus, most of it going to local authorities and the greater part to the central authority. If at the beginning of the

crisis, 40% of government credit went to the Central Authority, value that reached nearly 60% in 2009, but falls to below 15% by the end of 2012, the difference of 85% going to local authorities. Credit for local authorities is increasing because it co-finances a number of EU funded projects or tries to make allocations of funds more and more modest of the central budget to local budgets or own reduced revenues of administrative territorial units.

8. Conclusions

Total domestic credit in lei, at the current value continued to increase during the four years of crisis, it increased its value with about 60 billion lei. However, as a share of GDP, domestic credit a contraction of 4% after recording a maximum of 52% in 2009.

As a structure, credit for population limits its size, growing for the companies, and the government credit after rising early in the crisis, seems to reduce itself in volume in the last two years, while the greater part of it is moved to the local authorities.

The conclusion drawn is that in the four years of crisis the intermediary role of banks experienced a pronounced erosion, its lending capacity maintaining near the values of the beginning of the recession.

The Impact of Globalization in the Context of the Current Crisis

Haralambie George Alin
Petroleum-Gas University of Ploiesti
haralambiegeorgealin@yahoo.com

Abstract

The economic crisis triggered in 2007 in the U.S. had reverberations around the world, with serious consequences in the field of economic exchanges and financial, which required a rethinking of economic policy at the global level. The economies of the developed countries and emerging markets were affected, the crisis deepening the gap between heavily industrialized nations and developing states as well as the least developed states, in particular African states. In this context the world expected a minimal state involvement in the financial sector through the provision of funds to be used to meet the need of liquidity of banks. A natural consequence is the increasing indebtedness of these countries with naturally impact on the trade deficits. The financial crisis has boosted the role of governments in national economies, making at the same time necessary the cooperation at international level in order to adopt concerted measures for economic recovery.

Keywords: global economy, financial crisis, public debt, budget deficit, domestic demand
JEL classification: G01

1. Introduction

The world economy is a heterogeneous system manifested by differences on the size of the countries, demographic and economic potential of states as well as their economic system.[1]

The last decades of the twentieth century is emphasizing the process of globalisation manifested by the globalisation of large companies and structuring them in networks, trade liberalization and also by the rapid transmission of information, a natural consequence being the inability of global

economy of functioning for the benefit of all without solidarity and international cooperation.

Economic globalization manifests itself through an intertwining of economies, by increasing the role of foreign capital and investment and trade between the states.[2]

Amid the increasing interdependencies between States, the economic crisis has evolved rapidly worldwide in the financial sector, as a result of the collapse of major financial institutions, which had imposed a new form of development cooperation at the global level.

2. Anti-crisis policies and their effects on the economy

The current crisis was characterized by an initial period of economic recession that has put pressure on rising unemployment. Tax revenues have felt the strongest these macroeconomic imbalances which led to their reduction. Total public expenditure could not be adjusted in accordance with these revenue decreases. The result was the increasing deficits of the consolidated national public budget, that, in turn, have led to significant increases in public debt of the countries of the world.

The first step in combating the effects of the crisis was marked by the adoption by the central banks of some measures in the field of monetary policy, together with the implementation of fiscal stimulus packages by the majority of governments by, in order to restore financial equilibrium. At the same time some states have had to resort to public funds to rescue banks.

The measures were aimed at the reform of the international monetary system, and reducing the volatility of capital flows in the short term due to speculative operations.

Amid the growing budget deficit and the accumulation of large debts, many countries

have abandoned the stimulatory fiscal policies by adopting a policy of reducing public spending while increasing fiscal pressure.

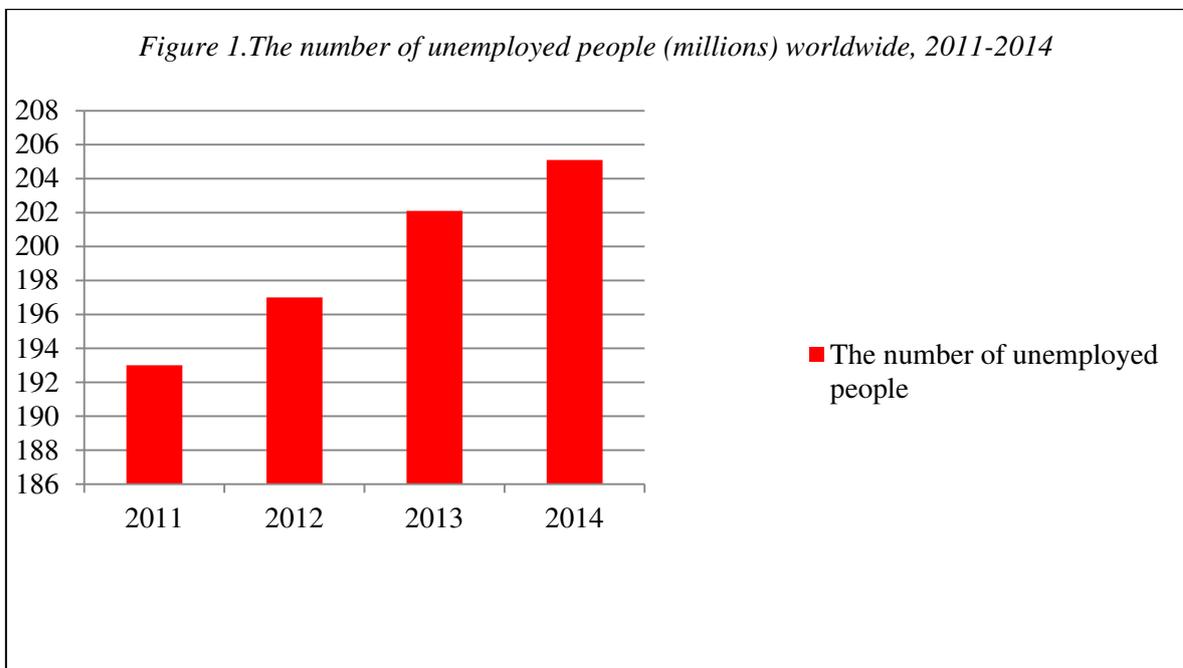

The measures taken have had the effect of lowering the expenditures in the private sector, with consequences over the production of goods and services, economic agents being forced to restrict the activity which has led to rising unemployment, lower wages with impact on consumer purchasing power and a further reduction in consumption by giving birth to a degressive spiral.

According to the agency for work within the UN, the number of unemployed worldwide has increased by 4 million, in 2012, reaching a total of 197 million, in 2012, reaching a total of 197 million. below.

The International Labor Organization's report mentions that young people are most affected by unemployment: approximately 13% of the planet's young (under 24 years of age) don't have a job.[3]

The estimates for the current year are pessimistic, 5.1 million people remain jobless, and in 2014, another 3 million, which reflects an economic decline, especially in developed countries due to the inefficiency of the measures adopted by the governments.

The same report shows an increase in long-term unemployment, due to the decrease in demand for goods and services, investment and demand on the labour market, as it highlights and figure

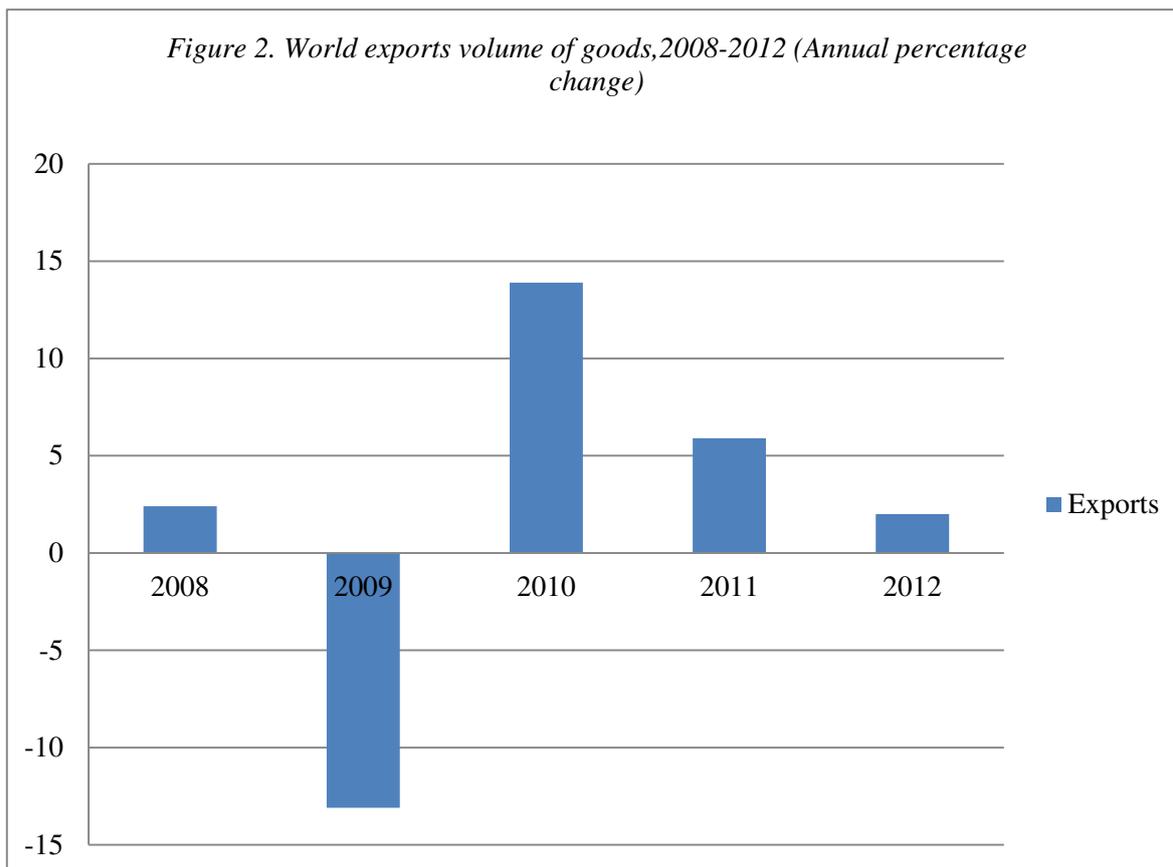

Source- based on data provided by The Report of International Labor Organization

The degree of indebtedness of households and economic agents to the banks in many countries continues to be high, financial institutions were reluctant to provide new financing.

Financial policy must have as single purpose external and internal investments stimulation by means of facilities of a fiscal

nature, investors are attracted to countries with a high level of qualification of the labour force and low wage costs.

In this situation, the developed nations were based to a large extent on domestic demand than on exports, which registered a decline globally, as demonstrated in Figure 2.

Source- based on data provided by UNCTAD, Trade and Development Report, 2012

If at the beginning of the crisis the world's States have embraced the doctrine of Keynes which implies that during downturns governments must increase the expenditure made from the budget, reduce taxes and lower interest rates which would have the effect of stimulating consumption and investment, in this way the global economy registering a recovering, subsequently they have resorted to reducing public spending, increasing fiscal pressure as well as the adoption of measures of tightening credit conditions that have resulted in the decrease in demand and the economy's entry into a new recession. The beneficial effects felt originally were canceled. The reasons which have led to the adoption of these measures were large budget deficits and the accumulation of huge debts that were paid to "regain the confidence of the financial markets" and that of the creditors. A huge pressure existed from the international financial institutions that have conditioned the granting of credits by taking measures such as those set out above.

Long term stability of the global economy and sustainable growth cannot be achieved

without a tighter regulation of the financial sector and the orientation on investments in fixed capital, which requires increasing the coherence between the multilateral trading system and international monetary system.

At national and regional level, a reorientation of fiscal policy that takes into account the macroeconomic situation in general is required, than a policy focused exclusively on balancing budgets or the attainment of the rigid public deficit.

Governments must pursue a policy based on increasing incomes of the population as the basis for sustainable and balanced development of the global economy, otherwise the economic recovery will not be possible.

Therefore, it is necessary a fundamental reorientation of macroeconomic policy, based on the expansion of consumption and investment in productive capacities as a prerequisite for economic growth, based on positive expectations for growth in revenue of the population and entrepreneur.

The pace of global recovery has seen a decrease in 2011. Global GDP in 2010

recorded a growth of 3.9% and in 2011 was 3.1%.[4]

The tendency manifested in previous years remained in the year 2012, gross domestic product growth at a global level (GDP) being about 2.5 percent due to the continuation of the crisis in the eurozone, where the governments of the member states have failed to find a solution to resolve global imbalances and problems relating to internal public debt.

3.Perspective on the dynamics of the global economy

The unconditional austerity policy adopted by most countries block return to a sustainable economic growth, estimates for the next period are grim.

In the report of the International Monetary Fund it estimates a growth for advanced economies, with an annual rate of between 1.3% and 2.6% in the period 2013-2017, since reducing tax revenues will continue to affect public spending. Taking into account the actual levels of government debt and deficit for these economies, it will require years of concerted political and economic efforts so that the level of government debt in the GDP of the United States, Japan and several countries in the eurozone to fall.

Also, the growth of the emerging economies and that of newly industrializing economies will slow down compared to the pace recorded in 2010. Instability in the eurozone will continue to shape the overall prospects in the coming years.

The world economy experiences a persistence climate unfavorable investment, determined by the macro-financial environment in the euro area, as well as economic-financial jams.

At european and international level it is necessary to implement a program aimed at reducing the effects of the crisis and the recession through:

- progressive income taxation, the reduction of tax evasion and the abolition of tax havens;
- stimulating economic growth through government spending, that must compensate the collapse of the private demand;
- indexing wages and pensions;
- strict control over speculative operations performed on the capital market both in

terms of the movement of capital and tax on earnings made;

-allocation of funds for investment in infrastructure, industry, agriculture, leading to the creation of new jobs.

4. Conclusions

Specialists in economics have concluded that in the evolution of economic activities there is a surface characterised by expansion and contraction in a certain sequence and regularity, the evolution of the economy are not linear, marked by periods of growth followed by setbacks.

The evolution of the main economic phenomena has a certain repeatability over time due to natural, socio-political and technological factors.

The cycles can be long, medium and short depending on the measures taken by governments for economic recovery.

Considerations on the Profile of Respondents to the Comment Letters Submitted for IFRS 9 Financial Instruments. Phase 1 and 2

Huian Maria Carmen

Universitatea „Al. I. Cuza” Iași, Facultatea de Economie și Administrarea Afacerilor
maria.huian@uaic.ro

Abstract

The paper examines the profile of the respondents to the exposure drafts published by the IASB as part of the IFRS 9 „Financial Instruments” project – phase 1 and 2. The analysis of the 650 comment letters submitted showed that preparers (consisting of financial institutions and their trade associations and also non-financial corporations and their trade associations) were the most active group of stakeholders, even though the accounting profession and the regulators were also very interested. The users had a low rate of participation in all 3 documents analyzed. The geographic analysis showed a 2-continent battle between Europe and North America with the Europeans submitting the greatest number of letters for the ED/2009/7 and ED/2009/12 and the North-Americans surpassing them in responses for the SD/2011.

Key words: financial instruments, comment letters, IFRS 9, IASB.

J.E.L. Classification: M41

1. Introduction

In 2008, the International Accounting Standards Board (IASB) has started a new project aimed at replacing the existing standard for financial instruments (IAS 39) with a *new* one, less complex, more relevant and useful. The project’s name is IFRS 9 Financial instruments. The Board divided its project to replace IAS 39 into three main phases.

The first phase was completed in 2010, in 2 steps: a) in November 2009, the IASB issued IFRS 9 “Financial instruments” on the *classification and measurement of the financial assets*; b) almost a year later, in

October 2010, the Board issued additions to IFRS 9 for *financial liabilities accounting*.

The 2nd phase called *Amortized cost and impairment of financial assets* is still to be completed. An ED (ED/2009/12 Financial instruments: amortized cost and impairment) was issued in November 2009, but due to negative public commentary and a different approach followed by the American standard-setter, a supplementary document was needed. Supplement to ED/2009/12 *Financial Instruments: Impairment* was published in January 2011 together with the American standard-setter: the Financial Accounting Standards Board (FASB). The comment period closed on 1 April 2011 and re-deliberations are on-going.

The 3rd phase dealing with hedge accounting consisted of an exposure draft ED/2010/13 *Hedge Accounting* that was published in December 2010. After several re-deliberations, on 7 September 2012 the IASB posted to its website a draft of the forthcoming general hedge accounting requirements that will be added to IFRS 9 Financial Instruments.

This paper sets out to analyze the profile of different stakeholders who responded through comment letters to the new accounting rules provided by the ED/2009/7 *Financial instruments: Classification and measurement*, ED/2009/12 *Financial Instruments: Amortized Cost and Impairment* and *Supplementary Document (SD/2011) on ED/2009/12*.

2. Research questions

This paper explores the involvement of stakeholders through *comment letters* written in response to the IASB’s issuance of EDs. Profile of respondents was defined based on their interests and their geographic distribution. Therefore, two research questions were developed.

RQ1 Did accounting profession, users, preparers, regulators and others write comment letters to IASB on the subject of financial instruments: classification and measurement (IFRS 9 – phase 1) and impairment (IFRS 9 – phase 2)?

RQ2 Did respondents from Africa, Asia, Australia and Oceania, Europe, North America and South America write comment letters to IASB on the subject of financial instruments: classification and measurement (IFRS 9 – phase 1) and impairment (IFRS 9 – phase 2)?

In this research, the *accounting profession* comprises professional accounting bodies (IFAC members), public accounting firms and other accounting groups.

Users include financial analysts and financial investors. *Preparers* include financial institutions, their trade associations, non-financial corporations, their trade associations and actuaries.

Preparers/users consist of insurance companies that use financial instruments in their operating activities, but also in their investing activities. *Regulators* consist of accounting standard setters, stock exchange regulators and other government entities.

Others are represented mainly by the academic community and individuals whose affiliation could not be clearly established.

3. Methodology

In order to achieve the goal of analyzing constituents' involvement in the process of developing an IFRS, we focused on the comment letters published on the IASB's website [7] for the 1st and 2nd phase of the IFRS 9 project and on the FASB's site [6] for the SD/2011. Additional data on corporations was obtained from respondents' websites.

For the ED/2009/7 “Financial instruments: classification and measurement”, the total number of letters submitted was 246. One letter could not be accessed due to the file being corrupted (CL27). In addition, one respondent sent two letters (Association of Danish Mortgage Banks). Therefore, the final number of comment letters analyzed was 244.

For the ED/2009/12 “Financial instruments: amortized cost and impairment of financial assets”, the total number of

letters submitted and analyzed was 192. The SD/2011 received 214 letters submitted and analyzed.

4. Results

Respondents from over 33 countries and several stakeholder interest groups submitted their responses to the 15 questions provided by the IASB through the **ED/2009/7**.

Of the 244 letters, 119 (49%) were sent by the *preparers* of the financial statements that were identified as financial institutions (50 letters – 20% of total letters), financial trade associations (34 letters – 14%) and non-financial corporations and their trade associations (35 letters - 15%) (Table 1). This is consistent to other researchers' findings [5]. In addition, the large number of letters from trade associations was not unexpected and could be explained by cost considerations.

The *accounting profession*, consisting of 18 professional accounting bodies – all IFAC members, 9 public accounting firms, and 9 other accounting groups – such as Association of International Accountants, Federation des Experts Comptables Europeens, comes 2nd with 36 letters (15%) and is closely followed by *regulators* (34 letters – 14%). *Users*, including the users/preparers category, only account for 13% of all answers (32 letters). The stakeholder interest group represented by the *others* sent 23 letters (9%) (Table 1).

The participation of financial institutions and their trade associations is significantly more important than other researches on financial instruments showed [1]. It has increased on the account of the non-financial corporations and their trade associations whose number has decreased. This could be explained by the major use and promotion of financial instruments by the financial institutions and by the effects of the recent financial crisis.

Respondents from over 35 countries and several stakeholder interest groups submitted their responses to the 12 questions provided by the IASB through the **ED/2009/12**.

Of the 192 letters, 96 (50%) were sent by the *preparers* of the financial statements that were identified as financial institutions - FI (35 letters – 18% of total letters), financial trade associations - FTA (35 letters – 18%)

and non-financial corporation and their trade associations (26 letters – 14%). *Accounting profession* and *regulators* sent 76 letters (40% of all) (Table 2).

The findings of the research are in line with several studies that found *users'* participation not very significant as measured in number of letters [2, 3]. 7 letters from users and 10 from users/preparers represent less than 10% of all letters. Therefore, the results of this research did not contradict the prior literature.

The *accounting profession*, consisting of 22 professional accounting bodies – all IFAC members, 9 public accounting firms (all big 4 and several others world known firms such as BDO, Baker Tilly, Mazars or Grant Thornton), and 13 other accounting groups, comes 2nd with 44 letters (23%). It is followed by *regulators* (32 letters – 17%). The last stakeholder interest group is represented by the *others* with 3 letters (1%).

Moreover, 68% (131 of 192) of the respondents also sent comment letters regarding the 1st phase of the IFRS 9 project: the ED/2009/7 Financial instruments – classification and measurement [4], which shows their on-going involvement in this project.

Comment letters for **SD/2011** were sent from more than 33 countries. Not surprisingly, the preparers were the most active by submitting 115 letters, 53% of all. Regulators and the accounting profession were almost tied at 16-17% (36 letters vs. 34 letters) while users maintained the low participation rate from the other EDs of 10% (21 letters) (Table 3).

In addition, 50% (107 letters) of the respondents were involved in the process of developing the other 2 exposure drafts from 2009. Moreover, some participants did not comment on the first ED on classification and measurement, but because of their interest in the impairment rules, they commented on both documents: the initial exposure draft from 2009 and the supplementary document from 2011 - 11.21% (24 letters).

Overall, RQ1 is supported. All major stakeholder interest groups participated significantly in the development of IFRS 9 through their comment letters on ED/2009/7, ED/2009/12 and SD/2011.

The geographic analysis for the **ED/2009/7** showed that most of the letters came from the EU (86 – 35.25%), USA (37-15.36%), Australia (18 – 7.38%) and Japan (15 – 6.15%). Europe alone, including non-EU countries and Pan-European respondents, provided almost half of the total number of letters (111 – 45.49%).

The most numerous group of respondents from a single country came from the USA (37 letters – 15.36% of total), followed by UK (28 letters – 11.48%). Other countries that frequently provided respondents were: France (14 – 5.74%), Canada (13-5.33%), Spain (12 – 4.92%), Germany (10 – 4.10%), and India (7 – 2.87%).

By continents, Europe dominated through the largest number of letters – 111 and 45.49% of all, North America came 2nd with 51 letters and 20.90%, and Asia came 3rd with 36 and 14.75% (Table 1). Anglo-Saxon countries (USA, UK, Canada, Australia and New Zealand) provided 99 letters (40.57%). In addition, few countries provided the majority of the comment letters (8 countries supplied almost 67% of all letters).

The geographic analysis of the comments letters submitted for the **ED/2009/12** showed that most of the letters came from the EU (69 – 36%) and USA (18 – 9%). Europe alone, including non-EU countries and Pan-European respondents, provided almost half of the total number of letters (90 – 47%). The most numerous group of respondents from a single country came from the UK (23 letters-12% of total), closely followed by the USA (18 letters – 9%).

By continents, Europe dominated again through the largest number of letters – 90 and 47% of all, Asia came 2nd with 30 letters and 16%, North America came 3rd with 28 and 15%, Australia and Oceania 4th with 14 letters and 7%, Africa 5th with 6 letters and 3% and South America 6th with 2 letters and 1%. International organizations provided 22 letters (11% of all) (Table 2). Anglo-Saxon countries provided 64 letters, 1/3 of total numbers. Again, few countries provided half of the comment letters (8 countries supplied 50% of all letters).

Considering that the **SD/2011** was a joint document issued by the two standard-setters, the international one - IASB and the American one – FASB, the reaction of the respondents from North America was

significantly stronger than for the previous documents. They clearly surpassed Europe by sending 87 letters – 40.65% of all compared to the 65 – 30.37% sent by the Europeans. Asia was 3rd with 27 letters – 12.62% and international companies came 4th with 15 letters – 7.01% of all. Australia was 5th with 12 letters -5.61%. As usual,

respondents from South America and Africa sent the lowest number of letters – 8 or 3.73% combined (Table 3).

These results are consistent with other studies [1, 5]. Therefore, RQ2 is supported; respondents from all continents provided their perspective on classification and measurement of financial instruments.

Table 1 Respondents to ED/2009/7 by Stakeholder and by Continent

Continent	Accounting profession	Regulators	Preparers			Users	Users/ preparers	Others	Total
			FI	FTA	Others

5. Conclusions

The goal of the paper was to examine the profile of the respondents to the exposure drafts published by the IASB as part of the IFRS 9 „Financial Instruments” project – phase 1 and 2.

The findings confirmed the ever-growing interest in the subject of accounting for financial instruments, interest that was significantly fuelled by the crisis of the financial markets.

The huge number of comment letters submitted by all stakeholder interest groups from all over the world highlighted that fact. Still, the preparers (consisting of financial institutions and their trade associations and also non-financial corporations and their trade associations) were the most active group of stakeholders. The accounting profession and the regulators were also very interested, being almost tied on the 2nd place. The users had a low rate of participation in all 3 documents analyzed which should be an alarming signal for the IASB who claims to consider them the most important users of the financial statements.

The geographic analysis showed a 2-continent battle between Europe and North America with the Europeans submitting the greatest number of letters for the ED/2009/7 and ED/2009/12 and the North-americans surpassing them in reponses for the SD/2011. Asians and Australians were placed 3rd and 4th in the analysis of all three documents, while respondents from Africa and South

America sent the lowest numbers of comment letters.

Conceptual Sides Concerning the Inter-Conditionality amongst the Underground Economy and Taxation

Iancu Eugenia,

Abstract

Since the taxation has practically represented a tool by which the state budget is provided, the tergiversation from their payment has become a phenomenon impregnated into the current economy. In this way, a major prejudice to the state budget is brought by the underground or unidentified economy. The weight of identified taxation tergiversation is much too low as comparing to the size of the total fiscal tergiversation, which includes the fiscal evasion of the underground economy, meaning the unidentified fiscal evasion. The underground economy has existed in all the countries of the world, in different percentages of GDP, and it is defined by the Belgian economist Pierre Pestieau as the assembly of the economic activities that are carried out outside the criminal, social or fiscal laws, or which are evading from the national accounts inventorying.

Keywords: taxation, underground economy, fiscal politics, budgetary politics, public budget;

JEL Classification: H21, H26, E62

Introduction

Within the free enterprise, the taxation has taken a double shape, as regards the economic agent. This is carried out by means of the compulsory take-offs towards the state, with influence over the enterprise's treasury, on one hand. On the other hand, the

enterprise can also use the fiscal principles and methods on its own interest.

The taxation has been delimited as a system of perceiving and encashment of the taxes and duties, as well as a coherent assembly of sources by rights, which regulates the contributors assessment and establishes in a judicial way the taxes and duties.

The fiscal politics concept comprises the assembly of measures initiated and implemented by the state, by means of the public budgets, in the view of carrying out and maintaining the macroeconomic equilibrium in the real world. This foresees the use of taxation as a tool on reaching the macroeconomic objectives, and represents the integrant part of budgetary politics that refers on choosing the public expenditures, the budgetary deficit etc. the taxes and public expenditures affects both the consumption, as well as the companies incomes, thus having a huge impact over the cost and availability of funds. By fiscal politics one should [1] establish the volume and provenience of the supply sources on the public budget, the methods of encashment that follows to be used, the aimed goals, as well as the means of accomplishing them.

Concisely analysis over two of countries owning the highest underground economy

Bulgaria

Bulgaria [2] has had an advantageous fiscal system, considering many points of view. Either one talks about lower taxes, about a predictable and steady fiscal system

or about the reduced bureaucracy, this seems to be an accurate environment in order to develop business. Bulgaria owns one of the lowest taxes within European Union, as regards the companies' profit. **The profit tax** in Bulgaria is 10%, and **the dividends tax** is of five percentages. The companies are not obliged in Bulgaria to submit quarterly fiscal declarations. The companies have the obligation on submitting a yearly profit tax declaration until the 31st of March, including for the following year. In the same term, the companies should pay the yearly profit tax, as well.

- An accountancy system is applied in Bulgaria, in accordance to the accountancy law of Bulgaria, where the accountancy is underlying on the International Standards of Accountancy, and respectively on the International Standards of Financial Reporting [2].

- After the Bulgarian Republic adhesion in 2007 to European Union, all Directives and Rules of European Union has been also available starting with that moment.

- A company in Bulgaria is not obliged to have an authorized accountant. The single requirement consists in the fact that a company should submit the accurate fiscal reports on time.

- The company's balance account should be submitted every year, in case a company is not registered for the VAT. As regards the balance account, the signature of an auditor is needed, but only in the situation of high developed enterprises.

As regards *the tax on personal incomes*, a quota of 10% has been applied starting with 2008, considering that until that time, a progressive taxation included within 10 and 24% was applied.

The standard quota of VAT in Bulgaria consists in 20%. As regards Bulgaria, there is no reduced quota for the first need products (food, medicines, school materials etc.). A lower VAT quota is applied for only the tourism agencies. As regards the hotel accommodation services and the tourists support services, the VAT is paid with a reduced quota of 9%. Concerning the intra-Community deliveries of goods and services on intra-Community acquisitions, the zero quota of VAT is applied. The VAT progress

in Bulgaria is illustrated in the following table:

Table 1 Progress of VAT quota applied in Bulgaria

Data of application	Reduced quota	Standard quota
01/04/1994		18
01/07/1996		22
01/01/1999		20
01/01/2007	7	20
01/04/2011	9	20

Source: CE, *VAT Rates Applied in the Member States of the European Union*, Brussels, 2012

The social insurances contribution quotas for 2012 are the following:

- As regards the normal work conditions – 22.3% (12.6% for the employer, 9.7% for the individual contribution quota). Here the 5% quota is included, afferent to the private managed pensions funds, for people born after 1960, and the quota of 1% for the unemployment;
- The contribution quota due by the employers and depending upon the risk class, as regards the industrial accident and professional diseases insurance is comprised between 0.4% and 1.1%, depending on the company's activity field;
- The contribution to social health insurances is of 7% (4.8% for the employer and 3.2% for the individual contribution quota);
- The contribution due by an employer towards the insurances fund, related to the wages claims, which is known at the value of 0%.

Romania

Romania hasn't been appreciated by the well-known foreign investors as one of the attractive countries, as regards the high span investments on long term, and this took place as result of many causes [4], amongst the following: the legislative unsteadiness; many legal provisions are not clear enough, are confusing and susceptible on various interpretations, even diametrically opposed; the high number of taxes, contributions, duties, tariffs, commissions, and especially of those parafiscal, [6] introduced and collected outside the fiscal regulations of judicial

attributes, therefore outside the taxation, with no control over the state; the corruption and bureaucracy that represent negative phenomena, of which the high investors take into account while choosing a country where the capitals can be placed.

The profit tax quota is situated at a level of 16%, and the companies are obliged to submit quarterly fiscal declarations, by which they oblige themselves on its payment.

The income tax quota is of 16% and it is applied over the taxable income that corresponds to every source included in any category, in order to determine the taxation on incomes; the independent activities, wages, the goods use surrendering, investments, retiring pensions, agricultural activities, premiums etc.

Starting with 1st of July 2010, the standard quota of VAT is of 24% and is applied to all deliveries goods and services performance, including the imports, for which the exemptions are not applied (with or with no rights of deductions), or one of the quota reduced by the VAT. In the same time, the VAT reduced quotas (5% and 9%) remained unchanged, and are applied for the same deliveries of goods or services performance, as until the time being.

The reduced VAT quota of 9% is perceived for the medicines dedicated to human and veterinary use, books, newspapers, the hotels accommodation or in locations of similar part, cinema tickets, entrance to museums taxes, historical monuments, zoological and botanical gardens, expositions and exhibitions, school books delivery, orthopedic prosthesis and products.

Table 2 *The quota progress applied in Romania*

Date of application	Reduced quota	Standard quota
01/07/1993		18
01/01/1995	9	18
01/02/1998	11	22
01/01/2000		19
01/01/2004	9	19
01/12/2008	5/9	19
01/07/2010	5/9	24

Source: CE, *VAT Rates Applied in the Member States of the European Union*, Brussels, 2012

The reduce quota of 5% is applied for the residences deliveries, as part of the social politics, including: the old people and retirees homes, children orphan asylums and centers of redemption and rehabilitation for the handicap minors, including the buildings and parts of them delivered as places to live, in some conditions. In this way, the reduced quota of 5% is also applied in the situation of the homes delivery, which have a serviceable area of maximum 120 square meters and a value that doesn't exceed the amount of 380.000RON.

As regards the quota of social insurances contributions (SAC) for the normal work conditions to an employer, this is of 20.8%, and as regards the employee, this has the value 10.5%. The social health insurances have the value of 5.2% for the employer, and the value of 5% for the employee. Both the employees and employers pay contributions to unemployment process of 0.5%, as well as other contributions.

The estimation of taxation in Romania

The taxes and duties system of Romania is characterized by a weak collection of them, with an inefficient management and an excessive bureaucracy, a basis of taxation relatively low, of many exceptions and legal deductions, as well as a high fiscal evasion.

In accordance to the OECD report [8], as regards the fiscal administrations, the efficiency of the management process on collecting the taxes is quite low in Romania, this being situated on the penultimate position included in the new member states group. In accordance to the World Bank report, *Paying taxes 2012*, Romania is placed on position 154 of 183 of countries at worldwide level [9], as regards the easy way by which taxes are paid, the number of taxes and duties payment every year, that a company in Romania should perform are about 113. Within the countries selected and included in Central and East Europe, Romania is placed on the last side of this chapter.

As an exemplification of weak collection of taxes, Romania collected 8.45 of GDP to incomes VAT in 2011, as Estonia, in conditions when the legal quota of VAT in Romania is higher than of Estonia (24% towards 20%). Moreover, Bulgaria, with a

structure of economy relatively similar to that of Romania and a legal quota of inferior VAT (20%), collecting even more of the tax imposed on the valued added tax in 2011, 8.6% of GDP.

Making a synthesis on those previously mentioned, it is possible to accomplish the next table that emphasizes the most important differences between the fiscal system of Romania and Bulgaria:

Table 3 Comparative analysis of taxation in Romania and Bulgaria

	România	Bulgaria
Profit tax	16 %	10%
Income tax	16%	10%
VAT	24%	20%
SAC	31,3%	22,3%
CASS	10,2%	8%
Unemployment	1%	1%
Payment of profit tax	Quarterly	Yearly

In this this way, one can emphasize a light direction of taxation in Bulgaria, as comparing to Romania, most of the taxation quotas being inferior, with the exception of unemployment quota, which is at the same level of 1%. Notwithstanding, it became paradoxical the fact according to which in a favorable fiscal environment, Bulgaria registers the highest level of the grey economy within the European countries (30.2%), followed by Romania, with a weight of 29.6% of the underground economy of GDP. It is obvious that the excessive fiscal task of our country and the unsteadiness of the fiscal system have obliged in a way or other the contributors to subtract from the declaration and payment of taxes. In antithesis, the reduced bureaucracy, the steady fiscal environment and a relaxed judicial system transforms Bulgaria into a new fiscal paradise, where everything is “allowed”.

Besides all these, Romania has been known as being part in the category of fiscal regulation category [9], which can favor the underground economy and the issuance of some arbitrary regulations, with the possibility of random interpretation and the lack of credibility as regards the actions of the competent institutions.

As directions to be followed in the fiscal field, the next can be emphasized:

- Improvement of the fiscal management and ensuring a steadiness of the fiscal legislation;
- Issuance of the fiscal strategy on long term;
- The professional application of fiscal regulations, in the view of stimulating the economic development;
- The improvement of collecting level on taxes and duties;
- Adopting the fiscal measures able to stimulate the work;
- Eliminating the difficulties for the exporters, building companies and SMEs;
- Reducing the social contributions;
- Stimulating the investments that generate the added value.

One of the measures that follow to be implemented in 2013 and that might establish a step on establishing the fiscal evasion diminution consists in the creation of a single channel of complementarity amongst the fiscal authorities and the contributors. This measure is necessary, since many times there has been doubtfulness in the interpretation of Fiscal Code [7] and in this way, the Romanian taxation would be much more simplified if a single entity might exist, in order to comment and clarify the fiscal provisions.

Conclusions

The European Union countries are free on issuing the own systems on taxation, systems of direct taxation, in order to carry out the objectives and requirements already existing on national level – with the condition to respect the free circulation of goods, persons, services and capitals and the principle of non-discriminating principle. In the basis of Treaty as regards the European Union functioning, in order to ensure a better performance of the unique market, the EU disposes of those competences, as regards the basis and the taxation quotas.

Although the European Union owns a common system as concerns the VAT, the member countries have the freedom on establishing the VAT quotas. Also, this has harmonized the structure and established the series of minimal levels for excise duties to alcohol, tobacco and energy.

Although owning a unique quota of taxation on profits of companies and incomes of physical persons (16%), reasonable quota as comparing to the other East – European countries, the social contributions in Romania are excessive. With an effective rate of 43%, Romania has occupied one of the highest fiscal tasks over the labor force. Moreover, the increase of tax on the added value, starting from 19% to 24% has placed our country amongst the states with the highest quotas of VAT within the European Union.

One considers that Romania should return as regards the economic point of view, and the fiscal authorities should take some measures [3]. Amongst these, the predictability and the steadiness of the fiscal system signify the most important issues, due to the fact that until now, the fiscal legislation has been modified many times, thus creating a confusion and disappointment in the contributors category. Another issue that might be improved refers to the fact that carrying out the fiscal obligations is enlarged on a high number of hours, and consists in carrying out an excessive number of payments. Finally, although the fiscal authorities have tried to implement many fiscal incentives, these haven't brought real benefic effects into economy. For instance, one might talk about the non-taxation on the profit invested, which actually consists in postponing the tax payment.

This paper emphasizes the research results, as regards the promotion of some fiscal politics in Romania that are essential on encouraging the labor force. One should need the diminution of social contributions level, in the context of having a high number of retirees, rather than employees. As solutions to this issue, this paper is underlying a proposal, according to which the encouragement of the SMEs sector and of enterprises comprised in the manufacturing and agricultural fields implicitly, should be created within an accurate frame towards the economic development and employment.

cusudorinela@yahoo.com

Abstract

Firm's financial performance is reflected by its profit and loss account. Still, all financial statements are needed in order to have a complete view on a firm's financial performance. As a general rule, several financial indicators are calculated in this sense. Hence, it would be of great interest to reduce the number of financial indicators into fewer, more synthetic ones. However, the new indicators should reflect the same information as the first ones. Statistics offers this possibility through factor analysis.

The purpose of the present study is to use factor analysis in order to generate a reduced number of relevant indicators that could help in analyzing firm's financial performance. The paper represents a case study on Romanian small and medium enterprises.

Key words: factor analysis, financial performance, principal components.

J.E.L. Classification: C58.

1. Introduction

Nowadays, firms are confronted with a permanently changing environment and need to adapt their activities in order to obtain good quantifiable results. Quantifiable results of a firm are summarized within financial statements.

Financial indicators are often the only tool for performance evaluation since they translate the whole activity of a company in

terms of profitability.[1]

Nonetheless, profits are targeted as the main indicator of financial performance. Still, several ratios reflecting firms' financial situation are based on profits - profitability ratios. Such ratios include return on equity, return on capital employed, return on assets, profit margin.

Developments in the field brought into attention new techniques of evaluating firm financial performance. These modern approaches to financial performance refer to a firm's results in terms of created value. Such approaches introduce the concepts of Economic Value Added, Market Value Added and other such measures of financial performance.

Within our research, we address the issue of financial performance given the multiple indicators used in its calculations. Overall, our objective is to create synthetic indicators reflecting firm financial performance. In order to achieve this objective, we conducted a Principal Component Analysis (PCA) using SPSS software.

2. Literature review

For centuries, financial indicators have been used in assessing firm financial performance. As Otley shows, “accounting measures of performance have been the traditional mainstay of quantitative approaches to organizational performance measurement”[2].

Literature in the field is vast and offers diverse opinions regarding financial ratios that are needed in assessing financial

performance. Hence, researchers in the field argue that there are multiple indicators that reflect a firm's financial performance. Abdeen and Haight [3] group financial performance metrics into two classes: traditional financial metrics and first class financial metrics. As a result, they refer to

earnings growth, market value, return on sales, cash-flow, asset turnover, etc., as traditional metrics (Table 1). First class financial metrics include economic value added (EVA), market value added (MVA), cash-flow return on investment (CFROI), etc.

Table 1 - Metrics used in assessment of financial performance

Traditional Metrics	First Class Metrics
Earnings growth	Value Based Metrics
Earnings Per Share	Economic Value Added (EVA)
Market Value	Value Based Management (VBM)
Return on Sales	Market Value Added (MVA)
Return on Assets Cash Flow ROI (CFROI)	Cash Flow ROI (CFROI)
Total Return to Stockholders Discounted Cash Flow (DCF)	Discounted Cash Flow (DCF)
Cash Flow The Balanced Scorecard	The Balanced Scorecard
Assets Turnover	
Inventory Turnover	
Accounts Receivable Turnover	
Capital Spending	
Budget Comparisons	
Cost Structure Improvement	

Source: Abdeen and Haight (2010)

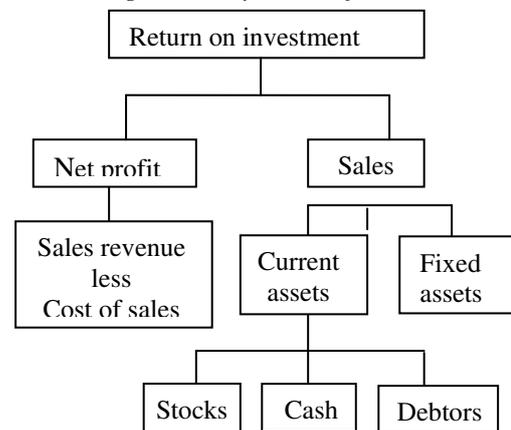

The so-called “first class indicators” are modern financial indicators, and, as Robu and Sandu [4] show, they reflect firm's orientation towards shareholders. In fact, the prior objective of a firm's management is to create value for its shareholders, by developing certain shareholder-oriented methods [5]. In essence, “the modern indicators for quantifying performance at microeconomic (company) level are built on the concept of value creation”[6].

Vasilescu identifies a series of basic qualities of the financial indicators [7]. First of all, he shows that financial indicators reflect in a synthetic and dynamic way the financial situation of a firm. Secondly, they ensure the interdependence between the economical, social and natural phenomena, preventing environmental degradation. Moreover, financial indicators reflect correlations between all firm activities (production, research and development, human resources, commercial, finance and accounting) and allow time and space comparisons.

Otley argues that “although over the life of an enterprise total net cash flow and total profit are essentially equal, this can mask the fact that in the short-term they can be very different.”[3] Thus, he shows, if the concern is with firm short-term profitability, the

“pyramid of ratios” can be used (Figure no.1). Still, a particular purpose of calculating ratios imposes several restrictions. Referring to long-term profitability, Otley considers profit to sales ratios and value added ratios as relevant.

Figure 1 - Pyramid of ratios

Source: Otley, D., [2]

Cormier, Magnan and Zeghal consider that relevance of the financial indicators should be determined by referring to market value, expected cash-flows and value added [8]. Based on an empirical study over a sample of 300 firms within France, Unites States of America and Switzerland, they investigate relevance of the financial indicators, concluding that net income, operational income, operating cash-flows,

residual income and value added are relevant financial indicators.

3. Methodology

Research consists of an empirical study on Romanian manufacturing firms regarding financial indicators of performance. The main objective of our study is to find an answer to the following questions:

- ✓ Are there any synthetic indicators that can reflect financial performance?
- ✓ Can we classify firms as efficient or not, given these indicators?

In order to conduct our study, we used factor analysis as research procedure. Factor analysis is generally used for reducing data or detecting a structure pattern.

We proceeded in our research by calculating a series of financial indicators for a sample of 137 manufacturing firms. Data was collected from financial statements of the selected firms, available on site of Romanian Ministry of Finance. The obtained database consisted of a 7 financial indicators calculated within our sample. The considered indicators are: return on equity (ROE), return on assets (ROA), natural logarithm of total actives (Log(A)), liquid ratio, debt ratio, reliability ratio and return on sales (ROS). As a result, our database is formed of 7 variables, respectively the mentioned financial indicators, and 137 observations made on manufacturing sector.

Referring to our sample, we note that:

- ✓ main activity of the firms is manufacture;
- ✓ number of employees is less than 250 - selected firms are small and medium enterprises (SMEs);
- ✓ firms registering extreme values of profitability were excluded in order to prevent distortions of the results.

Given that all these ratios are calculated in order to obtain an overview on firms' financial performance, but they are correlated because of formulas used in their calculus, we conducted a principal component analysis. Principal component analysis is a factor analysis method of extraction that allows finding a component (a linear combination of variables) that explains as much of the initial variation of variables (financial indicators) as possible. The procedure continues this way by finding other components until all variation is

explained.

Within any principal component analysis, several assumptions are made:

- ✓ variables are normally distributed;
- ✓ variables are linear - there is no collinearity and singularity;
- ✓ there are strong correlations between variables - $r > 0.3$.

Consequently, we tested these assumptions in order to ensure appropriateness of the used method. Firstly, histograms indicated that all variables are normally distributed. Secondly, the correlation matrix showed values of r -Squared higher than 0.3, signalling a strong dependence between variables. Lastly, Kaiser-Meyer-Olkin test and Bartlett test confirmed the appropriateness of the principal component analysis, given the sample.

4. Research results

The use of principal component analysis allows us to extract a number of components by taking into consideration several aspects.

First aspect refers to total variance explained by extracted components. Using this criteria, total variance explained by extracted components must exceed 70%. Within our sample, extraction of one component explains 44.291% of the initial financial indicators, extraction of two components explains another 37.321% of the initial variation, respectively a total explained variance of 81.612% of the initial variables, and so on, as Table 2 shows.

When extracting components we applied Kaiser rule. According to it, only those components that register eigenvalues higher than 1 must be considered. In our analysis, the first two components answer this criteria.

The scree plot confirmed that the optimal number of components to be extracted is 2. As a result, two components were extracted (Table 1).

Table 1 - Component score coefficient matrix

	Component	
	1	2
ROE	0.91	0.11
ROA	-0.54	-0.19
Log(A)	0.27	0.06
LIQ	-0.43	0.13
DEBT	0.07	-0.89

RR	0.32	0.72
ROS	0.97	-0.21

Source: Authors' processing using SPSS

Table 1 shows the percent (coefficient) of each financial indicator within the two extracted components. As

Table 2 - Total variance explained by using principal component extraction

Component	Initial Eigenvalues			Extraction Sums of Squared			Rotation Sums of Squared		
	Total	% of Variance	Cumulative %	Loadings			Loadings		
				Total	% of Variance	Cumulative %	Total	% of Variance	Cumulative %
1	3.100	45.291	45.291	3.100	44.291	44.291	2.584	43.912	40.912
2	2.052	38.806	84.097	2.052	37.321	81.612	2.569	36.700	80.612
3	.874	6.015	90.112						
4	.747	5.652	95.764						
5	.130	2.853	98.617						
6	.097	1.382	100.000						
7	1.529E-005	.000	100.000						

Source: Authors' processing using SPSS

Analyzing the rotated component matrix, we observed high correlations between the first component and ROE and ROS, respectively the second component and debt ratio and reliability rate.

Regarding the first component extracted, we can interpret it either by ROE or ROS, given that both are indicators of profitability. We prefer choosing the second indicator in interpretation of the first component.

The second component can be interpreted in terms of debt (negative correlation) or in terms of reliability (positive correlation). Given that the coefficient obtained for debt ratio is relatively higher than that of reliability ratio, we proceeded by using the first one in interpretation of the second component.

Considering the above aspects, we interpreted the two components extracted as follows:

✓ the first component is a synthetic indicator of profitability;

a result, these components can be expressed as linear combinations of the 7 considered financial indicators, using obtained coefficients - as multifactor regression models.

✓ the second component is a synthetic indicator of interest gearing.

As a result, the new designed indicators can be expressed as linear combinations as follows:

$$\text{Profitability (C1)} = 0.91 \cdot \text{ROE} - 0.54 \cdot \text{ROA} + 0.27 \cdot \text{Log(A)} - 0.43 \cdot \text{LIQ} + 0.07 \cdot \text{DEBT} + 0.32 \cdot \text{RR} + 0.97 \cdot \text{ROS}$$

$$\text{Interest gearing (C2)} = 0.11 \cdot \text{ROE} - 0.19 \cdot \text{ROA} + 0.06 \cdot \text{Log(A)} + 0.13 \cdot \text{LIQ} - 0.89 \cdot \text{DEBT} + 0.72 \cdot \text{RR} - 0.21 \cdot \text{ROS}$$

Hence, we can classify the 137 firms included in our sample using the two components extracted. Four classes can be distinguished:

- Efficient firms - profitable and debtless, containing 55 firms with good scores for both indicators (components);
- Relatively efficient firms - profitable and relatively indebted, containing 43 firms with high scores of profitability, but poor scores of interest gearing;
- Low-efficient firms - low-profitable and not indebted, containing 26 firms with low scores of profitability, but good scores of interest gearing;

- Non-efficient firms - non-profitable and indebted, containing 13 firms with poor scores for both indicators (components).

Therefore, the synthetic indicators extracted through principal components analysis offer the possibility of classifying firms as efficient, profitable and indebted firms, low-profitable and not indebted firms, and non-efficient firms. Within our sample, all four classes contained firms.

5. Conclusions

Principal Component Analysis represents a useful tool in data reduction. Moreover, it offers the possibility to determine the latent relationships between variables considered. As a consequence, design of new indicators is possible.

We used Principal Component Analysis on a sample of 137 Romanian manufacturing firms. Our findings show that it is possible to construct more synthetic indicators that reflect the financial performance of Romanian firms.

Within our empirical investigation, we extracted two components: the first one, interpreted in terms of profitability, and the second one in terms of gearing. We were able to classify firms within the sample as efficient or not given these two components. Efficient firms, considering our results, are firms that register a high return on sales ratio and are low indebted. Oppositely, non-efficient firms are firms with low profits and high debts.

Still, further research could add useful findings to our results, taking into consideration that sample used to conduct our analysis was a relatively reduced one.

A Cost Radiography and the Premise of the Application of the ABC Method in Overnight Hospital Stay

Ionete Toplicianu Selina

Valahia University of Targoviste, Doctoral School

selina_ionete@yahoo.com

Toplicianu Valerică

Valahia University of Targoviste, Faculty of Economics

vtoplicianu@yahoo.com

Abstract

The highly affected world economy has also left its mark on the health systems. In Romania, the health system copes with shortages, even though multiple reforms have taken place. The purpose of the present paper is to show the importance of “borrowing” the cost methods of the private system and to use them in the public health system, especially for the overnight hospital stay.

This transposition of methods has as a goal to make it easier to make decisions based on the calculation of the actual costs of hospitals.

Limitation of resources’ availability can be also found in this domain, and the resources’ efficient use is a desideratum for each manager. In this paper, the epistemological positioning is situated along the positivism-constructivism axis. The present study relies both on the literature in the domain and on observation and personal research out in the field.

Key words: health care system, cost accounting, ABC method, hospital

J.E.L. classification: I18, M41

1. Introduction

The economic-social problems which have put the world to a hard test have had deep consequences on the health cost. Although health is the basis of solidarity and economic productivity, the unbalances are obvious. Along with education, the health care system has been influenced by the decrease of budget allocation and by the economic problems in the private system.

The population’s health condition has degraded, while, at the same time, the pressure on subventions and on the reduction of the number of free health services has increased. These are the premises of the attempt to find new solutions to keep costs under control and to use the present scarce resources as efficiently as possible. The transposition of the cost accounting methods of the traditional productive system to the public health system represents a challenge but it may be a solution, as well.

The Standard-Cost Method has been adapted in such a way as to establish a code for diseases and to standardize human, material and financial resources necessary for the medical act during the overnight hospital stay. Thus, the DRG (Diagnosis Related Groups) system has been formed, by means of which hospital financing is provided.

We have employed the ABC Method in a larger study, considering that it answers best the need to know the actual costs.

2. Literature Review

In 1987, the famous professors Johnson and Kaplan published a paper, where they questioned the pertinence of the cost accounting system employed in the American private system[1]. At that time, they were very close to supporting idea of the cost accounting disappearance and its replacement by non-financial performance measure indicators.

In our opinion, cost accounting represents a complex and highly sensitive mechanism, requiring a toilsome costs calculation labour to get the information needed by the decisional process, in order to increase the

efficiency of the organizational activity by rationalizing the resources.

Alain Burlaud has made an analysis of the cost accounting pertinence in the public sector, starting from the complexity of the definition of its product, cost, and value [2].

However, the first work on application of the ABC method in the health system was issued in 1994 [3]. Later on, numerous authors (Alvarez[4], Camponovo [5], Nobre & Signolet [6] , Popesko & Novak [7]) showed the advantages of using ABC method in different hospital departments, i. e.: identification of the costs within the organization, of the relations between the costs but also of their influence on the whole activity.

Kaplan and Anderson (2004, 2007) assert that the cost calculation procedure by employing the ABC Method may have some difficulties because of the accounting system, in case it does not hold all the necessary information.[8] The use of this model requires time and resources, due to the huge amount of requested data.

By the study he carried out, Lawson Raef offers an image on the ABC method’s impact on the health environment, taking as reference the period 1994-2004.[9]

If in 1994, out of 24 hospitals, 3 of them had never heard about the ABC Method, 16 of them knew the method, but did not apply it, and only 5 of them implemented it, in 2004, all the 12 hospitals which were part of the study knew the method, but only one of them, implemented it for the cost calculation in the organization.

3. Identification of Expenses in the Overnight Hospital Stay

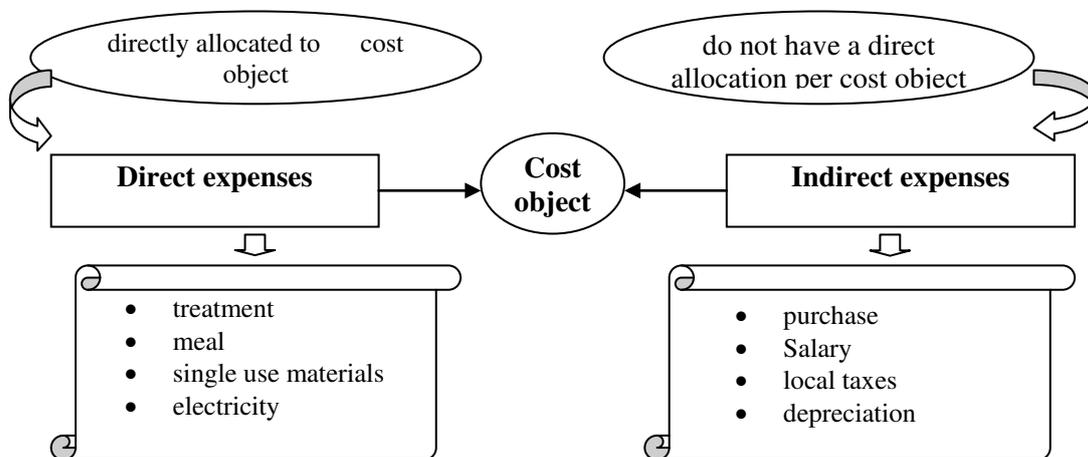

Due to the increase of health care consumption, the public hospital holds a special place in the healthcare system. When thinking of the organization in a public hospital, we can say that it lies on the border between specific and complex. Its different actors: the Romanian government, materials suppliers, medical staff, other non-medical employees, patients, the National Health Insurance House, have different interests related to the activity of healthcare production and provision.

The objectives of the public hospitals are hard to classify in a hierarchy: the quality of the services provided to the patient (how can it be measured), the accessibility of a number as high as possible of requests, continuity, equality regarding the treatment, efficiency in relation to the consumed resources, attractiveness and competitiveness (this is a competitive environment), diversity of jobs and skills.

To manage the resources and to apply the ABC method, identification of types of expenses inside the organization is necessary. Expenses may be simultaneously or chronologically established and divided into:

- *Direct and indirect expenses* (according to the resource destination) (Figure 1.).
- *Fixed expenses and variable expenses* (the definition of expenses according to the behaviour of resources, depending on activity level).(Figure 2.)

Figure 1. Direct and indirect expenses

Source: elaborated by the author

The classification in a certain expense group is done after a careful observation of the organization.

The equality relation is as follows:

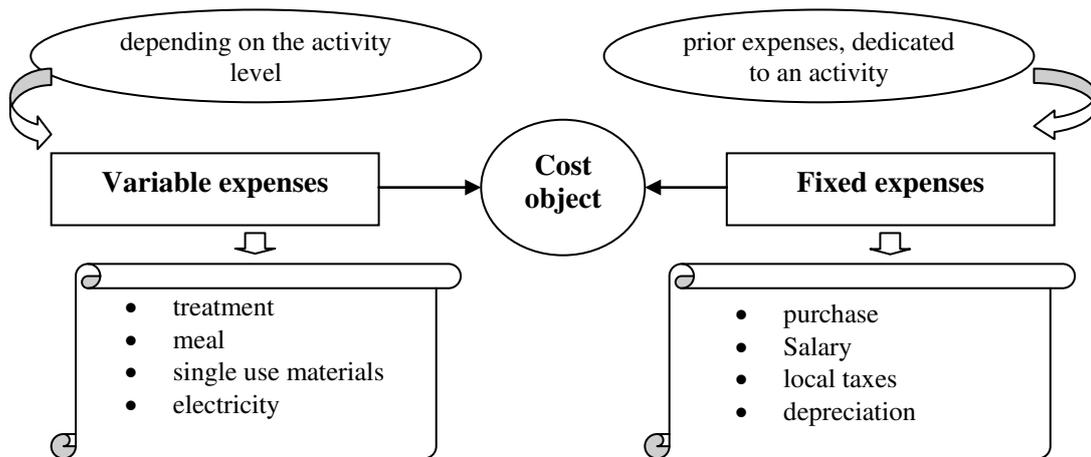

Direct expenses + fixed expenses = total expenses = variable expenses + fixed expenses

An expense is classified as direct or indirect only from the viewpoint of cost

calculation and of the allocation of that expense on a cost object.

The differentiation between fixed and variable expenses must consider the fact that an expense may be fixed in a case and variable in another, except for the case of meal and drug expense, which is always a variable expense.

Figure 2. Fixed and variable expenses

Source: elaborated by the author

4. Cost Structure in the Overnight Hospital Stay

The cost is defined by four dimensions, answering the questions: where, what, when and how.

The structure of the production cost varies depending on the industrial sector, yet it incorporates expenses pertaining to raw materials and the added value of the economic process. In the case of hospitals, the cost measures the use of resources for: maintenance, transport, meal, hospital stay, and any surgery procedure.

The division of costs in hospital is as follows:

DIRECT COST

1. Medical Expenses

1.1. Variable medical expenses

- consumables
- medical-therapeutic actions

1.2. Fixed medical expenses

- salaries
- medical materials (amortization

+ maintenance)

2. Logistics expenses

2.1. Variable expenses pertaining to logistics

- laundry
- reparation

Subtotal 1 Direct cost = 1.1. + 1.2. + 2.1.

INDIRECT COST

2.2. Fixed expenses pertinent to logistics

- other expenses (administration, informatics)
- administrative staff

Subtotal 2 Semi-complete cost = 1.1. + 1.2. + 2.1. + 2.2

3. Expenses pertinent to structure

- financial taxes
- amortization

Subtotal 3 Indirect cost = Fixed expenses pertinent to logistics + Expenses pertinent to structure

COMPLETE COST

Direct cost (Subtotal 1) + Indirect cost (Subtotal 3)

Semi-complete cost (Subtotal 2) + Expenses pertinent to structure

5. Responsibility Centres

The review centres gather in groups the expense elements which can not be directly distributed.

Theoretically, they are independent from the company's organizational chart. They are called: wards and activity, labour, and responsibility centres, and are useful for the measurement of an entity's performance. A first classification is in main centres and auxiliary centres.

Alain Burlaud and Claude Simon define the responsibility centre in terms of the means-objectives couple, in agreement with the organizational chart and the budgetary construction, as they may be simple intellectual or accounting constructions.[10]

If, on the level of an organization operating in industry, one may find standard cost centres and profit and investment centres, on the hospital level, one can say that there are activity (responsibility) or cost centres but there can be no profit or investment centres.

The organization of hospitals in review centres has a particular feature, since it achieves a double goal: that of internal management and that of external comparability, as well.

In the French analytical accounting guide, with applicability in hospitals, the organisation on centres aims to respect two principles:

- the principle of universality
- the principle of optionality

The universality principle supposes that the review wards should be connected to the major activities, so that comparisons in a standardization context may be allowed.

Through optionality, each entity has the possibility to review its own expenses depending on its internal needs, especially due to its large number of cost levels.

The tree-like organization is not obligatory and general, as it depends on the complexity of the healthcare organization, on the pertinence of the costs and on the informational system of the healthcare unit.

6. The ABC Method in the Overnight Hospital Stay

Academicians and experts have agreed on the ABC method stages, as follows:

- identification of major activities in organization;
- distribution of costs on cost centres;
- determination of the cost drivers for each activity;
- allocation of costs on products and activities.

In the non-profit society, represented by the public hospital, by the calculation of the cost pertaining to two diagnoses, to each activity we have attached: the involved staff category, the minimum time of the activity in the chronology of the activity flow, the average salary expense and, finally, the activity cost.

The drug-related expenses have been established on the basis of the pharmacy data, and the laboratory analyses on the basis of labour volume and reagent quantity used.

The direct expenses have been determined starting from handwork consumption per staff categories and tariff per minute, including drug consumption, medical materials consumption per patient and daily meal settled by law (lei/hospital stay), respectively. The other direct expenses have been distributed to the remaining diseases in the wards monitored in our study.

A cost driver has been attached to the indirect expenses of the hospital, as reference for their distribution (number of employees, number of labour hours, surface). The identification of the activity flow has been doubled by the determination of the cost driver pertaining to each activity. The measure unit is in relation to the production factors of the activity and is easy to measure (number of patients diagnosed, hospitalized, treatments, time etc). After establishing the cost drivers' value for the initially established activities, the patients are grouped in regrouping centres. The share of indirect expenses distributed to each centre, is determined depending on the identified repartition keys. To *determine the cost per unit per driver*, it is necessary to identify the expenses pertaining to each regrouping centre. The expenses specific to a particular centre are imputed to that centre, and the expenses done by more regrouping centres together, are be redistributed on the same, by using the cost drivers of those expenses.

After calculating the cost per unit per driver for each regrouping centre, we determined the cost per unit per each

diagnosis. In case the activities correspond to several diagnoses, the cost distribution will be done according to the cost driver, only.

After determining the cost per diagnosis, the post-calculation sheet can be elaborated, which contains both the segmented direct expenses, and the indirect expenses. Then, one may go on and compare the obtained cost per unit, by using the ABC method, to the one established by using the DRG system, taking into account the complexity index specific to each hospital.

Conclusions

The differences resulted from the present study highlight the disproportional financing of different diseases.

By using the ABC approach, hospitals have the possibility of separating and classifying their value-added activities. By the implementation of the ABC system, one can determine as accurately as possible the cost of the provided services. At the same time, by this method, non-financial data can also be included, for instance, the waiting time of the patient for radiology or for other medical investigations during hospitalization, having effects on the medical service quality.

The lack of protocols to stipulate the steps to follow from the patient's appearance in the emergency ward up to his/her discharge can lead to waste of materials, time and even to risk for the patient's life.

The present study has shown that most indirect expenses belong to the Regrouping Centre, to the administrative and service staff and to the Treatment Centre, where most of the indirect expenses pertaining to materials are allocated.

Water, electricity, heat-related expenses go to the centres with a larger surface, whose cost driver, in square metres (ATI and surgery block), has been established by us.

The National Health Insurance House, by its imposed system, influences the professional ethics and, consequently, the quality of the medical act. There is a tendency to keep stable patients in overnight hospitalization for a minimum time, in order to be able to compensate for the cases which,

by their severity and complexity, exceed the maximum allowed hospitalization time.

The ABC Method will be able to reflect the true image of the costs, after a careful selection of the drivers, which must offer useful details on sub-activities and necessary resources.

Consequences of the Adoption of European Fiscal Pact in Romania

Ispas Roxana

University of Craiova, Faculty of Economy and Business Administration,
roxispas1972@yahoo.com

Abstract

This paper aims to emphasize the implications that the signing of the European Fiscal Pact will have on Romania. At the same time are also taken into account the estimates of the European commission concerning GDP and the negotiation of the structural deficit level. The advantages and the disadvantages that influence Romania's economy and some measures for increasing the incomes are also shown from the economical point of view. The fiscal governance pact of the European Union may have a positive effect on Romania, imposing a better fiscal discipline and financial stability. The fiscal governance pact is essential in strengthening the discipline in public finances but will create problems in the authorities' capacity of stimulating the economy due to the budgetary constraints that it will bring.

Key words: fiscal pact, European Union, stability, advantages, member states.

JEL classification: H30

1. Introduction

A number of 25 states of the European Union (EU), including Romania, but without Great Britain and the Czech Republic, have signed the European fiscal pact, which stipulates mainly the fiscal regulations for the balance of the budgets with the coordination of the economic policy at a European level.

Great Britain has decided not to adopt the pact because it has not obtained a series of concessions for the financial sector.

Moreover, the Czech Republic has announced that it would not sign the fiscal pact because it does not consider that this significantly improves compared with the existing regulations. The Czech Republic does not exclude the possibility to join later.

The European fiscal pact shall imply a commitment from the part of the participant states for a solid fiscal governance, the introduction of some provisions to balance the budget in the Constitution, the consolidation of the regulations on the excessive deficit procedure through the automation of the sanctions and the transmission of the budget drafts to the European Commission for verifications. This is the first step towards the fiscal unit. The agreement has been supported by the European Central Bank, which has insisted that the governments from the Euro zone should order their internal policies.

The Netherlands, one of the most vocal and strong supporters of the fiscal austerity, has managed however to comply with the pact for almost one month. With a budget deficit of 5.8% it has exceeded the deficit limit set at 3%. The budget deficit of the Netherlands for 2012 and 2013 shall probably be of 4.6%, facing the same problems as Italy or Spain.

In a similar way, the economy of Spain reduced during the last trimester of 2011 for the first time in two years and it may enter a long recession. The Spanish budget ended in 2011 with 8.5% from GDP.

Spain has to find deficit reduction measures with 0.5%, having to impose austerity measures in order to save 16 billion EUR - when the economy of the country shall drop this year with 0.9% because of a stagnation of exports caused by the financial crisis from the Euro zone.

France has reduced with half the increase forecast for 2012 to 0.5%. The International Monetary Fund has sent a warning to Paris, requesting that in 2013, the public deficit should reach 3.9% from GDP.

Because the negotiations regarding the restructuring of the Greece's debts have not been finished yet, it does not receive a second financial portion of 130 billion EUR, and, without the loan, it has become

insolvent in March 2012, when it had to compensate the high value of the due liabilities.

Portugal shall need a new loan in order to avoid insolvency.

The countries from the Mediterranean area have had very strong public sectors and have to restructure. Major problems occur in Greece, Italy and Portugal. The restructuring shall take many years from now on, probably at least 3 - 4 years, in order to see positive effects in the economy of these countries.

Many economists consider the fiscal pact only a gesture to calm the discontent of the German voters on the repeated external financial aids and for the restoration of the market reliability.

In May 2012, Germany sent a series of conditions to France, through which they excluded the possibility of the renegotiation of the European Fiscal Pact and any initiative of increasing the deficits. The renegotiation of the Pact is not possible because it has been signed by 25 of the 27 EU member states and has as purpose the consolidation of discipline in the field of public finances. Germany does not want an increase of deficits, but an economic growth through structural reforms.

2. Research Methodology

Romania has offered, following the negotiations carried out, the participation of the Euro zone non-member states to the common meeting that all the signatory states have, under certain conditions.

According to the Romanian Executive Power, the Pact stipulates the obligation to maintain a structural deficit that cannot exceed the national objective on a long term, set forth for each member state, with an inferior limit of 0.5% from GDP according to the market prices. If the level of the public debt is significantly under 60% from GDP and there are not risks regarding the long-term sustainability of the public finances, the structural deficit may reach at almost 1% from GDP. The maximum cyclic budget deficit plus the structural one must comply with the limit of 3% from GDP. The new pact must be adopted through the Constitution, and this must take place until the end of 2013.

If deviations are recorded at these levels, a correction mechanism shall automatically

be launched, having to be introduced in the national legislation of each member state, in the same manner as the so-called "golden rule", on the limitation of structural deficit. If a member state does not translate these two provisions in the national legislation, the European Union Court of Justice may be notified in this matter.

The failure to comply with the decision of the court may lead to a financial sanction of maximum 0.1% from the respective country's GDP.

If regarding the level of the public debt, Romania ranks on a comfortable level, under 60% with a structural deficit of 0.5% from GDP, when the budget deficit target for 2012 is 1.9%, this seems more difficult to fulfill.

However, it is necessary to make the distinction between the two terms, "structural deficit" and "budget deficit". The budget deficit means one thing, remaining unchanged in the limit of 3% from GDP, and another thing is the structural deficit. The structural deficit and the cyclic deficit form the budget deficit. The structural deficit reflects the inability of the state to collect incomes and to spend the money available efficiently. On the other hand, the cyclic deficit is influenced by a certain evolution of economy, as it is now, during the crisis, when the smaller incomes are paid to the state, because many are bankrupt or pay less, because they have smaller incomes. Then the incomes of the state suffer a reduction.

The emphasis of the EU on the structural deficit reflects the emphasis of the member states on the solution of some structural problems and that are related to the public sector, so that the state should use efficiently the expenses, as well as the public services, and the private sector should not be "restricted"[1].

Moreover, Romania may benefit from a more extended maneuver margin regarding the structural deficit, because of the reduced level of the public debt.

On the other hand, the amendment of the Constitution is not possible in Romania on a short term (during an elective year). The introduction of the budget deficit in the Constitution represents the treatment of the effect, the deficit as a share of GDP, not of the cause, which is the share of the expenses from GDP.

The adoption of the fiscal pact provisions

means a certain limitation of the national sovereignty, but one that is not imposed, but self-assumed.

Although the media's attention is focused on the structural deficit, a more structured approach should start from the potential level of GDP. Although it is less difficult to understand, this constitutes the starting point for the classification of the European requirements on the deficit, implicitly for the budget elaboration, for the expenses that shall be made for the population.

According to the estimations of the European Commission and of the National Institute of Statistics, at the moment, the potential Gross Domestic Product, a key indicator for the determination of the structural deficit, has decreased significantly compared to the values from the second part of the last decade.

The potential GDP is the highest GDP that may be obtained without generating macroeconomic unbalances, the most visible effects being the inflationist pressures and the potential accumulations of deficits, if an austere, anti-cyclic fiscal policy is not implemented.

During the period 2004-2007, Romania, on the grounds of the reduction of the potential GDP, (the reduction of the economic increase), was found in a full process of consolidation of the disinflation process, reducing the increase of the prices to values comparable to the usual ones in Europe. If in 2004, an increase of 6% was sustainable, in 2007, the sustainability level decreased to 4%, and in 2012, to almost 2%.

The exceptional economic growth from 2008 meant an overloading of the economy, which increased within the given circumstances over the real capacity given by the total productivity of the production factors, people and capital.

From almost 6% in 2004 and 4% in the year of the adherence, 2007, the economic growth, and implicitly the potential GDP, reduced gradually to a level of only 2% in 2012. The reduction was determined mainly by the capital segment and, to a lesser extent, by the total productivity of the production factors.

We have to mention, however, that the values presented have considered the very low level of absorption of European funds, actually recorded in Romania.

A simulation (see Table) on the potential increase of the absorption degree shows that we could return to significantly higher values of the potential GDP, which would create much better perspectives, in terms of growth and favourable management of the structural deficit limit imposed by the Stability Pact.

Going on the assumption of a reasonable increase, it could go up to 3.5%. There are possible the next situations:

If we do not manage to increase the European funds and we continue with 2% GDP potential, a 3% economical increase, would impose a spending limit, to obtain a necessary budgetary surplus for the objective of 0.5% structural deficit.

a) If we do not manage to draw European funds in a significantly increased proportion, then, a 3.5% economical increase with 3.5% GDP would allow us a 0.5% deficit equal to our structural deficit objective.

The council tax draws the attention that Romania has one of the smallest GDP share of the budget revenues. These were only 32.5% of GDP in 2011, with 12.1 percentage points, under the European average, also the number of the financial administration is comparable to the one in Poland, a country with two times higher population. The lever of the income tax reported to GDP (taxes and social contributions), in Romania was 27.2% in 2011, 12.4 percentage points less than the average 27 EU (39.6%). The income taxes share in GDP was significantly lower than in Slovenia (37.8), Hungary (36%), Poland (32.1%) and Slovakia (28.5%), as shown in Council Tax report for 2011.

The tax revenue structure in Romania shows a high share of the receipts from the indirect taxes (46.32% from the total of the tax revenue, compared to 33.08%, the EU average 27), while the revenue from the social contributions was 32.35% (35.1% EU 27), and the one of the direct taxes was only 21.32% (31.81 EU 27).

Degree of absorption	GDP Potential
40%	3.1%
60%	3.6%
80%	4.0%
100%	4.4%

Comparing to 2010, the indirect taxes share has increased with almost three

percentage points, because of the TVA standard rate increasing and the excise, while the contributions and the taxes has reduced the relative importance, with a higher share decreasing in GDP than the reduction of the final tax revenue in gross domestic product. Under these conditions, we can see the indirect taxes as the most important component of the budgetary revenues tax consolidation. Romanian tax system is characterized by a poor collecting, with an ineffective administration and an excessive bureaucracy, a relatively low tax base, with many exceptions statutory deductions and a high level tax evasion.

As an example of the poor tax collection, Romania has collected 8.4 % from GDP, VAT income, in 2011, the same as Estonia, while the VAT legal share in Romania is higher than the Estonian one (24% and 20%). In addition, Bulgaria, with an economic structure, like the one in Romania, with a lower VAT legal share (20%), has collected even more VAT in 2011, 8.6% GDP. Regarding the social security, paid by the employees and the employers, budgetary revenues collected in 2011, was 8.3% from GDP, much lower than in Czech Republic (13.1% from GDP), and Hungary (12.3% from GDP), although the contributions rates were relatively similar.

In Council Tax's view, needs a radical reform of the tax collecting system, to ensure the significant increase of the revenues collected and the decrease of the administrative costs.

The Council believes that the reform needs to focus on: increasing levels of voluntary compliance of the contributors, especially by simplifying the tax code, and the tax procedure code, and, using a comprehensive program of government spending full transparency; increase efficiency and reduce collection costs, especially by strengthening tax administration number, computerization, statement and electronic payment aggressive promotion, increasing the quality of collecting staff and reducing corruption; indirect stimulation of a more sustainable economic conception, increasing the tax collecting level, suitable for a better accommodation of potential adjustments in Tax System, pointing in the direction of work stimulation (especially by decreasing the

contribution to social insurance, being at a high level at the moment),and increasing internet savings for decreasing the dependence on foreign capital flows in, for financing of investments, as the report shows.

The Tax Council is an independent authority established in the Budget and Fiscal Law, which intends to support the Government's activity in the process of developing and conducting fiscal policy and budget and to promote transparency and sustainability of public finances.

The Fiscal Council has among its attributions the publication of an annual report that analyses the unfolding of the fiscal-budgetary policy from the previous year compared to the one approved by the fiscal-budgetary strategy and the annual budget, it evaluates the macroeconomic and budgetary trends comprised in the fiscal-budgetary strategy and in the annual budget, as well as the objectives, the targets and the indicators set forth through the fiscal-budgetary strategy and the annual budget.

The leaders of 23 states have set forth a new inter-governmental agreement, meant to start up a new fiscal pact. Broadly, this means a higher fiscal discipline and a careful control of the national budgets. Great Britain has opposed to this agreement again.

In an agreement published on the European Council webpage, "the decision of the European leaders to overcome the current difficulties" is shown, as well as the fact that these decided "a new fiscal pact and a new significantly more intense coordination of the European policies", on Friday.

A consolidated construction for the monetary unity means:

- the European leaders commit to debate at the level of the Euro zone the reforms in the economic policy, planned by the member states from the Euro zone;

- the Governance of the Euro zone shall be consolidated and they shall regularly organize summits, at least twice a year.

- The excessive deficits from the states of the Euro zone shall be corrected, and the countries that face a financial instability shall receive support and the evaluation of the budget plan drafts.

The provisions of the Fiscal Pact

1. a new fiscal rule shall be imposed:

- the general budget of the governments must be balanced or in surplus

- the rule shall be introduced in the national legal systems

- the member states with an excessive deficit undertake to present to the European Commission a strategy aiming at the remedy of the excessive deficits

The revival of the Euro zone:

- The European Fund of Financial Stability (EFFS) shall receive more funds and shall get actively involved in the finance of the programs in progress

- The Pact on the European Stability Mechanism shall be viable, starting with July 2012

- In March 2012, the total capacity of the Fund as well as of the Mechanism was reevaluated

- The European leaders promise that they shall accelerate the capital payments so as to maintain a ratio of at least 15% between the paid capital and the outstanding amount from the MES issues and shall ensure an actual combined credit capacity of 500 billion EUR

- The member states from the Euro zone as well as other member states shall examine and confirm within 10 days the provision of additional resources for the IMF of up to 200 billion EUR (270 billion dollars under the form of bilateral loans, in order to ensure the fact that IMF disposes of proper resources to face the crisis.

The consolidation of the stabilization instruments means:

- The longer-term reforms must be combined with an immediate action in order to approach the existing tensions on the market.

- The leverage effect of the European Fund of Financial Stability shall be rapidly put in practice, through the means of two concrete options agreed by Euro group.

Romania shall be bound to continue the structural reforms, in order to classify in the structural deficit target of 0.5%. The problem is that a budget may be balanced or unbalanced even with collections of 10-20% from GDP, as the most liberal countries in the world have, and with 40 - 50%, as the majority of the EU states have. Romania finds itself in the middle of this range.

A scenario is "to bring to the surface the underground economy", and as a compensation to reduce the level of taxes on labor and consumption. In this case, the collection stagnates and cannot support the

level of expenses.

Another scenario is that all the taxpayers should be bound to contribute to the current levels, thing that so far has proved infeasible and even counter-productive.

Romania and the Fiscal Pact: Three risks

1. The limitation to 0.5% of the structural deficit, amount unitary set forth for all the countries of the pact, although their public debt differs considerably, from 6% (Latvia) to 160% (Greece) – Romania being around the threshold of 40% – it cannot achieve the fine-tuning requested by the economic optimization.

Romania could request a derogation for the extension to 0.7% or even 1% of the structural deficit. Without this concession, the economic growth would be artificially affected, and the potential of development would remain underused. 0.5% would preserve the gaps instead of allowing their recovery.

2. In case of a favorable economic evolution, it would be very difficult to explain to the population why the immediate bonuses cannot be granted and why the consolidation of the results must be accepted before distributing advantages on a long term.

The problem of national sovereignty limited through this superstate agreement is already debated. The second step, the intervention one, even at the level of experts, on the budgets presented to Brussels before passing on to the National Parliaments is unavoidable and shall trigger controversies.

3. The calculation manner is very difficult and the unvarying application would lead to important controversies on the compliance with the rule of 0.5% of structural deficit.

Negative effects may be expected on the European cohesion, as well as unbalancing reactions at an institutional level.

Concretely, Hungary is already confused by the sanctions imposed by the European Commission for exceeding the budget deficit. Greece hardly accepts the conditions imposed at the moment. At the same time, it contests the calculations regarding the budget "restructuring" calendar and the feasibility of the reimbursement of the public debt, scheduled on a medium and long term.

Three advantages:

1. The prevention of the policy deviances, of granting some elective benefits with an

unbalancing effect on a long term, through the means of the structural deficit. The best example in this matter is the decision to increase the pensions based on the presumed economic growth, which, in reality, has not taken place.

The pension point value was increased in advance (!) to 697.50 RON in October 2008, following the overoptimistic forecast of GDP increase with 6.5% in 2009. In reality, GDP decreased that year with over 7%, but, the pension point value had been increased to 718.40 RON in April and 732.80 RON in October.

2. The implicit obligation of any lawgiver to grant benefits to prove sustainability over time of the granted benefits. The practice has shown that, once given, the benefits cannot be withdrawn, even if the decision factors undertake the responsibility in this matter.

Again, we have to mention the reduction of the pension point value. This would have been logical, even in 2010, after the economic decrease recorded for the second consecutive year and after the reduction of the salaries in the budget sector. Although logical, it was not legal, according to the Constitutional Court.

3. The macroeconomic stability allows a rapid development, the better use of the available resources, for investments with a subsequent favorable effect and not for consumption. Everything is that the rule of 0.5% or the result obtained should be accepted as a value in itself, through the solid ensured frame of economic activity.

The increase of the VAT from 19% to 24%, measure taken by necessity to balance the budget, has affected the business environment and has stimulated the risk taking for the fiscal fraud. The competition has moved from technology and productivity to ability and accountancy.

3. Conclusions

The new fiscal pact has been very much debated lately, this being drawn up by initiators as a decisive solution to the euro zone issues. At a conceptual level, the new pact does not bring very many new elements, instead it introduces an automatic mechanism of correction and penalty in case deviances are recorded. The limits of 3% from GDP for the budget deficit and 60% from GDP in case

of the public debt have always existed, being set up through the pact of Maastricht in 1992. The stability and increase pact (1997) set forth that the structural position on a medium term of the budget should be close to balance or in surplus. The fiscal structure introduces the target of structural budget deficit of maximum 0.5% from GDP.

Undoubtedly, an important step forward is taken through the adoption of this fiscal pact, by introducing an automatic correction mechanism of the fiscal deviations, thus contributing to the increased discipline of the fiscal policies and to their better coordination. However, may this new fiscal pact be considered as being sufficient for the assurance of a good operation of the monetary union (euro zone)? The answer is probably no. The historical experience shows that the monetary unions must be accompanied by fiscal unions in order to succeed. The euro zone does not have a fiscal union yet, the member states having sovereignty over the leading of the fiscal policy. The common budget of the European union is only slightly over 1% from GDP, which is a very low level. Moreover, there are no fiscal transfers between the EU states when the asymmetrical shocks occur and the mobility and the flexibility of the labour force in Europe are relatively low.

The Impact of Financial Crisis on the Transactions in Off-Shore Zones

Ispas Roxana

University of Craiova, Faculty of Economy and Business Administration,
roxispas1972@yahoo.com

Abstract

In the following paper we have started from the premises that in the “money-wash” phenomenon analysis, the resulted money circulate in the entire world, through some geographic and institutional channels. Starting from the fiscal paradise characteristics we have accomplished a parallel between that and the financial paradise characteristics. In the second part of the paper, we have analyzed the offshore zones, showing also the methods of income placement in the respective countries with some conclusions.

Key words: Shadow economy, the latent economy, evasion from payment of taxes, criminal business, money-laundering,

JEL classification: G01

1. Introduction

If we analyze the money wash phenomenon it results that no matter what the in fractional method of the source, the “dirty money” circulate around the world through some geographical and institutional channels opened for the organized crime. It is obvious the existence of some privileged territories in this financial universe, where huge transactions can be made without any control.

Using the bank institutions, the criminal uses most of the time those who are a part of the so-called “fiscal paradises”. In a strict sense, almost every country in the world can be considered a fiscal paradise because one form or another, the companies and foreign physical persons are offered different stimulants to encourage their investments and to promote the economical growth.

The term of “fiscal paradise” is often incorrect used. To describe a country from this point of view there should be used

jurisdiction terms from the financial sector. A certain degree of financial and banking discretion is characteristic to all states. Almost all the states impose a certain level of protection for the banking and commercial information, but also most of them won't protect this information in the case of an investigation from the legal organs from a foreign country.

A jurisdiction of the bank and financial secret will almost all the time refuse to break its own rules about the bank secret even when it could be the case of a serious violation of the laws of a country.

There are considered fiscal paradises the following countries: Panama, Cayman, The Commonwealth of the Bahamas, Bermudas, The Channel Island, The Island of Man, Liechtenstein, Monterrey, The Netherlands Antilles [1].

Gheorghe Nistoreanu and Costica Paun also add to the fiscal paradises Singapore, Hong-Kong and Switzerland [2].

2 Problem Formulation

The great financial scandals that have appeared in the past years are marked by the same trait: the criminal formations take advantage of all the given facilities from the financial paradises and offshore bank centers (outside the home country) to wash illicit profits, aspect that imputes over the penal investigations in this field.

The way the fiscal paradises have appeared has been in some cases determined by the lack of intern resources, a lack that has been compensated by the state authorities, respective by granting some fiscal facilities to commercial societies and financial institutions, for those to establish the headquarters in that state. Therefore, it has lead to the situation in which almost half of the world financial flux is going through offshore channels: banks, assurance societies, mutual funds, foundations and holdings [3].

An ideal financial paradise has the following traits:

- There are no deals about the information exchange with any other countries;
- International corporations can be created with minimum of formalities
- The assurance of the bank secret for these corporations
- Very hard rules for the break of the bank secret
- A very well developed tourist activity through which there can be justified the incoming of cash money.
- The use of an universal value, preferably the American dollar, as local money
- A government relatively invulnerable to external pressures
- A high degree of economical dependence in the financial service sector
- The existence of modern communication systems (cable, telex) that are connected to other countries.
- A geographical placement favorable to business travels from and to foreign rich countries [4].

Fiscal paradises are a main component of the organized crime. They are used for the wash of money that came from a large diversity of illegal activities (drug deals, fiscal evasion, and contraband) [5].

Fiscal paradises give the foreign investors a very large variety of services, without the obligation of revealing the origin of the money, stating with the registration of international corporations and ending with the banking operations that are not in the attention of the authorities. Although the banking secret and the financial paradise are two distinct notions, they have in common both the legitimate purposes and the commercial justification. In the same time they offer an unlimited protection to the criminals that are willing to do business at any price. It should also be added that the foreign companies and physical persons to whom it's giving stimulants to encourage their investments consider a country a fiscal paradise but the local population won't regard the same the state politic because the government takes taxes for personal incomes, taxes for the imports and exports, taxes for the successions and donations, for immobile proprieties, etc.

Petruț Ciobanu [6] detaches in the financial paradises the so-called “banking heavens” that being the countries that are interested more by the banking secret than the tax reduction. These “banking heavens” are actually countries with a solid economical potential that offer different facilities for substantial capital contribution from other countries.

The characteristics of the fiscal paradises make of these a special attraction for the fond recyclers because they furnish a wave of secrecy over the transactions, so that the owner of a society that is a part of the fiscal paradise can't be associated with the fond flux. Furthermore, the banking and modern communication systems that the fiscal paradise countries have, allow the fast movement of the funds. All corporation types registered in the fiscal paradises- general societies, offshore banks, and captive assurance societies –can be used by the fond recyclers in all the steps of the money wash process: placement, stratification and integration.

In Eastern Europe one of the most encountered money wash schemes is that through the offshore zones. For example, the illicit income is placed in a bank account. The depositor, making a fictive loan contract with an economical agent from the offshore zone, transfers that money to the loaner account. The last mentioned, at his turn, makes a contract with a third economical agent. It is made the creating cession, the third person transferring the money in a bank, for example in Switzerland or Austria in the account of the “money washer”.

The offshore is the territory designated for both the international financial centers and for some banking operations. The offshore zones are a power source that absorbs international organized criminality, and being also an exploitation channel of the country capitals, of money wash and fiscal evasion. They have a dominant role in the washing process, being also very used.

3 Problem Solution

Offshore areas are characterized, mainly, through the absence of any registrations referring to the facto leaders of the companies, the legislation interdiction of the revealing of any information about these areas, the leading that are unwilling to

cooperate from the idea that in most areas, the fiscal evasion isn't a crime in the purpose of money wash. In some states, the intern legislations interdict the operation effectuation through the way of financial institutions from offshore areas; in others the law doesn't interdict such operations. In the states where the national value is permanently subdued to the inflation, the elicitor can establish limitations for the exchange with the purpose to realize the more powerful value. Offshore areas are usually those who give value exchange services for the strangers. In the states with a stable value, it is usually allowed the participation in offshore banking operations.

The distinctive element of the offshore is confidentiality. Moreover, the majority of offshore areas don't admit the decisions of the foreign judging instances. The revenue placement in these areas is made by several methods, such as:

- The physical transportation – the illegal obtained value can be placed into offshore areas through luggage, intermediary.

- Bank transfers

- Mailed or physically given checks.

- Trustworthy persons: accountant – who transfers money on the trust fond and then somebody else, transfers it in the offshore areas.

- Telegraphic services: Western Union, American Express –can be made through transfers without the precise identification of the sender and through the application of passwords, it can be avoid the knowledge of the beneficiary's identity.

Once the money reaches the offshore areas, the incomes are stratified and there are reintegrated. Through the most frequently used methods to return the income in the origin country are encountered [7]:

- Fictive loans: fictive corporations can open bank accounts in foreign countries; after this, the checks can be sent to the original state as credits from these fictive companies.

- Fictive investors- the illegal business is organized in the origin state and the fictive investors are usually placed abroad and used to get capital.

- Commissions –are paid for the finding of investments to exercitation of a business, negotiations for immobile acquisitions.

- Checks and transfers

- Physical transfer

The countries, cities or areas that have the typical characteristics for the “financial paradises” in Europe are [8]:

1. In Europe: Andorra, Cyprus, Gibraltar, Man Isle, Channel Islands, Liechtenstein, Luxembourg, Malta, and Monaco.

2. In Asia and Pacific: Cook Islands, Hong Kong, Macao, Marshall Islands, Nauru, Samoa, Singapore, Bahrain, Libyan.

3. In Africa: Liberia, Mauritius, Seychelles

4. In Caribbean Sea and Central America: Antigua, Bahamas, Barbados, Belize, Bermudas, Virgin Islands, Britannic, Cayman Islands, Costa Rica, Panama.

We will make a short presentation of the most representative fiscal paradises as a rapport of the United Nations names them in 1999 [9].

Panama became in a short while an important fiscal paradise and international bank center. Through the abrogation of a law of corporation's birth that is very less exigent, in the last years, there have been made more corporations in Panama (~ 50.000) than in all the fiscal paradises from Caribbean/Central America together. Excepting an annual tax of 100\$ there are no kind of taxes for foreign entities, no require to declare the incomes and no supervision from the government.

There is no demand about the minimum of invested capital, no requires for the maintenance of registers, and no stipulation about the frequency and corporation meeting schedules, like there is no need to trace any corporation evidential. At this is added a bank law that authorizes numbered and codified bank accounts. According to several experts in the field, that offer recommendations for the selection and use of the fiscal paradises, the laws of the banking secret and of corporation from Panama make this country an ideal paradise [10].

The *Bahamas Islands* form an independent colony of Great Britain and are situated in the Caribbean Sea at about 30 flight minutes from the east coast of USA. In the Bahamas Islands there are over 350 different banks, including most of the important banks of the world. About 95% of the total financial transactions volume that takes place here is connected to international

transactions for foreigners. The bank accounts are easy to open; they can be created even through mail.

There are no monetary or exchange restrictions for the foreign funds that can be transferred from country to country, easily. The banks and their depending governments strictly apply the banking secret [11].

Liechtenstein is an independent country situated between Switzerland and Austria. The banking secret is applied here even more strictly than in Switzerland. No so long ago here could be made trust for the income protection. Unlike most of the trusts, the “anstalt” from Liechtenstein is a commercial organism that is capable of having some specific activities that can give the person that is transferring the wealth to the trust. Most of the experts consider Liechtenstein and Switzerland interchangeable from the perspective of the fiscal paradises [12].

But it is admitted that the secret traditions of Liechtenstein assure probably the Switzerland superiority in the banking field. The more sophisticated foreign investors have created a nightmare financial secret through the use of the Switzerland bank accounts for corporations from Liechtenstein.

Although some of the smaller states have drawn certainly the dirty money, the most defying attempt to extract the illicit profits was initiated by the Seychelles Islands, which in the 90s have registered at least 10 million dollars in these banks. Under the pressure of the United States and of other members of the international community, Seychelles has given up selling its suzerainty.

One of the criticized paradises for the lack of any discrimination towards the customers is Antigua. In 1996, a rapport of the Senate commented that nobody attracts “dirty” money more than Antigua that has a banking industry with no regalements, doesn’t apply the reporting demands but sanctions toughly the revealing of the banking secret. In 1995, the bank number in Antigua grown with 75%, any person that had the capital of 1 million dollars could open a bank and many of them were nothing more than a simple room with a fax. The authorities from Antigua have tried to minimize the case of the European Union Bank when the bank directors have disappeared with 8 million dollars, suggesting that there have been taken measures to prevent the apparition of such a

situation. Still, they haven’t been able to explain convincingly, how can a country with a population of 70.000 inhabitants to assure an adequate supervision of the countless institutions and financial services from the island [13].

Bermudas is another fiscal paradise- an ex Britannic colony, with lifelong traditions of an international financial center. Its pride is a large community of professions in the field of financial activities (lawyers, accountants, bankers, assurance agents) with experience the field of foreign investors relations. The financial system from Bermudas is old, stable and respected worldwide and the telecommunications network is modern and efficient. The Group of the Bermudas Islands is situated at only 350 miles, in the coasts of North Carolina, are beneficiating of good flight connections with the United States and Europe. There are no controls over the money exchanges and any money quantity can be introduced or removed from the country. The banks in Bermudas offer a large variety of accounts and services (current accounts, of economies, fiducially and of custody, trust counts, investment management, brokerage services, executive services, management and corporation administration, immobile proprieties management and services for funkier credits). There is no law code that would govern the banking secret. But the existing banking secret works as a consequence of the common Britannic right, which is strictly respected in the banking community.

The banks from Bermudas are more restricting about the new customers, at least comparing to the other fiscal paradises from the Caribbean area. Generally, they prefer that the new customers to be recommended as a member of the professional community (not necessarily local profession). Despite these, with banking references and a corresponding id, anyone can open an account of their own. The legislation from the Bermudas allows very easily the birth and working of some captive assurance companies.

It is interesting the fact that in the Bermudas, there are only four banks (The Bank of Bermudas, National Bank, Bermudas Provident Bank and The Bank of N.T. Butterfield and Son) and two major law firms that take care of all or most of the

financial transactions form the island. All these entities have their meetings in the capital city.

Isle of Man is a small island (227 square miles), situated in the Irish Sea, between Great Britain and Ireland, British possession, that is enjoying a high autonomy that allows her to work a fiscal paradise. There is no money control and like any other fiscal paradise, the telecommunication equipment and the capacities of the Man Isle are excellent.

The air traffic goes through England and Ireland. Same as Bermudas, the legislation of the Man Isle is very attractive to the birth and operations of captive assurance companies. On the island there are 45 different banks. In contrast, a recent rapport says that there is only one hotel that offers rooms with separate bathrooms. The acquisition of corporations on Man Isle is easy and cheap and therefore is a very often used as a way of opening accounts in another part of the world in the name of a company that the Man Corporation is giving.

The Cayman Islands (Grand Cayman, Little Cayman and Cayman Brach) are situated at south of Cuba and are serviced by more major air companies that make systematical flights from Miami, Houston and other cities from the United States. The main activity on the Grand Cayman Island is the international banking activity, in the isle existing about a bank for 30 inhabitants. The image Cayman has, as a “fiscal paradise” island is very promoted by the governmental authorities and of the private economical sector. The legislation and current regalements are deliberately been elaborated to assure and increase the country’s reputation for financial and corporative use.

The law of banking and trusts, and also the Law of confidential relations are counted among the most severe and restrictive from the entire world. Not only that the revealing of information is a crime, but also the asking for information is against the law. Cayman possesses all the other characteristics of a well-done fiscal paradise, through which: a superior telecommunication system, no money restrictions or value exchange, the representation of most of the major international banks and local specialists in the field of international taxes.

Cayman is also proud of the specialized trusts in the birth and administration of foreign corporations. In 1992, there have been made in Cayman 2930 new corporations making the whole number to 16712 while the whole population of the Cayman islands is of about 17 000 persons.

Switzerland is not a fiscal paradise. Although the words “bank account in Switzerland” have become synonyms with “secret bank account” and even if Switzerland is without doubt, the safest, most stable place to hold secret money, it is not a fiscal paradise. The taxes for locals are high, but the taxes for foreigners that make money in Switzerland are up to 35%.

Of course, through Switzerland banks can be made some arrangements for investments outside the country to avoid high taxes from Switzerland, the profits being afterwards transferred back to safe Switzerland bank accounts.

The Switzerland banks offer an incredible range of services along the regular bank services, including that to act as brokerage agents, commercials in precious metals, administrators and even traveling agents for their customers. The operations banking secret and all the commercial or economical transactions represent a state of normal in Switzerland. The laws about the banking sector are part of the constitution of the country and are taken very seriously.

The Switzerland is making all the efforts to assure the confidentiality of the banking operations of their customers, up to the use of anted less envelopes, mail boxes they change frequently, post through personal messengers and the expedition of mail for the customers from France, Italy or Germany, to avoid the stamp of the Switzerland post.

Although the Switzerland legislation assures enough confidentiality to face the necessities or any foreign investor, there are too many cheaper and more accessible places that are faster to create corporations. Recently, through the application of a treaty of assistance between Switzerland and USA, the investigators that have worked using adequate channels from the Minister of Justice and the State Department have managed to get some data and documents about the accounts in Switzerland of some American criminals. The Switzerland themselves are feeling disappointed and

embarrassed by the abuses made by foreign criminals through their banking system. They fear the potential threat that it rises over the integrity of the system the millions of dollars in “easy made money” that could tempt the persons working there, otherwise with no mistakes from the Switzerland bank network. In May 1984 it was a national referendum that proposed the attenuation of the banking secret to allow the foreign officials from the field of law enforcement to access the documents referring to the foreign criminals. The referendum wasn't approved, but the simple fact that such a proposition has been made and supposed to vote was a step in the right way.

4 Conclusion

These methods can be applied separately but also together. In the same time, there can be outlined other methods such as: customers presented by a part, branch or another bank from abroad with a headquarter in the country that produces or makes traffic with drugs is a main component of the economy, the use of credit letters or other financial methods to transfer money in the countries where the customer doesn't always do business in, customers that make big and systematic transactions, including the electronically transfer, that can't be clearly identified as being of good faith or customers that receive huge systematized amounts of money from other countries that are usually associated with the production, relocation and accomplishment of drugs, with terrorist organizations, prescribed “fiscal paradises”; the making of huge balances that don't correspond to the business number that the firm usually has and after transfers into bank accounts from abroad, unexplainable

electronically transfers, without going through an account, traits of a foreign coin, frequent payment of traveling paychecks.

Views on the Internal Control System of Economic Entities

Lenghel Radu Dorin

„Dimitrie-Cantemir” Christian University, Faculty of Economic Sciences Cluj-Napoca
radulenghel@yahoo.com

Abstract

The internal control system has to be developed and implemented by the manager up to the level, which allows him a better control over the functioning of all activities for the realization of the objectives set. In accordance with Companies Law, the determination of the internal financial control system is the competence of the board of directors of the company, therefore, each responsible of an economic entity has the obligation to create an internal control system at entity level. The internal control system of economic entities is made up of the following forms of control: hierarchical control; reciprocal control; self-control; financial accounting control; financial preventive control; financial management control.

Key words: internal control concept, internal control objectives, internal control components, internal control system, internal control activities.

JEL: M40, M41

1. Introduction

The objective of this article is to present the author's opinion on the method of organization of the internal control system within economic entities. The economic entities have to create an internal control system with the purpose of monitoring and evaluating the effectiveness and efficiency of all the activities within economic entities. By the research carried out, we tried to answer the question: what are the forms and activities of control within economic entities.

2. Internal control concept

Internal control represents the assembly of policies and procedures adopted by management, which contribute: to the fulfillment of managerial objectives, to the

prevention and detection of frauds or errors, to the accuracy and exhaustiveness of accounting entries, and to the preparation in due course of financial accounting information. [1]

The role of internal control can be summarized to: the limitation of uneconomical and inefficient operations; the assurance of patrimony integrity; the assurance of a thorough and efficient management of activities; the observance of orders given by the management; the observance of legal provisions; the reality and accuracy of accounting information. [2]

According to the legislation in force, internal control represents the totality of policies and procedures elaborated and implemented by the management of the entity to assure: the attainment of objectives of the entity in an economic, efficient and effective way; the observance of field-specific rules, of policies and decisions of management; the protection of goods and information, the prevention and detection of frauds and errors; the quality of accounting documents, and the provision in due course of reliable information for the management.

3. Objectives and components of internal control

a. Internal control objectives

In the meaning of legal regulations regarding internal control (Order of the Minister of Public Finances no. 3055/2009), the internal control of the entity has the following objectives: the compliance with the legislation in force; the application of decisions taken by the management of the entity; the good functioning of the internal activity of the entity; the reliability of financial information; the effectiveness of operations of the entity; the efficient use of resources; the prevention and control of risks of not achieving the objectives set etc. [3]

Therefore, the internal control procedures have the objective:

- on one hand, to follow up the registration of the activity of the entity and of the staff behaviour within the framework defined by the applicable legislation, the values, norms and internal rules of the entity;

- on the other hand, to check whether the accounting, financial and management information communicated accurately reflect the activity and the situation of the entity.

The internal control applies throughout the operations carried out by the entity, as follows:

- a) prior to the realization of operations (which is done for the purpose of preventing the carrying out of the operations, which do not fulfil the conformity and legality conditions);

- b) during the operations (which implies checks between departments, employees, following the separation of tasks and assignments of the employees);

- c) after the completion of the operations (which represent checks on the method of observance of the legal provisions regarding the management of material and money values), in which case the check is designed, for instance, to analyse the profitability of operations and to acknowledge the existence of conformity or possible anomalies, which must be corrected.

The internal accounting and financial control is a major element of internal control.

The internal accounting and financial control aims at assuring:

- the compliance of accounting and financial information published, with the rules applicable to it;

- the application of instructions elaborated by management in connection with this information;

- the protection of assets;

- the prevention and detection of frauds and accounting and financial irregularities;

- the reliability of annual financial situations published and of other information communicated to the market.

b. Internal control components

For the persons responsible for the organization and implementation of internal control, we consider that the knowledge and understanding of internal control components are extremely useful. In order to reach its objectives, the internal control has the following closely connected components:

- a clear definition of responsibilities, resources and adequate procedures, methods and systems of information, appropriate instruments and practices (control environment);

- a system which aims, on one hand, at the analysis of the main identifiable risks regarding

the objectives of the entity and, on the other hand, at the assurance of existence of procedures of management of these risks (risk evaluation);

- appropriate control activities for each process, conceived to reduce the risks susceptible to affect the realization of the objectives of the entity (control activities);

- the internal dissemination of pertinent, reliable information, whose knowledge allows each person to exert his/her responsibilities (information and communication);

- a permanent supervision of the internal control device, and an examination of its operation (control monitoring).

4. The internal control system of economic entities

The internal control system has to be developed and implemented by the manager up to the level which allows him a better control over the functioning of all the activities, in view of realization of the objectives set.

In accordance with the companies law, the determination of the internal financial control system is the competence of the board of directors of a company.

The entity management establishes for each activity what are the most adequate forms of internal control, in view of limitation of risks and to provide a reasonable assurance that the management objectives are fulfilled.

The structure of the internal control system is made up of the assembly of internal control forms which can function in economic entities.

The internal control can be found in the structure of each activity, being a process accomplished by all the employees, so it is not a distinctive department in the entity.

Regardless of the moment of exertion, the internal control done with competence contributes to the avoidance of financial or accounting irregularities and to the consolidation of patrimony integrity.

Internal control is made up of the assembly of policies, measures and procedures adopted by the management of an entity, which is designed to assure its good functioning. The internal control is exerted by the whole management and execution staff, usually, along with the other job assignments, under the form of self-control, reciprocal control, administrative (hierarchical) control, etc., each of them following specific objectives delimited by the organization chart, the job description (job tasks), procedure

manuals, documents drawing up, approval and circulation charts and data processing charts, etc.

The internal control is exerted preventatively, simultaneously and subsequently, through all the employees or structures from the entity.

Internal control is more an attribute or a condition than a function or organizational structure.

The internal control system of economic entities is made up of the following forms of control: Sistemul de control intern al entităților economice este format din următoarele forme de control: hierarchical control; reciprocal control; self-control; financial accounting control; financial preventive control; financial management control. [1]

a. Hierarchical control

Hierarchical control is exerted within the current competences of the persons with management positions over the subordinate persons. Hierarchical control can be exerted: without notice, on the spot, by factual checks or documentation; by inspection or direct observation of the subordinate staff, of departments or sectors of activity; by direct discussions with the heads of subordinate departments, on the occasion of analyses at the end of the month; by immediate and direct measures which aims at removing the deviations and the accountability of persons at fault; by the creation at company level of a regular system of information and notices or presentation of reports by the subordinate persons; by the personal information or organization of discussions of leaders of the entity with the subordinate staff; the use of fast means of communication and information (telephone, intercom, emission-reception devices, internet); anticipated establishment of tasks which are to be confronted and regularly checked.

b. Reciprocal control

Reciprocal control is carried out between departments and employees based on material and informational flows established following the division of labour, specialization and separation of tasks. Reciprocal control is done in a permanent way by the circulation of documents between different departments of the entity, each department aiming that the document fulfils the conditions of form and substance established and carries the authorized signatures to enforce it or check it, to go to another department.

c. Self-control

Self-control assumes the checking of one's own activity, with the purpose of establishing whether the objectives proposed were achieved, whether the activity carried out is at requirements level.

d. Financial accounting control

The financial accounting control is permanently exerted by the staff working in the financial accounting department, at the moment of going through the stages regarding the registration of justifying documents in accounting books.

The head of the financial accounting department is liable for the unitary application of the provisions of this procedure.

The financial accounting control has the following objectives to check: the organization and running of accounting to date; the method of observance of accounting principles; the method of evaluation of elements of assets and liabilities; whether all the operations made the object of an entry (exhaustiveness); whether any entry is justified by an operation (reality); whether there are no errors in the computation of amounts (accuracy); whether the results of annual inventory were correctly valorized; the control of accounting correlations (correspondence of accounts, between synthetical and analytical accounting, the trial balance and the annual financial statements); the method of elaboration of trial balances and of annual financial statements etc.

e. Preventive financial control

The preventive financial control has as purpose the identification of projects of operations which do not observe the conditions of legality, regularity, reality, economicity, effectiveness and efficiency.

The preventive financial control has the purpose to prevent the employment and performing of operations which do not fulfil the conditions above, established by the management or by the regulations in force.

Private companies organize and exert preventive financial control by own articles of association, depending on their particularities and complexity.

The main operations, which are subject to the preventive financial control check in economic entities are: the conclusion of agreements with internal or external partners; the invoices of supply and delivery; the receipts and payments in lei and foreign currency; the payrolls and declarations regarding the social contributions of staff; fiscal declarations; consumptions of material goods; travelling deductions;

amendment of share capital; leasing and concession of assets, etc;

The preventive financial control is exerted on documents, in which the patrimonial operations are written before they become judicial acts.

The preventive financial control consists of the systematic checking of operations which make its object, from the point of view of:

- observing all the legal provisions, which are applicable to them, in force on the date of making the operations (legality control);

- fulfilling under all the aspects of principles and procedural and methodological rules, which are applicable to the categories of operations, of which the operations subject to control (regularity control) are part;

- following up the economicity, effectiveness and efficiency of operations and transactions (performance control).

The importance of preventive financial control results from the fact that it is a real filter of all patrimonial operations reflected in the justifying documents.

The preventive financial control is usually organized within the specialized financial accounting departments.

In view of thorough organization of the informational system and of the establishment in time of the moment in which the preventive financial control is efficiently exerted, the heads of economic entities will establish by internal decision the circuit of documents, the departments and staff involved and their responsibilities.

The preventive financial control is exerted by check, by persons from the specialized departments appointed for this purpose by the leader of the entity (usually the preventive financial control is exerted by the chief accountant or by the head of the financial accounting department).

The documents regarding the operations, by which the patrimony is affected will be accompanied by the checks of the specialized departments, by substantiation notes, by justifying acts or documents.

The persons appointed for the exertion of preventive financial control will take over the documents and will proceed, in a first stage, to their formal checking regarding: the completion of documents in accordance with their contents; the existence of signatures of authorized persons from the specialized departments; the existence of justifying acts specific to the operation presented for check.

If the requirements of formal checking are not observed, the documents are returned to the

issuer, stating in writing the reasons for return.

After the performance of the formal control, the persons appointed to exert the preventive financial control will move on to the substance check, by checking the operation from the point of view of its legality, regularity, reality, economicity, effectiveness and efficiency.

If need be, in view of exerting a preventive control as complete as possible, one can request other justifying acts as well, and the check of the legal department.

If following the substance check, the operation fulfils the conditions of legality, regularity, reality and performance, the check is given by the application of the seal and signature on the counterpart of the document which is archived at the economic entity.

After going through the procedures of documentary check and after giving the check or as applicable, the refusal of check, the person empowered will complete the register of operations subjected to preventive financial control.

If following the check it is acknowledged that the operations do not meet the conditions of legality, regularity, reality and performance, the persons appointed with the exertion of the preventive financial control will refuse with motivation in writing, to give the check of preventive financial control, recording this situation in the register of operations presented to the check of preventive financial control.

The refusal of check, accompanied by significant justifying acts, will be brought to the knowledge of the entity leader, and the other documents will be returned, under signature, to the specialized departments which initiated the operation.

The making on own responsibility of the operation refused at the preventive financial control check can be done by an act of internal decision issued by the leader of the entity. A copy of the act of internal decision will be sent to the internal audit department of the economic entity. At economic entities this disagreement is settled in accordance with the articles of association of the entity and with the internal policies and procedures.

In all the cases in which following a refusal of check, the leader of the economic entity orders making the operation on own responsibility, the head of the financial accounting department has the obligation to inform the board of directors in writing.

The head of the financial accounting department has the obligation to inform the Board of Directors on the operations refused at

check, but made on own responsibility by the leader of economic entities. The Board of Directors has the obligation to take the legal measures to reestablish the situation by law.

f. Financial management control

The financial management control is a subsequent control, able to compare the actual results with the legal provisions, to establish the deviations, to analyse and determine their causes, but also to propose measures of removal of inconveniences and sanctioning the persons at fault. It is organized by the leader of economic entities, in a distinctive department with competent staff. This subsequent financial control is exerted once a year, based on pre-established schedules approved by the head of the financial management department.

The financial management control is a form of financial control which is exerted after the carrying out of the activities and has the purpose, in most cases, to remedy deviations from the legal provisions or the internal norms.

The financial management control is done in whole or by survey, depending on volume, value and nature of assets, management conditions and the frequency of deviations subsequently acknowledged.

Based on the control acts drawn up (notes of acknowledgement or control reports), the head of the financial management control department presents the management of economic entities the conclusions of the control and the measures proposed for the removal of deviations acknowledged and the accountability of the persons at fault. The leaders of economic entities have the obligation to fully apply in due course the measures proposed, the sanctioning of the persons at fault, the recovery of damages and the forwarding of the acts provided by the criminal law to the investigation bodies.

The main objectives to check by the financial management control are: the existence, integrity and security of material assets; the method of use of material and money values; the method of establishment and awarding of salaries and rights assimilated to salaries; the method of making the receptions and storages of goods; the method of management of inventory items and of working equipment; the checking of the method of hiring the warehouse keepers and of the guarantees deposited by them; the method of making and settling the differences discovered on occasion of inventory-taking; the method of drawing up documents, of analytical and synthetical records (following up potential deviations); the method of performance of the preventive financial control and its role in the

patrimony administration; the method of fulfilment of money, financial and fiscal obligations; the method of fulfilment of measures disposed on the occasion of previous controls, etc.

This form of management control is currently found in commercial activity, under the form of management reviewers, who make the regular inventory of managements of merchandise.

5. Conclusions

As for the method of organization and functioning of the internal control system of economic entities, we can draw the following conclusions:

- each responsible of an economic entity has the obligation to create an internal control system at its level;

- the manager of the entity can resort to the services of professionals for the conception, development and implementation of internal control;

- the internal control is exerted by the whole management and execution staff, usually, along with the other job assignments, under the form of self-control, reciprocal control, administrative (hierarchical) control, etc., each following specific objectives delimited by organization chart, job description (job tasks), procedure manuals, documents drawing up, approval and circulation charts and data processing charts, etc.;

- apart from the control activities integrated in management line, specialized controls can be organized, carried out by specially created structural components (commissions, financial management control departments, management reviewers, etc.), whose activity is carried out on the basis of a plan, conceived by taking into consideration the risks;

- the internal control is exerted preventatively, simultaneously and subsequently, through all the employees or structures from the entity;

- internal control is more an attribute or a condition than a function or organizational structure;

- from the legal regulations (Order of the Minister of Public Finances no. 3055/2009), it does not result clearly what are the procedures and policies of implementation of internal control applicable to an economic entity and the types (forms) of internal control are not presented in detail, only a classification of them is presented by the time in which it is exerted

(prior to, during and after the completion of operations);

– in legal regulations only a certain form of internal control is developed, represented by the internal accounting and financial control, as if the other forms of internal control had not existed;

– as for the internal control components, they are presented in another form, but similar to the already dedicated models of internal control (Coso and Coco);

– the general objectives of internal control are presented in the legal regulations, but there are no differentiated objectives developed by each form of internal control;

– as you can see, the legal regulations allot a significant importance to just one of the internal control components, which is the internal accounting and financial control, from where it results the detailiation of the general objectives of the internal control of the financial and accounting function;

– yet, the management of economic entities does not have to limit the scope of internal control, only to the internal accounting and financial control, because the scope of internal control is much wider than the scope of internal accounting and financial control;

– as for the method of implementation of internal control activities, it is acknowledged that in most entities, they are not formalized (there are no specific internal control procedures);

– irrespective of the method of organization of internal control, the manager of the economic entity has to choose the most appropriate forms, techniques or procedures of internal control in the fulfilment of managerial objectives.

Abstract

The internal control system has to be developed and implemented by the manager up to the level, which allows him a better control over the functioning of all activities for the realization of the objectives set. Taking into account the particularities of the legal, organizational framework, staff, funding and other specific elements, as well as the internal control standards, the heads of public entities will dispose the necessary measures for the elaboration and development of management control systems of each organization, including the procedures, formalized by activities. The internal control system of public entities is made up of the following forms of control: hierarchical control; reciprocal control; self-control; financial accounting control; financial preventive control; financial management control.

Key words: internal control objectives, internal control components, internal control concept, internal control system, internal control activities.

JEL: M40, M41

1. Introduction

The objective of this article is to present the author's opinion on the method of organization of the internal control system in public entities.

Public entities have to create an internal control system with the purpose of monitoring and evaluating the effectiveness and efficiency of all the activities from the economic entities. By our research, we tried to answer the question: what are the forms and activities of control in public entities.

2. Internal control concept

According to the legislation in force, internal control represents the totality of

policies and procedures elaborated and implemented by the management of the public entity to assure: the attainment of objectives of the entity in an economic, efficient and effective way; the observance of field-specific rules, of policies and decisions of the management; the protection of assets and information, the prevention and detection of frauds and errors; the quality of accounting documents as well as the provision in due course of reliable information for the management. [1].

The role of internal control can be summarized to: the limitation of uneconomical and inefficient operations; the assurance of patrimony integrity; the assurance of a thorough and efficient management of activities; the observance of orders given by the management; the observance of the legal provisions; the reality and accuracy of accounting information. [2].

Internal control represents a continuous process in which the administrative management, the executive management, and the whole staff of public entities participate, by which a reasonable assurance is provided on the attainment of the objectives of the entity.

3. Objectives and components of internal control of public entities

a. Internal control objectives

Starting from the definition of internal control in public entities, it results that it has the following objectives: [3]

- the attainment of objectives of the entity in an economic, efficient and effective way;
- the observance of field-specific rules, policies and decisions of the management;
- the protection of assets and information, the prevention and detection of frauds and errors;
- the quality of accounting documents;
- the provision in due course of reliable information for the management.

The Management of public entities has to create objectives differentiated by each form of internal control, by the instatement of adequate control procedures (based on job descriptions and checking questionnaires).

From the objectives analysed above it results that the internal control in public entities is a managerial instrument used to provide a reasonable assurance that the objectives of the management of public entities are fulfilled.

b. Internal control components

By taking into account the particularities of the legal, organizational framework, staff, funding and other specific elements, as well as the internal control standards, the leaders of public entities will dispose the necessary measures for the elaboration and development of managerial internal control systems of each organization, including the procedures formalized by activities.

Romania agrees and uses the elements of the control framework proposed by the model COSO, which, implemented at the level of public entities, allows them to better manage the activities necessary for the fulfilment of objectives.

COSO defines internal control as a process carried out by the board of directors, the management and the whole staff of the public entity, designed to provide a reasonable assurance regarding the fulfilment of the objectives of the organization, considering: the efficiency and effectiveness of the operations; the reality of financial reports; the compliance with the laws and regulations applicable.

The components of the model COSO are represented by:

1) *the existence of a favourable control environment*, which represents the attitude of the whole staff of the public entity, including the general management, towards control, by its acceptance, use and appreciation. It represents the basis of all the other components of internal control, assuring a discipline in the organization which must be observed and a structure of the entity, so that the internal control system can be effectively applied.

2) *risk evaluation* allows for their hierarchization, for the identification of unacceptable risks, which aims at, on one hand, the analysis of the main identifiable risks regarding the objectives of the entity and, on the other hand, the assurance of the existence of procedures of management of these risks. At the same time, public entities have to create internal control activities, in view of avoiding the

unacceptable risks and maintaining the residual risks within the tolerance limits acceptable.

3) *control activities*, for each group of activities or subactivities, the management of public entity disposes the use of forms of internal control designed to eliminate or limit the associated risks. The control activities are carried out in the whole public institution, at all its levels and positions.

4) *information and communication* assure the knowledge of the elements of internal control by all those who will directly or indirectly have to implement them, as well as of the results of control. The effectiveness of communication sustains the management of the public entity and has to cover all the aspects of governance. Feasible IT systems can facilitate the decision-making process and can guarantee the accuracy and reliability of information with public character. The absence of an efficient communication leads to a poor perception of risks and, inherently, to the implementation of inadequate internal control instruments.

5) *monitoring* is a process which evaluates the performance of the internal control system and is exerted by the management of public entities, by continuous supervision activities and regular evaluations (internal control reports and internal audit reports). The internal control systems have to be monitored to evaluate the quality of the performance of the managerial internal control system over time.

The adoption of the model COSO envisages the creation of a robust managerial internal control system in public entities and the monitoring and effective and efficient management in public entities.

4. Structure of the internal control system of public entities

The Management of public entities will take measures for the development of own internal control systems based on internal control standards, by elaborating written procedures for each activity and each form of internal control.

Line Management in public entities establishes for each group of activities the adequate forms of internal control in view of elimination or prevention of risks.

The internal control system of public entities has to be permanently updated to allow the management to hold a permanent control over the functioning of the entity in its assembly, in view of reaching the objectives set.

The control activities which are forms of internal basic control, intrinsically attached to

the activities of public entity are represented by: self-control, reciprocal control and hierarchical control.

Apart from these three forms of control, intrinsically attached to activities and subactivities, of preventive financial control, the management of public entity has competences to instate, when the situation requires it, other forms of control which imply supplementary costs and distinctive working procedures, of which the most frequently used are: financial management control (patrimonial), inspections and other forms of control imposed by the management.

a. self-control of the activity

It is accomplished by each employee and implies the observance of own working procedures instated by the management of the public entity, by which the operations to execute, the responsibilities and different control devices (in fact, control keys attached to operations) are described to appreciate whether the operation was correctly executed.

b. mutual (reciprocal) control

It is exerted between the stages of a procedural chain, by each workstation, on the method of performance of operations by the previous workstation, to see whether own operations can be added, which will make the object of control at the following workstation.

c. hierarchical (administrative) control

It is exerted at the right higher hierarchical level by the persons who have a decision-making position, as responsible for activities from the public entity.

d. preventive financial control

d1. own preventive financial control

It is organized in all public entities, usually in the specialized financial accounting departments.

The preventive financial control has the purpose to identify the projects of operations (hereinafter referred to as operations), which do not observe the conditions of legality and regularity and, as applicable, integration within the limits and destination of state credits and commitment credits and which by their execution would bring prejudice to the public patrimony or public funds. The documents regarding the operations, by which the public funds or the public patrimony are affected will be accompanied by the checks of specialized departments, by substantiation notes and justifying acts or documents and, as applicable, by a proposal of employment of an expense or an individual or global commitment.

The persons appointed for the exertion of the

preventive financial control will take over the documents and will proceed, in a first stage, to their formal checking regarding: the completion of documents in accordance with their contents; the existence of signatures of authorized persons from the specialized departments; the existence of justifying acts specific to the operation presented for check.

If the requirements of formal checking are not observed, the documents are returned to the issuer, stating in writing the reasons for return.

After the performance of the formal control, the persons appointed to exert the preventive financial control will move on to the substance check, by checking the operation from the point of view of its legality, regularity, and integration in the limits and destination of state credits of the project subjected to the control.

If need be, in view of exerting a preventive control as complete as possible, one can request other justifying acts as well, and the check of the legal department.

If following the substance check, the operation fulfils the conditions of legality, regularity, and, as applicable, integration in the limits and destination of state credits or commitment credits, the check is given by the application of the seal and signature on the counterpart of the document which is archived at the economic entity.

After going through the procedures of documentary check and after giving the check or as applicable, the refusal of check, the person empowered will complete the register of operations subjected to preventive financial control.

The giving of the check or the refusal of the check cannot be imposed in any way to the person who exerts the preventive financial control, as the results of this control depend exclusively on the professional judgments of the controller. The persons entitled to exert own preventive financial control, are liable for the checked operations proportionally to their fault. The performance on own responsibility of the operation refused at the preventive financial control check can be done by an act of internal decision issued by the leader of the public entity. A copy of the act of internal decision will be sent to the internal public audit department of the public entity.

In case of refusal of check, the leader of the public entity can order the making of the operation on own responsibility, in which case the Court of Accounts, the Ministry of Public Finances and, as applicable, the higher hierarchical body of the public entity are

informed. The information of the higher hierarchical body will be done as soon as the performance of the operation was ordered, by the transmission of a copy of the act of internal decision and the motivation of the refusal of check.

The leader of the higher hierarchical body has the obligation to take the legal measures for the re-establishment of the situation by law. If by the operation refused at check, but performed on own responsibility by the leader of the public entity it brings prejudice to the patrimony of the entity and if the leader of the higher hierarchical body (as applicable) did not dispose the legal measures, the central inspection or the territorial inspections of the Ministry of Public Finances will be notified. The information of the Court of Accounts will be done on the occasion of making the management discharge controls or other controls of its competence.

The evaluation of own preventive financial control activity belongs to the audit structure of the public entity.

The evaluation of the activity of the person who carries out own preventive financial control activities is done every year by the leader of the public entity, with the consent of the public entity which checked the appointment, by grades, based on the information included in the internal public audit reports and in the reports of the Court of Accounts, where applicable.

d.2. delegated preventive financial control

The delegated preventive financial control is exerted by the Ministry of Public Finances, through the Body of Delegated Controllers, which functions as a distinctive structure, in the subordination of the Ministry of Public Finances.

The delegated controller is independent from the managerial structure of the public entity at which the check is exerted, by exerting a re-check of those projects of operations which are considered as having a high level of risk.

The delegated preventive financial control is exerted:

- at important public institutions (main credit release authorities), state Treasury and on the operations regarding public debt as well as operations funded from external funds;
- at other public institutions or legal persons of private law which manage public funds or manage the public patrimony, in case of operations with high risk.

The refusal of check of the delegated controller does not have character of blocking the financial operation, which is executed based on the decision on own responsibility of the

credit release authority, with the information of the Ministry of Public Finances and the Court of Accounts.

The preventive financial control will be gradually integrated in the scope of managerial liability, as far as the managerial internal control assures the elimination of risks in the administration of public funds.

e. Inspection

It is triggered following signals regarding potential irregularities, consisting of the examination of documents, facts, assets, with the purpose of establishing the deviations from the legality, taking measures for the protection of use of funds and public patrimony.

Within certain departments there was preserved a general direction with role of performing the inspections, considering the increasing number of complaints and claims, which had to be settled in due course, which exceeded the capacity of the other executive departments of settling in due course these complaints and claims.

f. patrimonial control (financial management)

The management of the public entity has competences of instating other forms of control when the situation requires it, forms of control which assume supplementary costs and distinctive working procedures, of which the most widely used is the financial management control (patrimonial).

The leaders of economic operators are obliged to assure the organization and exertion of the financial management control over own patrimony and the assets from the public and private patrimony of the state or of the administrative territorial units which are in administration, in concession or leasing.

This form of internal control has the objectives of checking the existence, the integrity, preservation and security of assets and values.

The financial management control is organized within economic operators and has the main following objectives:

- assurance of the integrity of the patrimony of the economic operator as well as of the assets from the public and private field of the state and of administrative territorial units in their administration, concession or leasing;
- the observance of the legal provisions and of internal regulations incidental to the economic financial activity of the economic operator;
- the increase of efficiency in the use of allotted resources.

The staff appointed to exert the financial management control has the main following assignments: [4]

- checks the observance of the legal provisions and of internal regulations regarding the existence, integrity, preservation and use of means and resources held by any title, and the method of their reflection in the accounting books;

- checks the observance of the legal provisions in the substantiation of the project of revenues and expenditure budget of the economic operator and of the projects of revenues and expenditure budgets of subunits from its structure;

- checks the observance of the legal provisions related to the execution of the revenues and expenditure budget of the economic operator and of the subunits from its structure;

- checks the observance of the legal provisions and of internal regulations regarding the method of performing the annual inventory of elements of nature of assets, debts and equity;

- checks the observance of the legal provisions and of internal regulations regarding the receipts and payments in lei and foreign currency, of any nature, in cash or by bank transfer;

- checks the observance of the legal provisions regarding the registration of economic financial operations in accounting books;

- checks the observance of the legal provisions and of internal regulations regarding the drawing up, circulation, preservation and archiving of primary documents, accounting documents and technical operational documents;

- elaborates economic financial analyses for the management of the economic operator for the purpose of substantiating decisions and improving performances.

The financial management control is organized at the economic operator for the control of own managements and at subunits from its structure.

The financial management control is exerted under the following forms:

- preventive control, which consists of checking the substantiation of revenues and expenditure budgets and of annexes to these;

- operational control, which consists of checking economic financial operations carried out during the current fiscal year.

The leader of the economic operator establishes by internal procedures: the method of elaboration and realization of the activity

schedule; the duration of performing a control action; the types of control acts, their circuit and highlighting method; the appointment of persons responsible for the fulfilment of the measures established.

The observations written in the control acts have to be precise, based on data and documents, eliminating any personal, unuseful and inconclusive elements and descriptions. For the deficiencies acknowledged, it shall be necessarily written the legal provisions or internal regulations violated, the economic, financial and patrimonial consequences, the persons responsible and the measures proposed.

The control acts are presented to the leader of the economic operator.

The leader of the economic operator analyses, disposes and follows up the fulfilment of the measures written in the control acts.

The leader of the economic operator assures every quarter or whenever it is necessary, the information of the board of directors regarding the exertion and results of the financial management control.

The person appointed by the leader of the economic operator, with assignments of financial management control, participates in the meetings of the board of directors when financial, accounting and financial management control problems are debated. The other public entities can adjust the financial management control procedure by the financial management control procedure of the economic operators.

5. Conclusions

As for the method of organization and functioning of the internal control system of public entities, the following conclusions can be drawn:

- a reasonable and flexible internal control system, which can change depending on realities, manages not absolutely, but within certain limits, to assure the fulfilment of managerial objectives of public entities with a higher probability and in better conditions;

- public entities agree and use the elements of the control framework proposed by the model COSO, which, implemented at the level of public entities, allows them to better manage the activities necessary for the fulfilment of objectives.

- the control activities are part of the managerial internal control process, by which the entity aims at reaching the objectives proposed;

– there are control activities which are forms of internal control intrinsically attached to the activities of public entity represented by: self-control, reciprocal control and hierarchical control. Along with these three forms of control, intrinsically attached to activities and subactivities, of preventive financial control, the management of the public entity has competences of instating when situation requires it, other forms of control, which assume supplementary costs and distinctive working procedures, of which the most widely used are: financial management control (patrimonial), inspections and other forms of control imposed by the management of the public entity;

– internal control targets the application of norms and procedures of internal control, at all hierarchical and functional levels: approval, authorization, checking, evaluation of operational performances, securitization of assets, separation of functions;

– managerial liability involves the responsibility for good financial management and performance at all the levels of a public entity, respectively for all the five internal control components. This means that the managers of public entities are obliged to report on the actions taken and decisions made to fulfil the objectives of the entity they manage;

– the line management in public entities establishes for each group of activities the adequate forms of internal control for the elimination or prevention of risks;

– the internal control system of public entities has to be permanently updated to allow the management to hold permanent control over the functioning of the entity in its assembly, in the attainment of objectives set;

– the internal control within public entities is based on the forms of internal control intrinsically attached to the activities of the public entity, which does not exclude specialized control staff, if the manager considers it necessary, control which implies the involvement of the staff from the entity in the activities carried out;

– irrespective of the way in which it is conceived and operates, internal control can offer only a reasonable assurance, and not an absolute one, that the objectives of the public entity are fulfilled, because of internal and external factors, which were not and could not be taken into consideration in the design (conception) of internal control, such as: human errors, negligence, carelessness, wrong interpretations, reasoning errors, etc; the abuse of authority manifested by certain persons with

management, coordination or supervision assignments; limitation of independence in the exercise of job assignments; frequent changes occurred in the internal and external environment of the entity; inadequate control procedures; unadjusted or adjusted and inapplied control procedures; the costs of internal control etc;

– the management of public entity is responsible for the implementation of a managerial internal control system which offers him a reasonable assurance that the objectives of the public entity will be fulfilled;

– when the management of the public entity does not hold a good control over the activities, there is the significant risk that the objectives of the public entity are not fulfilled, and the existence or continuity of the public entity is even threatened;

– the management of the public entity has to establish the most adequate activities and forms of internal control, which allow it to keep under control the risks and to limit their consequences.

Abstract

Taxpayers have different perception and attitudes towards taxation and react differently to fiscal stimuli: tax law and its loopholes, tax burden, tax representatives, fiscal policy decisions. On the other hand, tax administration acts, taxpayers react, but their goals seem divergent. Tax administrations around the world state their main objective, as it is increasing tax compliance. Tax compliance being related to economic factors is also related to socio-psychological factors as the literature in this field of research shows. Behavioral economics creates the bridge between economics and psychology and tries to understand what influences decision-making.

This paper aims to analyze, from qualitative perspective, the perceptions and attitudes related to tax payers. We also propose a condensation of the results of the interaction between taxpayers and tax, as well as their measurement possibilities.

Keywords: tax compliance, behavioural economics, research methodologies

J.E.L. Classifications: H20, Z13

1. Introduction

What is tax compliance and why do we need research in this field?

If taxes are very old, so is tax compliance defined as paying taxes, voluntary or enforced. Mostly, tax compliance is put aside with tax evasion, even if non-compliance is not necessarily intentional. If we need taxes,

we obviously need tax compliance and tax compliance research. But what makes taxpayers pay what they owe? Is it mathematical calculations of costs, do ordinary people calculate before making decision, are people rational or are they emotional at first? Tax compliance research literature provides a large number of studies that focus on the non-economic determinants of tax compliance.

In this review we describe the major theoretical aspects of tax compliance in a behavioral economics approach as well as the methodological concerns. The literature although not very old is very vast and there is a growing tendency to study tax compliance from a socio-psychological point of view.

The paper continues with the literature review in section 2, describing how tax compliance research started as well as the main paradigms in the field. We then focus on the determinants of tax compliance, especially on those incorporating psychological aspects. In section 3, we attempted to summarize the methodologies used in research stressing their limitations as well.

2. Literature review

2.1. Tax compliance research start and paradigms

Tax compliance research started on the base of the early work of Schmolders [1] in economics, behavioural economics and economic psychology.

Most of the publications in the field of tax compliance mention its start in the spirit of

economics-of-crime paradigm based on the general framework of criminal behaviour developed by Becker [2]; according to this paradigm taxpayers are motivated to comply only because of enforcement – audit and penalty rates as Alm [3] suggests. The decision made by a single taxpayer, seen as rational, is the choice of honestly paying all taxes or to evade them taking the risk of being caught, so it is about a higher utility – if the benefit of evading covers the cost of being caught, then the taxpayer will evade taxes. Consistent with this paradigm, Allingham and Sandmo [4] and Srinivasan [5] developed one of the earliest utility models being interested to study how higher tax rates influence compliance.

According to Alm et al. [6], the research paradigm in the field of tax compliance needs a rethinking. Both economists and psychologists challenged this paradigm whose need of rethinking comes from the following motives: there is more than one single taxpayer – there are other taxpayers too, who form groups and approve particular social norms, there are also tax accountants, tax authorities and the government. But these actors interact in different climates as Kirchler [7] introduces the concept of the climate of trust or distrust between taxpayers and tax authorities. The way these actors interact bring to discussion the important concept of trust and the concept of power and as Alm et al. [6] state, the dynamics of these two.

So this is why the paradigms need rethinking. The authors previously cited introduce three new paradigms:

i) The paradigm of tax compliance behaviour as a social contribution dilemma – where the social contribution dilemma appears when individual’s interests are opposed to those of the community. In short, it is about the decision whether to pay taxes or not when taxpayers think taxes are spent inefficiently and that other taxpayers don’t pay taxes. Trust is here of a great importance, both the form of interpersonal and institutional trust.

ii) The paradigm of tax compliance behaviour as behaviour of many different taxpayers – this model takes into account that taxpayers are not the same and different things, either financial or non-financial, motivate them. Consistent with this

interpretation, Braithwaite [8] identifies five types of motivational situations: two are positive – ‘commitment’ and ‘capitulation’ and three are negative – ‘resistance’, ‘disengagement’ and ‘game playing’.

iii) The pattern of tax compliance behaviour as a psychological contract (between taxpayers, government and tax authorities) focuses on the idea of social norm. As long as tax compliance is approved as a social norm, people will comply, but when tax evasion is accepted in the group, tax compliance ends to be a social norm.

These paradigms do not exclude the economic framework, but go beyond it, trying to find the substance of tax compliance and introducing other disciplines, like psychology. As Alm [3] shows, the analysis of individual decision-making using other social sciences like psychology is the the approach of behavioral economics. (The psychological view of tax behaviour can also be found in the book of Alan Lewis [9] "The psychology of taxation" and in Erich Kirchler’s [7] book „The Economic Psychology of Tax Behaviour”).

Regarding the first paradigm and the motives it has to be changed, Alm [3] found a way to improve the model of standard expected utility (Allingham and Sandmo, [4]) connecting it with the model of moral identity utility developed by Arkelof and Kranton [10]. According to the last one, the moral identity utility is a function of difference between the behaviour assumed ideal (by individuals) and the actual behaviour. If the actual behaviour approaches the ideal one, the taxpayer may feel happy since doing what is right, but if the distance between the types of behaviour is considerable taxpayers may feel guilt or frustration. Combining these two models it has been emphasized a resulting total utility model, as a way of going beyond the economic framework towards a behavioral one.

2.2. Tax compliance determinants and research findings

Kirchler [7] has made a classification of tax compliance determinants including: fiscal policy determinants – tax rates, law complexity, and determinants related to the rational decision making which include audit

probability, fines, and income. In a socio-psychological frame, the author includes: tax knowledge, attitudes, norms, fairness perceptions, tax morale as a motivation to comply. Trust (or distrust), and its relationship with the power to control was included in the interaction climate between taxpayers and tax authorities depending on the tax authorities approach – `cops and robbers` or `service` and client` and taxpayers cooperation resulting from these approaches.

Focusing on the socio-psychological factors, tax knowledge is important in understanding the complex tax law. As Kirchler [7] concludes generally surveys prove a positive relationship between tax knowledge and favourable tax attitudes, but the complexity of tax law makes taxpayers feel incompetent as McKerchar [11] note. Many studies attempted to examine tax knowledge: Sakurai and Braithwaite [12]; tax knowledge and its relationship with perceptions and attitudes towards taxes: Eriksen and Fallan [13], Niemirowski et al. [14]. Boame [15] suggests that tax knowledge does not necessary increase compliance, but taxpayer can use the tax knowledge gained to evade taxes. The question here is about avoidance and evasion – what is legal and what is illegal.

Regarding attitudes, there is a role they play in determining tax behaviour even if according to Ajzen [16] behaviour is only partly predicted by attitudes. In defining attitudes, according to Kirchler [7] there should be discussed three dimensions of attitudes: a cognitive dimension – a thought, a belief (e.g. taxes are useful to provide public goods), an affective – an emotion, a feeling (e.g. feelings related to the money loss) dimension and a behavioral or conative one – intention and action (e.g. responses to different fiscal stimuli – complying, using loopholes, evading). The relevance of attitudes toward taxation was examined in empirical studies and most of these studies found a significant, although weak relationship between attitudes and behaviour: Vogel [17], Dornstein [18], Porcano [19], Wahlund [20], Chan, Troutman and O`Bryan [21], Niemirowschi et al. [14]. Even if it is not sure that positive attitudes determine compliant behaviour, it is important the remark of Lewis [9] that if tax attitudes

worsen, tax evasion will increase. The relationship between attitudes and behaviour either compliance or non-compliance is therefore a complex relationship.

As determinant of compliance trust in political leadership and administration was studied by: Pommerehne and Frey [22], Torgler [23], [24]. The conclusion is that trust will encourage voluntary compliance. Kirchler [7] in his "slippery-slope model" (the "slippery-slope" term was used to illustrate the dynamics in the interplay between trust and audit) includes the importance of trust in authorities, power of authorities and enforced compliance. The essence is that compliance results under the condition of strong power of authorities and the trust, mutual trust.

Seen as a motivation to comply, tax morale is seen as an internalised obligation to pay taxes - Braithwaite and Ahmed [25], Frey and Fred [26]. Orviska and Hudson [27] relate tax morale with civic duty. Civic duty implies well-being by acting responsibly in society. Defining tax morale (and tax ethics, and the difference between them) is rather difficult but studies found a positive relationship between tax morale and tax compliance – Torgler [28], Eichenberger and Frey [29] and a negative one between tax morale and the size of the shadow economy – Alm and Torgler [30].

Tax morale was also analysed in relationship with religiosity – Torgler [31] found that religiosity raises tax morale. Another study – Grasmick et al. [32] found that `religiosity inhibits illegal behaviour`.

Finally, in an ethical hedonism perspective Lubian and Zarri [33] note that fiscal honesty brings us happiness. This is the point where economics meets philosophy and neuroeconomics as well as Harbaugh et al. [34] concluded after a neuroeconomic experiment that neural activity increases when tax assimilated voluntary transfers are made for a charitable cause.

3. Methodologies in tax compliance research and their limitations

In this paper we pay special attention in order to highlight tax compliance true economic theory, experimental design and survey results, as has been shown in the recent literature, but it is important to

consider this in strong correlations with cultural differences (Alm and Torgler [30]), quality of local governance (Fjeldstad [35]), level of education (Berhane [36]) or, even demographic characteristics (Asante and Baba [37])

Andreoni et al. [38] had identified four sources of information used to measure and study tax evasion: *audit data* that is data from tax returns examined by tax examiners, *survey data*, *tax amnesty data*, and *laboratory experiments data*. The problem of audit data is that it does not contain socioeconomic and demographic characteristics. Here it comes the advantage of survey data that can include socioeconomic, demographic and attitudinal variables. Most of the studies in the field use World Values Survey data. The problem with survey data is that being based on self-reports, the information can be inaccurate and in general as Andreoni et al. [38] points, survey result overstates compliance. Some determinants, for example perceptions and attitudes are not easy to measure. Most of surveys use Likert-type scales to measure taxpayer's degree of favouring tax evasion as Kirchler [7] notes. Despite of this, in a psychological spirit, Ariely [39] argues that "anything you measure will impel a person to optimize his score on that metric". This could be a confirmation that measurement can be a motivation towards change. Matching survey data with tax return and audit data is more useful (due to completing with social and attitudinal variables) as well as when incorporating in econometric models.

Tax amnesty data can be valuable due to the direct measurement of non-compliance, but its problem is the sample selection; a subset of evaders may not represent all the population. Another problems of tax amnesties data: first, according to Das-Gupta and Mookherjee [40] repeated tax amnesties reduced compliance (in the case of India). Secondly, Fisher et al. [41] found that tax amnesty did not bring many evaders out from the informal sector.

Finally, laboratory experiments data imply the study of tax compliance in a controlled environment. Taxpayers are given money, declare, pay taxes or penalties, experience audits or receive rewards. The problem of these data is that it can be considered unrealistic, as moral, emotional

and social factors can not be replicated in a laboratory.

According to Marriott et al. [42] the experimental methodology demonstrates the potential value in collecting behavioural data but has its limitations: data is collected in an artificial environment that has limited third-party impact, unlike in the reality, even if there is a reward, there is no adverse financial impact and finally there is another limitation from using students as a proxy for the taxpayers as a whole. Attention should be paid at the data preconditions and the sensitive questions in online surveys as well as Coutts and Jann [43] note.

4. Conclusions

Tax compliance research results show the importance of non-economic determinants of compliance, in other words entering the field of behavioral economics and experimental economics. When considering psychology, sociology, economics the process of measurement becomes difficult, there are some limitation for the various forms of data source and the way they are analysed. Our start in tax compliance research was by overviewing the major publications, the sift in research paradigms and making an idea about the methodologies.

The Fair Value – between Theoretical Predictability and Practical Modeling within the Romanian Accounting Area. Case Study for the Societies within the Transportation Field in Romania

Manea Marinela – Daniela
“Valahia” University of Târgoviște
m_manea7@yahoo.com

Abstract

The paper sets out to explore the approach of the fair value within the set of financial situations published annually by entities from the point of view of the external analyst, who is interested rather in the practical modeling of this aggregate than in the theoretical process of measuring. After going through the existing specialized literature we tested the way of measuring the fair value by the Romanian groups of societies within the transportation field. We focused our action on modeling at the entity level the net fair value, exponent of the recoverable value of the held fixed assets. We took this course of action because all entities measure, at the end of the report period, the inventory value—standard for the recoverable value within the Romanian accounting practice.

Key words: fair value, market value, updated value, road transportation.

J.E.L. classification: M41

1. Introduction

Internationally, two sets of accounting rules have the supremacy nowadays: the international ones, developed by ISAB, and the American ones, developed by FASB. IASB has accepted, in its own way, FASB's rules' influence by participating at joint projects with FASB, whose purpose is to limit the differences between IFRS and US GAAP. It must be noted that fair value's measurement is one of the convergent issues between the two sets of rules, IASB having already published international rules of financial reporting, IFRS 1 to IFRS 13. From these, the American rules' influence is

obvious within IFRS 5 “*Nonconcurring assets held for sale and discontinuous operations*”, respectively IFRS 3 “*Entities combinations*”. If initially IASB was equidistant from the prescribed evaluation bases, in recent years, it was requested a stronger reliance on fair value and, therefore, its extensive employment. International accounting rules are becoming more and more future-oriented, seeking to favor information users' predictions. Thus IASB once indicated that the fair presentation of the results and of an entity's financial position is more important than applying a set of rules.

2. Applications of fair value in the discovery of financial statements elements

Representations of the fair value for the recognition of patrimonial items, respectively for later notice can be at least the following [1] applications:

- ✓ coverage of intangible fixed assets with a potential buyer, starting with the second year of holding in entity, at fair value;
- ✓ recognition of tangible /intangible immobilisation depreciated either at the utilisation value or at the net selling price;
- ✓ for the tangible/intangible immobilization made as a contribution to the social capital, reflection in accounting is realized at their market value;
- ✓ immobilized tangible/intangible assets from exchange transactions are evaluated at the market value, respectively based on the best estimates, where market information is insufficient;
- ✓ immobilized tangible/intangible assets from entity combinations are recognized in the patrimony at market value;

- ✓ measurement and reflection in accounting of the residual value of tangible/intangible immobilization is realized at market value;
- ✓ tangible assets' recognition, such as special equipment, rarely traded on active markets at replacement cost – representation of fair value in accounting;
- ✓ both initial and subsequent recognition of tangible immobilization held for sale at the lowest value from book value and the fair value diminished with the sales' cost;
- ✓ subsequent recognition of property investments, in agreement with the IAS 40 conditions “*Property investments*” at market value;
- ✓ initial registration of the goods acquired through leasing at the lowest value from the good's market value and the updated minimal leasing value;
- ✓ initial recognition of long-term debts at their updated, market value;
- ✓ the subsequent recognition (at the end of the financial exercise) of the goods stock, products, merchandise etc. is performed at the net realizable value (market value), precisely for identifying any value losses/reappreciation;
- ✓ at the initial recognition (at the harvest time) of the agricultural production stocks, related to the biological assets, their market value it is used;
- ✓ initial recognition of commercial debts related to the current activity's income, in accordance with the IAS 18 conditions “*Income*” is obtained at the fair value – updated of the sums which are to be received;
- ✓ at the financial exercise's end, subsequent recognition of debts and commercial obligations denominated in foreign currencies is achieved at their updated value;
- ✓ the debts related to the employee's benefits are initially recognized at the corresponding value of the provided service, respectively at an updated value if the contributions are payable within one year after the accounting period when they have been rendered;
- ✓ at the initial recognition, long term liabilities are evaluated at their settlement value (reimbursement value) or at the updated value;
- ✓ subsequent recognition, at the financial year-end of cash denominated in foreign currencies is achieved at the value obtained from the sums in foreign currency.

3. Approaches of the fair value according to the specialized literature

For the time being, the term fair value is spread in the sphere of International Financial Reporting Standards through the IFRS 13 “Assessment on fair value”. In order to improve [2] the consistency and comparability of assessments on fair value, IFRS 13 establishes a hierarchy of the fair value through which the entry data that are to be modeled in the techniques of assessment are classified on three levels, as it follows:

- ✓ the level 1 entry data are, usually, *quoted prices (unadjusted)* from the market for identical assets available to the entity on assessment date [3];
- ✓ the level 2 entry data are pieces of information taken from the market, directly or indirectly observable for the analyzed asset, different from the quoted prices included in level 1 [4];
- ✓ the level 3 entry data are unobservable on the market for the asset [5].

Note that both the level 2 entry data and the level 3 entry data require modeling and adjustments. Adjusting the level 2 entry data varies according to the particular factors of the analyzed asset regarding the fair value's modeling, such as [6]:

- ✓ the condition and the location of the asset;
- ✓ the volume and the activity level on the markets where the entries are observed;
- ✓ the degree to which the entry data are afferent to the elements with which the analyzed asset is compared.

To the degree to which no observable entry data are available (level 2 entry data), the entity must develop unobservable entry data based upon the best pieces of information available under the given circumstances. In developing the unobservable data [7], an entity can start from its own data, but it must adjust the given data if the market information available in a reasonable way would indicate the fact that other participants on the market would use different data, or if there is an element specific to the entity which is not available for other participants on the market (for example, a synergy specific to the entity). It is not necessary that an entity undertake excessive efforts for obtaining information regarding the hypotheses of the market participants. However, an entity must take

into account all the information regarding the hypotheses of the market participants, available in a reasonable way. The unobservable entry data created in the above described manner are considered hypotheses of the market participants and meet the objective of the assessment on fair value.

When the entity uses level 2 entry data it is necessary to make a detailed presentation of the information connected to the employed assessment technique. If there is a modification [8] of the assessment technique (for example, changing the approach based upon the market with one based upon revenue or using an additional assessment technique), the entity must show that modification and the reason for which it was made.

For the assessments on fair value classified on level 3 on the fair value's hierarchy, an entity must provide quantitative pieces of information regarding the significant unobservable entry data employed in the assessment on fair value. An entity must not create quantitative pieces of information in order to comply with the provision of providing information if the unobservable quantitative information are not developed by the entity when it assesses the fair value (for example, when an entity uses prices from a previous transaction without adjusting them, or information regarding establishing the prices from a third party). However, when it provides these pieces of information, an entity will not overlook the unobservable quantitative data with an important role in assessing on fair value and which are available to the entity in a reasonable manner.

In modeling the final version of IFRS 13 “Assessment on fair value” IASB used the source of the American normalizer [9], which, through FASB issued in 2004 an Exposure Project regarding the way of measuring the fair value. In the FASB project one can notice three levels of fair value, the upper one represented by the market transactions that can be observed for the same type of asset, the second one represents the market transactions that can be observed for similar assets, and the third one is constituted from using models with the same contributions on the market or with another base. When the fair value is used, the entity

must present what level was used, and if it is level three, what the model was.

4. The application of fair value in Romania

For Romania the fair value is still new [10]. It is difficult for the professional accountants to clarify it on a conceptual level – as it will be seen from the research performed in this material – but even more problematical is its practical application. Regarding this matter, there can be noticed an attitude of reticence justified in the academic and professional environment in connection with the possibility of introducing an accounting system including the fair value, or, why not, based on the fair value. What could be the excuse for this behavior?

Mainly, the system focused on the fair value as a management representative based on value, is directed towards maximizing the shareholders and creditors' fortune. Under the circumstances of the Romanian instable economical environment, where the bankruptcy phenomenon is manifesting strongly for too many entities, does the concern of protecting these shareholders and creditors even exist? Since he brought funds as well, will the minority shareholder be granted protection and will his economical interests be pursued? Is it possible, in the Romanian economy, to obtain an accounting support guaranteeing to the minority shareholder the profitability corresponding to the invested capital and the risks he has taken? Here are so many questions that must be answered by the Romanian economical environment.

Carrying on with the idea of the minority shareholder's protection, the Romanian accounting should find the best solution for evaluating the patrimonial items mirrored in the financial situations at the lowest cost from the historical cost and the fair value. At the time being, in Romania, at least on a conceptual level, a combination of the two systems has been adopted – historical cost and fair value, with an important significance for the former. Beyond the conditions of the accounting regulations, putting into practice the system based upon the fair value remains a necessity rather than an actual fact.

How did this situation come to be, actually? One possible explanation would be that, for the moment, too many hindrances

are restricting the applicability of the concept, such as:

- ✓ a profound study and theoretical reflection rather poor for the alternative methods of evaluation in accounting;
- ✓ the insufficient theoretical development of the fair value concept by not knowing in practice its successive modelling stages;
- ✓ the scarcity of information on the market, as a result of the imperfect economical conditions;
- ✓ the opacity and lack of vision of the professional accountants who are not willing to accept the change of a familiar, easy to work with evaluation system, with another, more complex one that requires alterations and estimations difficult to achieve;
- ✓ the Romanian present accounting system's reduced ability to apply evaluation at a fair value, which requires specialised professionals – usually, the fair value is the evaluators' attribute.

Concerning the last point, only a few entities can afford hiring a professional evaluator, respectively creating a specialized department because this implies a sustained financial effort. Using outer consultants is not an option for Romanian companies either, especially during this crisis period. This is why, in our opinion, if professional accountants would have the necessary expertise, they could successfully shape the fair value, at a minimum cost for the entity for which they are providing accounting services. Additionally, ensuring the estimation's objectivity can be guaranteed through the ethical standards provided by an accredited organism to which that specific professional accountant has adhered.

5. Testing the implementation of the fair value concept within the Romanian accounting practice

To test how the fair value concept is implemented into Romanian accounting practice we started from the consideration that shaping it has a great effect on the assets held by the entity and thus our research methodology has focused on applying the concept in this direction. We proceeded to realizing a research regarding the implementation of the fair value concept within the Romanian accounting practice: that is, the way in which entities acted in

reflecting in the published financial situations of the initial and subsequent value of the fixed assets according to the approach of fair value; initial recognition of trade receivables afferent to the income from the current activity, in accordance with the IAS 18 “Incomes” on fair value; subsequent recognition of the receivables and commercial debts expressed in foreign currency on updated value etc. A number of 211 groups of societies were selected within the transport field, as follows: 67 societies that work in road transport, 23 societies that work in railway transport, 27 societies from air transport, 43 societies that work in naval transport, 51 companies of merchandise transport and customs agencies. It sought to identify those entities that use in accounting practice the concept of fair value, taking into account the applicable law, the tax limitation that do not motivate the professional accountants to model two sets of financial statements – one according to the tax provisions and another taking into account the economic reality and which would result in a true accounting image.

From the set of annual financial situations published by the entities the external analyst focused his action of identifying the tools and levers through which the entities quantify the fair value of the held fixed assets. It was found that (outside the reassessment process, the responsibility of value measure, often belonging to professional assessors), the Romanian entities are not interested in quantifying the fair value of the held assets. Eloquent in this sense is also the process of recognizing the temporary value losses, since the Romanian entities have many difficulties to overcome in measuring the recoverable value. First of all, there is no data base for the modeling of the net fair value. Knowing that in measuring the fair value the entity's access on an *active market* is decisive, we tried to identify on entity levels if the held assets can be sold on an active market. If the asset can be sold on an active market, its fair value is the estimated price that could result from a normal transaction, between partners that acted knowingly, cautiously and without constraints, price that corresponds to the actual value of the flows the entity waits to obtain by selling it, except the disposal costs. When a market value cannot be measured (also as a consequence of the fact that the

given asset is rarely sold, or because of a lack of an active market), *the fair value is estimated*, based upon the best available information in order to reflect the sum that the entity could gain from selling the asset. It is the case of those productive tangible assets such as machines and equipment more difficult to sell on active markets, where it is necessary *to perform analogies with recent transactions* of the entities regarding similar assets, compliance with reasoning that will take into account variables like production capacity, working state, age, etc. Maybe this is why, in estimating the fair value minus the disposal costs the entity will comply with certain **recognition criteria** given both by the conditions encountered on the market and by the specialized character of the respective assets.

Covering the above, the external analyst has the difficult task of extracting from the set of published annual financial situations all the elements that could lead us to the conclusion that within the Romanian space the fair value assessment is applicable or not. From the analysis performed on the 211 groups of societies within the transport domain we obtained the following information:

- ✓ more than 80% of the studied entities did not even set out to treat the issue of value depreciation according to IFRS, most of the professional accountants do not know the techniques and instruments specific to modeling certain elements like the net fair value, cash flows, discount rates, etc;
- ✓ in the places where a dissemination of the knowledge was realized regarding the quantification of some values like: unadjusted quoted prices; information taken from the market directly or indirectly observable for the analyzed asset, different from the quoted prices destined for estimation the fair value; the Romanian professional accountants resorted, in more than 75% of the cases, to the contribution of the specialist assessors, which led to a much too simple solution, from the point of view of accountants and much too difficult to accept by the management who must cope with additional financial tasks for paying some obligations with services provided by the assessors. Especially under the conditions of the financial crisis, the Romanian entities cannot afford to allocate important financial

resources for modeling some aggregates which could very well become the mission of the professional accountants within the entity;

- ✓ therefore, it is utterly necessary to rethink the tasks and responsibilities that fall on the shoulders of the professional accountants, so that in the near future the above mentioned concepts and aggregates can be easy to quantify in the entity by the accountants without resorting the assessors;

- ✓ coming back to our study, in the accounting practice of the Romanian entities, an overwhelming percentage – more than 80% from the analyzed societies did not transparently reflect in the published annual set of financial situations the way in which they measured the aggregates specific to the creative accounting such as the before mentioned cash flows, the discount rate, the use value of the held fixed assets, etc. We cannot even discuss about the steps or stages that precede the modeling of such values, and therefore we find ourselves in the impossibility of outlining conclusions and of resizing the sample of analyzed societies;

- ✓ out of the 211 groups of societies within the transport field, as a consequence of the data precariousness identified within the set of annually published financial situations, in the end a number of 37 societies were retained: 10 societies that work in road transport, 7 societies from railway transport, 8 societies from air transport, 6 societies from the naval transport and 6 companies of merchandise transport and customs agencies;

- ✓ out of the group of 37 analyzed societies only 8 (Bat Mediaș S.A., Roman S.A., SMR S.A. Baș, Aerostar S.A., S.C. Construcții Aeronautice S.A., Hercules S.A. Brăila, Baza Ateliere și Transport S.A. Arad, Farex S.A. Brăila) consequently applied the working instruments and techniques specific to the creative accounting in modeling the fair value through the means of professional accountants within the entity;

- ✓ for other 10 groups of societies out of the 37 analyzed, the help of specialist assessors was required – it is the case of Atlas S.A. Galați, Comautotransport S.A., Dacia Mioveni, Electroputere S.A., Construcții Feroviare Craiova S.A., CNFR Navrom S.A., Giurgiu Nav S.A., Romportmet S.A., Șantierul Naval Orșova S.A., Severnav S.A.;

✓ in the other 19 cases the reduced capacity of the current Romanian accounting system of implementing the creative accounting, the precariousness of market information, the opacity and lack of vision of the professional accountants led to the failure of implementing the IFRS provisions within the practice of the Romanian entities.

However, it cannot be considered that the Romanian societies do not apply the IFRS provision consequence of the precariousness of implementing the fair value in accordance with IFRS 13 “Assessment on fair value”. From modeling the inventory value at the end of reporting period, the external analyst can claim that the Romanian societies have adopted their own practices in modeling the net fair value. For the future the option of adherence of the Romanian practitioners to the instruments and techniques specific to IFRS remains open.

6. Conclusions

Without a shadow of a doubt our action of identifying the way of implementing the IFRS provisions in the Romanian area can be subject to criticism and will run into a series of impediments, like:

- ✓ the strong connection of accounting to fiscality which limits the interest of the Romanian professional accountants to transpose the information from the financial situations by implementing two treatments, an accounting one and a fiscal one;
- ✓ although the financial situations should represent the projection in the communication scheme of concepts, regulations and specific accounting practice of the entities, in the Romanian space, these are not yet sufficiently formalized, with influences on the precariousness of information provided to the users, either internal or external (here we refer to the insufficiency of information regarding the discount rate of the cash flows from the future use of the assets held by the entities, impossible to identify from the composition of the financial situations annually published by the Romanian entities);
- ✓ precarious deep study and theoretical reflection of the alternative methods of assessment in accounting;
- ✓ precariousness of market information;

- ✓ opacity and lack of vision of the Romanian accountants;
- ✓ reduced capacity of the current Romanian accounting system of implementing the creative accounting, since the dialog state between the accounting norms and the accounting policies is still unidentified, between the freedom to choose accounting procedures and the obligation to provide the users relevant and credible information.

However, this action, in fact not very difficult to go through for the external analyst, does not have the objective of being more or less just – it is certainly subjected to limits – but to constitute an “alarm signal” for the management of those entities that, out of the desire for transparency and loyalty of information, will run into the challenge of implementing the creative accounting with all its difficulties that stem from here.

Abstract

Education is one of the main resources of a country. Germany is one of the countries that have put a strong emphasis on developing and improving the quality of education, and this was important in the development of its economy over time. In Germany, education is mainly the responsibility of the States (Lands) in the Federal Republic (sixteen lands). Each of them has their own laws, so that each University is different. Although the university education system in this country is characterized by a strongly decentralized system, at the same time it is one of the most competitive systems worldwide.

Key words: analyses, public finances, perspective, quality

J.E.L. classification: H52, H75, I21, I23

1. Introduction

The education system in Germany has undergone numerous changes, perhaps the most important being the 1990 unification of the Federal Republic of Germany in the 16 federal States, 11 in the West and 5 in the East. The Unification resulted in the proliferation of West German Law as applicable to all, and resulted in a massive restructuring of the education system in the East. Education system in Germany has faced new challenges due to the different philosophies such as equality of education for both sexes and especially to adapt the

traditional system to the new requirements of globalization and technological development. The next major challenge for the education system in Germany was the introduction of the Bologna system. Although Germany was not one of the bigger sympathizers of the Bologna system, due to the desire of integration and globalization, bachelors and masters system was adopted in 2001. The German system of higher education is considered powerful but at the same time differentiated depending on the following factors [1]: European standards implemented by the adoption of the Bologna system of education; differences, depending on the area in which the University is situated and differences resulting from decisions taken by the Government of each land.

The education system in Germany is particularly characterized by the fact that it makes a distinction between students according to their competence. Thus, since kindergarten, children are followed closely up to admission to College. The education system in Germany is complex and the most important step is the secondary school, where students can choose their career in the future more easily. If you judge strictly after the organization of the education system [2], we can say that this system is beneficial to society. Thus, the best of the students will follow the courses of the university, the best of them will follow the doctoral studies, and students who have specific vocational, artistic talents can orient themselves in time for a career in art. Although controversial because of the differences created between students, this system proved effective so far

and has given rise to the fame and prestige of the educational system in Germany. Graduates can orient in time to technical and vocational schools, due to their skills and further supported and driven by teachers.

2. The higher education system in Germany – a historical perspective

The demand for higher education simply exploded in the 1950, due to the growth of birth rates in the 1930s. This demand leads to increasing numbers of institutions of higher education throughout Germany. Then, the creation of the Council for science in 1957 promoted expansion of the German higher education system. By the early 1960s a trend of integration by the engineering and technical schools into Universities of applied science was noted. Thus, between 1970 and 1990, the number of students has doubled, and between 1980 and 2010 their number increased from 2.12 million to 1.36 million only in West Germany [3]. Overall if in the 1960, 10% of children went to College at the beginning of the 21st century, this percentage increased to 30%.

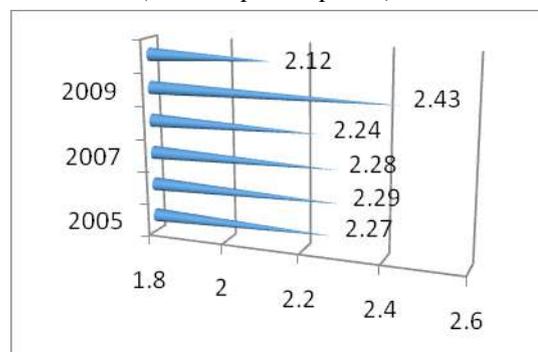

After the adoption of the Bologna system the number of foreign students in Germany has also increased. Although the representatives of universities and students in Germany have criticized this system because of the reduction of the number of semesters, it was decided to promote the idea of unification in the EU. The scope of Bologna system itself has been to reduce the duration of the school, greater flexibility for students, encourage mobility and facilitate intercultural experiences. After the adoption of the Bologna system, Germany has adopted a comprehensive policy to promote the internationalization, to and from the country. Germany is now among the countries with the strongest mobility of students. After the number of applicants each year, the foreign students in Germany are in third place in the preferences of the students after the USA and the United Kingdom. In 2011, 240,000 international students were enrolled in German institutions of higher education. Although the cost of living is quite high, many of the students from Eastern Europe choose Germany due to the prestige of universities. The admission process is long and very strict, so that many of the students

are forced to choose other destinations, although the universities do not enjoy the same rating.

Universities are State controlled and they are financed by the Ministries of Education due to the Federal structure of Germany. Relations between the Ministries of the Federal States and universities are governed by various acts of Superior Education and are coordinated by the HRG (general act on education) available in all States. Moreover, there are a series of private universities, which offer a wide range of disciplines and colleges of Theology and religious sciences.

Currently there are 409 higher education institutions. Of these, more than 100 are private institutions that offer recognized diplomas, but have few students due to higher tuition fees than in state universities. Chart 1 reflects the number of students enrolled in higher education in Germany, both public and private. Demand for higher education has seen an upward trend in all of Western Europe, from 13.6% in 2000 to 16.8% in 2009. This trend was maintained also in the case of Germany.

Chart 1 Evolution of the numbers of students enrolled in German universities 2005-2010 (million participants)

Source: authors' processing based on the data supplied by Eurostat, DAAD

We observe an almost constant evolution for the number of students in every year. Exception is the year 2010 when their number dropped by 300,000. Most of the drop is due to the low number of students registered in private universities. The peak in the number of students registered in the University system in Germany was reached in 2009, when their number was more than 7% higher than the number of those enrolled in universities in 2005. These oscillating developments can be attributed to several factors, among which we can mention the

birth rate, the phenomenon of migration or the economic conditions.

In 2010, Germany was the first place in terms of the accessibility of higher education. The raised standard of living and the relatively small fees compared to the prestige of universities make Germany one of the most accessible countries for university education. All costs for a student relative to the average level of income is 28.38% of GDP per capita. In comparison, in the U.S. these expenses represent 87.49% of the total.

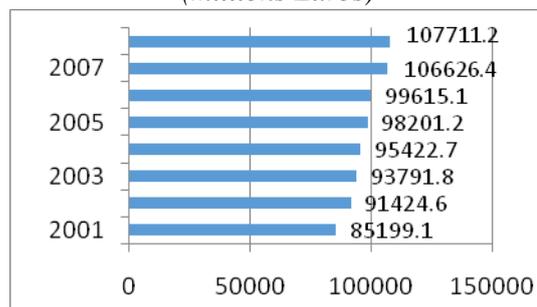

The prestige of the University is also given by the large number of Nobel Laureates who have been trained in German universities, between them even Albert Einstein and also by the 140 institutions which have the right to grant doctoral titles. They offer the best conditions for young doctoral students. At this time, in Germany there are more than 80,000 PhD students. Around 25,000 doctoral studies are completed each year, the biggest number in Europe. Most of the titles of doctor are in engineering and technology [4]. Financing possibilities are quite limited, however, the students can choose between work at the College, a part-time job or scholarship. These scholarships are limited in number, being granted for a period of two or three years, the beneficiaries being required to reapply every year [5]. Until the implementation of the Bologna system, we can say that doctoral studies lacked a very high importance in Germany. Typically, those who chose to continue their studies through the doctorate were employed as assistant professor.

To settle the financial problems of the PhD students, in 2006, the Ministry of education and research of Germany has adopted the "Initiative for Excellence" with the aim of promoting higher education and research in the universities, through German Research Center. It provides annual funding of one million Euros for young researchers and doctoral students from 40 universities that have research programs. Moreover, this initiative creates so-called clusters of excellence [6] connecting Universities with German research institutions (6.5 million Euros per year). Another objective is the choice of nine Universities of excellence every year that will receive funds for future projects. From this point of view we can say that the young doctoral students and

researchers in Germany have access to the best education and research programs, such as a value comparable with programs offered by Universities in the US and United Kingdom.

Germany is not one of the countries that provide impressive amounts for education as a percentage of gross domestic product. From this point of view, it hardly ranked 26th among OECD member countries, Norway first country in this top allocates 9 percent of the GDP, followed by Denmark with 7.7%. As a comparison, the US spends almost as much as the all European Union. However, Germany is ranked No. 18 in the rankings of the most educated countries (24 per cent of the population between 25 and 64 having completed higher education). The first in this top is Canada with 44%, followed by the US with 38.4% of the population having graduated from higher education. Sweden, Finland, Denmark, and Norway are also in top 10 [7].

Chart 2 Changes in total expenditure for education in Germany between 2001-2008 (millions Euros)

Source: authors' processing based on the data supplied by Eurostat

As one can see, the trend of total expenditure allocated to education in Germany is rising from one year to another. For the period under review, in 2008, an increase of more than 26% of these expenses compared to the year 2001 was recorded. This is a positive development as long as growth is maintained in the future years and does not let them influenced by the development of national and world economy.

Germany has been sharply criticized for the fact that these expenditures, as a percentage of GDP, are very low in comparison with other OECD countries, although in comparison with other EU countries, the amounts are large. An OECD report showed that between 2000 and 2005 the average of these expenses in Germany

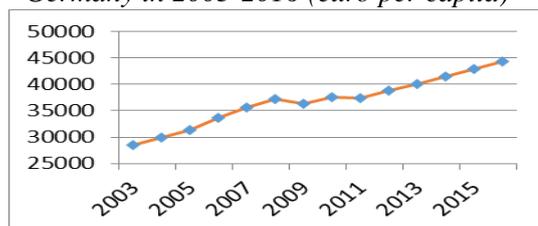

was less than 10% of GDP, while the OECD average was 13.2% [8]. The same study indicates that Germany is threatening to produce more higher education graduates than the market can absorb, especially in science and engineering. As a percentage of GDP, expenditure on education in Germany has not undergone significant changes, regardless of the economic situation from 2001 to 2008, being situated around 4-4.7%. Germany is one of the promoters of the "Europe 2020" project. Thus, sustaining increased expenditure on education, research and development in each member country of the Union, it is most likely that Germany will continue to support the increasing amounts of money necessary to finance higher education.

3. The present and future of the higher education system in Germany

Education is an important part of public spending in all Member States of the European Union. The budgetary allocation increases as an individual move from one level of education to another. Thus, the budgetary allocation for students is higher, although, overall, the bulk of public spending is targeted at secondary education system. This development strategy "Europe 2020" has led to discussions on the budget allocation per student to increase in each Member State in order to promote fairness and equal opportunities within universities in the Member States and to increase the efficiency and competitiveness of higher education institutions. This becomes more difficult to achieve in the current conditions of the euro area and uncertainty of the international economic crisis. In addition to the international economic context, the possibility of increasing the sources of funding for education depends on several factors, such as: the evolution of births, the evolution in the number of students, the level of GDP/capita, etc.

In order to be able to outline an idea as to how the budgetary allocation will be affected as a consequence of the development of GDP/inhabitant we will use the forecasts supplied by International Monetary Fund (IMF) with regard to this indicator. Based on these data, we propose to identify the way in which the budgetary allocation will evolve in the coming years.

Chart 3 growth Rate of GDP/capita in Germany in 2003-2016 (euro per capita)

Source: authors' processing based on the data supplied by the IMF

We can observe a gradual upward trend in GDP/capita. By 2016, it is projected to register an increase of 40% by comparison with the 2003 level. Starting from the premise that the University educational system depends directly on the economic developments of the country we can envisage how the budgetary allocation are expected to evolve as a percentage of GDP/capita. Starting from historical values registered during the period under review for both GDP per capita and the amount of the budget allocation we can calculate the coefficient of correlation between the two variables obtaining a value exceeding 0,92. This value indicates the strong intensity of the relationship, which will make the funds allocated by the central authorities for the funding of the University system to record the same growth trend. This strong connection can also influence the University system negatively, when the economy is going through a period of turmoil, like the one in 2009, when gross domestic product decline was defaced in the amount of funds allocated to the higher education system.

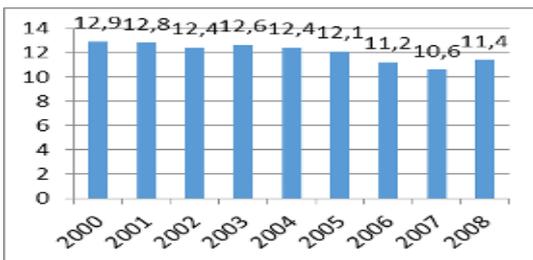

Superior education in Germany has gone through a radical change from providing higher education services selectively to only certain people, to a system of mass education rather, facilitated by the introduction of tuition fees. This change was due to the society, economic development, the increase in purchasing power, technological development, globalization, resulting in a greater appetite of young people to education. In addition, the current trends of orientation towards the knowledge-based society and innovation lead to higher demand for specialized labor force. Germany is one of the supporters of this process for the development of Europe. It is known that the economic well-being of a nation and the degree of competitiveness is determined by

the quality of education and its inhabitants. As Germany does not have outstanding natural resources, exploiting the human resources is essential for its development.

Discussion on the introduction of tuition fees in Germany was long and finally, on January 26th 2005, the Federal Constitutional Court of Germany has agreed that 7 of the 16 Lands of Germany should have the right to introduce such fees in the Universities and in the Universities of applied science. State universities that apply to tuition fees are those in the Lands of Baden-Wurttemberg, Bavaria, Hamburg, Hesse, Lower Saxony, Westphalia, Saarland [9]. Even though tuition fees charged are modest in comparison with those recorded at the international level, 500 euros per semester, internal mobility recorded a significant growth, students focusing on universities that don't request study fees.

As we said, in recent years Germany has experienced an increase in the number of unemployed persons with higher education, particularly in science and technology. Their number has increased with the onset of the crisis. There is an average number of unemployed persons with higher education somewhere between 11 and 12 percent, a fairly large percentage for a country with the level of development of Germany.

Chart 4. The evolution of unemployment with tertiary education as percent of unemployment in Germany, 2000-2008 (%)

Source: authors' processing based on the data supplied by Trading Economics

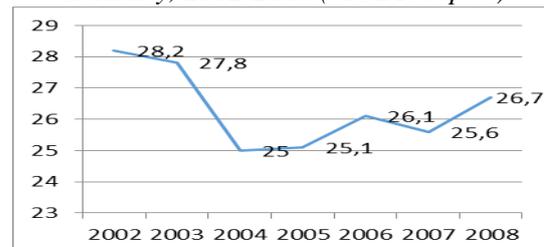

The highest level of unemployed persons with higher education was recorded in 2000, with the value of 12.9%. This trend has been declining, with a historical minimum for the analyzed period by 10.6% in 2007, but this trend was not maintained, reverting to a value of over 11% in 2008.

It is curious that, even under these conditions, the labor market of Germany is open and very attractive to graduates of higher education from other countries. A

solution for solving the problem of the lack of jobs for graduates is the creation of new research and development centers. Germany is one of promoters in projects of innovation, research, development and deployment of new technologies. Even if it implies many funds, investing in human capital is beneficial for increasing the competitiveness and future development of all sectors of the economy.

Another solution could be a better preparation of the students in the school. Although Germany has a very powerful teaching program which allows practical knowledge assimilation, the number of unemployed persons with higher education proves a lack of correlation between the labor market and the academic environment. At this point, the allocation of the budget for a student is quite small for a country with world-class universities. Most of the European States decided to decrease the amounts earmarked for education to students in State Universities. United Kingdom decided to reduce their budgets by 40%, increasing the fees for those students who have not "caught" a budgeted place. In contrast, France has decided to supplement these funds with 19 billion Euros in 2010, as well as Germany, which adopted a system of gradual growth of such loans by 2013.

Chart 5. Budget allocation per student in Germany, 2002-2008 (%GDP/capita)

Source: authors' processing based on the data supplied by World Bank

We notice a decrease in the budget allocation for the student during the period 2002-2005. The average expenditure per student was \$ 12336 [10] in 2006, the majority of the funds coming from public funds (73%). The budgetary allowance has increased, however, since 2006 and will increase gradually until 2013. Germany has been criticized for this level of budgetary allocation for students in terms of the level of GDP per capita, the highest in the EU. France, which has a lower standard of living

in recent years, has increased the budgetary allocation for students achieving on average 30% of the GDP/capita. In order to adapt the education system in Germany at a future in which more funds are requested by education and an increasing number of foreign students and residents applying for higher education the Pact 2020 has been created. In this sense, the project provides an increase in the number of foreign students; increasing funding for higher education institutions-increase in funds from the federal budgets by 20% in order to provide greater flexibility to the universities and to facilitate the creation of institutional strategies; and it's facilitating access to higher education by offering more scholarships and more favorable lending conditions;

Another purpose of the Pact is to ensure non-discrimination between women and men and equal opportunities to all graduates. In the future, the experts estimated an increase in the demand for labor force specialized in mathematics, computer science, natural sciences. Specialists provide estimates, thus a decrease in the number of 2020 wedge of unemployed persons with higher education.

4. Conclusions

Education in Germany is a complex one, targeted towards performance from preschool to higher education. It is obvious from the beginning that talent is recognized and appreciated, and the level of education and training of the population is one of the indicators for measuring the country's competitiveness. Financing the higher education system is primarily the duty of the State, the Provinces, so that the competition between universities has always been fierce, and Germany's progress in the field of research, development and innovation is justified. It has always recognized the importance of education, the creation of specialized workforce, proof being the presence of the German universities in the most important institutions of higher education in the world.

Although there are concerns about the future of higher education, it is unlikely that Germany would not identify the reforms needed to ensure its sustainability. Education has always been one of the main resources for economic growth and further

development. Higher education Pact adopted will provide the necessary funds for the modernization of the universities to provide the best conditions for study. The German economy is dependent on such qualified human resources, innovative capacity and to maintain competitive position. In this regard, the agreed reforms in 2011, in line with the strategy "Europe 2020", a percentage of 10% of GDP for education by 2015, of which 3% for research and development. The percentage for education is difficult to obtain without the impressive economic growth considering the fact that the average for the preceding year was between 4-4.5 percent. The percentage of 3% for research is viable; in 2009 this was 2.8% of GDP.

Germany has all the trumps required to create an efficient educational system. The correlation between tuition fees and the prestige of the institution is the correct one. The degree of absorption of the market after graduation and high standard of living are important arguments in Germany's ranking among the top countries with educational systems.

Foreign Direct Investments Under the Impact of Public Sector's Corruption in the European Union's Economies

Mardiros Daniela-Neonila
„Alexandru Ioan Cuza” University of Iași
Faculty of Economics and Business Administratio
mardirosdaniela@yahoo.com

Abstract

The present paper takes as its starting point a series of definitions associated with public sector corruption and the relationship between that and the state institutions. Later research continues with the presentation of some of the effects related to the previously phenomenon brought in question and some of the criteria used to define it. The final part of the paper is devoted to presenting Foreign Direct Investments (FDI) in several European Union economies (emerging and developed) and to the revealing of the relationship existing between these and the corruption in the economies brought into discussion.

Key words: emerging economies, FDI, corruption, relation.

J.E.L. Classification: D73, H10, H11,

1. Introduction

Any definition of corruption includes its political side expressed by the existence of an executive who, irrespective of the level it stands in terms of authority manifestation (central or local), acquires the attribute of being "for sale"[1]. This idea is circumscribed to the World Bank definition of corruption where the phenomenon is perceived as "public power exercised in exchange for a win", with the small and large valences of it but which may, ultimately, to the state capture by the private interests. In the public sector, corruption occurs as a result of the existence of state's weak institutions, both in terms of power and human infrastructure. Thus, when state institutions are weak, the rules can be

ambiguous, leaders are not accountable for their actions and bribery, nepotism and other unpleasant behaviors related to corruption are emerging[2]. The presence of such corruption manifestations involves a combination of public servants, public officials, individuals, companies or industries, so we can not exclude the influence of the private sector over the corruption existent in the public sector.

2. Corruption effects and the criteria used for its classification

Later defining corruption we put ourselves the question: Can we define and it is enough, or corruption matters and if so, why? The answer is affirmative and the explanation is the one that although the analyzed phenomenon apparently does not directly make victims, its implications are producing undesirable effects widely spreading such as: inhibition or reduction of growth and investment rate; growth of the infant mortality and reducing of the literacy - through incorrect direction of the public funds; damaging how the countries formulate their economic policies; the influence exerted over the governments in relation to the spending of public money, by redefining the structure and size of government spending, etc.[5]. In summary, public corruption hinders the economic development (by distorting markets and competition), spreading cynicism among citizens, undermines the rule of law and deteriorates the government legitimacy. Like any phenomenon, corruption have not only causes but also effects (encouraging cynicism and reducing the interest in political life participation; political instability; reducing competition between politicians and parties

regarding satisfaction with the priority of voters' interests by bringing to the fore the personal interests or groups interest; decreasing of the transparency of decision making process; supporting the political activity by actions based on patronage and money etc.[6]. Paradoxically, the corruption effects are not only negative but the phenomenon can have, in some ways, also a number of positive connotations[3]. Therefore, it can be envisaged, as a general matter, a number of possible effects or consequences of corruption with respect to the time horizon, the affected area, respectively, in terms of customer-initiator relationship. Although none of the corruption's effects size is not negligible, we will focus, below, over some economic-financial particular aspects of the phenomenon systematized in Table 1.

Table 1. Corruption effects with impact over the economic growth

Effects	Comments
Significant impact on economic growth on FDI chain	Businessmen are often warned that bribery is required before opening a business and corrupt officials or officials may claim, as to which, part of the obtained revenues. The private sector interpreted therefore corruption as a kind of tax particularly harmful in nature, given the need for secrecy and the uncertainty that the one who received bribes will fulfill the promises once made[6]. Therefore, under such financial (through the advanced amount) and mentally (induced by the uncertainty) stress, the investor reduces its intention to invest. However, public officials which are favoring certain companies over others, encourage the competition distortion on the investment plan and maintain on market unprofitable firms, the negative effect associated to the same state being the one of economic growth slide

Effects	Comments
	down[4]. Certainly that the corruption-investment relationship may evolve and vice versa in the sense that a high level of corruption may give rise to a number of opportunities for investors seeking speculative situations in their pursuit of profit. Thus, investors favored by the state institutions will see between the corruption level and their profit directly proportional relationship, while investors discouraged by the favoritism granted to others will perceive corruption as a negative phenomenon at their business address. Therefore, to be on par in terms of the opportunities to invest, the interested one will be rather concerned about the quality of state institutions inside these economies rather the corruption level.
Misdirected “talent”	Financial incentives could attract the most talented and well educated to engage themselves in seeking of supplementary incomes, rather than productive work, which negatively influences the growth rate of a country[5]. However, the frustration that arises from the fact that the most attractive workplaces are occupied, mostly by people who are not the best but enjoy substantial support, has the effect of intelligence migration.
Diminishing aid flows	Through funds diversion, aid received by the less economically advantageous economies can get to finance, ultimately, unproductive and unnecessary expenditure of the government[9]. As a result, many donor agencies

Effects	Comments
	of such funds focused on issues of good governance in the recipient economies and, in cases where it has proved of poor quality, withdrew their financial support.
Loss of tax revenue	Takes the form of tax evasion or under the form of inappropriate tax exemptions.
Adverse budgetary consequences	By lowering the tax collection level or rising the public expenses level. In the first case there is a mobilization to the budget of some amounts lower than those projected as being necessary to finance the public spending. As such, money are tight, public services and economic activities can not be adequately insured according to the initial planning, the "final beneficiary" of this situation being, in fact, the economy in its entirety. The second case can lead to a "chronic" of the deficit state or to achieve or, worse, to overcome the excessive budgetary deficit, fact which entails after it a series of economic and financial restrictions.
Poor quality for the public services infrastructure	In this direction, the corruption translates as: maintaining in public administration of incompetent people who can make a negative impact on the proper course of things either in ignorance or in bad faith; dysfunctional state institutions; the existence of a corrupt system for the allocation of the public procurement contracts; etc.
Possible distortion of the public sector	Corruption can tempt government officials to choose the structure of budgetary expenditures

Effects	Comments
spending structure	(defense, public order, national security, general public services, housing, environment and water and so on to the detriment of the social-cultural expenses, for example), less according to public welfare and more in relation to possible illicit gains associated with some of them (bribe). In this respect, are preferably large projects, whose value is difficult to monitor because they present opportunities for corruption exercising (it is more attractive and more advantageous to take as bribe considerable amounts associated with large infrastructure projects, of high-tech or for defense systems than bribe for small projects to which the monitoring of the public money spending is much easier – the one whose purpose is the development of publications, teacher training and so on).

Further on we will follow the evolution of Foreign Direct Investments under the impact of different levels of corruption, for 2007-2011 period of time.

3. Foreign Direct Investments under the impact of corruption

The starting point is identified by the Foreign Direct Investments identified with the net inflows of money made for holding at least 10% of the voting shares of a company which is conducting business in an economy, other than the one of the investor. Generally putting the problem, the level of the foreign direct investment (FDI), shown in Table 2, is much higher in developed countries in the European Union, compared with emerging economies inside the same area due to economic and political stability of those areas, and due to the existence of an

appropriate legal framework and of effective state institutions whose voice is heard clearly.

Develloped economies average (avg.)						21.7

Regarding the two factors (corruption and FDI), the dependency relationship between them, established in the literature with economic modeling is, in most of the cases, an opposite one but there are opinions according to that, the impact of corruption on Foreign Direct Investments can not be certainly surprised[7]. In other words, according to the first theory (which is corresponding to the link between the two approaches terms through the cost associated with an investment in a corrupt environment), the more corruption is higher, the more the value of foreign direct investment value size is reduced, the explanation of this fact being the one that for the investors, the investment cost in the economies governed of corruption are increasing by the value of the latter one (represented by bribery). As a result, the investor interest decrease and, in the same manner, evolve the Foreign Direct Investments flows in the countries with a high levels of corruption[10].

Another aspect of the relationship between corruption and Foreign Direct Investments is the approach of it in terms of state's institutions quality[8]. Thus, in the opinion of some authors (2), the more that institution are stronger, the more the Foreign Direct Investments level is higher. Related to the two theories looking the type of the bond existing between corruption and Foreign Direct Investments, for the analysis of the link between the two mentioned variables we present the data from Table 3.

Developed economies average (avg.)						6.91
"0" associated with this indicator shows a highly corrupted economy, and the value "10" indicates a highly pure economy in terms of corruption.						

Source: own processing using the data from source [12]

4. Conclusions

After analyzing the data from Tables 2 and 3 we can say that, in terms of value, for the economies of the European Union, between corruption and Foreign Direct Investments is difficult to detect a link which move in a certain sense, in all discussed cases. Supports this statement the following situation: for the example analyzed, the lowest average level of corruption is registering, for the developed economies

group, in the case of Denmark (9.3) but, nevertheless, the highest average level of Foreign Direct Investments is associated to Luxembourg whose level of corruption (8.3) is higher than that of Denmark. The emerging economies presents, that feature, a fluctuating behavior of Foreign Direct Investments in relation to corruption in the public sector. Thus, the lowest CPI score (denoting the highest level of corruption) is associated with Bulgaria and Romania (3.7).

Abstract

The introduction into the problems raised by the present paper is done by sizing the framework in which the corruption phenomenon makes its presence, in the state's public sector of the emerging economies. Related to the definition of the phenomenon itself, that is connected to the abuse of public power and its causes and effects are as numerous, as difficult to quantify. Therefore, we propose in this paper an analysis of some of the effects of corruption through the conduct of public officials (with focus on their granting of favors for different groups and interests), the diversion of public funds to companies or individuals and, not least, the revealing of the confidence manifested by public opinion looking the government efficiency in fighting corruption. The area of study was the European Union area with systematization in emerging and, respectively, developed economies.

Key words: economy, effects, public funds, corruption.

J.E.L. Classification: H10, H11

1. Introduction

Generating essential public services for the members of society, the public sector is governed by a particular form of monopoly, resulting from lack of competition in terms of state institutions providing such services[2]. Putting also for the public sector the problem of efficiency, we can say that we can not talk about efficiency in this sector due to a series of factors, one of them being the corruption phenomenon[1]. So, as consequence, the lack

of corruption means a good governance which should ensure an environment characterized by the existence of certain public policies and public institutions that act efficiently in all sectors of the economic life. Whatever is the type of economy that characterizes a country (developing, emerging or developed), that suffers in a greater or less measure, the state intervention reflected in the objectives that the government aims to achieve[4]. Typically, public sector corruption may occur when some taxpayers, which can roughly be seen as sources of revenues through taxes they pay, are provided with poor public services, when some of them are served preferential for a bonus, or when they are asked by officials or public officials to pay bribe.

2. Behavior of public officials due to corruption in the public sector of the economies inside the European Union

First of the effects generated by corruption's existence in the public sector and one of the subject of this study are the favors that some public officials are granted to companies in exchange for illicit gains[3]. To capture the current situation in the emerging and developed economies of the European Union about this item we use the data collated in Table 1.

Table 1. Existence of favors granted to companies by public officials amid corruption in the public sector of the European Union economies

GB	4.3	4.1	4.2	4.3	4.22
Develloped economies average (avg.)					3.94
The indicator shows the extent to which public officials grant favors to patronage public companies or to individuals in the public auctions process {the values between [1, 3.3] shows a typically bias of the previous entities while values in the range (3.3, 7] shows a neutral public officials related to this issue}.					

Source: own processing using the data from source [16]

The interpretation of the Table 1 data creates the premises to formulate the following conclusions: for the European Union economies, a low levels of corruption contributes to the existence of a neutral position of public officials when it comes to granting favors to companies or individuals in relation to the award of contracts; the emerging economies, unfortunately characterized by a high level of corruption, has as peculiarity of the public sector, an unethical behavior of public officials who, frequently, grant such favors, their consequence being [14], often, the maintaining on market of unprofitable companies, that consume more than they produce, the increasing on illegally ways of their profits, by providing a monopolistic position in some situations, the population impoverishment who must bear the cost of services provided by some of these companies, all with a negative impact on economic growth and, hence, on the life quality [5]. The medium value associated to the indicator is for emerging economies of 2.69, respectively, of 3.94 for the developed one (the higher the index value is less, the involvement of public officials in such actions is greater). For Romania's case, the average index is 2.40 which indicate a strong involvement of public officials in such activities.

3. Embezzlement of public funds to companies, individuals or interest groups due to corruption in the public sector of the European Union economy

Another manifestation of corruption is the misuse of public funds for the purposes of channeling public money to various beneficiaries who are not destined (companies, interest groups or individuals) [6]. Also in this case, between the two sizes raised there (corruption and diversion of public funds) exist a reciprocal relationship: the more misapplication of such funds is intense and should be "rewarded", with both the corruption is proving to be more and the more corrupt administration is, with more the possibility of such state of affairs is more likely[8]. To capture how corruption creates such a state we propose a systematic analysis of Table 2 data.

Table 2. *Embezzlement of public funds due to corruption in the public sector of the European Union economy*

In general, the value "1" associated with this indicator shows a normal presence of the phenomenon and the value "7" indicates total lack thereof. The significance of the value range associated to the indicators was as follows: for

2008-2010, a high diversion of public funds due to corruption is given by the indicator belonging to the interval (1, 3.8] and the poor existence of the analyzed phenomenon positions the values, of these indices in the [3.8, 7] range; in 2010-2011, a high degree of public funds diversion amid corruption is given by the index membership to the interval (1, 3.7] and the poor existence of the analyzed phenomenon is positioning this indicator value in the [3.7, 7] range; the 2011-2012 range of time shows a high degree of public funds diversion due to corruption through the membership of the indicator in (1, 3.6] range and the poor living positions of the analyzed phenomenon is positioning numerically this indicator values in the [3.6, 7] range.

Source: own processing using the data from source [16]; Legend: HI - high intensity of occurrence of the phenomenon of misappropriation of public funds, LI - low intensity of occurrence of the phenomenon of misappropriation of public funds.

For the part of conclusions affected to this indicator related to the corruption level, the interpretation of the Table 2 data leads us to consider the existence of reduced diversion of public funds to private interests for the vast majority of European Union developed economies (the average value associated to this indicator being, in this case, 4.87). Unlike this situation, the emerging economies from the same studied area shows, as feature, a public sector governed by a high degree of misappropriation of public funds resulted in a high frequency of occurrence of the phenomenon (the average value associated to the indicator being 3.20). Romania ranks an unwanted third place, after Bulgaria and Hungary, with an associated value of 3.12 for the described indicator.

4. Assessment by public opinion of the government actions in fighting corruption inside the European Union Economies

In our presentation things can not be stopped here because tackling corruption would not be complete only by presentation of the phenomenon itself, causes that induce and the effects it produces, without bringing into question the efforts that governments, as part of the public sector of the economy, do

to keep under control and combating the corruption phenomenon[7][13]. Thus, in influencing economic activity, the most powerful tool that state benefit is the ability to exercise coercive power and regulation, whose final product is the public policy-making in different areas (limiting wage growth, consumer protection by advertising and product quality control, setting limits on contaminants issues, directly involved in producing goods and services of strategically or military economic interest, or producing public goods to be used even by those who do not pay for it and which may not be provided in sufficient quantity by private initiative - national defense, education, health etc.). If these decisions are taken in relation to a thorough search of economic reality and for public good purpose, they will prove their effectiveness and efficiency, state's role being realized. Often this does not happen, the public decision-making process becoming a prerogative of determined individuals who do not use rational criteria for the priorities. So, the public needs ranks secondly. Therefore, the expected response of the economy and the social environment or fail to appear, or is found in complete contradiction with the expected one, the lack of effectiveness and efficiency of governance making their presence felt[9].

To avoid such an undesirable state of affairs, it is imposed an analysis and an appreciation of how the state is involved in the economy, in other words, must be determined a measure of state's effectiveness[10][11][15]. All over the world, governments are accused of lack of efficiency, in conditions that politicians decide, or should decide according to the common good, fact which, unfortunately, does not happen in reality.

Politician's interest overlap with those of the majority population in a greater extent in a country characterized by a high level of democracy, but expresses their strong divergent character in emerging, frontier or developing economies[12]. Without alludes to corrupt officials who use power for personal enrichment, everywhere in the real world, these representatives of state adopt decisions according to their own interests or to those of similar groups, promoting and maintaining corruption, through this type of behavior.

To avoid or reduce the incidence of this latter phenomenon on the economy and, therefore, on meeting the public interest, governments have taken a number of measures of keeping under control, respectively curb corruption[14]. The evaluation of their effectiveness by citizens is subject to Table 3.

From Table 3 data we can say that, generally speaking, the public opinion in the European Union is skeptical when it comes to assessing the effectiveness of the governments from the respective countries in their fight against corruption. If for the developed countries of the Union, public distrust in government action on combating and limiting corruption stands, as GCB 2010-2011, around 42.4% of the total number of respondents, emerging economies from the same area are recording, as feature, a public sector burdened by people's mistrust in the efficiency of the government's anti-corruption actions, associated with a value for this indicator over the one of the European Union economies (61.33% of the total number of respondents according to Global Corruption Barometer (GCB) 2010-2011.

Source: own processing using the data from source [17]; Legend: I-inefficient, F-very efficient, E-efficient: ld-no data about the subject matter related to the country.

Also in terms of the indicator analyzed in Table 3, Romania is on top looking the public distrust in government fighting effectiveness (as authority of the public sector) against corruption, being followed by Lithuania, Latvia, Poland, Hungary and Bulgaria.

5. Conclusions

As was expected but not desirable, the situation of the emerging economies relative to the developed one from the European Union area is characterized by a low level of corruption (for developed economies case) fact which is denoting a neutral position of public officials when it comes to granting favors to companies or individuals in relation to the award of contracts. At the opposite pole, the emerging economies unfortunately are characterized by a high level of corruption, has as feature of the public sector an unethical behavior of public officials who, frequently, grant such favors, their consequence being, most of the times, the maintaining on market of unprofitable companies that consume more than they produce.

Also regarding the public funds misappropriation, the emerging economies leads detached being characterized by the existence of a public sector where there is a high frequency of occurrence of the phenomenon (mean value of the associated indicator being 3.20). As for the efficiency of government actions fighting corruption, for

the developed economies of the European Union the public distrust in government action to combat and limit corruption lies, according to GCB 2010-2011 around the value 42.4% of the total respondents while, the emerging economies from the same area are recording, as feature, a public sector burdened by the distrust of people on the efficiency of the government's anti-corruption actions much higher, associated with this index value of 61.33% by the total number of respondents, according to GCB 2010-2011 (last report made public).

Abstract

General image of a company and good conduct of its business depends on the accounting policies implemented. Also, the accounting policies have influence also on the results presented in financial statements, useful to develop various economic and financial relations. We have analyzed the influence of accounting policies that are most often used just to try to find answers / solutions to questions such as "when it chooses their accounting policies, which are the most important factors that the company should take into account?", "how can the company obtain a favorable situation: by applying the temporary accounting treatment or by applying the permanent accounting treatment"?.

Key words: accounting policies, financial position, financial performance, accounting treatment.

J.E.L. classification: M40, M49.

1. Introduction

The accounting policies are the specific principles, bases, conventions, rules and practices adopted by an entity in preparing and presenting the financial statements. [1] Although accounting policies enjoy a broad approach in the explanatory notes, the major effect of accounting policies is reflected in the balance sheet and profit and loss account and thus in determining indicators which are established based on the financial statements.

As mentioned, the effective implementation of the accounting policies is the purpose of drawing up the balance sheet and profit and loss account, from which we can estimate the position and financial performance of the company. By analyzing the two concepts, the manager can form an opinion about the situation of the company, how resources are used, which financing needs the company has, and if it has it how can it obtain it, as well as its ability to honor its financial commitments reached to maturity.

2. Accounting policies

When it comes to accounting policies it appears a series of questions such as "what are the optimal accounting policies to be applied in a given situation", "if it appears that we have chosen accounting policies that are most appropriate, can we change them from one year to another?". The answer to these questions is found in the provisions of rule IAS 8 "Accounting Policies, Changes in Accounting Estimates and Errors ". Thus, synthesizing the considerations for selecting and applying the accounting policies, we emphasize the following [2]:

- existence of a standard or an interpretation specifically applicable to a transaction, event or condition will result in the application of that regulation;
- absence of a Standard or an Interpretation specifically applied to a transaction, event or condition, will require the use of professional judgment

in developing and applying the accounting policies aiming relevant and reliable information, it will be considered the following sources in descending order:

- requirements and guidance for standards and implementations involving similar and related issues;
- definitions, recognition criteria and measurement concepts for assets, liabilities, income and expenses set out in the Framework for the Preparation and Presentation of Financial Statements;
- selecting and applying accounting policies will be done consistently for similar transactions, events and conditions, it is permissible the change of an accounting policy only if it is required by a Standard or an Interpretation or if providing reliable and more relevant information of transactions, events or conditions in the financial statements;

- if the effect of applying an accounting policy is not significant, that policy should not be applied.

However, there are situations where there is flexibility in the application of one or another accounting treatment, whose influence on financial statements varies depending on the circumstances. In this case we can talk about the accounting policies for the valuation of assets (at cost or revalued amount), policies on the treatment of interest expense, investment subsidies policies, development costs, stock assessment methods. Thus, a crucial factor in presenting the financial position and performance is the choice of accounting treatment to be applied by the enterprise.

The influences of the most used accounting treatments on the financial position and performance of the enterprise and, on the economic-financial indicators determined based on the financial situations are presented ahead [3].

Reevaluation of assets:	<ul style="list-style-type: none"> • has influence on the financial position • has influence also on the financial performance
Capitalizing the interest expenses	<ul style="list-style-type: none"> • has influence on the financial position • has influence also on the financial performance
Recognition of the subsidies at advance income	<ul style="list-style-type: none"> • has influence on the financial position • has no influence on the financial performance
Capitalisation of development costs	<ul style="list-style-type: none"> • has influence on the financial position • has influence also on the financial performance
Evaluation methods of stocks	<ul style="list-style-type: none"> • has influence on the financial position • has influence also on the financial performance

Figure 1: Influence of accounting treatments on the financial position and performance

Revaluation of assets involves recognizing of assets at fair value and recording the difference from the revaluation in equity. Thereby there are affected the balance sheet items (total assets and total equity) with major influence in decisions made by users of financial statements.

Capitalization of interest costs [4] is their

recognition in the acquisition or production cost of the asset. Thus is increased the value of the assets and the result presented is greater than when entering the interest costs in the income statement. To capitalize interest costs it must meet certain criteria for recognition. Capitalization of these costs improves the coverage degree of interest

expense in profit, which is part of the record indicator for assessing the activity of companies that are considered for medium and long term financing.

Accounting treatment for investment subsidies [5] received by the company includes: a) their recognition as deferred income and they will be resumed on current income (depreciation subsidy) each year for the use of that asset, being affected elements such as assets, deferred income, current income or b) their recognition by reducing the accounting value of the asset, case in which it is affected the asset value, the result being the same. Between the two accounting treatments for investment grants recognition, the one which involves reducing the asset value provides a more favorable image of the company.

Capitalization of those development costs

that meet the criteria for recognition as an asset will have as a consequence the increase of the total value of the assets without diminishing the result. Regardless of the option chosen, capitalization or registration in the profit and loss account of these expenses, each year result differs significantly from one treatment to another, although the cumulative result for five years (life useful duration) is the same.

Stock assessment methods have a significant influence on both the balance sheet that presents the final result of the exercise value of the stock and the profit and loss account which gives information about the value of the inventory costs consumed or sold.

Accounting treatments	Solvency	Indebtedness	Coverage of the interests from profit
	Equity/Total assets	Total debts/Equity	Profit before interest and tax expenses/ Interest expenses
Reevaluation of assets	↗	↘	—
Capitalizing the interest expenses	↗	↘	↗
Recognition of subsidies by reducing the accounting value of the asset	↗	↘	—
Recognition of the subsidies at advance income	↘	↗	—
Capitalizing the development expenses	↗	↘	—

Figure 2: Influence of the accounting treatment of economic-financial indicators

In case of revaluation of assets [6], in the first year is achieved a significantly improved value of economic-financial indicators. In subsequent years, however, that increase in value recognized in the balance sheet will be found in the form of depreciation, in proportion to the number of remaining years from the useful life of that asset so that the

entire increase will be transferred to the profit and loss account as an expense. And yet, after the end of the useful life of the asset, in the equity structure is found further the increase asset value, which leads us to say that such an accounting treatment provides a permanent favorable image.

Regarding the capitalization costs

(interest expense and development costs), in subsequent years, the value of the capitalized expenses will lead to increased depreciation of that asset, at the end of the useful life of the asset, the influence on the balance sheet and on the profit and loss account being null.

Whether the grant is recognized in advance income or decreases the accounting value of the asset, its influence on the result is the same. In this case, at the end of the useful life of the asset, the influence on the balance sheet and profit and loss account is null.

If in the statements of capitalization of costs and the recognition of the grant, it is obtained a temporary positive image by the end of the useful life of the asset, in the case of the revaluation of assets the obtained image is a permanent one (unless there are significant changes in the market value the asset). Invariably, certain accounting treatments give a much more favorable image to the company than others.

Given these accounting treatments influence on the financial position and performance, the company must use the flexibility allowed to get a true picture of the activity and must not follow the selection of policies that lead to the most favorable image.

3. Conclusions

In selecting the accounting treatments, the companies must not consider the strategy and objectives of short-and long-term financing (obtaining a bank loan, a mortgage bond issue), but to better reflect its image.

Proceeding in this manner, the interpretation of financial statements and how to determine the economic and financial indicators leave no room for other interpretations. A higher degree of profit interest coverage, in the case of their capitalization, should not be questioned as long as they met all the criteria for recognition of these costs in the cost of the asset and hence, they will generate future economic benefits for the company. Also, in the case of the revaluation, a lower level of indebtedness will reflect the actual economic and financial situation of the company, as revaluations have a real basis, the revalued value being the fair market value, that is the

amount for which an asset can be exchanged or a liability settled voluntarily between parties knowingly, within a transaction where the price is determined objectively.

Even if the influence is higher or lower on the financial position and performance, the accounting policies must be selected and applied so as to result in financial statements reflecting the true image of the company.

Abstract

In this paper we propose to realize an analysis of the Romanian economy in the period 2004-2012, analysis in which we follow the main macroeconomic indicators and their impact on the economic "health" in this period, highlighting two significant moments that have produced dramatic effects, respectively 2005, when introducing flat tax of 16%, and 2010, when budgetary wages were reduced with 25% and VAT increased from 19% to 24%. More specifically, our goal is to highlight the impact of these events on population, its way of saving, credit, inflation, namely to determine if these fiscal measures had the expected effects on the economy.

Key words: flat tax, vat, macroeconomic indicators, population.

J.E.L. classification: E21, E24, H12, H31

1. Introduction

Real wages in the economy, gross and net, had an oscillatory dynamics in the analysed period. If the interval 2004-2008 (third quarter) is characterized by a period of economic growth, following years correspond to substantial reductions of macroeconomic indicators.

The 2005 tax reform affected directly and immediately the net wage, tax reduction from 25% to 16% leading to stimulation and giving economic agents the opportunity to hire labour with attractive salaries. The reform also aimed to relaxing the tax burden on all employees and compliance of fiscal equity regarding the taxation of labour so that persons with high income should not have

additional taxes than those with lower income.

Increase of real wages (gross or net wages) occurred when in Romanian economy happened both structural and behavioural changes.

Regarding the structural changes in the economy, we refer to modifying exchange rate regime of RON, massive capital inflows in recent years and labour migration (this being reflected in the dynamics of deposits of population- their trend is increasing in the analysed period).

As changes in economic behaviour, we should mention the developments that have reduced the size of the underground economy, respectively the incentives for declaring the real level of wages and number of employees. Other potential factors in this respect are restrictive monetary conditions and positive shocks of supply, the latter being an important determinant of the evolution of inflation.

2. Flat tax and its impact on the economy

Introduction of the flat tax of 16% determined indeed an increase in the net wage per economy, and had in general a beneficial effect on all macroeconomic indicators, but these positive aspects were produced only on short term, on medium and long term that had not the expected effect.

Flat tax stimulated both importers and bankers and led to a boom of credits in 2005. Basically Romanian economy developed by credits and imports, but in reality this development should have been determined by production. In 2005 industrial production increased by only 2%, the number of employees in economy increased by 2%

compared to 2004 and foreign investments in Romania increased as well [1].

Precisely, the growth during 2005-2008 was not real, sustainable, because it was determined in principle by domestic demand (due to increase of net wages), which was caused by:

- fiscal relaxation, namely the introduction of flat tax of 16%, which led to increase of income of population in short time;
- greeting loans in an easy way (loans to households recorded a spectacular advance);
- money that labor earned outside the country and brought to Romania.

Regarding the occupancy rate of labors, indicators as the number of unemployed, unemployment rate, number of employees showed continued improvement. The number of employees also increased steadily over the period. Following the introduction of the flat tax also increased the ratio between net and gross wages from an average of about 73% in 2004 to an average of about 77% in 2005. Net earnings increased in 2005, due to higher gross wages more or less correlated with labor productivity index, but also due to lower income tax on wages.

The conclusion is that the flat tax did not produce the expected effect, excepting the immediate period after its introduction.

Negative effects in the economy in the analysed period resulted in:

- developed social divisions, increasing social polarization between rich and poor; population with small wages earned less and consumption increased through bank loans, especially for those with high salaries;
- at first sight, flat tax helped the population that paid lower taxes and was charged for consuming and not for earning; once with higher income, it increased consumption (basically revenues to state budget came mainly from indirect taxes, VAT, excise duties on imported goods);
- irrational development of consumption caused the increase of inflation (in fact, the inflation target for 2005 was missed because of this), real interests on deposits became negative, and finally savings and investment suffered;
- external deficit was also affected, the trade balance and the current account.

This happened because the surplus remained after introducing flat tax stimulated consumption, which was reflected in higher imports (persons with high income, for whom the surplus resulting from the flat tax was significant, spent first for imported goods such as cars, luxury replacement apparatus, and so on).

- for business environment: flat taxation affected small businesses in Romania, generally undercapitalized, and encouraged speculative foreign migratory capital (we should notice the flat tax impact of small entrepreneurs, when thousands of SMEs ceased their activities) [2].

We believe that the flat tax was not enough in order to strongly influence the labour; it should have been accompanied by reducing social contributions which in our country are among the highest in Europe. The fact that in 2005 revenues to social security budget decreased shows that the effect of the flat tax on labour was insufficient: there were not created enough jobs to offset the reduction of revenues. Most wages were negotiated between employers and employees in net form, while gross wages, to which social security contributions are calculated, in some cases have decreased as a result of the flat tax.

The flat tax generated in the first year a significant reduction in tax revenues collected as tax base had not have an increase rhythm to offset the reduction of tax rate. Decrease of fiscal revenues from income tax was offset by increase of fiscal revenues from value added tax. It is a normal evolution, if we think that the remaining income for taxpayers was used for consumption, which led to higher levels of indirect taxes collected to the budget. Basically there was a significant increase in indirect taxation than reduction of direct taxation, and finally there was an increase in tax burden and not a fiscal relaxation, as expected.

3. Austerity measures and the impact on the economy

The period 2005-2008, precisely the third quarter of 2008, was a flourishing period for Romania, characterized by economic boom

(driven by domestic demand). Beginning with IV quarter of 2008, the economic crisis appears and all economic indicators record dramatic declines.

In 2010, the situation is recovering sensitive, but it simultaneously applies two shocking measures, with significant impact on the overall economy: reducing budgetary wages by 25% and increase of VAT from 19% to 24%.

a) Reduce budgetary wages by 25%. This reduction did not contribute only to decrease of income and implicitly the decrease of aggregate demand but also reduced debt repayment and developed pessimism of economic actors.

Before applying the measure, the average wage in the public sector was 2108 Ron and fell to 1701 Ron. The reduction with 25% of budgetary wages also caused a decrease in social security contributions in the last six months of 2010, with the landmark contribution of 31.3% of gross salary, which is divided between the employee (10.5%) and employer (20.8%). Basically, the conclusion is that cutting wages had a major impact on the pension system.

Increase of wages by 15% in early 2011, followed by an increase of 8% from summer 2012 come to mitigate the impact of reducing wages in 2010 in nominal terms.

b) VAT increase had a positive impact on revenues in August of 2010. However, this impact was short-lived, because on macroeconomic level it had noticed a decrease in household income and thus a decrease in income tax revenues. This increase was not entirely absorbed in the economy, it was situated partly in product prices. It also decreased the purchasing power of the population.

At industry level the VAT increase was felt in the pre-financing costs, particularly at new investments. The increased VAT meant also closing activities in transport, distribution and in other sectors clients have become more reticent. Banking sector also recorded additional costs, which increased the cost of financing for businesses.

The increase in VAT determined the increase of excise rates, with implications for amplification of tax evasion, because, in practice, any tax increase leads to development of underground economy and tax evasion.

VAT increase led to higher prices for goods, even if most traders tried to delay as much as possible the transfer of this cost growth to consumers- we mention the promotions in the first days after 1 July (the date when VAT became 24% instead of 19%) [3].

In conclusion, the economic effects of the VAT increase were:

- Rising prices;
- Reduce consumption; VAT determined to certain products price increases, the impact came from consumers to business reducing profit margins.
- Closing of business based on services related to the circulation of goods (distribution, delivery, transport), many of which are brought from the unique internal market or China;
- Rising of unemployment: firms have revised production costs, "walking" the pay scale and establishment plan;
- Budget deficit: tax increase was made in order to finance the budget deficit, but the effects were opposite to expectations;
- Tax evasion: VAT is a tax often applied to other taxes such as excise duties. Excisable goods have suffered a big price increase, and in these conditions tax evasion becomes more attractive (not just for those who have to pay these fees but also for those who need to collect or to control).

4. Evolution of savings in 2004-2012

The most important factors that influence the decision process of saving are: income, consumption and investment process.

The main prerequisite of saving is the existence and size of income. Changes of real values of various forms of income and their strong dynamics in time had a decisive impact on the propensity of saving of population. Household income in the current period have seen a dramatic evolution, but a contradictory one. Developments in this area have included most of the quantitative and structural parameters for revenues, all components of household income being involved in these changes. Therefore, there have been changed their actual size (expressed by the power purchase), the apparent dimensions (nominal), their share in

the total revenues of the society, structure of income, the report between different categories of income, population distribution by size of income.

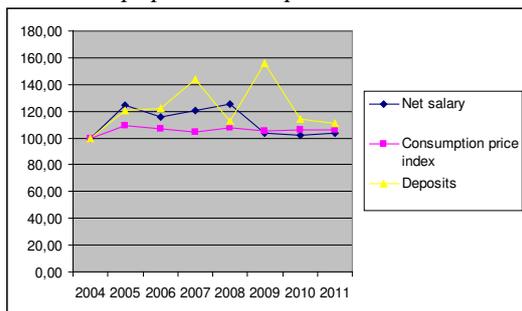

Evolution of household savings during 2004-2012 had significant fluctuations (upward trends beyond 2008 even if our country was affected by the global financial and economic crisis).

Net earnings of population were in continuous growth. Compared to 2008 the increase was 15% as a result of occasional bonuses (including quarterly bonuses at Easter), sums of net profit and other funds (including lunch and gift vouchers), salary negotiations, achievements of production or higher revenue (depending on contracts).

Regarding the influence of inflation on saving process for household sector, we can say that during inflation period, all goods, whose value grows slower than the general price level is devalued. In other words, people's purchasing power has diminished. About the influence of the price factor on the process of saving should be noted that price stability fosters savings and its growth hampers it, as feeding the opinion that it is not worth to save because money is devalued, losing their purchasing power.

Figure below shows the 2005 and 2010 taxation impact on net wages, warehouses of population and consumption price index (CPI)

Fig.1. Correlation regarding Net wage- population deposits-CPI

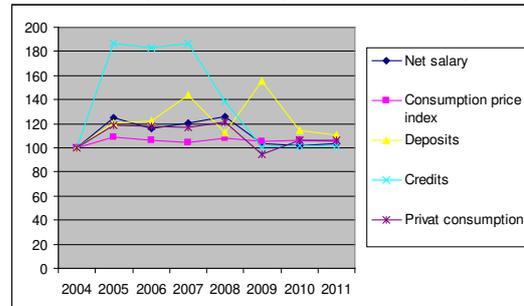

Source: INS, Monthly bulletins, 2005-2012, BNR, Monthly Bulletins, 2005-2012

The flat causes a huge jump for all three indicators compared with 2004. But saving does not increase significantly after the introduction of flat tax, which suggests that population, in terms of revenues growth,

"focuses" mainly on consumption. Compared to 2009, when deposits had a maximum, in 2010, when budgetary wages were reduced, saving process recorded a minimum, so reducing income affected deposits and continued to decline also in 2011 [4].

Fig 2. Correlation regarding net salary - credits-deposits-CPI-private consumption

Source: INS, Monthly bulletins, 2005-2012, BNR, Monthly Bulletins, 2005-2012

Flat tax led to a huge increase in loans, but compared with their growth, other indicators had lower intensity of increase, except net salary [5].

Can notice an increase in terms of savings (deposits increased significantly in 2007 and reached a peak in 2009; we believe the cause of this were the fear and uncertainty of people regarding precarious financial situation because of the economic crisis).

The year 2010 brought the collapse of credits and also a significant decrease in deposits and earnings. However, in terms of household consumption, it is one of the few indicators that did not suffer a substantial discount. The conclusion drawn is that no matter how much the income of population would reduce, it would still invest in its needs (food, clothing).

5. Conclusions

The level of taxation in Romania during 2004-2012 determined mainly the reducing of macroeconomic indicators. The introduction of flat tax in 2005 did not produce the desired effects, it had immediate positive effects only in the immediate period from its implementation. Among the negative effects there are: raise of social divisions, reducing direct tax revenues in favour of indirect taxation, grew of consumption and

consequently increasing of inflation, boosting lending and reducing savings, credit and economic development through imports and credits.

In terms of austerity measures, they have had a negative impact on the economy: lower net wages, reduction of social security contributions, rising prices, and thus reduce of population consumption, the decline of savings (due to lower net wages), encouraging tax evasion, closing of business related to services based on the movement of goods.

The level of taxation in Romania is high, although we have an attractive flat tax, yet social security contributions and VAT values are extremely high. We propose in this sense a reduction in social security contributions to employer, VAT reduction and simplification of tax legislation. We believe that these measures would improve the economic situation, stimulate investment, production and job creation.

Case Study on Export Accounting Based on Commission

Mihalache Anita

George Barițiu University, Brașov, Romania
anita.mihalache@gmail.com

Abstract

Export of goods is a component of foreign trade activity that includes all operations through which goods manufactured in one country are sold in other countries. As active participants in the foreign trade, foreign trade companies can export goods on their own or on commission. When a company acts as an intermediary between the local producer of the exported goods and the external client but doesn't handle the goods itself, its accounting has some particularities that this paper aims to point out.

Keywords: export, commission, accounting, foreign trade company

J.E.L. Classification: M41

1. Introduction

Export of goods on commission represents an indirect form of export. The foreign trade company (F.T.C.) exports the goods in their own name, but on the account and risk of the manufacturing companies, thereby the results of the export activity are reflected in the manufacturing company's accounting [1].

This form of export is based on firm contracts signed between F.T.C. and the manufacturing companies, between F.T.C. and the external providing services companies, such as the transporting company and the insurance company, depending on the delivery policy, and also between F.T.C. and the external clients.

The contracts signed between F.T.C. and the manufacturing companies are commission based and stipulate that the manufacturing companies are committed to provide a specified quantity of goods that the F.T.C. will sell at a fair market price. Also

the F.T.C. must pay the value of the sold goods to the manufacturing companies after deducting their own commission.

For their services F.T.C. are paid in commission established in percentage rates, either on the F.O.B. value of goods, or on the external value, depending on the delivery policy. The commission size varies accordingly with the type and value of the exported goods.

The objective of the commission contracts isn't the transfer of goods from the manufacturer to the F.T.C. but the provision of specialized services on the conclusion and the unfolding of international sales-purchase contracts.

The exported goods in the form of commission export follow the next route [2]:

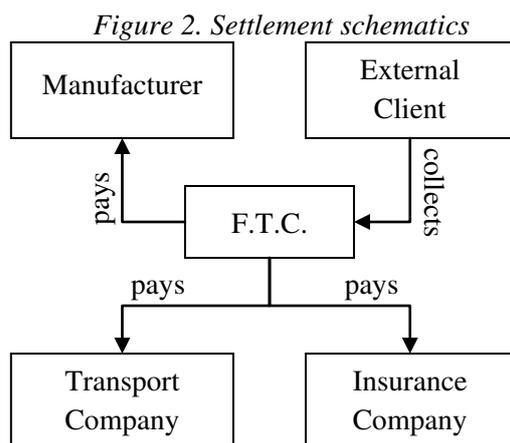

Figure 1. Route of the exported goods

Settlement of the exported goods is operated on the reverse route of their movement as follows [1]:

- The value of the exported goods is collected from the external client in foreign currency (accounted in lei at the day's rate);
- The external F.O.B. value of goods is paid to the manufacturing company, except the negotiated commission that is deducted by the F.T.C.;
- The external services providers are paid for their services according with the delivery policy;
- All settlements are registered in foreign currency and in lei at the day's rate. That's why the F.T.C. must calculate the exchange rate difference which can be favorable (it is registered as an income) or unfavorable (it is registered as an expenditure).

The settlement procedure is presented in the next figure.

F.T.C. does not reflect in their own accounting the expenses and incomes from the sale of goods, it only registers income from commission and exchange rates differences and their own managing expenditures.

2. Particularities of export on commission accounting

As opposed to the export of goods on their own, export on commission has a number of specific features in F.T.C. accounting regarding incomes, expenditures and results (gains or losses).

In the F.T.C. accounting are reflected only their own expenses as: energy, water, postal and telecommunications, unfavorable exchange rates differences, depreciation of fixed assets and so on. As for incomes, F.T.C. only registers those from commission; from favorable exchange rates differences and other own incomes.

F.T.C. accounting will not reflect the price of goods as incomes or the cost of goods as expenditures. Also it would not reflect any incomes or expenses regarding the services provided by the external service providers (external transportation and external insurance). All of the above will be reflected in the manufacturer's accounting.

F.T.C. accounting will reflect however the value collected from the external client and the value paid to the manufacturer and the external service providers.

In the F.T.C. accounting the income composing the turnover is reflected only in the account 704 "Income from work performed and services rendered" that registers the value of the commission collected from the manufacturer.

The account 707 "Income from sold goods" will not be used for registering the value of the exported goods but the account 401 "Suppliers" used on the analytical account 401.M "Supplier manufacturer" because the export is made on the account and risk of the manufacturer which is a client of the F.T.C. but also the supplier of the goods.

The account 708 "Income from various activities" will not be used for registering the external services value (transport and insurance) that compose the external price of the goods but the account 401 "Suppliers" used on the analytical account 401.T "Suppliers transport" for the value of the external transportation of goods and the account 401.I "Suppliers insurance" for the value of the external insurance of goods.

The accounts for registering goods will not be used because the F.T.C. is not the owner of the exported goods.

The income and expenditures structure highlights the fact that the result of the export on commission is determined by subtracting the F.T.C. own expenditures from the commission earned for the transaction.

3. Case study

A F.T.C. carried out export of goods on commission for which the following information are known:

- F.T.C. issues the invoice for the exported goods in the C.I.F. delivery policy for the sum of 20.000 euros on March 1st 2012;
- The external insurance value for the exported goods is 2.000 euros;
- The external transportation value for the exported goods is 3.000 euros;
- F.T.C. commission is 10% of the F.O.B. value of goods, including V.A.T.;
- On March 3rd 2012 the goods value is collected from the external client;
- On March 4th 2012 the settlements are made with the manufacturer for the exported goods, with the transport company for the external transportation services and with the insurance company for the value of the external insurance of the goods;
- In the 3rd month of 2012 the F.T.C. registered the following expenditures:
 - o Wages 3.100 lei;

- Telecommunications 700 lei, excluding V.A.T.;
- Depreciation of a company’s car 400 lei;
- Electrical energy 200 lei.

The exchange rate evolution is listed below:

Table 1. Exchange rate

Date	1 euro
March 1 st 2012	4,3 lei
March 3 rd 2012	4,32 lei
March 4 th 2012	4,35 lei

For the above information the following accounting registrations were made:

A. Registering the issued invoice to the external client:

Before the registration itself we must determine the F.O.B. value of the exported goods, which is shown in the next table:

Table 2. Determining the F.O.B. value of the exported goods

Elements	Value in euro	Value in lei
External C.I.F. value	20.000	86.000
Insurance value	2.000	8.600
Transport value	3.000	12.900
External F.O.B. value	15.000	64.500

For registering the invoice to the client stating that the goods were delivered, the following accounts are used:

- 4111.E “External client”
- 401.M “Supplier manufacturer”
- 401.I “Supplier insurance”
- 401.T “Supplier transport”

And the accounting entry is as follows:

4111.E			
“External client”	=	%	86.000
		401.M	
		“Supplier manufacturer”	64.500
		401.I	
		“Supplier insurance”	8.600
		401.T	
		“Supplier transport”	12.900

B. Registering the commission invoice issued for the manufacturer

Before the registration itself we need to determine the value of the commission and the value of the V.A.T. using the next table:

Table 3. The commission value

Elements	Value in euro	Value in lei
Commission V.A.T. included	15.000*10%= 1.500	6.450
V.A.T.	290	1.247
Commission excluding V.A.T.	1.210	5.203

For the registration of the commission we will use the following accounts:

- 4111.M “Client manufacturer”
- 704 “Income from performed work and services rendered”
- 4427 “Collected V.A.T.”

And the accounting entry is as follows:

4111.M			
“Client manufacturer”	=	%	6.450
		704	
		“Income from performed work and services rendered”	1.247
		4427	
		“Collected V.A.T.”	5.203

C. Registering the withholding of the commission from the external F.O.B. value

From the debt to the supplier, which is the manufacturing company, the F.T.C. withholds the commission value. For this operation the following accounts are used:

- 401.M “Supplier manufacturer”
- 4111.M “Client manufacturer”

And the accounting entry is as follows:

401.M	=	4111.M	6.450
“Supplier manufacturer”		“Client manufacturer”	

D. Registering the collection form the external client

In order to register the collection made form the external client we must calculate the currency exchange rate difference, because the collection is made in a different date at a different exchange rate.

Value of goods on the date of delivery
20.000 euro * 4,3 = 86.000 lei

Value of goods on the day of collection
20.000 euro * 4,32 = 86.400 lei

Exchange rate difference = 400 lei

The difference is a favorable one because the exchange rate is higher at collection than at invoicing, therefore it is registered as an income.

The following accounts are used:

- 4111.E “External client”
- 5124 “Bank accounts in foreign currency”
- 765 “Income from the exchange rate difference”

And the accounting entry is as follows:

	5124				
“Bank accounts in foreign currency”	=	%		86.400	
			4111.E		
			“External client”	86.000	
			765		
			“Income from the exchange rate difference”	400	

E. Registering the payment made to the manufacturer

In order to pay the manufacturer for the exported goods we must establish the rest of the payment after deducting the commission from the external F.O.B. value. The calculation is demonstrated in the next table:

Table 4. The net amount to pay the manufacturer

Elements	Value in euro
External F.O.B. value	15.000
Withholdings	1.500
Net amount of payment	13.500

Before registering the payment we need to determine the exchange rate difference because the payment is made on another date as the invoicing.

Value of payment on the date of invoicing
13.500 euro * 4,3 = 58.050 lei;

Value of payment on the date of payment
13.500 euro * 4,35 = 58.725 lei;

Exchange rate difference = 675 lei.

The difference is an unfavorable one because the exchange rate is higher at payment than at invoicing, therefore it is registered as expenditure.

The following accounts are used:

- 401.M “Supplier manufacturer”

- 5124 “Bank accounts in foreign currency”
- 665 “Expenditure regarding the exchange rate difference”

And the accounting entry is as follows:

	%				
			5124		
			=	“Bank accounts in foreign currency”	58.725
			401.M		
			“Supplier manufacturer”	58.050	
			665		
			“Expenditure regarding the exchange rate difference”	675	

F. Registering the payment made to the external insurance company

Before registering the payment we need to determine the exchange rate difference because the payment is made on another date as the invoicing.

Value of payment on the date of invoicing
2.000 euro * 4.3 = 8.600 lei;

Value of payment on the date of payment
2.000 euro * 4,35 = 8.700 lei;

Exchange rate difference = 100 lei.

The difference is an unfavorable one because the exchange rate is higher at payment than at invoicing, therefore it is registered as expenditure.

The following accounts are used:

- 401.I “Supplier insurance”
- 5124 “Bank accounts in foreign currency”
- 665 “Expenditure regarding the exchange rate difference”

And the accounting entry is as follows:

	%				
			5124		
			=	“Bank accounts in foreign currency”	8.700
			401.I		
			“Supplier insurance”	8.600	
			665		
			“Expenditure regarding the exchange rate difference”	100	

G. Registering the payment to the external transport company

Before registering the payment we need to determine the exchange rate difference

because the payment is made on another date as the invoicing.

Value of payment on the date of invoicing
3.000 euro * 4,3 = 12.900 lei;

Value of payment on the date of payment
3.000 euro * 4,35 = 13.050 lei;

Exchange rate difference = 150 lei.

The difference is an unfavorable one because the exchange rate is higher at payment than at invoicing, therefore it is registered as expenditure.

The following accounts are used:

- 401.T “Supplier transporter”
- 5124 “Bank accounts in foreign currency”
- 665 “Expenditure regarding the exchange rate difference”

And the accounting entry is as follows:

	%		5124			
		=	“Bank accounts in foreign currency”	13.050		
401.T				12.900		
“Supplier transport”						
665				150		
“Expenditure regarding the exchange rate difference”						

H. Registering the F.T.C. own expenditures

Next we will present the registration of F.T.C. own expenditures as follows:

- wages:

	641		421			
		=	“Debt regarding the employees”	3.100		
“Personal expenditures”						
- telecommunications:

	%		401			
		=	“Supplier telecom.”	868		
626				700		
“Postal and telecom. expenditures”						
4426				168		
“Deductible V.A.T.”						
- depreciation

	681		281			
		=	“Depreciation of fixed assets”	400		
“Depreciation expenditures”						

-	electrical energy		401			
	%			=	“Supplier energy”	248
			605			
			“Energy expenditures”			200
			4426			
			“Deductible V.A.T.”			48

I. Closing the income and expenditure accounts

The income and expenditure accounts are closed using the result account. If the income are larger than the expenditure the companies results are gains, if the situation is reversed the companies results are losses.

Registering the closing of the income accounts is made as follows:

	%		121			
		=	“Gain or loss”	5.603		
704				5.203		
“Income from performed work and services rendered”						
765				400		
“Income from the exchange rate difference”						

Registering the closing of the expenditure accounts is made as follows:

	121		%			
		=		5.325		
641				3.100		
“Personal expenditures”						
626				700		
“Postal and telecom. expenditures”						
681				400		
“Depreciation expenditures”						
605				200		
“Energy expenditures”						
665				925		
“Expenditure regarding the exchange rate difference”						

J. Calculation of the gain or losses

The next step is to show the “gain or loss” account and to establish its balance. If the balance is debtor it results in loss, but if the balance is creditor it results in gain. The balance of the gain or loss account for the F.T.C. is shown below:

Figure 3. The gain or loss account

121 “Gain or loss”	
5.325	5.603
C.E.B. 278	

4. Conclusions

There are both advantages and disadvantages when a F.T.C. is exporting goods on commission. On one hand the major advantage is that the export of goods is made on the account and risk on the manufacturer company, but, on the other hand, the major disadvantage is that the gain of the F.T.C. is calculated only from the negotiated commission. Thus F.T.C. must cover all of its own expenditures from this commission.

In the case of the studied F.T.C. we can conclude that it was able to cover its own expenditures from its own incomes and obtained a gain of 5% of turnover. This rather small gain was caused, in some part, by the payment exchange rate difference which was 925 lei (unfavorable) as against the collected exchange rate difference which was 400 lei (favorable).

In any case, exporters must assure a margin that allows them to cover the potential losses due to the exchange rate differences.

5. List of Abbreviations:

- F.T.C. – foreign trade company;
- F.O.B. – free on board (delivery policy);
- C.I.F. – cost insurance and freight (delivery policy);
- V.A.T. – value added tax;
- C.E.B. – creditor ends balance.

Abstract

The financial crisis has highlighted the need for an EU framework for bank recovery and resolution. The European Commission proposed on Wednesday a series of measures to introduce European standards in terms of bank recovery and resolution. These standards ensure that in future the authorities will have the means to intervene decisively before the onset of both problems, and in the first phase of a possible crisis. The proposed tools are divided into powers of "prevention", "early intervention" and "resolution". This article aims to show what exactly to aspect from these measures and what European Bank Union means..

Keywords: bank management, economic crisis, prevention, early intervention, resolution.

J.E.L Classification.: E50, M 10

1. Introduction

No bank in the European Union or Romania should be "too big to fail". The financial crisis has clearly demonstrated the need for more robust mechanism for crisis management at the national level and also the need to create mechanisms more capable of dealing with cross-border bank failures. During the crisis, there were many resounding failures (Fortis, Lehman Brothers, Icelandic banks, Anglo Irish Bank), which revealed many serious deficiencies in the existent mechanisms. In the absence of mechanisms to organize an orderly liquidation, EU Member States had no choice but to save entities in their financial sector.

On 6 June 2012, the European

Commission published a legislative proposal for a Directive designed to avoid future taxpayer bailouts of troubled banks. The proposals aim to ensure authorities will have the means to intervene decisively before problems occur, or if they do occur, to intervene as early as possible. Banks that have deteriorated beyond repair would be partly rescued by unsecured creditors rather than taxpayers. The proposals include:

- Preparatory and preventative measures – including recovery plans, resolution plans, powers to address or remove resolvability impediments and intra-group support agreements;
- Early supervisory intervention;
- Resolution tools – including selling all or part of a failing firm to another firm, separating "good" assets into a new firm, putting "bad assets" into an asset management vehicle and a "bail-in" tool which involves a firm being recapitalized with creditors having their claims reduced or converted to shares
- Enhanced co-operation between national authorities for a so called bank union.

2. New management measures to avoid future bank bail-outs

The crisis has brought forward the shortcomings of financial regulation and triggered major improvements at global and EU levels [1]:

- *Solvency:* Better and more capital requirements. The Basel regulatory frameworks introduced a major overhaul in order to capture all risks of banks in particular in the area of market and counter party risks. This new prudential regulatory framework enhanced also significantly the quantity and quality of

capital for banks. It is estimated these capital requirements have to be multiplied by five since Basel II by 2013 in Europe.

- *Liquidity*: Proposed in Basel III as well, new liquidity standard includes a liquidity coverage ratio (LCR) and a net stable funding ratio (NSFR). The LCR is designed to bolster the short term resilience of a bank’s liquidity risk profile by ensuring that it has high quality liquid assets in sufficient quantity to survive a plausible severe stress scenario lasting for 30 calendar days. The NSFR is designed to promote resilience over a longer timeframe by creating additional incentives for banks to use more stable resources of funding on an ongoing basis.
- *Lower interconnectedness and improved market transparency in particular for derivatives transactions*: First, the G20 and Europe (EMIR Regulation) in particular have agreed that standardized OTC derivatives need to be traded on an exchange not bilaterally, and cleared through a central counterparty (CCP). This will strengthen the system by making financial institutions less interconnected. Second, OTC derivatives trades will have to be reported to a trade repository, which registers electronically all relevant details of an OTC derivatives transaction over its lifetime. And third, banking and market supervisors are developing rules to make sure that the risks of derivatives that are not centrally cleared are covered by appropriate capital and margining.
- *Holistic view of financial risks*: regulation and supervision also encompasses the shadow banking. Another critical element of the reform agenda is to monitor and, where appropriate, to address the risks posed by shadow bank. The FSB brought forward two approaches: a monitoring exercise, by which authorities regularly exchange data and information on shadow banks in their specific jurisdictions; the framing regulatory responses to specific risks already identified in the shadow banking. In that respect work is ongoing in five priority areas, including money market funds, securitization and repo markets, with specific recommendations expected within months. (See Eurofi Executive Paper on Shadow Banking)
- *Macro- and microprudential supervision*:

“For any global system to be robust and resilient safeguards are needed and a proactive supervision is one of them. Full, consistent, and timely rules are important but not sufficient.” This is why a macro and micro prudential supervision in Europe, and in particular in the Euro area, is also vital. (See Eurofi executive summary on a European Banking Union).

European Commission plan to avoid future bailouts through some changes in certain key areas, from prevention and early intervention to resolution [2].

A. Preparation and prevention:

- First, the framework requires banks to draw up recovery plans setting out measures that would kick in in the event of a deterioration of their financial situation in order to restore their viability.
- Second, authorities tasked with the responsibility of resolving banks are required to prepare resolution plans with options for dealing with banks in critical condition which are no longer viable. Recovery and resolution plans are to be prepared both at group level and for the individual institutions within the group.
- Third, if authorities identify obstacles to resolvability in the course of this planning process, they can require a bank to change its legal or operational structures to ensure that it can be resolved with the available tools in a way that does not compromise critical functions, threaten financial stability, or involve costs to the taxpayer.
- Finally, financial groups may enter into intra-group support agreements to limit the development of a crisis and quickly boost the financial stability of the group as a whole. Subject to approval by the supervisory authorities and the shareholders of each entity that is party to the agreement, institutions which operate in a group would thus be able to provide financial support (in the form of loans, the provision of guarantees, or the provision of assets for use as collateral in transactions) to other entities within the group that experience financial difficulties.

B. Early intervention [2]

Early supervisory intervention will ensure that financial difficulties are addressed as soon as they arise. Early intervention powers are triggered when an institution does not meet or is likely to be in breach of regulatory capital requirements. Authorities could require the institution to implement any measures set out in the recovery plan, draw up an action programmed and a timetable for its implementation, require the convening of a meeting of shareholders to adopt urgent decisions, and require the institution to draw up a plan for restructuring of debt with its creditors.

In addition, supervisors will have the power to appoint a special manager at a bank for a limited period when there is a significant deterioration in its financial situation and the tools described above are not sufficient to reverse the situation. The primary duty of a special manager is to restore the financial situation of the bank and the sound and prudent management of its business.

C. Resolution powers and tools [2]

Resolution takes place if the preventive and early intervention measures fail to redress the situation from deteriorating to the point where the bank is failing or likely to fail. If the authority determines that no alternative action would help prevent failure of the bank, and that the public interest (of access to critical banking functions, financial stability, integrity of public finances, etc.) is at stake, authorities should take control of the institution and initiate decisive resolution action. [2]

Harmonized resolution tools and powers, together with the resolution plans prepared in advance for both nationally-active and cross-border banks, will ensure that national authorities in all Member States have a common toolkit and roadmap to manage the failure of banks. The interference in the rights of shareholders and creditors which the tools entail is justified by the overriding need to protect financial stability, depositors and taxpayers, and is supported by safeguards to ensure that the resolution tools are not improperly used.

According to the framework, the main resolution tools are the following [2]:

○ The sale of business tool whereby the

authorities would sell all or part of the failing bank to another bank;

- The bridge institution tool which consists of identifying the good assets or essential functions of the bank and separating them into a new bank (bridge bank) which would be sold to another entity. The old bank with the bad or non-essential functions would then be liquidated under normal insolvency proceedings;
- The asset separation tool whereby the bad assets of the bank are put into an asset management vehicle. This tool cleans the balance sheet of a bank. In order to prevent this tool from being used solely as a state aid measure, the framework prescribes that it may be used only in conjunction with another tool (bridge bank, sale of business or write-down). This ensures that while the bank receives support, it also undergoes restructuring;
- The bail-in tool whereby the bank would be recapitalized with shareholders wiped out or diluted, and creditors would have their claims reduced or converted to shares. An institution for which a private acquirer could not be found, or which could be complicated to split up, could thus continue to provide essential services without the need for bail-out by public funds, and authorities would have time to reorganize it or wind down parts of its business in an orderly manner. To this end, banks would be required to have a minimum percentage of their total liabilities in the shape of instruments eligible for bail-in. If triggered, they would be written down in a pre-defined order in terms of seniority of claims in order for the institution to regain viability.

In order to deal with EU banks or groups that operate across borders, the framework enhances cooperation between national authorities in all phases of preparation, intervention and resolution. Resolution colleges are established under the leadership of the group resolution authority and with the participation of the European Banking Authority (EBA). The EBA will facilitate joint actions and act as a binding mediator if necessary. This lays the foundations for an increasingly integrated EU-level oversight of cross-border entities, to be explored further in the coming years in the context of the review of Europe's supervisory architecture.

To be effective, the resolution tools will require a certain amount of funding. For example, if authorities create a bridge bank, it will need capital or short term loans to operate. If market funding is not available and in order to avoid resolution actions from being funded by the state, supplementary funding will be provided by resolution funds which will raise contributions from banks proportionate to their liabilities and risk profiles. The funds will have to build up sufficient capacity to reach 1% of covered deposits in 10 years. They will be used exclusively for supporting orderly reorganization and resolution, and never to bail out a bank. National resolution funds would interact, notably to provide funding for resolving cross-border banks.

European Bank Union

On 12 September 2012 the Commission adopted two proposals for the establishment of a single supervisory mechanism (SSM) for banks led by the European Central Bank (ECB). The proposal for the SSM regulation aimed to confer upon the ECB specific supervisory tasks over credit institutions in the Euro area. The accompanying proposal for the regulation on the European Banking Authority (EBA) aimed to introduce limited amendments to the Regulation setting up the EBA to ensure a balance in its decision making structures between the euro area and non-euro area Member States.

Key elements of the SSM [3]:

- The establishment of the Single Supervisory Mechanism (SSM) is a first step towards a banking union and one of the pre-conditions for direct recapitalization by the ESM. An integrated “Banking Union” will also include a common bank resolution mechanism, underpinned by a single rulebook.
- The SSM applies to all the euro-area Member States and is open to the participation of other Member States who wish to embark on a path of deeper integration for supervision.
- Non-euro area Member States may decide to join the SSM by establishing a close cooperation between their competent authorities and the ECB. In that case they may, on an equal footing with the euro-area Member States, participate in the activities of the newly created Supervisory Board which is in charge of planning and executing the supervisory tasks conferred upon the ECB.
- The Regulation confers key supervisory tasks and powers to the ECB over all the credit institutions established within the euro area. The ECB carries out its tasks within a SSM composed of the ECB and national competent authorities.
- Within the SSM, the ECB will be responsible for the supervision of all 6000 banks of the euro area. In particular:
 - the ECB shall ensure the coherent and consistent application of the Single rulebook in the euro area.
 - the ECB will directly supervise banks having assets of more than EUR 30 billion or constituting at least 20% of their home country's GDP or which have requested or received direct public financial assistance from the EFSF (European Financial Stability Facility) or the ESM.
 - the ECB will monitor the supervision by national supervisors of less significant banks. The ECB may at any moment decide to directly supervise one or more of these credit institutions to ensure consistent application of high supervisory standards. The work of national supervisors is integrated into the SSM: for instance, the ECB will send instructions to national supervisors, and national supervisors have a duty to notify the ECB of supervisory decisions of material consequence.
- The governance structure of the ECB will consist of a separate Supervisory Board supported by steering committee, the ECB Governing Council, and a mediation panel to solve disagreements that may arise between national competent authorities and the Governing Council. Clear separation between the ECB's monetary tasks and supervisory tasks is fully ensured.
- For cross-border banks active both within and outside Member States participating in the SSM, existing home/host supervisor coordination procedures will continue to exist as they do today. To the extent that the ECB has taken over direct supervisory tasks, it will carry out the functions of the home and host authority for all

- participating Member States.
- The rules on the functioning of the EBA will be adapted and its role reinforced. The EBA will continue developing the single rulebook applicable to all 27 Member States. In order to foster consistency and efficiency of supervisory practices across the whole Union, it will develop a single supervisory handbook. It will also ensure that regular stress-test are carried out to assess the resilience of European banks. There will be safeguards for non-euro zone Member States by means of double majority voting requirements for EBA decisions on mediation and on technical standards. This ensures that decisions are backed by both a majority of the participating and the non-participating Member States.
 - The SSM is envisaged to be in place one year after the entering into force of the agreed texts. To allow for a smooth transition some flexibility by means of transitional arrangements is foreseen.
 - After agreement on the pending proposals on banking restructuring and resolution and deposit guarantee schemes, as a next step the Commission will make a proposal for a single European resolution mechanism to deal efficiently with cross-border bank resolution and avoid taxpayers' money going into rescuing banks.

There are at least five main reasons why Europe is committing itself to a banking union. For the most part the implications of these various rationales are consistent, but there are also tensions between them. Key structural choices about the banking union will often hinge on the prioritization of these various objectives [4]:

- Dealing with existing bank weaknesses that contribute to the euro crisis.
- Reducing the risk that banking will contribute to later stages of the euro crisis.
- Restoring the effectiveness of the monetary policy of the ECB.
- Reintegrating the European banking system.
- Fixing long-standing problems with the “single market” in banking in the EU.

3. Conclusions

The proposals adopted by the European

Commission for EU-wide rules for bank recovery and resolution will ensure that in the future authorities will have the means to intervene decisively both before problems occur and early on in the process if they do. Furthermore, if the financial situation of a bank deteriorates beyond repair, the proposal ensures that a bank's critical functions can be rescued while the costs of restructuring and resolving failing banks fall upon the bank's owners and creditors and not on taxpayers. The European Commission intends Member States to finalize their implementing measures for the proposed Directive by 31 December 2014 and apply the measures from 1 January 2015. The bail-in tool should be applied from 1 January 2018. All these measures could prevent further international banking failures, but making them work will take cooperation among national authorities.

According to Vítor Constâncio [5], Vice-President of the ECB, the prospect of the creation of Banking Supervision at the European level, complemented by future European banking resolution, is the more far reaching change introduced since the inception of the euro. It reveals the willingness of Member States to continue to deepen European integration and create at the same time a better framework for the effective functioning of the euro area. Few could have foreseen such momentous developments. A man of vision and a great European, Tommaso Padoa-Schioppa, who preceded me as the member of the ECB's Board responsible for financial stability wrote in 1999 a few weeks after the inception of the euro [6]: *I am convinced, however, that in the future the needs will change and the multilateral mode will have to deepen substantially. Over time such a mode will have to be structured to the point of providing the banking industry with a true and effective collective euro area supervisor. It will have to be enhanced to the full extent required for banking supervision in the euro area to be as prompt and effective as it is within a single nation”*

pitumirela@yahoo.com

Abstract

Understanding the transmission of the changes in interest rates within the inter-banking money market to the interest rates applied by banks to their clients is essential for knowing the way in which the monetary policy influences the economy.

The correlation between the inter-banking interest rate and the active interest rate is important for all participants to the financial market. The traits of this correlation are even more important within the financial systems in which banks play the main role such as those in Romania.

In this context, the purpose of the hereby study is to analyze how powerful is the correlation between ROBOR and the interest rate on new credits, in Romania.

Key words: ROBOR, interest rate on credit, correlation coefficients; credit.

J.E.L Classification: D4, E50, G21, L10.

1. Introduction

Transmitting the changes in interest rate within the inter-banking money market to the interest rates applied by banks is a topic of interest for all participants to the financial market: the monetary authority, the trade banks, and the public.

To reach the monetary policy objective, starting with 2005, NBR has adopted the mechanism of inflation targeting.

NBR is facing uncertainties related to the inflation targeting mechanism, to the state of the economy, and to a series of factors that do not depend on the monetary policy. In this context, the relation between the interest rate

from the inter-banking monetary market and the interest rate on the credits given by the banks is a relevant indicator.

Banks also have precise goals on making profit, and risk and liquidity management. The spread between the interest rates within the inter-banking monetary market and those applied on the non-governmental credit market may be the key for obtaining banking performance.

The banks' clients are those bearing the credit cost and are the main beneficiaries of the decrease in the active interest rate.

Last but not least, the financial analysts are taking an interest in the interest rates' transmission mechanisms.

2. Theoretical aspects concerning the interest rates' transmission mechanisms

The relationship between the interest data from the monetary market and those applied by the banks in the crediting relationship is of a permanent interest to economists. Adopting the inflation targeting mechanisms by the modern central banks brought this correlation more often in present-day.

Some important contributions in this field were the studies carried out by Hannan and Berger [1], Neumann and Shape [2] that are studying the interest rates' pass-through in USA. Next, there is Lowe and Rohling [3] who evaluate the stagnation in the process of transmitting the changes from the inter-banking monetary market to the retail credit market in Australia.

Over the last decade, more and more studies are intended for this subject, and the case studies moved their focus to the Euro Zone and at the level of economies in Eastern and Central Europe: Mojon [4], De Bondt

[5], Sander and Kleimeier [6], Van Leuvensteijn et alii [7], Borio [8], Radu [8].

The studies carried out over the past years indicate that the banking competition degree might have a significant impact on the bank interest rates' level and in terms of the market rates' pass-through to the bank interest rates.

3. Correlation coefficients

The correlation analysis is used to study the intensity of the connection between variables. The correlation measures the intensity of the connection between variables. Depending on the type of variables taken into consideration, the statistical connections can express either associations (the case of nominal variables), or correlations (the case of numeric variables). The envisaged model shall measure the correlation. This can be expressed by covariance, the Pearson correlation coefficient, and the degrees' correlation coefficient (Spearman and Kendall).

The Pearson correlation coefficient is marked by $\rho(X,Y)$ and is defined by the next relation:

$$\rho(X,Y) = \frac{\text{cov}(X,Y)}{\sigma_x \cdot \sigma_y} = \frac{\sum_{i=1}^N (x_i - \mu_x)(y_i - \mu_y)}{N \cdot \sigma_x \cdot \sigma_y}$$

where:

- $\text{cov}(X,Y)$ - covariance;
- x_i, y_i, μ_x, μ_y are values of the corresponding variables and their medium level;
- N - the number of the pairs of values;
- σ_x, σ_y - the average square deviation for X , respectively Y .

The correlation coefficient is obtained by standardizing the covariance. The value of this coefficient is between -1 and +1. If it takes the value of zero, then there is no connection between the variables. The sign of ρ shows the sense/direction of the relation between variables. The plus sign indicates a direct connection (as the values of variable X are increasing, the values of variable Y are also increasing), and the minus sign point out a reverse connection (as the values of variable X are increasing, the values of variable Y are decreasing).

The absolute value of ρ indicates the intensity of the connection, namely: the closer it gets to 1, the stronger the connection is, respectively the closer it gets to zero, the weaker the connection is. A correlation coefficient of +1 points out a perfect connection between variables, and one equal to -1 shows a perfect reverse connection.

The Spearman coefficient is an extension of the Pearson correlation coefficient where the values of the connected variables are replaced with the corresponding degrees. The coefficient is marked with θ and is calculated applying the relation:

$$\theta = 1 - \frac{6 \sum_{i=1}^n d_i^2}{n(n^2 - 1)}$$

where:

- d_i represents the difference between the degrees of the correlated values,
- n as the number of the studied units - the pairs (x,y) .

The Kendall coefficient is defined by the relation:

$$\tau = \frac{S}{0,5n(n-1)} = \frac{2S}{n(n-1)}$$

where $S = Q + P$, in which P is the number of higher degrees taken further against the considered degree, and Q is the number of lower degrees taken further (the minus sign is applied). S is calculated for the degrees of the dependent variable Y , set in order after the degrees of the factorial variable X .

The degrees' correlation coefficient has the variation range of $[-1,+1]$ with the same significance as in the case of Pearson correlation coefficients.

4. Loans interest rate in Romania

Although there is a strong connection between the interest rate of the deposits attracted by the commercial banks and the interest rate of the given loans, this fact does not have a correspondent in Romanian reality.

The banks in the Romanian banking system mostly have a private foreign capital and are dependent of the external financing

and the inter-banking market.

The interest rate of the lei and foreign currency loans is generally higher as the loan’s maturity is larger, because the non-reimbursement risk of the loan increases with reimbursement deadline.

Still, there are situations when interest rates for longer maturity loans may be lower than shorter maturity loans, especially at times when inflation is high.

Interest rates for euro loans are essentially dependent of the interest rate at which the loaner bank can refinance from the international markets.

Currency credit access induces a currency risk for the clients and they must take it into consideration as an extra cost over the loan interest rate.

The lei loans’ interest rates are higher than those for foreign currency loans due to the higher inflation in Romania compared to other countries, but also because of the monetary policy interest rate.

Accordingly, the total amounts of money paid by clients for lei credits, nowadays, tend to be higher than for currency credits. That is why clients have a tendency to access currency loans rather than lei, in order to pay lower interest rates for their credits.

Nevertheless, we must point out the fact that currency risk may deteriorate the financial position of the clients that access currency credits and have a lei income.

In 2007, the average banking interest rate was 11.62% for the new loans given to non-financial companies in lei, and 7.95% for the currency ones. 2008 is characterized by a significant increase in the interest rate for loans given to non-financial companies in lei (19.51%) and a slight drop for the currency loans (7.63%).

The interest rate decrease tendency for lei and currency alike takes place over 2009-2010 when they reach 9.4% and 5.63%, respectively.

Over the following years, the interest rate has a small increase reaching 9.79% in 2012 for loans given to non-financial companies in lei, and 4.87% for currency loans.

5. The ROBOR interest rate - loans correlation. A regression model

The fundamental relation between the interest rates and the loans offered by the commercial banks and the interest rates on the inter-banking market may be approached from the marginal cost and the refinancing cost perspective.

Within this model, the starting point is the idea that banks take loans on the inter-banking market in order to offer loans to the public. The hypothesis is in correlation with the Romanian reality, even under financial crisis conditions. [10].

Therefore, we have set to study the correlation between ROBOR and the loans interest rate. The data we have used covers the period January 1st 2007 – February 31st 2013 and are as follows:

- 1M and 3M ROBOR monthly series (as averages per month of the daily series);
- The loans interest rate for new credits in lei (average monthly series – noted RL_CS).

We have thus obtained 74 observations.

Table 1 Pearson Correlation ROBOR 1M - RL_CS

		ROBOR_1M	RL_CS
ROBOR_1M	Pearson Correlation	1	0.907*
	Sig. (2-tailed)		0.000
	N	74	74
RL_CS	Pearson Correlation	0.907*	1
	Sig. (2-tailed)	0.000	
	N	74	74

* Correlation is significant at the 0.01 level (2-tailed).
Source: own calculations.

The correlation analysis has revealed that there is a strong correlation between ROBOR and the loans’ interest rate.

Based on the calculations, we can observe that the value of the correlation coefficients is set between 0.729 and 0.896 for the Kendal and Spearman coefficients, and at 0.907 for the Pearson coefficient. (Table 1, Table 2).

Table 2 Nonparametric correlation ROBOR 1M - RL_CS

			ROBOR_1M	RL_CS
Kendall's tau_b	ROBOR_1M	Correlation Coefficient	1.000	0.729*
		Sig. (2-tailed)	.	0.000
		N	74	74
	RL_CS	Correlation Coefficient	0.729**	1.000
		Sig. (2-tailed)	0.000	.
		N	74	74
Spearman's rho	ROBOR_1M	Correlation Coefficient	1.000	0.896*
		Sig. (2-tailed)	.	0.000
		N	74	74
	RL_CS	Correlation Coefficient	0.896**	1.000
		Sig. (2-tailed)	0.000	.
		N	74	74

* Correlation is significant at the 0.01 level (2-tailed).
Source: own calculations.

The calculations prove a strong direct correlation between the one month lei deposits interest rate attracted on the inter-banking market and the new loans offered in the national currency.

Table 3 Pearson Correlation ROBOR 3M - RL_CS

		ROBOR_1M	RL_CS
ROBOR_1M	Pearson Correlation	1	0.912*
	Sig. (2-tailed)		0.000
	N	74	74
RL_CS	Pearson Correlation	0.912*	1
	Sig. (2-tailed)	0.000	
	N	74	74

* Correlation is significant at the 0.01 level (2-tailed).
Source: own calculations.

The calculated Pearson correlation coefficient in the case of ROBOR RL_CS is 0.912, therefore larger than in the first analyzed case. Thus, it is attested that the modifications of the interest rates on the inter-banking market (specifically ROBOR 3M) is immediately transmitted in the costs of the lei loans given by commercial banks.

Table 4 Nonparametric correlation ROBOR 3M - RL_CS

			ROBOR_1M	RL_CS
Kendall's tau_b	ROBOR_1M	Correlation Coefficient	1.000	0.738*
		Sig. (2-tailed)	.	0.000
		N	78	74
	RL_CS	Correlation Coefficient	0.738**	1.000
		Sig. (2-tailed)	0.000	.
		N	74	74
Spearman's rho	ROBOR_1M	Correlation Coefficient	1.000	0.904*
		Sig. (2-tailed)	.	0.000
		N	74	74
	RL_CS	Correlation Coefficient	0.904*	1.000
		Sig. (2-tailed)	0.000	.
		N	74	74

* Correlation is significant at the 0.01 level (2-tailed).
Source: own calculations.

In order to estimate the evolution of the lei interest rate (RL_CS) according to the ROBOR 3M modifications, we have used a linear regression model. The points cloud is presented in Figure 1.

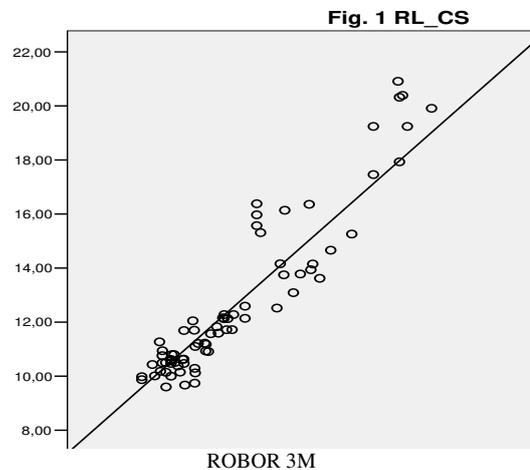

Table 5 Model Summary and Parameter Estimates

Dependent Variable: RL_CS

Equation	Parameter Estimates			
	R Square	F	Constant	b1
Linear	0.832	355.402	6.063	0.781

The independent variable is ROBOR_3M.
Source: own calculations

The results of linear regression application are presented in Table 4. It must be mentioned that the estimation error is smaller than 1%, and the R Square level of 0.832 shows the functionality of the model.

6. Conclusions

The structural characteristic of the financial Romanian system where banks have the dominant position is relevant within the study. The period January 2007 – August 2009 that we have analyzed is characterized by a growth tendency for the inter-banking rates, under the influence of the strong economic and financial shocks produced on the external and internal markets. [10].

As a result of the global financial crisis and the decline of the economic climate, the risk prime became larger and the banks had as a main objective the management of the loans portfolio.

Within the analyzed period, the channel for the transmission of the modifications in the interest rate of the inter-banking monetary market towards the loans' interest rates is functional. Contrasting to the 2005-2007 period when the high liquidity of the market compared with the relatively shallowness of the monetary market made ROBOR modification to be transmitted inertly towards the loans' and deposits' interest rate, the analyzed period shows a strong correlation. The affirmation is sustained by the high levels of the Pearson correlation coefficients calculated at 0.907 and 0.912. The nonparametric correlations are also strong: the levels of the Kendall and Spearman coefficients are between 0.738–0.896.

The evolutions have determined a direct strong correlation between the inter-banking monetary market's interest rate and the loans' interest rate margin. [11]

The adjustment function determined on the linear regression model allows us to estimate the active interest rate according to the possible modifications of the ROBOR 3M. A further development of the analysis could consist in investigating the determinants in the evolution of the interest rates spreads.

Concentration and Competition in the Romanian Banking System

Munteanu Irena

Piti Georgiana

Ratea Mihaela

Ovidius University of Constanta

irena.munteanu@yahoo.com

georgiana.piti@yahoo.com

ratea.mihaela@yahoo.com

Abstract

In this paper we try to assess banking concentration in Romania for 2001 – 2011 period, taking into account the evolution of market share of the first five banks in the system, HHI (Herfindahl-Hirschman Index) for assets, loans and deposits, also the banking system performances highlighted by indicators like ROA and ROE. In the analyzed period there are three approaches: in the first period banks have had very good performances in the context of a less competitive banking environment, after the privatization of some state capital banks, when the leader of the market lost market share in the favor of more efficient banks and the financial crisis the banks are still facing it today.

Key words: banking concentration, Pearson correlation, Herfindahl-Hirschman Index, banking system, concentration ratio.

J.E.L. code: G21.

1. Introduction

Over time market structure and competition were key points in the European financial and economic system. Thus, relationships between competition, performance, efficiency and stability were given special attention in theoretical literature as well as in empirical research. The competition ensures the availability of quality products and services for the final consumer, a higher degree of innovation, lower prices. It also enables efficient banks enter the market, or to expand in spite of inefficient ones. However, as noted by the

former FED chairman, Alan Greenspan, the intense competition in the banking system may lead to a reduction in profit margins and encourage risky investments, which may cause financial instability and can induce systemic risks. Therefore, a balance must be found to ensure the stability of the banking system and maintain free competition [1].

Overall in the Romanian banking system, the competitive mechanism between banks is working. On some markets, the increased concentration degree is a key concern for the future, the growth of this indicator is a direct result of the market crisis that has removed some players from the system. The financial crisis has seriously affected banks activity, both incomes and profit rates were significantly reduced. Also, the evolution of ROE was negatively influenced, from values of 15-20%, considered reasonable for the banking sector in normal market conditions, fell to zero and even turned negative in some periods. The larger banks have suffered less significant corrections of these indicators, as opposed to small banks whose profitability indicators were negative.

The Romanian banking system has high connectivity with the European banking system, being mostly owned by foreign capital (34 credit institutions with majority foreign capital accounted for more than 81.2 percent of bank assets in June 2012) [2].

2. Literature Review

The literature on the measurement of competition in the banking industry can be divided into two major streams: structural and non-structural approaches. The most relevant structural approaches used are Structure - Conduct-Performance Hypothesis (SCP) and Efficient Structure Hypothesis

(ESH). As the name suggests, the structural approach analyzes bank competition based on structural indicators, such as concentration ratio (the market share of the top three or five banks) or Herfindahl-Hirschman Index (HHI) and assume that a higher banking concentration implies weaker competition in the banking system and increase profitability. [3]

There are a number of studies that address these measures of bank competition and concentration.

Studies have been undertaken nationwide such as: the Germany - Hempell for Italy - Coccoresse for Spain - Maud and Perez for Finland - Vesala for Canada - Nathan and Neave for Japan - Molyneux et al (1996). [4] Studies performed exclusively for Romania are in very low numbers. Thus, we can mention: Mereuta and Căpraru [5] using structural indicators (CR5 and HHI) to measure banking concentration during 2003-2009, reaching the conclusion that in the entire analyzed period, concentration in the Romanian banking system increased, which characterizes a monopolistic competition.

In this paper we focused on the most frequently used concentration ratios: the k concentration ratio and the Herfindahl-Hirschmann Index.

Simplicity and limited data requirements make the k bank concentration ratio one of the most frequently used measures of concentration in the empirical literature. Specifically, it implies summing only over the market shares of the k largest banks in the market, taking the following form:

$$C_k = \sum_{i=1}^k S_i$$

where S_i represents market share of company i .

There is no rule for the determination of the value of k , so that the number of banks included in the concentration index is a rather arbitrary decision. The concentration ratio may be considered as one point on the concentration curve, and it is a one-dimensional measure ranging between 0 & 1.

Herfindahl Hirschman Index (HHI) is widely used in most theoretical treaties on measuring of concentration and often serves as a reference for evaluating other concentration indices. In the United States, the HHI plays a significant role in the implementation of antitrust laws in the banking sector. [6]

In other words, in U.S. an application for the merger of two banks will be approved without further investigation if the basic guidelines for the evaluation of the concentration in deposit markets are satisfied. HHI index has often been labeled as "full information" index because of the broad spectrum of information it provides about the size of a bank and its influence in the market. The HHI takes the following form:

$$HHI = \sum_{i=1}^n S_i^2$$

where S_i represents bank market share, and n the number of banks on the market.

As mentioned, the Herfindahl Hirschman Index stresses the importance of larger banks, giving them greater weight than smaller banks and incorporates each bank, thus avoiding arbitrary cut-offs and insensitivity to share distribution.

In Table 1 it is highlighted the range used by European Commission, Department of Justice – Federal Trade Commission – USA.

Table 1. Range used for HHI

Concentration Degree	Value HHI	
	European Commission	DoJ Antitrust Division + Federal Trade Commission
Low	<1000	<1500
Moderate	1000-2000	1500-2500
High	>2000	>2500

* Source: Competition Council, The development of competition in key sectors 2012

Concentration Ratios are often used as input dates for public policy measures regarding the banking market structure. Policymakers can select suitable indicators of concentration, depending on the characteristics of the banking market, perceptions of the impact that small or big banks have on competition in certain markets and, not least, perceptions regarding the relative impact of size distribution and number of banks.

These characteristics and perceptions were designed to determine the most suitable indicator for the market. Concentration rate is also used for determining the impact of the concentration on competition.

3. Measuring banking concentration

The research regarding the degree of concentration in the Romanian banking system are shown in Table 2.

There are figured Herfindahl-Hirschman Index values based on three pillars (assets, loans and deposits) which perfectly highlights an overview of banking activity.

Between 2001-2012 there has been a general downward trend of the HHI on the three basic components, but according to the levels used by the European Commission a value of HHI > 2000 indicates a high degree of concentration in the Romanian banking sector, which reduces competition on the market.

The concentration degree at the end of 2007 was stable, although in the last quarter there were slight decreases in market share in favor for small and medium banks, most showing more aggression in terms of loan activity.

The concentration decreased slightly in 2008 and in terms of loan activity.

Table 2. Results for HHI for 2001-2012

	2001	2002	2003	2004	2005	2006	2007	2008	2009	2010	2011	2012
Herfindahl Hirschman Index (HHI)												
- for assets	4426	4004	3797	3589	3552	3672	3003	2959	2642	2735	2959	2992
- for loans	3574	2785	2105	2945	3446	4238	3170	3505	1606	1324	1036	n.a
- for deposits	4372	3760	2925	3344	3249	3981	3540	2704	1482	1361	1478	n.a

* Source: own calculations

Table 3. Concentration Ratio results: 2007-2012

	2007	2008	2009	2010	2011	2012
1 largest bank (CR1)						
- For Loans	21.9%	20.4%	19.1 %	19.8 %	20.11 %	19.3 %
- For Assets	23.5%	22.7%	15.25 %	14.3 %	12.19%	n.a.
- For Deposits	21.7%	20.4%	13.22 %	12.42%	12.8%	n.a.
3 largest banks (CR3)						
- For Loans	43.7%	42.87%	39.06%	40.03%	41.00%	40.4%
- For Assets	21.7%	45.75%	31.48%	28.51%	25.32%	n.a.
- For Deposits	50.4%	46.96%	29.48%	28.11%	29.02%	n.a.
5 largest banks (CR5)						
- For Loans	55.2%	54.37%	51.24%	52.63%	54.57%	54.5%
- For Assets	56.2%	59.25%	40.00%	36.4%	32.25%	n.a.
- For Deposits	59.4%	51.88%	38.46%	33.48%	38.50%	n.a.

The concentration degree at the end of 2007 was stable, although in the last quarter there were slight decreases in market share in favor for small and medium banks, most showing more aggression in terms of loan activity.

The concentration decreased slightly in 2008 and in the first quarter of 2009, on both parts, loans and deposits. In late 2009, the market share of the top 5 banks in total assets decreased to 51.24%, but on the elements of active developments are not homogeneous.

Credit market decreased to 40% and on the liabilities side, the top five banks accounted 38.46% of total deposits. In late 2011, the market share of the top five banks in the Romanian banking system reached a level of over 54% of assets, the highest value for this period, about 38% of deposits and 32.25% of the loans - the lowest for the period.

4. HHI-ROE and HHI-ROA Correlations

The correlation analysis is used to study the intensity of the relationship between variables. Strictly speaking, the correlation is a measure of the intensity of the relationship between variables. Statistic links, depending on the type of variables, can express combinations (for nominal variables), or correlations (for numeric variables). In this specified model it will be measured the correlation. This can be expressed through: covariance, the Pearson correlation coefficient.

Literature and empirical studies show that there is a link between banking concentration and their performance. [8], [9],[10].

We propose to study whether there are links between the degree of banking concentration in Romania and performance of banks.

The data series used are short which limits the relevance of the results, but covers a relatively long period of time if we relate to the Romanian banking system market economy.

For ROE, ROA indicators and Herfindahl Hirshmann coefficient were used annual average values published by National Bank of Romania. (NBR) [11], [12]

Table 4. ROE – HHI Correlations

		ROE	IHH
ROE	Pearson Correlation	1	0,788*
	Sig. (2-tailed)		0,002
	N	12	12
HHI	Pearson Correlation	0,788*	1
	Sig. (2-tailed)	0,002	
	N	12	12

* Correlation is significant at the 0.01 level (2-tailed).

Source: own calculations

In Table 4 it can be seen that between ROE and HHI there is a relatively strong direct correlation. Thus we can say that the banks' financial performance are increasing when the concentration is higher.

Regarding the correlation ROA-HHI is noticed that in this case the increase in concentration leads to higher economic return in the system. (Table 5)

Table 5 ROA- IHH Correlations

		ROA	IHH
ROA	Pearson Correlation	1	0,892*
	Sig. (2-tailed)		0,000
	N	12	12
HHI	Pearson Correlation	0,892*	1
	Sig. (2-tailed)	0,000	
	N	12	12

* Correlation is significant at the 0.01 level (2-tailed).

Source: own calculations

Moreover, the high value of Pearson correlation coefficient, 0.892 indicates a strong correlation between the two indicators.

5. Conclusions

A high degree of concentration shows that the same number of banks has control over a large part of the market, and this could lead to anticompetitive behavior. In most cases, there is a significant relationship between concentration and competition. Romanian banking market concentration increased from the onset of the financial crisis, mainly due to the elimination of certain competitors from the market.

Empirical studies show that the

concentration influences banking performance. The study on Romanian banking market shows that there is a strong direct correlation between the concentration measured by the Herfindahl Hirshmann coefficient and bank performance measured by ROE and ROA.

For a decade it is spoken that in Romania there are too many banks, but so far nothing has happened. BCR remains the largest bank by assets in the system and no one can compete without an acquisition. In 2012 the largest 5 banks in Romania have become stronger: more than half of the total assets of the banking system are concentrated in these five banks. Experts from McKinsey & Company say that in the future Romanian banks will turn their strategy to the most attractive segment. [13], [14].

In fact, a whole world is looking for new models for the future, since analyzes indicates too many banks for how much business can be produced.

Accounting Support Function for Supply Chain Management

Munteanu Petrică

*Faculty of Economics and Business Administration, "Alexandru Ioan Cuza" University,
Iasi*

mp05_ro@yahoo.com

Abstract

Recording past facts and events, accounting may be erroneously considered useless for Supply chain management. Since we are aware of the complexity of the subject, we tried to bring SCM in the area of accounting and of the relationships that can be established between these two research fields.

For this reason, the objective of our research is to point out the usefulness of accounting and its products in insuring the performance of Supply chain management. Our study reveals the support function of accounting for Supply chain management.

The main conclusion is that, through the nature and destination of the financial-accounting information, Supply chain management cannot ignore the importance and usefulness of accounting in attaining its performance. Although it does not meet all the requirements, integrated with the Enterprise Resource Planning (ERP) technology, accounting is a support function that insures most of the information necessary for the good planning and coordination of the supply, production, and sale processes in a Supply chain.

Key words: accounting, Supply Chain Management, economic decisions, financial-accounting information, performance.

JEL classification: M15, M41.

1. Introduction

Council of Supply Chain Management Professionals (CSCMP), states that Supply Chain Management includes the planning and management of all the activities involved in supply and provision, conversion and all the Supply management activities. What is important is that it also includes the

coordination and collaboration with the chain partners, which can be suppliers, agents, service providers, and customers. In essence, Supply chain management integrates the offer and demand management within and between companies. Supply chain management is an integrating function, whose main responsibility is to relate the major business functions and processes within and outside companies, in a unitary and effective business model. It includes all the previously mentioned Supply chain management activities, as well as production operations, insuring the coordination of the processes and activities with and beyond marketing, sales, product design, finance, and information technology.

Martin Christopher [1] makes distinction between the *Supply chain* and *physical distribution*. The Supply chain is concerned with the management of the physical flow, which starts with the supply sources of a producer plant, and ends at the consumption point of a product, while physical distribution is more limited, being concerned solely with the flow of the finite products from the producers to the consumers.

Philip Kotler [2] also makes a distinction between physical distribution, a more traditional activity, and supply, which rather focuses on the market. Thus, physical distribution starts from the end of the production line and concerns the final product, and then solutions need to be found to make the goods available for the customer, involving the lowest costs. In what concerns supply, it starts from the customers, with their needs and demands, and then it aims to find the best solutions to achieve the products.

We can therefore notice that distribution starts upstream and goes downstream, and supply starts downstream, meaning a customer's demand, and goes upstream, beyond the producer, to the suppliers of raw

materials. On this logic of supply, the notion of Supply Chain was built.

Association Française pour la Logistique (ASLOG) defines the *Supply chain objectives* – the right product, in the right quantity, at the right moment, and the *Supply chain management* – the global management of the resources in order to best meet the customers’ demands, expressed or predicted.

The authors who tried to find a generally accepted definition [3], [4], reached the conclusion that there is none, which implies negative effects on the development of practice and research in the field. In recent studies, Stock and Boyer made a review of 173 definitions of SCM [5].

Modern Supply chain theory and practice say that SCM implies total integration between providers and customers, and its main benefit is the reduction of the costs and stocks. In essence, the Supply chain and Supply chain management mean, for a company, starting to be or remaining competitive, in a challenging global environment [6].

After reviewing specialized literature, we noticed the diversity of opinions, the importance of the topic, and the resemblances/differences between SCM and logistics, as well as the fact that the usefulness and connections of accounting to this problem are neglected in studies. At present, the accounting system of the companies needs to be designed so as to be able to provide decision-makers, in an operative manner and even in real time, with relevant information on the evolution and dynamics of the activity of the company on the short and medium term, as well as the customer’s reaction to the product, productivity, investments and costs dynamics, etc. [7].

2. Accounting functions, designed to respond to the needs of SCM

In the opinion of G. Norris [8], *financial and accounting activities are support processes*, along with others such as human resources and design, providing information flows and processes specific for SCM.

Accounting is the science that observes and quantifies the existing numerical language and movements in the structure of economic resources controlled by the

enterprise determines the extent of these changes, defines the causes that have led, ultimately determining the nature of the results obtained [9].

Development of accounting in line with diversifying the needs of users, requires a nuanced approach to functions. The base was recorded at a time of wealth and the transactions between traders.

Over time was observed and confirmed that accounting was always the place where economic decisions were taken. Author Michel Capron [10] states that one of the functions of accounting is the *auxiliary power*.

For the activity of making process, accounting performs the following functions [9]:

- recording and data processing function;
- information and observation function;
- management control function;
- legal or evidentiary function;
- forecasting function.

Suggestive name of these functions makes us not itemized each one, but to insist on those who have the most significant utility for Supply chain management.

Summarizing, we can say that *the function of recording and processing of data* provides support economic events that will be used in producing the information. *We must recognize that in fact converge to the recording accounting data* [11].

Information and observation function of providing information about the business managers and the performance parameters and further correction of deviations. *Legal position (probably)* takes into account the reality and credibility of economic events expressed in monetary standard. When we talk about *forecasting function*, we need to refer to its utility for setting future plans and strategies, based on accounting information for a period concluded. Even if we refer only to the Supply chain or the whole business, it is important to establish where we came from, where we stand, by which we are going, where should we go and what to do to get there. All these require retrospective in the past objectivity to recognize reality and forecasting future goals. It is the task manager that can find a reliable partner in accounting to be well and properly informed and get the desired performance.

Imposed economic dynamics, both in

doctrine and in practice carrying several countries, the emergence of *provisional accounts*. In functional terms, they are tools to prevent difficulties they may encounter and enterprise routing efforts. From the methodological point of view, take the past of financial accounting information and correlate underlying the forward-looking information found in budgets network of the enterprise. According to the authors M. Ristea and C.G. Dumitru [12] any management that aims performance must accept the forecast financial documents.

Given the importance of costs and revenues for evaluating Supply chain performance management, it should be noted that the accounting allows *understanding and application of the most appropriate indicators showing the evolution of costs, revenues and profitability*. Another remark is that, to meet customer orders in the shortest time and lowest cost involving - requirement of SCM planning requires availability of materials, personnel, mechanisms and tools. Planning can be done taking into account developments in the past and forecasts, information such as accounting.

Moreover, the new systems are increasingly facilitating the registration and recording of financial and economic operations, we wondered whether the function of accounting information and forecasting long passed first [7].

3. Management accounting, source of information only to managers

Management accounting can be defined as the process of identifying, measuring, interpreting and communicating information (both financial and related operations) used by management to plan, evaluate and control the enterprise and ensure knowingly use its resources [13].

Decision problems can differ greatly, so that the diversity and complexity of the information is very important. Management accounting, headed and analytical, internal managerial knowledge is considering cost activities to optimize them. It provides useful information regarding monitoring and assessment developments, *is one that monitors the transformation of material into finished products, with detail on centers and products*.

Quantifying the costs and profitability follow each link of the Supply chain is essential. An analysis of this tool is the performance indicators that can provide business guidance for the employment prospects and targets in a SCM project.

Frequently, the Supply chain is described with *costs and revenues involved in each component* [14]: costs with suppliers/raw materials and materials, transport costs, costs of production, storage and distribution costs, revenues customers. These costs and revenues are specific instruments of financial accounting and, especially the management.

Management accounting not meet the needs of external users. It comes solely to assist managers and their decisions. It is aimed at developing budgets and cost forecasting, measurement of business performance (profitability, productivity) at product/service, station, link. Based on this information, supplemented in some cases by those from internal audit scope, the manager can make corrections or invest resources at the chain link.

The purpose of management accounting is to provide the manager strictly those elements necessary to help him understand the phenomena and processes occurring in the body, to provide intelligence on which can make decisions relevant repercussions can provide decision taken at the same time to have leverage to make a permanent and effective control [15].

In management accounting the activity is oriented towards business processes that are essential to intervene customers, suppliers and other partners [16]. It is concerned about:

- relationship between inter-organizational processes and values;
- interface between organizational processes, working techniques, structures, systems and cultures;
- alignment of organizational processes, strategies, products and services;
- how resources are deployed, used and consumed by organizational processes while creating value.

Of the mentioned we deduce the opinion that *accounting meets the specific needs of Supply chain management*.

4. Importance of quality and accessibility of accounting information for a performance management

To be useful, information must be accessible, that means visible. Visibility refers to the availability of information regarding activities and operations across the Supply chain among its members [17].

Supply Chain Management is an art gained through strategy and planning to sell the thing, ie answering the application, when must promptly and at that time and place, ie through efficient distribution network, making a profit as possible better. This requires continuous improvement of services offered to customers. SCM software aims to reduce costs, an efficient resource allocation, customer satisfaction and maximizing profits. Information is which carries out and strengthens the link between all functions and processes of SCM. It is that which owned at the right time and used effectively, can guarantee managerial performance. It is therefore very important that the quality and availability of the information that manager needs.

Regardless of the source of financial information, financial accounting (general) or the management, they must be visible, centralized and easy to understand, in order to provide control over everything that happens along the Supply chain.

If we refer only to management accounting, it must maintain a flexibility in compiling and interpreting information. This facilitates searching and presenting the clear, understandable and at the optimum time, the alternative to fair and safe decisions. The process is essentially future-oriented and information must satisfy the criteria of utility and relevance [18].

Besides the quality characteristics that must satisfy information to be harnessed properly, it is necessary at the same time, that the manager has the required knowledge of accounting data interpretation. Most of the information are strictly related to the accounting expertise and remain with the understanding and interpretation of the professional accountant. Therefore, collaboration between him and the manager is important and beneficial. It shows the consequences of decisions taken or manager to be taken and proposed solutions for improving business. Holder of a considerable experience and open-minded, professional accountant is not just tasks and new skills but

also new responsibilities. Intervenes in decision making as a consultant and verifies by specific performance indicators, the actions of managers.

5. Conclusions

Theoretical research is particularly important for the conceptualization, strategy, and planning of Supply chain management, but the most efficient practices can only be designed after careful observation and analysis of practice. Practical experience, based on theoretical knowledge, is the main source for the most appropriate solutions to the problems of a Supply chain.

Without claiming to provide a definition, we consider that *Supply chain management is a dynamic complex, with a global vision on the processes and connections between them, which involves the best harmonization (balancing) decisions and strategies of the requirements of all the participating actors: the providers that want to sell established volumes, the producers that insure certain production capacities and volumes, the distributors that can insure certain sale capacities, the customers, whose demand varies and becomes ever more diversified (to the purpose of reducing costs and increasing profitability). SCM means a unique approach, specific to the market segment, which allows meeting the customers' demands at the highest level, involving the smallest costs possible.*

Subscribe to benefits of this study, highlight the support function of accounting and finding the elements specific to accounting that can insure and increase the performance of Supply chain management, also the importance of becoming aware of and giving the appropriate place to accounting/its information products, as well as possible solutions to better information of SCM.

Abstract

The financial scandals of recent years have further strengthened the hands of the proponents of fair value accounting. By shining a bright light into dark corners of a firm's accounts, fair value accounting precludes the dubious practices of managers in hiding the consequences of their actions from the eyes of outside observers. The debate presents a new start for fair-value accounting going forward and standard setters' push to extend fair-value accounting into other areas. In our research, we found important issues as an attempt to make sense of the controversies. While there are legitimate concerns about implementations of fair-value accounting , it is less clear that these problems apply to the stipulations of fair-value accounting in the accounting regulations. We believe that historical cost accounting is not the remedy. Fair value accounting is used when reliable fair value estimates are available and when they convey information about operating performance.

Key words: fair value, historical cost, IFR

J.E.L. Classification: M41, G32

1. Introduction

The recent financial crisis has turned the spotlight on fair-value accounting (FVA) and led to a major policy debate involving among others the European Commission as well banking and accounting regulators around the world. Critics argue that fair-value accounting has significantly contributed to

the financial crisis and exacerbated its severity for financial institutions in the U.S. and around the world. On the other extreme, proponents of fair-value accounting argue that it merely played the role of the proverbial messenger that is now being shot. In our view, there are problems with both positions. Fair-value accounting is neither responsible for the crisis nor is it merely a measurement system that reports asset and liabilities values without having economic effects of its own.

In this article, we attempt to make sense of the current fair-value debate and discuss whether many of the arguments in this debate hold up to further scrutiny. We come to the following four conclusions. First, much of the controversy about fair-value accounting results from confusion about what is new and different about fair-value accounting as well as different views about the purpose of fair-value accounting . In our view, the debate about fair-value accounting takes us back to several old accounting issues, like the tradeoff between relevance and reliability, which have been debated for decades. Except in rare circumstances, standard setters will always face these issues and tradeoffs and fair-value accounting is just another example. This insight is helpful to better understand some of the arguments brought forward in the debate. Second, there are legitimate concerns about marking asset values to market prices in times of financial crisis once we recognize that there are ties to contracts and regulation or that managers and investors may care about market reactions over the short term. However, it is not obvious that these problems are best addressed with

changes to the accounting system. These problems could also (and perhaps more appropriately) be addressed by adjusting contracts and regulation. Moreover, the concern about the downward spiral is most pronounced for fair-value accounting in its pure form but it does not apply in the same way to fair-value accounting as stipulated by IFRS.

However, as our third conclusion highlights, there could be implementation problems in practice. It is important to recognize that accounting rules interact with other elements of the institutional framework, which could give rise to unintended consequences. For instance, we point out that managers' concerns about litigation could make a deviation from market prices less likely even when it would be appropriate. At the same time, it is important to recognize that giving management more flexibility to deal with potential problems of fair-value accounting (in times of crisis) also opens the door for manipulation. For instance, managers could use deviations from allegedly depressed market values to avoid losses and impairments. Judging from evidence in other areas in accounting (such as: loans and goodwill) as well as the savings and loans crisis, this concern should not be underestimated. Thus, standard setters and enforcement agencies face a delicate tradeoff (between contagion effects and timely impairment).

Fourth, we emphasize that a return to historical cost accounting (HCA) is unlikely to be a remedy to the problems with fair-value accounting. HCA has a set of problems as well and it is possible that for certain assets they are as severe, or even worse, than the problems with fair-value accounting. For instance, HCA likely provides incentives engage in so called “gains trading” or to securitize and sell assets. Moreover, lack of transparency under HCA could make matters worse during crises.

We conclude our article with several suggestions for future research. Based on extant empirical evidence, it is difficult to evaluate the role of fair-value accounting in the current crisis. In particular, we need more work on the question of whether market prices significantly deviated from fundamental values during this crisis and

more evidence that fair-value accounting did have an effect above and beyond the procyclicality of asset values and bank lending.

2. Fair-value accounting: pros and cons

Under the historical cost regime, shortsighted firms find it optimal to sell assets that have recently appreciated in value, since booking them at historical cost understates their worth. Despite a possible discount in the secondary market, the inertia in accounting values gives these short horizon firms the incentives to sell. Thus, when asset values have appreciated, the historical cost regime leads to inefficient sales.

A remedy to the inefficiency in the historical cost regime would be to shift to a fair value regime where asset values are recorded at their current transaction prices. This is only an imperfect solution, however. When markets are only imperfectly liquid in the sense that sales or purchases affect the short term price dynamics, the illiquidity of the secondary market causes another type of inefficiency. A bad outcome for the asset will depress fundamental values somewhat, but the more pernicious effect comes from the negative externalities generated by other firms selling. Under a fair value regime, the value of my assets depends on the prices at which *others* have managed to sell their assets. When others sell, observed transaction prices are depressed more than is justified by the fundamentals, and exerts a negative effect on all others, but especially on those who have chosen to hold on to the asset. Anticipating this negative outcome, a short-horizon bank will be tempted to preempt the fall in price by selling the asset itself. However, such preemptive action will merely serve to amplify the price fall. In this way, the fair value regime generates endogenous volatility of prices that impede the resource allocation role of prices.

Fair-value accounting is a way to measure assets and liabilities that appear on a company's balance sheet. IFRS 13 “Fair Value Measurement” defines fair value [7] as “*the price that would be received to sell an asset or paid to transfer a liability in an orderly transaction between market participants at the measurement date*” - that

is, an *exit price*. When quoted prices in active markets for identical assets or liabilities are available, they have to be used as the measurement for fair value (Level 1 inputs). If not, Level 2 or Level 3 inputs should be used. Level 2 applies to cases for which there are observable inputs, which includes quoted prices for similar assets or liabilities in active markets, quoted prices from identical or similar assets in inactive markets, and other relevant market data. Level 3 inputs are unobservable inputs (e.g., model assumptions). They should be used to derive a fair value if observable inputs are not available, which is commonly referred to as a mark-to-model approach.

Fair value is defined similarly under US GAAP as the amount for which an asset could be exchanged, or a liability settled, between knowledgeable, willing parties, in an arm's length transaction. In determining fair value, IFRS make similar distinctions among inputs as FAS 157 “Fair Value Measurements” [9]: Quoted prices in active markets must be used as fair value when available. In the absence of such prices, an entity should use valuation techniques and all relevant market information that is available so that valuation techniques maximize the use of observable inputs (IAS 39). It is recognized that an entity might have to make significant adjustments to an observed price in order to arrive at the price at which an orderly transaction would have taken place.

Under IFRS, fair values are most frequently used for financial assets and liabilities. But even for financial assets and liabilities, there is a mixed attribute model with a multitude of rules stipulating that some items are reported at fair value and others are reported at historical cost. Moreover, unrealized gains and losses of items that are reported at fair value may or may not affect net income, depending on their classification. Few dispute that transparency is important. Proponents argue that fair values for assets or liabilities reflect current market conditions and hence provide timely information, thereby increasing transparency and encouraging prompt corrective actions. But the controversy rests on whether fair-value accounting is indeed helpful in providing transparency and whether it leads undesirable actions on the part of banks and firms. Opponents claim that

fair value is not relevant and potentially misleading for assets that are held for a long period and, in particular, to maturity. That prices could be distorted by market inefficiencies, investor irrationality or liquidity problems and fair values based on models that often are not reliable. Fair-value accounting contributes to the procyclicality of the financial system.

3. The choice between fair value and historical cost accounting

In the accounting literature the choice between fair value and historical cost accounting is one of the most widely debated issues. While the debate dates back to the 1990s it is still unsettled. One impediment to moving the debate forward is the lack of evidence on the choice between the two accounting practices, when the choice is determined by market forces rather than regulators. We exploit a quasi-experiment embedded in the recent mandatory adoption of the International Financial Reporting Standards (IFRS) to study the “market solution” for the choice between historical cost and fair value accounting methods. Our approach follows that private markets often differ from regulators in their accounting method choice.

We consider that our work has a number of advantages. First, unlike most other accounting standards, IFRS provides a free choice between fair value and historical cost accounting for non-financial assets. The second and more important advantage of the current setting is that IFRS requires ex ante commitment to one of the two accounting policies. It is, ex ante, in management's interest to limit the scope for future opportunistic actions, e.g., earnings management. Therefore, managers have stronger incentives to respond to market demands and commit to the accounting treatment that maximizes the value of the firm, i.e., is more efficient.

In our research we contribute to the debate over fair-value accounting by adding benefits of fair value accounting for non-financial assets such as increased value relevance and information content, reduced information asymmetry, and increased comparability. Our findings suggest that the choice to use fair value is not random and

occurs when benefits outweigh the costs. Yet, our evidence suggests that the vast majority of managers find the net benefits from fair value accounting to be rather limited. Indeed, our evidence is consistent with opportunistic revaluations of non-financial asset documented in settings where fair value accounting is mandatory.

The choice between historical cost and fair value must be stated in the accounting policy section of the annual report following the IFRS adoption and must be applied consistently going forward (analogous to revenue recognition or inventory valuation methods). A company that chooses to use fair value must revalue assets *every time* the book value is materially different from the market value (IAS 16 and IAS 40). A company that chooses historical cost *cannot* perform upward revaluations in the future. A switch between historical cost and fair value is considered a voluntary change in accounting principles and needs to be justified to auditors, lenders, equity investors, and potentially to regulators. Therefore, the choice between fair value and historical cost in our setting effectively represents an *ex ante* commitment, and as such is unlikely to be driven by earnings management considerations. Indeed, the early studies argued that discretionary revaluations are related to contracting motives – consistent with the finding that leveraged companies in danger of violating covenants are more likely to revalue assets.

High-quality financial reporting standards present in the body of IFRSs, with extensive disclosure requirements and evolved recognition and valuation procedures, expected to increase transparency, diminish information asymmetry, and, consequently, facilitate predictions in order to support investment decisions on capital markets.

4. Revisions of financial statements

In September 2007, the IASB decided to revise the standard IAS 1 "Presentation of Financial Statements" to "aggregate information in the financial statements based on common characteristics", no longer permitted disclosure of performance with other elements, and all information on transactions with owners manifested as such will be presented separately. Revision of

IAS 1 standard was the IASB-FASB convergence program, American influence is obvious accounting, in fact acknowledged even by the IASB. Review introduced a new financial statement, statement of comprehensive income. Which summarizes the income and expense recognized in profit or loss and on those recognized directly in equity, reporting such information on the overall performance of the entity. According to IAS 1 revised standard, the statement of changes in equity. Submit only information on changes in equity as a result of transactions with owners. Standard revised IAS 1 to assess the overall performance of an entity by calculating the total comprehensive income. Defined as "change in equity during the period arising from transactions and other events, other than those changes resulting from transactions with owners which manifests itself as such" (revised IAS 1). Basically, total comprehensive income is calculated by the same logic IAS 1 standard announced by the last review as the "total recognized income and expense." Total comprehensive income comprises all components included:

- Profit or loss, and in
- Other items of comprehensive results.

Other comprehensive income are defined as items of income and expense (including reclassification adjustments related) are not recognized in profit or loss as permitted by IFRS norm.

Components of other comprehensive income include:

- changes in revaluation surplus (according to standards IAS 16 "Intangible assets" and IAS 38 "Intangible Assets");
- actuarial gains and losses related to defined benefit plans recognized in accordance IAS 19 "Employee Benefits";
- gains and losses arising from translating the financial statements of foreign operations (in accordance with IAS 21 "Effects of changes in foreign exchange rates");
- gains and losses on revaluation of financial assets available for sale (in accordance with IAS 39 "Financial Instruments: Recognition and Measurement");
- the gain or loss on the hedging instrument that is determined to be an effective hedge (in accordance with IAS 39 "Financial Instruments: Recognition and Measurement").

Reclassification adjustments for the amounts that were recognized as other comprehensive income elements in the current and prior periods reclassified to profit or loss during the period.

5. Overall performance reporting

According to the revised standard IAS 1, company performance may be reported:

(a) in a single statement: statement of comprehensive income, or

(b) in two financial statements:

- Profit and loss of the components of profit or loss of the period, and

- Statement of comprehensive income that begins with profit or loss reporting period and of the components included in other comprehensive income. For clarity, in the following, we call this form of presentation simplified format. At minimum, the statement of comprehensive income includes the following elements in place:

(A) revenue;

(B) the cost of financing;

(C) share of the profit or loss from associated companies and joint ventures accounted for using the equity method;

(D) income tax expense;

(E) a single amount includes the sum of: 1) gain or net loss (after tax) from discontinued operations and 2) gains or losses (after tax) recognized at fair value less costs to sell or on the disposal of assets or groups of assets failure constituting the discontinued operation;

(F) the result of the exercise;

(G) each component of other comprehensive income classified by nature (excluding amounts in (h));

(H) the other comprehensive income of associated companies and joint ventures accounted for using the equity method;

(I) total comprehensive income.

6. Reporting information on other comprehensive income

Before the review in September 2007, Standard IAS 1 does not specify the manner of reporting tax related items of income and expense recognized directly in equity, companies must be guided by the provisions of IAS 12 standard and after examples provided in the Implementation Guide of old IAS 1 standard.

Thus, according to Standard IAS 12 "Income Taxes", current tax and deferred tax relating to items that were recognized directly in equity must, in turn, be charged or credited directly to equity. And the examples of preparation of statement of changes in equity included in the standard application guide before last revised IAS 1 is shown the line item: Tax on items recognized directly to or transferred from equity, suggesting that the items of income and expense recognized directly in equity shall be presented before the tax effect and the amount of income tax relating to those items to be presented globally. Unlike its predecessor, the revised standard IAS 1 states that an entity shall disclose the amount of income tax relating to each component of other comprehensive income, including reclassification adjustments relating to or in the statement of comprehensive income (or in the "simplified" if drawn) or in the notes. Also revised standard IAS 1 clarify that an entity may present components of other comprehensive income either:

(A) a net tax effects, or

(B) the gross value (before tax effects) with a total amount of income tax relating to those components.

Revised IAS 1 makes a clear conceptual boundary adjustments for reclassifications, insisting on their turn, prevents falls in the category than adjustments that lead to a reclassification of other comprehensive income to profit or loss. The adjustments for reclassifications can be generated only by the rules of IAS 21 and IAS 39, such as the sale of foreign operations or derecognition of a financial asset available for sale leading to reclassify a component of other comprehensive income to profit or loss. Instead, standards IAS 16, IAS 38 and IAS 19 can not generate adjustments for reclassifications for other comprehensive income items recognized in accordance with these standards can not be reclassified to profit or loss.

For example, the revaluation surplus recognized directly in equity according to standard IAS 16 can be transferred to retained earnings when the asset sale or the extent of its use and depreciation, but this transfer is done without affecting profit or loss.

Fair value accounting overcomes price distortions by extracting the information conveyed by market prices, but in doing so, it also *distorts* this information. The choice is between relying on obsolete information or

the distorted version of current information. The ideal of having an undistorted, true picture of the fundamentals is unattainable.

7. Conclusions

Fair-value accounting recognizes losses early thereby forcing entities to take appropriate measures early and making it more difficult to hide potential problems that only grow larger and would make crises more severe. But this benefit gives rise to another set of tradeoffs. Fair-value accounting introduces volatility in the financial statement in “normal times” (when prompt action is not needed). Full fair-value accounting can give rise to contagion effects in times of crisis, which need to be addressed – be it in the accounting system or with prudential regulation. In our view, it may be better to design prudential regulation that accepts fair-value accounting as a starting point but sets explicit counter-cyclical capital requirements than to implicitly address the issue of financial stability in the accounting system by using historical costs. It is an illusion to believe that ignoring market prices or current information provides a foundation for a more solid financial reporting system.

We need to make more progress on the question of whether fair-value accounting did in fact contribute to the financial crisis through contagion effects. At present, there is little research that would answer or even directly speak to this question. Fair-value accounting did not cause entities failures because the fraction of assets reported at fair value was small in most cases, and in those cases where the fraction of fair-value assets was larger, the share price reflected even higher losses than were reported by the entities. While this argument and the accompanying evidence point to real losses as the source of entities failures, they do not provide convincing evidence that there was no contagion. The failure of some companies could have increased market illiquidity, which in turn may have spilled over to other banks via fair-value accounting. Moreover, it is tricky to use companies' share prices as evidence that fair-value accounting did not have any negative effects for entities with a large fraction of fair-value assets since the share price may already reflect the negative real effects of fair-value accounting.

Abstract

The evolution of accounting as social practice is linked to human evolution as an economic entity. The accounting as a system as it is today, is the result of a long historical process, during which it was transformed from a simple registration technique of trade into a means of control and provision, and then into an instrument of management and information provider for a wide range of users, from management to shareholders and external collaborators of the company, as a basis for decisions-making related to the unit.

Keywords: accounting language, accounting science, accounting technique, accounting art

J.E.L. Classification: M40

1. Introduction

Over time, the definition of accounting has been closely aligned with the development of knowledge in this field, but also with the social, economic and cultural context in which this knowledge occurred. Each time, however, researchers have encountered difficulties to define it only by a single meaning.

Accounting evolution has generated heated controversies about its status. In the face of these controversies and many attitudes of thinking took place and continues today a dispute “To what extent accounting can be considered art or science, technique or social game, communication language or genuine social good?”.

In the EDRL (D.E.X.) accounting is defined as: “all registration operations based on rules and special regulations, all movement of funds and materials in an institution; the booking; or the science that deals with the theory of these operations” [12].

If we make a summary of the various concepts relating to the status of accounting in the light of the nature of its state, we distinguish the following meanings:

- accounting as art
- accounting as a technique
- accounting as language
- accounting as a science.

2. Accounting as art

Since 1514 accounting is considered as art by Luca Paciolo, later in 1870 by Francesco Marchi and in the Romanian literature, professor Theodor Stefanescu consider the accounting as art, and then he defines it as the “science which teaches us the art of uniting a house trade accounts or any other public houses which manage funds” [11].

Over time, other Romanian professors take in their work definitions of French literature that considers accounting “the art to record and systematize the monetary value of commercial transactions and financial events, to issue synthesis accounting documents and interpret the results” [2].

The Americans, by the American Institute of Certified Public Accountants (AICPA) also considered in 1941 the accounting as the art of recording transactions, events and outcomes with financial character in a summary form and in cash in order to be

interpreted, and in 1980 they completed and formulated this opinion concluding that accounting information is the support of economic decision development in an economy entity.

In the aesthetic sense, the notion of art cannot be applied in accounting. We can speak though about an “art” of accounting to the extent to which, thereby, we understand a human activity that requires skill and some knowledge.

In the EDRL (D.E.X.) art is defined as “a human activity aiming to produce some aesthetic values and using ways of expression with specific nature; all works (from an era, a country etc.) belonging to this activity” or “a particular skill in an activity; ability, mastery” or “occupation that requires much skill and some knowledge” [12].

The definition of accounting as art is rooted in the socio-historical context of the emergence of double-entry accounting, thus in its inception. At that time, the accountants were organized in professional associations with conditional access, which made the accounting profession to be considered superior to all others. In Italy at that time, the accounting profession was regarded as superior to all others, and double-entry art secrecy contributed to growing the prestige these professionals enjoyed. Here is what mentioned the author of the first double-entry accounting work, printed in German in 1549: “I do not want to say that before me weren’t good accountants as they are today, but they keep the accounting in secret and they do not give it to daylight or do not bother to show it to others” [4].

The necessary knowledge for bookkeeping are becoming very required by an economic environment in training, based on the seeds of capitalism, which converts them into an “art of accounting” as a specific area along with other art of the time.

Skills and abilities necessary for bookkeeping allowed the qualification of accounting as art. However, we believe that the correct meaning of this approach is rather the same kind of reasoning applying to the “art of gastronomy”, “sports art” or “art craft” where genius or grace alone is not sufficient or decisive, but it is also required a knowledge base, skills, ability, technique and social utility [9].

Thus viewed things, we cannot talk about accounting as art but the art of accounting, between the two concepts there are essential differences even if both are creations of the human spirit. Professor Niculae Feleaga, competent field researcher, presents in his work “Taming the accounting jungle” the reasons underlying the existence of accounting [7]:

- because there are commercial trades between human beings or companies;
- because human, financial, natural and technical resources are limited;
- because there are third parties interested in financial information produced by the companies.

The economic reality in which individuals and companies live is represented in a synthesis and abstract accounting mean. But like any representation of reality, human, professional mastery, put a different emphasis on this reality. It is also one of the reasons that explain the seemingly inaccessible to amateurs in this area, the authority that experts in accounting and adjacent areas (taxation, finance) have in organizations and social recognition through the income they get from practicing accounting [10].

Gradually, as the knowledge necessary to practice the profession are more elaborate, the accounting is increasingly defined as an art and a science, as results from some definitions: accounting is “the science and art of keeping the accounts” (Francesco Marchi, 1870) or later, in the early twentieth century, Rene de la Porte considered that: “accounting is a science, and only its technique is an art”.

3. Accounting as a technique

In French literature, authors of studies devoted on the field and in particular Bernard and Esnault and Cristian Hoaran considered the accounting as a “quantitative technique for collecting, processing and analyzing information on the legal and economic events in the life of the enterprise” [1].

In the course of history, the status of the accounting technique, in its evolution corresponding to various social practices, is recognized as a practical part of the theory and not a simple routine, such as simple calculations or some workbooks.

It was always felt the need for a rigorous system of accounting procedures, goals and principles for the practice of accountancy.

If at the beginning the organization of simple operations of input and output of values was enough, in time, the reality has imposed the need to record and trace all patrimonial mutations.

Thus, after generalizing the double-entry bookkeeping, the accounting seeks to record the origin, source of funds that went in, supplied the patrimony and their use regardless of their form or nature.

Some authors consider the accounting a management technique. In general, the term “technical” means a set of processes belonging to an art or a craft, used to obtain a specific result. If we limit accounting only to the records it seems like the accounting responds to this definition. But we must keep in mind that by technique we also understand applying theoretical knowledge. In this latter sense, the technique is an inherent part of science.

The name of “quantitative technique” given to accounting means that it performs the measurement, meaning number expression in natural standard (physical), but most of all, value standard of the economic reality.

Some authors consider that the accounting technique mainly consists in applying the principle of double entry bookkeeping, defining accounting as a technique of observation and control of an enterprise activity, which is based on continuous and correlated recording due to double entry principle, the set of internal and external financial flows of the enterprise. The crisis in the years 1929-1933 was not only a financial and economic crisis but also a crisis of financial information. Investors were in the uncomfortable position of being very poorly informed. The “art”, meaning the force of judgment of professional accountants, as a result of accounting technicalities, was insufficient to meet the new economic and social environment conditions.

After the EDRL (D.E.X.), technique means “all procedures employed in practicing a profession, a science” [12].

From this perspective, accounting is really a technique, this status being the most often cited in the literature. Thus: “Accounting is a quantitative technique for collecting,

processing and analyzing information on the legal and economic events in the life of the enterprises” or: “Accounting is a technique that allows the appearance of a business activity and results and, more generally, of an organization”.

4. Accounting as language

In the business world, communication is the knowledge support and accounting can be considered the “formal language of communication”.

The practical side of the accounting language is characterized by the connection that must exist between accounting information communicated, their usage by various stakeholders, and also regarding the control on certain activities or entities, results that influence the decisional process.

The accounting syntax is the set of accounting rules and procedures to be followed to record accounting transactions and to prepare synthesis documents, starting from the symbols that form the accounting vocabulary. The accounting syntax ensures the organization of the accounting structure.

Semantics of the accounting language deals with the meaning of the signals transmitted by the accounting and refers to the correspondence between the object described – the organization and the model it represents – the accounting.

The practical aspect of the accounting language refers to communication, through accounting information, between different users of accounting.

Thus, the accounting syntax is grouping rules, methods and procedures used to record operations, to collect and process information, to prepare, present and publish summarized documents based on symbols that form the accounting vocabulary. The symbols of accounting language are: debt, credit, assets, liabilities, turnover, balance, position, net position, revenues, expenses, debtors, creditors, parties etc.

The accounting syntax has the role to organize the accounting structure such as grammar organizes natural language. The accounting semantics gives meaning to signs transmitted by accounting, ensuring the correspondence between the real world (economic, social environment etc.) and its reflection (accounting).

The practice of accounting language is directly related to accounting disclosure and their use by beneficiaries (managers, owners, third parties, tax authorities).

The status of the accounting language is generalized once with the output of accounting information from the organizational boundaries, with its address to third parties. The common language of accounting is based on [6]:

- precise definition and terminology;
- common assessment methods;
- uniform rules of operation of accounts;
- summarized documents presented by an identical manner.

The accounting language is precise, concise and complete, but also has limits. Those who operate in the market of accounting information can communicate without any problems because the information is transparent.

5. Accounting as a science

In the EDRL (D.E.X.) science is defined as “all systematic knowledge about nature, society and thought; all the knowledge in a particular field of knowledge” [12].

Changes in economic and social environment make the national accounting systems dependent on this environment and its evolution. Postulates, principles and accounting rules that confer the character of science are voided of stability and are not based on objective, verifiable relations. This makes it difficult to define accounting as a science, but it is certain that it is the subject of scientific research.

Specialists studying the accounting theory have not reached a consensus and could not yet define a theory to be universally accepted. On the other hand, there are theoretical studies that have not yet found their practical application [10].

- There are currently four major families of accounting theories:
 - descriptive and inductive theories, that have succeeded only an inventory of the problems;
 - descriptive and deductive theories, that have had the ambition to describe an orderly practice;

- normative and inductive theories designed based on the observation of practices considered to be the most satisfactory and presented as reference (are included in this category the generally accepted accounting principles);

- normative and deductive theories designed based on the objectives assigned to accounting and also presented as references.

Other authors are firm in asserting that accounting is a science because it has elements of science, namely: the domain which is the object of the research, the method of research used and its utility in the economic and social life.

Accounting has a language, an object and a research method of the object that defines it to other sciences:

The object of study of the accounting is the organizations’ patrimony, the economic processes (supply, manufacturing, sales) that occur in organizations, sources of origin of money and material items and the results of the activity [5].

The research method of accounting is based on its own methods: balance sheet, account, trial balance.

The usefulness of accounting in the economic and social life is determined by the need for organizations to know accurately and in a timely manner the size and structure of assets, activities, results and the interests of third parties (associates, shareholders, partners) to have accurate information about the situation of tax bodies and organizations in order to establish obligations due. As a science, accounting is part of the system of economics [9].

6. Conclusion

Recently, some accounting theorists have brought in discussion other possible approaches.

In practice, the use of accounting information in economic decision-making processes often generates conflicting interests among different categories of users (shareholders, unions, managers, state, customers, creditors, suppliers and so on).

Thus, these conflicts between different categories of users of information accounting distort the truth, leading to a situation where accounting is a “social game”.

The practice has also proved that the economic life discipline was achieved by accounting functions through the rigor required by specific accounting methods and procedures. Starting from the fact that the order, rigor, discipline and morality in economic life are given by accounting, determined that for human society accounting is allocated the role of “social good”.

Another approach considers accounting as a techno-science, meaning a technique fed not only by past knowledge, generated by practice, but also by the results of the research.

Another approach considers accounting as an information system because it has all its features. An information system is defined as “an organized grouping of resources (equipment, software, personnel, procedures) that allow the acquisition, processing, storage, communication of information (in the form of data, images, texts etc.) within the organizations”. Accounting is practiced by people, involves the use of tangible and intangible assets (it is in symbiosis especially with the new information and communication technologies) and from technical point of view, it consists of acquiring, storing and disseminating information.

According to the General Accounting Plan in France, accounting is “a system of organizing financial information which allows identifying, sorting, recording digital databases and presenting situations that reflect a true and fair view of the assets, financial situation and results of the entity at the closing date”. As a result, many theorists and practitioners believe the accounting is, first of all, a simple system of information, but still having its specificities. The accounting is the only information system producing an overall representation, a global model of the enterprise.

Abstract

In a society of free people, obviously, it cannot be proceeded in the same mode, and as result, the economising must be rewarded through the possibility of obtaining expendable goods, destined for later use, or capital goods, destined for productive use.

In liberty conditions, there does not exist, a saving without rewards, and the reward cannot exist if the goods that it contains, indifferently if they are expendable or capital goods, do not become the private property of the person who makes the savings. The person makes savings because he has a purpose, which he freely chooses: to improve his living conditions. He can wish that for himself or others, but certainly not for strangers, or the state.

Key words: savins, inflation rate, interest rate, population

JEL Classification: E2, E22

1. Introduction

Analyzing the phenomenon of saving people in Romania (in the present thesis) covers the period January 1994 - September 2012, following the effects of inflation released, the deposit rate and the average monthly salary savings. Therefore, we considered multifactor regression model of the form:

$$Y_t = \alpha + \sum (\beta_i * X_{it, i=1, \dots, p}) + \varepsilon_t$$

Where:

- Y_t is the dependent variable;
- α coefficient constant term;
- β_i independent variables coefficients;
- X_{it} independent variables;
- ε_t random variable;
- p number of variables as the regression is;

Aims at quantifying the link there, on the one hand, the quantity of savings of households (economically dependent variable or outcome) and, on the other hand, inflation and interest outward.

2. The impact of inflation and saving

Modeling the impact of inflation and the saving in interest liability is based multifactor regression model of the form, where is the dependent variable - E (household savings), the coefficient constant term, the coefficients of independent variables, independent variables - II (inflation rate - I, the interest rate liabilities - R), random variable, then the number of variables is regression (1), and t the time (January 1994 - September 2012).

The model will be:

$$E = \alpha + \beta_1 * I + \beta_2 * R + \varepsilon$$

Given the fact that generally most economic phenomena and processes are linear, we chose for our country if the linear regression model using the software package EViews 7.1.

The savings of the population has significant growth potential, a situation that requires a more detailed analysis in terms of

influencing factors. If a stable market economy, the savings are largely predictable trajectory, in a country in transition; the amplitude varies with a much higher, driven by many factors, many of whom were subjective. In Romania, after 1990, the evolution of savings was basically determined by the wage inflation rate, banks' interest rate of consumption, of the exchange rate, rotation speed etc. of money.

Thus, below we propose to quantify the econometric relationship between the main factors (inflation rate and deposit rate) and the savings in the 1994-2012 period and to analyze, based on simulations, their impact on growth, relatively slow, the saving process in Romania.

The inflation is a phenomenon much more profound than the increase of prices, alternating the ensemble of the economic mechanism in more ways: a) the forming of prices; b) income repartition; c) economic decisions; d) saving strategy;

In what concerns the influence of inflation on the saving process in the household sector, we can say that in the inflationist period, all the goods, whose value grows slower than the general level of prices, are losing value. In other words, the population's buying power has diminished. Connected with the influence made by the price factor on the saving process it must be cleared out that the stability of prices stimulates savings, and the increase of prices lowers it, thus it feeds the opinion that it is not worth saving money because they lose value, losing their buying power.

Situations can intervene, however, when the lowering of prices exercises a contradicting action on the population's savings. Thus, the more substantial lowering of prices on certain goods, can lead to the situation of not being necessary to save money for their purchasing, being able to purchase them from the current income.

As consequence, a high rate of inflation annihilates the backup way function of currency and implicitly annihilates the saving tendency of the population, in the frame of a market economy. Thus, we can say that the population's saving process is a function resembling:

$$E = f(I)$$

where: $E = \text{saving}$

$I = \text{inflation rate}$

meaning:

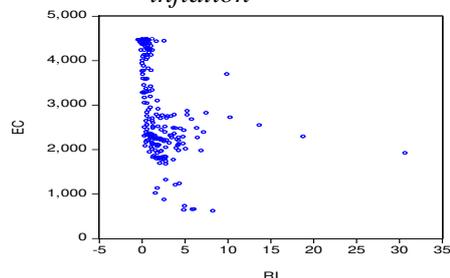

$$E = C(1) + C(2) * I$$

Thus, the inflation hits in the buying power, in the real salary of the population, those more affected being those with low or fixed incomes; in other words, the inflation destroys the population's savings made from the use abstinence.

In our country's case, in the January 1994 – September 2012 period, the statistic data took from the Annual Reports or BNR 1994-2012 and ran through the software package EViews 7.1 have demonstrated an indirect link between the inflation rate and the saving process, link that cannot be considered, representative. The question is posted “Why does the inflation rate influence savings only in a proportion of 15,6%?” The answer can be found in the content of the saving notion, process that is influenced by numerous factors, like income, interest rate, consume, and exchange course and so forth.

To observe the nature of dependency between the two variables we have drawn in the following diagram three graphics:

Figure 1- Correlogram for saving and inflation

Source: data gathered from the BNR reports and ran through the software package EViews 7.1

Table 1 - Linear regression

Dependent Variable: EC				
Method: Least Squares				
Sample: 1994M01 2012M09				
Included observations: 225				
Variable	Coefficient	Std. Error	t-Statistic	Prob.
RI	-143.0089	21.89892	-6.530410	0.0000
C	3252.980	79.19198	41.07715	0.0000
R-squared	0.160538	Mean dependent var		2963.880
Adjusted R-squared	0.156773	S.D. dependent var		1072.595
S.E. of regression	984.9356	Akaike info criterion		16.63188
Sum squared resid	2.16E+08	Schwarz criterion		16.66224

Log likelihood	-1869.086	Hannan-Quinn criter.	16.64413
F-statistic	42.64626	Durbin-Watson stat	0.114493
Prob(F-statistic)	0.000000		

Sursa: EViews 7.1. calculations

The model is not a representative one for describing the link between the inflation rate and saving rate, link which can have the following form.

The equation (model) which describes the link between savings and inflation rate is:
 $E = 3252.980 - 143.0089 * I$

In conclusion there can be observed that a modification with a percentage of the inflation rate determines a modification with 1,43 lei of the saving. So, the inflation as a economic unbalance state is negatively preponderant having numerous consequences on the population:

- the decrease of the population's buying power;
- the incline towards consumption is stimulated;
- the incline towards saving is discouraged;

3. Correlation between interest rate and saving

Correlation between growth and increased interest income from savings made, highlight the link directly proportional: if interest rates increase saving becomes more attractive, but at the same time, becomes less necessary. Thus:

$$E = f_2(R)$$

Where $R = \text{deposit rate}$ $E = \text{household savings}$

If $f_2(R) = c_1 + c_2 * R$ then

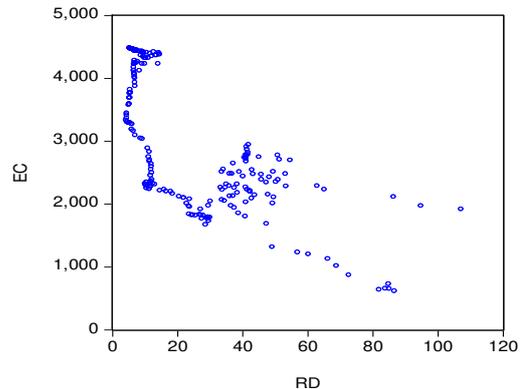

$$E = c_1 + c_2 * R$$

In Romania deposit rate affects the population's savings rate of 43.85% which can be regarded as a significant influence. But unfortunately, our country is a country where some people have extraordinary amounts and therefore have a seasonal savings. For example, even if banks offer attractive interest rates the world has nothing to save if we think they need months to make supplies of winter or to start a new school year.

In other words the interest rate causes a change in the same sense of volume savings. Residual values, estimated current and

corresponding dynamic model are presented in the following chart:

Given the values obtained from testing, we consider representative link that describes the dependence between deposit rate and savings related will have the following form:

$$E = 3858.329 + 36.69619 * R$$

In conclusion it is noted that a one percent change in interest rates causes a change in savings of 36,69 Lei (if the interest rate increases by one percent then the savings will increase to 36,69 lei and vice versa). So individuals do not save for the pleasure of holding idle cash, but they save to make placements paid through an interest rate that they increase their future wealth. Populations

being the victim of illusions money, no interest in purchasing power than that the interest rate. They take into account the real interest rate, nominal interest rate that is possibly correct to remove the depreciation due to inflation. It follows that saving is an increasing function of real interest rate.

4. Correlation between inflation, interest rate and household savings

If we analyze the correlation between inflation, interest rates and household savings is observed that both (the inflation rate and deposit rate) influences the rate of 51,68% savings (see table below):

Tabel 3 - Econometric test results describing the relationship between inflation rate and savings deposit rate

Dependent Variable: EC				
Method: Least Squares				
Sample: 1994M01 2012M09				
Included observations: 225				
Variable	Coefficient	Std. Error	t-Statistic	Prob.
RD	40.26826	3.114403	-12.92969	0.0000
RI	-38.55046	21.72488	1.774484	0.0774
C	3867.465	76.49935	50.55552	0.0000
R-squared	0.521142	Mean dependent var	2963.880	
Adjusted R-squared	0.516828	S.D. dependent var	1072.595

F-statistic	120.8013	Durbin-Watson stat	0.053338	
Prob(F-statistic)	0.000000			

Source: calculations EViews

Saving is the prerequisite for the existence of positive real interest rates (over inflation). Based on the data processed using

the linear model can plot statistical observations:

- As seen most influence the interest rate and saving the same direction, followed by volume inflation, if it is the opposite effect. A low inflation, positive real interest rates will lead to greater savings.
- Following tests carried out using EViews 7.1 package we can say that the model is representative and will have the following form:

$$E = C1*I + c2*R$$

$$E = 3867.465 - 38.55046*I + 40.26826*R$$

5. Conclusions

The conclusion that inflation is an important factor encouraging people under the form of savings deposits, but also a major disincentive. If potential depositors want to preserve the purchasing power of saving money means that there is a saving incentive in the form of deposits, savings reverse this discouragement arises from the fact that people prefer alternative saving rate when bank liabilities is lower. We note, however, that inflation is a causal factor in the process of saving deposits form.

Considerations Concerning the Quality of the Services Provided by Accounting Professionals in Romania

Pașcu Ana-Maria

“Alexandru Ioan Cuza” University, Faculty of Economics and Business Administration,
Iași

pascuanamaria26@gmail.com

Abstract

The position of the accounting professional implies great responsibility because of the services provided and, irrespective of the country where they come from or of the professional body to which they belong, they perform an activity specialized in accounting, financial consultancy, audit, evaluation, and liquidation. Given the current economic conditions, an “over-certification” of their activity is required. Under these circumstances, quality in audit must provide the users a better perception on the quality of the supplied services, as well as the guarantee of harmonizing the professional behaviors of the members. The purpose of this study is to present, based on the activity reports of the professional bodies in Romania, the current status in the implementation of quality in audit and in the accounting profession.

Key words: accounting professional, quality of accounting services, quality in audit.

J.E.L. classification: M41, M42.

1. Introduction

Insuring quality in the audit profession implies a succession of coherent measures to be implemented in all the stages of this approach.

In order to make their activity more efficient, the accounting professionals must know and apply the appropriate norms and procedures for meeting all the objectives in conditions of performance and high quality. Punctually, we are concerned with the regulations of: the national ethics code of the accounting professionals, the rules

concerning the continuous professional training of financial auditors, the norms concerning the quality assurance system, the norms and procedures for revising the quality of financial audit, the norms concerning documentation in audit, the norms for reporting audit, and other norms for regulating this profession. The mentioned regulations are not aimed at suppressing the initiative and fair judgment of the auditor. However, if the auditor considers it necessary to stray from the usual audit techniques, they must prove the need to do so and to show that the approach they chose is closer to fulfilling the objectives of the audit mission [1]. At the same time, it is absolutely indispensable to be familiar with the International Audit Standards (ISA) and with other professional standards (ISRS, ISAE, the Internal audit standards, etc.).

According to the *Statements of Membership Obligations (SMO)* issued by the International Federation of Accountants (IFAC) in April 2004 and revised in November 2006, **SMO 1: Quality Assurance** presents the conditions to be met by all bodies that are IFAC members, in revising the quality assurance programs for their members, in fulfilling the audit commitments of the financial statements.

Reaching true excellence in audit requires creating an institutional culture where quality is a fundamental value reflected in the leadership competences of the management and in the relationships with other institutions [2]. Quality control becomes essential in planning, executing, and reporting the audit mission. Post-audit checks evaluate if this control improved the efficiency and effectiveness of audit. Moreover, the attention of the providers of accounting financial and audit services must provide the users with information of the highest quality, in compliance with the

provisions of the Green Card of the EC of October 2010, which mentions that “*robust audit is the key to re-establishing the trust of the participants to the market; it contributes to protecting the investors and to reducing the cost of capital for the companies*”.

2. Purpose, Objectives, and Methodology of the Research

In our study, we aim to present some viewpoints in specialized literature that concern quality in audit and in the accounting profession at the national level, as well as to stress the current status of knowledge in what concerns the quality of the services provided by accounting specialists.

We wish to give an answer to the question: *Are there explicit references and a legal frame that concerns assuming and implementing quality in the accounting profession in Romania?*

The research methodology used in performing the study concerns both qualitative and quantitative methods. The quantitative part concerns a study that stresses the approaches taken by professional bodies in Romania in order to improve quality in audit. This study suggests a comparative analysis of the Activity reports of the two professional bodies, CECCAR and CAFR.

3. Valences of the Quality of Financial-Accounting Services from the Perspective of the Two Representative Professional Bodies, CAFR and CECCAR

In Romania, there are two professional bodies that coordinate and implement all the necessary approaches for the financial-accounting and audit activity to be performed according to the International Audit Standards, in compliance with the criteria for high quality.

One of the professional bodies with major incidence on implementing and insuring the quality of the accounting profession is the **Chamber of Financial Auditors in Romania (CAFR)**, as a competent authority that, under the supervision of the *Public supervision body*, performs revisions in order to *insure the quality of the financial audit activity*, since its creation.

Within CAFR, an important function is

fulfilled by **The Department of Monitoring and Professional Competence (DMCP)**, a *specialized structure that performs revisions in order to insure quality in the financial audit activity*. This structure also concerns other activities and professional services performed by financial auditors, natural persons and audit companies. As a result, all financial auditors that are members of the Chamber, natural persons and audit companies, are the object of a *quality assurance system*. This approach is organized as an independent system, according to the provisions of OUG 75/1999 concerning the financial audit activity, republished, with subsequent modifications and amendments, and of the Organization and Functioning Regulation of the Chamber. At the same time, it is also required to consider that after OUG no. 90/2008 concerning the statutory audit of the annual financial statements and of the consolidated annual financial statements, all the references to “financial audit” that exist in legislation will be read as references to “statutory audit” [3], when audit is concerned with verifying and certifying the annual financial statements. OMFP 3055/2009 uses the phrase “statutory audit” in art. 5, par.2. The approach is compliant with the changes to the European Directives in audit. As a matter of fact, *financial audit* also includes *statutory audit*, according to Law no. 26/2010 for the modification and amendment of OUG no.75/1999 concerning the financial audit activity.

The inspections concerning quality assurance are performed in compliance with the provisions of the *Norms on revising the quality of financial audit and of other activities performed by financial auditors, approved by the Decision of the CAFR Council no. 168/08.25.2010*.

The activity performed by the Chamber includes several attributions, such as: insuring the implementation of the control system for the activity of the members of the Chamber by scheduling, organizing, and performing quality inspections; monitoring the compliance by the members with the norms of the Chamber and with the International Audit Standards (ISA); reporting the control activity in order to insure quality; monitoring the financial auditors evaluated with lower grades, by

organizing additional annual professional training courses; making suggestions for improving the quality assurance regulations; informing the Professional Behavior and Discipline Department in case deviations from the norms of the Chamber are noticed.

In Romania, it is absolutely required for the members to comply with the quality assurance provisions concerning: the requirements of the *Code of Ethics*, adopted by CAFR through the Decision of the CAFR Council no. 161/04.14.2010; *the provisions of the International Audit Standards (ISA)* and of other *professional standards (ISRS, ISAE, the Internal audit standards)*; the provisions of the *Norms concerning the revision of the financial audit activity and of other activities performed by financial auditors*, approved by the Decision of the CAFR Council no.168/08.25.2010; the procedures concerning *the revision of the financial audit activity and of other activities performed by financial auditors*, approved by the Decision of the CAFR Council no. 182/09.22.2010; the procedures included in the *Guide for quality in audit of March 2010*; compliance with any other *regulations issued by the Chamber*, relevant in applying the revision procedures for the quality of the activity (continuous training, computing and paying the membership fees, etc.).

The second professional body with a significant incidence in insuring the quality of professional services is *The Body of Accounting Experts and Certified Accountants in Romania (CECCAR)*. It manages the accounting profession in Romania, watching and taking actions for the Romanian accounting professionals to provide the stakeholders only high quality financial-accounting services, which would meet the requirements of the market and of the business environment. The fundamental objectives of the Body are focused on: certifying the quality of the services provided by its members, initial training and continuous professional development of the accounting professionals by meeting the demands for deontological behavior. The attributions of the professional body in this context also refer to: granting the right to exert the profession of accounting expert and certified accountant, withdrawing the right to exert the profession of accounting expert and certified accountant, controlling the

competence and morality of its members, and last but not least, *controlling the quality of the services provided by its members*.

A specialized structure of the Body of Accounting Experts and Certified Accountants in Romania is the *Department for Monitoring the Application of Professional Norms and Quality Audit (DUANPAC)*, which makes revisions, according to the law, to insure the quality of the financial audit activity, as well as of other professional activities and services performed by financial auditors, natural persons and audit companies.

The *quality audit* performed by CECCAR refers to the *set of measures concerning the analysis of the ways of organization and functioning of an office, evaluating the application within it of each and every professional norm, including checking the compliance with the member obligations*. This activity is performed both on the office and on each and every accounting professional. Quality audit is based on *five fundamental principles* [4]: universality, confidentiality, adapting audit, partnership, and harmonization.

4. Case Study concerning Quality Assurance through Professional Bodies in Romania

In this respect, we will analyze the activity of the Department for Monitoring and Professional Competence, as well as that of the Department for Monitoring the Application of Professional Norms and Quality Audit, according to the activity reports published by them.

Starting from the previously mentioned theoretical ideas, we notice that, in order to improve the activity performed by financial auditors, the activity initiated in recent years, 2009-2011 by the DMCP members, mainly focused on:

- Creating quarterly and monthly inspection schedules;
- Meeting the strategic objectives of the Chamber concerning the monitoring and guidance of the audits that received scores B, C, or D;
- Complying with Decision no. 44/ March 23, 2005 of the CAFR Council, including
- Other regulation and representation

activities.

According to the Report on the activity performed by DMCP, in the year 2007, 350 financial auditors, members of CAFR, were subject to quality inspections, in 2009 - 303 financial auditors, and in 2010 - 284 financial auditors. In 2011, quality inspections were performed on 423 national financial auditors, members of the Chamber, of which 211 (49.9%) are audit companies and 212, that is, 51.1%, auditors that are natural persons. The auditors inspected in 2011 are 149% compared to the auditors evaluated in 2010 and 139% compared to 2009. We could also notice that most auditors performed financial audit activities. At the same time, quality inspections have been performed on other activities and professional services, corresponding to 319 financial auditors, representing 80% of the total evaluated auditors. Of them, 82 members (26%) performed other missions than financial audit.

We can see that the number of persons that were subject to quality control was increasing, which means that the concern with the importance given to the quality of the accounting profession intensified. At the same time, there was a situation when 19 CAFR members have not been checked, because a financial auditor reported to the Chamber the activity as a UCAPI member; two auditors performed a hot/cold review; six auditors reported their activity erroneously to the Chamber; and 10 auditors were included in the theme action concerning checking the way the activity was performed.

For the same period, DMCP inspectors performed, in 10 audit companies, checks and investigations of aspects mentioned in various notifications of public and regulating institutions. According to art. 24 of the *Norms concerning the control of the quality of the audit activity*, the evaluation is done by the inspection team, in relation to the degree of meeting the verification objectives, which express the way in which the auditor complied with the requirements of the Audit Norms and of the relevant International Audit Standards (ISA). In what concerns the grades given for the fiscal year 2010, in comparison with the corresponding periods in previous years, they show an increase in the percentage for the numbers of A grades and a drop in the C grade given to the inspected

auditors, while the number of auditors evaluated with grades B and D remained constant. To this there contributed, on the one hand, *the higher quality of the activity performed by the members of the Chamber* who were inspected, and on the other, *the impossibility to compare the data recorded for the fiscal years 2009 and 2010, which were affected by abnormal events, such: improvement of the structure of the audit companies inspected in 2010 and influencing the data recorded for 2009*. We mention that the auditors who received grades B, C, and D were constantly monitored and guided in the period 06.20.2009 – 06.20.2010, as a session of compulsory additional courses were was organized in July 16–18, 2010.

The minimum value of the fees collected by audit companies, of 15 lei/hour, was noticed in the year 2011 in the case of an auditor, legal person, whose activity was evaluated with A, corresponding to an audit mission of a contracted value of 2.500 lei, made for a period of time of 180 hours.

The maximum fee of 422 lei/hour, for the year 2011, belongs to an auditor, legal person, evaluated with A, corresponding to a period of 240 hours, reaching a total value of 101.302 lei. At the same time, the largest contract, of 150.000 lei, corresponding to a period of 500 hours, with a value of 300 lei/hours, was that of an auditor, legal person, evaluated with A.

If we look at natural persons, an hourly rate of 316 lei was collected by an auditor, natural person, from Bucharest, for a contract of 56.937 lei, a value obtained in an interval of 180 hours. The highest fee reported by a natural person was 62.070 lei, corresponding to an activity performed over 240 hours, meaning a value of 259 lei/hour.

According to the provisions of Annex 1, chapter VI, letter B, point 36, letter “h” of Decision no. 274 of December 15, 2011, for the modification and amendment of Decision no. 182 of September 22, 2010 for the approval of the Procedures concerning the revision of the financial audit activity and of other activities performed by financial auditors, “until February 15 of each year, the Chamber of Financial Auditors of Romania will publish on its own web site the lean fee resulted from the quality inspections made the previous fiscal year”.

Following the quality inspections

performed by the Department for Monitoring and Professional Competence, for the calendar year 2011, on the audit mission of CAFR members based on the financial statements of 12.31.2009 and 12.31.2010, there resulted a mean hourly fee of: 97 lei/hour.

As for **CECCAR**, it has been performing quality audit activities for over 11 years. In 2008, it had a spectacular growth, receiving particular importance in the general profession management system, by insuring a high standard of the works made by accounting professionals and by raising the users' trust in the activity performed by the professionals.

As a result, the activity of the Department for Monitoring the Application of the Professional Norms and Quality Audit has been very intense recently, the total number of offices audited in 2008 was 2010. A total of 3.624 customer files have been examined, of which: 2.723 files for bookkeeping missions, 263 files for analyzing accounting, 162 files for statutory audit, and 476 files for special missions (accounting expertizes) [5].

In the same time, concerning to the quality of the audit process for legal accounting expertise for 2008, the accounting experts presented, in order to be verified and receive the quality approval for complying with the Professional Standard no. 35 and with the National Code of Ethics for the accounting professionals, 8.291 legal accounting expertise reports from various activity fields, which means a 25% raise compared to 2007, when the number of files was 6.651. We could see that 788 files in the analyzed period took into account the observations made by the quality auditor.

Subsequent analysis showed that this department gives special attention to the aspects referring to quality in the accounting profession, performing an intense activity in this field. The number of verified entities is growing from one year to another, and the results create favorable conditions to performing and developing the accounting profession as a whole.

In the year 2011, responsibility for public interest was again one of the major objectives of the accounting profession, which aimed to insure high quality services supplied by accounting professionals, which is a function of the professional accounting standards, of

personal competences and values, and of regulating systems, since all must be coherent and support each other.

The control of the quality of the professional services supplied was in the foreground of the activities for 2011, for which permanent actions were taken, thus insuring a higher standard of the missions performed for the recipients, contributing therefore to improving the users' confidence in the members of the professional body.

The number of offices scheduled to be audited in 2011 was 2.619, of which 2.341 were actually performed (1,383 natural persons and 958 legal persons), representing a percentage of 89% of the number of scheduled offices. Of these, 2.180 were offices approved by the High Council to be audited, plus 370 offices that received grade C for the year 2009, as well as those that obtained grade D for the year 2010.

Most clients resorted to the members of the Body for accounting services (89.5%), followed from a large distance by requests for legal accounting expertizes (5%), other services that imply knowledge of accounting (1.2%), extrajudicial expertizes (0.7%), financial and fiscal consultancy (0.6%), patrimonial evaluations (0.6%), personnel salary services (0.5%), other types of audit (0.3%), assistance in creating and reorganizing trading companies (0.2%).

The number of files under work analyzed in 2011 in the 2.341 audited offices is 6.532, and in relation to the missions, the situation is as follows: 5.358 files for bookkeeping and services of drawing and analysis of financial statements (82%); 1.174 files for special missions (18%); no files have been examined for statutory audit works. Moreover, the quality auditors also made suggestions for quality classifications of the 2.341 audited offices in the year 2011, which were carefully analyzed by DUANPAC in order to issue Dispositions to the audited offices: for quality class A – no offices were suggested; for quality class B – 1,408 offices, that is, 60%; for quality class C – 791 offices, that is, 34%; for quality class D – 133 offices, that is, 5.5%; for quality class E – 9 offices, that is, 0.5%.

The fact that over half of the audited offices were ranked in quality class B (60%), as well as the fact that a significant percentage was ranked in classes C (34%)

and D (5.5%), is explained because in the organization of the respective offices, the professional standards issued by the body are not appropriately applied.

The measures for reducing the differences, taken by CECCAR, have the following structure: 26.687 recommendations for reducing the differences; 2.341 measures for participation in courses for acquiring the professional and ethics standards; 791 measures concerning performing a new check within maximum 2 years; 142 concerning notifying the council of the branch; 133 measures concerning issuing a new code within maximum 1 year; 9 measures concerning the implementation of a permanent supervision system.

5. Conclusions

Nowadays, society needs more and more certification / attestation services provided by the accounting profession. Considering the importance and complexity of the services supplied by accounting professionals, we believe that quality assurance is an essential condition for obtaining performance. Therefore, *continuous professional training is needed in order to perform a responsible and quality activity.*

Quality is a fundamental parameter for any field of activity. In the case of audit, certified information guarantees the users' trust and, through it, business development. Also, before performing this study, we were wondering if *the accounting profession is regulated enough in what concerns the quality of the activity performed by its active members.* The bodies that manage and coordinate the accounting profession in Romania, respectively CECCAR and CAFR, currently have the human resources, including the necessary regulations that allow optimizing this activity. The compliance with the Code of Ethics and with the professional deontology is also, in our opinion, an essential premise for improving the quality and responsibility of the accounting professional. All these would not be possible without the implementation of *quality control departments in each individual professional body.* We can notice an increase in the number of natural persons or audit offices subject to activity control or to quality audit, from one year to another. This action is

confirmed by *giving grades (A, B, C, D), which, in our opinion, lead to better quality management.* Also, we can notice that the final dispositions issued by the professional bodies are communicated to the offices for reducing the deficiencies in the established terms. Therefore, in a specific activity, irrespective of its nature, nothing can be worse than lack of control and its actions.

We can say that the accounting profession in Romania, through the two professional bodies that govern it, takes all the approaches, starting from establishing the regulations according to the international norms, imposing their application and the compliance with them by all its members, to the verification of the activity performed by them.

Abstract

The theme of our research is related to the new type of relationship between financial audits (statutory) and unique regulation of financial markets in Romania. Recent developments in the regulation of financial markets require a new perspective on the role and place of financial audit in Romania. The main elements of our study are: the relationship between the audit committee and regulatory authority; quality of financial reporting for financial market entities. In this case, financial regulation can coexist with compliance audit. For those synergies to be real we felt that our research must answer the questions on the link between financial auditor independence and audit committee role with financial reporting quality. Our research results show the high importance of the audit committee in ensuring the high quality of financial reporting in the financial markets and seeks to identify potential points of conflict between audit conservatism and unique market regulation.

Keywords: audit conservatism, financial markets, regulatory authority, audit committee, financial reporting.

JEL: M42, M48

1. Introduction

The achievement of this research is the result of the emergence of a regulatory entity for financial markets in the institutional landscape of Romania. This entity will regulate the capital market, insurance market and private pensions market, while money

market will remain under the authority of the central bank. Under these conditions new elements occur that redefine the relationship between financial (statutory) audit and regulatory policies of public authorities in the field. It is a well-accepted notion that auditing reduces the information risk in accounting reports, thereby improving investors' investment decision [2]. Thus, we focus on the link between auditing and investment efficiency. Specifically, we model the interactions between the regulator authority and investors' decisions and assess how auditing mediates these interactions. We focus on two aspects of auditing: audit quality and auditor conservatism. Audit quality is the probability that an auditor will detect misstatements in financial statements. The audit process may produce either conclusive evidence or inconclusive evidence. Inconclusive evidence (i.e., auditor doubt) raises the issue of the nature of the auditor's attestation. We refer to the attestation of an auditor who, when in doubt, disapproves a favorable client report as auditor conservatism and to the attestation of an auditor who, when in doubt, approves a favorable client report as auditor aggressiveness. Our definition of auditor conservatism is consistent with that used in the auditing profession. When in doubt, a conservative auditor requires her client to make a downward adjustment to the financial statements or else she will issue a qualified or adverse opinion. If the auditor knows her client's financial condition without doubt, a request for a downward adjustment is viewed as a "correction," not as "conservatism." The capital market's pricing rule induces the firm demand for auditing, that, in turn, affects the firm's auditor fee decision. In turn, auditor

fees, balanced against the auditor's litigation risk, determine the auditor supply of auditing. Overall, the demand for and the supply of auditing determine the equilibrium auditor conservatism and audit quality. Companies with high business risk induce auditor conservatism, while companies with low business risk induce auditor aggressiveness. This finding contributes to the literature by linking auditor conservatism to client characteristics and therefore identifying the determinants of auditor conservatism in a capital market setting. We also provide a theoretical explanation for the positive relation between firm business risk and conservatism that has been documented. If auditor conservatism is in force, a greater client pressure on auditors improves audit quality, but if auditor aggressiveness is in force, a greater client pressure on auditors impairs audit quality. Client pressure on auditors can take the form of potential client businesses for the auditor, such as nonaudit services and repeat audit engagements [7]. This result is contrary to the popular belief that client pressure on auditors is always bad. We find that client pressure is desirable when the auditor is conservative. The nature of investment efficiency depends on the auditor's attestation. Given auditor conservatism, an unfavorable report triggers overinvestment. Given auditor aggressiveness, a favorable report triggers underinvestment. In specifying the conditions under which investment inefficiencies arise, we contribute to the literature by identifying the real effects of auditing.

2. Auditor independence and conservatism

The audit committee is a means of enhancing the integrity and quality of the financial reporting process. A strong and independent audit committee may thus potentially serve as a vehicle for auditors to use in their ability to maintain true independence from the pressures of management. Current recommendations that dealt with strengthening the independence of the audit committee (e.g., audit committees should be comprised solely of independent directors), processes and mechanisms to make the audit committee more effective (e.g., audit committees should have formal written charters), and mechanisms that will

enable the audit committee to be more active participants in enhancing the effectiveness of the financial reporting process and thus assist auditors in their quest to maintain independence (e.g., all members of the audit committee must have financial literacy and at least one member must have financial expertise). Regularity has provided a vehicle to protect auditor independence by enhancing the type and degree of communication between the external auditor and the audit committee. For example, auditors are now required to discuss the quality and not just the acceptability of accounting principles and estimates. In theory, this should give the auditors an opportunity to question overly aggressive accounting policies pursued by management. When conservatism is strong, a greater client pressure on auditors diminishes audit quality, when the auditor aggressiveness is in force, a greater client pressure on auditors impairs audit quality. Client pressure on auditors can take the form of potential client businesses for the auditor, such as nonaudit services and repeat audit engagements. This result is contrary to the belief that client pressure on auditors is bad. We consider that client pressure is desirable when the auditor is conservative. But when, little is known about how auditors and audit committee members define financial reporting quality and how that will affect the type of communications between the auditors and the audit committee. Further, recent research provides evidence that the changes resulting from the new international auditing standards may indeed result in an enhancement of the auditors' ability to maintain their independence from the pressures of management by more active involvement of the audit committee (AC) with respect to the financial reporting process and with internal auditing. There is a positive association between the effectiveness and knowledge of the audit committee and the quality of financial reporting and that more active and independent audit committees were associated with a decreased incidence of financial statement frauds. Audit committee members with more knowledge in auditing were more likely to express support for external auditors in reporting disputes with management. This implies that audit committees with financially astute members will be more likely to help auditors in their

struggle to maintain their independence from the pressures imposed by management. Experienced external auditors believe that the lack of financial expertise of audit committee members negates the effectiveness of the committee. The effectiveness of audit committees and their ability to help auditors in their quest to maintain true independence may also be somewhat hampered by the strong influence of management. It would be difficult for the external auditor to obtain support audit committees reporting to a dispute with management, if there is a lack of consensus on what constitutes quality financial reporting.

3. Financial regulators versus financial auditors independence

The tasks of the regulatory model shall include the following:

- a. undertaking measures aimed at ensuring regular operation of the financial market;
- b. undertaking measures aimed at development of financial market and its competitiveness;
- c. undertaking educational and information measures related to financial market operation;
- d. participation in the drafting of legal acts related to financial market supervision;
- e. creation the opportunities for amicable and conciliatory settlement of disputes which may arise between financial market actors, in particular disputes resulting from contractual relations between entities covered by FSA supervision and recipients of services provided by those entities;
- f. carrying out other activities provided for by acts of law. The aim of financial market supervision is to ensure regular operation of this market, its stability, security and transparency, confidence in the financial market, as well as to ensure that the interests of market actors are protected.

Supervision of the financial market

A stable, competitive and financial system founded on integrity provides the basis for a functioning economy, sustainable employment and secure levels of affluence. The task of supervising the financial markets is therefore a crucially important one in all national economies.

Integrated supervision

As an integrated supervisory institution, the FSA, which was founded in 2013, brings together responsibility for supervising all significant providers and functions under one roof. The authority supervises, insurance undertakings, pension companies, corporate provision funds, investment firms and investment service providers, investment funds, financial conglomerates and exchange operating companies. As an integrated financial supervisory authority, the FSA is able to accommodate all official processes under one roof. As a public body, the FSA has full sovereignty. It is able to issue binding standards, such as regulations and decisions, or impose sanctions such as the withdrawal of licences to operate. In addition, it monitors the companies that fall within its supervisory remit over their entire life cycle, from granting the licence that allows them to trade, through the ongoing supervisory cycles while they are active to liquidation, withdrawal or return of trading licences.

Tiered structure of supervision

Any efficient and effective supervisory system builds on the work of upstream supervisory instances. This is referred to as the tiered structure of supervision. The first tier of monitoring and control is provided by each financial institution's own internal auditing department. The institutions' supervisory boards and auditors form the second tier, which, while appointed by the individual companies, is composed of independent, third-party experts. The state system of supervision takes over at the third stage. All three institutions cooperate closely, and form the Romanian system of supervision of the financial market.

Mission

The primary mission of the institution is to assist through legal, administrative and informational means for the maintenance of stability and transparency on the non-banking financial sector, and to ensure the protection of the consumers of financial services and products.

Regulatory activity

The FSA's regulatory activity includes drafting and adoption of regulations and instructions provided for in the legislation, issuance of guidelines and instructions regarding the implementation and interpretation of the codes and laws. The

Commission adopts secondary legislative acts concerning laws' implementation in relation to the carrying out of financial supervision. The regulation of the market participants' activity is in conformity with the European legislation, norms and practices.

Supervision

The unified financial supervision over the supervised entities' activity monitors compliance with the legal requirements, the companies' financial status and the reliability of information that they provide. The FSA's supervisory activity is being carried out through off-site supervision and on-site examinations of the licensed market participants' activity. The purpose of FSA's controlling activity is prevention and termination of legal violations in view of ensuring protection of the interests of investors, insurers and the insured persons.

Licensing regime

In its licensing activity the FSA is guided by the principle of impartiality and implementation of a unified approach and criteria with respect to all applicants. The FSA examines the documents that have been attached to the applications for permit issuance or amendment of one that has already been granted in view of their compliance with the regulatory requirements.

Sanctions

Upon establishment of offences on the supervised entities' side, the FSA imposes coercive administrative measures. They include the issuing of recommendations to undertake specific actions, fines and property sanctions. Our analysis indicates that the regulatory concern about nonaudit services potentially damaging auditor independence and audit quality is partially valid. If we interpret a violation of auditor independence as the auditor biasing her opinion in favor of the client due to financial incentives, then auditor aggressiveness in our model is a violation of auditor independence. Opponents have countered that restricting nonaudit services may be inefficient because it damages the synergy between audit and nonaudit services. We have deliberately assumed away any synergies between audit and nonaudit services and any direct benefits of nonaudit services to the client firm. The relationship between the National Securities Commission - the regulatory body of the capital market - and financial audit can be

extended to the single regulatory authority, authority to possess a broad area of responsibility. In this sense, insurance companies and private pension funds can assimilate capital market entities, when acting as investment funds. In this case, financial regulation can coexist with compliance audit. For those synergies to be real we felt that our research must answer the questions on the link between financial auditor independence and audit committee role with financial reporting quality.

4. Research methodology

We conducted this research in an effort to identify the possible divergence between the type of regulations that can emit single regulatory authority and the audit process. New regulator will operate on two levels, issue general regulations apply to all three categories of financial markets, capital market, insurance market and private pensions market, but in the same time and in greater extent will issue specific regulations of each market in part. We want to identify the extent to which audit the entities in these markets will be influenced by these changes. Interest is our largest to determine whether the audit can identify any changes in the new regulatory requirements on quality of financial statements. We conducted a study to show the effects of regulation of the single financial authority to audit :

- Functions and responsibilities of the audit committee.
- Quality of financial reporting.
- Communication with the audit committee.

Research Question 1: What do financial auditors consider as important functions and responsibilities of audit committees and what are the resulting implications of these issues for auditor independence?

Research Question 2: What are the factors that financial auditors perceive determine financial reporting quality and what role does the audit committee play?

Research Question 3: What factors affect the level and quality of communications between the financial auditors and the audit committee?

Our research sought to identify the challenges and opportunities raised by a single financial supervisory authority to the independent financial auditor. The study was conducted on a total of 34 respondents who expressed an opinion on the functions and responsibilities of the audit committee, the quality of financial reporting and the quality of communication with the audit committee. The major functions of an audit committee are to oversee the financial function of the Company. They should have oversight responsibility for systems of internal controls, quality financial reporting and disclosure and financial risk management. Almost half of the respondents (45 percent) also indicated that ensuring quality internal controls and overseeing the audit process, including regularly reviewing the relationship between the company and its external auditors, are important responsibilities of an audit committee. This latter finding suggests that audit committees potentially may evaluate if there is too close of a relationship between management and the auditors that may call to attention a perceived lack of independence on the part of auditors. Surprisingly, despite the emphasis placed by the auditing profession on the potential importance of the interactions between the audit committees and the internal auditors, few auditors (14%) stressed the role of the audit committee in enhancing the effectiveness of the internal audit function. The legislation requires has called for the auditor to discuss with the audit committee the quality and not just the acceptability of the financial reporting process. This recommendation is consensus on what constitutes “quality,” it will be highly unlikely that audit committees would align with auditors in financial reporting disputes with management. However, the recommendation raises the issue of how “financial reporting quality” is to be defined. In this regard, auditors were asked an open-ended question regarding factors they consider important in determining financial reporting quality.

5. Conclusions

In conclusion, we asked three questions regarding communications between the external auditor and the audit committee.

First, in an open-ended question auditors identified audit committee factors or characteristics that encourage an open and frank communication. The most frequent factors cited were: competency (45 percent); independence (24 percent); private meetings with the audit committee (19 percent); and receptive to auditors questioning financial reporting positions (19 percent). In a second open-ended question we asked participants to identify auditor or audit firm factors that encourage strong communication. There were no overwhelming factors noted. However, those that were cited were: develop a strong relationship with the audit committee (21 percent); knowledge of client/industry/ audit committee (17 percent); frequent meetings (10 percent); challenge the audit committee on financial reporting issues (10 percent); alter the contract with the financial auditor (longer term, limit liability, rotation, hired by audit committee) (10 percent); and willingness to lose a client (10 percent). Our country, as a parcel part of the international agreements concerning the regulations institutions of insurances and pension funds, respectively, signer of Memorandum of Understanding on Cooperation Between the Financial Supervisory Authorities, Central Bank and Finance Ministries of the European Union on Cross-Border Financial Stability and taking into consideration Romania’s market structure, where the monetary market holds 94%, and the difference of less than 5% representing the capital market, the insurances market and the market of private pensions, heads to a dual model, similar to the one of Bulgaria, in which the monetary market regulation stays at BNR, and the regulation of the other markets will realized by one institution. This model presents the advantages of a real moment projection of the financial market characteristics from Romania, leading to the growth of financial stability and a better risk management on this market, leading to a better reference with the European profile institutions. The disadvantage of this kind of institutional regulation consists in the implementation in a certain inferior situation of the financial markets, other than the monetary market, which might affect the developing rhythm in the future. It requires an alignment of regulations for financial markets with

international audit standards without undermining its independence in condition of audit conservatism, all print can be made good communications with the audit committee. Therefore, it is possible that the mixed empirical evidence on the economic consequences of the directives of financial authority is due to the use of pooled samples in empirical studies that combine firms with the independence of auditors.

Empirical Evidence of a New Trilemma

Percic Stanislav
Apostoaie Constantin-Marius

stanislav.percic@yahoo.com

Abstract

The scope of this research paper is to investigate the trade-off which appears when dealing with the “new trilemma” (formed by price stability, financial stability and sovereign debt sustainability) brought forward by Duvvuri Subbarao. More specifically, the paper offers interesting empirical proofs on the existence of trade-off within the “holy trinity” using the Principal Components Analysis (PCA) and confirming the robustness of the results with a cross-country panel OLS regression.

Key words: trilemma, holy trinity, price stability, financial stability, sovereign debt stability, Principal Components Analysis

J.E.L. classification: C31, C38, E31, G21, H63

1. Introduction

In the economic context created by the international financial crisis triggered in 2007, central banks were called to face an additional challenge, other than the traditional one – of *maintaining the stability of the prices* – namely: the development and maintaining of a stable financial environment and the ensuring of the premises necessary for obtaining macroeconomic stability. However, this challenge is not a novelty, for the preservation of financial stability is actually one of the reasons for which these institutions were created from the very beginning (especially if we consider the bank run episodes towards the end of the 19th century and the beginning of the 20th century). In this context, this research paper aims at investigating the trade-off that appears when dealing with the *new trilemma* (or the *Holy Trinity*) that the Governor of the Reserve Bank of India [22], [23] brought

forward. More specifically, the paper highlights the positive and negative effects that the central bankers would face if they were to expand their responsibility from a single objective to multiple objectives of price stability, financial stability and sovereign debt sustainability. To better highlight the existence of trade-off within the *new trilemma* two individual empirical techniques have been used: the *Principal Components Analysis* (PCA) and an *estimated cross-country panel OLS regression*.

The rest of the paper is structured as follows: section 2 briefly sketches some aspects related to the international context given by the relation between price stability and financial stability as main responsibilities of central banks and the involvement of the ECB in ensuring the stability of the states in the euro area. Section 3 of the paper presents the methodology and data sources while in section 4 the authors normalize the data. Section 5 and 6 presents some empirical arguments supporting the existence of the new trilemma while section 7 concludes and gives perspectives for policy.

2. International context

During the past two decades, the financial turbulences which occurred in the financial globalization process determined the intensification of the debates amongst authorities, as well as in the literature, with regard to the relation between price stability and financial stability; in this context, two essential approaches, namely the *traditional approach* and the *new environment approach* took shape [3]. Moreover, national authorities had to use several fiscal, monetary and prudential instruments in order to ensure macroeconomic and financial stability in the given context. In order to attain these objectives, monetary authorities had to work closely with other institutions, particularly

tax and regulatory authorities, but this approach did not affect their independence. If, in the economy of the years before 2007, the mission of central banks, including the European Central Bank (ECB), was simple or at least clearly defined – they had to *keep inflation at low and stable levels* – the events from the last years posed a new challenge for monetary authorities, that of preserving financial stability. In addition, in the context of the sovereign debts crisis in the Euro Area, ECB is called to become actively involved in ensuring the stability of the states in this area.

The financial crisis is considered by some [23] a punishment for central banks because of the fact that they neglected financial stability in their “wild race” to ensure price stability. ECB was thus forced to grant more attention to financial stability (although there are still for and against opinions with regard to the statutory involvement of a central bank in ensuring the stability of the financial system, as well as with regard to institutional arrangements), while not losing sight of price stability. In addition, ECB is called at present to take into consideration the possibility of becoming involved in ensuring the stability of the sovereign debt market. In this case, the problem is whether the *new trilemma* – simultaneously ensuring *price stability*, *financial stability* and *sovereign debt stability* – is truly impossible? The literature does not have any theories to support the fact that these objectives are incompatible. We can go even further and argue that the three objectives can support one another and that together they sustain economic development and growth, thus constituting not an impossible trinity but, on the contrary, as argued by Subbarao [23], a “Holy Trinity” of objectives. The question to which we must find an answer is not whether it is possible or whether we should try to (simultaneously) achieve all three objectives (the answer being more than obvious), but to what extent ECB should become involved in solving this trilemma. The opinions are also divided in this respect.

As the sovereign debt crisis worsens, several voices – from academic circles and from the area of economic policies – ask the European Central Bank to adopt a more *active* attitude for solving this problem by purchasing a larger volume of securities (sovereign debt). The absence of a lender of

last resort (LOLR) was considered an essential weakness of the euro area. After forming a general view with regard to the current situation, we mention the position adopted by most German officials, who declared themselves against the involvement of the LOLR function of ECB in the problem of sovereign debt, and the position of South-European officials, who are in favor of such involvement. The position of the French officials is balanced, although we may notice a slight sympathy for the *pro* camp.

Focusing our attention on the long-term financing operations (LTRO) of the ECB, we notice that they have been firmly analyzed and debated. As concerns the LTRO operations from February 2012, by supplying a significant and cheap volume of liquidity to commercial banks, ECB officially expressed its intention to prevent a liquidity crisis which may have ruined one or several banks in the euro area, as it happened in the case of the Lehman Brothers collapse. According to another interpretation of the actions undertaken by BCE – which is maybe at the opposite pole in relation to the first interpretation – the monetary authority has thus indirectly supported the market of sovereign bonds. The two opposite camps are delineated by the very way in which they position themselves in relation to the two interpretations: one *for* and the other *against* the involvement of ECB (by undertaking the function of LOLR) on the market of sovereign bonds [4].

3. Methodology and data sources

To better highlight the existence of trade-off within the *new trilemma* – simultaneously ensuring *price stability*, *financial stability* and *sovereign debt stability* – two different empirical techniques have been used, namely: the *Principal Components Analysis* (PCA), known also as Hotelling transform or Karhunen-Loeve transform (using the SPSS software), and an *estimated cross-country panel OLS regression* (using the EViews software).

The study uses yearly data from 2007 to 2011 for the countries from the Euro Area (17 countries) for 3 main categories of variables: price stability, financial stability and sovereign debt stability.

To capture the movement of price

stability, the analysis uses the overall index of HICP (Harmonised indices of consumer prices), excluding alcohol and tobacco (with 2005=100 as reference period), from the Eurostat data base.

As mentioned earlier in the study, unlike price stability, financial stability is not so easy to measure given the interdependence and the complex interactions of different elements of the financial system among themselves and with the real economy. However, this didn't stop researchers from central banks and elsewhere to try capturing the conditions of financial stability through various indicators of financial system vulnerabilities. Following the findings of Gadanez and Jayaram [12], the study assess financial stability through four main indicators of key sectors of the financial system: GDP growth (pertaining to the *real sector*), real exchange rates (reflecting the conditions in the *external sector*), private sector credit (a proxy for the *financial sector*) and house prices (for describing the *household sector's* health). Therefore, using the Eurostat scoreboard platform we extracted for the 17 countries the following indicators to assess *financial stability*: the Real Effective Exchange Rates (percentage change, 3 years), the Real GDP (year over year percentage growth), House Prices (year over year percentage change) and the Private Sector Credit flow (percentage of GDP).

As for sovereign debt stability, we used an indicator that captures the volatility in General Government Debt (as year over year percentage of GDP) from the Eurostat scoreboard platform.

4. Normalizing the indicators

Given the fact that the indicators mentioned above do not always present the same measurement unit, their values have to be normalized. The most employed normalization methods used in the literature are: statistical normalization, empirical normalization, axiological normalization and mathematical normalization [1]. To normalize the indicators, the study uses the following formula:

$$I_{it}^n = \frac{I_{it} - \text{Min}(I_{it})}{\text{Max}(I_{it}) - \text{Min}(I_{it})}$$

where, I_{it} represents the value of one of the indicators mentioned above during a t period while $\text{Min}(I_i)$ and $\text{Max}(I_i)$ are the minimum respectively the maximum value registered for a certain type of indicator in the analyzed period. The results, I_{it}^n , is the indicator's normalized value.

Regarding the four main indicators describing *financial stability*, the study aggregates their individual values into a *composite financial stability* index (giving them the same importance regarding their weight in the index).

In conclusion, the research uses the following yearly variables for the 17 countries:

Table 1. Input data used in the study

Ps – Price stability	<i>Individual indicator:</i> HICP (2005 = 100) - annual data (average index and rate of change), overall index excluding alcohol and tobacco
Fs – Financial stability	<i>Aggregate index</i> grouping the following individual indicators: - % Change (3 years) of Real Effective Exchange Rates with HICP deflators; - % y-o-y change in House Prices; - Private sector Credit flow as % of GDP; - % y-o-y growth of real GDP.
Ds – Stability of Sovereign debt	<i>Individual indicator:</i> y-o-y General Government Debt as % of GDP

Source: Eurostat, Eurostat scoreboard platform

5. Empirical results of the PCA analysis

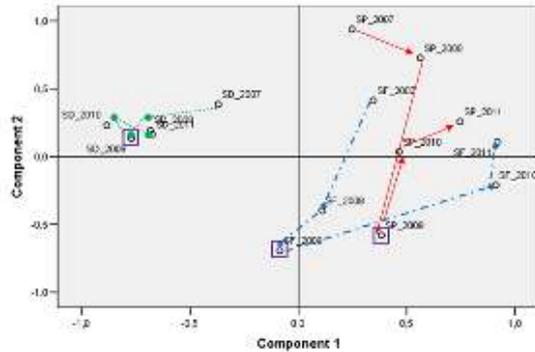

The aim of the principal component analysis is to explain the variance-covariance structure of a set of variables through a few linear combinations of these variables. Its general objectives are (1) data reduction and (2) interpretation.

The Principal Component Analysis was chosen since it represents a powerful tool for analyzing data by reducing the number of dimensions, without important loss of information. In other words, the PCA reduces the large dimensionality of the data space (observed variables) to the smaller intrinsic dimensionality of feature space (independent variables), which are needed to describe the data economically.

After applying the PCA method, a series of results were obtained, but the authors consider appropriate to focus on and to interpret the most representative and suggestive results: *Component Plot* and

Graphic of regions representations. It should be noted that all the necessary steps were covered, directing the research towards the two factorial axis graphs.

Figure 1. Component plot

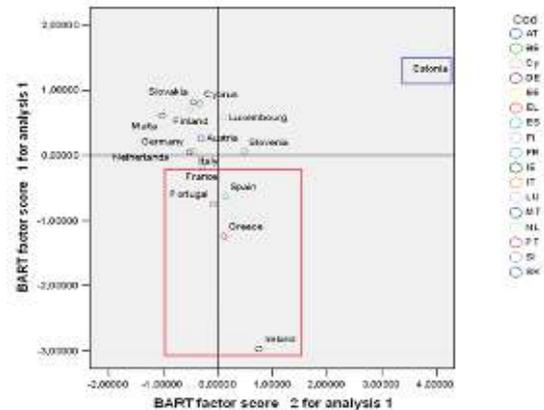

Source: Authors elaboration

The position of variables from the first axis of the Component Plot graph shows a *strong and direct relationship* between two analyzed variables: *financial stability* and *price stability* (see Figure 1). Therefore, a variation of price stability will lead to a *strong and unidirectional* (the same direction) variation of financial stability. Nevertheless, the situation is different when dealing with the third variable (sovereign debt stability): there is an *inverse relation* between this variable, on the one hand, and financial stability and price stability on the other hand. One can see the positioning of the **Ds** variables on the left side of the graphic, while on the right side there are the **Ps** and **Fs** variables.

When analyzing the trajectory that the values of the three indicators displays over the 5 years period, one can notice a “V”-shape pattern (for all three variables) with an extreme value in 2009 (see Figure 1). An interesting aspect is the fact that the positions of the three indicators are quite reversed in 2009. In other words, there is a *direct* relation between financial stability and sovereign debt stability, and an *inverse* relation between the above mentioned variables and price stability. Nevertheless, this exception comes to reinforce the rule according to which in a market economy, especially in the case of the Euro Area, all the three points of the *new trilemma* cannot be touched at the same time (when dealing with the same institution) thus highlighting the existence of a trade-off between the 3 types of stability.

Figure 2. Graphic of state representations

Source: Authors elaboration

The second graph (see Figure 2) reflects the adjusted position considering the stability priority of the Euro Area countries in the 2007-2011 period. One can see that countries like Portugal, Ireland, Greece and Spain formed a separate aggregate group from the rest of the Euro Area countries. When overlapping the two charts (Figure 1 and 2), one can notice that the **PIGS** countries directed their macroeconomic policies towards maintaining *financial stability* and *price stability* in 2007-2011 (with the sacrifice of sovereign debt stability). Thanks to a substantial financial effort, Italy detached itself from the group of **PI(I)GS** countries and realigned to the group of (relative) stable states, directing their macroeconomic policies to maintain the *sovereign debt stability*.

Another interesting observation should be made by the different positioning of the last newcomer in the Euro Area: Estonia (in 2011). The Baltic state is situated in the area concerned with assuring *price stability*, focusing its attention on achieving the main objective of the Central Bank. Estonia will have to make a considerable effort to align with the other states from Euro Area.

Using the *Principal Components Analysis* method and focusing on the most representative and suggestive results, the research paper highlighted the existence of the *New Trilemma* in the Euro Area.

6. Empirical results of the cross-country panel OLS regression

In the second analysis, the paper estimates

a pool equation by using the least squares (OLS) method (and AR), with correction for *random effects* in the cross-section dimension, in order to highlight the trade-off within the *new trilemma*. As a dependent variable, the research paper takes into consideration each of the three indicators describing the trilemma (P_s , F_s and D_s) as follows:

$$M_s^0 = c + \omega_1 * M_s^1 + \omega_2 * M_s^2 + \varepsilon$$

where, M_s^0 is, at a time, one of the three indicators describing the trilemma (P_s , F_s and D_s) and M_s^1 and M_s^2 are the other two indicators; c is the constant and ε is the error term.

The estimated models, regressing P_s , F_s and D_s on the other two common regressors, with a crosssection random effect, are presented below:

$$P_s = 0.33 + 0.38 * F_s - 0.20 * D_s + \varepsilon_1 \quad (1)$$

(0.117)*** (0.186)** (0.109)*

$$F_s = 0.49 + 0.13 * P_s - 0.21 * D_s + \varepsilon_2 \quad (2)$$

(0.046)*** (0.063)** (0.061)***

$$D_s = 0.77 - 0.61 * F_s - 0.19 * P_s + \varepsilon_3 \quad (3)$$

(0.087)*** (0.172)*** (0.106)*

() - standard error in parenthesis;

***, ** and * being the 1%, 5% respectively 10% significance level

According to the results of the three estimated pool equations (1, 2 and 3), for the 17 countries in the Euro Area, and for the 5 years period (2007-2011), there is a **direct** relation between the indices of *financial stability* and *price stability* (depicted from the positive sign of the estimated parameter in equation (1) and confirmed by the results of equation (2)), and a **negative** relation between each of these two indices and the indicator of sovereign debt stability (as one can conclude from the negative sign of the estimated parameters in equation (3) and confirmed by the results of equation (1) and (2)).

Therefore, one can say that for the Euro Area, the countries pursuing *financial stability* and/or *price stability* in the 2007-2011 period, have lost in term of *sovereign debt stability* proving thus empirical proof of the existence of the new trilemma.

7. Conclusions

Ensuring financial stability is a natural concern of central banks, resulting from their

specific prerogatives with regard to the elaboration and implementation of monetary policy, the role of bank of the banks and with regard to the regulation and monitoring of payments in economy. The significant changes on financial markets in the context of the current international crisis, the increase of the risks for financial stability, as well as the severe negative consequences of financial instability for the functioning of financial institutions and markets and for economic growth and price stability determined central banks to pay more attention to ensuring financial stability during the past years.

The Principal Component Analysis (PCA) showed us that there is a strong and direct relationship between financial stability and price stability (where a variation of price stability will lead to a strong and unidirectional variation of financial stability) and an indirect relation between these variables and sovereign debt stability (with a *V-shape* pattern over the 5 years period span of the trajectories for the three indicators and). The results highlight the existence of a trade-off between the 3 types of stability. The above mentioned trade-off within the *new trilemma* is also confirmed by the results of the cross-country panel OLS regression. Therefore, for the Euro Area, when pursuing *financial stability* and/or *price stability* in the 2007-2011 period span, countries have lost in term of *sovereign debt stability* proving thus empirical proof of the existence of the new “Holy Trinity”.

Abstract

In the economic context of competitive market of today and from the perspective of European integration, even big companies can get in trouble. Because their executives or managers are not able to deal with difficult issues by taking effective and timely measures, companies may not keep the position in their field of activity and end up in a situation of lack of liquidity, record profit decreases or excessive debt. If they are not recovering quickly, even viable companies lose the moment of market and especially the possibilities to generate cash and the creditors, bondholders, investors, management and employees are forced to seek solutions to recover various rights to society.

Keywords: Company in difficulty, Insolvency, Reorganization, Restructuring Strategies, Liquidation.

J.E.L. Classification: M41

1. Introduction

The financial crisis represents a situation of economy characterized by instability and uncertainty.

In Romania, the financial crisis was perceived at its real dimensions long after release, although there were clear signs that outlined an economic recession: closing many factories that were operating in Romanian economy before 1989 and that were more or less profitable, loss of important markets, restricting others,

alarming rate of unemployment, withdrawal of foreign investors.

A healthy market economy is characterized by free and rapid circulation of goods and money in a loop that repeats continuously: production-goods-money-production. In this course, the commerce is the engine of the market economy, but the freedom of commerce has created competition, and this led to commercial risk [1]. Thus, commerce appears as an economic activity, as a more or less predictable risk. In terms of risk, an economic activity may be bankrupt as far as it does not provide money needed to initial cycle resumption[2].

In general, a business failure comes from a continuous process of degradation of its financial-economic status, predictable process based on anticipated failure symptoms. Whereas in the past 20 years the issue of bankruptcy was the area of interest of many researchers and practitioners and has been legally, economically and financially addressed, we wonder why in an economy in which companies economic inability to pay is chronic, and companies capital diminishes obviously, their managers and clients prosper and no one is punished for fraudulent bankruptcy[3].

Unfortunately, the facts show how many companies are in insolvency. The statistics of Romanian companies that manage to successfully escape from insolvency is only 2%, 98% of the companies reaching to bankruptcy.

In terms of accounting, liquidation prohibits the beginning of any economic activity since the moment of dissolution judgment of the entity. To liquidate the

company will be used and will be determined the liquidation values or of forced sale, namely: the amount that can reasonably be collected from the sale of a property in a time too short to be consistent with the time specified in the definition of market value[4]. Liquidation value is calculated based on the sale of individual assets as quickly as possible, taking into account the costs associated with liquidation (commissions, fees, administrative costs, legal fees and taxes and so on).

2. Need for reorganization procedure

The main purpose of the reorganization plan coincides with Law no 85/2006, namely covering debtor's liability in insolvency.

The main way to achieve this goal, in the modern conception of the law, is reorganizing the debtor and maintaining the company in commercial life, with all the social and economic consequences resulting from it. Thus it is revealed the economic function of the procedure established by Law no 85/2006, namely the need for rescue company in insolvency by reorganizing it, including economic restructuring and only secondarily, in terms of reorganization failure or lack of debtor viability, the use of bankruptcy procedure in order to satisfy the interests of the creditors.

Reorganization by debtor's work continuity assumes some structural changes in the current activity of the company in difficulty, maintaining the object of activity, but aligning the conduct of business to the new strategy, according to available resources and to those to be attracted, all these applied strategies are designed to make profitable the company's core business.

The reorganization plan, according to the spirit of Law no 85/2006, must meet the *lato sensu* reorganization goal, namely maintaining debtor in business and social life, with the effect of maintaining the debtor's services and products on the market. However, reorganization means to protect the interests of creditors who have an extra chance to achieve their claims. This is because, in the modern conception of the law, is more likely that a functional business to produce resources needed to cover liabilities than debtor's assets liquidation in bankruptcy. Arguments that plead for

liability coverage of the debtor company by reorganizing its business are emphasized especially in the current economic context characterized by an acute liquidity crisis and significant decrease of demand for the purchase of property. In this economic context, the attempt to cover debtor's liabilities by liquidating its property will require a fairly high recovery interval generated by market circumstances affecting demand for the assets of the debtor company[5].

The reorganization plan proposes to act for the structural change of society on several levels: economic, organizational, managerial, financial and social primarily aiming to pay debtor's liabilities, viable recovery of the activity under strict control of the receiver in terms of achieving the mentioned goals.

2.1. Economic aspect

Economically, reorganization procedure is a mechanism that allows the trader being in a precarious financial situation, to recover and to pursue trade.

From a conceptual point of view, the reorganization means drawing realistic goals that must be achieved within the timeframe planned in terms of new business employment, launching new goods and services on the market and improving the quality and quantity of products and services already launched. The reorganization plan is a real recovery strategy, based on the adoption of appropriate policies for management, marketing, organizational and structural policies.

2.2. Social aspect

Reorganization of the company and business continuity expresses its social effects by keeping existing employees within the company, and recovering the activity will require new employment.

This report is designed so as to create the possibility of increasing the number of directly productive employees who have a significant role in the marketing, as the company seeks to gain considerable profit from its business, profit meant for the payment of liabilities.

At employment, the company will consider, in addition to the criteria of

competence and efficiency, the former employees left without jobs for extrinsic reasons, employees of which most have not found another job after dismissal or work for wage small, for lack of an alternative.

2.3. Advantages of the reorganization

The main premises for company reorganization are the following:

- its ability to recover activity;
- society still has good relationships with suppliers;
- its material basis allows it to operate;
- existence of surplus assets in relation to the core business of the company that generates rental income or may be an alternative source of income by selling them.

Starting company's reorganization proceedings and resuming the trading process will create the opportunity to generate additional cash flows which will allow the distributions to creditors after the first receipts from the procedure.

Selling all assets of the company in case of bankruptcy would eliminate any chance of recovery for unsecured and budgetary creditors that leads to the alienation of this property to a value below not only its real value but also secured creditors value that would meet claim in much smaller amounts than reorganization.

Continuing reorganization proceedings are measures intended, by their purpose, to satisfy the interests of secured, wage, budgetary creditors and certain unsecured creditors and debtor's interests that continue to operate with all social and economic consequences thereof[6].

Reorganization process involves other advantages:

Continuing current activity considerably increases the merchantability level of the goods of an “active” company to the situation of a “dead” company's patrimony (patrimony that, unused, undergoes inevitable degradation until alienation);

Also, continuing work considerably increases the chances that the company's assets to be sold as a set in operation (as a business), even in the event of inadvertent opening of insolvency proceedings;

2.4. Advantages for secured creditors

As far as secured creditors are involved, the implementation of reorganization plan has benefits regarding the recovery of claims held by them. The percentage of coverage of such claims, as it is proposed to be achieved by the Payment program is 100% of the secured claims.

Assuming openness to the debtor on the bankruptcy proceedings regarding covering claims in this category there is only partial risk of their coverage. This risk is mainly caused by latent market for existing real estate of the debtor's assets and the current liquidity crisis in the financial market caused by current financial crisis.

2.5. Advantages for wage creditors

Wage creditors would recover the debt also in bankruptcy, but only after liquidating assets and payment of procedure expenses. However it is noted that a part of the wage creditors in the table are still enrolled employees of the company, for them continuing company's work means the chance to keep their work under a labour market hit hard by massive layoffs in the private economy.

2.6. Advantages for budgetary creditors

The reorganization alternative is the only that ensures the budgetary claims, given that, although there are unencumbered assets of the liquidation value of their tasks does not cover claims resulting from the continuation of the business after the opening of proceedings, which according to art. 123 are paid before budgetary claims; only recovering the activity can provide the necessary resources to cover several categories of claims, including budgetary claims;

Reorganization process offers another clear advantage of budgetary creditors: approved system of instalment payment provided in the reorganization plan establishes a rigorous regime of control of payments made to state budgets;

2.7. Advantages for suppliers

The main advantage for suppliers of the debtor is the opportunity to partially recover financial claims held against the debtor. Thus, if the debtor is insolvent this category of creditors, which is found in the group of unsecured creditors, will have no chance to recover claims held against the debtor. This is because in the event of liquidation of the debtor's assets, the financial resources will cover the value of secured claims, wage claims and claims arising out of continuing work after the opening of proceedings, liquidation of the debtor's assets not generating sufficient financial resources for making distributions to unsecured creditors.

Continuing commercial activity necessarily involves continuing collaboration with suppliers with which continues the development of commercial activity currently, some of it creditors of the company. Working with an economic partner whose widely raw material is satisfied in this segment of the market is an important source of revenue for companies supplying, source that would disappear if insolvent.

3. Conclusion

The bankruptcy of a company situates the debtor and creditors on antagonistic positions, first seeking full recovery of the claim against the debtor's wealth, and the latter maintaining the company in business life. If the interests of creditors in bankruptcy preclude the possibility to save the interests of the debtor, whose wealth is sold (liquidated) entirely, in case of reorganization the two goals are aggregated, the debtor continuing his work with the result of its economic growth, and creditors take advantage of the maximization of capital value and additional cash acquired, and thus achieving claims in a higher proportion than that which would be achieved in the event of bankruptcy.

Comparing the degree of satisfaction of claims under the two procedures shows that in both cases there is a marketable assets for the payment of liabilities, but that in the reorganization procedure, at the liquidity obtained from the possible sale of the debtor's wealth that are not necessary successful to the plan is added the substantial

profit resulted from continuing the debtor's activity, all meant for payment of liabilities.

Criteria for Substantiating Decisions under Risk

Piciu Gabriela Cornelia

Financial and Monetary Research Center „Victor Slăvescu”, Bucharest, Romania
gabriela_piciu@yahoo.com

Abstract

Exponential technological societal development was made possible through risk-taking, and economic growth could not be realized if certainty was put prior to risk. The market economy has in its essence assuming some risks, that without them the activity of an economic agent under risk would be impossible.

Key word: decision, risk management, intensity of the risk

Classification J.E.L.: G02

1. Introduction

Risk management has as a vital component: the decision activity, considered as a continuous process of suitability of the structures and instruments of the financial and banking entities to the challenges and requirements of the financial market environment.

The decision activity, interpreted in a both descriptive and normative approach, circumscribes to a system in action subject to rules and an immanent decisional logic, regardless of the quality of the decision act and the performance of the system. [8]

The decisional acts in the financial-banking branch targets in the first place the insertion of performance entities in an environment characterized as uncertain, risk generator and loss for the financial entities, improvement in the decisional act implying system analysis and decision logic. Analysis which can be methodologically segmented in three phases: [2]

1. Knowing the essential elements of the determinant factors and variables of the decision process and the impact of the risk concerning them;

2. Critical analysis of decisional processes utilizing principles, methods and

tools specific for the analysis and modeling of complex systems;

3. Highlighting deviations and decisional deficiencies with respect to the character, intensity and amplitude of the risks and also determining corrections and adjustments necessary for the decrease, covering and elimination of the risks. [10]

Whether structural modeling of the decision-making process is done in descriptive perspective in order to understand and describe the risk oriented decisional mechanism, or from the normative perspective in order to formulate and set rules regarding the decisional process, the essential elements of this process are the following:

- the decider which represents the subject which adopts the decision in risk conditions;
- the decisional problem, which emphasizes the characteristics and the impact of the risk;
- the possible decision alternatives within the decisional situation given;
- establishing the set of criteria upon which the decision maker chooses favorable alternative;
- qualitative and quantitative analysis of the consequences of decision alternatives;
- choosing the favorable decision option, this representing the core of the decisional act;

2. Analytical process for decisions taken under risk

Analytical process for decisions taken under risk circumscribes some cognitive methodological elements necessary for the adequate functioning of the decisional process, namely:

- accentuating the trigger element of the decisional act which can be: covering, decreasing or eliminating the risk;
- clarifying the decisional tension

determined by the information gaps, and also aiming for the formulation of the decisional problem;

- elaboration of an analysis and interpretation decision model during risk conditions;

- setting a decisional brainstorming session in order to offer decision alternatives and to permit the most favorable alternative choice;

- the implementation of the decision, monitoring and controlling the achievement of its objectives.

The decision process analysis during risk conditions of financial and banking entities is based on two complementary methodologies:

- *constructive methodology*, which deals with the structural and instrumental reconfiguration of the activity affected by the risk, aiming to avoid the manifestation of the loss generating risk;

- *ameliorative methodology*, dealing with the adaptation and adequacy of the existing structures and instruments with the purpose of decreasing the losses generated by the risk.

Overall the financial entity, the loan decisions during risk conditions may generate losses which represent the quantitative value dimension of the incapacity of the financial entity to completely master the environment meaning the loans market. Depending on the development and size of the losses due to the risk, the credits are structured on risk classes, credits with losses regardless on their nature or their dimension, constituting bad loans.[4]

Confronted with an uncertain environment, characterized as a diversity of risks, the financial and banking institutions often base their loan decisions on credit rating systems, this representing the main element of risk evaluation and maintaining rigor to the internal process of lending. In this sense, improving the system of credit rating and monitoring the credit facilities may lead to the increase the rigor and objectivity of the risk analysis, to an accurate identification of the types of risk and to a correct quantification of them.[5]

The experience of utilizing this system highlights the fact that the distinction between different types of risk within the portfolio of the financial institution is essential, but also that their ranking and the

establishment of the loan risk classes (their number varying from 5 to 20) is vital.

The importance of the rating in substantiating a loan decision resides in the fact that by utilizing both a coherent and complex methodology and instruments of quantification that can be flexible, information related to the degree of risk concerning each loan may be provided. But also information may be give on certain categories (groups) of loans and on the entire loan portfolio of the financial entity. [1]

Generally, for the classification depending on the risk of a loan associated to a client, the bank needs relevant information for the adoption of any decision. Information that have a mix of qualitative and quantitative indicators provided mainly by the financial and accounting documents of the client.

In the conditions of increasing competitiveness between the financial and banking institutions, the internationalization of the activities and processes accomplished by them, of more complex and volatile financial instruments being transitioned on the market, the decisions of this entities assume in the first place an adequate estimation of the risks and in the same time the establishment of mechanisms and instruments in order to diminish, transfer or cover the risks.[9]

At the level of the banking entity the *improvement of the decision process* during risk conditions should focus of the following *four aspects*:

1. defining, integrating and implementing the risk management function;

2. enhancing the internal credit rating systems in order to evaluate qualitatively the portfolios and the credibility of the customers;

3. utilizing the instruments and statistical and econometrical modelling methods of risk administration;

4. Promoting a decisional strategy focused on the project analysis that can permit the selection of the markets, the consolidation of the portfolios and the improvement of the performances.

3. Criteria for substantiating

Decisions under risk condition are characterized by the existence of more states

of nature of processes with probabilities of appearance that are known and through the application of less controllable and insufficient known variables. In this situation the choice of the optimal variant or option can be done using more rules and through the use of the degree of optimum choice affiliation method.[3]

1. Pessimistic criterion of Abraham Wald

This criterion takes into account the minimum earning that corresponds to each state of functioning. The optimum option is that which will lead to the highest of the minimum earnings. It can be said that the best choice in the Wald sense is if:

$$U_{opt} = \max_a \min_b U_{ab} \quad (1)$$

Where: U_{ab} is the utility of the option “a” in objective conditions “b”.

2. Hurwicz optimistic criterion

The optimum choice is the maximum earning for each state of functioning, followed by the decision or action of insurance leading to the biggest of the maximum values. The rule is the following:

$$U_{opt} = \max_a \max_b U_{ab} \quad (2)$$

Where: U_{ab} is the utility of option “a” in objective conditions “b”.

Practically maximum utilities will be chosen of all the options, out of which the maximum utility will be chosen, that maximum utility determining the optimum option.

Another formulation of the same criterion is the choice of the optimum option through the maximization of the relationship:

$$\text{Max} [\xi U_{ab}^1 + (1 - \xi) U_{ab}^0] \quad (2')$$

Where ξ is a coefficient chosen by the decider included in the interval [0,1], measuring the optimism;

U^1 is the maximum utility of option “a”;

U^0 is the maximum utility of option “a”;

U_{ab} is the utility of option “a” in objective conditions “b”.

3. Criterion of minimum regret (Savage)

The criterion has at its core an analysis of the effects of an erroneous decision in

relation with a good decisions and chooses as an optimum choice that which the regret of not being chosen the optimum option in minimum. [6]

The regret is the difference of a random option with respect to an optimum one, within each state of the objective conditions and it states as follows:

$$R_{ab} = \max (U_{ab}) - U_{ab} \quad (3)$$

Where: R_{ab} is the regret of not choosing option “a” in objective conditions “b”;

U_{ab} is the utility of the option “a” in objective conditions “b”.

After measuring the regrets, the optimum option will be the one for which the maximum regret is minimum, meaning:

$$U_{opt} = \min_a (\max_b R_{ab})'$$

4. Maximum likelihood criterion

The criterion consists in determining the state of the most probable (the highest probability of happening) and choosing that decision of insurance which will maximize the utility corresponding to that state. In this respect, it is assumed that the probabilistic repartition of the states of functioning is known, and thus of the corresponding utility. Thereby, the following rule:

$$U_{ab} = \max_b (U_{kb})' U_{kb} = U_{kb} (p_k = \max_a P_a)$$

where: P_a are the occurrence probabilities;

U_{kb} is the utility of state “k”, with the highest occurrence probability, in objective conditions “b”

5. Method of the degrees of affiliation to the optimum choice

Important strategic or tactical decisions are adopted in uncertainty conditions, the need of the optimization of the decision act led to the formulation of this method that has at its base the theory of fuzzy sets. This theory assumes covering certain steps:

a) Formulating the decisional options, the consequences and choosing the optimization criteria. The consequences of the options due to incomplete information to decision makers or the imprecision of the information are presented in fuzzy terms:

$$U_{ij} = \| a_{ij} \| = \begin{pmatrix} a_{11} \dots a_{12} \dots \dots a_{1n} \\ a_{21} \dots a_{22} \dots \dots a_{2n} \\ \dots \dots \dots \dots \dots \dots \dots \dots \\ a_{m1} \dots a_{m2} \dots \dots a_{mn} \end{pmatrix}$$

b) For each consequence (U_{ij}) it is done a variable change like the following:

$$U'_{ij} = \frac{|a_{ij} - a_j^*|}{a_j}$$

whenre: a_{ij} -is the value of the option consequence “i”, considering the criterion “j”;

a_j^* -is the value of optimum consequence, considering criterion “j” for an optimum option, after a certain criterion, $U_{ij} \approx 0$.

c) Establishing the degree of affiliation of each option to the optimum option for each criterion of optimization. Generally, the degree of affiliation to the optimum option is given by an exponential function having the form:

$$\mu(U_i) = \mu_{ij} = e^{-kU_{ij}} \quad (8)$$

Where: k- coefficient of affiliation

The value of k is differentiated according to the importance of the optimization criterion.

For k it is recommended to be given values between 3 and 6.

The values μ_{ij} are written in a matrix $\|\mu(z_{ij})\|$ which emphasizes the degree of affiliation of each alternative z_{ij} to the optimum option.

d) The choice for the optimum option is done trough aggregation of the matrix elements grades of affiliation to the optimum value after one of the optimization rules of the decision under risk and uncertainty. [7]

5. Conclusions

High degree of complexity of the financial and banking systems combined with the relatively low decision capacity of the human factor determined the management of the financial and banking entities like any other management structure regardless of their nature or dimension, to create, promote, use instruments and means of sustaining and enhancing the decision making acts, among those the methodology, modeling and computerized decision making are remarked.

Significance of Volatility in Option Pricing

Pochea Maria-Miruna

miruna.pochea@econ.ubbcluj.ro, angela.filip@econ.ubbcluj.ro

Abstract

This paper examines the significance of volatility in option pricing considering that the option's theoretical price depends on the accuracy of this parameter's estimation. One of the assumptions of Black-Scholes model according to which the volatility is a constant parameter and may be determined based on historical data is not realistic. Thus it is considered that a more appropriate estimate of volatility is implied volatility. This study investigates the correlation between implied volatility and strike price known as volatility smile and the relationship between volatility and option's maturity – the volatility term structure. Testing these correlations on the Romanian options market is quite difficult because of the low market's liquidity.

Keywords: volatility smile, volatility skew, volatility term structure, volatility surface.

JEL Classification: G11, G13.

1. Introduction

Estimating volatility is the most delicate aspect in valuing an option because the option price is very sensitive to volatility changes. It is the source of different estimates of price options that can change suddenly, even if the price of the underlying asset is stable. This correlation is very important because it allows speculating on exchange rate volatility. For example, if an investor is expecting a higher volatility than the market anticipates, he will purchase options that he considers undervalued hoping that the market will correct before the option expires and will sell it at a higher price. If he estimates a higher volatility than the market, he will sell overpriced options. So we can

talk about selling or buying volatilities not options.

A call option is not absolutely overvalued, but in relation to a given value of a model. Since the models used by operators are similar, the difference between the price observed on the market and the one calculated at a time can come only from a different estimation of volatility. Consequently, volatility is a very important parameter in option pricing, and the accuracy with which the volatility will be estimated determines the accuracy of option pricing. In other words, it is not enough to use a good pricing model, but you have to make the best possible volatility estimation.

The problem is that volatility is not observable. Empirical studies have shown that volatility of the underlying asset is not constant, which contradicts the assumption of Black-Scholes model that volatility does not vary over time (Negrea B., 2001). A first approach is to estimate it from historical data - historical volatility. An alternative solution is the implied volatility which is the volatility for which the price calculated with the Black-Scholes model equals the market price (Weizmann A., 2007). In other words, the premise of this approach in estimating implied volatility is that the market is efficient.

An adjacent theory to the Black-Scholes model assumes that volatility follows a diffusion process with jumps followed by a Brownian process. This category of pricing models is known as pricing model with stochastic volatility.

2. The role of historical volatility in option pricing

Estimating volatility from historical data has been used by several researchers such as Black & Scholes (1972), Galai (1977) and

Finnerty (1978). Historical volatility is measured by the standard deviation of returns on the underlying asset for the period preceding the moment of the option pricing. If we exclude dividends and if S_{T-t} and S_T are the underlying asset prices at the beginning and at the end of the period, the rate of return will be:

$$R_t = \frac{S_T - S_{T-dT}}{S_{T-dT}} = \frac{dS}{S} = d \ln S$$

It is assumed that the current rate of return of the underlying asset follows a geometric

Brownian motion $\frac{dS}{S} = \mu dt + \sigma dz$, where

dz is a Wiener-Levy process, *i.e.* variable dz follows a centered normal law with variance dt . We say that R_t follows a lognormal law or that $\ln(1 + R_t)$ follows a normal law or

$\ln \frac{S_T}{S_{T-dT}}$ follows a normal law.

Black-Scholes model assumes that the volatility of the underlying asset is constant, and the best estimate of the volatility for daily data can be done using the following formulas:

$$\sigma^2 = \frac{1}{n-1} \sum_{i=1}^n \left(\ln \left(\frac{S_t}{S_{t-1}} \right) - \mu \right)^2$$

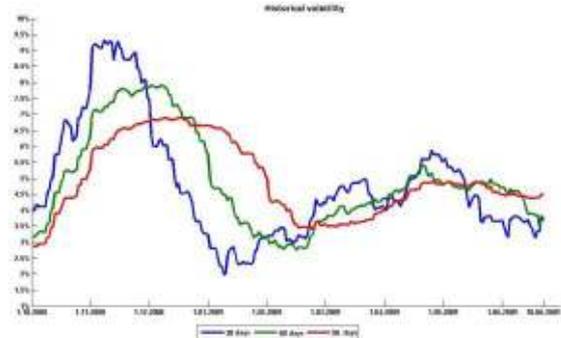

$$\text{where } \mu = \frac{1}{n} \sum_{i=1}^n \ln \left(\frac{S_t}{S_{t-1}} \right)$$

where n is the number of past observations used to calculate the volatility. Generally, the number of observations for calculating the volatility is equal to the number of days remaining until the maturity of the option.

Black-Scholes model assumption regarding the stationarity of the underlying asset price does not reflect the reality. Also, the historical volatility may not be stochastic only considering a calculation period as a rolling window. In fact, the volatility depends on the number of observations used in calculating volatility. This approach has been criticized especially because investors' perceptions on risk are linked exclusively to the past variation of prices. Therefore we can say that it is a subjective estimation of market volatility, that there is a significant difference between the option's market price and its theoretical value. Thus it is considered that a more appropriate estimate of volatility is the implied volatility.

The next figure shows the volatility of DESIF5 futures contract since October 1, 2008 until its maturity in June 18, 2009. To calculate the historical volatility we used rolling windows of 30, 60 and 90 days. As can be seen, as the number of observations used in calculating volatility is higher, the variation curve of the volatility curve is flatter.

Figure 1. Historical volatility of DESIF5 IUN09 contract

Source: Authors' processing

3. Implied volatility – an alternative measure of volatility

Implied volatility is the future theoretical volatility of the underlying asset obtained with the current price of the option. Implied volatility is calculated by the reversal running of the valuation options models (Notger C., 2005).

According to put-call parity relationship, implied volatility should be identical for European call and put options when the two have the same underlying asset, the same strike price and the same maturity. This observation is partly true for American options for which implied volatility can be estimated with Barone Adesi Whaley model. If the underlying asset does not generate revenue, even the Black-Scholes model can be used in order to determine the implied volatility.

The studies on volatility evolution conclude that volatility is strongly correlated with the maturity and the strike price of the option. If the changes in implied volatility take the form of a descending curve, the phenomenon is called *volatility skew*. This shows that implied volatility is lower for options with higher strike prices (deep in the money put options or deep out of the money

call options) than the options with lower strike prices (deep out of the money put options and deep in the money call options). In summary, volatility is lower when the prices are increasing and higher due to the decrease of prices, while the variations are of equal values. This correlation was first observed by Fischer Black in 1976 and is called "Black effect".

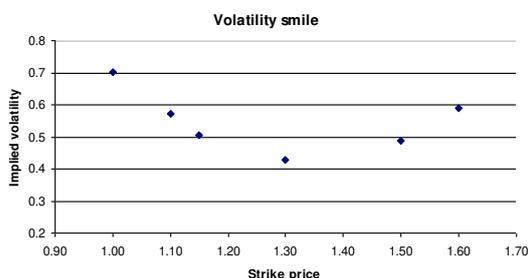

The curve variation of implied volatility to the strike price indicates higher values of volatility for extreme strike prices (deep out of the money options) and lowers for at the money options. The function that reflects the relationship between implied volatility and the strike price is called *volatility smile*. Practically, this distribution shows that operators give more chances to out of the money options to become in the money at the maturity than the Black-Scholes model.

4. Volatility smile and volatility skew

The researches on evolution of volatility concluded that it is strongly correlated with the maturity and the option's strike price. The function that reflects the relationship between implied volatility and the strike price is called *volatility smile*.

The next figure presents a volatility smile for a call option on DESIF5 futures contract with the maturity in December 2009, traded on 31.07.2009, close price for DESIF5 DEC09 being 0,9801 lei/share.

Figure 2. Volatility smile for options on DESIF5 DEC09

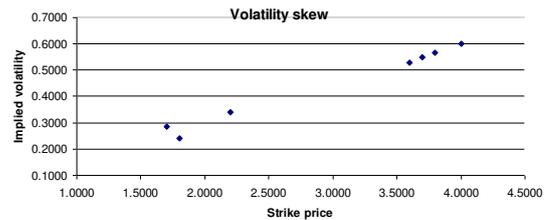

Source: Authors' processing

As we can see, the correlation between implied volatility and strike price observed on the well-developed world market are also confirmed on the Romanian options' market: calls deep in the money have a higher implied volatility decreasing until options become at the money and then rising again as

options approach out of the money. So, the previous figure confirms the presence of volatility smile on the Romanian market.

The next figure shows a volatility skew for a call option on DESIF5 futures contract with the maturity in December 2008, traded on 19.08.2008, close price for DESIF5 DEC09 being 1,82 lei/share.

Figure 3. Volatility skew for options on DESIF5 DEC09

Source: Authors' processing

Even if the volatility skew is not obvious for the call option above, it can be easily seen that when the option is at the money it has the lowest volatility (24.02%) and when it is deep out of the money its implied volatility is maximum (59.93%). In other words, the strike prices that are more distant from the point where the option is at the money have a higher implied volatility. An investor can take advantage from these differences if he will sell the option with maximum implied volatility and buy the one for which the implied volatility is minimal and the curve of volatility skew flattens. This strategy can generate profits even when futures price of the underlying asset does not change in the same direction.

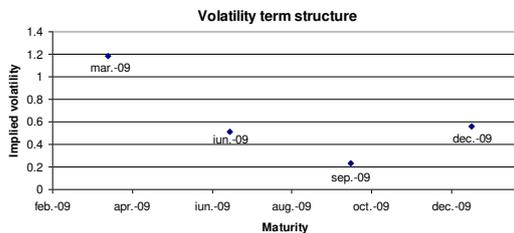

5. Volatility term structure and surface

In addition to the volatility smile, traders take into account the volatility term structure in pricing options. This notion reflects the correlation between volatility and maturity. Practically, the volatility used for at the money option pricing depends on the maturity of the option. Volatility tends to be an increasing function as the maturity of the option approaches because most speculators prefer to bet on the short term surprises. This relationship between implied volatility and maturity is closely related to events that will happen immediately on the market. For example, it is well known the situation in

which stocks' volatility increases significantly the day that the company announces its financial results. Similarly, we see that the implied volatility of options with underlying assets such as stocks increases in the near announcement, and then decreases as new information is incorporated in the stock's price. Options with closer maturities present greater amplitude of implied volatility than those with longer maturity.

Figure 4 shows the evolution of volatility up to maturity for options that were traded on 13.03.2009, with the underlying on DESIF5, the strike price 0,4 lei/share and the maturity on March, June, September and December 2009.

Figure 4. Volatility term structure

Source: Authors' processing

As can be seen in the previous figure, the volatility term structure for the most liquid options on the Romanian market follows nearly the same shape as observed on the developed markets. Surprisingly, the contract with the maturity in December has a high level of implied volatility (56,09%). A possible explanation could be the low liquidity of the Romanian futures market.

Volatility surface combines the volatility smile and the volatility term structure. An example of volatility surface that might be used for foreign currency options is shown in table 1. The entries in the table are implied volatilities calculated based on Black-Scholes model. At any given time, these entries correspond to options for which reliable market data are available.

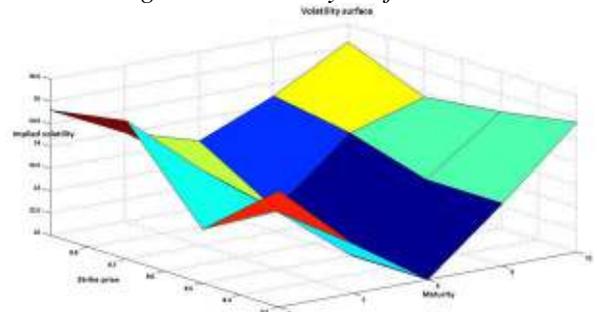

Table 1. Example of volatility surface

Strike \ Maturity	0,4	0,5	0,6	0,7	0,8
1 month	34,6	33,1	32,0	33,4	34,9
6 months	33,2	33,3	32,0	33,4	34,6
9 months	35,1	33,7	32,5	33,9	34,4
12 months	34,8	34,0	33,5	34,2	35,1

Source: Authors' processing

The graph below shows the volatility surface from the previous table.

Figure 5. Volatility surface

Source: Authors' processing

Since there are no available data for all strike prices and all maturities and as the prices of out of the money options with longer maturities remain unchanged over long periods of time, interpolation techniques can be used in order to complete the volatility surfaces.

6. Conclusion

The correlation between implied volatility and strike price identified on the most developed markets around the world is also confirmed on the Romanian options' market: calls deep in the money have an increased implied volatility which decreasing until the options are at the money, afterwards increasing again until the options tend to become deep out of the money.

Besides volatility smiles, traders also take into account volatility term structures in order to price options. On the Romanian market the volatility term structure is not quite identical to the structure observed on international markets even for the most liquid options. A possible explanation might be the low liquidity of the Romanian futures market. More than that, computing implied volatility for a short period of time, a day for example, is very difficult. Furthermore, as directly observable prices of options are limited it is hard to obtain complete information for estimating the value of a portfolio.

Substantiation of Budgetary Indicators. Their Features and Sizes in Education Institution

Popa Ionela

"Constantin Brâncoveanu" University of Pitești

popaionela80@yahoo.com

Abstract

In Romania, the aspects concerning the budget process are laid down in Law 500/2002 regarding public finance. According to this law, budget inputs and outputs as well as the specific regulations of a fiscal year are provided and authorized for a budget year by an annual budget law.

Budgeting, a set of steps taken by state competent bodies in order to materialize the financial policy applied by governmental authority, takes place in the following stages: setting out the budget statement, approving the budget, budget execution, budget execution completion, controlling and approving budget execution completion.

The present paper aims at highlighting several features of how budget substantiation of budgetary indicators takes place in the budgets of public institutions which are entirely funded by the public budget and local budgets..

Key Words: budget, budgetary indicators, substantiation.

J.E.L. Classification: H61, I22

1. Introduction

The State achieves its economic and financial policies choosing a volume of financial resources and a certain structure of their origin. Subsequently, these resources are allocated through public spending made by state institutions for certain purposes (public order, defense, education, culture, etc.).

The financial system has financial relations, relations have an important role in the budget that shows training, allocation and use of budgetary funds needed by national and state-level administrative units - relationships that take place within unified budgets.

Our country needs resources in the society and options for financing these needs are reflected in the consolidated state budget, whereas the management of public funds is done through: the state budget, the state social insurance budget, budget of local special funds, the Treasury budget, budgets of other institutions with autonomous character, while ensuring financial balance.

Law 500/2002 - Public Finance Law defines the general government as "all budgets, components of budget, aggregated and consolidated to form a whole". Consolidated budget components are also highlighted in the law: state budget, state social insurance budget, special funds, treasury budget, budgets of public institutions, autonomous budgets of public institutions wholly or partly funded from the state budget, budget insurance, state social and special budgets, as appropriate, budgets of public institutions financed from own revenues, budget funds from foreign loans contracted or guaranteed by the state and whose repayment, interest and other costs are paid from public funds, external grants budget.

The most important requirement of the entire budget management is the consistent implementation of the sizing requirements of financial resources with the possibility of their insurance. Concordance between "what you want" to "what can be" budget management is carried out so that, finally, the objectives are met.

In light of its role, the state cannot conceive of unmet needs, but uses public budget as a tool for the purpose of sharing resources collected. As a document approved by law, the budget is an important milestone of reporting the extent to which the state is involved in economic and social life, the economy capability to contribute to the establishment of financial resources, as well as how the state intends to manage them.

The numerous needs that must be met under conditions of limited resources involve state attention in choosing the best forecasting method and application costs of measuring the efficient allocation and use of public funds.

2. Forms of Financing Education Institutions

Budget substantiation of public institutions which receive their own incomes (it is the case of undergraduate education institutions) is done only for the expenses that are covered by budgetary allocations.

Financing educational institutions shall be in accordance with Law 1/2011, basic finance, funding and financing the complementary needs.

Executing **basic finance** in the normal education process takes place according to national standards. This ensures the state budget, the amounts deducted from VAT and state income taxes by local budgets for expenditure categories as follows:

- a) expenditures on salaries, bonuses, allowances and other payments established by law, and related contributions;
- b) expenditures on staff training and ongoing assessment;
- c) the costs of periodic reviews of students;
- d) expenses for materials and services;
- e) maintenance costs.

Basic finance in education institutions is calculated by multiplying the standard cost per student / pre-primary school specific coefficients and curriculum of students and annually approval of the Government decision:

$$F_b = C_s \times S \times k_i \times k_{rui}$$

Where:

F_b = volume of basic;

C_s = standard cost per pupil in secondary education

E_i = the number of students enrolled in the profile/education level

i 1 ... n = level/ profile / educational pathway

K_i = coefficient of differentiation levels / profiles / educational pathways

K_{rui} = coefficient of differentiation for rural / urban level/ profile / chain of education

There is also the **complementary financing** of capital expenditure, social

spending and other expenses associated with the educational process. It ensures local budgets, the amount deducted from the VAT for the following categories of expenditure:

- a) investment, repairs;
- b) subsidies for boarding and canteens;
- c) expenditure on national assessment of students;
- d) expenditure on student grants;
- e) expenses for transportation of students;
- f) expenses for commuting teachers according to the law;
- g) expenses for the mandatory periodic health examination of teachers, except those for whom the law provides it is free;
- h) expenditure on competitions organized in extracurricular school and educational activity schemes;
- i) charges for insurance in related work for staff, preschoolers and students;
- j) management of information services situations;
- k) expenses for participation in European cooperation projects in education and training.

The complementary funding is approved through the annual state budget law. Public finances are distributed in communes, towns, cities and districts of Bucharest by DG's county or Bucharest and with the assistance of the county school inspectorates respectively of Bucharest.

The calculation of the additional funding is:

$$F_c = S F_{ci}$$

Where:

F_c = fund for additional funding;

F_{ci} = fund needed to cover costs of the "i" of activity

Additional funding is provided as a lump sum from the Ministry of Education', Youth and Sports, for the awards of education institutions with outstanding results in the inclusion or school performance. Local councils, concerned sectors of Bucharest and county councils, namely the General Council of Bucharest additionally contribute to giving grants to these institutions, based on its own methodology.

Supplementary funding is achieved based on agreements between an education institution and a financial body.

$$F_s = C_s \times S \times k_{si}$$

Where:

F_s = fund needed for additional funding
 E_{si} = number of students receiving category "i" additional activity that will be funded
 C_s = standard cost/ student
 K_{si} = correction factor applicable for standard cost / student activity financed in addition

Education institutions can get their incomes from specific activities by the law, donations or other legal sources. Their incomes diminish not in terms of basic, complementary or supplementary finance, and are used as decided by the Board. At the end of the fiscal year, unspent money remains in the account of the education institution and the latter reports next year's budget.

the Director and Board of Directors of the education institution is responsible for budgets approved by the law.

3. Substantiation of Budgetary Indicators. Their Features and Sizes in an Education Institution

The substantiation of budgetary indicators involves the following steps:

The draft budget is approved by the Board and accompanied by a background note and it is submitted to the City Council.

The City Council reviews and corrects it if necessary, taking into account the compliance of projects in the development program of the school, the number of students approved by the Board and approved by the competent institutions for development and modernization projects of the school, additional funding programs approved by the law or other competent institutions, including the local council.

After its acquisition by the City Council, it is submitted to the County Council together with background notes for each form of financing (basic, additional and supplementary).

The County Council collects data from local councils, allocation coefficients calculated for the cost of local students, using the same methodology that they use in local councils for schools. In the next step, there are the necessary funds for education based on the three forms of funding that will be

requested from the state budget and the amount of funds needed to be allocated to the education fund balancing local budgets.

The National Pre-University Education Funding Council under Article 104, paragraph 4 of National Education Law no. 1/2011 determines the standard cost per student and sent to the Ministry of Finance proposes a funding level for education allocated from the state budget by type of financing and allocation coefficients counties to fund education approved by the law. The Ministry of Finance includes the state budget, the necessary fund indicators representing the three forms of financing. After the approval of the state budget, allocations are done on three structures:

1. from the state budget to the County Council
2. From the County Council to the Local Council
3. the City Council to the school.

Upon receipt of the proper budget as a gross amount, the school prepares its budget. It is endorsed by the Board of Directors approved by the City Council. After completing these steps, the budget becomes operational.

4. Conclusions

Analyzing how the theory discussed above is put into practice identifies a number of issues:

Student cost standards for personnel expenses and material costs determined in accordance with Government Decision no. 1395/2010, amended by GD no. 926/2011, have been found to be sufficient to ensure the annual costs in many schools.

Under these circumstances, the core funding is proposed based on the standard cost per student (Art. 104 of Law no. 1/2011), using the formula funding. Core funding is based on the payroll for the current school year and the corresponding historical costs year.

It is difficult for officers, teachers in other specializations than finance, for other staff in this type of entity except the financial – accounting department. Instead, let us understand the requirements of the Ministry of Finance which should be "translated and adjusted".

In any entity, although there is some

management control system, otherwise there is functioning with frequent and serious distortions. Each supervisor has to organize themselves and adopt some measures in their work: defining individual tasks of staff, establishing working methods, creating an information system, supervising staff activities etc., meaning nothing else than a system with its own internal control management.

The public nature of the funds and assets (and the private property items in the state or administrative - territorial units) that manages a public entity requires that its internal control system be developed, perfected by allowing the general manager / officer, and officers from other hierarchical levels within the entity to exert good control over the operation of the public entity as a whole and their individual conducts in its activities should be focused on achieving objectives.

Exit Routes and Performance Measurement for Private Equity Investments

Popescu Tudor

Babes-Bolyai University, Faculty of European Studies,
Cluj-Napoca, Romania
tudor8019@yahoo.com

Abstract

Private equity is an alternative form of financing companies, besides classical methods (bank loan or bonds), which is done in exchange of a part of the share capital of the company. This funding is realized by investors interested in the company that also offer portfolio companies expertise in order to increase their value. The investors' gain is the difference between the selling price and the buying price of the shares. Therefore, the divestment process is of great importance for the investors. Because the shares are not liquid, the divestment process is complex. There are five different routes an investor can follow in order to liquidate the investment. Once the exit is over, the investor can measure the performance of the investment in several ways. The article presents the entire exit process and performance measurement of the investment.

Keywords: private equity, investment, exit route, performance

J.E.L. classification: G24, G34

1. Introduction

Private equity is a form of equity investment into private companies that are not quoted on a stock exchange. Private equity is distinguished by its active investment model, in which it seeks to deliver operational improvements in its companies, over several years [22].

The definition of the private equity activity has changed in time, including today any investment in share capital of companies, listed or not, accompanied by the active involvement of investors in their activity, through a well developed strategy, with the

express purpose of helping to increase the value of the respective companies and to generate profits by selling the shares at a higher price than the acquisition one. Thus, private equity operations offer financing and expertise to portfolio companies in exchange to a part of their share capital. The profit realized by private equity investments is represented by the difference between the selling and the buying price of the shares. This difference is a result of active involvement of the investors in the activities of companies in order to increase their value. The role of private equity activity is to increase the performance of the company, because “any economic entity must increase its performance in order to survive” [5].

The divestment process represents the final stage of a private equity investment. It is a very important process for the investors, because the profits that they make depend of its success.

2. The exit process

The divestment (exit or liquidation of the investment) is a process through which the founders, management or investors in a company find buyers and sell a part or all the shares of the company. Through an exit, the investors realize gains, and the company can receive an infusion of capital and/or a new strategic direction from the buyer.

Investors change their stocks in money when they liquidate the investment (exit – selling the owned shares). Most of them target a 38% Internal Rate of Return (IRR) and 5 times investment multiple for a 5 year period [6].

The exit term in this context can be called divestment and it means that the private equity investor sells his contribution to a company, totally or partially, to reduce his exposure. In order to make money from the

investments, the private equity investors have to transform their non-liquid shares into cashed gains.

Private equity investments are non-liquid and therefore cannot be sold as easily and fast as public companies' stocks on the market. While venture capital funds focus on start-up companies with a 7-10 years investment plan, private equity and buyout funds only have a 3 to 5 year plan. The successful selling of the shares is not critical only to realizing substantial gains, but also to attracting extra capital.

An essential feature of the private equity funding is the limited time of the investment, therefore the exit process being of utmost importance. Because there is a limited period of investment time, private equity funds must finalize the investment relation with the companies in the portfolio after a certain period of time. In this way, investors have to liquidate investments at a certain point.

2.1. Potential exit routes

According to authors and practitioners in this field [3][11][23], there are five important exit routes for an investment: trade sales, secondary buyouts, initial public offers (IPO), buy-backs and write-offs. Also, liquidation can be partial or complete, for all the five methods, with the mention that trade sales usually refer to the entire owned package, and by initial public offer (IPO) a total and immediate exit is not very likely. Besides the five methods, some authors claim that recapitalization can also be a method of partial liquidation of an investment. Still, recapitalization does not change the structure of the shareholders and therefore cannot be called liquidation. Also, another method through which the investors may recover their money is liquidation of the company.

The process of every one of these methods is different and has distinct requirements based on the size and features of the company. Every method has different costs, different execution time, different requests regarding the necessary documents which have to be made public, impact on the fees that have to be paid, etc.

a. Trade sale. Selling the company to a competitor or a partner is the most common exit route in Europe. If the stake in the company represents a majority and the whole

company is sold, we are talking about merger or acquisition type of liquidation. The sale can also be made to a financial investor.

Trade sales are usually complete liquidations, and are made against money, in comparison with partial sales, much more rare, in which you usually receive shares at the buying company.

The buyer in a trade sale is usually from the same industry (strategic investor) and follows product and technology integration of the two companies (the buying company and the acquired company), either horizontally, or vertically. Strategic acquisitions may include the merger of two related companies (such as supplying raw materials, or companies that apply certain patents). Because they work in the same industry, the buyer may best evaluate the value of the bought and resulted company. Due to the synergies created, strategic buyers usually pay more. But a synergy is not always created by combining two entities. Many times, at the base of the acquisition lie different reasons, such as the desire to seize human personnel, certain patents, client database, etc. Also, the desire to buy can be placed on the necessity of the buyer to have a certain technology and can be cheaper (in time and money) to acquire a company that already holds the technology rather than to develop in internally.

The anticipation of the buyer regarding the resulted gain by combining the two companies determines the sum that he is willing to pay for the targeted company. The price is negotiated between the two companies on the basis of the power of negotiation and information held by both the parties regarding the generated synergy.

b. Secondary sales and secondary buyouts. Specialized literature differentiates secondary sales and secondary buyouts. Different to the trade sale, the secondary sale is a method of liquidating the investment, where only the investment fund has to sell its shares, but not the managers or other investors. The buyers are usually strategic investors. They do not have access to inside information as in the case of a takeover. Also, synergies are harder to realize, as the two companies do not merge. Therefore, the prices are lower than in the case of trade sales. This is not such a common method.

By contrast, secondary buyouts are

transactions through which the company is sold from one financial investor to another. This phenomenon grows due to the large sums of money used in the industry.

c. Initial public offer (IPO). Initial public offers are very attractive for investors as a way to liquidate an investment. Primary public offers market gives the possibility to obtain liquidities and at the same time keep a certain stake in the company.

New listed companies need to have a very high growth potential in order to maintain a high price after listing. Plus, they need to have a proved competitive advantage, capability to maintain market share, and to be situated in areas favored by the analysts. The investor can bring an added value to the offering process by choosing an investment bank which can lead the offer. The bank has to be experienced in the company's industry and to have analytical experience and coverage in the respective field.

In the case of a public offer, the company is selling a part of the shares to the public. These public offers are followed (most of the times) by the listing of the company on the stock exchange. From all the methods of liquidating an investment, the initial public offer is the only one through which the company receives directly an infusion of capital, offering at the same time (if it is listed on the stock exchange) the possibility of shareholders to liquidate their investment at any time.

It is a form of divestment which lasts a long period of time, because the private equity funds that have invested in the company are not allowed to sell their shares for 12 months (the lock-up period) after the company is listed on the exchange, as to not create panic among the investors, resulting in massive sales and low stock price. An initial public offer does not represent a liquidation method in itself; it only precedes and facilitates such an option. Investors who buy the newly emitted shares have a low degree of initiation, in comparison to the private equity funds, but this fact is countered by the interest of those involved in the emission to keep their reputation, and thus to evaluate accurately the stock price. One of the disadvantages of such a public offer is the high cost of the entire operation.

d. Buy-back. In a buy-back transaction, the private equity fund sells its shares back to its

initial owner or the company. Buy-backs are very common in the case of investments which seem to be without success, companies that do not have growth potential, a reduced value and are at the beginning of the investment period. In many funding contracts, there is the clause which stipulates that investors can resell their stocks to the owner or to the company if certain established targets are not fulfilled, such as performance levels or the failure to list the company on the stock exchange.

With all these, most of the times, the owners do not have the necessary resources to buy the shares back. In order to go through with the buy-back, the entrepreneur or the firm must get a loan, thus raising the debt of the company. The managing team can therefore discipline itself, having to deal with high credit interests.

e. Recapitalization. Recapitalizations do not truly represent a form of divestment, because the stake of the investors is not reduced. The financial exposure of the investors is reduced by receiving an extraordinary dividend possible only by contracting another credit.

The idea is to re-debt the acquisitioned company after the reimbursement of a part of the initial credit. There are several methods to recapitalize a company. A recapitalizing through loan means a credit to buy-back its own shares. The price that can be paid is limited to the company's potential to be in debt. These types of methods are usually applied in situations of take-overs (LBO – leveraged buyout), because the acquired companies are big in size, mature and used to generate constant cash flows sufficiently large to be able to pay the debts.

Another method assumes the involvement of other investors. The company may be at a development stage which presents more interest to a more powerful investor.

f. Write-offs, in case of a failed investment.

If the acquired company does not manage to reach the targeted performance level, but only manages to survive, the investors are no longer involved in restructuring it and it temporarily goes into a flat line. These types of investments sustain only the life-style of the employees and the shareholders, not having the hoped growth potential.

2.2. The exit process

The entire exit process can be detailed over several steps, with are detailed below.

1. Identifying the exit opportunity. The identification of an opportunity to realize the exit lies at the beginning of every exit process. Lieber [15] believes that there must be periodical evaluation of the investments in order to identify the exit opportunities. The preparations for the exit process have to be made as early as possible, even before beginning the investment.

2. Evaluating the companies in the portfolio and the exit routes. The second step presumes the detailed evaluation of the company and the possible exit routes. Although in the first step there is an evaluation, here the evaluation is more thorough. In this step the investors also appeal to field experts, analysts, evaluators, investment banks, etc.

3. Planning the exit process and mandating the consultants. In this stage, the private equity company, alongside the management, start to prepare the exit plan, this being known only by those directly involved.

4. Sharing assignments, negotiating benefits. While most of the duties have been assigned in step three, here follows the informing of more persons regarding the exit intention. Preparing for an exit requires many human resources, and can distract the management’s attention from the current operations. The involvement of more people is required and the exact assignment of the tasks. In this stage there can still be discussions regarding benefits given to certain key persons.

5. Preparations before beginning the exit process. Before beginning the process, a lot of preparations are required: advertising materials, legal and financial documents, financial projections, and everything that leads to the accurate evaluation of the business. Most of the times, the company can be visited by potential buyers.

6. Launching the exit process. After the preparations and analysis of potential buyers, the exit process begins, formally or informally, by offering potential buyers pertinent information. The information is revealed only after signing a confidentiality agreement, thus protecting the interests of the

company. If there are several exit possibilities, those are not revealed to the investors.

7. Unrolling the process, client negotiations. Once the exit process is launched, extra information is given to potential buyers, if solicited.

8. Exit opportunities and options evaluation. After receiving offers, the private equity company and the consultants must evaluate the possible exit routes and offers. This process can last a few weeks, and interested buyers may be called to bid for the company.

9. Closing the transaction. After a few rounds of detailed negotiations, the transaction can be completed, which will lead to the change in company owners.

10. Post-transactional evaluation. After closing the transaction, an evaluation regarding how it went can be made, in order to identify aspects which can be improved.

3. Performance measurement

The concept of performance is a reference both in theoretical approaches and in practice due to the fact that the field of economic performance includes various terms, through the most important we can mention competitiveness, productivity, profitability and business growth [18].

Once the exit process has come to an end, a performance measurement of the entire operation can be made, or in case of several investments of a private equity fund, an evaluation of the entire fund. While standard methods of quantitative evaluation of risks and reward have made great progresses, for other “alternative” forms of investments, including risk funds, a standard profitability evaluation of the private equity activity has not been established. The lack of trustworthy data about the performances and secret nature of the transactions is completed by the attempt of background managers to avoid publicity regarding the earnings generated by the funds they run. This means that most of the performance based reports are incomplete. With all these, as investors become more and more sophisticated, and funds start to attract a more diverse range of investors, the transparency in this field is beginning to grow.

The difficulty of measuring the risk and

reward profile of private equity funds is not owed entirely to the lack of information, but also to the imperfection of the secondary market for such share packages. As a consequence, for every investment there are only two moments when the price of the transactions can be observed objectively – at the moment of purchasing and exiting. Therefore, historical data lacks, and evaluating the performance of a private equity fund becomes complex.

Because investments in private equity can be made either through a fund either direct (co-investment), there are two ways of measuring the performance from the point of view of an investor: either by analyzing risk and reward features in a fund, either by analyzing the performance of the investment in a certain company. While the first approach is relevant for all the investors in a fund, the second one is important only for the manager of the fund and its investors. Because the first one is more relevant to all the investors, it is more often used. Next we present three methods of measuring the performance that can be applied in both situations. Cash flows represent the basis of analysis for all the three methods.

a) Investment multiples. Because of the long term orientation and lack of liquidity of private equity investments, we can use as a method of measuring the performance, the ratio between the invested and returned capital. The ratio between the invested and return capital is an easy method to measure the profitability of an investment and it represents the multiplying rate of the invested capital. Unfortunately, this method does not take into account the period of time in which these earnings are made. This fact makes it almost impossible to compare the performance of two different funds. The following concept offers solutions to this problem and is used with a higher rate of success.

b) Internal rate of return (IRR) based on cash flows. Internal rate of return has become the standard measurement system of the profitability of a private equity activity at the investor level, singular investments, as well as at background and field investments level. This rate represents the up-to-date rate for which the present value of cash flows is zero. Mathematically, the internal rate of return can be expressed as being the solution to the

following equation, where T represents the life span of the fund, and CF_t represents the cash flow generate in the t period:

$$\sum_{t=0}^T CF_t(1 + RIR)^{-t} = 0$$

c) “Public market equivalent” (PME) based on cash flows. Kaserer and Diller [13] explain the objective of the approach through the public market equivalent as: *“Given that the investor invests – in terms of present value – Euro 1 in a private equity fund, how many Euros would he have to invest in a given public market index in order to generate a cash flow equivalent investment and, hence, in order to end up with the same terminal wealth? The PME is exactly the answer to this question”*. This indicator represents the ratio between the profitability obtained by investing in a private equity fund and reinvesting the intermediary gain on the stock market, and the profitability obtained by investing the same amount on the stock market. This permits calculating the performance of a fund by eliminating the problem connected to reinvesting at the same internal rate of return. Mathematically, the indicator can be expressed through the following formula:

$$PME = \frac{\sum_{t=1}^T cf_t \prod_{i=t+1}^T (1 + R_{it})}{\prod_{t=1}^T (1 + R_{it})}$$

where:

R_{it} = The net return of a public market index in the period t

cf_t = the normalized positive cash flow of the private equity fund in period t

If the private equity fund has a superior performance then the investment in the stock market, the PME value is greater than 1. The public market equivalent can be used to compare the profitability of the funds, as well as to compare the individual investments.

4. Conclusions

Private equity is an alternative form of financing companies, besides classical forms (bank loans or bonds). This financing is done against a stake in the company’s share capital. Besides financing, private equity investors offer expertise to their portfolio companies, in order to help increase their value and realize profits from selling the shares at a higher price than the purchase

price.

The divestment is the final stage of any private equity investment. The exit is the final goal of any private equity investment and of its success depends the profit realized by the investment. The exit process is a very complex one and ideally has to be planned even before the investment is made. Investors change their stocks in money when they liquidate the investment (exit – selling the owned shares). Private equity investments are non-liquid and therefore cannot be sold as easily and fast as public companies' stocks on the market.

According to authors and practitioners there are five important exit routes for an investment: trade sales, secondary buyouts, initial public offers (IPO), buy-backs and write-offs. Among these, the IPO is the only exit route that provides financing to the company.

The exit process comprises 10 steps that differ based on the exit route chosen by the investor.

Once the exit process is finished, a performance measure can be made for the entire investment. Because of lack on information about private equity deals, the performance measurement is a complex task. The three most used methods of performance measurement are the investment multiples, the internal rate of return (IRR) and the public market equivalent (PME).

Abstract

Analyses based on the study of financial flows allow coherent merge to study the financial equilibrium of the firm's performance. If static analysis to assess the financial imbalance at some point, but does not explain its evolution, in contrast, dynamic analysis highlights the evolution of financial imbalance, but does not indicate the extent of it. It follows that the two kinds of analysis are complementary and should be pursued simultaneously.

Dynamic analysis is based on the concept of streams-streams and streams of Treasury funds. The notion of flow of funds is fundamental to building the dashboard or instrument panel uses funding resources.

Key words: cash-flow, dashboard, funds, resources.

J.E.L. classification: M41.

1. Introduction

The funding is an important financial document, because starting from the classical synthesis documents such as the balance sheet and income account results, allow to obtain more information on the company and which are not provided by them directly, such as: investments, debt underwriting volume, volume of dividends distributed, self-financing capacity level. It appears that the funding allows an analysis of the different strategies adopted by the undertaking.

The dashboard is funding an array of

means and resources in explaining variation in the elements of heritage in the course of the reference period (usually a year) and has two parts. [2]

Funding for the development of the instrument panel is to explain the formation of the Revolving Fund and its relationship with Treasury balance through monetary flows (receipts and payments) for the financial year ended. Shall be determined mainly on the basis of two successive balance sheets and explains the connection between the top and the bottom of the sheet through the Revolving Fund variance

2. Development phases of financing

To develop an array of funding must go through two phases:

(a) determination of variation Revolving Fund as a result of the change in capital structure at the top of the sheet.

(b) the determination of the variation of net Treasury) as a result of the amendment need Revolving Fund (the bottom of the sheet) articulated with variation of working capital.

Through an array of funding streams is highlighted by the financial resources mobilised by the enterprise, namely: of self-financing (internal); in consideration of external loans and the use of these financial resources for investments; payment of dividends and the repayment of loans. [3]

The funding is set by using: the balance sheet positions and variations in flows shown in the profit and loss account.

Changes in balance sheet items are obtained from a balance sheet variables

(differential) or the difference between two consecutive balance sheets (both being detained before they affect the result).

Variations in this manner in order to identify four types of financial flows:

- an increase in assets due to the acquisition of an asset or the debt growth, requiring greater use of funds;
- a decrease in liabilities, which means all use of funds;
- an increase in liabilities, due to new commitments made by the enterprise, provide new resources;
- a reduction in asset consecutively or in realizing the assets, either in reacoperirea previous claims held by an enterprise also offers new resources.

The funding dashboard highlights this variation in a detailed and analytical form. Increase in inventories gross funds expressed not only the realization of new investments, it may be due to the acquisition of new fixed assets, fixed assets growth in previous years. In the same way, changes in amount (value) of long-term debt can result in new debt and made (increase) in liabilities and returned (decrease).

These variations are classified according to their term. In fact, the picture cuts off funding and resources uses with maturity over one year (which have the top of the sheet) the uses and resources with maturity less than one year (the bottom of the sheet). [4] Figure No. 1. exemplifies this structure:

Figure No. 1. the funding Dashboard

USES	RESOURCES
Uses long or medium: • increase of assets restrained • permanent capital reduction	Long-term resources and medium: • increasing the permanent capital • reduction of assets restrained
Uses: • increase of circulating assets • decrease in short-term debt	Short-term resources: • increase in short-term debt • reduction of circulating assets

Source: Feleagă, N., Kingsley, L. *Accounting policies and options*, Economic Publishing House, Bucharest, 2002, pp. 110

The funding comprises two parts:

The first part examines how, in Dynamics, structural balance between stable elements of functional, i.e. balance sheet

variance working capital net global (Δ FRNG). This part of the painting is the result of investment and financing of the enterprise during the period analyzed.

$\Delta = \Delta$ FRNG sustainable RESOURCES Δ USES stable

Explanation of variance FRNG starts from the identification of the sources of capital and continues with an explanation of the use of those sources in the upper part of the sheet.

The starting point in the construction of the painting represents financing gross operating surplus revealed in the account as a potential source for the self-financing capacity of the company. [5]

Part II of the Finance Panel explaining variation in the revolving fund net overall based on items in the bottom of the functional review, highlighting issues of work and health personnel on their Treasury. This part examines how he has used the revolving fund net global balance between cyclical elements of the functional balance of the monetary balance between receipts and payments. [6]

Δ FRNG = Δ Δ Payables net current assets-short term

3. Interpretation of financing

In the interpretation of the funding must be taken into account and uses significant resources, i.e. the changes affecting the top sheet (acquisition of fixed assets, contracting of loans of over one year). The funding allows the appreciation of the company's financial policy coherence, as follows:

- analysis of investment and financing of the company, highlighting them rapidly if the investments are financed by long-term or not;
- checking whether the financial balance principles were applied during the current period, whereas the long-term policy implications of the Revolving Fund.

Uses and resources under one year is characterised by instability and discontinuity in evolution, elements conducive to a fair and reasoned analysis. However, it should be highlighted the consequences of long-term policy on assets and liabilities in the short term and the need for variation Revolving Fund of the Treasury.

The evolution of the bottom of the balance sheet is presented in a manner that

emphasizes net variations of different posts: inventories, short-term debt service for the NFR, then Bank debts and short-term for the Treasury. [7]

4. Picture of cash flows

Cash-flow from operating activities relative - Operating activities are the main revenue generating activities and any other activity, except for those defined as activities of investment or financing.

The value of the cash flows arising from operating activities is a key indicator of the extent to which the company generated enough cash to maintain its ability to pay dividends, etc., without having to have recourse to other external sources of finance.[8]

Cash flows from operating activities are derived from the principal revenue-producing activities of the firm. Therefore, they generally result from transactions and other events that contribute to the formation of the net result for the financial year in question.[9]

Thus, as streams of Treasury operation with predilection: proceeds from the sale of goods and provision of services; Revenue from fees, fees, fees, fees; payments to suppliers of goods and services; payments to or on behalf of employees; payments or receipts from income tax, other than those that can be identified within the investment and financing activities.

Norm IAS 7 provides for two ways of operating cash-flow:

Direct method-which has the advantage of presenting cash flows from current transactions of the company, referring to receipts and payments (credit inputs and outputs) rough;

Indirect method-according to which the net result is corrected to take into account:

- the influence of operations non cash;
- any report or regularization of receipts or payments in the past or future, alleged exploitation;
- of the items of income or expense associated with the cash flows related to investment or financing.

IAS 7 recommends businesses use direct method, because this method allows obtaining information which may prove to be useful for estimating future cash flows,

which is not possible by applying the indirect method. However, even if the international body recommends using direct method indirect method has the advantage of reconciliation between the accounting details and operational Treasury. [10]

Annex to IAS 7 standard provides examples on determination of cash flows on the three activities, either through direct method or indirect. On the basis of examples, can be reached, however, on the next presentation, from the figure no. 2.:

Figure No. 2 Cash-flow related to operating activities (direct method)

Revenue generated by customer relations + Cash receipts from royalties, fees and other revenue -Payments in favor of suppliers -Payments in favor of and on behalf of the staff of the -Interest and dividends paid to ¹⁾ -VAT Payments + Other revenue generated by mining -Other payments generated by mining -Income tax Payments on profits ²⁾ Extraordinary Items ± = Net cash Flow more or less relative to operating activities 1.) These flows could be included also in the category of funding flows 2.) These flows could be distributed among the activities of the investment and financing.

Source: Feleagă, N., Kingsley, L., *Accounting policies and options*, Economic Publishing House, Bucharest, 2002, pp. 187

Under the direct method, information on the main categories of payments and receipts may be obtained either from the accounts of the company, either by adjusting sales, cost of sales and other items in the profit and loss account for the period: changes and advances, obligations and stocks; other items not requiring cash and other items whose monetary incidents consist of streams of investment or funding (Figure No. 3.).

Figure No. 3. Cash-flow related to operating activities (indirect method)

Result before taxation ± and extraordinary items <u>Elimination of income and expenses without affecting the Treasury:</u> + Depreciation and provision charges -Income from depreciation and provisions

Elimination of income and expenses unrelated to the operation:

Result from disposal of fixed assets +
Result from disposal of securities +
placement
+ Interest expenses
-Income from interest and dividends
-Investment Subsidies paid out of income
= ± Operating Profit before change in revolving fund requirement
Stock Variation ±
+ Customer accounts and Change other operating receivables
Variation in prepaid expenses +-
Vendor accounts and Variation ± other Payables from operations
The income advance Variation ± (in operation)

Other processes involving information collection and payment type:

-Interest and dividends paid to ¹⁾
-The taxes on benefits Payments ²⁾
Extraordinary Items ±
= Net cash Flow more or less relative to operating activities

1) these flows could be included also in the category of funding streams.

2) these flows could be distributed among the activities of the investment and financing.

Source: Felegă, N., Kingsley, L., *Accounting policies and options*, Economic Publishing House, Bucharest, 2002, pp. 190

In accordance with the indirect method, the net cash flow from operating activities is determined by adjusting the net result, taking into account the impact of:

- changes occurring in the course of the year, inventories, receivables and Payables from operations;
- other items that are not of the nature of the cash, as depreciation, provisions, deferred income taxes, the losses or gains unrealized exchange rate differences;
- other items for which the impact is achieved through the Treasury investment flows and the funding.

Cash-flow from investment activities - cash-flow from investment activities show the size of the expenditure incurred for the purchase of resources for the benefit of future generation (and, implicitly, cash), such as:
[11]

- payments for purchase of fixed assets and other long-term assets, including capitalized development costs and disbursements incurred by the enterprise products for asset headings themselves;
- proceeds from the sale of fixed assets and other long-term assets;
- receipts/payments related to the sale/purchase of equity and debt securities of other companies, as well as receipts/payments related to the sale of holdings in joint ventures (other than receipts/payments for instruments considered to be cash equivalents or held for commercial purposes);
- cash advances and loans to third parties (other than advances and loans granted by a financial institution);
- revenue arising from the repayment of advances and loans to other parties (other than advances and loans granted by a financial institution).

IAS 7 does not specify which headings are set corresponding to these streams. However, the examples given in annex rule leads to the following presentation layout (see Figure No. 4.):

Figure No. 4. Cash-flow related to investment activities

-Purchase filiaRon x (-) the Treasury purchased
FiliaRon Leasing + y
-Purchase of fixed assets
-Acquisition of investments
+ The proceeds resulting from the disposal of fixed assets
+ The proceeds resulting from the disposal of investments
+ Interest received
+ Dividends received (paid)
= Net cash Flow more or less relative to the investment activities

Source: Felegă, N., Kingsley, L.- *Accounting policies and options*, Economic Publishing House, Bucharest, 2002, 193

Cash flow from financing activities - financing activities are those activities that give rise to changes in the size and structure of the capital and borrowed capital of the firm.

Separate presentation of these flows is important because it is useful "suppliers" of society in the capital appreciation of the amounts they will withdraw from the funds

(equity).

The Treasury movements resulting from financing activities [12] refers to (Figure No. 5):

- proceeds from issuance of shares or other equity instruments;
- payments to shareholders for the purchase or redemption of shares;
- receipts/payments from the issuance of bonds, bank loans;
- rates payments made under financial leasing contracts.

Figure No. 5. Cash flows related to financing activities

+ Capital growth, cash
-Reimbursement of capital in cash
+ Issue (Contracting) of loans (other than cash)
-Repayment of loans (other than cash)
-Repayment of debt resulting from the contracts of tenancy-finance
-Interest and dividends paid to
= Net cash Flow more or less relative to financing activities

Source: Feleagă, N., Kingsley, L., *Accounting policies and options*, Economic Publishing House, Bucharest, 2002, pag. 194

5. Conclusions

Information provided by array may serve also to assess the relationships between the three types of activities. One and the same operation (more complex) can assume the Treasury movements included in the different categories. Thus, when the repayment of a loan covers both interest and capital [14], the relevant interest may be classified as operating activity flows, while the corresponding share capital corresponding to the financing activities flows.

If we refer to the usefulness of cash flows in financial diagnosis, the main goal is the presentation of information to assist investors and creditors to accurately predict the amount of cash that will be distributed in the future in the form of dividends or interest, or to assist in the assessment of risk. The term risk, in this context [15], includes both the variability of expected future income and the probability of insolvency or bankruptcy.

With regard to the use of cash flows in financial diagnosis, two lines of analysis are considered relevant, namely: risk analysis of

bankruptcy and profitability analysis.

Is Patent Box a Solution to Retain and Attract Innovative Businesses in EU?

History, Concept and Further Development

Ristea Luminita
Spiru Haret University
Trandafir Adina
Spiru Haret University
trandafir.adina@yahoo.co.uk

Abstract

Nowadays the concept of intellectual property (IP) became very important and sensitive. Using literature review, this article approach the IP problem from a business and taxation perspective. The key issue concept of patent box regime was treated presenting the main differences towards R&D tax credits in different countries. Our main conclusion is that, first of all, each country should understand the concept of patent box regime and after that shall research the ways to properly implement it in the local environment and legislation.

Key words: intellectual property, R&D tax credits, Patent box regime

J.E.L. Classification: O34

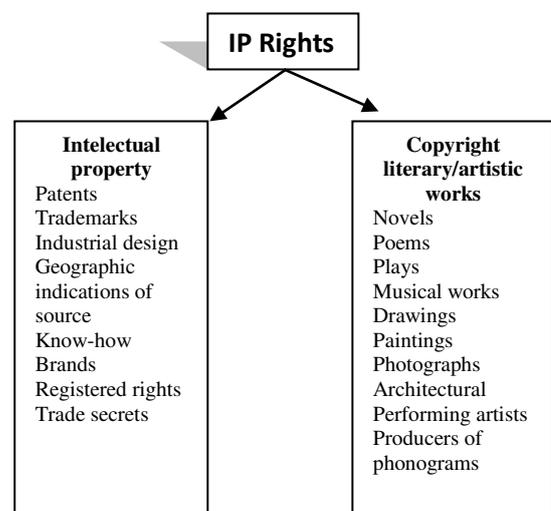

1. Introduction

Nowadays businesses have become more focused on building and deriving value from creating and exploiting intangible assets and the concept of intellectual property (IP) became very important.

There are many definitions for Intellectual property (IP) but the essence is that IP is a legal concept which refers to protecting the products of human intelligence and creation, creations of the mind for which exclusive rights are recognized [11, 12, 13].

IP is divided into two categories [9]: Industrial property and copyright (see Figure no.1)

Figure no.1 IP rights categories

Source: own processing of informations from the scientific literature

From a business perspective IP should be considered as the most important strategic asset of a company, rather than legal papers and evidences that is the key driver of business performance and differentiation[2].

Taxation in case of IP is one of the key consideration for companies but also for each state authority. Due to the fact that IP is highly mobile and can be easily separated from the jurisdiction where it was developed companies prefer to move IP offshore to minimize tax consequences [4].

This article approach the new concept of Patent Box from a business and taxation perspective. It is structured in five parts: the second part approach the differences between R&D credit regime and Patent Box, the third part treats the new concept of Patent Box as a tax incentives for business environment and the fourth part approaches the application of patent box regime in different countries. In

the last part of article we conclude that the main important start point is to understanding the new concept of Patent Box and its regime and to customize its application in accordance with local framework.

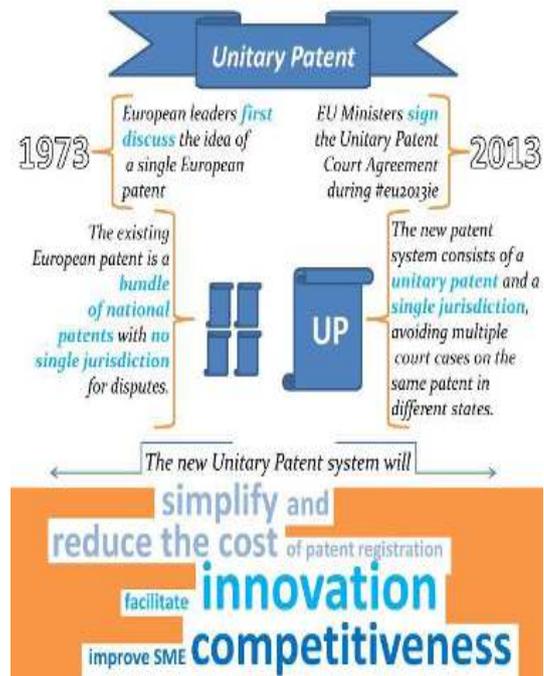

2. R&D credit regime versus Patent Box regime

In very tight connection with IP, the R&D expenditures represent a continuous concern of countries and governments for innovation inputs and increasing productivity [7]. EU as a whole and each country's government have established R&D intensity targets, see: Sheehan and Wyckoff (2003) on one side and scheme tax credit, that give tax relief, to encourage R&D investment on the other side [3].

Starting point for a global approach within EU was done at the Lisbon summit (2000) that announced its aim to make EU “the most competitive knowledge-based economy”. The advancement of intellectual property (IP) and research and development (R&D) activities is widely believed to be an important element in achieving this aim. At a subsequent EU Summit in Barcelona EU member states committed to spending 3% of gross domestic product on R&D investments by 2010 [15].

As a step forward the 24 member states of EU signed on February 2013 the international agreement establishing a Unified Patent Court (UPC). Once the agreement enters into force, as soon as it has been ratified by 13 member states, the signatory countries will form a unified area as regards patent law [16]. The UPC is the third element of what is known as the *patent package*. Two regulations establishing enhanced cooperation for unitary patent protection and its translation arrangements were adopted in December 2012 [5].

Figure no.2 The Unitary Patent system

Source: <http://www.eu2013.ie/news/news-items/20130219upcfeature/>

Following these announcements, a number of EU jurisdictions have introduced favourable tax rules for IP and/or R&D activities, with a view to attracting and retaining investment in their countries, such as: R&D tax credits or patent box regime [14].

R&D tax credits refer to fiscal incentives granted on the “input side” at the front end of the innovation value chain, in the years when research and development expenditures are incurred, i.e. serving to incentivize activities designed to result in innovation and encouraging more basic research [10].

Patent box regimes are relatively new and refer to fiscal incentives granted on the “output side” at the back end, in the years when income is generated from exploiting IP, rewarding companies that can capitalize on that research and turn into profit, targeting commercialization of the research outcomes [6].

3. How to qualify for a patent box regime

The first country that develops this system was Ireland in 1973 [3], followed by another EU and non-EU nations: Belgium, France, Luxembourg, The Netherlands, Spain, Switzerland and China. Starting with the 1st

April 2013 also the very conservative UK will have a patent box in place [18].

The “patent box” terminology apparently refers to the application of a lower tax rate to a separate schedule or “box” of income [20].

Patent box represents tax incentives that allows business income resulting from qualifying IP to be taxed a lower rate than regular income. This preferential treatment of IP income is meant to provide firms with a stronger incentive to innovate and commercialize the innovations, domestically [1]. State authorities would like to encourage investment and economic growth and to retain and attract innovative and high-tech businesses to the country that apply this system [8].

Relief takes in the form of either the application of a reduced tax rate on income earned in the patent box or a deduction for a portion of the patent box income. Countries that have implemented a patent box regime include Belgium, China, France, Hungary, Ireland, Luxembourg, the Netherlands, and Spain. The UK government has announced its intention to adopt a patent box regime effective in 2013 [17].

It is important to mention that not only patents are included in this regime but any types of IP that qualify for preferential tax treatment from country to country. For example Ireland, Luxembourg, Spain, and Switzerland have expanded lists of qualifying IP, including designs, copyrights, models, and certain types of information and China's regime included also know-how. In the 2009, the Netherlands expanded its patent box into a so called “innovation box” including as IP that may qualify also R&D –based products or other services that have not a result a patent or a trademark [19].

4. Criteria of application of Patent box regime in various countries

Application of patent box regime differ from country to country in respect of [9]:

- **definition of qualified IP**

Includes from country to country patents and other IP elements

- **types of entity**

The definition includes nearly all business models. For an entity to qualify, a Patent can be legally held by, or an exclusive licence granted to, a company, joint venture,

partnership or cost-sharing arrangement, opening up the applicability of the regime to many more businesses.

- **eligible taxpayers.**

Patent box regime should be limited or not to corporate taxpayers and, if not, whether it should apply to domestic branches of foreign companies or not

- **acquired IP**

Qualified IP must be self-developed or can be acquired from others

- **contract IP**

IP development activities must be carried out by the taxpayer directly or may be carried out by other persons, whether related or unrelated and there is the permission for cost-sharing arrangements under certain conditions..

- **election the incentive regime**

From country to country there may be or not a written obligation to submit an election into the patent box regime, specifying the accounting period on which the company is entitled to amend its tax return (elective or automatic regime).

- **ownership rights**

Companies must only own the IP rights or they must also have contributed to their development, or they must be actively involved in the management of the rights

- **exclusivity of the licence**

IP rights are held under and exclusive licence or not

- **calculation of taxable basis**

It differs from country to country and may be determined taking into consideration gross or net IP income (royalties). Also in taxable basis may be included or not gains from the sale of qualified IP and damages for breach of IP (infringement payments). Due to the often lengthy patent approval process another issues is how to treat income earned pending approval of a patent. In case of companies that own a single licence agreement that covers both qualified and non-qualified IP it is necessary to separate the agreement for the purpose of correct taxation.

- **taxation**

There are 2 options applicable: reduce rate on qualified IP income or deductions

- **treatment of patent losses**

Losses may be fully deductible in the current period and may be carried forward and used against any future profits or not.

There may be unlimited or limited certain period of time applicable in case of carry forward the losses. Any unused patent box deduction may be or not carried forward

- **cap on benefits**

There are from country to country different percentages of the IP deduction

- **foreign tax credit**

There may be limitation or not to impose additional limitations on the credit otherwise allowable for foreign taxes withheld on royalties.

- **Antiabuse rule**

Might be needed to address situations where royalties from a foreign related party qualify for the IP box and the local taxpayer simultaneously makes deductible payments to the foreign related party.

5. Conclusions

A thorough understanding of the Patent Box is only an important starting point. However translating Patent Box accounting principles into a practical patent action plan is not straightforward.

Companies at the very least will need to evaluate their patent portfolios and modify their existing patent strategy, and companies embarking on a patent filing programme for the first time will need patent education and expert guidance.

The following questions at least need careful consideration for any company included in this system:

- Are products covered by the existing patents and if not should be filing additional patents?
- In which Patent offices should be filing applications for patents to ensure rapid grant and earlier Patent Box benefit?
- Does this regime mean that previous assumptions regarding whether and when to file for patents no longer hold true?
- Up to now we have not thought it worthwhile securing patents; does this require reconsideration?
- In which corporate entities should the company hold the patents?
- It is needed to formalise intercompany arrangements regarding use of group held patents?
- Should it be looking to acquire patents by other means, including joint ventures with universities etc?

Should it be considered opportunities for in-licensing patents?

Introducing Patent Box Regime in UK – a possible model to be followed in Romania

Ristea Luminita
Spiru Haret University

Trandafir Adina
Spiru Haret University
trandafir.adina@yahoo.co.uk

Abstract

In the last decades the concept of intellectual property (IP) became very important and therefore the EU jurisdictions have introduced R&D tax credits or patent box regime as incentives to attract foreign investments. Using literature review, this article approach the R&D and patent box regime applied in UK starting with 1 April 2013. Our main conclusion is that, the Patent Box needs to be seen in the context of the efforts of European countries made to introduce specific reliefs for revenues that derives from IP and also to fight against tax avoidance using off shore jurisdictions.

Key words: intellectual property, R&D tax credits, Patent box regime

J.E.L. Classification: O34

1. Introduction

EU jurisdictions have introduced R&D tax credits or patent box regime as incentives to attract and retain investment in their countries.

The UK Government has been keen to make the UK's tax system more competitive in the high-tech arena as a result against departures of UK headquartered multinationals from the UK due to unfavourable fiscal climate and used both R&D tax credits and new introduced patent box regime [2].

This article approach the new concept of Patent Box applied in one of EU membre states and mainly in the UK. It is structured in four parts: the second part approaches the differences between R&D credit regime and Patent Box applied in UK, the third part

includes a structured presentation of the new regime regime applied in UK since 1 April 2013. In the last part of article we conclude that even if, Romania has not yet adopted patent box regime and uses only R&D tax credits, following the advanced development of technological IP and the very qualified local IT labour force, the patent box may be an option to increase local competitiveness and UK model may be an example to be followed.

2. R&D and Patent Box regime in the UK

R&D tax credits refer to preferential corporation tax treatment for R&D-related expenditure carried out in the years when research and development expenditures are incurred [9]. The allowable costs are, in general, staff costs and consumables and costs of hiring sub-contractors are subject to additional rules and will not necessarily be eligible for the enhanced relief [1].

UK defined two treatment of R&D expenditure, one fiscal treatment for SMES and another treatment for large companies.

Small and medium-sized enterprises (SME) those companies meeting the conditions of having less than 500 and employees and either turnover of less than €100m or - a balance sheet total of less than €86m that have to be satisfied for two consecutive accounting periods [3].

For these companies it is applied a preferential treatment for an additional tax deduction of 125% of the qualifying R&D expenditure incurred, with effect from 1 April 2012 [3].

A large company will only be eligible for a maximum additional deduction of 30% of the qualifying R&D expenditure in the period [3].

Patent box regime is are relatively new and refer to fiscal incentives granted in the years when income is generated from exploiting IP and targeting commercialization of the research outcomes [6].

The process of introducing Patent Box regime in UK was a very laborious one and started since 2009, when the Government announced the possibility of a favourable fiscal regime referred to as the ‘Patent Box’ introducing tax relief for research and development expenditure and law rate of corporation tax for income from patents [4].

In November 2010, Her Majesty's Revenue & Customs and Her Majesty's Treasury launched an initial consultation document named “*The Taxation of Innovation and Intellectual Property*” setting out a series of corporate tax reforms and confirmed the intention to introduce Patent Box regime [16].

On March 24, 2011, the UK Chancellor of the Exchequer delivered the annual Budget setting out the fiscal plans for the government for the coming year that included also the introduction of the patent box regime effective April 1, 2013 [5].

In June 2011, as stage 2 consultation it has been issues the document “Consultation on the Patent Box” which gives more detail on the design proposals.

On December 2011 the draft legislation and explanatory notes, Patent Box, response to consultation, and The Patent Box: Technical Note and Guide to the Draft Legislation have been made public.

Legislation to introduce the Patent Box was included in the Finance Act 2012 receiving Royal Assent on 17 July 2012. HMRC have also published a Technical Note on the legislation [5].

Starting data in application of this new fiscal regime is 1 April 2013. According with HMRC technical Note, the Patent Box legislation: “will encourage companies to locate the high-value jobs associated with the development, manufacture and exploitation of patents in the UK and maintain the UK’s position as a world leader in patented technologies”. UK sectors that will be most probably positively affected may be pharmaceuticals, life sciences, manufacturing, electronics and defence use

patents and are likely to benefit from the Patent Box [8].

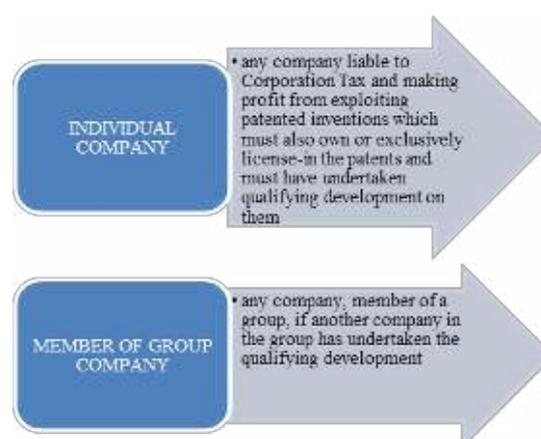

3. Effective Patent Box application in the UK

From 1 April 2013 companies will be able to elect and apply a reduce rate of 10% of corporation tax on profits generated from qualifying patents whether received as a royalty or embedded in the sales price of products and limited other forms of intellectual property such as such as regulatory data protection (also called ‘data exclusivity’), supplementary protection certificates and plant variety rights¹. This rate will be effective until 2017 [12].

Companies qualifying for the Patent Box are also likely to be undertaking significant research and development and qualifying for R&D tax credits. If the requirements of the rules are met Companies claiming R&D tax credits will be able to benefit also for certain research and development (R&D) expenditure under the R&D tax regime and will not be penalised when calculating their profits for Patent Box [15].

Beneficiary of the Patent Box will be both individual companies as well as companies member of a Group of companies. (see picture below) [17].

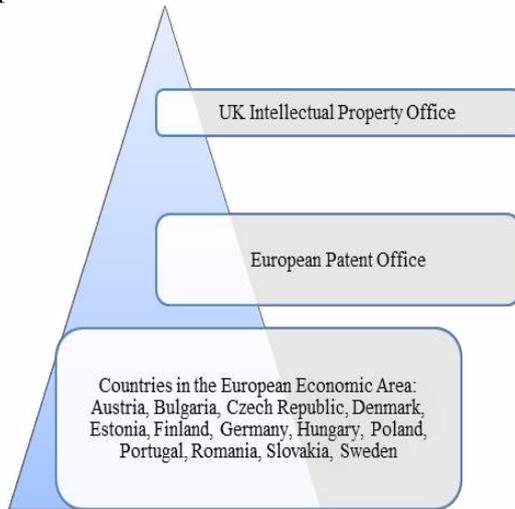

Figure no.1 Patent Box applied to individual company and member of a group company

Source: Own processing of informations retrieved from the <http://www.hmrc.gov.uk/manuals/cirdmanual>

Beneficiary from Patent Box regime can be any company that owns or exclusively licenses-in patents granted by the following

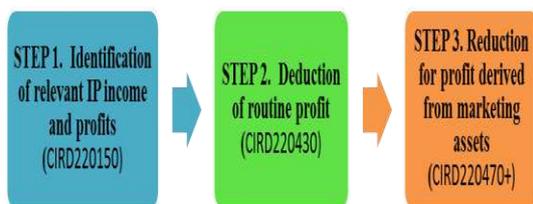

partners:

Source: Own processing of informations retrieved from the <http://businessrouttable.org>

The regime applies to new as well as existing patents owned or developed through partnerships, joint ventures and cost-sharing arrangements, however the claimant company or group has a significant involvement in development of either the patented invention or activity, or a product incorporating the patented item or activity [13].

The method for determining the profit eligible for 10% rate is, in principle a three step process as follows [10, 11]:

Source: Own processing of informations retrieved from the <http://www.forbes.com>
Calculation of the part of a company’s overall profit which will come within the Patent Box and qualify for favourable treatment involves several steps calculation and uses specific terms [14].

STEP 1. Identification of relevant IP income and profits (CIRD220150)

The starting point for STEP1 (Identification of relevant IP income and profits) is the total gross income, that is computed using the standard accounting rules, i.e. the correctness of accounting recordings is of greatest importance.

The next action refers to identify the relevant IP income (RIPI). RIPI shall be included in the total gross income of the trade, excluding financial income and can arise from five different ways of exploiting IP rights (CIRD220160):

- CIRD220170 Head 1 - sales income (Sales of “qualifying items” and associated items)
- CIRD220200 Head 2 - licence fees (Licence Fees or royalties from the grant of rights over qualifying IP assets)
- CIRD220220 Head 3 - proceeds of sale (Proceeds of realisation of qualifying IP assets (i.e sale or other disposal)
- CIRD220230 Head 4 - damages for infringement (Infringement income, that is compensation paid from an infringement or alleged infringement)
- CIRD220240 Head 5 - other compensation (Damages, Insurance and other compensation receipts)

Source: Own processing of information retrieved from the <http://www.bakerilly.co.uk>

A specific term of ‘notional royalty’ is introduced by CIRD220250 if a company derives some of its total gross income from the exploitation of the patented invention but the income does not fall into any of the five heads. In this case it may be able to deem some of that income to be RIPI for the patented item.

The next step in this stage consists in computing the net income attributable to RIPI using two methods: apportion the total profits or allocation the expenses to RIPI and using several specific adjustments.

STEP 2. Deduction of routine profit (CIRD220430)

The routine return represents the profit a business might have made if it did not have access to unique IP and other intangible assets. (CIRD220430) and must be deducted from the profit attributed to RIPI to arrive at the amount of that profit that is attributable to the intellectual property.

Using the cost plus methodology a “routine profit” is calculated by deducting a notional 10% return on certain operating expenses from profit determined according with STEP1 presented above. These

expenses include capital allowances, premises costs, personnel costs, plant and machinery costs and miscellaneous services.

STEP 3. Reduction for profit derived from marketing assets (CIRD220470)

A business needs to identify how much of the IP profit calculated at STEP 1 and 2 above is due to the patent and how much is due to marketing assets such as brands.

The Patent Box is not designed to reward other forms of IP and this is the reason why the profit associated with intangible assets, such as brand or other marketing assets is removed. At this point profits generated between application and grant, subject to certain conditions, may be also added to the figure calculated above. In many cases this figure is nil and in others a simplified small claims treatment can be applied [7].

From 1 April 2013 companies may elect into the Patent Box regime. The Patent Box allows qualifying companies (CIRD210000) to be taxed at a reduced rate on the profits from patents and other specified intellectual property [6].

The Patent Box reduces the rate of tax by allowing an additional deduction (‘the Patent Box deduction’) from the profits of the trade for corporation tax purposes for each of the accounting periods it is a qualifying company.

The Patent Box deduction is a proportion of the relevant profits from patents and intellectual property. CTA10/S357A(3) provides the calculation for the Patent Box deduction as [10]:

$$\text{Patent Box deduction} = \text{RP} \times (\text{MR} - \text{IPR}) / \text{MR}$$

Where:

RP is the Relevant Intellectual Property Profits (CIRD220000)

MR is the main rate of corporation tax (CTM03510), and

IPR is the 10% Intellectual Property Rate of corporation tax.

As an example if a company has corporation tax trade profits of £100.000 and all of these qualify for the Patent Box, when the main rate of corporation tax is 21%, then the tax payable will be calculated as follows:

Trade profits chargeable to	£100.000
corporation tax	
Patent Box deduction	£100.000
x ((21-10)/21)	(£52.400)

Profits chargeable to	£47.600
corporation tax	
Tax payable (£47.600 x 21%)	£10.000

Source: Own processing of informations retrieved from the <http://www.hmrc.gov.uk/budget2012>

So it can be seen from this that relevant IP profits of £10.000 have an effective 10% rate of tax.

In order to phase in the benefit of the Patent Box only a percentage of the relevant IP profits of the trade will be included when calculating the Patent Box deduction (CIRD201020).

The relief is phased in from 2013 to 2017. In the 2013 financial year only 60% of the relevant intellectual property profits will be included when calculating the Patent Box deduction. This will increase 10% a year until it reaches 100% in the 2017 financial year (CIRD260170).

The percentages for each financial year are:

Year	2013	2014	2015	2016	2017
Percentage of RP	60%	70%	80%	90%	100%

Source: <http://www.bakertilly.co.uk/publications/Pages/The-Patent-Box-10-tax-rate.aspx>

If an accounting period falls within more than one financial year the RP for that accounting period should be apportioned to each financial year.

Companies without patents may wish to consider whether they have products or processes which could be patented, such as IT/software.

4. Conclusions

The Patent Box needs to be seen in the context of the efforts of European countries made to introduce specific reliefs for revenues that derives from IP and also to fight against tax avoidance using off shore jurisdictions.

There are new issues to be considered by the consultants in advising companies how to benefit from this new regime and to maximise the benefit, as follows:

- Identification existing patents and also the other IP elements that can be patented
- Correctly determination of qualifying income from patents

- Performing a correct calculation of taxable basis using the three-step method
- General planning for intellectual property and specific tax advice in the field of IP and property rights
- Fiscal planning and structuring that may contribute to securing benefits taking into consideration group profit arrangements.

Even if Romania has not yet adopted patent box regime and uses only R&D tax credits, following the advanced development of technological IP and the very qualified local IT labour force, the patent box may be an option to increase local competitiveness.

Of course a very structured approach based on broad consultation among the most important player, state authority (that needs to take into consideration substantial compliance and administrative burden) and beneficiaries of this regime needs to be followed in the next years.

The Role of Cost Accounting in the Management of the Activity Center

Ruse Elena

Andrei Saguna University

elenaruse17@yahoo.com

Susmanschi Georgiana

Spiru Haret University

georgianasusmanschi@yahoo.com

Abstract

Cost accounting is supporting managers to establish the development strategy of the company. The information provided is used in the decision making process regarding the production and marketing of products.

Estimating the future cost influences the development strategy of an activity. Thus, there are costs that vary proportionally with the volume of production, while others remain fixed whatever changes appear in the business volume.

Analysis of costs evolution is related to the type of calculation method. Rapid determination of production costs can be achieved using an evolved method as variable costs method, which allows the calculation of some broad-spectrum indicators, necessary to support decisions.

Extended version of the method emphasizes profitability analysis based on sales volume through indicators such as: balance point, range safety and so on.

Thus, the analysis based on the relation „Cost-Volume-Profit” can be used in order to optimize the results of the activity center.

Keywords: cost accounting, direct-costing, cost analysis.

J.E.L. Classification: M41

1. Introduction

Cost accounting provides information that managers use in the decision-making process of the enterprise. Information provided by management accounting and costs is used by managers to select and implement a strategy.[1]

They use this information to coordinate their decisions regarding the conception,

production and marketing of products and services.

Developing strategy of an activity is close related to the estimation of the future cost, through the elaboration of cost budgets by type.[3]

There are costs that vary gradually with production volume or with operating activity; others remain fixed whatever changes occur.

Cost assessment is based on the type of analysis (total costs or unit costs).

2. Product costing through Direct-Costing method, extended version (depending on sales volume)

Rapidly defining the production costs that can allow the establishment of some broad-spectrum indicators, led to Direct-Costing.

Using this method involves determining the overall profitability or by activity types, products, s.o.

To determine product costs using the Direct-Costing method, extended version (considering sales volume), the production and sales process of an activity center were analyzed for a period of one month.

The results are summarized in Table No.

1.

Table 1. Determining earnings per activity center

Products	Sales volume	Total expenses	Final result
1	2	3	$4 = 2 - 3$
A	64012	44872	19140
B	9729	7414	2315
C	748477	632597	115880
D	112705	91938	20767
E	10105	7820	2285
F	4049	3142	907
G	23838	19920	3918
H	136	126	10

I	350	282	68
Total activity center	973404	808114	165290

Source: personal processing

According to data, the final result was obtained by deducting from the sales volume, the total expenditure incurred to obtain production for the period of calculation.

Based on the results obtained through Direct-Costing method (extended version), it can be determined the unit cost per product as a ratio between variable expenses and product quantity of the activity center.

The cost calculated in this manner is a partly cost because it includes in the calculation only the variable costs, fixed costs being included at the section level, which are not taken into account.

Unit costs per product of the activity center are determined in Table No.2.

Table 2. Unit costs per product determined with Direct-Costing method

Product	Quantity (kg)	Total variable costs (ron)	Unit cost per product (ron/kg)
1	2	3	4 =3/2
A	71.247	36.973	0,52
B	10.459	6.126	0,58
C	837.848	522.329	0,62
D	125.228	75.957	0,60
E	11.082	6.454	0,58
F	4.519	2.591	0,57
G	28.304	17.289	0,61
H	114	104	0,91
I	2.336	237	0,10
Total activity center	1.091.137	668.060	0,61

Source: personal processing

3. Activity center productivity through specific indicators of Direct-Costing method

Analysis of the correlation between activity volume, costs and profits can be achieved by means of some indicators such as:

3.1. Balance point (critical point)

Balance point is determined based on the

$$P_e = \frac{C_F}{Cb_u}$$

ratio:

where:

P_e – balance point;

C_F – fixed costs related to the activity center;

C_F – 140.050 ron;

Cb_u – gross contribution per unit;

$$Cb_u = \frac{M / C_v}{\sum Q} = \frac{305.340}{1.091.137} = 0.28 \text{ kg}$$

where:

M/C_v – gross contribution margin related to the activity center and variable expenses ($M/C_v = 305340$ ron).

$\sum Q$ - total amount of production

obtained over a period of one month ($\sum Q = 1.091.137$ kg).

Therefore,

$$P_e = \frac{140050}{0.28} = 500.178 \text{ kg}$$

From the calculation of balance point it results that the company should produce 500.178 kg product in order to obtain zero profit, i.e. incomes to cover expenses entirely.

For the sale of 1.091.137 kg products and getting a turnover of 973.404 ron, the total costs achieved are 808.114 ron of which 668.060 are variable costs and fixed costs of 140.050.

Therefore $\sum Q = 1.091.137$ kg.

From the data:

$C_T = 808114$ ron;

$C_T = C_v + C_F$;

C_v – variable costs;

$C_v = 668060$ ron;

C_F – fixed costs;

$C_F = 140050$ ron.

Margin rate on variable costs is:

$$r = \frac{M / C_v}{CA} = \frac{305.340}{973.404} = 0,31$$

Variable costs rate is:

$$r^1 = \frac{C_v}{CA} = \frac{668.060}{973.404} = 0,69$$

The calculation of balance point is based on the assumption that all outputs produced

are soled and therefore the value of volume production coincides with the volume of dissolution.

Balance point calculated taking into account the equalities:

a. Calculation based on the ratio:

$$CA = C_V + C_F.$$

If sales line is denoted with y_1 and total expenditures line with y_2 , then the equations of the two lines are:

$$\begin{cases} y_1 = CA \\ y_2 = C_V + C_F \end{cases}$$

Since $x = CA$, C_V is calculated according to the CA as follows:

$$C_V = r^1 \cdot CA = r^1 \times x$$

Therefore:

$$\begin{cases} y_1 = x \\ y_2 = r^1 \cdot x + C_F \end{cases}$$

It results that:

$$\begin{cases} y_1 = x \\ y_2 = 0,69 \cdot x + 140050 \end{cases}$$

Balance point is determined by equalizing the two equations:

$$x = 0,69x + 140050$$

$$x(1 - 0,69) = 140050$$

$$x = \frac{140050}{0,31} = 451774$$

The solution of the system of equations represents the total sales to be made to cover total production costs, expressing the **value balance point**.

b. Calculation based on the equality:

$$R = 0 \text{ or } M / C_V - C_F = 0$$

Equaling CA to x, we obtain:

$$M / C_V = r \cdot x$$

Therefore:

$$y_1 = r \cdot x - C_F$$

It results that:

$$y_1 = 0,31 \cdot x - 140050$$

Balance point, in this case, is obtained from the equality:

$$y_1 = 0$$

Therefore:

$$0,31 \cdot x = 140050$$

Where:

$$x = 451.774 \text{ ron}$$

The solution of this equation expresses the value of sales that cover the expenses incurred in obtaining production, i.e. the value balance point.

3.2. Safety range and dynamic safety index

To determine the safety range we used the dissolution volume per product, presented in Table No. 3.

Table 3. Determination of dissolution volume per product of the activity center

Product	Quantity (kg)	Share of product in total products	The balance point afferent each product (ron)	Unitary price (ron/kg)	Determination of dissolution volume for each product (ron)
1	2	$\frac{3}{2/\text{quantity}} =$	$4 = 3 \times P_e$	5	$6 = 4 \times 5$
A	71.247	0,0652	32.612	0.90	29.351
B	10.459	0,0095	4.753	0.93	4.420
C	837.848	0,7678	384.036	0.90	345.633
D	125.228	0,1147	57.370	0.90	51.633
E	11.082	0,0101	5.152	0.91	4.689
F	4.519	0,0041	2.051	0.90	1.846
G	28.304	0,0259	12.955	0.84	10.892
H	114	0,0001	50	1.20	60
I	2.336	0,0021	1.199	0.15	180
Total	1.091.137	1	500.178	-	448.691

activity center					
--------------------	--	--	--	--	--

Source: personal processing

Selling the products at section level is:

$$dP_e = 448.691 \text{ lei}$$

Total dissolution is:

$$D_r = 973.404 \text{ lei}$$

Safety range is:

$$Is = D_r - dP_e = 973404 - 448691 = \\ = 524713$$

It results that production may decrease by up to 524.713 lei without affecting the balance.

Dynamic security index is:

$$Id = \frac{Is}{CA} \times 100 = \frac{524713}{973404} \times 100 = 54\%$$

Thus, dissolution volume may decrease by up to 54% without affecting the balance. If this percentage decreases more will reach record losses.

4. Conclusions

The calculations and analysis performed under cost-price-volume ratio are a joint management instruments that can be used to optimize the outcome of economic activities. This can be done by determining the influence it has on the outcome, by the changes of the factors that led to the establishment's (sales price, production volume, variable costs, fixed costs and production structure).

Abstract

Modern management of economic entities, regardless of the nature of society, whether it is a public or a private entity, cannot be developed without a rigorous and flexible control. Running a company requires a permanent and systematic control of the business.

Fraud in general can be defined as cheating, dishonest act committed by someone, usually to make a material profit from the rights of others, and act as thieves sum stolen by fraud. The emergence of fraud in a company is an issue that must not be lost of sight by the management entity. Fraud detection in time can have significant negative effects for the entity.

Some of the internal audit's role in the entity consist in proposals and recommendations to mitigate the risk of fraud. In this aspect, internal auditors must notify management at the first clues of a fraud existence and support management in their actions.

Keywords: internal audit, fraud, preventing fraud, internal control.

J.E.L. Classification: M42

1. Introduction

Patrimonial entities whose business is conducted in a dynamic and aggressive business environment have to be flexible, be able to adapt easily and quickly to these changes in order to survive, conduct an efficient activity and ensure that the principle

of continuity activity is respected.

Economic entities operate in an aggressive competitive environment full of risks, with the final aim: profit. To be able to achieve this target, managers need to master and control the business in order to efficiently allocate resources for profit and to ensure continuous development of the entity.

2. Internal audit. Concept. Objectives and functions

According to IIA (Institute of Internal Auditors), internal auditing is an independent, objective assurance and consulting activity designed to add value and improve an organization's operations. It helps an organization accomplish its objectives by bringing a systematic, disciplined approach to evaluate and improve the effectiveness of risk management, control, and governance processes.

In the context of a challenging economic and financial environment, internal audit objectives are focused on some areas:

- ensure maximization of profit;
- eliminate any factors and causes that could lead to lower profits;
- ensuring the integrity of heritage;
- increase operational efficiency by limiting and /or exclusion of inefficient operations;
- increasing the fidelity and accuracy of accounting information;
- legal compliance and requirements management;
- ensuring a healthy climate, discipline, for the activity in terms of profitability and high efficiency;
- motivate and empower their employees,

resulting in improved business and assuring a real feedback.

The Government Ordinance no.75/1999 regarding financial audit, establish also the main objectives of internal audit which are the following:

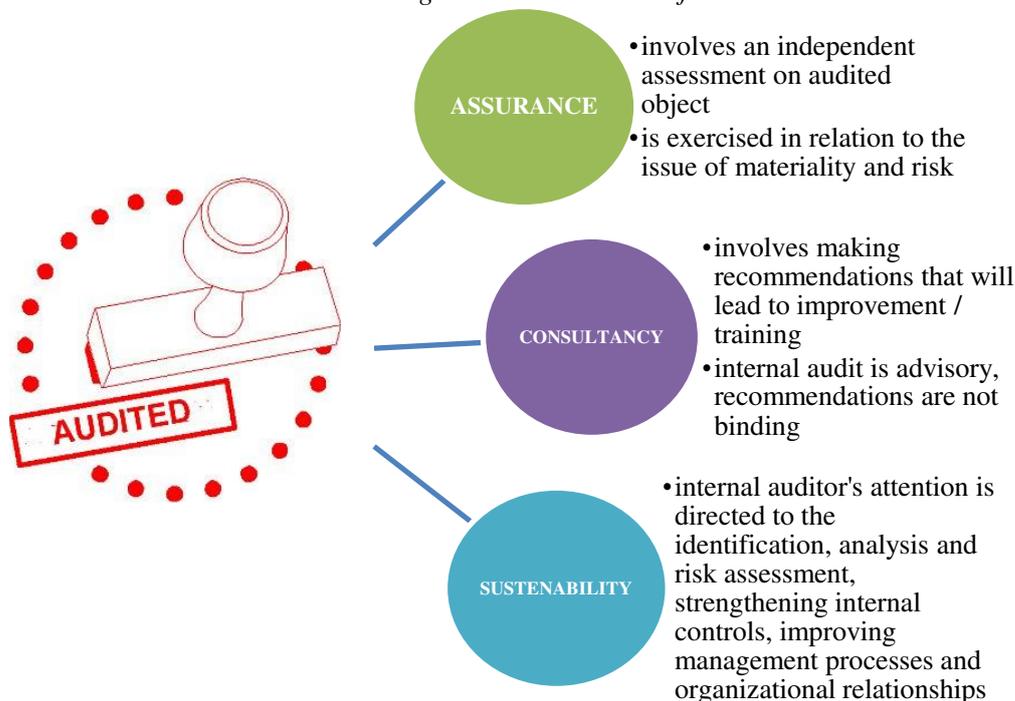

- verification compliance of activities in the economic entity audited with policies, programs and its management in accordance with the law;
- assessing the adequacy and application of financial and non-financial controls conducted by management in order to increase efficiency of the economic entity;

- evaluating the appropriateness of financial and non-financial data / information designed for an appropriate knowledge of the economic reality;
- protection of property and identifying methods to prevent fraud and losses of any kind.

Internal audit functions emerge even from the definition given by the IIA (presented above).

We briefly present the 3 functions of internal audit (Fig.2.3. Internal audit functions).

Figure 1. Internal audit functions

Source: personal presentation

3. The concept of fraud

Fraud in general can be defined as cheating, dishonest act committed by someone, usually to make a material profit from the rights of others, and act as thieves sum stolen by fraud.

In the economic sense, in business the concept of fraud is associated with the concepts of irregularities / irregularities / malfunctioning / deficiencies / irregularities.

Wrong concept refers to any deviation from the legality, regularity, any breach of the provisions of agreements.

The following terms, deviations/ deficiencies / malfunctions are considering non regulatory framework, procedural code violations, that it finds errors, omissions, willful misconduct.

We present some definitions of fraud:

- According to the Law 500/2002 regarding public finances, irregularities and fraud are all illegal acts committed with intent to deceive;
- Fraud shall mean any intentional act or omission in connection with the use or presentation of false statements or documents, incorrect or incomplete, including offenses [5];
- fraud is any illegal act characterized by

deceit, concealment or betrayal of trust that do not depend directly on the threat of violence or physical force [2];

- Any illegal acts characterized by deceit, concealment or betraying trust. These acts are not necessarily characterized by the use of threat of violence or physical force. Fraud is perpetrated by individuals and organizations in order to obtain money, goods or services to avoid payment or loss of services, or to secure personal or business advantage.[5]

Fraud can be committed in favor or detriment of the economic entity.[2]

Fraud committed in the benefit of the entity favors entity in an unjust way, represents an unfair advantage being capable to deceive even a third party. In this category of fraud fall fiscal fraud, illegal commercial activities, selling of fictive goods, s.o.

Fraud committed in detriment of the entity favors in general one or more of the employees, a third party or other entity directly or indirectly. In this category of fraud fall bribery, embezzlement of funds and assets, billing services or supplies that were not provided, omission of information with intent.

4. Internal audit and fraud

Based on internal audit objectives, we can say that from a conceptual perspective, in practice, there is an apparent mismatch between the intentions of managers for effective management and the means used to achieve it. This standstill agreement of management tools, (especially internal audit) that have not evolved since structural and functional changes of economic entities, although such a development would have been natural.

Internal auditors are in the position that provides support particularly important in the transition of the company from what was to implement a viable, efficient and effective control model, Companies that place a higher importance of internal control are the same trend in terms of internal audit. [3]

According to Internal Audit Standards, Section 1200 - Powers and professional conscientiousness, Subsection 1210 - Proficiency: 1210.A2 Internal auditors must have sufficient knowledge to identify signs of fraud, but that does not mean they must have

the same level of competence as and a person whose primary responsibility is detecting and investigating fraud.

Also internal audit standards, respectively glossary of terms, find the term in the definition of fraud and internal audit mission, namely: the internal audit mission means a mission, task or activity specific review of internal audit, such as internal audit, a review of control self-assessment, investigation of fraud or a consulting assignment.[2]

The most effective tools that can be used to prevent fraud are management control and internal audit, the task management system being installed and processes to serve as preventing and discovering fraud within the company.[1]

In an entity where internal audit is as part of organizational culture, internal audit is accepted with interest, but in an entity experiencing significant potential risks, the lack of compliance with key regulations with reduced efficacy and its external fragility due to embezzlement of funds, assets is obvious that the manager will be judged and praised by the findings of the internal auditor.

A suggestive feature of internal audit is that the internal auditor has a degree of freedom offered by the mission plan, which situate him above routine concerns or stressful work of being regular.

Internal audit is not related to the entity's staff only if it participates in theft, fraud for which he is responsible and will make account, for the rest audit addresses how the structure of the entity meet its own rules.

Auditors contribute to the deterrence of fraud by examining and evaluating the relevance and effectiveness of the internal control system, considering the risk exposures of the entity specific to each area.

In this sense, internal auditors determine whether:

- Organizational environment stimulates awareness regarding the need for internal control;
- Are set realistic goals and objectives;
- There are written rules that describe prohibited activities;
- Communication system allows to obtain adequate and reliable data;
- Are established and maintained rules regarding authorization of operations and transactions.

In case of irregularities found, internal

auditor warns the entity’s authority and may suggest fraud investigation, which is to carry out detailed research to determine whether there has been a fraud.

Auditing a fraud involves certain duties of the internal auditor, such as:

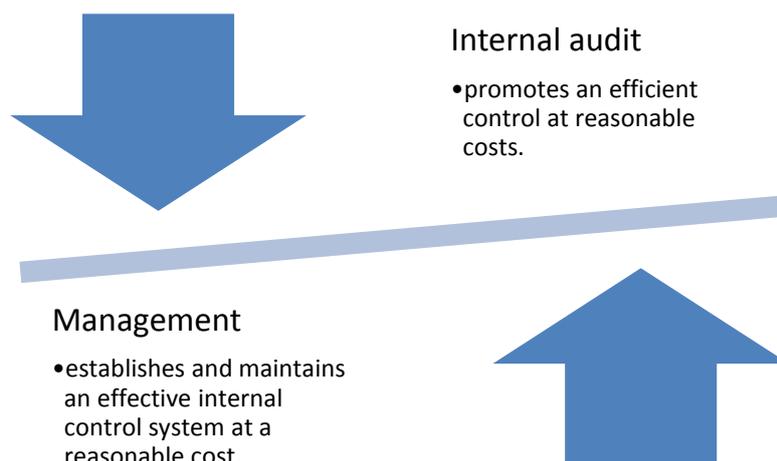

- Research and evaluation of existence and significance of possible complicity. This is essential for avoiding providing information to those involved in committing fraud;
- To determine the knowledge, skills and other competencies needed to perform an investigation with efficiency;
- Defining the procedures to be followed in order to detect fraud;
- Conducting investigative activities in compliance with management, legal

counsel and other experts considered to be useful during investigation.

What’s to be kept in mind is that the responsibility of the internal auditor regarding fraud detection and fraud prevention results from internal audit’s first objective, that being to help members of the company to fulfill their tasks in an efficient manner by providing analyzes, evaluations and recommendations on the activities reviewed.

Both management and internal audit play a part in preventing fraud, but their roles are different. While the management of an entity has responsibility in establishing and maintaining an efficient control system at a reasonable cost, internal audit role lies in promoting the implementation of an effective internal control system at a reasonable cost.

Figure 2. Responsibilities of management and internal audit regarding the internal control system

Source: personal presentation

Internal audit department applies pressure on management through its role of promoting an efficient control of all activities and by implementing effective controls management will determine an increase of internal audit performance.

Internal auditors tests associated with reasonable controls conducted by management lead to improving the chances of detecting any hint of fraud and, if necessary deepening investigation. A well-designed internal control system allows to reduce the risk of fraud.

5. Conclusions

The internal audit task switch providing

their assistance, assessing risks and control strategies, suggesting initiatives, solutions, proposals and recommendations to mitigate the risk of fraud and improve control strategies.

Internal auditors must at first clues of fraud to notify management to develop its own investigations and research on fraud certainty, persons involved and the size, but to oversee further the entire process and assist management to act in consequence. [4]

Solvency Margin in Insurance Field – The Need for IFRS Compliance

Sahlian Daniela Nicoleta

Stanila Georgiana Oana

Ispas Simona

Academy of Economic Studies

daniela.sahlian@gmail.com

gostanila@gmail.com

i_sximyy@yahoo.com

Abstract

The framework for insurance and reinsurance now in use needs updating. The proposal for a new solvency framework, called Solvency II, is introducing a risk-sensitive approach, taking into account optimal allocation of capital market, consistent valuation of assets and liabilities ("fair value" concept), timely calculations and more transparency, in accordance with the IFRS. The purpose of the paper is to offer a practical approach of calculation and reporting regarding the main liquidity and solvency indicators for implementing the Solvency II model at national scale. The study having a predominant methodological qualitative fundament based on casuistic and experience of national and multinational companies operates on the wide field of insurances. High value of the research is produced by the new approach of calculation and reporting solvency margin based on risk management, which is a beginning in Romania, lining up to international accounting insurances research.

Key words: *fair value, adequacy of capital, solvency margin, risk management, Solvency II*

J.E.L. Classification: G22, M40

1. Introduction

A particular characteristic of insurance is that the production cycle is inverted: insurers receive a premium up-front, but are only obliged to pay-out if the risk materializes at some future date. This is the main reason why States control insurance, because it exposes policyholders and beneficiaries of

insurance contracts to loss in the event that an insurance company goes bankrupt. As a consequence, State intervention has tended to focus on introducing measures that guarantee the solvency of insurance undertakings.

This study is concerned with explaining how the Solvency II regulations will affect risk management in the life and non-life insurance industry, and whether these changes can result in opportunities for insurance companies. These are indeed contemporary events over which we have no control, referring to a “how” question. Thus, the method being used is *case study research*.

Since this study is not concerned with social critique, we will focus on the choice between a positivist and an interpretive perspective. The purpose of this study has emerged gradually through discussions with different stakeholders. The process has been iterative in the sense that new stakeholders have been contacted, our frame of reference revised and the purpose rephrased several times. Therefore, the aim when entering the field has been to test theories developed or discovered in the earlier stages of our thesis. Considering possible effects from Solvency II is not a new idea, although there seems to be lack of empirical evidence that supports it. Therefore, we think that a *positivist research approach* best corresponds to our needs.

One could argue that different stakeholders are likely to have different views on the complex subject we have chosen to investigate. As Lee [7] writes, an interpretive research approach acknowledges that one phenomenon can be interpreted differently by two individuals, and that this fact needs to be considered in the research. We have seen, for example, proof of interpretive research in the way we have dealt with changes to the purpose of the study

as well as conflicting opinion of interviewees. The main reason for doing so is that any current assessment of potential effects of Solvency II is deemed somewhat subjective. In five to ten years time, a purely positivist, and perhaps quantitative, study should be feasible, while it certainly is not today. In brief, this study is mainly guided by a positivist research approach, but it also has some elements of interpretive research.

2. The previous situation for the insurance supervision

The main elements of current insurance supervision in Europe are the Directives 73/239/CEE and 88/357/CEE, which correspond to the Non-Life Assurance Directive from 1973 and can be considered as the first generation of solvency guidelines. Furthermore, the second generation, the Directives 79/267/CEE and 90/619/CEE that are the Life Assurance Directives from 1979 came up. The third generation of directives is represented by the Non-Life Assurance Directive 92/49/CEE and the Life Assurance Directive 92/96/CEE. Those were established in 1992 and formed the foundation of the European domestic insurance market [2]. The essential improvements within these guidelines were the omitted preventive product control and the implementation of the principle of the member state of the head office, including mutual acceptance of harmonizing supervision rules as well as the creation of a sufficient solvency margin.

The first, second and third life and non-life directives commonly known as Solvency 0, specify which assets should be used for calculating the solvency margin. They also specify that the *required solvency* margin should be the greater of the *adjusted premium index* or the *adjusted claims index*.

In 1998 the Insurance Group Directive was adopted. Main elements of this directive were the calculation of the adjusted solvency of insurance groups. This should confirm the available equity as an actual state on the one hand and the determination of a target solvency as minimum of verifying equity on the other hand. In this way double gearing can be avoided. This directive was in most European countries established in 2001.

3. Solvency I

After the implementation of the European Single Market it became obvious that there has to be a rearrangement of the supervisory regulations. The first step was made in 1994 with formation of the Müller-Commission. Its task was a critical review of the previous situation within the insurance market and to compile realignments.

Consequences of the realignment were stricter requirements in order to ensure solvency. Now, according to the regulations solvency has to be guaranteed at every single point in time and not only at the end of the fiscal year. Resultant from this, insurance companies were forced to improve their information systems to provide reliable data on a daily basis [10].

From now on, a solvability margin was required to cover unexpected losses and future risks. The available solvency consists of free and not mortgaged equity without intangible assets. This is the basic capital, compulsory and free reserves and the retained earnings or debit carryover after deduction of distributed dividends.

The calculation of the capital requirement under Solvency I is relatively simple: a percentage of premiums and claims in non-life insurance and reinsurance and a percentage of technical provisions and of capital at risk in life insurance

The required solvency margin is specified as:

- the greater of the adjusted premium index and the adjusted claims index during the current or previous financial year,
- or the last year's required solvency margin multiplied by a ratio concerning outstanding claims.

To calculate the actual solvency within equity, several changes for Non-Life and Life-Insurance companies (Life and Non-Life insurance business have to be considered separately, since they face different maturities and types of insured risks), were established:

- as before, valuation reserves can be assigned to equity on application, but *now* there is also the possibility to assign them to guaranty funds.
- only on application 50% of the not deposited basic capital could be deducted from the actual solvency amount and

therewith lower the amount insurances have to provide, as long as 25% are deposited. The maximum deduction equals 50% of the solvency margin. Now, this border is also valid for lower-ranked liabilities [5].

The system is clearly outdated. It is retrospective and not prospective. It does not require management of insurance companies and insurance supervisors to look at the individual risk position of each insurer. It does not take account of a number of important risks, such as the asset/liability management risk, credit risk or market risk. Furthermore, it fails to provide insurance companies with the necessary tools to cope with increased international competition, with the emergence of new risks and with the growing pressure of capital markets. From an internal market perspective, it does not allow a real comparison between the financial position of insurance companies from different Member States, as the system fails to harmonize the most important element of an insurer's balance sheet, the technical provisions.

Finally, the development of new techniques, particularly in actuarial science, allow for a more accurate analysis of risks. Since the foundations of the current EU solvency regime were laid in the 1970's, the landscape surrounding solvency, including the insurance sector itself, financial markets, the approach to prudential regulation, techniques for risk management, actuarial methods and accounting standards have changed dramatically. The current solvency regime has been left behind and one of the most important consequences is a dislocation between regulatory capital and insurance companies' own assessment of the capital they need given the nature of their business

4. Solvency II

In 1999, the European Commission started the project SOLVENCY II in order to renew the actual insurance supervision and to harmonize it with the banking system within the EU member states. This project should be realized in two big phases and should find its completion due to an EU-directive that is valid for all member states:

- the first phase - **construction of the general conditions** - includes an analysis of the existing situation, a discussion about

possible basics, principles and concepts as well as the commitment of the main features of the future system. Phase I was started in May 2001 and was completed with the document of the EU Commission: “SOLVENCY II – Reflections on the general outline of a framework directive and mandates for further technical work“, on 19th September 2003.

- the second phase – **design and implementation.**

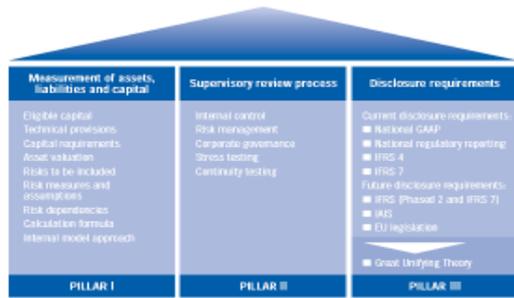

The new system should provide supervision authorities with appropriate qualitative and quantitative tools to assess and regulate the overall/total solvency of an insurance company. Furthermore, it should offer incentives to record and minimize risks. An efficient control belongs also to the target settings as the creation of equal/fair competition conditions.

All relevant types of risk should be regarded and a possibility to use internal risk management systems will be provided. Sufficient equity capital as protection of SOLVENCY I's preferential. Other aims are the protection of the insurance company, the avoidance of exorbitant complexity, the allowance of market developments, the definition of principles (without going too far into detail), and the prevention of overcapitalization.

The European Commission involved different international organizations and associations like the IAIS (International Association of Insurance Supervisors), the IAA (International Actuarial Association), the auditing company KPMG, and the national supervision authorities to develop SOLVENCY II in a proper and professional way. Due to this consortium, representatives of supervision authorities out of over 170 countries participate in this development process [5].

SOLVENCY II has got the same look as BASEL II – three pillars that should interact with each other without overlapping, to create a consistent framework.

Table 1. The three pillars of Solvency II

(Source: CEA, 2006)

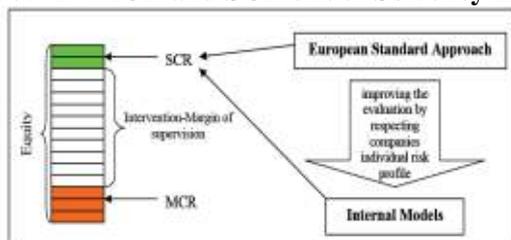

4.1. Pillar I

The first pillar of SOLVENCY II deals with the regulations concerning the financial resources. Those are supervisory specifications with respect to technical provisions, investments and solvency margins. Since SOLVENCY II wants to keep the probability of insurer defaulting below 0.5% within one year, certain capital restrictions/requirements are needed.

Particular important are the mentioned technical provisions. They have an extensive impact on the solvency requirements, since their calculation should be identical with the developments of the International Accounting Standards (IAS/IFRS). A detailed consideration of this point is here not possible, since there is not sufficient data available at this point in time.

The capital requirements of Pillar I (MCR and SCR) will capture and sufficiently measure all risks on the balance sheet. Within Pillar I MCR and SCR are the central elements. CEIOPS developed a Standard Approach to determine these requirements. The calculations should be based on “fair values” (market values) for assets and liabilities. However, this approach is not finalized yet and need still improvements. That is why also internal models should be developed to meet the specific needs of the company (see also Figure below).

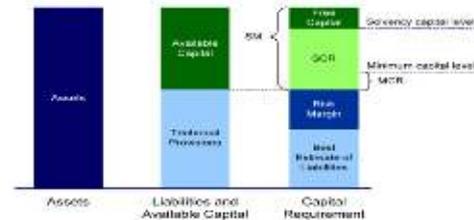

Table 2. MCR and SCR under Solvency II

(Source: Schubert, 2007)

The most important change according to SOLVENCY I is the market oriented evaluation of assets and liabilities. On the basis of this the equity requirements of Pillar I will be calculated [3]. It will be distinguished between Minimum Capital Requirements (MCR) and Solvency Capital Requirements (SCR). SCR could also be constituted as aimed economic capital.

Table 3. Relating the MCR and SCR to assets and liabilities

(Source: CEIOPS, 2006)

MCR defines that amount of capital on their shortfall the activities of an insurance company would have an unacceptably high risk for the insured person. If the capital of the company falls below the MCR ultimate supervisory actions shall be initiated. The MCR should be considered as a simple, robust and objective indicator [1].

SCR should warrant a capitalization that gives an insurance company the opportunity to absorb huge unexpected losses to provide the insured person an appropriate security that payments will be made if necessary. The SCR should represent that amount of capital, which is needed to fulfill all obligations within a certain time horizon to a particular confidence level [1].

A catalogue of different possible actions is available to the supervisory authority in case of a shortfall of the optimum level. These actions could be used before a definite intervention becomes necessary.

The calculation of the capital requirements could be performed either on basis of a standard model or through an internal approach, which has been developed by the company itself and has been investigated and permitted by the supervision authority. In this way it is guaranteed that also small firms can develop a risk management within their possibilities.

The standard approach should be a holistic method that contains all basic risk for both assets and liabilities.

4.2. Pillar II

The second pillar is constituted on the mentioned Sharma report for further qualitative elements of supervision. Among this belong the principles of internal control, proper risk management, and the formulation of combined principles and instruments of supervisory control [3].

The commission intends to develop a supervisory controlling procedure that is based on the actual directives and the fundamentals of BASEL II. For insurance companies this would lead to a methodically administration, an appropriate internal control, and an obligation of disclosure to supervision authorities. On side of the authorities these rules bring along minimum competences to inquire, rights to intervene and specific operation barriers [2].

According to the principles of BASEL insurance companies have to have a measure to assess their equity configuration in relation to their specific risk profile, as well as a strategy to maintain their equity.

The supervisory authorities have to evaluate the quality of the internal assessment tools and the strategies to maintain equity, as well as the ability of the insurer to keep the predetermined minimum coefficients [1]. Furthermore, they have to be able to claim higher equity configurations for a company or a national market, if necessary, and they have to go after a precocious intervention to avoid non-sufficient equity configurations.

Additionally to the actual regulation for banks, also definitions about the amount of accruals and investment management have to be included [2].

Also clear regulations about risk evaluation methods and intervention rights with regard to target capital configuration are relevant. Also the harmonization of European statutory provisions plays a role. For that purpose a certain degree of analogy in interpretation and procedures of supervision authorities is needed. This becomes especially obvious while considering international insurance companies with subsidiaries that are controlled by a supervision authority [1].

4.3. Pillar III

The third pillar of SOLVENCY II will increase the market transparency and market discipline, due to an increase within the disclosure requirements [3]. The aim is to provide all market participants an insight into the solvency situation of a firm. This contributes to a corporate management that is effective and aware of risks.

The effort of the European Commission is thereby strongly orientated on the guidelines of BASEL II. This is done with respect to the fact that companies within the insurance sector do not depend on each other as much as in the banking sector.

The publication of supervisory information occurs next to the requirements of disclosure of financial markets, rating agencies and external accountants. The coordination of these information requisites is important, especially with regards to the continuous developments of the International Financial Reporting Standards (IFRS). For that purpose a consultation of the IASB is needed, to reduce the administrative burden for firms [7].

A fair balance between the public interest of information on the one hand, and the interest of competition of the insurer on the other hand, will be decisive for the future disclosure rules. However, unfavorable information of an insurer could aggravate an already bad situation of a company.

Due to fact that the obligations of the third pillar are pretty close to the procedures and measures of Pillar I and II, their detailed definition will be done during the work on SOVLENCY II.

5. Conclusions

The insurance market faces radical change due to Solvency II. Indeed, the French Society of Financial Analysts (SFAF) has called the new framework a “Revolution in value measurement and strategy” for the insurance sector. To fulfill the solvency requirements, insurance companies must review both the business processes and the profitability of their business lines. Certainly, Solvency II is revolutionary in that it provides:

- A better and more detailed measurement of risks;

- A global focus on enterprise risk management (not only technical risks but also financial, operational and other risks);

- The evaluation of company assets at market value according to IAS/IFRS accounting principles.

The impact of the Solvency II regime in Europe will be significant. It will not just change the regulatory capital requirements from the current, simplistic, Solvency I measures, but will fundamentally change the way that firms are required to look at their governance, risk and capital management processes. It will:

- Change the regulatory capital requirement by introducing a higher requirement based on a 1 in 200 (99.5 percent) confidence level over a one-year time horizon

- Change how firms calculate and manage their capital by requiring risk-based capital requirements and an articulated risk and capital management strategy

- Change how firms allocate capital within groups by setting out minimum capital requirements at both a group and solo level (currently subject to consultation), this will mean the European entity will be required to hold sufficient capital (what this means exactly is still under consultation)

- Increase the ability of analysts, policyholders and regulators to compare firms due to greater risk-based disclosures (currently subject to consultation)

- Increase the role of regulators by introducing a regulatory regime that focuses on risk and capital management while giving the supervisors greater powers of intervention, in particular in setting supervisory capital requirements

- Increase consistency between the supervision in different territories through application of a common framework, with peer review between supervisors to ensure consistent application. This should result in less ability for firms to undertake regulatory arbitrage, although many of the aspects of the current consultations suggest this harmonisation will take time to achieve.

Abstract

Auditing is a field of action in financial accounting.

Currently, audit means verification of audited accounts of enterprises, as the financial audit leading to certification.

The paper highlights the results of a study conducted by the authors on the literature review regarding the risk assessment in financial audit.

The main objective of this paper is to present some aspects related to audit risk assessment and also to analyse the three types of risks proposed by the International Auditing Standards.

Key words: risk assessment, audit, inherent risk, control risk, non-detection risk

J.E.L. Classification: M4

1. Introduction

The task of auditing financial statements requires taking some risks and their identification should be made as early as the planning stage works.

Risk identification is one of the main objectives pursued by the auditor during the audit mission.

Auditing financial statements must be made such a way as to provide useful information for taking concrete and real economic decisions, to decide when to buy or to sell a capital investment, to assess deficiencies in managerial responsibility, to assess the enterprise capacity of pay and other benefits to offer its employees to assess collateral for loans to entities, to determine taxation policies, to calculate profits and dividends.

The financial statements are presented

annually for the common needs of a large mass of interested users. For users interested they are the only source of information on their needs.

In the audit engagement, the auditor aims at identifying and assessing the risks of material misstatement of the information contained in the financial statements to the extent that is due to fraud or accounting errors. Risk identification can be done by understanding the audited entity and the industry, considering internal control, which is an important basis for designing and implementing responses to the assessed risks of material misstatement [5].

The auditor should establish some risk assessment procedures to provide a basis for identifying and assessing risks of material misstatement in the financial statements significant precious and statements [5].

These procedures, however, do not provide sufficient appropriate audit evidence and a reasonable degree of certainty that they have been properly prepared in all their essential points, such as during an audit the auditor must form an opinion on the assessment of audit risk [5].

Given the existence of inherent limitations of the audit and any internal audit system, the risk is inevitable that some material misstatement may not be detected [3].

The purpose of the audit of financial statements is to establish guidelines for identifying areas prone to hazards, assessing the risk and its components which will reduce the risk to plan the audit to an acceptably low level.

2. Audit risk assessment

Audit risk assessment must be carried out for all audit activities in order to achieve an efficient and effective audit, the auditors

using professional judgment and appropriate audit procedures.

Risk assessment in the audit process is a systematic activity applied to assess the likelihood of non-compliance with the legal framework in force operations.

The risk in the audit process is the fact that the auditor, the decision will expose an opinion that accounting reports will be considered as true, transactions will be considered legal and regular and solid financial management, while such real situation does not exist there.

Audit risk is the likelihood of information, some errors or deficiencies in the audit of the audited entity financial statements which the auditor may not identify.

Audit risk is the possibility that relevant errors exist in the annual accounts and the auditor to issue an opinion wrong.

Thus, you have to limit auditor audit risk to a minimum [1].

The auditor should calculate the risk of such a degree audit assurance that material errors and deficiencies assume that existing financial entity's financial statements will not exceed the insurance policy established by audit.

Audit risk assessment, including the stage of obtaining the methods and techniques used in auditing financial statements, allow auditors to prioritize the implementation of the audit.

It reveals that auditors should be always ready to adapt to situations audit program setting the significant facts, which were known at the time the audit program.

From the point of view of the possibility of achieving the risk can be:

- Potential risks;
- Possible risks;

Theoretical potential risks are likely to occur if no control is exercised in order to prevent or detect them in order to correct the error that might occur, these risks are common to all economic entity subject to audit activity.

Potential risks can be identified in an economic entity when it has no means limited to them, so it is possible to produce a number of errors without them being identified. [4]

The International Auditing Standards identify three types of risks:

- inherent risk;

- control risk;
- non-detection risk.

Inherent reference to this error in accounts in case there were no internal controls [1].

2.1. Inherent risk

Inherent risk assessed by the auditor must be based on knowledge of the entity audited and the information collected from its management system, under certain circumstances, such as:

- the nature, the specific activities of the entity;
- the experience, honesty and knowledge management / people in charge, and changes in its composition for the period audited entity, eg. inexperience of management may affect the financial statements;
- factors influencing the industry in which the entity operates, for example, the state of the economy and competitive conditions identified by determining coefficients financial trends and technology and so on;
- the complexity of the legislative framework, transactions or facts which require specialized expertise;
- factors affecting the financial condition of the entity, eg. lack of funding to the established institutional structure complexity;
- the circumstances under which pressure management may be prone to distortion of financial statements, for example, the existence of insolvent companies in the branch.

If, in the company of the audit subject there is no internal control inherent risk can be found in an account balance or a class of transactions that contain significant errors, being found either individually or other errors calculated balances or classes of transactions.

In the assessment of inherent risk, the auditor must rely on personal judgment, considering the evolution of customer activity in recent years, but the business sector in general [6].

In assessing inherent allowed other factors.

2.2. Control risk

Control risk is due to the fact that there were no errors were discovered and corrected in a timely internal control [1].

Control risk assessment is carried out in two stages:

- assessment, which is the process of assessing the efficiency / effectiveness of the accounting and internal control systems in terms of preventing or detecting and correcting material misstatements;

- final evaluation, which is performed by the auditor before the audit and will confirm or not the assessment of control risk.

In assessing control risk, the auditor will consider a number of factors:

- conducting improper inspections due to human error as a result of reasoning or misinterpretations, committed negligence / carelessness;

- control environment, in particular the existence of managerial control;

- substantive procedures, the auditor plans to perform.

Inherent risks and related controls are in interconnection is preferable simultaneous evaluation of these two components.

If tied inherent and control risks are high, acceptable non-detection risk we must be low to reduce audit risk. If risks related inherent and control risks are low, the auditor may accept the risk of non-detection higher, but simultaneously reduce audit risk to an acceptably low level.

Data presented in accounting can be divided into three categories, each bearing specific risks:

- repetitive data resulting from the economic activity of the entity;

- data points, complementary to repetitive and that can occur from time to time (inventory valuation at the end of the financial year). These may be given significant risks if errors are discovered in time;

- data exceptional character appearing in exceptional operations (mergers, liquidations, review, etc.).

In these cases, the data are more prone to risk because staff may not be sufficiently prepared for these situations and there comparative elements [1].

Detection risk makes its presence felt in situations where errors were not detected by audit procedures [1].

Non-detection risk is the mutual dependence of procedures related to audit work. Control risk assessment with risk assessment influences inherent character, actions and procedures related to the volume of audit work that is performed to reduce

detection risk, and therefore audit risk to acceptably low level.

To reduce the risk of detection (audit risk), the auditor will consider the following factors:

- timing procedures related to audit work, for example, at the end of the audit period and not once (period) term;

- volume of procedures related to audit work, for example, applying a larger sample;

- the procedures related to audit work, for example, application-oriented test taking evidence outside entity, not within it.

Some detection risk will always exist, even if the auditor will conduct a full audit.

The inherent risk and control related are higher, the more audit evidence the auditor should obtain to perform procedures related to audit work to reduce audit risk.

In an economic entity, regardless of the number of internal controls and auditor would apply whatever control techniques annual financial statements, however no absolute certainty that they do not contain errors [1].

Risk assessment audit in 1988 Accounting Principles and Auditing standards, proposed a method to determine the relationship between the three components [2].

This mathematical method has remained to this day and is calculated based on the following relationship:

$$AR = IR * CR * RN$$

where,

AR represents Audit Risk

IR represents Inherent Risk

CR represents Control Risk

RN represents Detection Risk

Through this relationship can be expressed level of audit risk, which can be calculated both quantitative (percentage) or qualitative (low, medium, high) [2].

Calculating the level of audit risk in percentages assume that the auditor has determined if the level of trust inherent in economic operations by 100%.

In this case accounting error detection risk will be 10%. If you decide to assign and control risk rate of 100%, the risk of undetected errors will be 50%.

So, the more the audit detection risk is lower with the higher level of trust in

economic transactions subject to auditors audit activity.

Risks identified will underpin efforts auditor orientation to other areas where errors can lead to true image alteration financial position, performance and changes in financial position presented financial statements [1]

The audit risk detection means that the auditor must check carefully the financial statements they audit to avoid being put in a situation where inadequate to express an opinion when the financial statements are materially misstated.

To assess the risks in the business of auditing, the auditor should use professional judgment and to establish certain procedures that will achieve an acceptable level of detection risk.

3. Conclusions

Audit risk assessment process is a complex activity and systematically applied to assess the likelihood of non-compliance with the legal framework in force operations.

The risk in the audit process is the fact that the auditor, the decision will expose an opinion that accounting reports will be considered as true, transactions will be considered legal and regular and solid financial management, while such real situation there.

The calculation of standards based on the premise that the three components of audit risk are independent this is not reflected during an audit because the auditor may determine a level of control that can detect errors inherent generate risk [2]. Such separate risk assessment and risk control inherent will demonstrate a real level audit risk assessment.

To improve the risk assessment activities still hear, intend to make certain that you have software based on some theoretical models and to help auditors in obtaining easy solutions for risk assessment in auditing financial statements [2].

This software could help auditors that audit risk detection relies on the reasoning of professional and overcoming subjectivity in performing audits.

Abstract

The authors investigated the economic essence of the financial control effectiveness. Established that the resources consumed during the control procedures have a form and measure and can be identified quantitatively. Advantage as a result of the financial control can be expressed by a quantitative and attributive indication. Therefore, the financial control effectiveness as well as factors that influence are not confined by the economic component.

Keywords: effectiveness of the financial control, resources, advantage, action factors.

J.E.L. classification: M42 – Auditing

Problem statement. Nowadays the financial control is the function of an effective management. It is constantly developing on the basis of clarification of the theoretical data and improvement of the methodical techniques of practice. Today favourable conditions for the synthesis of scientific knowledge and creating theoretical construction of understanding the financial control effectiveness are created in Ukraine. In a practical aspect it is necessary to systematize factors which influence the parameters of the effectiveness. It is utterly important to take into account peculiarities of the control system of activities of Ukrainian enterprises.

The problem of improving the effectiveness of the financial control is actual in the Ukraine. The market environment of Ukraine has its own ways of development.

Therefore, foreign methodology of developing and experience require substantial transformation and adaptation. And at the same time, it is unacceptable in domestic economic environment.

A lot of works of Ukrainian scholars such as B. Valuev, N. Vygovska [10] V. Maksimova, L. Napadovska, V. Panteleyev, S. Buchan, L. Sukhareva, V. Shevchuk are dedicated to the problem of understanding and measuring the effectiveness of the financial control in Ukraine. Most authors define "effectiveness" as the excess of benefits over costs [1, 8, 9].

Intensity of economic development in Ukraine requires the renewal of fools of the financial control. The Ukrainian market environment has its own ways of development. Therefore foreign methodical techniques and experience require substantial transformation and adaptation. And in some cases, the practical application of them is impossible in domestic environment.

Basic results of the research. Economic essence of the financial control effectiveness. Modern philosophical studies concerning the conceptual comprehension of the organizing measure confirm the existence and importance of the force of structure elements interaction: «activity – effectiveness – success» [7].

The theory of effectiveness distinguishes notions «effect» and «effectiveness». Obviously, the «effect» (from lat. effectus – performance, action) means a result, effect of a cause or action. An effect can be defined by mathematical, social, cost constituent. If the results of actions get a cost evaluation, an

economic effect is determined. Consequently, an effect is a result of operation or action.

Paul Heyne considers that «effectiveness is a positive factor that is much paid attention by the economists. No wonder that, «effectiveness» and «efficiency» are practically synonyms. Both notions characterize resulting quality of the use of facilities for achievement of goals» [4].

A. Azrilijan defines the «effectiveness» as to have an influence or to have / produce an effect. He also specifies the concept of economic effect as an effective result of economic activity which is usually measured by a difference between a money profit from activity and money charges on its realization. Economic efficiency is a major evaluation index of effectiveness of an enterprise activity. It forms by comparison of the results of activity [6].

S. Mochernj in his Encyclopedia of Economics gives the definition: «effectiveness is ability to produce an effect, effectiveness of the process, project and others like that, that is doing the things right to provide desired result» [3, p. 508].

Thus, economic effectiveness is correlation between the effect and the costs. An economic effect is the achieved result in different forms (as a rule, it is money). That is why, defining the economic effectiveness economists very often appeal to the system of analytic indices and financial coefficients [1, 8, 9].

In regard to the financial control effectiveness, we should not confine ourself to its economic constituent. Nowadays the main task of economic regulation is not only achievement of the goals by the state organs but improvement and harmonization of socioeconomic interests that will favour the self-development of market relations. Thus, the principals of the theory of the financial control effectiveness must be revised. One-sided treatment of the control effectiveness as a result of the control procedures-task ratio is inadmissible.

Analyzing the effectiveness of the production control the costs are implied as consumable resources (tangible and intangible, money, labour and intellectual asset, time, etc.). Resources have their own unit. It allows to compare costs between different options of procedures of the control

and also evaluates the effectiveness of this control over time.

We believe that the value is not only the amount of consumed resources, but also their ratio. For example, when using an aggressive strategy by the business minimization of the time of its implementation is the priority, while spending financial resources is of minor importance. For the introduction of innovative technologies is justified by high cost of intangible assets, investments in intellectual assets. In the pre-crisis situation, resources limitation, preference is given to the available workforce, work skills, creativity, patriotism and corporate spirit.

Conventionally, this category should include forced costs associated with the implementation of control procedures themselves. In particular, the loss of trade during the continuous inventory of goods in stock and trading floor; holding control procedures that require the presence of staff in off-hour and so on.

So, in general, the costs in the context of the effectiveness of the financial control can be identified and quantified.

Identification of benefits requires comprehensive approach. A quantitative assessment is not only the priority, "values" description of benefits as a result of control is also very important.

Under the Law of Ukraine «About Financial Accounting and the Financial Reporting in Ukraine» an economic benefit is potential possibility of getting money by means if using an enterprise's assets [1, article 1]. On our opinion, the priority aims of the financial control effectiveness are not only quantitative estimation but also «value» evaluation of the benefit (the effect) according to the control results.

Whereas the effectiveness of control the absolute benefit is the level of gaining the aim of control, the completeness of tasks performance of it, enterprise management improvement, transition of management to a new qualitative level.

The criteria for advantages as a result of the control is to determine shortcomings in the organization of internal control, violations and persons responsible for them, and to establish the areas of risk for management.

So, at first glance, the idea that the effectiveness of the control is the excess of

advantages over costs is fair. However, to achieve absolute effectiveness of the control as mathematically maximal performance is impossible in practice.

The law of diminishing returns confirms that the best results can be obtained in conditions of not least costs. Positive synergistic effect is much paid attention under the dynamism of market processes. Obviously, the effect of synergistic effect is not predictable.

In addition, the adaptation of existing propositions in practice for running companies indicates the subjective performance criteria of financial control. Professor Vygovska N. proposes to apply the Delphi method for evaluation of the effectiveness [10]. In spite of the fact that the scholar offers quite clear evaluation criteria, peer review is the subjective a priori.

Investigating the effectiveness of management Podolchak N. underlines the importance of the perception of balance and imbalance interests of managers [8]. Thus, the different user groups serve different parameters of the control performance criteria. For example, for the accounting control the priority criterion is the legitimacy and credibility of mapping business transactions in accounting and reporting. For the control of the financial flows the priority criterion is an economic feasibility and legality of the financial transactions. For the monitor tax payments this criterion is completeness and timeliness of payments to the budget [5].

Thus, the concept of effective control should be considered from the standpoint of the theory and practice of management. According to the management theory the control of effectiveness is based on a combination of philosophical aspects of management:

- ontology – identifies the essence of effective control as an economic category, defines an object, subjects of the control effectiveness;

- axiology – identifies the goals and objectives of financial control, determines the desired / admissible ratio of costs and benefits of control effectiveness criteria, taking into account the interests of the user group;

- epistemology – explores the economic reality using the control procedures;

- praxeology – estimates the impact of control measures on the basis performance criteria of the control.

According to the practice of the control effectiveness it is the optimal control procedures in existing economic conditions. The effectiveness of control is being established by means of obtaining relevant information about the real conditions of management system and highlighting the segments of high economic risk.

The rate of the financial control effectiveness is influenced by the following factors:

- general principles of organization and financial control management in Ukraine;

- rationality of organizing the control in the company,

- effectiveness of instructional techniques.

Factors of an objective activity are relevant to the first group of factors that determines the effectiveness of the financial control in Ukraine. Thus, it shows the passivity concerning performance of them.

The special feature of the Ukrainian National Economy is fundamental changes in the control legislation. The danger of this factor requires immediate response management and rapid assessment of economic consequences. The existence of contradictions, inconsistent activities, lack of coordination between tax officials, subjectivity of controllers define the risk of financial and other losses of enterprises. It concerns not only the payment of fines, costs for challenging the results of inspections, but also the loss of business reputation.

The purpose of the Tax Code of Ukraine was to systematize the statutory provision in this field and approaches to the application of tax penalties. Approbation of these new rules in practice showed normative legal gaps that require urgent solution. This led to numerous changes in the Tax Code, but did not remove the need to develop internal regulations of the State Tax Service and introduce clarity into the specific control procedures.

State of the market dynamism is an external factor which can show up slowly. The development of the national market is closely connected with general economic laws of the world economy, but it has its own characteristics. The negative factors influence management are the following: reduction of types of business transactions,

lack of resources (money, labor), nonrelevant economic information for decision-making in crisis situation. To provide effective control it is necessary to be aware of a basic tendency of the national and international market development and their interrelation. If some negative long-term tendency occurs, it is in vain to expect financial favour in the market, even if the company is characterized by financial stability.

Many scientists focus on factors of internal control. We agree with the opinion of scientists who think that a major impact on the control effectiveness is a skilled personnel in the system of internal financial control. Besides in the conditions of economic relations not only professional competence, development of vocational competence, abidance by schedules and plans are important but also non-standard professional thinking, professional judgment and professional intuition and foresight, a comprehensive understanding of management. Incontestable reputation of the controller is also of great importance.

Lack of experienced personnel in the sphere of the control decreases effectiveness of the measures to improve the information system of the enterprise. It is very important for the personnel to have not only basic education and skills but also the ability and desire of self-improvement, professional competence, practical skills of working with documents, adaptation potential, resistance to stress. All these factors should be taken into account while selecting candidates for post. In addition, to maintain quality of skill level consistency in the training of personnel is necessary, ranging from university training to the professional development in the desired direction of the enterprise.

Disparity of an average salary in the country or region to qualification level is another side of the personnel problem. The reluctance of qualified personnel to perform duties for improper payments forces professionals to train for a new profession for getting higher wages. The system of motivation at the enterprise which include systematic moral and material incentives, social support of personnel, introduction of the productivity factor and others can overcome the problem.

Generally, the factors that determine the effectiveness of the control include the

structure and function of internal control. Obviously, the regularity and complexity of internal control procedures improve the quality of the reliability of management information that is based on economic decision-making. Typically, the control performance criteria include the following formal features: the existence of the developed regulations on control department, job descriptions, plans and programs of inspections, the existence of the developed test methods and measures to coordinate activities of controllers who take into account the specificity of a particular market participant. Detailed elaboration of practical approaches to controlling positively influences its effectiveness. While drawing up a comprehensive plan and program of verification experts try to cover all areas of management focusing on segments of economic risk.

However, not always compliance with these criteria ensure the control effectiveness. For example, for the micro and small enterprises the internal financial control is usually embodied in one person. For the large enterprises with geographically branched structure, both the structure of the control and exchange of information on inspection results and the validity of decisions are of great importance.

The basis of the quality of managerial decisions is the quality of information of the control system. Simplicity and transparency of information links between departments and divisions, targeting and timeliness of disclosure management and violations have positive impact.

Of primary importance for the control procedures effectiveness for coverage of its management system is the measure of the use of special software. On the one hand, the intensity of professional automated programs contributes to the system of administration development in Ukraine. In addition, professional development, raising additional funds for the acquisition, software licensing and software renovation, are required within the enterprise. The introduction of automated management programs to order or improvement well-known software products (widening, deepening, or vice versa, simplifying functionality of modules) are the alternatives for improvement of management. The maximal adaptability of the program to

the internal and external environment of enterprise, responsibility of employees for the quality of products and servicing guarantee are doubtless advantages.

Relevant innovation is the introduction of electronic documents for the purpose of reporting that aims to improve the effectiveness of information processing. But not always perfect new technology, information resources, automated networks, servers, Internet connection, etc. increase the risk of late / incorrect reporting. Perhaps, with the lapse of time, these drawbacks will be eliminated. But now it is important to strengthen the control over the documents circulation, aimed at timely and efficient reporting.

In Ukraine, expert system programs are generally used in reputable audit firm. However, the problems of economic information security and unconscientiousness of its use are burning. Time limit on work in computer environment contributes to enhancing of the personalization of the responsibility.

To assess the financial control effectiveness it is important to assess the performance of controllers. In particular, the quality and completeness of proper control applications show the professional competence of a controller. It is necessary to check the order of procedures and time limit during this control. In some cases by means of interviewing participants of the control procedures.

The criterion is the assessment of the legality of commercial transactions under the control. In particular, this criterion is the completeness of coverage of legislation on management under examination, including sanctions for improper performance of them. Also, a legality verification procedures carried out by the controller of investigation is checked.

Completeness of the control plan fulfilment is a kind of an indicator of the performance of the controller. Factors of instructional techniques of the control effectiveness are usually determined by the results of operations and context of the certifications. Although the conditions for the use of the certain certifications including audit of the financial statements, sampling audit can have always the risk to be unreliable.

Conclusions of the research. Providing the activity of the financial control effectiveness takes place in the context of the management theory and practice development. According to the management theory the financial control effectiveness is based on the combination of philosophical aspects of management. A new review of the leading conceptions of philosophy of activity, their ideas, concept-category set and methodology give possibilities to describe, research and work out adequately the modern problems of the financial control effectiveness.

From position of the control effectiveness practice it is an optimality of the control procedures in existing business environment. The control effectiveness is not limited by the economic constituent. It implies obtaining relevant information about the real state of the control system including the problems of certain segments of high economic risk.

Identification of the factors which determine the constituents is very important for the estimation of the financial control effectiveness. Their descriptions will allow to set optimal / admissible / actual resources and benefits ratio to obtain a successful result.

Bucharest University of Economic Studies
maria.caratas@me.com

Abstract

This paper evaluates the role of information technology and CAATTs and the way they could increase companies' effectiveness in the near future. Our study focuses on the global trend of adopting new technologies at a large scale in internal audit in order to produce high qualitative audit results. The present paper highlights the necessary changes faced by companies during the CAATTs' adoption process. Organizations arrive to change their conduct of business and to promote efficiency above all.

The conclusion of our study states that new technologies and CAATTs do have a significant impact on internal audit and risk management as well as on corporate governance as a whole. Moreover, our findings demonstrate that auditors should be prepared to use effectively those techniques and tools by increasing their skills and core competencies concerning auditing and data analysis and especially their capacity to understand and foresee risks.

Key words: internal audit, risk management, CAATTs, information technology, computerized audit

J.E.L. Classification: G34, M42, M49

Introduction

Current changes characterizing information technology and management practices influence directly the risk management which is seen as a tool for reducing risks. Under such circumstances, internal audit plays a vital role in managing

risks by using newest auditing techniques and tools.

This paper contains the first results of a more extensive research performed with the aim to build a doctoral thesis. Internal audit does represent a constant in the research work. The motivation for this paper reflects our intention to investigate the impact of information technology and CAATTs on internal audit and risk management. During our research work, we have elaborated the concepts of internal audit and risk management, by mentioning some relevant definitions within a literature review. Then we have dealt with the connection established between those two concepts and the way by which they arrive to increase corporate governance effectiveness. In order to realize the current profile of internal audit focused on risk management, we introduced information technology and CAATTs' concepts that seem to be able to help auditors achieve better audit results. Even if CAATTs represent a paradigm studied long time ago, we highlight nowadays the urgent need for using those auditing tools and techniques within modern organizations. Finally we have formulated some conclusions, outlined a few limitations of our study and suggested further areas for research.

Internal audit and risk management as conceptual frameworks

In today's business environment, internal audit has become a vital factor for all companies. According to laws and regulations, financial reports must be audited periodically in order to ensure that those reports are fairly presented. Day by day, audit activities become more challenging for

auditors all over the world as well as for all market's participants. We believe that it is very important to give some definitions of internal audit and risk management in order to approach their contribution to the modern business landscape.

According to IIA's definition dating from 1999, internal audit is seen as “an activity which should evaluate and contribute to the improvement of risk management, control and governance”. [1] Meanwhile, internal audit is considered also as an important means of enterprises for strengthening operational management. [2] Internal audit has constantly developed because of the social and economic overall evolution (Wang, 1997). [3] This is an important managerial control device directly linked to the organizational structure (Cai, 1997). [4] During this era of globalization and of complex changes, Jayalakshmy et al. (2005) highlighted the pressures auditors are facing in order to maintain trust and integrity. [5] Other authors have been interested in understanding internal audit new functions and also information technology's impact on internal audit (Staciokas and Rupsys, 2005). [6] These authors state that internal audit functions include not only the internal control, fraud investigation and advice, but also identification of organizational risks. In such circumstances, information technologies could support auditors in consulting management with regard to risk.

Therefore, our findings suggest that at present, internal audit's main objective should be that of understanding those areas representing greatest risks to the companies. Auditors should assess risks and find ways to communicate with management in order to build effective risk management strategies. Thus, internal auditing becomes an active factor interfering into risk management. It helps organizations achieve their objectives by bringing a systemic approach in order to improve risk management effectiveness and that of corporate governance as a whole.

Within today's governance models, a significant place is dedicated to internal audit and risk management functions. Some research papers have treated the relation between the two mentioned functions and nowadays, we can notice a deep interest concerning their integration at the organizational and operational levels. The

responsibility for managing risks is now shared between management and auditors. However, risk management is perceived as a central task of corporate governance while internal audit should help management find solutions not just problems and difficulties. Meanwhile, management is expected to use internal audit as part of fraud's investigation and risk prevention.

Risk management is a concept designed for use by an organization in order to manage and control risk. The top 5 critical risks as they are seen by PWC (2012) are the following ones: fraud and ethics; mergers and acquisitions; long programs. [7]

Within this context, internal auditor's role becomes really clear. The “new floor” for an effective internal audit, as it is presented by PWC, consists in navigating the new risk landscape, thinking and acting strategically, aligning resource allocations, leveraging the second line of defense. [7] Moreover, internal audit should “assess the adequacy of the framework, the risk management processes and the control environment with a view to identifying where gaps exist” (Dickinson, 2010). [8] In such circumstances, communication becomes a critical component of an effective internal audit function. Auditors are supposed to communicate very closely with managers not ignoring shareholders' expectations and mainly the risks.

However, risk is usually defined as a concept used to express uncertainty about events. Risk is always aligned to change. Moreover, risk management covers the identification and mitigation of risks which may prevent companies from achieving their objectives.

The conclusion for this section of our research paper states that both internal audit and risk management have been considered as main elements of corporate governance. However, the relation created among these two elements remains confused. Nowadays, we are witnessing an urgent need for integrating them in order to increase governance effectiveness.

Information technology and Computer-Assisted-Auditing Techniques and Tools

Internal audit functions have expanded far beyond controls concerning financial

reporting. All market's participants feel nowadays a significant need for increased and relevant information. In such circumstances, IT proves an important impact on internal audit and risk management. Therefore, internal auditors should integrate IT in their activities in order to perform an effective risk-based audit. However, computerized audit has not been used at a large scale yet because of different kind of reasons. Only big companies use widely information technology in auditing because they do have the possibility to invest in IT and to support auditors in increasing their expertise and skills. For the moment, there are a lot of auditors that may not have the background and expertise to address significant risks over information technology.

Technological advancement plays an important role in internal audit. Optimizing information technologies and techniques, audit will change its operational perspective. It will require more sophisticated tools and applications as well as a relevant expertise and advanced skills. However, the proliferation of newest technologies has as a consequence the increase of risks such as: data protection, information security, privacy. Moreover, IT infrastructure proves often as relatively insecure. “Because of the nature of information, security risks is evolving continuously, internal audit function needs to stay ahead of the threat curve” (PWC, 2012). [9] Information technology's adoption is influenced by different factors such as cost, mentality, knowledge and skills, management support. Especially IT cost should not be ignored. It implies both money and effort. Therefore we consider that, by adopting IT in audit practices, companies will be able to reduce audit costs and increase its effectiveness. However, before introducing new technologies in audit activities, organizations should rethink all the significant aspects of auditing (Vasarhelyi et al., 2012). [10] A very important issue treated by some researchers refers to auditors' acceptance of information technology. As it was shown by Bagozzi (2007), the Technology Acceptance Model (TAM) is the subject of over 700 research papers. [11] Adopting new technologies, organizations should conquer their resistance to organizational change.

The definition given by Nazari et al.

(2009), shows that information technology is “an instrumental in accessing what human knowledge has created”. “It supports the gathering, organizing and sharing of knowledge assets”. [12] In the literature concerning information technology, there are authors that highlighted the importance of organizational culture to information technology's development (Alavi et al., 2005). [13] According to Kim et al., (2009), information technology does have a significant impact on internal audit profession. Meanwhile, technology features will have an important influence on technology acceptance in this profession. [14]

Recent research papers have identified the impact of IT on internal auditing (Curtis et al., 2009). [15] A few years ago, some authors provided overviews of IT audit processes and tasks (Hall and Singleton, 2005) [16], (Pettersson, 2005) [17]. However, we notice a restraint academic research on the IT audit processes especially that designed to highlight the factors influencing IT audit quality. Some authors treated the auditors' IT proficiency as a critical component for IT adoption in auditing (Leader, 2004). [18] Smith (2007) studied potential improvement opportunities for IT audit [19] and Dowling (2008) focused on IT implementation within internal auditing. [20]

We assume that technological advancements have increased the importance of internal audit and control. For such a reason, computerized audit could be seen as an effective audit strategy being able to improve audit quality and productivity and also to reduce enterprises' costs (Banker et al., 2002). [21] Computerized audit includes new technologies allowing the effectiveness of audit activity. The major advantage of such an audit strategy is that it could reduce costs and time auditors usually spent on manual examinations. Computerized audit could also enable auditors to better understand the internal control structure. We also noticed that computerized audit enables auditors to monitor organizations' systems and procedures, but also data's integrity. Furthermore, by leveraging technology, computerized audit could allow enterprises to produce immediately audited financial statements. However, it requires serious increases in investments for technology and

various new skills for auditors.

Nowadays, Computer-Assisted-Auditing Techniques and Tools are not accepted at a general level because of different reasons. Among the different modern categories of CAATTs, we remember the following ones: test data, integrated test facilities, parallel simulation, embedded audit modules, generalized audit software. We think that for the moment, only big companies show a great interest in adopting CAATTs because of their financial possibility to implement such technologies. As it was shown long time ago, CAATTs' investment decision is also influenced by other factors such as: technological, organizational and external environment of companies (Tornatzky, et al., 1990). [22] Moreover, the decision of accepting CAATTs or ignoring them is determined not merely by firms' perception, but also by the technology characteristic designed to fit with audit main tasks.

Coderee (1993) explained how CAATTs could automate some of internal audit functions. Firstly, the author presented CAATTs' benefits for audit planning and reporting. Among those benefits, we remarked: the increase of audit coverage, the improvement of audit skills, the increase of auditors' independence and credibility and the growth of cost-effectiveness. [23] However, in today's changing environment, audit tools and techniques are growing more complex and sophisticated.

As a conclusion of this section, we suggest that information technology and CAATTs could be able to help internal auditors in their activity. Over the years, auditors will use at a large scale various technologies such as: CAATTs, audit reporting, control monitoring. All these will support auditors in foreseeing future risks and preventing fraud which will surely improve audit's results. Using effective information tools, auditors will be able to monitor different risks. Therefore, we consider that internal auditors should increase continuously their skills and competencies in auditing, data analysis and data extraction.

Conclusions

The present paper gave us the opportunity to prove that new technologies, information

systems and data processing have changed in time the way companies conduct their business and also the expected results. We revised the literature in the field in order to understand the impact of information technology and CAATTs on corporate governance as a whole. The accounting and auditing professions have to play an important role in improving the quality of information provided and in assuring its reliability. For such a demarche, we studied a wide range of articles and journals covering areas of internal auditing, risk management and corporate governance. Our findings state that internal auditors could be more helpful in detecting and reporting fraud, in preventing risks since they work with the management, as integrated functions. We also discovered some authors that had studied the way by which auditors used audit tools, software and technologies. We noticed a sort of auditors' resistance and also some limitations due to technologies' high costs, to companies' short-term needs and to the lack of significant skills.

As a main conclusion of our research, we assume that the introduction of those sophisticated tools and techniques would support internal auditors and managers to build a serious risk profile for the existing and future projects. Furthermore, new research papers will contribute to the generalization of more progressive auditing practices using information technologies among a large number of organizations all over the world. We also encourage future studies referring to organizations' needs to hiring high quality internal auditors, opened to changes and challenges of information society and technologies, able to increase corporate governance effectiveness.

Convergences and Divergences between Cash Flows and Cash Flows Company

Spineanu-Georgescu Luciana
Spiru Haret University
lspineanu@yahoo.com

Abstract

Within three decades has admitted that due to shortcomings in the profit and loss account is widely used cash flow statement, cash and payments respectively, to reflect the funds generated from current operations of an enterprise, as and major investments and financial transactions that occur during the year. The primary objective of the analysis is to reflect the performance of the combined effect of decisions, operational, investment and financing, and interpretation in parallel balance sheet and profit and loss account of the period may lead to better conclusions than separate analysis of consolidated these situations.

Keywords: statement of cash flows, balance sheet, profit and loss account.

J.E.L.: M41

1. Introduction

Information on the cash flows of an enterprise is useful to users of financial statements, placing them with a basis for assessing the entity's ability to develop cash and cash equivalents, and its needs to utilize those cash flows.[1] Economic decisions taken by users require an evaluation of the ability of the entity to generate cash and cash equivalents and the timing and certainty of their generation.[2]

Enterprise value in monetary terms should be viewed in terms of expected future results of further work which the financial plan assumes that any investment activity is justified only in the light of the expected benefits to be obtained, even if not in all cases the assessment relates only profitability criteria.

This idea is based on the anticipation that comes from the company believes that the

estimated future benefits to be generated from property owned by the ability to generate income on capital, to produce profit and also to distribute dividends.

2. Cash flows of the company

Currently it can distinguish between static traditional financial analysis, based on synthetic accounting documents for the year, the balance sheet and income statement respectively, and dynamic financial analysis, showing past and projected development and targeting particular beneficiary capacity and financial flows.

Cash flow statement is presented using comparisons between opening and closing balance of the year and the use of key indicators of profit and loss, all interpreted in terms of uses of cash or resources:

- cash-flush activities absorbed the cost or at unprofitable;
- influence of changes in working capital requirements on cash;
- placing cash in investment in fixed assets or repayment or debt;
- reunification cash resources or through additional borrowing or by reducing existing investment in assets;
- impact of the issuance of new shares or redemption thereof on cash;
- within the volume of cash dividends paid to shareholders;
- corrections in the balance sheet or profit and loss account for depreciation, amortization or other items that do not generate cash;
- net impact of currency changes on the availability of the company accounts.

Therefore, the cash flow statement thus offers a panoramic related impact of currency movements on all management decisions of a period.[4]

Analysis of financial balance in terms of

cash flow leads to the estimation of future cash needs on the basis of the past, knowledge of which is useful both shareholders interested in the existence of sufficient cash to pay dividends and creditors interested in recovering loans.

At the same time, knowledge of the future cash flows of interest to potential investors updated cash flow method is one of the business valuation methods. This analysis is practiced in the Anglo-Saxon, yielding information on cash flows and the company's capacity, considered the main criteria by which investors (current and potential) base their investment decision.

The literature and foreign cash flow is defined separately.

Romanian authors believe that an important part of financial-economic analysis, is represented by the cash flow whereas economic practice is considered that any activity must release any money, resulting in a surplus of capital to invest in the business. A business can be profitable to make a profit, but not solvent, the lack of liquidity due to the gap between receipts and payments that you make in the financial cycle. From this we can conclude that financial flows highlights the money circuit in an enterprise.

The economic approach are reported are two schools of analysis of cash flow: French and Anglo-Saxon.

French current exhibit variation in cash flows (cash flow) due to the interaction between long-term equilibrium and short-run equilibrium, ie variation due to changes in working capital and working capital need.

Anglo-Saxon theory explains variation in the same net cash, cash-flow on account of the change in cash due to operations management (operational), including the need for working capital changes due to investment operations (only in fixed assets, intangible) and financing operations (through equity and borrowed capital).

Equality between cash flow and net cash variation is less forced, some specialists consider as net cash is a result of the company after deducting treasury short-term bank loans. That is why we believe that cash flow (financial) must be understood as treasury enterprise switching between two points, the end and beginning of the period studied. In favor of this assessment lies the

fact that bank loans are the source of funds is found in the financing component flows, cash flow and therefore can not take the final calculation only one final source of funding sources neglecting the rest from operating activities or management and investment.

Although information on the cash flows are preferred by users because of the fundamental relationship receipts, payments and easy understanding of this type of information, the practice of accrual accounting makes it difficult to obtain them.

Whatever choice theory, as applied to process certain receipts and payments, and their record of operating, financing and investment, cash-flow information analysts considered absolutely necessary to assess a company's financial position and its ability to generate cash, changing financial position and determining future needs for liquidity, maturity and risk of future receipts.

Cash flow analysis is required both by managers to develop enterprise development strategy and investors to base their investment decisions. Cash-flow method is applied to both the current situation and to organize the company. Furthermore it is considered that policies can be developed to a company other than starting from cash flow. On the other hand, the financial strategy of the company, cash flow is the quintessence of any business plan and moving the cash flows are of great art of financial management.

3. Cash flow available

Attracted cash flows generated by the investment and support is quantitative methodology for evaluating the effectiveness of investment projects, for which knowledge of their characteristics is essential.

Financial management has established cash flow available (free cash flow) as cash flow more suitable for the evaluation of a project or investment.

Cash-flow is the cash available at any time available in stand company used to pay equity investors, ie shareholders or creditors, as the strategic future investment needs. Free cash flow (FCF) is an approach, developed specifically for this type of analysis value in practice being able to find some differences in the exact definition of this indicator, its application to specific situations.

Cash flow available (Free Cash Flow - FCF) of the company and its shareholders is cash flow emitted by conducting all business activities (operating, financing and investing), the result of the difference between revenue as inputs cash (cash inflows), and payments as cash outflows (cash outflows), performed by the undertaking during a financial year.

This indicator is determined on the basis of profit and loss forecast, drawn up following the completion of the new investment. In the income statement are projected sales of products and/or services and certain additional expenses incurred in the operation of the investment.

Analysis of cash flow available after its origin reflects liquidity surplus cash generated by operations after finance growth management of the enterprise (property changes and the need for working capital).

Under this analysis, it starts from the value of cash flow resulting from operating activities of the enterprise, will be reduced by the amount of cash allocations for the maintenance and development of existing production capacities and net working capital.

Analyzed by destination, the available cash flow consists of two components: cash flow available to shareholders and cash flow available for creditors.

The first component provides growth equity and pay shareholders by paying dividends, and the second component provides payment of interest and repayment of debt outstanding during the financial year.

Both ways of calculating the cash flow available lead to the same result, what differs is the perspective from which it is analyzed.

4. Cash flow of exploitation

Operating cash flow represents cash generated expression (or consumption) of all mining operations broadly. This reflects not only the flow emitted from the operation in the narrow sense but also financial flows generated by operations (excluding interest and tax) and extraordinary.

Under current accounting rules, the resulting cash flow of the business for the three activities:

- Cash flow from operating activities;
- Cash flow from investing activities;

- Cash flow from financing activities.

Cash flow from operations reflects the operating performance of the company form of a cash surplus or cash in the absence of contrary vulnerability available. In this case, it means that exploitation operations consume liquidity in place to exhale, payments or receipts are lower. Referring to the above, the company is unable to meet the needs of self-financing of investments (economic capital maintenance) to ensure its growth through new investment or to pay taxes or dividends. Long-term adverse circumstances jeopardize the company which is the consequence of poor economic profitability (surplus profit before deduction of income tax and interest expense) or unduly increasing financing needs of business operation (the huge increase need for working capital).

Exploitation operations resulting from the company's core business, resulting in cash flow from Exploitation (Operating Cash Flow, OCF) have the highest share in the operations management.

Therefore, the cash flow management is determined primarily by the size of cash-flow operation.

Cash flow from operations after deducting tax (Income Tax) of operating income, plus depreciation.

Cash flow from investment activities may be determined both by the direct method and the indirect method: via direct method is calculated as the difference between payments for the purchase of fixed assets and the proceeds from the sale or repayment and the remuneration of financial assets in the form of dividends and interest received.

A third component of the cash flow is cash flow from financing activities which encompasses both revenue streams and expenditure flows, generating payments. Proceeds from the capital increase transaction (by issuing new shares) and / or increases in financial liabilities (by contracting new loans or by issuing bonds of the company. Payments are in the form of reimbursements for medium and long term loans and sometimes the redemption of the stock market and outside of its own shares on account of net profit.

By adding the three components of cash flow (cash flow from operating activities, cash flow from investing activities, cash flow

from financing activities) to obtain the available cash flow of the company, previously.

5. Conclusions

Cash-flow approach in terms of boundaries implies that in terms of results, cash flow provides indirect and incomplete information on the slope of the company to make a profit, is used for this purpose, with caution. As expressed an approximation of the cash flow, cash flow proves its worth in terms of funding, which leads to a the ability of the company to distribute dividends and finance investment needs of any issue of shares or debentures, possible impairment adjustment for working capital and liquid, respectively treasury permanent situation.

An Approach to Enterprise Risk Management for Archive Depos

Șerbănescu Iuliu Cosmin

The Bucharest University of Economic Studies

The Faculty of Finance, Insurance, Banking and Stock Exchange

serbanescucosmin@yahoo.com

Abstract

ERM (Enterprise Risk Management) should be considered a solution to the inherent problems within the undertakings. Without deceiving, it really stands for an optimization and replacement of insurance contracts, as a method of potential risk transfer.

The way a manager deals with these realities is transposed in the final value-added framework for the stakeholders. As a consequence, his decisions are based on a prior debate with those involved (shareholders, creditors, insurance companies, market regulatory bodies, even partners).

This paper work debates the solutions for archive deposits from an ERM point of view, emphasizing the possible solution for risk mitigation.

It is also stated the importance of hierarchy of controls as an adequate method regarding the risk treatment. The debate underlines the necessity for rethinking the risk management according to domain specificity.

The solutions provided consider the fire risk for this legal entity, as the core cause for major prejudice.

Keywords: Enterprise Risk Management, risk mitigation, insurance optimization, risk program, risk control.

JEL Classification: G22, G32.

1. Introduction

Every legal entity needs protection against different types of risks, due to the fact that they jeopardize the business continuity. The easiest solution is to conclude an insurance contract, but the claim process and

the prolongations of file closure represent possible impediments.

Sometimes, ERM is supposed to suppress the need for an insurance portfolio, but this is another point on the international agenda, because the risk manager or the risk officer had to take into account the alternative to merge underwritings techniques into the risk program as a whole.

The insurance market is under pressure from the global economic crisis, so insurance premiums reflect the best of underwritten risks extent. Insurers are required to provide evidence of underwriting risk capacity, while the biggest fears are related to their ability to pay benefits and indemnities to beneficiaries, insured persons and third parties that suffer a prejudice due to insured's action.

2. The ERM framework

The initial framework for this topic is based on different norms, regulations, such as [4]:

- ISO 31000;
- Sarbanes Oxley Act;
- COSO and COSO II.

ISO 31000 represents the framework for a successful enterprise risk management, because this comprises an improved perception for the risks affecting the company and by all means the strategic decisions are made in knowledge-based environment.

The Sarbanes Oxley Act, also known as Sarbox or SOX, has the following main topics: the compulsory accuracy of the financial information that is to be revealed and secondly stiff penalties for fraudulent actions.

COSO consists mainly in choosing the check-ups for the optimization of actions intended to fulfill the goals. These should be stated by the shareholders for a longer period

of time so as to permit effective adaptation to risk alterations.

3. The archive depos particularities

The risk management solution must be supported by the following aspects:

- Building architecture (pavement, cabling solutions, effective fire-prevention solutions, windows position);
- Personnel involved (adequate training to deal with specific problems).

The building is supposed to be of concrete and brick, with all utilities, air-conditioned system, humidity regulator and fire-prevention systems (sprinklers and fire extinguishers).

The main risks that can be identified are:

- Theft and vandalism;
- Fire;
- Water pipe and flood;
- Inappropriate temperature and humidity;
- Pests.

4. The hierarchy of controls for archives

Although it may seem like a forced comparison between the insurance and risk control, basically a reference from part to whole, it cannot be overlooked the need to be analyzed in parallel. Basically, insurance companies take those risks that risk managers or those entitled to handle the destinies companies wish to transfer to those who are specialize in underwriting. On the other hand, when we talk about risk management process, reinsurance is a small part of this complex process.

Risk elimination means either to actually eliminate the possibility of risk occurrence (which often is at least very difficult, if not impossible), either to subsequently cancel the adverse consequences of its materialization.

Risk substitution is considered to be the replacement of the analyzed reference with another object, process, with minor implications in terms of risk. Because we cannot bear in mind always about risk elimination, this step appears to be the optimal one.

Risk isolation. On this occasion we can discuss the way, although the risk occurs, we can take actions so that its materialization (possible in fact) doesn't cause further risks

or it doesn't permit consequences seen as possible to affect the entity that was previously risk assessed.

Engineering. In this framework we talk about proactive measures through which we combat interaction with the generator of a possible the risk.

Addressing the need for administrative action. Following such a decision, we can discuss the implementation of a code of conduct at the concerned entity level, taking into account actions relating to employees who work in that area and procedures on how to operate and maintain the equipment.

In addition to the previous controls we could opt for PPE (personal protective equipment).

Risk management can consider all these options, but we knew that the most effective are the first. Unfortunately they are the most expensive, so the company's financial resources should be spent on a certain priority to cover major risks.

Subsequently determining hazards that may generate and spread the risk of fire, we have to proceed in order to assess the probability of this danger and also the assessment of the consequences which may arise from events previously associated. Thus, from the point of view of likelihood, we have the following patterns:

- very likely;
- likely;
- unlikely;
- highly unlikely.

5. Fire risk

The fire risk must be interpreted in the context of direct causes of happening, but also based on the aggravating factors that may occur when triggering it. In case that risk elimination or isolation is impossible, the solutions mainly refer to the possibility to mitigate the consequences they may feel throughout the company.

I identified some perils for the archive according to fire risk procedures:

- The raw materials used for the in building construction are unsuitable according to the actual destination provided by the landlord;

- The electric wiring is very old.

The measures undertaken for the first situation consisted mainly in the removal of stored papers and boxes that lay on the ladder between the floors and the attic (there is no elevator, due to the building height).

This proposition was made according to increased speed of propagation of fire and difficult access to the upper structure of the attic, hence the roof [5].

Another problem is emphasized as we take into consideration the persons. There a risk of trip and fall, both on the materials themselves, but also because it becomes impossible to view any cables that are found alongside the walls or the signs painted on steps.

But one should not attain a transformation of these perils in major tortious elements. In fact the fire risk can be caused not only by material clutter in a room (debris from different sources) and blocked access for fire patrol, but also the lack of normal functioning of fire prevention systems. The intervention could be done on fire escape, but this must be in a state of functioning and also to provide access to all levels.

For the second peril, the wiring will be replaced by a specialized company in the field, that will compulsory provide guarantees in this respect. The grounded extension cords that are used at the present time should be extended, in order to prevent heating due to the winding wire of the coil form.

The electrical installation should not be overstressed by the air conditioning system, which is preferably to be split on a separate circuit. Meanwhile, if this is impossible, we can call the mobile air conditioning, to be powered by the car battery, but this solution is one intermediate.

Of course the fire risk can start also from the non-compliance on smoking regulations as this is mentioned in designated areas or in accordance with the regulations of the employer. Smoking bans during rendering activity may lead to finding premises unfit for the vice, which ultimately trigger a large fire.

Polypropylene channel installation must be done in concrete floor, so to prevent further damage as a result of unanticipated events. Thus water infiltration through walls waterproofing will produce a lesser damage.

Obviously, this thinking should be considered in the broader context of risk management, as an effective control cannot be exercised only to the extent identified major risks. They can lead to consequences worthy of consideration or on the other hand some that have a major incidence by frequency of records.

6. Conclusions

I underpin the necessity to overcome the basic preoccupation for sophisticated software-based programs. In fact the risk control

In order to erect a successful risk program, we have to gather all the information the environment could provide.

Also one should emphasize that the solutions deemed to decrease the risk frequency and intensity, must be adequate in terms of costs compared to insurance conditions and premiums.

It's obvious that we have to protect our investments, but this could be done by the fulfillment of a few basic conditions:

- Check the insurance conditions, exemptions and deductibles that are stated in the negotiations with insurance undertakings. Special terms will have to be explained for the specific domain, otherwise the solution to cry off the contract is imminent;
- Insure you made a checklist for the risk stratification, because one must deal for the beginning with the most dangerous risks, no matter how expensive are the solutions;
- Assume and accept the workers 'opinions, due to the fact that they are dealing ceaselessly with risks.

Sometimes the risk managers are supposed to improve their understanding of business environment [1]. Ancillary risks, determined by an alteration of known factors, must imply new solutions.

As long as we postpone for good the treatment of these problems about possible future prejudices, it's normal to accept an increase in the difference (gap) between the value of a property lost and the expenses. We should have been taken a few steps to fight the risk.

In fact the risk manager wants to enhance the company strength on the behalf on shareholders.

Abstract

The purpose of this paper is to describe the social and economic mutations from the conceptual framework and the factors leading up to the occurrence of these mutations.

In this matter, the paper will approach areas in which social and economic mutations interfere and also getting to interact with the object of management sciences, modifying the current state of the concepts and processes involved in the development of knowledge, both tangential on certain categories of information and plenary over representative elements of management sciences.

Keywords: social and economic mutations, paradigms, knowledge, management science, interdisciplinary.

J.E.L Classification: A12, B41, F00.

Introduction

The economic-social mutations have a pronounced interdisciplinary character and are currently perceived as an evolutionary add-on in constructing the processes that energize every activity developed with the emerging purpose of locating in the reformed category of areas as a perfectly integrated element that globally excels because of the ease to line up and also adapt to a new dimensional the already existing information.

In this paper, the notion of “mutation” embraces the meaning of modification, transformation and preexisting element of correlative phenomenon.

This paper treats the management sciences as a table of domains that integrates accounting, management, audit, financial management and financial analysis of the company, focusing towards on seizing the existence of dominant theories in every discipline.

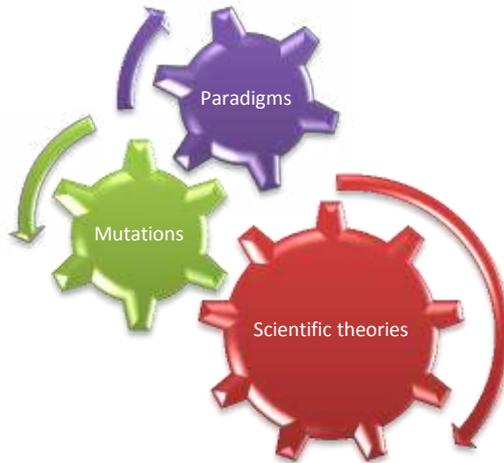

Paper content

In a personal sense of acknowledgement, the factors leading to the emerging of economic-social mutations are as follows:

- **Inherent evolutionary factor** – the factor that gathers an assembly of elements that do not allow to humans the modeling and manipulation of the social environment. Inside this group of factors a few examples are highlighted: the tangible effects of time passing, the global climate phenomenon that brings influence over the environment and leads to the necessity of adaptation to a newly created environment, the notion of “knowledge” being an extension of it.
- **The gnosiological factor** (base knowledge) refers to giving a full attention to native human characteristics valuation that through definition places the human as a central element in knowledge development throughout the “sin-qua-non” acceptance process of resulted changes.
- **The creative factor** – a factor born from the gnosiological factor that approaches the economic-social mutations through new ideas formed as a result of research by the academicians. The creative factor has a pronounced originality character and represents an important lever for the

statutory elements of the future social environment.

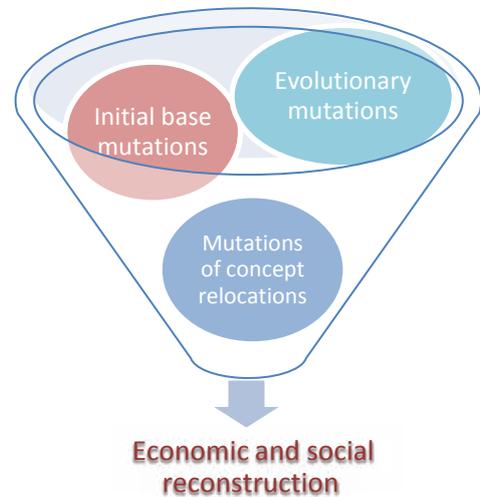

Figure no.1 Economic and social evolutionary mechanism

Taking into consideration the precursory factors to economic-social mutations, we propose the following classification:

- **Initial base mutations:** within this classification, the mutations refer to buildups that can start as principles, fundamental thesis, new paradigms, concepts or theories.
- **Evolutionary mutations:** this concept shares the notion of “change” in two visions:
 - **Exclusive vision** that aims the transformations in different environment changes, in which the human is regarded as an exterior element with a small influence on the emerged changes. In this category it is observed the self-regulation ability of the existing global resources.
 - **Inclusive vision** places the human in the center of the events, both directly involved in determination of environment change and active player with an important role in the adaptation to change process.
- **Mutation of concept relocation:** those mutations results from transmittance of particular sets of information from a domain to another and from adjusting this set of information and absorbing it in a new social buildup having as ground base the relevant takeover criteria of these concepts.

Figure no. 2 Economic and social reconstruction

These mutations certify the transversal character of domains and the extension through adaptation at environmental changes.

The proposed classification firstly describes in a relevant manner the extended character of all type changes that intervene as link points between the observable environment and the one that changes it at certain moments, and secondly, this classification allows to mutation classes to be absorbed by certain factors, to link and even evolve from a class to another.

Further, this paper aims to detail the conceptual framework of economic and social mutation classifications described at the beginning and exemplify each of the mutations categories on the quadrant that embeds the management sciences, offering for each of the disciplines a succession of explications.

Initial base mutations bring into discussion at an ideational level the concept of knowledge. Thus, at the base of environment’s transformations lies an emerging ground, namely the punctually enounced theories that guide the transformations from any of presently identified domain.

When we say environment, we use a broad acceptance of this notion: the description of proper structure for the development of cultural, economic, social, demographic, academic etc. elements.

Knowledge at an ideational level is

described in a comprising manner by Professor PhD. Maria Niculescu as being “the process in which the human, in a specific context, gives meaning to the world (real or imaginary) based on representations (ideational – cognitive and axiological representations that give signification to our existence and generates attitude, engagements and behaviors). Knowledge reunites the assembly of knowledge, theories, beliefs, experiences etc. through which the human builds and rebuilds his future”. [1]

Knowledge, reaching an uplifting place in the development of all domains at a global level, its conditioned by the existence of postulates, of setting up ground information, firm information regarding a higher form of scientific knowledge that reflects the reality, by the existence of a theory considered scientific. Taking into consideration these intercessions appeared the concept of “paradigm”, concept that defines the prevailing theory in a certain historical framework.

The American philosopher and historian Thomas Kuhn used the concept of “paradigm” in his reference piece of work “The Structure of Scientific Revolutions” saying that a paradigm is described as “the practices that define a scientific discipline at a certain point in time.” [2]

In accounting, among the various theories that enrich domain’s specific practice and science we name the Positive Theory of accounting [3], Normative Theory of accounting [4]. From these theories an assembly of theories emerges, namely: the Theory of Agency, the Transactions Costs Theory, the Perfect financial markets Theory.

In the economic-financial analysis and the company’s financial management the above mentioned theories find an extended applicability, to which other economic-financial theories are added: theories regarding the optimal share capital structure (the Theory of Games, the Theory of Signaling, etc.), company’s organizational theories (the Theory of Hierarchical Funding, the Theory of Property).

About management, we point out some of the reference theories: the Theory of Scientific Management [5], the Theory of Bureaucracy [6], the Theory of Organization and Administration [7], etc.

In audit, various authors tried to develop

scientifically theories regarding the audit activity, standing out were Tom Lee [8], David Flint [9], and Littleton [10]. Among the applicable theories in this domain, we name: the Theory of Agency, the Theory of Games, the Theory of Credibility, etc.

Evolutionary mutation with non-inclusive vision

For this type of mutations, in which there are mentioned the effects that are out of human control and in on self-regulatory of globally resources incidence, we exemplify the amount of modifications over specific domains.

The evolutionary mutation with non-inclusive vision over the global warming had as result the implementing of new regulations regarding green certificates, fact that started the adopting of these certificates into accounting.

These certificates refer to producing electrical energy from renewable sources (Aeolian, solar, geothermal, etc.) and are “bought by electrical energy suppliers and also by electrical energy producers for the energy related to final own energy consumption, other that own technological consumption or the energy related to consumers connected to direct lines from the power plant, profile companies being mandated to comply with a certain amount of renewable energy in the overall electrical energy supplied to final consumers.” [11]

Romania assumed the commitment to sustain the renewable sources electrical energy by the adherence to the European Union process, looking into reducing the primary resources imports, development of new working places, protecting the environment and sustainable development encouragement.

This intercessions mark not only the accounting, but the other disciplines: the strategic management, the production management or operations management, the audit through the imposed control procedures on imposed regulations, the financial management and analysis through computing the performance indicators related to applicable regulations.

Another example of non-inclusive evolutionary mutation that emerged after the global warming is the re-settlement of

borders between several countries, for example the border between Switzerland and Italy, glaciers that mark the border between the two countries melted and there resulted the re-settlement of borders. [12]

Evolutionary mutations with inclusive vision

Having the human as central point, these mutations present the development of the principal domains over new branches, adapted to the environment, emerging several types of: accounting (creative accounting, banking accounting, etc.), management (project based business management, sustainable development management, etc.), audit (statutory audit, European funded projects audit, etc.), economic-financial analysis and company’s financial management (through correlations with new added elements into the computing mechanism).

Mutations of concept relocation

In the above mentioned domains, these mutations take the shape of sets of indicators: economic, demographic, social, monetary, financial etc.

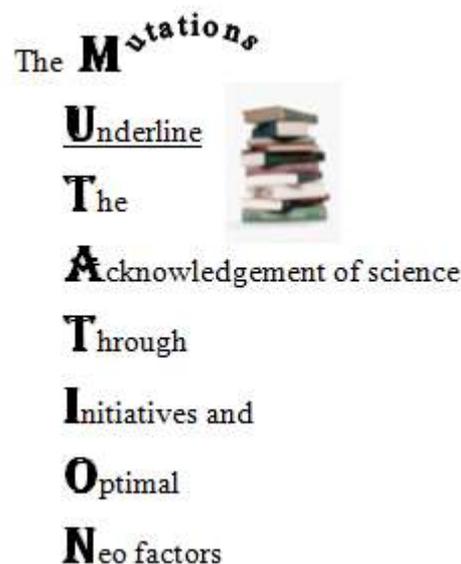

We can affirm that the discipline of accounting represents a forming base for the financial statements (P&L, balance sheet, annexes). Throughout the phenomenon of concept relocation, accounting supplies information based on these financial statements to other disciplines like financial analysis, company’s financial management, disciplines that use the amount of information in computing of some indicators, like the financial and operational balance indicators, the cascade of intermediary balances of management.

Another example of relocation of concept can be noticed in management, where the control-evaluation function represents a relocation base for the internal control system, concept used also in auditing through specific procedures and controls.

The mutations of concept relocation refer to a vast field placed into a continuous development. The society tries to adapt at current demands all fields of activity, as result a series of concept transformations take place (evolutionary mutations) that, later on,

goes back from the base domain to other domains (mutations of concept relocation) where a viable applicability is found for the entire economical dimension.

Figure no.3 Mutations

Conclusions

Mutations are whether initial base mutations, evolutionary mutations or mutations of concept relocations represent a phenomenon that deserves to be debated and observed because, overall, describes a history of humanity, of the world. Those, whether that include or exclude the fully or tangentially involvements of humans are very important links to emerging global knowledge.

If we look into present mutations, as a result of previous mutations, we can only say that its generates effects also for future, therefore point out future directions of technological phenomenon, of predecessor mutations and the ability to adapt to newly created conditions of the global economic dimension.

Although transformations and general changes, rise, sometimes, a benefit of doubt, its sets a framework for supreme purpose mutations of the global economic dimension as basis element considered tangible and also intangible, timeless due to its continuous development, here, grouping the wonderful progress that humanity has achieved.

In the study “The dialects of modern scientific spirit” philosopher Gaston Bachelard alleges that: “there is no science but for what’s hidden [...] to discover is the only active way of knowing. In a correlative manner, making someone to discover is the only mean of teaching him”. [13]

Thus, we can say that mutations represent the creating force of the complex process of development for all existing domains and will always stand as basis for the universal evolutionary mechanism, gathering into the society answers to presently asked questions and therewith rising new questions that awaits the research intercession in order to get an answer.

The Evolution of Public Debt in Romania in the Context of the European Fiscal Compact

Talpoş Ioan

Abstract

The Stability and Growth Pact and recently, The European Fiscal Compact are based on the assumption that national tax policy Member States could have a negative impact on partner countries. Eurozone countries have pledged to respect the Stability and Growth Pact, its observance is an example of a fiscal rule enshrined in an international treaty that raises a delicate question: Can a treaty resulting from political compromise to include constraints economic, which are contrary to economic theory? Strong expansionary policy risk was considered, but not too restrictive and risk policies. Pact was revised in 2005, but his initial basic principles have remained unchanged.

Key words: stability and growth pact, public debt, fiscal policy, GDP.

J.E.L. Classification: G30, H61.

1. Introducere

European Commission's legislative proposals on strengthening the Stability and Growth Pact the "Euro Plus Pact" and The European Fiscal Compact are meant to force all Member States to introduce binding fiscal rules in their constitutions. EU authorities have not learned lessons from the disastrous management of Euro zone before the crisis, this management focusing on rigid fiscal rules and not on precise coordination of macroeconomic strategies and these increased disparities in the EU in the context of a moderate growth. Debt crisis has consolidated the perspective that automatic

fiscal rules are necessary. Supporters of this rule can rely on arguments such as: the threat of financial markets, the need to reassure financial markets, the German force, and the growth of EU solidarity through SGP rules.

Supporters of stricter rules point out the threat coming from the financial markets and rating agencies. If a country does not include such rules in its constitution, it will lose the precious AAA rating. Thus, financial markets would borrow at reasonable rates only countries that do not tend to fall into debt. On one hand, countries which tend to accumulate huge foreign exchange reserves (such as China and oil-producing countries), pension funds, and insurance companies will want to have large parts of public assets. On the other hand, they refuse to lend without high risk premiums, countries wishing to duty and refuse to understand that their accumulation of liquid assets has a counterpart in terms of debt. These conflicting demands could cripple the world economy. In 2011, most Euro zone economies were close to a primary structural balance, in other words, their debt remained relatively stable even if they borrowed at an interest rate equal to the growth rate. In addition, the euro zone has a much higher interest rate than countries outside it, with smaller imbalances. Thus, there is a specific cost for the Euro zone countries.

2. Romania's public debt

During the period analyzed, Romania's public debt had a *continuously upward evolution*, reaching the amount of **222768, 7 million lei and 39.6% of GDP** at 31 December 2011, *being 3, 52 times higher than at the end of 2006*, as results from the

calculation performed based on data from Table. 1.

Table 1: The evolution of Romania's public debt and its components, in absolute terms, as well as their shares of GDP during the period 2006-2011

9	Exchange rate at end of the reporting period	Euro/lei	3,3817	3,6102	3,9860	4,2296	4,2848	4,3197

Source: Ministry of Finance reports on public debt in the period 2006-2011 and own calculations

Government debt's share to GDP has recorded a continuously increasing evolution - from 18.4% in 2006 to 39.6% in 2011, but this curve is flatter than the evolution curve of public debt stock's nominal values, as Gross Domestic product evolved uptrend -

from 344651.0 million lei in 2006 to 563100.0 million lei in 2011, the last value being 1.63 times higher than at the end of 2006.

In 2009, when the size of GDP fell to 23646, 5 million compared to the value from

the previous year, and the stock of public debt increased by 37.534 million lei, the debt-to-GDP ratio reached 30%, with a

relative increase of 40, 85% from the share recorded in 2008 and 63, 04% of the share recorded in 2006, as shown in Table 2.

Table 2: Romania's public debt stock to GDP ratios and its relative increases in the period 2006-2011

Name	2006	2007	2008	2009	2010	2011
1.Public Debt [% of GDP]	18,4	19,9	21,3	30,0	37,9	39,6
2.Relative increase to previous year [%]	**	8,15	7,04	40,85	26,33	4,49
3.Relative increase to reference year [%]	**	8,15	15,76	63,04	105,98	152,17

Source: own calculations based on the data from Table nr.1.

Given these data, we can say that **the evolution of Romania's public debt stock had an unexpected "outbreak" in 2009 [1] [8]**, due to the effective entry into economic recession.

A significant increase in public debt was also recorded in 2010 (46565, 4 million lei, compared to the December 31, 2009), but the relative growth rate to the previous year, as a share of GDP, declined to 26, 33 %.

In 2011, the relative growth rate of public debt's share to GDP over the previous year was greatly reduced, being only 4, 49%.

Obviously, if the accumulation of public debt would continue in the future at the pace recorded in 2009 and 2010, *the fiscal policy would become unsustainable [2][13]*.

If in Romania there are no risks to fiscal regarding the sustainability of public finances on short-term, there is serious concern that existence of sound public finances can become a problem in the medium and long term.

Growth rate of public debt in 2009 and 2010 is dangerous in the absence of fiscal consolidation measures, currently the main problem being a consolidated budget deficit, both literally and structurally [10] [11].

In this respect, given the significant pressure imposed by aging on public spending and social transfers and implicitly on consolidated government deficit and public debt in the E.U. member states (including Romania), *the European Commission has proposed two indicators for*

monitoring the risk that public debt becomes unsustainable [3] [12]:

- **S1**, quantifying the adjustment effort of the primary budget balance required in order to reach in 2060 a level of 60% of GDP for the public debt stock;
- **S2**, quantifying the adjustment effort of the primary budget balance required for meeting the intertemporal budget constraint.

Since it recorded a level of 6, 9% of gross domestic product (under an European average of 5, 4%) for S1 indicator and a level of 9, 1% of gross domestic product (under an European average of 6 5%) for S2 indicator, **Romania was included in the group of countries to which high risks of non-sustainability of public finances on long-term are associated [4]**, along with Greece, Ireland, United Kingdom of Great Britain and Northern Ireland, Cyprus, Malta, Spain, Netherlands, Slovenia, Slovakia, Latvia, Czech Republic and Lithuania.

A better correlation between fundamental macroeconomic indicators, including pressures coming from international financial institutions, will be required in the coming years to ensure public debt's sustainability and Romanian economy credibility [5][9].

In Table no. 3 are given the shares of local government debt and public debt - with its two components – in the total public debt recorded in late 2006-2011.

Table 3: The shares of local government debt, local public debt and their components in Romania's total public debt in the period 2006 - 2011

Name	U.M.	2006	2007	2008	2009	2010	2011
TOTAL PUBLIC DEBT	%	100	100	100	100	100	100
GOVERNMENT DEBT	% of TPD	94,52	92,5	91,59	92,65	94,03	94,37
Internal Government Debt	% of TPD	40,78	50,81	56,07	57,25	56,71	48,53
External Government Debt	% of TPD	53,74	41,69	35,52	35,4	37,32	45,84
LOCAL PUBLIC DEBT	% of TPD	5,48	7,5	8,41	7,35	5,97	5,63
Internal Local Government Debt	% of TPD	2,44	4	5,17	4,78	3,88	3,66
External Local Government Debt	% of TPD	3,04	3,5	3,24	2,57	2,09	1,97

Source: own calculations based on data from Table 1.

As can be noted, the share of government debt in Romania's public debt is extremely high [6], and its progress has been decreasing in 2007 and 2008 compared to 2006 - from 94, 52% to 92, 50% and 91.59 %, and thereafter was slightly increasing, reaching 94, 37% at the end of 2011.

Consequently, the share of local government public debt in Romania's public debt is relatively low, with an upward trend - from 5, 48% in 2006 to 8, 41% in 2008 and a downward trend over the next three years, reaching just 5, 63% at the end of 2011.

Analyzed on all its components [7] [8], there is a continuous increase in the share of internal government debt by the end of 2009 - from 40, 78% in 2006 to 57,25% in 2009; that was followed by a slight decrease in 2010, to 56, 71% and even a sharper decline in 2011 (reaching 48, 53%).

Correspondingly, the share of external government debt has decreased from 53, 74% at end of 2006 to 35, 40% at the end of 2009, for next year to climb slightly to 37, 32%, and went upwards even more in 2011 , reaching 45, 84% of total public debt.

A brief analysis of EU Member States' shares of public debt in GDP, at the 31st of

December 2011, **highlights the favorable situation of Romania in this respect.**

Thus, with the share of 33, 3% shown in this figure, **Romania ranks 4th** in order of increasing ratio of public debt in GDP, being preceded only by Estonia (6.0%), Bulgaria (16.3%) and Luxembourg (18.2%).

With large size public debts as a share of GDP and in absolute terms, the "top-ten" at the fall of 2011 is: Greece (152.4%), Italy (120.1%), Portugal (107 8%), Ireland (106.5%), Belgium (98.2%), France (86.0%), United Kingdom of Great Britain and Northern Ireland (85.3%), Germany (81, 2%), Hungary (80.8%), Austria (72.4%).

According to EU-ESA 95 methodology, it is estimated that during 2013-2015 the estimated level of government debt to GDP ratio will decline from 33.4% to 32.6%, according to data presented in Table 4.

If we take into account a relatively constant further development of local government debt, equaling the average share recorded over the period 2006-2011 (1.9% of GDP), it means that at the end of the four years of the 2012-2015 period, Romania's public debt will reach the level of 35.3% and 34.5%, **which is well below the standard of 60% of GDP set by the Maastricht Treaty.**

Table 4: Projection of Romania's government debt and its components ratios to GDP, for the period 2012-2015

Name	2012	2013	2014	2015
GOVERNMENT DEBT	33,9	33,4	32,6	32,6
Internal Government Debt	17,2	17,2	16,8	16,3
External Government Debt	16,7	16,2	15,8	16,3

3. Conclusions

The levels of public debt *will be, without any doubt, sustainable* and will represent an advantage for Romania, given the new rules on levels of public debt and structural budget deficit introduced by the new *Treaty on Stability, Coordination and Governance in the Economic and Monetary Union* - which was signed by Romania on March 2, 2012.

Romania's public debt sustainability can be achieved through *a mix of fiscal and budgetary policies*, which aim to reduce budget deficits and increase primary budget surpluses, and *monetary policy measures*, meant to ensure the monetary stability and following the prospect of Romania's accession to the Euro zone.

Abstract

The study analyzes the differences between the accounting policies of the companies listed on the BSE group and showed that there are differences between the accounting policies used by companies in different fields of activity. Mainly, differences can be seen between companies providing financial and insurance services, on the one hand, and those working in industry, on the other hand.

Keywords: Accounting principles, accounting policies, impairment.

J.E.L. Classification: M40, M41.

1. Introduction

General rules have been developed so that everyone who keeps accounts and/or receives accounting reports can be able to interpret them fairly and correctly. These rules form the conceptual framework of financial accounting, generally called accounting principles.

Although each principle is governing a particular issue, all accounting principles form a coherent and unified system, meaning that there is interference and mutual ties of interdependence between all the principles, and no principle can be violated without the risk of affecting the others.

These principles are not similar to the immutable laws of nature in physics or chemistry. They are developed by accounting

specialists to serve the needs of decision factors and can be changed each time when better methods arise.

Moreover, the choice and definition of accounting principles is considered to be the consequence and the demonstration of power influence. Building accounting information in an accounting system starts with the setting of one or more objectives and the establishment of accounting principles and rules. Definition, implementation and acceptance of these principles and rules gives objectivity to the chosen accounting system and provides a certain accurate, clear, sincere and complete image of the enterprise business.

Since there is more than one accounting system, the accounting principles are not absolute but relative. This relativity is given by the assumed objectives of accounting. In accounting theory and practice, the debate on the accounting principles resulted in different opinions, often contradictory on their definition, application, classification and interpretation. Lack of consensus on accounting principles and thus their relativity led us to the hypothesis that their choice, recognition and implementation is influenced by the objectives set by the accounting system, the economic and political environments and the types of company governance.

In this paper we present several accounting principles used for preparing and presenting the financial statements of the legal entities.

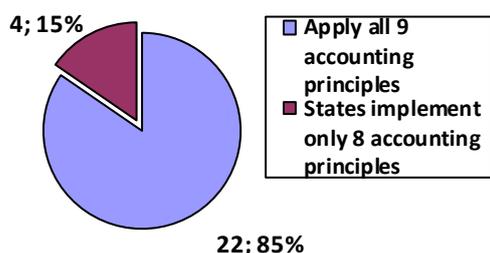

2. Major aspects of the accounting principles and policies

Through an analysis of the financial statements and notes to the financial statements of each company, we extracted principal accounting policies used by these entities.

Given that accounting policies incorporate essentially methods and procedures, basis of calculation, evaluation rules, and each entity's own practice, we tried a comparative presentation of these issues. We conducted/performed a comparative analysis of practices in companies listed on the Bucharest Stock Exchange (BVB) to better reflect applying of the accounting policies in the Romanian companies. In this study we included only Romanian companies listed on the BSE Tier I, comprising a number of 26 entities.

The characteristics of firms aspects of accounting policies used in the explanatory Note 6 entitled just ”Summary of Significant Accounting Policies”, with the exceptions of those whose main activity is financial service and insurance. These companies should disclose the accounting policies in the explanatory Note 1 to the financial statements.

Figure 1: Number and percentage of companies listed on the BSE First category (Tier I), stating that their annual financial statements are in accordance with those 9 accounting principles

Source: own

Companies that apply all 9 accounting principles (the principle of prudence, going concern principle, consistency principle-based accounting principle, separate evaluation of assets and liabilities principle, the principle of intangibility of the opening

balance sheet, netting principle, the principle of substance over form and materiality principle) we actually included those that did not mention specifically the accounting principles applied for preparation their financial statements. Main reason for which we have included them in this category is that usually companies apply all the principles to provide users a better image on the elements of fortune. 11 companies included in the study did not specifically mention the principles used in the preparation of annual reports. This category also includes companies that provide financial and insurance services.

Biofarm SA, Antibiotice SA, CNTEE SEPS and Impact Developer & Contractor SA are the four companies that do not mention the full application of the 9 accounting principles.

Biofarm S.A. does not specify the principle of inviolability of the opening balance sheet. The other three listed companies have not considered being necessary the applying of the principle of materiality. However, their financial statements received agreement under accounting rules from an approved auditor.

Over 65% of companies listed on the BSE Tier I work in manufacturing or in financial intermediation. No more than three companies fit in every other category. Unless if OMPF 3055/2009 or its accounting policies requires the use of fair value, accounting records on which these financial statements have been prepared in lei (RON), usually at historical cost.

3. General accounting policy on property, plant and equipment

Property, plant and equipment are assets from which future economic benefits are expected to flow to the enterprise and are held for more than one year [3]. These assets are usually recognized initially at its acquisition or production cost.

4. Cost / valuation of non-current assets

Non-current assets are initially recognized at the acquisition cost, for the purchased against payment, the amount of contribution to the establishment of the contributed

capital, or at fair value at the acquisition date, for those received free of charge.

The initial cost of property, plant comprising its purchase price includes import duties, non-refundable purchase taxes and any directly attributable costs of bringing the asset to its working condition and location for its intended use.

5. Revaluation of property, plant, and equipment

If an asset's carrying amount is decreased as a result of a revaluation, the decrease shall be recognized in profit or loss. However, the decrease shall be recognized in other comprehensive income to the extent of any credit balance existing in the revaluation surplus in respect of that asset. The decrease recognized in other comprehensive income reduces the amount accumulated in equity under the heading of revaluation surplus. The value of that eventual uncovered difference is recorded as an expense.

Periodically, usually every 3 years, company buildings existing at the year-end are revalued to fair value at that date [1]. Fair value replaces acquisition cost and the resulting revaluation differences are reflected in the trial balance and annual financial statements for the year in which the development took place and it is accumulated in equity under the heading of revaluation surplus.

The following methods were used for revaluation:

- The market comparison method was used for the valuation of lands and buildings;
 - The replacement cost method was used for other equipment.
- At the balance sheet date, tangible assets are stated at the revalued amount which is their fair value.

6. Depreciation of property, plant and equipment

All tangible fixed assets, except land, are depreciated according to duration of life prescribed by law, as amended.

Depreciation is determined by applying of depreciation rates on the depreciable amount of tangible fixed assets. Depreciation is calculated from the month following its acquisition until full recovery of the input

value of tangible assets. Depreciation of tangible fixed assets is determined and recognized in the financial statements as an expense using straight-line depreciation method. Depreciation of an asset begins when it is available for use until the full recovery of the input value. Economic life is the period in which an asset is expected to be available for use by an entity. By law, the Board of Directors sets out the depreciation method and normal useful life of fixed assets. Most companies determine depreciation making use of terms established by Government 2139/2004 for approving the classification catalog and useful life of fixed assets. Some of them chose the regulatory minimum depreciation periods as useful life of assets.

Depreciation is calculated on a straight-line basis reducing balance, although degressive depreciation or accelerated depreciation is permitted, over the whole useful life of asset. Land has an unlimited useful life and therefore is not depreciated. This complies with the legal stipulations regarding land regime. Assets under construction are not depreciated over time until the relevant assets are completed and put into operation [2].

Only three companies included in the study mention the application of a different method of depreciation. So over 88% of companies only apply straight-line method of depreciation. For some of the tangible assets owned, the three companies mentioned above apply also degressive depreciation regime, where regulations permit.

Regarding depreciation of plant and machinery, we can again make a clear separation between companies that offer financial and insurance services and industry. Companies in the first category have fewer tangible assets in this category that are often vehicles, whose impairments are short periods. In contrast, industrial activity requires technical installations. They are used in operating activities for a long service life, in more operating cycles. This explains the use of high use periods.

Furniture, office automation equipment and other tangible assets in this class, BRD stands out a fixed amortization period of 10 years. This is unusual for companies, considering the variety of property that may fall into this category. This variety may

explain the large variations in depreciation periods from other companies included in the study.

BRD provides financial services and this activity does not require ownership of more tangible. BRD actually has only items of furniture that fall under this section. This is why it chose a fixed amortization period of ten years.

7. Impairment of Assets

Property, plant and equipment are carried at acquisition cost less the accumulated depreciation and any cumulative impairment losses [3].

The company’s non-current assets carrying value, other than inventories, is reviewed at each balance sheet date to determine whether there is value decreases. If such value is likely to decrease, the recoverable amount of that asset is estimated. An adjustment for impairment is recognized in profit or loss, if necessary.

Adjustment for impairment can be reversed if there was a change in existing conditions when determining the recoverable amount. Reversal of impairment adjustments can be made only in such a way as the net amount does not exceed historical net book value, taking into account depreciation and impairment before.

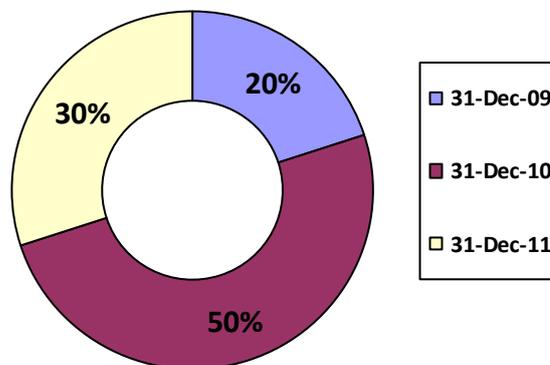

8. Other issues relevant to the accounting policies of tangible fixed assets

Accounting for tangible fixed assets is guided by categories and over individual items, by quantity and value. Limit value at which an asset is classified as tangible fixed assets is 1,800 Romanian lei, according to the Government Decision no. 105/2007 on setting input value of fixed assets. Assets whose values are below this limit are recorded as inventories. Some companies separate the gross carrying value of tangible fixed assets that are fully depreciated at December 31, 2011.

Land evaluation is carried at fair value. All companies in the sample perform regular revaluations of land, usually for a period of 3 years. A company included in the sample does not have land ownership. However, only 10 companies mention the exact date of the last land revaluation.

So, as you can see from the chart below, 50% of companies that indicated the exact date of the last land revaluation have done this operation in financial year 2010.

Figure 2: Classification of companies according to the date of the last land revaluation

Source: own

Construction evaluation is performed in the same way, that is the regular revaluation of buildings. However, the difference does how to deal with depreciation for buildings. There are two ways of handling this:

- Whether a reassessment is made both of the inventory value and the accumulated depreciation;
- Or give up to accumulated depreciation and add / subtract the difference to achieve fair value.

Based on the sample of companies listed on BSE, Tier I, we concluded that most companies turn to the first of two accounting options. However, companies focus more on building evaluation than to land evaluation; buildings’ values are very large and have a great share of total tangible assets. Only a company included in the sample has not owned buildings.

Half of the sampled companies mention the exact date of the last buildings revaluation, as follows:

- 4 companies have reassessed building on 3 December 2009;
- 3 companies made the last assessment of buildings and special constructions at the end of the accounting year 2010;
- 6 companies have revalued buildings to present the fair value at the date of the last

financial statements i.e. those studied for this analysis, December 31, 2011.

Equipment, plant and machinery, but also furniture, office equipment and other tangible assets are valued by the majority of listed companies at revalued amount. However, some companies have preserved (at least three of them) net book value of these tangible assets at historical cost. Despite lands or buildings, revaluation of the above tangible assets can be made for longer periods of time. For example, SC Prefab S.A. has not reviewed this type of fixed assets at the end of the year 2008.

9. Conclusions

Accounting policies for assets should not differ greatly from one company to another, especially if you compare companies that apply the same accounting rules required for annual financial statements. Moreover, the companies included in this study are all listed on BSE, First Category. This makes us believe that the accounting policies should be very similar.

However, they are operating in different various fields. These differences entail distinctions between accounting policies and methods used in establishing tangible fixed assets value.

Abstract

The purpose of this article is to present issues of assessment and reassessment of tangible assets due to fair value in the context of harmonization of national accounting regulations with International Financial Reporting Standards. The main objectives considered when drafting the article are to identify both tangible Romanian accounting standards and according to the international presentation on the effects of fair value and their subsequent assessment of the entity's financial position and assets. The scientific approach is based on information from national and international literature and practice of documenting the company achieved at F.D.E.E. Electrica Transilvania Sud Distribution S.A. In preparing the paper, we chose the combination of quantitative research with qualitative research in order to achieve expected results from research undertaken research tools in the two categories of methods: literature review, the study acts, comparison, descriptive analysis, case study, data interpretation method.

Key words: tangible assets, fair value, assessment, reassessment, IFRS

JEL Classification: M41, O13

1. Introduction

How an enterprise assesses elements that comprise the financial statements is vital as they fulfill a core function of financial

reporting, namely a primary means of communicating financial information to outside entity. Moreover this information is useful only if they satisfy certain decision-making process to ensure quality reporting features.

Assets typically have a significant share in the total assets of the entity and have significant implications in presenting financial position because they are the main generators of economic benefits, being held for the activity for more than one year. The decision to invest in an asset is very important and has implications for cash flows of the entity and future expenses asset impairment.

2. Tangible assets - conformity of national rules with the rules of IAS / IFRS

Comparing the categories of fixed assets covered by OMFP 3055/2009 national and standards IAS 16 Property, Plant and Equipment and IAS 38 Intangible assets internationally, we find that the main issues that require consideration include: recognition and measurement of assets, the determination of the carrying amount of assets, the depreciation charges and losses impairment to be recognized in relation to them; to ensure transparency in disclosure so that users are able to assume responsibility for decisions and their effects are adequately informed of the various categories of users of financial statements. The objective of IAS 16 Property, Plant and Equipment is to prescribe the accounting treatment applicable to tangible assets and to establish a uniform

basis for disclosure in the financial statements of parent companies so that financial statement users can easily understand tangible information society.

According to the same standards qualify for classification as tangible elements, elements [1] that: are held for use in the production or supply of goods or services, for

rental to others or for administrative purposes, and is expected to be used during more than one period.

As recognition of the cost of an item of property shall be recognized as an asset if, and only if it satisfies the conditions reported in the next table:

Table 1. Highlighting the recognition of assets

Element	Recognition criteria met			Recognition
	Future economic benefits are probable for the entity	Cost of the asset can be measured reliably	Expected to be used over several accounting periods	
	X	X	X	21xx

Source: Projection realized by the authors

Nationally, the accounting regulations approved by Order no. 3055/2009 Romanian notice align with the accounting standard IAS 16 Property, Plant and Equipment, in terms of tangible recognition elements. We mention that, compared with the international standard where there is a limit value for the recognition of an item of property, the tax code provides condition limiting value (1,800 Ron - the limit set by Government Decision no. 105/2007), that is tangible recognized as fixed assets [2].

3. Effects of the option "fair value" in the subsequent evaluation of fixed assets in groups II and III

The company in the subsequent assessment presents in the balance sheet, a tangible input value, less cumulative value adjustments according to art. 109 accounting regulations approved by OMFP 3055/2009 [3]. On the other hand, the Tax Code provides in art. 253 paragraph 6 that the tax on buildings due to legal persons not revaluated in the last 3 years and 5 years prior fiscal year is based on the reference rate set by the local council decision, between 10% and 20%, respectively 30 % and 40%, applied to the building inventory value recorded in the accounts of legal entities under accounting regulations in force [4].

So the fact that national rules do not require all categories of tangible assets revaluation within an entity and facilitate the fiscally re just some of them (buildings)

demonstrates, this time dependence tax accounting rules and accounting professional education not to deviate from the rules imposed by the state, even if the entity property image is damaged.

In contrast with this dependence of taxes, standard IAS 16 Property, Plant and Equipment, in the evaluation after recognition launches the choice between the cost model and the revaluation model so that after recognition as an asset, an item of property, plant and equipment whose fair value can be measured reliably shall be carried at a revalued amount, being its fair value at the date of revaluation less any subsequent accumulated depreciation and any accumulated impairment losses.

To show the size of the rules of IAS / IFRS we considered necessary the revaluation of fixed assets in groups II and III in order to highlight the effects of this option and "fair value" of the property company FDEE Electrica Transilvania Sud Distribution S.A. since the last review of these groups was made in 2008.

Evaluation of fixed assets belonging to groups II and II of FDEE Electrica Transilvania Sud Distribution S.A. was made based on the data provided by it and the observations made in the field. Thus, for determining the fair value of fixed assets evaluation methods were applied methodology of application which will be presented in the paper. So the approach is to update the carrying amount of special assets for the period 31.12.2008-31.12.2010

inflation index. The purpose of evaluation is to determine the economic value of the assets remaining updated in groups II and III for the month December 2010. Because in this case it's specialized assets whose technical characteristics (capacity, power, etc.). Could not be made available to us by the company proceeded to update the book value of the

inflation index calculated for the period 31.12. 2008-31.12.2010 which is 1.1665 Ron, calculated based on the inflation index published by the National Institute of Statistics for the months in the period.

Table 2. Summary results of the calculation of fair value of fixed assets in groups II and III

-RON-

Asset	Revalued asset values	The difference in the value of inventory	The difference of accumulated depreciation	Revalued amount Remaining value	Remaining value	The difference between the revalued amount and the remaining value
Account 213	24.997.813,43	3.568.036,38	640.789,66	20.508.655	17.581.408,28	2.927.246,72
Account 214	255.715,85	36.498,67	9.895,23	186.365	159.761,56	26.603,44
TOTAL	25.253.529,28	3.604.535,05	650.684,89	20.695.020	17.741.169,84	2.953.850,16

Source: Projection realized by the authors

So, after reassessment process by updating the book value of fixed assets group II with the inflation index, the result is a positive difference from revaluation totaling 2,927,246.72 Ron, the difference is treated as an increase in reserves of revaluation - account 105, because we have no knowledge of the existence of a previous decrease recognized as an expense for the asset.

Accumulated depreciation on revaluation in the amount of 3,848,350.34 Ron was restated proportionately with the change in the gross carrying amount of the asset thus obtaining a difference of accumulated depreciation of 640,789.66 Ron. Therefore, the carrying amount of the asset after revaluation worth 20,508,655.00 Ron equals its revalued amount. Regarding, fixed assets revaluation process in Group III showed a positive difference from revaluation totaling 26,603.44 Ron, the difference is treated as a from revaluation increase reserve - 105 Revaluation reserve account. Accumulated depreciation on revaluation amounting to 59,454.77 Ron was restated proportionately

with the change in the gross carrying amount of the asset thus obtaining a difference of accumulated depreciation of 9,895.23 Ron. Therefore, the carrying amount of the asset after revaluation worth 186,365.00 Ron equals its revalued amount.

We also recalculated on the revaluation of fixed assets in groups II and III, in proportion to change their gross value and accumulated depreciation to be recorded in the accounts as of January 1 of the year following that for which revaluation. In addition, we note that the situation will reflect balances as at 31.12.2010 together with differences persisting positive values, so for fixed assets account group II 213 Plant and machinery, vehicles, animals and plantations 24,997,813.43 Ron and Account 105 Reserves from revaluation 2,927,246.72 Ron. In the case of the fixed assets of Group III balance is account 214 Furniture, office equipment, equipment 255,715.85 Ron and 26,603.44 Ron account 105 Revaluation reserves.

4. Effects of adjustments to fair value of property in accounts 213 and 214 according to standard IAS 16 Property, Plant and Equipment on the entity's financial position and assets

As a result of the above data, following the revaluation of fixed assets in groups II and III at fair value were recorded positive

differences on the inventory value and accumulated depreciation. So how presentation affects the fair value of the elements of accounts 213 Plant and machinery, vehicles, animals and plantations and 214 furniture, office equipment, financial position and performance of the entity is as follows:

Table 3 Influence of adjustments according to standard IAS 16 Property, plant and equipment on the synthetic balance at the end of financial year

-RON-

Account	Balance 31.12.2010		Adjustment IAS 20		According to IAS 20	
	Output	Input	Output	Input	Output	Input
105	0	351.971.804	0	2.953.850	0	354.925.654
213	623.497.544	0	2.927.247	208.351.589	418.073.22	0
214	3.798.532	0	26.603	1.639.309	2.185.826	0

	Name of item	Balance 31.12.2010	Name of item	Balance 31.12.2010
Balance sheet	Plant and machinery	415.145.955	Plant and machinery	418.073.202
	Other equipment and furniture	2.159.223	Other equipment and furniture	2.185.826
	Revaluation reserve	351.971.804	Revaluation reserve	354.925.654

Source: Projection realized by the authors

Therefore, further evaluation of initial recognition at fair value of fixed assets in groups II and III also increased position 08 Plant and machinery in the balance sheet by the amount of 2,927,247 Ron and position in row 09 Other installations, tools and furniture balance sheet to the amount of 26,603 Ron, while also increasing position 69 revaluation reserves total amount of 2,953,850 Ron. As for the account of result we mention that the calculation of depreciation in fair value will update as of January 1 of year 2011.

5. Conclusions

The analysis of tangible assets in the international accounting standards issued by the IASB, we find that the role of accounting rules have, and to provide, without much ambiguity various aspects of accounting practice in the transparency of financial accounting information. The empirical study presented confirmed Norm IAS 1, so that the analysis of documents of FDEE Electrica Transilvania Sud distribution differences were noted in the subsequent evaluation of fixed assets in groups II and III, the temporary difference between the carrying amount and tax base of assets. So these differences clearly highlights the absence of

compliance with international reference potential and highlights the link between national taxation and accounting rules underlying financial statements that are issued. So by translating financial statements in accordance with IAS / IFRS we tried to get a version of financial accounting information to meet information needs of external users, in particular, potential investors and / or creditors who wish to obtain information transparent and real as possible on the financial position and performance of an entity.

The existence of this relationship negatively affects the quality characteristics of financial statements so that they have different values depending on the referential elements that adopted. According to the teacher Horomnea E. "any information gains in value because it can be compared over time or space" [5], we believe the development of a solution for this condition image is to ensure disconnection of tax accounting and compliance of financial statements with the rules IAS / IFRS.

Profitability of the Banking System in Romania

Tofănică Ramona-Ionela
„Alexandru Ioan-Cuza” University of Iași, Doctoral School of Economics
ramona_tofanica@yahoo.com

Abstract

This paper is an overview of the literature regarding the notion of performance, especially in the banking system in our country, expressing my own point of view regarding profitability of the banking system in Romania once with the beginning global crisis.

Key words: bank, profitability, Romania

J.E.L. classification: M41, G21

1. Introduction

Once with waiving the centrally planned economy and with transition to a market economy based on competition, the term “performance” began to be used in the literature and mainly in the economic life of our country since 1990.

In terms of etymology, the term “performance” comes from the Latin “performare”, which means to give full shape to something, respectively to fulfill a predetermined objective.

According to economics literature, the meaning of this word comes from English, from words “to perform”- which means to make something regularly and methodically, and “performance”, which implies the result obtained after executing a task.

2. Bank profitability

The performance describes the evolution of the results achieved in a certain period because the “performance” term is the product of a comparison, whether it is a comparison with others for the same period, whether a comparison with himself at different times.

Of the concept of performance we can associate three other notions namely efficiency, economicity and effectiveness,

widely debated in the literature in our country, from which we separated elements on which experts were agreed. [1]

Efficiency requires either minimizing resources to achieve a predetermined result, either maximize the results obtained with a certain amount of resources, in all cases by creating a report, a comparison of effectiveness (outcome) and effective effort (expense) to obtain the result by a system or process.

Economicity represents engaging resources at minimum cost.

Effectiveness is the quality of an action to produce the expected results and acts as a control criterion of the level and the degree of achievement of objectives.

In the specialty literature, there are several meanings of “performance”, namely performance is success, the result of the action, or action itself. [2]

Information about the performance of an institution, especially on profitability, are useful to predict its ability to generate cash flows with existing resources, as well as to make judgments about the efficiency with which institution may use the new resources.

The diversity of definitions of the concept of performance shows that it is interpreted differently by users of financial and accounting information according to their interests.

In banking, however, performance is viewed primarily in terms of stability and efficiency and less in terms of competition, the latter being rather a consequence of the performance level. [3]

Bank profitability represents an important objective of bank management covering: [4]

- optimization of bank resources and of investments;
- optimizing intra and interbank settlements;
- rationalization of operating costs;
- on time collection of interest based;
- promotion of new banking products and

services;

- attracting new customers, profit, etc.

The concept of bank profitability can be defined both vertically, the territorial units (profit center) and horizontally, taking into account actual and potential effectiveness of a bank's business segment, these conceptual elements are included in the general version bank strategy.

Banks in Romania are organized into centers of activity, respectively territorial units and subunits that have resources and involve costs. Thus currently, some banks ask themselves if certain operational units in the country are effective or not. On the other hand began to be promoted decentralization elements such as increasing credit limits for operational units, free marketing and strategy for attracting new customers.

One of the basic requirement governing the organization and assess the profitability of a bank is the existence of an integrated information system that will lead to the submission and processing of data and information in real time and, in particular, the transfer of real-time price for deposits or investments.

The problem of principle for determining profitability is the actual cost of bank management. For an accurate reflection should seek financial management costs, reflecting all movements within the system (input and output sources).

The methodology for calculating profitability involves: [4]

- statements of investments and of resources in domestic and foreign currency and determining the interest on surplus or deficit of resources, taking into account at the same time the minimum reserves established in accordance with the rules of the central bank;
- correcting extra-profit accounting data determined from operative unit results in the previous paragraph;
- based on credit quality, proceed to include the costs and bear the results of specific risk provisions.

In conclusion, the preparation profitability models should comply with procedures that include: [3]

- calculate profitability at the center of activity;
- collect and evaluate calculations of cost

and / or profit centers;

- monitoring the profitability of all centers of profitability, including those in center;
- methods of reporting analyzes carried out;
 - achieve profitability analysis and presentation of results to bank management.

3. Indicators for appreciation bank performance

Indicators for appreciation bank performance have a high expressiveness, reflecting a multitude of aspects: the level of profit generation, operational efficiency and management, etc.. These indicators resulting from accounting data reflecting the period.

Bank balance, as in any other field, is the official document which includes bank management patrimonial situation (balance itself) financial results (profit and loss), annex with data supplements the information presented in the balance sheet and income statement, and the management report.

The content and structure of its balance sheet enables benchmarking and knowledge of changes in the composition of assets and liabilities, but at the same time represents the main tool for complete and clear analysis of the bank's assets, its financial situation and results.

In banking practice, banking performance evaluation is done using a set of indicators whose size is the result of comparing posts of balance sheet.

Analyzing bank performance indicators presented by western literature and Romanian banking theory and practice have made their grouping according to the main directions and objectives of the bank management, as follows: [4]

- indicators for assessing the overall effectiveness of banking;
- indicators of asset quality;
- indicators for assessing the solvency and liquidity;
- indicators for assessing profitability;
- indicators for the analysis of income and banking cost.

In my paper I stopped in analysis the indicator of profitability of the Bank sistem starting with the crises which started in the end of 2007.

4. Indicators of profitability

Literature and occidental banking practice for assessing the overall profitability of the bank include a number of indicators, of which: [4]

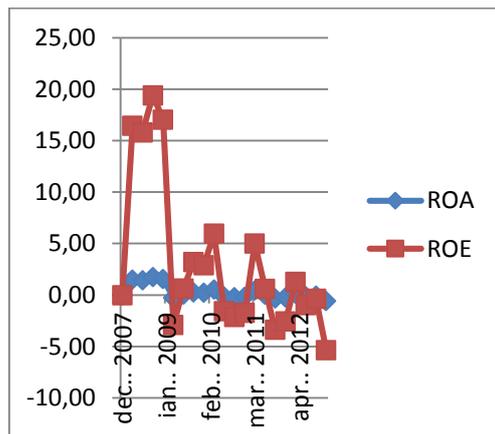

- The return on capital or equity (ROE-Return of Equity), measures the percentage yield of each monetary unit of equity:

$$ROE = \frac{\text{net income}}{\text{total own funds}} * 100$$

- The return on assets (ROA-Return of Assets), measures the net income generated by each monetary unit of assets:

$$ROA = \frac{\text{net income}}{\text{total assets}} * 100$$

Figure 1

Source: Personal analyzeof data from www.bnr.ro

Like we see in figure 1 in 2008, the profitability rates (ROA and ROE) continued their slightly downward trend, although the evolution of operational efficiency was positive in 2007, amid increased attention from credit institutions on judicious management of operational costs. Return on equity (ROE) had a slightly lower level than the previous year (11.44 percent in 2007 to 11.67 percent in 2006), while net profit dynamics comparable to that of equity.

In 2009, values for ROE and ROA at the end of December 2008, 18.1 percent and 1.7 percent, are comparable to those of the parent banking company with subsidiaries in Romania.

In 2010, ROE and ROA had a strong

downward trend in 2009 compared to 2008 (2.7 percent and 0.2 percent, compared with 17 percent and 1.6 percent), due to lower growth in net profit compared to growth average aggregate assets and average equity.

In 2011, in the case of profitability indicators (ROE and ROA), downward trajectory continued in 2010 for the second consecutive year. In late June 2011, ROE and ROA levels are slightly improved from the same period a year earlier, moving in positive territory.

- Funds multiplier (EM), compares assets with its own funds, so that a high value of this indicator shows a high degree of financial leverage (Financial Leverage). This indicator measures simultaneously both profit and risk.

$$EM = \frac{\text{total assets}}{\text{total own funds}} * 100$$

Between the three indicators is a direct correlation, as follows:

$$ROE = ROA * EM$$

In assessing profitability can be used and the following indicators: [4]

- rate interest charges as a ratio of total spend interest and operating income;
- other expenditure rate, the ratio of expenditure other than interest and total operating income;
- provisions for credit outstanding rate, the ratio between total provisions and operating income;
- the tax rate, the ratio of income tax and total operating income, etc.

5. Conclusions

Measuring performance can be done using a complex set of indicators that can provide a complete overview: how resources were involved, how were risks controlled, the results obtained, the way in which to market received the products and services offered, especially if increased or not the trust capital enjoyed by the public.

Performance management is based on the information and in turn creates information where feedback does not work, performance will not pass a certain level.

Is indicated that bank performance is evaluated at short intervals during the international financial crisis, requiring a more

focused approach for supervision of credit institutions. In addition to the objective side, based on rigorous calculations and formulas, performance leaves much room for interpretation and subjective attitudes, depending on the perspective from which the performance is seen.

The actual international financial crisis forces banks to increase social responsibility and change their own behavior management, because when banks competed in spectacular performances, the State was not required to intervene, and today when states put taxpayers to cover huge losses, banks must show signs of recovery from within.

Financial performance of credit institutions in the international financial crisis will undoubtedly be affected by high levels of reserves established as a reflex to adapt to market conditions.

At December 31, 2011, the main indicators of profitability in the banking sector (financial profitability rate - ROE and economic rate of return - ROA) were negative, although slightly more favorable than in September 2011 (-2.6 percent - 3.4 percent and -0.2 percent from -0.3 percent). In late June 2012, ROE and ROA recorded slightly negative (-1 percent and -0.1 percent).

Auditor's Role in the Use of European Structural Funds

Țogoe Greti Daniela

Faculty of Economics and Business Administration, West University of Timisoara
greti_togoe@yahoo.com

Abstract

Structural Funds audit is a requirement in the contract for financing the project and provides a range of activities such as:

- *analyze and verify the nature, legality and regularity of expenditure; verify the use of amounts received as advance;*
- *auditing of third parties, dealing specially designated expense accounts and budget project*
- *project monitoring income (including advances received from finance, interest on advances and other income generated by the project) etc.*

The objective of the mission is that the auditor agreed upon procedures apply audit procedures agreed upon nature auditor and the entity and any third party, and then to report the findings.

The audit report should describe the purpose and procedures in sufficient detail for the interested parties to understand the nature and extent of the work performed. The report is restricted to those parties that have agreed to the procedures to be performed.

Keywords: structural funds, eligible expenses, auditor, factual findings.

JEL Classification: M42, M49

1. Introduction

European Union acts by the Structural Funds, Cohesion Fund and other financial instruments to support the overall objectives (convergence, regional competitiveness and employment, European territorial cooperation), to eliminate economic and social disparities between regions, for the purpose of economic and social.

For the period 2007-2013 are three financial instruments known as Structural Funds that:

- The European Regional Development

Fund (ERDF)

- The European Social Fund (ESF)
- The Cohesion Fund (CF)

and two complementary actions, namely:

- The European Agriculture and Rural Development (EAFRD)
- The European Fisheries Fund (EFF).

Increased access to European Union Structural Funds is a necessity in the current period, for at least two reasons:

- These funds can help reduce the gap between western Romanian economy and economy - European
- The training effect produced by European Structural Funds can lead to sustained economic growth, which can make the current recession of the past.

In 2007-2013, Romania is eligible for all three structural funds available for the implementation of European Union cohesion policy.

European Regional Development Fund finances activities of 14 key areas: research and technological development, computerization of society, transport, energy, environment, tourism, culture, urban and rural regeneration; support for companies and entrepreneurs; investment in social infrastructure, including the health and education.

The Cohesion Fund finances major transport projects (including projects for railway transport, multi-modal transportation and shipping).

For those familiar with waste and unreasonable use of public funds, access to European Union Structural Funds proves difficult because the justification of these funds takes place on a clear, both in terms of eligibility of expenditure and in terms of the rules related to public procurement.

A very important role is independent auditors called to express, on a contractual basis an audit opinion on how the funds were used and whether the conditions of the Grant Contract and whether the amounts requested

for payment is eligible expenses are true, accurate and payable.

2. Mission specific activities performed by auditors

The main activities [1] carried out by the audit team consists of:

- analyze and verify the nature, legality and regularity of expenditure;
- control use of amounts received as advance;
- auditing of third parties;
- reconciliation of expenditure with specially designated accounts and project budget;
- verification of income project (including advances received from finance, interest on advances and other income generated by the project).

The auditor should plan the audit [3] in a manner which ensures that the mission will be accomplished in terms of economy, efficiency, effectiveness and agreed term. The Auditor verifies that the information in the request for reimbursement of expenses are reconciled to the beneficiary's accounting system and records (e.g. trial balance, analytical and synthetic records of accounts):

- examining procurement rules that apply to each category of costs, types expenditures;
- check cash inflows of the project.

The auditor makes an analytical review of the expenditure headings request for reimbursement of expenses:

- check whether the budget request for reimbursement of costs reflects the budget financing contract (authenticity and authorization of the initial budget) and expenditures were made in the budget agreement financing;
- check that the total amount claimed for payment by the beneficiary does not exceed the maximum grant amounts provided under and by category of expenditure;
- check that any amendment to the budget financing contract complies with the conditions for such amendments (including whether need to apply an addendum to your agreement).

The auditor [4] develops and fulfills the verification work program in accordance with the objective and scope of this engagement

and the procedures to be performed. During the implementation of these procedures the auditor [5] may apply techniques such as inquiry and analysis, (re) computation, comparison, other clerical accuracy checks, observation, inspection of records and documents, inspection of assets and obtaining confirmations. Following the procedures for verification of expenditures, auditors will have to determine whether:

- the expenses are accounted for in accordance with the purpose specified in the primary documents of the project expenditure categories;
- in terms of record keeping, to be active measures to ensure archival documents on 31.12.2021;
- project expenditure incurred in procurement contracts were necessary to conduct the project;
- all project expenses are recorded in the beneficiary's accounts based on documents that are identifiable and verifiable, and be backed by originals that have entered the code project and word Project funded by ROP;
- Separate accounting on the project, using different analytical accounts;
- procurement were assigned with respect Law 34/2006;
- the services were rendered, as each invoice is documented records partial reception/work statements certified by authorized personnel law.

Financial auditor [6] obtains sufficient appropriate evidence from these procedures to produce a report of factual findings. For this purpose, the auditor may use the guidance [7] [12] provided by the International Standard on Auditing 500 "Audit Evidence" and in particular paragraphs that refer to "sufficient appropriate audit evidence." Auditor exercises professional judgment [8] about what is appropriate and sufficient evidence if it considers that the guidance provided by ISA 500, the terms and conditions of the funding for this commitment is not enough. Indicative list of the types and nature of evidence that the auditor may find the verification of expenditure include:

- Accounting records (electronic or manual) from the beneficiary's accounting system, such as ledger, its chapters and all accounts of salaries, fixed asset registers

and other relevant accounting information;

- Proof of procurement procedures and tender documents, tenders for auction and evaluation reports;
- Proof of commitments such as contracts and order forms;
- Proof of service provision as approved reports, time sheets, transport tickets (including boarding passes) etc.
- Proof of receipt of the goods and receiving documents from suppliers;
- Proof of completion of works such as invoices and receipts;
- Proof of payment such as bank statements, notices of payment, proof of payment of the subcontractors;
- For petrol and diesel costs a summary list of the distance covered, consumption vehicles used, fuel and maintenance costs;
- Records regarding payment of salaries and related personnel and contracts, the payroll, time sheets. For staff recruited locally for a fixed period contracts, details of remuneration paid, perhaps those responsible locally, broken down gross wages, social contributions for insurance and net salary;
- Information on the precise location of premises where documents are originals in case verification by the European Commission.

The audit procedures were used as the basis of information in addition to the above evidence and a number of existing documents beneficiary's accounts [9], such as:

- accounting ledgers provided by Law no. 82/1991, as amended and supplemented by subsequent (electronic and / or paper);
- the beneficiary's own budget chapters, subsections, paragraphs, titles expenses, articles and paragraphs;
- checking balances analytical and synthetic (in electronic and / or paper);
- plugs account for various operations (electronic and / or paper);
- accounting notes (electronic and / or paper);
- contracts and order forms;
- invoices;
- statements of work and payment conditions;
- minutes of final reception and partial;
- minutes of commissioning;
- notes receiver and finding differences;

- bank statements and orders;
- contracts of employment between customer and employee;
- decision by which the employee is assigned to be part of the implementation team and its tasks in the project;
- time-sheet's actual time worked on the project (including part-time contracts) approved project manager;
- payrolls;
- other documents: consumer bills, roadmaps, airline transportation, auto fuel bills fixed quantities, travel orders, inventories, sheet asset etc.

Once you are satisfied that sufficient appropriate evidence obtained, the auditor shall prepare audit report in accordance with ISRS 4400 [10] and the contract concluded with the customer service.

Audit reports [13] prepared by independent auditors must fulfill the following conditions:

- be prepared in accordance with International Standards on Auditing;
- be based on sufficient evidence, relevant and solid;
- include all information necessary to ensure understanding of audit findings;
- include only findings that are supported by relevant and sufficient audit evidence . Audit opinion must be supported by evidence justifying the conclusions of the audit.
- be concise and contain only relevant aspects of the audit scope

3. Conclusions

Independent financial auditor's role in the projects financed from EU Structural Funds is to assess whether the expenses claimed by the beneficiary in the application for reimbursement were actually, accurate and eligible. Depending on the findings obtained by it, the beneficiary can obtain funds from projects financed by EU Structural Funds. Projects financed by European funds are conditional on fulfillment of criteria for reporting on how the project and its development.

Audit work of a project is essential for assessing the conduct of its correctness, and the way in which they were Europeans manages money. The audit report must include an opinion authorized the objectives

assumed by contract. The report shall be drawn from the results found by testing and auditing the auditor's judgment, while respecting auditing standards applicable international and/or national and funder requirements.

If the audit opinion is unfavorable, or assumed by contract funding targets are not met or are met without compliance beneficiary will be required to reimburse the European Structural Funds.

The Analysis of the Economic and Financial Performance Based On the Rates of Return in Hospitality Industry Companies On the Romanian Seaside

Trandafir Raluca-Andreea

*OVIDIUS University of Constanta, Romania, Faculty of Law, Administrative Sciences and
Sociology*

trandafirraluca@hotmail.com

Mirea Marioara

OVIDIUS University of Constanta, Romania, Faculty of Economical Sciences

mm_mirea@yahoo.com

Abstract

This research uses the rate of return method in hospitality industry companies, regarding the theoretical bases and the meanings of the concept of performance, by analysing two hotel companies from the Romanian seaside. The analysis of the activity of the two hotel complexes reveals the impact that the development of the Northern and Southern areas of the Romanian coastline has on their performance. The use of the rates of return gives the possibility to obtain different information and creates the possibility to make a comparison in all three planes, i.e. rules, time and space, in terms of a company's financial and economic activity.

Key words: the rates of return, hospitality industry companies, the economic and financial performance.

JEL classification: M41

1. Introduction

“The rate of return is a ratio between an indicator of results (profit or loss) and an indicator that reflects a workflow (net turnover, resources consumed etc.) or a stock (equity, total assets etc.)” [11]. The main operational rates of return in the economic and financial analysis of a company are: the economic rate of return, the financial rate of return, the commercial rate of return, the rate of return on the resources consumed.

The research was conducted by analysing two distinct hotel companies and, ultimately, we have tried to correlate important aspects found in SC Complex Condor SA and SC THR Marea Neagra SA. It can be noticed that the activity of these hotel companies is clearly affected by seasonality, being open for a period ranging from four to nine months. In order to obtain a conclusive outcome of our research, we chose to report data from the annual financial statements at the average euro exchange rate set by the RNB (the central bank) for the income and expenses cash flows, from the income and loss account and, for the balance sheet items, we used the Euro exchange rate from 31 December, set by the RNB. We considered necessary the expression of data in Euro as reference currency, given the dynamics in the analysed time horizon and the influence it had in the development of revenue and expenditure, ensuring the comparability of results over time.

SC Complex Condor SA was founded in 1995, with the legal form of a joint stock company, the main activity of the company being “Hotels”, located in Mamaia. The company has a 4 star rated hotel and a restaurant where: it provides services in the field of tourism, runs import-export operations and commercializes goods by its own units or employees.

Condor Hotel is located in Mamaia, at 50 m from the beach, in the Casino area. The hotel is built on six levels and has 272 beds in the 125 double rooms, 6 matrimonial rooms, 6 single rooms and 2 suites.

The core business of *SC THR Marea Neagra SA* is national and international tourism, catering and entertainment. According to the NACE classification, the main activity of the company is “Hotels”. *SC THR Marea Neagra SA* is a legal entity registered in the Trade Register in 1991 and the company’s shares are listed and traded on the Bucharest Stock Exchange since 2002, with the symbol “EFO”.

The company’s tourist supply is promoted and marketed both on domestic and foreign markets, the largest share being held by the domestic tourism (96%). The tourist package includes all services, i.e. accommodation, food, treatment, recreation, thereby aiming to attract different types of tourists. It appears that Romanian tourists’ motivation differs from that of foreign tourists, the latter’s requirements being higher in the degree of the comfort provided. Due to the ongoing development of national and international tourism, the requirement for high quality services is increasing, thereby triggering measures to improve the service supply and the modernization of the material basis.

“The company has over 11,000 beds and over 16,600 public eating places located in several resorts, divided into units of 4, 3, 2 and 1 star, 2 aqua park sites with a total capacity of 650 seats and 3 treatment units with a capacity of 6,000 procedures per day.

SC THR Marea Neagra SA has about 12% of the total number of beds in the tourist reception structures from the tourist resorts on the Black Sea seashore and 2.2% of the entire tourism sector conducted nationwide. Of the total number of tourists registered in the company analysed, the share of foreign tourists is very small, i.e. only 0.02% tourists” [8].

2. Analysing the rates of return at SC Complex Condor SA

Table 1 contains the values of all the indicators necessary for the calculation models of the rates of return.

Table 1. Indicators used in expressing the rates of return at SC Complex Condor SA Euro

Indicators	2006	2007	2008	2009	2010
1.Total assets	2229898	6278610	5890722	5727589	5645745
2.Equity	342550	418427	269414	221338	41227

15. Profit before tax and interest	328671	452643	291543	220862	41961
16. GOS (gross operating surplus)	344489	500210	497851	304519	232948
17. Interest rate	6.69	10.72	188.46*	0	0

Source: Data processed and calculated from the financial statements of SC Complex Condor SA

* The interest rate in 2008 has an atypical value in relation to the remaining period due to the fact that the company prepaid the interest on the contracted loan.

a. The economic rate of return (R_e) expresses the efficiency of the use of the asset in order to get profit. It is one of the most important rate of return and it measures the performance of the entire capital invested, materialized in the company’s assets. For the company’s activity to be considered effective, the indicator value must be higher than the inflation rate in the period analysed. According to specialist authors, there are more versions for the calculation of the economic rate of return at *SC Complex Condor SA*, illustrated in Table 2.

Table 2. The economic rate of return at SC Complex Condor SA, during 2006-2010 %

Indicators	2006	2007	2008	2009	2010
1. $R_e = CP/TA * 100$	14.74	7.21	4.95	3.86	0.74
1.1. $R_e = TI/TA * CP/TI * 100$	14.74	7.21	4.95	3.86	0.74
2. $R_e = CP/C_{inv} * 100$	15.48	7.31	5.01	3.90	0.75
2.1. $R_e = TI/C_{inv} * CP/TI * 100$	15.48	7.31	5.01	3.90	0.75
3. $R_e = GOS/TA * 100$	15.45	7.97	8.45	5.32	4.13
3.1. $R_e = P_{net}/TA * 100$	14.74	7.21	4.95	3.86	0.74
3.2. $R_e = P_{net}/C_{inv} * 100$	15.48	7.31	5.01	3.90	0.75

where:

NP- Net profit;

TA- Total assets;

TI- Total/ current income;

C_{inv} - Capital invested;

P_{bit} - Profit before tax and interest;
E – Equity;
NT - Net turnover;
TP – Taxable profit;
IR – Interest rate;
FD- Financial debt;
ORRT- The operating result related to the turnover;
OERT- Operating expenses related to the turnover;
CP – Current profit;
OR – Operating result;
TOE - Total operating expenses.

Model 1. In 2007, there was recorded a rate of 7.21% compared to a rate of 14.74% in 2006, against the background of the increase in the current profit by 44.99%, but in a lower extent than that of the total assets, which increased by 181.56%. During 2008-2010, there was recorded a decrease in the economic rate of return to 4.95% in 2008 and to 3.86% in 2009, reaching 0.74 in 2010 due to a decrease in the current profit with 38.83 in 2008 compared to 2007, with 27.78 in 2009 compared to 2008 and with 94.98 in 2010 compared to 2009, while the total assets decreased by a percentage of up to 7%.

Model 2. In this case, the economic rate of return is influenced by the variation in the current profit, in the same percentages as in the model presented above, and in the invested capital, which grew by 191.59% in 2007 compared to 2006 and which, in the other years, decreased with up to 5%.

Model 3. We notice a significant decrease in 2007 compared to 2006, when the economic rate of return recorded a value of -7.48%, while the total assets increased by 181.56% and the gross surplus increased in the proportion of only 45.20%. In 2008, we note an increase in the proportion of 8.45% of this rate due to the decrease in proportion of only 0.47% of the gross operating surplus against a decrease of 6.18% of the total assets in 2008, compared to 2007. During the remaining period analysed, the indicator decreased according to the GOS decrease weights while the total assets decreased by a percentage of up to 4%.

In model 3.1. and 3.2., the economic rate variation is influenced by the variation in the profit before tax and interest, by the total assets and also by the invested capital, whose variation was significant in 2007 compared to 2006, when the capital invested grew by

191.59%, the total assets increased by 181.56 and the profit before tax and interest also increased by 37.72. During the remaining period, it decreased according to the weight of the other indicators analysed above.

b. The financial rate of return (R_f) - is the indicator in whose terms the capital owners assess the efficiency of their investments and, thus, the appropriateness of their maintenance. Usually, this indicator should have a higher value than the average interest rate on the market.

Table 3. The financial rate of return at SC Complex Condor SA, during 2006-2010
%

Indicators	2006	2007	2008	2009	2010
1. $R_f = NP/E * 100$	78.30	92.94	88.30	77.62	20.94
1.1 $R_f = TI/TA * TA/E * NP/TP * 100$	78.30	92.94	88.30	77.62	20.94
1.2. $R_f = TA/E * NP/TA * 100$	78.30	92.94	88.30	77.62	20.94
1.3. $R_f = TA/E * NT/TA * NP/NT * 100$	78.30	92.94	88.30	77.62	20.94
1.4. $R_f = TI/E * TP/TP * NP/TP * 100$	78.30	92.94	88.30	77.62	20.94
2. $R_f = [R_c + (R_c - ID) * FD/E] * (1 - tax rate / 100)$	2.51	5.33	3.54	1.28	0.62

In 2007, against the background of the increase in the net profit by 44.99% and of the equity by 22.15%, compared to 2006, there was registered a growth of the rate at 92.94% in 2007, compared to 78.30% in 2006. During 2007-2009, the rate variation was influenced by the variation in the net profit while the capital underwent insignificant changes, the rates reaching approximately equal values ranging between 77.62% and 88.30%. In 2010, compared to 2009, there was noted a significant decrease in the value of the financial rate of return to 20.94%, especially due to the massive fall of 94.98% in the net profit, due to the operating loss in 2010.

c. The commercial rate of return (R_c) - is the clearest expression form of the efficiency in the tertiary sector, including tourism, and, therefore, the most widely used.

Table 4. The commercial rate of return at SC Complex Condor SA during 2006-2010
%

Indicators	2006	2007	2008	2009	2010
1. $R_c = ORRT/NT * 100$	22.98	29.84	16.82	9.45	-2.04
1.1 $R_c = (NT - OERT) / NT * 100$	22.98	29.84	16.82	9.45	-2.04
1.2. $R_c = (1 - OERT/NT) * 100$	22.98	29.84	16.82	9.45	-2.04
2. $R_c = NP/NT * 100$	26.17	32.30	19.48	19.76	1.23
3. $R_c = GOS/NT * 100$	33.61	41.54	40.76	35.03	33.18

The commercial rate of return is influenced by the operating efficiency,

respectively by the policy of strictly tracking the expenses and of maximizing the turnover. However, in 2010, there was recorded a negative value of this rate, of 2.04%, due to the significant decrease in tourist flows but also due to the economic crisis, as a factor independent of the company’s management; thus, there was recorded a negative operating result related to the turnover, which triggered a negative commercial rate of return.

d. The rate of return on the resources consumed (R_{rc}). If we take into account the values obtained according to the models used in order to calculate the rate of return on the resources consumed, included in the table below, we find the following: if we consider, as calculation elements, the indicators “operating expenses” and “operating results”, the rate of return on the resources consumed record positive values (model 1) and, in the models where we take as calculation basis the operating expenses related to turnover and the operating result related to the turnover, we get negative values in 2010, due to the effects mentioned in the above cases .

Table 5. The rate of return on the resources consumed at SC Complex Condor SA, during 2006-2010

Indicators	2006	2007	2008	2009	2010
1. $R_{rc} = OR/TOE * 100$	32.88	43.62	20.91	11.02	-1.45
2. $R_{rc} = ORR/OERT * 100$	29.84	42.54	20.21	10.44	-2.00
2.1. $R_{rc} = (NT-OERT)/OERT * 100$	29.84	42.54	20.21	10.44	-2.00
2.2. $R_{rc} = (OR/OERT - 1) * 100$	29.84	42.54	20.21	10.44	-2.00

3. Analysing the rates of return at SC THR Marea Neagra SA

Table 6 contains the values of all the indicators necessary for the calculation models of the rates of return.

Table 6. Indicators used in expressing the rates of return at SC THR Marea Neagra SA Euro

Indicators	2006	2007	2008	2009	2010
1.Total assets	67600916	94811181	87743852	82473560	82438584
2. Equity	65698060	92993364	85863855	78373694	77092589

16. GOS (gross operating surplus)	2465900	2893783	2255887	1245015	1023257
17. Interest rate	3.02	6.77	8.77	21.60	22.61

Source: Data taken over and calculated from the financial statements at SC THR Marea Neagra SA

Table 7. The economic rate of return at SC THR Marea Neagra SA, during 2006-2010

Indicators	2006	2007	2008	2009	2010
1. $R_e = CP/TA * 100$	2.99	6.35	4.23	1.69	0.96
1.1. $R_e = TI/TA * CP/TT * 100$	2.99	6.35	4.23	1.69	0.96
2. $R_e = CP/C_{inv} * 100$	3.04	6.43	4.30	1.77	1.02
2.1. $R_e = TI/C_{inv} * CP/TT * 100$	3.04	6.43	4.30	1.77	1.02
3. $R_e = GOS/TA * 100$	3.65	3.05	2.57	1.51	1.24
3.1. $R_e = P_{net}/TA * 100$	3.02	6.39	4.28	1.87	1.18
3.2. $R_e = P_{net}/C_{inv} * 100$	3.07	6.48	4.35	1.95	1.25

Model 1. In 2007, there was recorded a rate of 6.35% compared to a rate of 2.99% in 2006, against the background of the increase in the current profit by 198.16%, at the expense of the total assets which increased by 40.25%. During 2008-2010, there was recorded a decrease in the economic rate at 4.23% in 2008, at 1.69% in 2009, reaching 0.96 in 2010, due to the decrease in the current profit by 38.30 in 2008 compared to 2007, by 62.37 in 2009 compared to 2008, and by 43.21 in 2010 compared to 2009, while the total assets decreased by up to 8%.

Model 2. In this case, the economic rate of return is influenced by the variation in the current profit, in the same percentages as in the model presented above, and in the invested capital, which grew by 40.87% in 2007 compared to 2006, and, in the other years, it registered a decrease of up to 8%.

Model 3. There was recorded a slight decrease in 2007 compared to 2006, when GOS recorded an increase by 17.35%, while the total assets increased by 40.25% and, during the remaining period, the indicator decreased according to the GOS decrease weights, while the total assets decreased by up to 8%.

As in the previously presented models, the variation in the economic rate is influenced by the variation in the profit before tax and interest and, to a lesser extent, by the total assets and by the invested capital whose variation is insignificant.

Table 8. The financial rate of return at SC THR Marea Neagra SA, during 2006-2010
%

Indicators	2006	2007	2008	2009	2010
1. $R_f = NP/E * 100$	2.53	5.42	3.74	1.48	0.63
1.1 $R_f = TI/TA * TA/E * NP/TI * 100$	2.53	5.42	3.74	1.48	0.63
1.2. $R_f = TA/E * NP/TA * 100$	2.53	5.42	3.74	1.48	0.63
1.3. $R_f = TA/E * NT/TA * NP/NT * 100$	2.53	5.42	3.74	1.48	0.63
1.4. $R_f = TI/E * TP/TI * NP/TP * 100$	2.53	5.42	3.74	1.48	0.63
2. $R_c = [R_c + (R_c - ID) * FD/E] * (1 - \text{tax rate} / 100)$	2.51	5.33	3.54	1.28	0.62

Except for 2007, when the net profit increased by 202.87% and the equity increased by 41.55% compared to 2006, in the remaining analysed period there was registered an increase in the rate at 5.42% compared to 2.53%, the rate variation being influenced by the variation in the net income, while the equity underwent insignificant changes.

Table 9. The commercial rate of return at SC THR Marea Neagra SA, during 2006- 2010
%

Indicators	2006	2007	2008	2009	2010
1. $R_c = ORRT/NT * 100$	11.03	11.42	7.48	-4.21	-18.00
1.1 $R_c = (NT - OERT) / NT * 100$	11.03	11.42	7.48	-4.21	-18.00
1.2. $R_c = (1 - OERT/NT) * 100$	11.03	11.42	7.48	-4.21	-18.00
2. $R_c = NP/NT * 100$	14.83	39.39	30.11	16.28	9.68
3. $R_c = GOS/NT * 100$	21.98	22.62	21.18	17.49	20.36

The commercial rate of return is influenced by the operating efficiency and, respectively, by the policy of strictly tracking the expenses and maximizing the turnover. However, in 2009 and 2010, when there was a significant reduction of the tourist flows because of the economic crisis as a factor independent of the company’s management, there was recorded a negative operating result related to the turnover, resulting in a negative commercial rate of return.

Table 10. The rate of return on the resources consumed at SC THR Marea Neagra SA, during 2006-2010
%

Indicators	2006	2007	2008	2009	2010
1. $R_{rc} = OR/TOE * 100$	19.18	36.62	22.47	11.97	9.90
2. $R_{rc} = ORRT/OERT * 100$	12.40	12.89	8.09	-4.04	-15.26
2.1. $R_{rc} = (NT - OERT) / OERT * 100$	12.40	12.89	8.09	-4.04	-15.26
2.2. $R_{rc} = (OR/OERT - 1) * 100$	12.40	12.89	8.09	-4.04	-15.26

If we take into consideration the values obtained according to the models used in order to calculate the rate of return on the resources consumed, included in the table above, we find the following: if we take as calculation elements the indicators “operating expenses” and “operating results”, the rates of return on the resources consumed record positive values (Model 1.); and in the models where we take as calculation basis the operating expenses related to the turnover and the operating result related to the turnover, we get a negative turnover in 2009 and 2010, due to the effects mentioned in the above cases.

4. Conclusions

The research was based on the economic and financial information on the two hotel companies. Each economic unit analysed, i.e. SC Complex Condor SA and SC THR Marea Neagra SA, has its particularities and reach specific aspects met in the hotel industry activity.

Thus, SC Complex Condor SA has an activity that could be relatively characterized as linear, in the sense that it recorded a profit from its core activities in the first 4 years of the analysed period, experiencing the effects of the economic crisis only in 2010. It should be noted that this hotel company changed its management policy in the last three years of the analysed period, i.e. it became oriented towards the development of the accommodation activity at the expense of catering. This was achieved by restricting the space for catering because, once with the economic crisis, the tourists became oriented towards tickets including accommodation with breakfast only.

The external influences positively impacting the activity of this company refer to the location of this hotel in Mamaia, in the Casino area. The resort has seen in recent years the largest flow of tourists due to infrastructure and opportunities for leisure and entertainment, and also due to the diversification of services.

SC THR Marea Neagra SA is a representative company due to its presence in four southern seaside resorts but also due to its significant weight in the hospitality industry from the Romanian seaside in proportion of about 12% of total beds, and of

2% of the total beds nationwide. The company is listed on the Bucharest Stock Exchange and it recorded profit in each year of the analyzed period; however, its main particularity is that the recorded profit is not made from its basic activity but from the sale of assets.

Although our analysis of the rates of return for the 2 hotel companies is a unitary one, we can state that it is not relevant to compare the results obtained from this research as it would not be fair; the two hotel companies differ by their material bases and by the degree of the diversification of their services. From this research it is noted that, although there is a discrepancy between the values of the elements that led to the calculation of the rates of return between SC THR Marea Neagra SA and SC Complex Condor SA, the values of the rates of return are inversely proportional to the values of their components.

Regarding the calculation of the economic rate of return, we should note the following values for the period 2006-2010: at SC THR Marea Neagra SA, the total asset value was between minimum 67,600 euros and maximum 94,811 euros, and the value of the current profit – between minimum 794 thousand euros and maximum 6,019 thousand euros; at SC Complex Condor SA, the total assets value ranged between minimum 2,223 thousand euros and maximum 6,279 thousand euros, and the value of the current profit – between minimum 42,000 Euros and maximum 453,000 Euros.

The economic rates of return calculated for the analysed time horizon is as follows:

SC Complex Condor SA recorded a value of the economic rate of return of 14.74% in 2006, 7.21% in 2007, 4.95% in 2008, 3.86% in 2009 and 0.74 % in 2010, compared to SC THR Marea Neagra SA which, during the same period, recorded 2.99% in 2006, 6.35% in 2007, 4.23% in 2008, 1.69 in 2009 and 0.96% in 2010.

Except for 2008 and 2010, when there were insignificant differences, in the remaining period, the economic rate of return at SC Complex Condor SA was superior to the rate of return at SC THR Marea Neagra SA.

Regarding the financial rate of return, there were recorded the following values during 2006-2010: for SC Complex Condor, the value of the financial rate of return was: 78.30% in 2006, 92.94% in 2007, 88.30% in 2008, 77.62% in 2009 and 20.94% in 2010, compared to SC THR Marea Neagra SA which, in the same period, recorded: 2.53% in 2006, 5.42% in 2007, 3.74% in 2008, 1.48 in 2009 and 0.63% in 2010.

In conclusion, the rates of return reflect the reality of the activity of the two hotel companies in the sense that, although SC THR Marea Neagra SA recorded a profit in the annual financial statements, this profit was achieved from the sale of assets compared to SC Complex Condor SA which achieved profit from its current activities.

contabweb@yahoo.com

Abstract

Traditional performance measurement indicators have the disadvantage that they provide information about the historic financial performance of the company and do not reflect de social and environmental performance.

From an economic-financial perspective, the traditional indicators highlight only the results of the capital use without taking into account its cost. Consequently, if we limit ourselves to the use of traditional indicators we can find companies that make a profit without creating value for the shareholder and consuming instead the existent one.

The emergence in recent decades of performance measurement indicators by the creation of value was a step forward both at theoretical level and in the company practice. The article aims at presenting the informational valences of modern performance measurement indicators.

Key words: EVA, MVA, value, performance

J.E.L. classification: M40, M41

1. Introduction

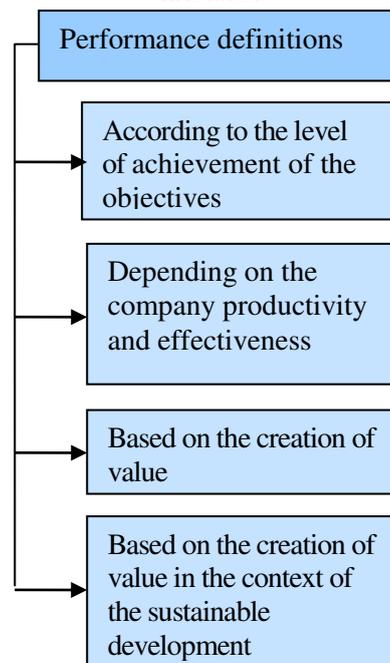

The concept of performance is encountered in various fields of the human activity. Etymologically is derived from the Latin word “performare” meaning completing a certain intended activity. Over time, the term "performance" was used to assess the activity of a company and to assess its competitiveness. This explains the fact that, being assessed in a different way by the participants to the company's life, depending on their interests, performance can be studied

from the perspective of each category of users of the accounting information [1]. Nowadays, company performance is no longer viewed only from the economic and financial perspective, but also from the social and environmental perspective as well.

2. Performance definition and measurement

Studying the economic literature, it can be noticed that in the definition of the concept of performance were outlined four main views. Performance definitions found in economic literature can be schematized as in Figure 1.

Figure 1. Performance definitions in economic literature

Source: Prepared by the authors based on [2]

The measuring of company performance is necessary [3] for:

- knowing the results obtained in all fields of activity and at the level of each of the company divisions;
- comparing the results with the proposed objectives;
- the justification of employing further resources;
- doing comparisons between the results;
- the elaboration of company overall diagnosis and establishing future actions in order to increase the performance.

The traditional indicators for the performance measurement have the disadvantage that they only provide information about the historical performance obtained by the company. These indicators do not take into account the cost of the invested capital but only highlight the results of its use. Consequently, if performance measurement is limited to the use of traditional indicators we can find companies that make profit but do not create value for their shareholders (consuming instead the existing value) [1] and companies that make profit but have no performance in social and environmental fields.

In the economic theory and practice several indicators are used that measure the value created by the company during an accounting period as compared to a reference period.

This category of indicators was designed to eliminate the disadvantages of the indicators determined based on accounting data, which not always take into account the cost of equity or the excessive use of rates. This category includes indicators such as: the economic value added, the market value added, the cash value added, and the cash flow return on investment.

3. Economic Value Added

The economic value added (EVA) is a modern performance measurement indicator representing the net operating profit after taxes diminished by the cost of capital [4]. EVA is a registered trademark of Stern Stewart & Co.

$$EVA = NOPAT - Cc$$

where:

NOPAT – net operating profit after taxes;

Cc – cost of the capital.

The cost of the capital is calculated by multiplying weighted average cost of capital with the total invested capital.

$$Cc = WACC \% \times TIC$$

where:

WACC – weighted average cost of capital;

TIC – total invested.

The invested capital includes the equity capital and the interest bearing borrowed capital. Thus, the cost of capital in absolute value is the sum of the cost of the equity capital and the cost of the borrowed capital.

In order to determine the level of the economic value added we start from the operating result, without taking into account the result of the financial and of the extraordinary activities.

Within the concept of economic value added, the operating activity is considered as the only activity that creates value for shareholders. Financial and extraordinary activities are viewed as collateral. Consequently, the correct assessment of the net operating profit is essential for the calculation of a real level of the economic value added.

If we take into account the formula used to calculate the economic value added, we believe that in order to maximize the result, managers can act in several ways, such as:

- increasing the management efficiency in order to achieve a maximum level of the operating result;
- using capital as strictly necessary.

The use of the indicator EVA is advantageous for many reasons. The main advantage of EVA is the measurement of the value created by the company.

EVA reflects the actual economic profit made by the company, not the fiscal one and this aspect is important for decision makers.

It can be calculated both at the level of the whole company and at subunit level, according to the current information needs. This aspect is important in determination of responsibility for managers of each level.

Another advantage is that it has conceptual simplicity. Conceptual simplicity facilitate the calculation of the indicator at the level of the company using its own employees.

Motivation is a key factor for all human actions. EVA can be a mean of motivating company managers, who can receive bonuses according to its level.

Another important aspect is that using EVA will allow for the co-measuring of the value created in cash and not percentages.

In management theory is generally accepted the relationship between a manager's authority and responsibility. EVA is based on items on which managers can act directly (such as invested capital and financial structure).

In a world in crisis and in an uncertain economic environment, EVA has also the advantage that is a strategic planning tool.

EVA also has disadvantages such as the high number of restatements and their high cost, capturing only financial performance (based also on the financial statements), and the need to implement an entire EVA philosophy, not only the tool (which is more difficult).

Experts from Stern Stewart & Co consulting firm deem that in order to achieve a level of the economic value added that should reflect the actual performance of the company it is necessary to make 160 accounting adjustments. In practice specialists in companies make only approximately 10-15 adjustments and calculation methodology varies from one company to another. In order to ensure comparability of data in time and space, it is necessary that whatever the methodology adopted in the company, it should be maintained for a longer period.

At the same time, the use of EVA has other limitations, such as:

- company performance is assessed only from the point of view of investors. Today a company with performance is one that meets both the expectations of the internal as well as those of the external environment;
- the indicator cannot be used on short term in the case of business sectors where investments are made on long-term;
- its use is hampered by the large number of accounting adjustments that are required and by the lack of a unitary methodology.

It should be taken into account that performance measurement must be made through several indicators (in order to diminish their limits), both financial and non-financial.

A multidimensional and flexible performance measurement system generates competition, performance remuneration and creation of value.

Therefore it is considered that it is good to use, in addition to EVA, a number of other indicators specific to the creation of value.

4. Market Value Added

The market value added (MVA) expresses the wealth generated by the entity for own shareholders, beyond the net book value of the company assets [4]. It is determined as the difference between the stock market value of the shares and the book value recorded for the equity. The calculation formula for MVA is:

$$MVA = MV - IC$$

where:

MV – market value;

IC – invested capital.

The stock exchange value of the shares is determined by market capitalization.

If MVA is positive it means the creation of wealth for shareholders by increasing the value of the invested capitals. If the value of MVA is negative, it means the reduction of the value of the stock capitalization under the value of the own capitals of the company.

The indicator itself shows how much value has been added or lost from the investment made by the shareholders according to M. Dincă [5] (profitable companies create market value added on the market, increasing the return on capital invested, and unprofitable companies will lose some of the value of the initially invested capital).

MVA does not take into consideration the opportunity cost of the invested capital and neither the sums distributed to shareholders, this being its main disadvantage. Unlike EVA, MVA cannot be calculated but at company level and not at the level of each division. This is a problem, especially for big companies, where is essential to know the contribution of each division to company performance.

The level of MVA depends on the level of the return on invested capital: when the economic rate of return exceeds the cost of capital, the market value of the shares exceeds the initial investment. We will find this situation in the case of EVA too, which if it is positive entails a positive MVA (the increase in the EVA leads to the increase in MVA).

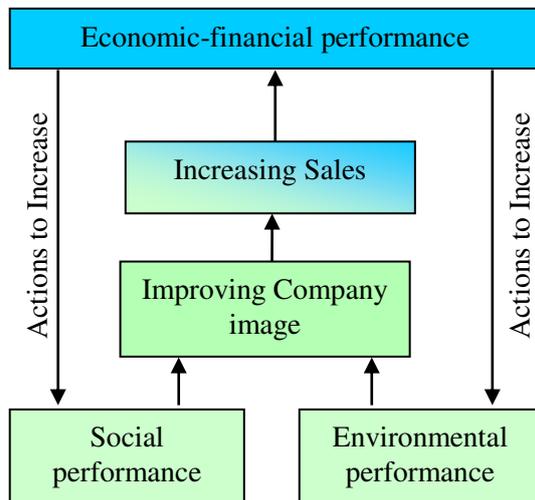

5. Performance management

Performance measurement is not enough, it must be one component of performance management.

Companies with remarkable social and environmental performance will obviously have a more favourable image among costumers and will also have a competitive advantage [6].

A modern performance management should take into account all kinds of performance, not only economic and financial one. There is an interdependence between the three types of performance, as shown in figure 2.

Figure 2. Relationship between economic-financial, social and environmental performance

Source: prepared by the authors

In the last three decades, the costs for the environmental protection and for social protection increased constantly.

An important part of performance management is the adoption of a system of indicators to reflect the performance. To be relevant and to receive the users` trust this system should be integrated and non-contradictory.

We consider that we can not speake about performance if it can not be measured. Performance exists if it can be described by a set of measures or indicators, more or less complex.

Professor H. Savall created “the hidden cost-performance method”, also called socio-economic method wich seeks to reconcile the

economic and social dimension of the company, with the purpose of increasing the efficiency of the management [7].

Revealing hidden cost of the company is a challenge for the managers.

Key performance indicators (KPI) enable measurement of the achievement of company objectives. KPI have the role to help the company management to define and measure the progress towards objectives. Each of the indicators should be selected so as to measure an aspect of business that is crucial for its success.

Informational limitations of outcome indicators were grouped by M. Siminică [8] as follows:

- limitations due to accounting system;
- limits imposed by nature indicators;
- limitations due to management actions.

In modern management of organizations we find three fundamental interdependent concepts: performance, value and cost. Company performance can not be analysed without taking into account the costs of the company and the value created inside it.

Clipici and Gâdoiu [9] consider that “the increase in the value of a company depends directly on its capacity to generate cash flows”.

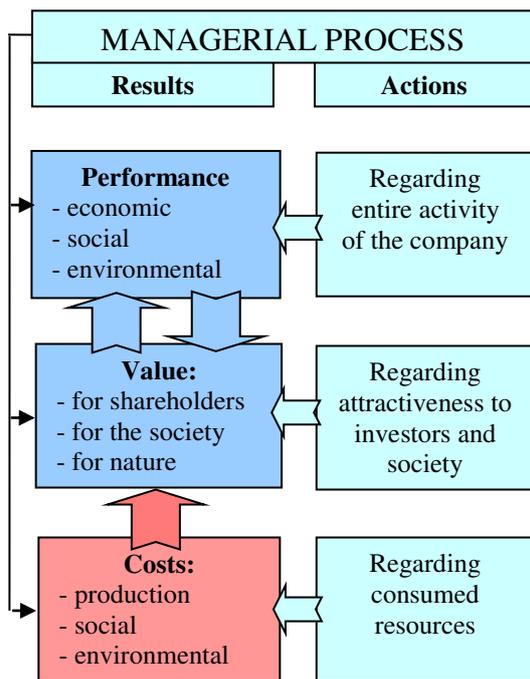

Lower costs have the effect of increasing the value created inside the company and also increasing company performance. A company with greater performance can act on the level of its costs. Managers can act upon each of the three variables: performance, cost, value.

All this three variables should be viewed in relation with the three main beneficiaries of company` activity: the shareholders (for the economic and financial aspects), the society (social aspects) and the nature (environmental aspects), as shown in figure 3.

There is a permanent need for a more precise and accurate knowledge of the costs at company level. This need results on the one hand from the limited nature of the resources, and on the other hand, from the desire to increase company performance.

In the absence of compulsory regulations, in most countries, the decision to report social and environmental performance is left to the company management. In the absence of standards for the elaboration of such reports, most companies choose to report only economic and financial performance.

Figure 3. Relationship between performance, value and cost

Source: prepared by the authors

The problem is not new. More than ten years ago, Tilt and Lubansky [10] concluded that “the distribution of power in society allows individual groups (such as corporations) to ignore their obligations without penalty”. We consider that state involvement in this area is absolutely necessary.

In order to prevent a failure in the implementation of a system of performance measurement indicators, is absolutely necessary that managers have permanently in mind the needs of the company and its resources.

6. Conclusions

We consider that the use of modern indicators to assess performance does not entail giving up traditional indicators. These indicators can still be used but the company management must bear in mind that in order to achieve actual performance it is necessary to create value for shareholders.

In our opinion there is no single indicator that expresses the true performance of the company, because performance is a complex concept with multiple sides. Each indicator has its advantages and disadvantages. In order to assess performance, companies must use a set of indicators capturing performance in all its aspects.

The sustainable maintenance of any company on a competitive market cannot be achieved without the continuous concern for its performances, value and cost.

Performance measurement requires managers to consider that the concept of performance has many faces and the measurement should take into account the complexity and the peculiarities of the business activity.

The system of indicators designed to measure company performance has to offer a response to some challenges such as:

- reflecting not only economic and financial but also social and environmental performance;
- reflecting hidden costs and hidden performances of the company;
- measuring the value created for the shareholders;
- evaluating the risks assumed by the company in its attempts to obtain performance.

Regarding the modern indicators, it must be noticed that they are far from being the entire solution of the problem represented by performance measurement. The modern indicators were created in order to eliminate the inconveniences of traditional indicators, but trying to solve older problems, lose sight of others that became their own inconvenience.

Managerial decisions should be substantiated based on a set of reliable indicators able to provide the necessary information in at the right time. The quantity of information received by the manager should in excess. It should be metered to facilitate the management process.

Analyzing Banking Risk

Udrea Ionel

University of Craiova, Faculty of Economics and Business Administration
ionel.udrea@yahoo.com

Abstract

The banking activity focuses on achieving optimal results; however, like any other human activity, it is also susceptible to a broad range of risks.

Banking risk as a prospective and probable event whose onset is likely to inflict losses, can be induced by clients with whom the bank enters into contract agreements, by factors associated with the organization and the functioning of the bank's internal systems, by congruity issues between internal procedures and the general legal framework, as well as the environment in which banks operate.

Concisely, the wide range of risks associated with banking activities are caused by a series of variables brought about by the involvement of credit institutions within both local and international financial systems.

Keywords: banking risk, loss, banking activities, risk management, banking operations.

J.E.L. Classification:G29

1. Introduction

In any human activity, risk occurs in the form of an unwanted yet probable, either predictable or unpredictable event, which, depending on its magnitude, may cause financial losses or lead to failure to fulfil targeted goals.

Risk is defined as “an event with a negative effect upon the subject, the economic agent, respectively.”[1]

Generally, risk represents a social, economic, political or natural category with the following characteristics:

- it represents an uncertain, yet probable event;
- it represents an event that materializes into losses or failure to achieve targeted

profit;

- the effects of risk, once set in, may become difficult or impossible to eradicate;
- risk may occur within any area of human activity;

Banking activity as an integral part of human activity is liable to all kinds of risks, which grow in accordance to the rapid and highly frequent changes of social, economic, regulatory and technological factors.

2. Banking Risks

Banks play a crucial role within the framework of market economy. Economic activity and investments are unconceivable outside the scope of banks and that of the mechanisms of free economy. The entire activity of all the other economy actors is carried out through banks, which need to fulfil the following main functions:

- the function of acquiring excess resources available within the economy, by means of savings products;
- the function of mediating between economy actors that hold excess financial resources and place them in savings products, and the entities that suffer a deficit of financial resources thereby resorting to bank credits;
- the function of transferring funds within the economy.

Therefore, the main goal of banks is to attract deposits and other reimbursable funds from the public and to grant credits independently. [3]

Considering the importance of all these activities and the effects they have upon the entire economy, proper identification and assessment of underlying risks become crucial prerequisites.

Banking risk refers to “the entire range of risks which banks need to mitigate in order to carry out their current operations” [4].

Consequently, banking risk refers to the probability that a given transaction may fail

to yield its expected profit, or worse yet, to sustain a certain degree of loss. [5]

In light of that, the concept of risk becomes almost synonymous to the concept of loss, which is why identifying, assessing, monitoring and minimizing risks become crucial priorities in ensuring security and stability not only for individual banks, but for the entire banking system as well.

From this point of view, setting up an adequate system to mitigate risk scenarios requires thorough knowledge not only of banking activities, but also of the environment in which these activities are carried out, as well as of the beneficiaries of bank services and products.

The activity of identifying and managing risks is conceivable exclusively within the context of a proper evaluation of bank-specific internal activities.

Systematic analysis of banking activities requires proper identification of crucial activities, whose flaws or failures may hinder a credit institution's ability to fulfil its obligations stipulated in the regulatory framework, or even force that institution to discontinue its operations.

The process of identifying and assessing any risks related to crucial banking activities begins with a thorough analysis of internal factors (nature of the activity, flowchart, quality and complexity of processes, quality and complexity of systems, quality of the staff), as well as external factors (the local and international economic environments, technological progress, legal changes), which may amplify the effects of risk upon bank-specific activities.

The final step in the process of identifying and assessing risks is to identify controllable risks – which the bank may decide to arrogate or attempt to mitigate, depending on its strategies – and any uncontrollable risks within the scope of the bank, which the bank may decide to accept or eliminate by discontinuing any activities affected by those particular risks.

Monitoring risk begins by building a specific strategy, accounting for the bank's general strategy, the size of its funds, requirements of the regulation framework and the economic context in which that bank carries out its operations. Such a strategy should pinpoint all the major risks to the bank's activity, as well as establish

acceptable margins based on the bank's performance and the evolution of the banking and financial markets.

All these activities aimed at identifying, analyzing, assessing, monitoring and controlling banking risks are generally handled by an independent organism as part of the banking institution, whose objective is to track the levels of all major risks through means of analysis and control, so that the bank can fulfil its set goals at the projected level of profit while adhering to its own business strategy.

3. Classification of Banking Risks

Given the diversity and complexity of bank operations, banking risks can be classified into the following main categories [6]:

- financial risks,
- operational risks,
- business-specific risks,
- event-related risks.

3.1. Financial Risks

These highly intricate risks mainly refer to:

- liquidity risk,
- credit risk,
- market risk (interest rate risk, exchange rate risk, pricing risk).

3.1.1 Liquidity Risk

Liquidity risk refers to the risk brought about by inability of the bank to fulfil its obligations at maturity. Liquidity represents the ability of the bank to turn assets into cash in due time and with minimal expenditure so that it properly meets pending requests from business partners.

From this point of view, liquidity risk may refer to:

- inability by the credit institution to finance its asset stock on contract-established maturities and interest rates;
- impossibility by the bank to turn its assets into liquidities when needed and for a reasonable prices.

The main contributors to this risk are:

- the state of the real economy;
- media reports;
- inadequate development of the

financial market;

- client financial indiscipline;
- poor congruence between the maturity of deposits and due dates on credits and other bank products.

Identifying, assessing, monitoring and controlling liquidity risk mainly involve the following activities:

- in-depth analysis of acquired and placed funds;
- analysis of client behaviour and its impact on bank liquidity;
- assessing short-term, medium-term and long-term required liquidity size while accounting for records, seasonal factors, market evolution, legal rulings and payment behaviour of credit-holding clients;
- pinpointing liquidity-generating and liquidity-consuming elements.

3.1.2 Credit Risk

It occurs when a client of the bank, tied to a contract, is unable to fulfil his or her obligations in accordance to the conditions and deadlines stipulated in the contract, thereby causing the asset holder to sustain losses. These losses may be the result of bankruptcy, a temporary change in the market climate, or any other factors that may affect the debtor's payment capability. This risk is generally a consequence of incomplete payments, either on due date, or on any subsequently set date of payment. [9]

The credit risk is identified, assessed, monitored, controlled and arrogated by implementation at bank level of proper credit policies, which should account for at least three important chapters, such as:

a. A chapter addressing credit risk reduction, which should include prerequisites pertaining to:

- eligible clients,
- eligibility conditions,
- acceptable collateral,
- high exposures,
- adequate diversification of credit risk.

b. A chapter dedicated to asset classification principles (handled placements) to establish the rules regarding the assessment of the counterparts' reimbursing capability, both prior to credit granting and subsequently, on a regular basis.

c. A chapter addressing the policies for establishing provisions to cover for any

foreseen losses.

As far as credit institutions are concerned, credit risk arrogation is a process that involves going through a series of predefined stages to decide whether to approve or reject a client's credit request.

3.1.3. Market Risk

Market risk can be defined as the risk of loss or immobilization as a consequence of unfavourable evolution of market coverage.[10]

Considering the extremely tight bond between credit institutions and financial markets, these risks are believed to be very complex and likely to occur at any level of the banking activities. Under the category of market risks, interest rate and currency risks require the most attention.

Interest rate risk refers to the risk of sustaining losses or failure to yield targeted profits because of adverse interest rate changes within the financial market.

Identifying, assessing, monitoring and controlling interest rate risk requires completion of the following set of activities:

- selecting placements and fixed rate interest debts;
- identifying placements and interest rate sensitive debts;
- establishing an acceptable balance by the bank between interest rate risk and profit.

Exchange rate risk refers to the risk of financial losses or failure to yield targeted profits because of unfavourable fluctuations in the exchange rate.

Identifying, assessing, monitoring and controlling interest rate risk involves:

- identifying foreign currency assets and liabilities managed by the bank;
- identifying the currencies for which the bank is most liable;
- identifying the factors with greatest impact upon the evolution of the exchange rate;
- identifying the most adequate means of covering for the exchange rate risk;
- establishing an acceptable balance by the bank between exchange rate risk and profit.

3.2. Operational Risks

These represent a particular risk of loss determined by the employment of inadequate or inefficient processes, systems and human resources, or by external events and actions.[7]

Identifying, assessing, monitoring and controlling operational risk are aimed at insuring a series of processes, procedures and systems tailored to meet the level of complexity of the activities within a bank, as well as insuring human resources that possess the skill set needed to fulfil assigned tasks in an effective manner.

The category of operational risks includes the following events that negatively affect the credit institution:

- internal fraud – consists in damages caused by at least one individual within the bank that deliberately commits fraud, illegally seizes assets by infringing internal directives and laws, etc.;
- external fraud – consists in damages caused by theft, counterfeiting, etc.;
- staff recruitment and workplace safety policies and procedures;
- clients, products and services – refers to losses caused by transgressing obligations towards clients through misconduct or neglect;
- damages caused to physical assets owned by the credit institution following force majeure events;
- downtimes and/or improper functioning of the bank’s internal systems – damages caused by improper functioning of applications that handle bank activities;
- process execution, delivery and management – losses caused by non-compliance with operation processing and banking processes instructions or delays.

3.3. Business Risk

It refers to the current or future risk of profit or capital losses determined by changes within the business environment or by unfavourable business decisions, inadequate implementation of decisions or lack of reaction to changes within the business environment. [8]

This category of risk affects the environment in which a bank operates, comprising the economic environment, the political environment, as well as the payment infrastructure and the entire legal framework.

3.4. The Risk of Unwanted Events

This particular risk encompasses all the events that may jeopardize not only the yielding of predicted profits, but the entire spectrum of bank activities. Such events include, but are not limited to economic, financial, political crises, etc.

4. Conclusions

Thanks to the intensification of the crediting activity, bank activities had been expanding constantly until the mid 90s relying simply on the intermediation of attracted deposits, which shifted the focus towards management of deposit-related risks.

Over the last decade, however, bank activities have become increasingly sophisticated, fuelled by the rapid innovations in the financial markets, the internationalization of financial flow, technological progress and, on a marginal level, by the current financial crisis which raises new challenges to bank managers, challenges that can only be overcome by effectively reducing risk (in all its instances) to increase profitability.

Under these circumstances, and considering that bank-related activities by nature cannot be divorced from various forms of risk, the main object of financial management is to keep such risks well under control.

Radiography of The System of Credit Institutions in Romania

Udrea Ionel

University of Craiova, Faculty of Economics and Business Administration
ionel.udrea@yahoo.com

Abstract

The system of credit institutions provides for any national economy an instrument which ensures a good circulation of the money flow, as well as a fundamental means for the achievement of the balance between the supply and demand of monetary funds, both components of economic development. An overall characterization of the system of credit institutions in Romania must take into consideration its capacity to accomplish its main attributes, namely attracting funds from physical and juristic persons in the form of deposits and granting loans in terms of bank prudence, to those who are interested.

Keywords: banks; the credit cooperative organizations; the saving and crediting banks in the housing sector; banks of mortgage credit; institutions issuing electronic currency.

J.E.L. Classification:G29

Introduction

The importance of each component of the system of credit institutions and of their totality has entailed the society's interest in legislating it in order to provide real levers for testing the manner in which banking activities are carried out and consequently for setting out specific methods for achieving control within the banking system. [1]

System of credit institutions in Romania

The system of credit institutions in Romania can be defined as the totality of credit institutions, of all types, organized within the framework of regulation and supervision by the central bank.

Within a more extensive analysis, the system of credit institutions can be

considered as the totality of institutions functioning as banks, to which all the other authorized credit institutions, bank instruments and techniques will be added, as well as the regulations of banking activities. In view of the manner of operation and the activities they can accomplish, according to the authorization, we consider that the system of credit institutions consists on one hand of proper banks and on the other hand of the other credit institutions as they are defined by the regulations in force. In this context we can define the “bank” institution as the state-owned or private institution performing a banking activity of professional nature, for which it is authorized according to the law. Conformably to the legal provisions in force, the notion of banking activity refers but is not limited to attracting deposits or other reimbursable funds from the public and granting credits on its own account. [2]

In essence, the term of deposit as fundamental instrument of banking activities refers to a sum of money granted by a physical or juristic person to a credit institution on the following terms:

- that the sum be entirely repaid, with or without interest or any other facilities, at demand or at a time agreed by the depositor together with the trustee;
- that the deposit won't refer to transference of property, provision of services or conferring guarantees.

The notion of credit refers to any payment obligation for a sum of money in exchange for the right to a reimbursement of the paid sum, as well as the payment of an interest or of other expenses related to this amount or any other extension of the due date of a debt, and to any obligation of acquiring a bond which incorporates a debt or another right for the payment of a sum of money.

In order to determine if a crediting activity is carried out in a professional manner, the following points must be taken into consideration:

- performing the activity as an independent economic activity, aiming at obtaining regular income;

and

- the existence of internal structures specialized in the crediting field dealing with the management and analysis of this activity in a distinct manner, on the basis of pre-established rules and by taking into consideration the crediting activity for the planning of the company's budget or for making provisions regarding the company's general activity. The other credit institutions forming together with banks what is known as the system of credit institutions differ from banks in that they cannot carry out operations of attracting deposits or other reimbursable funds from the public as a professional activity. Taking into consideration that this field of economic activities has a fundamental role within the overall economic system, the conditions of access to these activities are strictly regulated, the carrying out of these activities being prohibited without a permit issued in this respect by the National Bank of Romania. On these grounds, it is stated that the system of credit institutions in Romania is a system organized on two levels, including on the first level the National Bank of Romania as a main factor of management of the monetary policy and on the second level the credit institutions with main object of activity consisting both in attracting funds from physical and juristic persons, as deposits or negotiable instruments, payable at sight or at term, as well as in granting credits and performing cash services in the case of banks, or granting credits inclusively the services due for their own members, crediting activities within the housing sector and the issue of electronic currency. The credit institutions represent the main financial medium of an economy, because according to the law they mainly represent entities carrying out the following activities of professional nature:

- a) attracting deposits or other reimbursable funds from the public and granting credits on their own account;

- b) issuing means of payment as electronic currency.

This definition achieves, in essence, an enumeration of the most important functions and operations of the credit institutions. Romania's EU accession and the adjustment

of the financial-banking legislation to the European norms caused within the internal legislative provisions the substitution of the syntagm of banking institution by the notion of credit institution. Moreover, the Government Emergency Ordinance 99/2006 regarding the credit institutions and the adjustment of the capital regulates the legal conditions of the credit institutions, including in this category:

- banks;

- the credit cooperative organizations;

- the saving and crediting banks in the housing sector;

- banks of mortgage credit;

- institutions issuing electronic currency.

A concise analysis of these categories of credit institutions allows us to point out significant differences among credit institutions regulated and supervised by the National Bank of Romania. In the specialized literature, the bank is defined as a state-owned or private financial credit institution also, its main roles consisting in:

attracting the temporarily

available financial means of the customers in accounts opened for them;

granting credits on various terms;

making transfers between customers' accounts and transfers between accounts opened at other banks;

issuing credit instruments and making transactions with such instruments;

sale and purchase of currency and other currency operations.

The legislative frame defines banks as the credit institutions that can carry out the following activities, within the limits set by the authorization they have been conferred [3]:

- a) attracting deposits and other reimbursable funds;

- b) granting credits, including, among other credits: consumer credits, mortgage, factoring with or without recession, financing of commercial transactions, including contractual ones;

- c) financial leasing;

- d) payment operations;

- e) issuing and managing means of payment, such as: credit cards, traveler's cheque and the like, including issue of electronic currency;

- f) issuing guarantees and assuming obligations;

g) transaction on their own's account and/or on customers' account, on terms of the law, with:

1. instruments of the money market, such as: cheques, drafts, promissory notes, deposit certificates;

2. currency;

3. futures contracts and financial options;

4. instruments based on the rate of exchange and the rate of interest;

5. real estates and other financial transferrable instruments;

h) participation in the issue of real estates and other financial instruments, by their subscription and investment or by investment and provision of services related to such issues;

i) consulting services regarding the structure of the capital, the business strategy and other aspects related to commercial transactions, services related to mergers and acquisitions and the provision of other consulting services;

j) management of portfolios and consulting services related to it;

k) custody and management of financial instruments;

l) brokerage on the interbank market;

m) delivery of services regarding the provision of data and references in the crediting field;

n) renting of safe-deposit boxes;

o) operations involving precious metals and gems and objects manufactured from them;

p) acquiring shares in the capital of other entities;

r) any other activities or services, if they are limited to the financial field, complying with the legal provisions which regulate the respective activities, depending on the case.

These are the activities which banking institutions in general can carry out, yet the impossibility of dividing these activities in all the above mentioned directions has entailed a certain specialization of them, thus the so-called specialized banks have emerged, which, in addition to the basic operations preponderantly carry out banking operations of a certain type or of a certain field. However, in view of the fact that a bank is an institution that has been given the right to make money transactions, its activity is subject to two great categories of regulations: on one hand we take into consideration the Statute of the National Bank of Romania

(law 312 of 28th of June 2004) and on the other hand the Government Emergency Ordinance 99 of 06.12.2006 regarding credit institutions and the adjustment of the capital, approved with amendments by the Law 227/2007 which represents the legal operation framework. The same general legislative framework is completed by the norms issued by the National Bank of Romania on the grounds of the attributions conferred by the law number 312/2004 and not least by the provisions of the constitutive act of banking companies and of norms and internal procedures.

Thus, taking into consideration the provisions of the Government Emergency Ordinance number 99/ 2006 with subsequent amendments, **the credit cooperative** represents the credit institution set up as an autonomous association of physical persons voluntarily joined together to accomplish their needs and common aspirations of economic, social and cultural nature, its activity being particularly carried out on the grounds of mutual aid for its cooperating members. [5] We can thus determine as a defining characteristic of these credit institutions the fact that they are set up as a voluntary association of physical persons and that the banking activity within the credit cooperatives is carried out especially with and for the cooperating members. For all that, the law does not completely prohibit the provision of banking activities for other persons besides the cooperating members. In view of the above mentioned aspects we consider that the area of activities allowed for the credit cooperatives should be limited due to the fact that the essential purpose of these institutions is the mutual aid, especially for the cooperating members.

The saving and crediting banks within the housing sector represent credit institutions specialized in the long-term financing of the housing sector, with the main object of activity consisting in saving and crediting in a collective system for the housing sector.

In other words, the activity of these credit institutions is based on the essential element of saving and only subsequently on crediting. In conclusion, we can consider that these institutions carry out activities that are similar to those of usual banks, save for the

fact that they are limited to crediting within the housing sector.

Mortgage banks are, according to the legislative provisions in force, credit institutions with main object of activity consisting in granting mortgage for real investments and for attracting reimbursable funds from the public by issuing mortgage debentures. Under these circumstances, the essential element of the activity of mortgage banks consists in attracting and investing the resources on the basis of a mortgage guarantee, while not being entitled by the law to attract deposits from the population.

The institutions issuing electronic currency are credit institutions specialized in issuing electronic currency and respectively, providing financial and non-financial services related to the activity of issuing electronic currency and providing services of storing information on electronic medium on behalf of certain public institutions or other entities. In other words, the institutions issuing electronic currency can attract funds but only for the purpose of issuing electronic currency.

The non-banking financial institutions are entities, other than credit institutions, which carry out crediting activities of professional nature, complying with the conditions established by the law, being able to perform the following crediting activities:

a) granting credits, including but not being limited to: consumer credits, mortgage, real credits, microcredits, financing of commercial transactions, factoring operations, discount operations;

b) financial leasing;

c) issuing guarantees, assuming of guaranteeing obligations, assuming of financing obligations;

d) granting credits with reception of goods as pledge, respectively pawning by pawn shops;

e) granting credits to members of associations with no patrimonial object, set up on the basis of free consent of employees/pensioners, with a view to supporting their members by financial loans granted by these entities, set up under the legal form of mutual insurance;

other forms of financing of the crediting nature.

In essence, the syntagm of non-banking financial institutions includes the consumer

credit companies, the financial leasing companies, the mortgage companies or pawn shops or mutual insurances. In actual fact, the non-banking financial institutions are like banks, which cannot attract however deposits or other reimbursable sources from the public. The financing sources result from individual resources or are borrowed from other credit institutions, from other financial institutions or, depending on the case, from other sources provided by the legal regulations in force. In consideration of the transposing and implementation within the national legislation of the Norm 2007/64/CE of the European Parliament and of the Council, of 13th of November 2007 regarding the payment services within the home market, the Government Emergency Ordinance number 113 /12.10.2009 was passed, regulating the conditions of access to the activity of providing **payment services and of its implementation on the Romanian territory**, the prudential control of payment institutions as well as the norms regarding transparency for the conditions and requirements for information with regard to payment services, the proper rights and obligations of users of payment services and of providers of payment services in the context of providing payment services of professional nature. This emergency ordinance applies to services provided by the following categories of providers of payment services:

a) credit institutions in the sense of article 7 paragraph (1) point 10 letter a) of Government Emergency Ordinance number 99/2006 regarding credit institutions and the adjustment of the capital, approved with amendments and supplements by the Law number 227/2007, with subsequent amendments and supplements;

b) institutions issuing electronic currency in the sense of article 7 paragraph (1) point 10 letter b) of the Government Emergency Ordinance number 99/2006, approved with amendments and supplements by the Law number 227/2007, with subsequent amendments and supplements;

c) providers of giro mail services who provide payment services according to the applicable national legislative framework;

d) payment institutions;

e) the European Central Bank and the national central banks, when they do not act

as monetary authorities or as other entities involving exercise of public authority;

f) the member states or their regional or local authorities, when they do not exercise their function of public authorities.

The payment services which can be provided by authorized institutions, in the context of the previously stated law are the following:

a) services allowing depositing cash in an account of payments, as well as all transactions necessary for the operation of the account of payments;

b) services which allow cash withdrawals from an account of payments, as well as all other transactions necessary for the operation of the account of payments;

c) performing the following payment operations when the funds are not covered by a line of credit: direct debit, including singular direct debit, payment operations using a card of payments or a similar instrument, operations of transfer-credit, including operations with scheduled payment order;

d) performing the following payment operations when the funds are covered by a line of credit opened for a user of the payment services: direct debit, including singular direct debit, payment operations using a card of payments or a similar instrument, operations of transfer-credit, including operations with scheduled payment order;

e) issuing payment instruments and/or acquiring payment transactions;

f) money remittance;

g) performing payment operations where the payer's consent for the provision of a payment operation is given by any means of telecommunication, digital or computerized means, and the payment is effected to the operator of the computerized or telecommunication system or network, who acts exclusively as an agent between the user of payment services and the provider of goods and services.

Conclusions

As a conclusion we can state that, to a great or to a less extent, according to the conferred authorization, each of the institutions presented above can carry out one or more activities which are limited to

banking activities. They have characteristics which essentially differentiate them from the proper banks, operating on a certain market niche and applying to certain categories of specific customers.

The Economical and Ecological Importance of the Environmental Impact Assessment

Ungureanu Mihaela

“Alexandru Ioan Cuza” University of Iasi,
Faculty of Economics and Business Administration
myhaella5@gmail.com

Abstract

Balancing human needs of the immediate future with those of the distant future has led to the concept of sustainability, understood by the fact that economic activities should not be extended over the ability of total capital – including natural one –, keeping a stock of capital being a safe measure to ensure increasing sustainable benefits.

The world of business has learned that a primary purpose of obtaining short-term financial benefits, despite the sustainable benefits to maintain economic balance by even the ecological balance. Sustainability of resources ensures business continuity and hence the possibility of long-term gains. Even if their value varies in the short term, it is important to obtain their safety also in the future.

Keywords: environment, performance, EMS, EIA.

JEL Classification: M42, Q51, Q56

Introduction

Natural environmental degradation issues are increasingly globally addressed, particularly through the implementation of some collective actions. In 1972 at the Stockholm Conference were discussed factors that endanger the natural environment and its conservation needs. Following the discussions have resulted as possible solutions:

- *Stockholm Declaration;*
- *Action Plan* with three components:
 - global environmental assessment program (Earthwatch);
 - environmental management activities;
 - support measures.

These are considered the basis of the first international framework for treating environmental problems. *Principle 13* (of the 26 principles of the Declaration) provides that for a more rational management of resources, which to lead to an improved environment, states should adopt an integrated and coordinated approach of their development plans to ensure that their development is compatible with the need to protect and improve the environment for the benefit of populations [3].

The efforts reorientation necessity for achieving the integration objective has materialized after eleven years after that event, in 1983, when the United Nations established the World Commission on Environment and Development, known as the Brundtland Commission. This committee has developed and published in 1987, after the ecological disaster at Chernobyl, the document *Our Common Future (Brundtland Report)*, which was formulated within the next occurrence of Agenda 21 and the 27 principles of the Rio Declaration and which defined the sustainable development as the development that meets the needs of present generations without compromising the ability of future generations to meet their own needs. Two years later, UNEP (United Nations Environmental Programme) organized a workshop on environmental auditing [4].

In June 1992, in Rio de Janeiro was held the United Nations Conference on Environment and Development, which gathered the representatives of the most important countries. On that occasion, internationally, has been officially recognized the need to integrate economic development and environmental protection objective of sustainable development.

In 1997 was made an assessment of progress into the five years after the Rio

Conference, as highlighted a number of shortcomings, mostly related to social equity and poverty. These aspects were evidenced by:

- reduction of official assistance granted for development and increasing international debt;
- failure to improve technology transfer;
- institutional coordination failure and inability to reduce excessive levels of production and consumption.

As a result, was called for the ratification reinforcement and a stronger implementation of international agreements and conventions on environment and development.

The United Nations Summit on Sustainable Development held in Johannesburg from 26 August to 6 September 2002, reaffirmed sustainability as a central element of the international agenda and gave new impetus to implement comprehensive measures against poverty and the destruction of nature. Through the *Johannesburg Declaration* was assumed a collective responsibility to advance and reinforcement of the three interrelated pillars of sustainable development: economic, social and environmental development at local, national, regional and global levels [3].

1. Natural capital in the economic life

Natural capital represents a source of economic welfare and conservation of its resources is in fact providing benefits for entrepreneurs. If natural assets are not valued, just as those recorded in accounting accounts, this is directly reflected on the financial position and performance of enterprise. At the same time, in addition to their own needs, companies can help to support sustainable development, meeting obligations to future generations [7].

The American professor Lester Brown, who founded in 1974 the World Watch Institute, says in his manifesto *Ecoeconomia* that processes such as deforestation, over-exploitation of groundwater, favors the current yields but compromise productivity on long term.

Introducing the real value of natural capital and its consumption, contributes to a more accurate setting priorities, eliminating the major causes of environmental problems such as overexploitation of forests. As

traditional accounts are using accounting policies, subtracting amortization of assets to calculate income, so should be treated also the forests. If trees could be exploited in a way that allows a continuous growth rate, they would produce an annual income. Otherwise, an excessive exploitation, with no chance of regeneration, should be treated by accountancy as an impairment a fixed assets. For example, if into a region are two sawmills that cut in a short time the whole forest they have access to, the resulting production will bring the profits hoped. But, without complying with some criteria for rational exploitation, without reforestation actions to fill gaps left, the next production cycle will be compromised. Thus, it becomes necessary to seek new resources to resort to intermediaries, that will increase the existing costs. In these conditions, the profitability will decrease and will be impose measures such as increased selling prices, reduced wages or even staff, etc. Entrepreneurs will be pleased even with some earnings decreased, the survival on market will became their main propose. Is notes the risk that such a situation it requires on the continuity. Concluding this example, we can say that protecting natural capital shall ensure the future resources, obtaining economic benefits and most importantly, providing continuity in the market [5].

Assessing the costs of maintaining natural capital becomes more necessary as the main feature of the economic transformation is the irreversibility.

In 2008 he published a study entitled *Economics of Ecosystems and Biodiversity* (TEEB) initiated and funded by the European Commission in cooperation with Germany and other partners, which has been presented in Brussels. It sought an overall estimate of assessing the annual loss of ecosystem services to 50 billion euros. It is estimated that, in the absence of measures, affecting biodiversity could cost the European Union 7% of GDP by 2050, that would add more damage of the marine ecosystem. Thus it was proposed an economic assessment of ecosystem services and the value obtained being taken into account in all decision making levels [3].

Under certain scenarios, if the world's population would double by 2050 compared to 2000, GDP per inhabitant will increase by

2.5 times, but at the same time the demand for food would triple, energy consumption will increase by 2.6 times and water consumption by 1.5-2 times. Domain specialists show that if the growing trend of population, economy and consumption rate will continue as until now, the environment will be overloaded, which will more and more destroy the natural resources, implicitly life.

2. Environmental management system: certification and implementation

The evolution of concepts concerning the relationship between socio-economic and environmental activities in the context of sustainable development principles was made in two directions [2]:

➤ the first direction, comprising binding agents to achieve socio-economic development of opinions, agreements, permits operation with the authorities in relation to the environmental protection. In this situation the forms for assessing the environmental impacts are regulated by national environmental framework legislation and detailed secondary legislation and national tertiary in the field;

➤ the second direction of a voluntary nature, through the socioeconomic agents, stimulated by some potential advantages, is committed to increase environmental performance. In this case the environmental impact assessment forms are covered by the named standards (ISO 14000 and EMAS) with a European or international recognition.

Basic regulations of environmental management are made available to practitioners but the ISO 14000 series of international standards. Among these most are operated, published since 1996, others are in the planning stage. ISO 14000 standards cover a range of five directions [1]:

- environmental management systems;
- eco-audit;
- eco-marking;
- evaluate environmental performance;
- life cycle assessment of products and services.

A prerequisite for the functionality of such a system is the establishment of a scheme of documents consisting in procedures and instructions, prepared to be permanently implemented to ensure an

effective and efficient communication. EMS provides a structured approach to planning and implementation of environmental protection measures that allow all entities to measure performance in relation to the environment and to periodically evaluate the improvements made by its protective measures. EMS scope can be extended at company level or at a site in accordance with recognized standards:

- ISO 14001 international standard;
- EMAS.

The enterprises have also the freedom to develop their own EMS, for their own activities, which do not necessarily have to be certified by international standards.

Establishing the procedure for organizing and coordinating the environmental management system was achieved for [2]:

- introduction in organizations carrying out activities with environmental impact a management and environmental system;
- evaluating and improving the environmental performance of organizations;
- providing environmental information to the public and other stakeholders outside the organization.

The objective of EMAS, to continuously improve the environmental performance of organizations is accomplished by [3]:

- development and implementation by organizations of environmental management systems according to ISO 14001;
- the systematic, objective and periodic evaluation of these systems performance according to ISO 14001;
- providing information on environmental performance and maintain a dialogue with the public and other stakeholders outside the organization;
- active involvement of employees in the organization and into their own training, adequate initial and advanced, enabling active participation in the development and implementation of environmental management systems.

The amount of decisions affected by the costs of interaction with natural environment is increasing, so that such a system becomes increasingly important, not only into environmental management as well as for other management activities such as designing processes and products, allocation and control of costs, supply process, price and performance evaluation policies.

3. Environmental Impact Assessment and specific indicators

A component of the sustainable development concept is to control the environmental impact of socio-economic activities. Controlling the impact requires detailed knowledge of the phenomenon, which involves the stages of identification, estimation, evaluation etc. Is what is intended by the general concept of Environmental Impact Assessment (EIA) [4].

At the level of international law are promoted, by the ISO 14000 series, the environmental management system or some other national legislation and concepts, including:

- eco-audit;
- life cycle analysis;
- evaluate environmental performance.

The type of used risk assessment depends on the nature and scope of the study, the amount of data available and other factors. Also the detail degree of risk assessment may vary from a simple qualitative to a semi-qualitative analyzes an and even entirely quantitative risk assessments.

Should be noted that EIA is not just about the primary indicators that describe the quality or the environment; they are analyzed in correlation with indicators that characterize the economic and social effects of pollution. In this case the principle that is used to estimate the cost is that of evaluation the cost of bringing the affected area to the situation prior to pollution or the cost necessary to prevent pollution.

Inserting an economic dimension to analyze pollution of the natural environment is difficult due to the great diversity of situations, but it can become operational for some specific cases and particular aspects. Cost of pollution can be divided into four categories [7]:

- damage cost, or the cost of direct losses (crops destroyed, occupational diseases, etc.);
- avoidance cost, i.e. economic and social cost of avoiding damages (air filtration equipment, protective equipment etc.);
- attenuation cost, i.e. the cost of resources needed to mitigate pollution and their inclusion in standards;

- tracking cost, the cost or resources required to design, planning, monitoring and controlling pollution.

Estimating these costs can provide an overall assessment of the pollution and only their fully treatment is able to reveal the real extent of pollution.

Environmental risk assessment is a scientific method for evaluation of risks associated to substances, activities, lifestyles and dangerous natural phenomena that may have detrimental effects to the environment or human health. In this respect, a distinction is made between the terms of:

- *hazard* – the possibility of consequences of an event or combination of circumstances that can harm human health and/or environment (for exempu, transport of oil by sea in tankers);
- *risk* – the probability of producing a specific effect in a given time and under given circumstances, or combination of consequences coupled with the likelihood of consequences.

Risk assessment area covers [1]:

- health and safety risk assessment (social risks caused by hazardous industrial activities);
- contaminated land risk assessment (risks to humans, ecosystems, property);
- pollution risk assessment (aquatic ecosystems, terrestrial and aerial);
- risk assessment of natural disasters (floods, earthquakes, volcanic eruptions).

The following table (Table no. 1) presents a summary of the stages to be taken in a chariot impact assessment of economic activities on the natural environment.

Table no. 1 – Stages of the EIA

No. crt.	Stages	Content
1.	Preliminary analysis	- setting objectives (identification, selection); - description of the study's objective; - EIA limitation.
2.	Identifying the effects	- analysis of the system and sub-systems generating impact; - analysis of the impact areas; - describe the impact effects.
3.	Estimating the effects	- estimating the size and importance of effects; - analysis the probability of showing the effects.
4.	Assessment of the effects	- defining the list of effects that can be assessed; - assessing the effects of various sectoral and global sets of criteria.

5.	Design actions and strategies	- identify actions to mitigate negative effects; - identify actions to stimulate positive effects; - evaluation of actions with alternative sets of criteria; - the design of action strategies (stage funds).
6.	Comprehensive assessment and action plan proposal	- timescale, budgets, responsibilities.
7.	Communication and dissemination of results	- social inquiry; - collection, selection, comments and suggestions.
8.	Completion and submission to factors decision	- tracking the effects.

The first step in analyzing an eco economic system in order to assess the state of the environment is to identify indicators that characterize the system. This identification process is difficult and its success ultimately depends on the experience of the analysts involved.

In general, for the overall environmental assessment both from an both ecological and socio-economic perspective, the indicators can be group in:

- environmental or ecological indicators;
- socio-economic indicators.

Ecological indicators can be grouped either in environmental factors (water, air, fauna, flora, etc.), or certain types of subsystems identified in the system. These types of subsystems (subsystem climate, terrestrial subsystems, sub-aquatic) depend on the type of proposed human activity and represent *second level indicators*. Selecting indicators must also take into account the degree of disturbance that can be tolerated and the type of options that remain open for a future use of these natural resources potential [5].

Should be considered certain elements strictly relating to feasibility of evaluation activity, including [3]:

- the cost of environmental impact assessment;
- preliminary duration of the study;
- the required database;
- the necessary training level;
- methodological complexity.

So that such an evaluation to be effective it is necessary to establish limits for investigating both the expansion and the deepening, which allows targeting to achieve significant results.

Conclusions

Environmental management system and, more recently, quality management system as defined in ISO 19011, provides information on how the management of an organization complies with all regulations, practices, procedures, internal organizational elements specific environmental issues. It aims to establish managerial and operational performance of the unit in relation to the environment.

The Environmental Impact Assessment is a scientific method for evaluating the natural risks associated to substances, activities, lifestyles and dangerous natural phenomena that may have detrimental effects to the environment or human health. EIA is not just about the primary indicators that describe the quality of the environment; also it requires an analysis about the correlation with the indicators that characterize the economic and social effects of pollution.

An Answer to the Need for Businesses’ Compliance with Green Demands – ECO-AUDIT

Ungureanu Mihaela

“Alexandru Ioan Cuza” University of Iasi,
Faculty of Economics and Business Administration
myhaella5@gmail.com

Abstract

Integration of environmental policy objectives in middle of economic activities involves changing patterns of production and consumption. This change can be done by regulations, taxation, judicial decisions, demands from public etc. Involvement must come not only from the authorities and civil society, but also from economic environment implied.

Environmental audit represents a stage in the voluntary diagram of management and environmental auditing, based on a harmonized EU scheme called EMAS (Eco-Management and Audit Scheme). Eco-audit represents a response to the need for monitoring and control the impact of economic activities on the natural environment.

Keywords: eco-audit, environment, environmental auditor, EMAS.

JEL Classification: M42, Q51, Q56

Introduction

The economic practice has shown that speculative businesses are leading to tensions in relationship with social and natural environment, resulting in even endangering of the continuity. Economic prosperity can not exist without respect and concern for people, environment or community as a whole. Reporting social behavior of the company in a similar annual reporting of financial matters, supports the establishment of a social report (corporate social reporting) between the entity and the community to which it belongs.

Environmental protection expresses all the actions taken under internal and external regulations of the company, whether

voluntary or compulsory. The compliance criterion is not an economical one, but is intended to prevent or reduce environmental impact [3].

The efforts reorientation necessity for achieving the integration objective has materialized after eleven years after that event, in 1983, when the United Nations established the World Commission on Environment and Development, known as the Brundtland Commission. This committee has developed and published in 1987, after the ecological disaster at Chernobyl, the document *Our Common Future (Brundtland Report)*, which was formulated within the next occurrence of Agenda 21 and the 27 principles of the Rio Declaration and which defined the sustainable development as the development that meets the needs of present generations without compromising the ability of future generations to meet their own needs. Two years later, UNEP (United Nations Environmental Programme) organized a workshop on environmental auditing [7].

1. Eco-audit or environmental audit

The last years have been the period in which the eco-audit has consolidated its position as a voluntary instrument of self control of environmental management within an entity.

Eco-audit is an objective analysis multidisciplinary method of an enterprise performance of an undertaking in relation to the environment in which it operates. Audit covers manufacturing processes, materials storage mode, operating procedures and environmental management and aims to identify potential environmental impacts and liabilities arising thereof. More specifically, eco-audit is a methodical and documented verification process of evidence obtained and

evaluated objectively to determine whether the activities, events, conditions, environmental management system, or information related to these problems are in accordance with audit criteria, the results being communicated to the beneficiary. Typically, such an audit aims to facilitate management control of practices and possible environmental impact assessment of the policy environment, including environmental objectives and targets of the organization [4].

ISO 14010 defines this concept as a methodical and documented verification process of the audit evidence obtained and evaluated in an objective manner to determine whether the activities, events, conditions, the environmental management system and related information are in the accordance with audit criteria.

Improving the legislative framework for environmental protection had as result implementation of certain principles for damages recovery, such as the “polluter pays” and other economic principles regarding pollution. Environmental audit differs from other techniques for assessing environmental impact, having as main objectives [5]:

- evaluating if the ecological systems and equipments are operating at design parameters in accordance with the requirements of maintaining natural equilibriums;
- assess the fulfillment of company policy and regulations on environmental restrictions;
- assessing compliance with the laws and regulations established at national, regional and global level;
- reducing human exposure to the effects of environmental degradation.

The eco-audit of the organization defines in writing the objectives of each audit or audit cycle including the audit frequency for each activity. The purpose of each audit or each stage in the audit cycle, as appropriate, shall define and explicitly specify [1]:

- covered areas;
- audited activities;
- environmental criteria to be considered;
- the period covered by the audit.

Eco-audit includes analysis of factual data necessary to evaluate the environmental performance of the organization.

Advantages of the eco-audit consist in [5]:

- helps protect the natural environment;
- allows monitoring compliance with the rules in the field;
- helps to identify current or potential environmental problems;
- reduces risks of disputes, accidents as result of damages to the environment;
- allows the identification of opportunities for achieving certain savings through actions such as reducing waste volume;
- facilitates the exchange of comparative information between enterprises.

According to context of assessing environmental performance of an activity, the literature is noting three main types of eco-audit [4]:

- eco-audit prior purchase;
- eco-audit prior sale;
- transversal eco-audit.

The audit itself must be preceded by an environmental review outlining the forms of economic and social activity’s impact on the environment. Each audit is planned and prepared in accordance with the objectives, in particular to ensure:

- appropriate allocation of resources;
- assuming the role and responsibility of each person involved in the audit process (including auditors, management and staff).

Preparing for audit should include familiarization with the organization’s work and environmental management system established within the organization and evaluation of results and conclusions of previous audits.

Audit activities shall include [2]:

- discussions with staff;
- inspection of the equipment and operating conditions;
- analyzing records, written procedures and other relevant documentation in order to assess the environmental performance of the activity being audited and to determine whether:
 - meet the standards, regulations, objectives and targets;
 - the existing management system of environmental responsibilities is appropriate.

The practice of this domain develops five main types of eco-audit, each with their own ends, as shown in Table no. 1 [6].

Tabel no. 1 – The main types of eco-audit

Types of eco-audit	Aims pursued
Contaminated land audit	- identify responsibilities for contamination of soil and water in the area of a site or building; - determining the costs / benefits incurred; - establishing authority and sanctions.
Ownership transfer audit	- identify risks and responsibilities associated; - analysis of previous compliance.
Compliance audit	- analysis of current activities; - assess how they comply with the requirements of national regulations.
Environmental management system audit	- systematic analysis of the existing EMS; - testing and certifying compliance with ISO 14001; - ensuring a continuous operation.
Environmental management plans audit	- analysis of implementation of measures to reduce the effects on the natural environment; - monitoring the occurred effects.

Source: Ungureanu M., “Role of environmental audit in the modern enterprise”, *Annals of Tibiscus University of Timișoara, Economic Science Series, Vol. XVIII, pp. 88-96, Editura Mirton, 2012.*

In certain circumstances, the audit types listed above can be combined. Detailed coverage sphere of audit varies according to specific objectives. Depending on the purpose of the audit, it can be done by specialists or independent consultants or persons with appropriate training, personnel belonging to the company or department subject to audit.

Among others should be also used random checks to determine effectiveness of the entire management system. The audit shall include at least the following steps [1]:

- familiarity with management systems;
- assessing strengths and weaknesses of the management systems;
- obtaining relevant evidence;
- evaluating audit findings;
- preparing audit conclusions;
- reporting audit findings and conclusions.

The audit or audit cycle is carried out, if necessary, every three years. The frequency with which any activity is audited will vary depending on:

- nature, scale and complexity of activities;
- relevance of associated environmental impacts;
- importance and priority of the problems detected by previous audits;
- history of environmental problems.

Complex activities with significant environmental impact should be audited more frequently. Organizations define their own audit programs and the frequency is taking into account guidance issued by the Advisory Committee EMAS.

2. Environmental auditor – a new profession in the modern business world

Eco-audits are performed by persons or groups of persons with experience in the audited areas and sectors, with relevant knowledge and experience including environmental, managerial, technical and legal and audit preparation and skills required to achieve objectives. Resources and time allocated to the audit are consistent with the goals and objectives. The organization's top management shall assist the audit process. According to purpose of the audit, it can be performed by independent consultants or experts or people with appropriate training, belonging to the personnel of enterprise or department submitted to audit [6].

Auditors should be independent of the activities they audit to make an objective and impartial evaluation. Accreditation bodies may accredit as environmental auditors persons, organizations or combinations thereof. Detailed procedural requirements and criteria for accreditation are defined and established by the accreditation body in accordance with the general principles of competence.

As a minimum requirement for such accreditation, may be listed the following skills that an environmental auditor must meet [5]:

- knowing and understanding the general functioning of environmental management systems, relevant standards and guidelines issued by the Advisory Committee EMAS and the accreditation body;

- knowing and understanding the legislative, regulatory and administrative requirements relevant to the activity under review;

- knowing and understanding environmental issues, including their size in the context of sustainable development;

- knowing and understanding the technical aspects relevant to environmental issues activity subject to verification;

- understanding the overall functioning of the activity subject to verification, to assess whether the management system is appropriate;

- knowing and understanding the eco-audit requirements and methodology;

- possession of knowledge about informational audit according to the environmental report.

Each candidate must demonstrate to the accreditation body the knowledge, relevant experience and technical capacities in the areas mentioned above.

An environmental auditor must have documented procedures and methodologies, including quality control mechanisms and confidentiality provisions for verification requirements. After consulting with the organization, he establishes a program to ensure that all elements required for registration with EMAS are verified in a period not exceeding 36 months. Information required by an environmental auditor are the ones from the entity’s environmental report.

The auditor should ensure that the organization and its staff are not subject to any financial constraints, commercial or otherwise, which might influence their judgment or could damage trust in their independence of judgment and integrity in relation to their activities and to comply with all applicable rules in this area [5].

At the end of each environmental audit, auditors must prepare a written report, whose form and content must provide a full and formal presentation of all audit findings and conclusions to be officially communicated to the management at the highest level. This report provides an overview of the activities carried out in a company or institution, the main effects on the natural environment, the environmental context in which it operates and environmental program objectives. For

each activity are reported the results of the environmental audit [4].

Fundamental objectives of a written audit report are:

- documents supporting the purpose of the audit;

- situation of compliance with the organization's environmental policy and environmental progress of the organization;

- providing to the management information about the effectiveness and accuracy of monitoring the environmental impact of the organization;

- documents supporting the need for corrective action, as appropriate.

The structure of the eco-audit report is generally seen, but may change depending on the specifics of each organization checked. Thus, in general, an eco-audit report has the following structure (Table no. 2):

Tabel no. 2 – The structure of the eco-audit report

I. GENERAL DATA	Name of activity
	Location
	Beneficiary of the study
	Activity profile
	Holder of study
II. DESCRIPTION OF THE ACTIVITIES	Purpose and necessity
	Authorizations owned
	Description of proposed activities
	Industrial processes involved
	Quality of environmental factors
III. CONCLUSIONS AND PROPOSALS	Environmental Impact Assessment

Eco-audit measures the environmental performance and environmental entity's position. In this way, the eco-audit provides a function similar to the financial one. An eco-audit report contains, ideally, a statement of environmental performance and environmental entity’s position and can also determine what needs are to sustain and improve the performance and position indicators. It specifies the requirements for an environmental management system, delivering an organization’s control framework fo the impacts of activities, products and services on the environment.

Conclusions

Eco-audit refers to an examination of how the activity has or has not a negative impact on the environment, although the specific elements of such an analysis; this analysis is based on an order for a specific customer who wants to be aware of of an organization's environmental issues.

Environmental management system audit and, more recently, quality management system audit as defined in ISO 19011, provides information on how the management of an organization complies with all regulations, practices, procedures, internal organizational elements specific environmental issues. It aims to establish managerial and operational performance of the unit in relation to the environment.

Eco-audit activities will identify whether an EMS is properly implemented, efficiently maintained and if provides useful information to management. Environmental risk assessment depends on the nature and scope of the study, the amount of available data and other factors. Also, the manner of the assessment can vary from a simple qualitative analysis, to semiquantitative analysis and even to a purely quantitative assessment.

Rational consumption of natural resources is, in terms of accounting, primarily to reduce costs, increase the value of intangible assets, reputation, organizational culture, even human capital when it is considering the health of employees in particular and of the community in general. Involvement must come not only from the authorities and civil society, but also from economic environment involved. Eco-audit represents a response to the need for monitoring and control the impact of economic activities on the natural environment. Thus, implementation and expansion of environmental audit beyond the need to align with EU legislation represent a factor to achieve the overall performance of an entity (by economic, social and environmental objectives), including benefits to be achieved on medium and long term.

Performance Analysis on Intermediary Balance Management Panel

Ungureanu Sebastian

Doctoral School of Economics, Alexandru Ioan Cuza University, Iași,

sebastian_ungureanu2000@yahoo.com

Abstract

The research focused on the use of an indicator system that allowed diagnostics company activity on the situation past, present and future. Stages of analysis consisted of data collection on the Company's business, examining financial information taken from the profit and loss of business making a diagnosis based on cause - effect relationship and take action to achieve superior performance in the future.

Thus, an analysis of the level and structure of turnover, production year and added value financial performance indicators relevant for establishing the financial performances and guiding the company's development strategy.

Keywords: intermediate management balances, added value

JEL classification: C50, M40, M41.

Introduction

In market economy conditions frequently occur changes in the number and structure of economic entities. Being in competition, the issue of comparing them, especially when it comes to external growth operations, the participation of a new partner or shareholder capital, fixing the insurance or guarantees for loans requested, unachievable goals in the absence of an annual financial statements that give a true and comprehensive global picture of the entity and the transactions in which they participate, based on relevant and reliable accounting information.

Getting information is not confined to recording data on phenomena and processes subject knowledge, but also includes all operations of information systematization, processing, analysis and interpretation. In present, problems of modern management

involve the use methods and models, mainly statistical and mathematical (econometric) through which to obtain relevant indicators, for financial performance establishment and the company's development strategy guidance.

The intermediate management balances is a variant of the account's profit and loss. This shows the stages of making a financial training result.

These stocks, defined as margin (difference) can be divided into two categories: - SIG – Activity;
- SIG – Profitability.

SIG – Activity, measures the level of operating activity (turnover, margin trading, production year, added value) and the use of material, financial and human resources in the business, while *SIG - profitability*, measured 'financial soundness of the business' through flow results achieved during the financial year.

SIG - activity characterizes economic performance while *SIG - profitability* characterizes the financial performance of the company. [1]

Analysis of intermediate management balances on the operating activities of the company

From the point of view of economic analysis, intermediate management balances characteristic for exploitation are indicators of production and marketing aggregating all business results, materialized in finished goods, semi-products, benefits, intended for market or use for their own interests, which are fixed by enterprise. [1]

Schematic SIG - activity presents data from the profit and loss account of SC AEROSTAR S.A. Bacău and is presented in Table no 1.

Table no.1. Intermediate management balances –S.C. AEROSTAR S.A. Bacău activity

Source of data: <http://www.aerostar.ro/> (own interpretation)

From the data in Table no.1 were found the following:

All the intermediate management balances on operating activities increased in 2011 compared to 2010 and in 2010 compared to 2009. Turnover recorded an 0.94% upward trend in 2010 compared with 2009 due to increased of sold production with 1.29%, an increase in 2011 compared to 2010 by 0.07% due to increased of sold production with 0.08%, even if the income from the goods have been continuously decreasing.

In all three years analyzed, the highest share in turnover is hold by the sold production, reflecting the major contribution to the formation of turnover.

The increased production year by 1.27% in 2010 compared to 2009 was a result of the increased sold production by 1.29% and the production for its own purposes and capitalized by 70.29%, and moreover the increased production year by 0,14% in 2011 compared to 2010 was a result of increased sold production by 0.08%, output in its own purposes and capitalized registering a fall of 38.22%.

Added value increased year over year primarily due to lower intermediate

consumption, which is observed in the last two years analyzed.

This increase in added value compared to turnover and production year is favorable characterizing the economic activity of the enterprise.

Turnover analysis

Turnover is the main indicator that measures the level of income, is at the same time one of the most important goals of any enterprise. The calculation of turnover is:
 $CA = \text{sold production} + \text{Income from sale of goods} - \text{Trade discounts granted} + \text{Income from interest recorded by the entities in ongoing leases} + \text{Income from subsidies related to turnover}.$

Turnover is an indicator of economic performance, which characterize the volume of business conducted with third parties after the current activity of the company and represents the total amount of revenue from the sale of products, works and services and other operating income, less rebates, remises and other discounts applied to customers.

Turnover is an indicator of volume, but when seeking it's dynamic becomes performance indicator. [2]

Turnover must have a minimum share of 85% of total operating income and 75% of total revenues of the company so that they reflect a normal achievement of business.

Turnover of the company SC Aerostar S.A. Bacau is income from repair and upgrade services, support services and engineering, for platforms in the portfolio or expertise, as well as from the manufacture of assemblies and aerostructures parts, manufacture of landing gear, hydraulic components and systems and commercial aircraft maintenance services.

The level and structure of turnover

The turnover should cover operating costs and provide a benefit realization and present a real growth trend in the volume of the company’s businesses. [3]

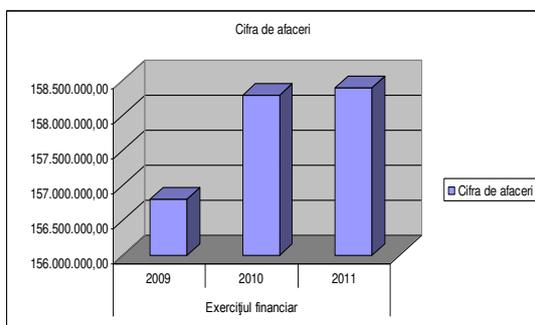

The study of turnover over a period of time, provide information about the company and its tendency, by its inclusion or the inclusion of its object of activity in one of the foundations of the life cycle: launch, growth, maturity, decline. Evolution of turnover is detailed in Table no. 8, the data being taken from Annex no. 1 "stock elements".

12	Share of production sold in CA	Pv/CA	%	98,32	98,66	98,67

Source of data: <http://www.aerostar.ro/> (own interpretation)

Fig. no. 1 The turnover evolution

(Own interpretation)

The turnover in 2011 slightly increased compared to 2009 of approximately 1.01% and 0.07% compared to 2010. In those three

years analyzed the largest share in the structure of turnover is the sold production of approximately 99% which reflects the high importance given to core business namely manufacturing.

From the analysis results a normal in achieving activity because the turnover exceeds the minimum threshold of 85% of total operating revenues and 75% of total revenues.

Analysis of the production year

The production year is the indicator which measures the total value of the work done by the company in a financial year.

The production year consists of goods and services produced by the firm, regardless of the destination: sale, storage or immobilization, is regarded as the global production of the financial year. [4]

$$P_{ex} = P_v + P_s + P_i$$

Analysis of the production year implies following aspects:

- The level and structure of the production year;
- Year production dynamics based on the inflation rate

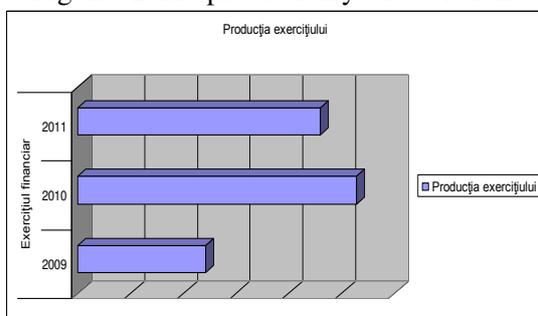

The level and structure of the production year

Table no. 3 The production year evolution

Nr. crt.	Indicators	Symbol	UM	Financial year		
				2009	2010	2011

8	Growth rate of the P_{ex}	$I_{P_{ex}}$	%	100,00	101,84	99,56

Source of data: <http://www.aerostar.ro/> (own interpretation)

Fig. no. 2 The production year evolution

(Own interpretation)

During the review is found that in 2010 there was an increase of 1.84% of the production year, and in 2011 a decrease of 0.44% of the production year.

In all three years analyzed shows that production sold actually participate in the training exercise production.

This indicator determines the evaluation of the overall volume of activity and helps the calculation and analysis of the added value.

Analysis of added value

Added value expresses the company's capacity to create wealth, more accurate what the company adds by its own activity to the economic cycle.

Added value characterizes bulk activity undertaken by the company after deducting intermediate consumption. In other words, the enterprise produces goods and services but consume some other production companies and only the difference between what it produces and what it consumes for this purpose increases the value of their production. [4]

Turnover is not a good indicator to assess the size of an enterprise because it expresses only the revenues from sales of production.

It is noted that the work output will be higher as production factors are more modern and with a high degree of automation and higher efficiency equipment. [5]

However, the indicator must be interpreted cautiously and must be correlated with other indicators of performance, since an increase in added value can be the result

of the increase in stocks of finished products, because of the too high selling prices.

Analysis of the added value implies following aspects:

- The level and structure of the added value;
- Dynamics of the added value based on the inflation rate. [6]

The level and structure of the added value

Subtraction method for the added value analysis

According to this method, the added value expresses the difference between the production year (plus margin trade) and intermediate consumption (consumption of goods and services from third parties). [4]

$$V_{ad} = P_{ex} + M_c - C_i$$

Commercial margin is an element of the added value expressing the supplement value produced by the company through marketing activities.

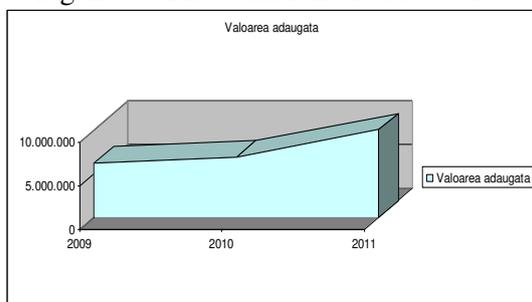

Intermediate costs deducted from added value represents the total consumption of goods and services provided by third natural or legal persons.

Table no. 4 The structure and the evolution of added value

Nr. crt.	Indicators	Symbol	UM	Financial year		
				2009	2010	2011
1	Commercial margin	M_c	RON	295.373	262.840	369.033
2	Production year	P_{ex}	RON	154.765.266	156.693.715	157.025.991
3	Intermediate consumption	C_i	RON	148.590.939	149.835.330	147.039.362
3.1	Raw materials and consumables		RON	50.949.227	54.498.964	38.746.854
3.2	Other materials expenses		RON	4.341.903	2.896.780	4.168.893
3.3	Energy and Water		RON	5.665.342	5.666.362	7.307.017
3.4	External services		RON	87.634.467	86.773.224	96.816.598
4	Added value	V_{ad}	RON	6.174.327	6.858.385	9.986.629
5	Growth rate of the M_c	I_{M_c}	%	100	-11,01	40,40
6	Growth rate of the P_{ex}	$I_{P_{ex}}$	%	100	1,25	0,21
7	Growth rate of the C_i	I_{C_i}	%	100	0,84	-1,87
8	Growth rate of the V_{ad}	$I_{V_{ad}}$	%	100	11,08	45,61
9	Turnover	CA	RON	156.808.447	158.289.213	158.402.223
10	Added value rate	R_{VA}	%	3,94	4,33	6,30

Source of data: <http://www.aerostar.ro/> (own interpretation)

Fig. no. 3 The evolution of added value

(Own interpretation)

The increasing of the added value throughout the period of analysis, reflecting an increase of wealth at the expense of

enterprise resource. This is due to continuing production year on an upward trend. Intermediate consumption increased in 2010 compared to 2009 by 0.84% and in 2011 recorded a decrease of 1.87%. Also observed that the growth rate of production year (IPEX) is less than the growth rate of added value (IVAD) which means a lower degree of exploitation of resources, namely reducing the capacity to create wealth and represents a future warning.

Conclusions:

In order to improve a process or task, you first need to know the level of performance.

Performance measurement involves knowing objectives and comparison with the achievements. The assessment of it also implies some limitations because in the current environment the economic and technologically environment is complex and uncertain. [5]

A sine qua non condition for performance is to identify the types of risk faced by a business. Their evaluation provides useful information in finding the most effective tools for their management.

Analysis of revenues and expenses grouped by nature of their work was a starting point in assessing the performance of SC AEROSTAR S.A. Bacau. The analysis of data taken from the profit and loss account revealed a higher growth rate than revenue expenditure, this reflects positively on the company's gross profit, net profit and other economic and financial performance indicators.

Another method of analysis that characterizes the performance through the income statement is the development of intermediary balance management panel. [6]

All management interim balances on operating activities increased in 2011 compared to 2010 and is an increase in 2010 compared to 2009.

Turnover recorded an 0.94% upward trend in 2010 compared with 2009 due to increased of sold production with 1.29%, an increase in 2011 compared to 2010 by 0.07% due to increased of sold production with 0.08%, even if the income from the goods have been continuously decreasing.

In all three years analyzed, the highest share in turnover is hold by the sold production, reflecting the major contribution to the formation of turnover.

The increased production year by 1.27% in 2010 compared to 2009 was a result of the increased sold production by 1.29% and the production for its own purposes and capitalized by 70.29%, and moreover the increased production year by 0,14% in 2011 compared to 2010 was a result of increased sold production by 0.08%, output in its own purposes and capitalized registering a fall of 38.22%.

Added value increased year over year primarily due to lower intermediate consumption, which is observed in the last two years analyzed.

This increase in added value compared to turnover and production year is favorable characterizing the economic activity of the enterprise.

The Risks in the Insurance of Persons

Văduva Maria

„Constantin Brancusi” University of Targu Jiu, Faculty of Economics and Business
Administration, Romania
vaduva.maria9@gmail.com

Abstract

The insurances of persons can be divided in two categories, depending on the insured risk in the base insurance: insurances of persons that cover the risk of death; insurances of persons, others than those of life, which cover in the main insurance the corporal integrity or the person's health.

At the production of the insured event, the insurant receives an insurance indemnification corresponding to the initialed established sum, sum covered according to the insurance contract. Additional clauses can be added at both types of insurances, which extend the cover through the main product in exchange of an insurance supplementary premium.

In the insurance practice, this carries the denomination of insurance of persons. The origin is in antiquity, being a prudence proof. Life and health insurances have been recognized as essential and necessary elements in the individual's and his family's financial program.

Cuvinte cheie: insurances, annuity, the validity period, the contract, the payment.

Clasificare J.E.L.: A10, M20

1. Introduction

The insurances of persons have as object guaranteeing the payment of a sum to the insurer, in the case of the production of an event related to the insurant's natural persons: he's corporal injury, sickness, death or survival.

In the case of insurances of goods, the insurer is engaging not to harm the insurant for the suffered damages through the damaging or destruction of the insured goods as a consequence of the insured risk

production. Having repairing character, the indemnification owed by the insurer cannot be bigger than the damage suffered by the insurant and neither than the insured sum.

In the case in which a natural or legal person had insured a good whatsoever, from error or with the intention for a sum bigger than the real value of this and has paid the insurance premiums afferent to this overestimated sum, at the destruction of by a catastrophe, the insurant has the right to a limited compensation at the value of the registered damage, without exceeding the insured sum of this.

Such is the case in the insurances of persons. Here the insured sum is established in a contractual mode by the insurant depending on his financial needs and possibilities[1]. The insurant can conclude more insurance contracts against the same event and for different sums, without being prevented by law or by the insurant to make this thing. At the production of the insured risk, the insurant or the beneficiary of the insurance has the right to collect the insurance rights from all insurants, because here it is not about the damage as in the insurance of goods. Not having a repairing character, the insurance of persons does not suffer restrictions at which the insurance of goods is submitted.

2. The insurances of persons

If after the production of the insured risk, the insurant has suffered a corporal injury or has contracted an illness, which has affected the labor power, he has the right to an insurance indemnification, which can make possible the restoration of his financial situation existent before the production of the accident or contraction of the disease.

The insurances of persons can classify depending on the insured risk, the moment of the premium payment, the moment of the

insured sum collection and the form that this dresses up.

We have seen that depending on the covered risk, the insurances of persons can be[2]:

- ✚ Survival insurances;
- ✚ Insurances of death;
- ✚ Mixed life insurances;
- ✚ Accident insurances;
- ✚ Insurances of sickness;
- ✚ Other forms.

In the survival insurances, the insurer engages to pay to the insurant at the expiration of the contract, the insured sum with the condition that this should be alive. In the validity period of the insurance, the insurant paying the owed premiums accumulates an amount of money at the insurer's disposal, the amount that becomes exigible at the expiration of the contract. The amount thus saved follows to be used by the insurant at the right moment, for the most different aims; to purchase a building, a motor car or other goods with big value or of prolonged use; to move with the family in a different region or country; to make a leisure, business and study travel, etc.

According to the contractual conditions, the insurant takes the possession of the insured amount, only in the case in which he is alive at the expiration of the contract. But if he had died previous to the expiration of the validity term of the contract, the insurer considers himself released of the engagement taken through the contract and he has no obligation towards the insurant's successors. The accumulated amount by the insurant during the validity contract remains as rightful to the insurer, after the insurant's premature decease.

Another survival insurance is the annuity insurance, according to which the insured amount is put at the insurant's disposal under the form of some periodical payments with the title of annuity.

The fund, from which the annuity is paid, is made on the account of a unique premium paid by the insurant at the conclusion of the contract, either on the account of the premiums gradually paid by the insurant on the validity period of the contract. The payment of the annuity can be made in two different manners: the payment of the annuity starts immediately after the concluding of the

insurance contract, either from an ulterior date.

This is the most frequent form met in practice: o longer or shorter period of time, the insurant deposits the owed premiums for the constitution of the fund, from which the latter will bear the annuity.

In the annuity insurance, the insurer will pay the annuity only in the case in which the insurant is alive at the expiration date of the contract. The insurant's previous death sets free the insurer in front of the insurant's heirs.

A survival insurance, which has as consequence the loss of the right over the insured amount from the insurance beneficiary's side, in the case in which the insurant has died previous to the expiration of the insurance, is not too attractive and it does not stimulate the spirit of saving[3].

In order to avoid the loss of the premiums paid by the insurant, in the case of the death in the validity period of the contract, there are taken some measures in the international practice: for example – it is written in the contract the clause of counter-insurance, which allows the reimbursement of the premiums afferent to the survival risk; the insurer keeps the premium afferent to the risk of death. If at the expiration term of the insurance, the insurant is alive, he cashes the insured amount, while the premium for the risk of death remains as the insurer.

The insurance of death protects the insurant against the risk of death.

The insurants use different forms of insurance, which to satisfy the most different preferences, as death is a future and sure event, but uncertain about the date. In a formula, the insurance covers the risk of death at any date that this would happen.

For this purpose, the insurant engages to pay premiums all his life in order to beneficiate of such protection. It is also known the solution that limits the premium payments at a certain period of time: on duration of n years, until the date of x , until the insurant's retiring. In all these cases, we have to deal with a temporary insurance of death. It is also known the solution of transformation of the life insurance of death in an optional life insurance, which consists in the transformation at a certain moment, of the life insurance of death, in life annuity insurance.

The insurance of death on limited term obliges the insurant to pay the amount written in the contract, if after the insurant's death took place in the validity period of this. If at the expiration of the contract the insurant is still alive, the insurer is exonerated of any obligation towards the insurant, arising from the contract. So, the insurance of death is not an insurance of saving, but one of protection against a determined risk.

The two insurances of life, of survival and of death, each one covers in part a single risk, creating like this the impression that one of the parts is always loser. In reality, the survival and death, constituting alternative risks, it cannot ever produce simultaneously.

The mixed insurance of life. In order to make more attractive its reports with the insurants and in order to simplify under the organizational aspect, the insurer offers a product that covers both risks in a single contract, denominated mixed insurance of life.

By including two alternative risks in a unique insurance contract, the contradictory character of the two risks do not disappear, but it is created only the impression that the insurants gain in the case of production of any risk: in the case of insurant's death, the beneficiary of the insurance takes possession of the insured sum and in case of survival, the insurant personally cashes the insured amount foreseen in the contract. The insurant gains in both circumstances, but this thing is obtained with the price afferent to the covering of the two different risks, with the bearing of the premiums owed both for the risk of death, and also for the one of survival. If it would not tax each risk taken over, if it would not sell every guarantee against any risk that it is offered to an insurant, the insurer would not be able to equilibrate the cashed premiums with the owed indemnifications, the incomes realized with the assumed arrangements towards the insurants.

In the international practice, the mixed insurance of life knows different variants in what concerns the validity term or the form under which the insured amount is granted. Mixed insurances with long term are being practiced, at the expiration of which the insured amount is paid to the insurant, if this is alive or to the beneficiary, if the insurant

had died previously. In any case, there cannot be perceived premiums in the account of the respective insurance from the insurant's death.

The insurances of accidents. They follow to protect the natural persons from the black-letter consequences of some unforeseen events, which affect life, the corporal integrity or the capacity to work. The injured persons receive with title of indemnification either a contractual amount, or more fractionary payments in order to insure the expenses with the medical care, restoration of health and compensation of the lost income. In case of permanent invalidity, the insurer owes to the insurant the whole insured amount or part of this depending on the degree of invalidity established by the commission of medical expertise.

In the insurance of the contract, the insurer can accept the renewal of this for a new period, eventually with a major premium or to reject it, if the injured person has suffered a higher degree of invalidity, which have reduced him, totally or partially, the capacity to work.

The insurance of disease has as object the protection of the persons that have suffered a temporary incapacity to work determined by disease.

Near the insurances of life, in the international practice are met other forms of insurances of persons among which the insurances of permanent health, of natality, etc.

The permanent health insurance follows to eliminate the poverty, often associated with a durable incapacity to work, provoked by an accident or a disease. From the moment in which an insurant was medically examined or accepted for a permanent health insurance, the insurance contract keeps its validity for a number of years (ex. the age of retiring) and cannot be canceled by the insurer. The premiums are annually paid and usually do not modify from a year to another. If the insurant has contracted incapacity to work after a disease or an accident, he has the right to an insurance indemnification, which is periodically granted as long as the incapacity state is maintained or until the insurant reaches the retiring age or has died. The insured employees benefit from an indemnification on the permanent health insurance line in the period when they were

sick and which varies between a month and a year. This limitation is produced on the grounds that in the sick period the employees are entitled to a share of wages. The size of the indemnification granted by the insurer in the period of incapacity to work is established by the insurant together with the insurer, at the conclusion of the contract, but it cannot exceed 75% from the insurant's income realized before the rendering sick, from which it is deduced the amount received from public funds.

The permanent health insurance is practiced in Great Britain.

The dotal insurance is conceived as a modality to gradually constitute a dowery to a child until this reaches majority. The insurer honors this insurance, if the beneficiary of the insurance is alive at the date of reaching majority, when the insurance becomes exigible. In the hypothesis in which the beneficiary of the insurance has died previously to this date, the insurer is exonerated of any legal responsibility to that contract. If the respective contract foresees a clause of “counter-insurance” in the case of insurance beneficiary's premature death, the insurer is obliged to return the cashed premiums.

During the execution of some contracts of life insurances appear critical situations, which put some of the insurants in the impossibility to honor the assumed arrangements (the payment of the owed amounts) or have to cash in advance the insured amount or a share from this in order to get out from a deadlock. In the aim to solve such problems, the insurance contract is completed with certain provisions, which offer to the insurants supplementary guarantees. Ex.- how to proceed in the situation in which the insurant has arrived in the impossibility to pay no more the insurance premiums from independent causes of his will, how the insurant to be sustained after a serious accident and has lost the capacity to work or has died.

The insurance that contains such provisions determines the complementary insurance[4].

The concrete forms of life insurances differ from one country to another and even from a period to another.

Life insurances are concluded either in an individual way, or in group. There are special

laws in every country, which regulate the way to conclude and to execute the insurance contract, incriminate the deviations from the legal provisions, establish the sanctions applied to those guilty of violating the legal dispositions.

3. Conclusions:

Concrete aspects of the relations between the insurer and the insurant find the reflection in the insurance contract, which contains the insurant's surname, first name and the date of birth, the insured risk, the validity term of the contract, the owed insurance premium and the date at which this becomes eligible, the insured amount and the modality to pay this. Life insurance can be concluded with or without the insurant's medical examination depending on the insured amount and on the object of the insurance.

On the grounds of the medical exam results, the insurer accepts (with the payment of a normal premium or an increased one) or to reject the insurance demand, due to the dragged risk, the high value that it presents. The persons with a poor health, more vulnerable to diseases for their protection and of their families appeals to an insurance more frequently than those having a good health, which is also reflected in the individual financial results[5].

Together with the individual insurances, the insurance companies also conclude collective insurances. Ex.- when the personnel of a production section (mine, construction site, forestry operation, etc.) works in conditions having a high risk, the economic agent can conclude an insurance of accidents or of death for all the personnel from the respective section, when a commercial organization sells goods in installments, it can conclude a collective insurance for all its customers encountered in the same situation in order to place in safety in the case in which some of these would arrive in the impossibility to pay no more the installments due; a commercial bank that can provide consumer credits to some natural persons can appeal to the collective insurance of its customers.

The group insurance presents the advantage that there exists the selection of risks, which is met in the individual insurance and is less expensive than this.

In the collective insurance are included all the persons that make up the respective group with the condition that each part to express its agreement to this insurance. This, because a share from the insurance premium is borne by the contracting party of the insurance, and the other share is in the insurant's task.

Abstract

The crisis has been perceived as a tsunami wave starting from the United States and gradually affecting the countries in Europe and all over the world and advancing kilometer by kilometer. “When the crisis reaches Romania”, “finally the crisis will hit us as well” or “the climax of the crisis will be reached in X month” are some of the useless phrases which we have heard and keep hearing daily in mass-media. Nevertheless, a closer analysis will reveal the fact that the economic disturbances generated by the subprime crisis in the United States are nothing but a facet of a much more complex relationship combining the external economic factors with other factors exclusively related to the Romanian environment. ID or any other type of loose crediting has been aggressively promoted in the local financial environment in spite of the repeated warnings of the National Bank.

Keywords: crisis, propagation channels, systemic risk, financing sources

J.E.L Classification: E52, E58

1. Introduction

The Romanian economy is exposed to the effects of the international crisis [1] out of two reasons. Firstly, over 90% of the assets of the Romanian banking system are held by foreign banks, with a high degree of concentration of the Austrian, German and Italian banks (together holding 70%), a thing which exposes the Romanian banking system to the same problems the banks in these three

countries have. Secondly, over 90% of the RON transactions are made by non-residents (and they come to maturity in less than 7 days) exposing the Romanian national currency to large fluctuations on the short-term in case of some external shocks. Romania withstands the impact of the financial and economic crisis through two propagation channels: [2]

a) The financial channel determined by the credit restriction and appreciation on a global scale and leading to the following consequences:

- The rise of the costs of the credits taken by the population, firms and the state;
- The business model practiced by the banks in Romania and by other financial institutions according to the pattern “we borrow externally and credit locally” will radically change generating a lack of liquidity on the financial markets;
- Foreign investors give up to or postpone the decisions regarding certain investments they would have liked to make in Romania;
- The portfolio investments have been substantially reduced.

b) The economic channel determined by the economic contraction in the developed countries having the following effects:

- The decrease of the export;
- The reduction or cessation of the activities supplying components for the industries affected by the recession – auto, metallurgy, garments, constructions etc.;
- The decline of the money transfers in Romania made by the Romanian workers from abroad;
- The reduction of the rhythm of economic growth.

The economic contraction can lead to the impossibility of paying certain debts by physical and juridical persons and implicitly to the appearance of solvability problems for banks and other financial institutions as well as to social tensions.

There is an interdependent relationship between the two channels so that the Romanian financial system is affected by both the afore-mentioned channels because of the generalized liquidity crisis and the reliability crisis at the level of the population.

2. The concept of systemic risk

The financial crisis [3] started as early as 2007-2008 reveals new dimensions of the concept of systemic risk in the banking activity. Thus, “the risk of chain reactions leading to the bankruptcy of a number of interconnected institutions” is gradually extending threatening to encompass the activity of the “shadow banking system” – an unregulated sector created in order to avoid the strict regulation typical for the banks.

The evaluation of the systemic risk from the banking system in Romania remains traditional taking into consideration the fact that the level of development of the financial technologies and the risk tolerance are extremely low. Thus, those non-banking financial institutions which make up the shadow banking system and which by using sophisticated financial products with a high degree of risk have damaged the stability of the American financial system do not show any signs of concern in Romania.

According to the specialists, the contagion effect manifests itself through two channels:

The exposure channel – which refers to the potential for the emergence of the “domino effect”, potential given by the real exposures on the interbanking markets and the payment and compensation/clearing systems

The informational channel – which refers to the massive and contagious cash withdrawals by the insufficiently informed deponents regarding the types of shocks affecting banks and the reciprocal physical exposures.

In Romania, the systemic risk is visible in relationship with the liquidity of the credit institutions as a consequence of the attitude of some banks to found their financing strategy of increasing the number of credits by attracting

interbanking resources. The alert crediting dynamics, superior to that of the deposits attracted by the non-banking clientele has induced the increment of the value of the credit indicator on deposits from 91.1% in 2006 to 109% in 2007. Under the circumstances, the balance has been supported by the increase of the weight of the interbanking resources from 22.3% in 2006 to 28% in 2007 at the same time increasing the dependence of the Romanian banking system upon resources with a high potential of volatility [4].

The degree of concentration and their increasing value amplify the exposure of the crediting institutions to the liquidity shocks on the basis of eventual changes in a negative way of the feeling of the institutional investors regarding the placement perspectives in the Romanian banking system.

The structural analysis of the interbanking resources emphasizes the dominance of the external resources provoked especially by the mother-bank. Taking into account the fact that at the end of 2007 the sums attracted by the mother-banks represented approximately 70% of the total interbanking resources used by the credit institutions in Romania, the most probable risk scenario could be the situation in which the mother-banks would be affected by a shortage of liquidity. Even under such circumstances, they would restrict the financing of the branches in Central and Eastern Europe only on condition that the liquidity crisis is extremely severe because an important part of the profits of these mother-banks come from the respective branches. Taking into consideration the fact that the autochthon banking sector is dominated by banks in Austria and Greece which do not seem to face difficulties in the context of the present turbulences, the severity of a possible external shock is limited.

In parallel with the accentuation of the resources coming from the mother-banks the financing the internal market has increased. Testing the resistance of the Romanian banking system to the internal risk of interbanking contamination shows that triggering a chain bankruptcy process is the least likely since the autochthon interbanking bilateral exposures have generally been reduced in relationship with the funds and the liquid assets of the crediting banks.

The perspectives of the emergence of a powerful systemic process within the Romanian banking system are connected to an eventual generalization of the behavior of

the crediting institutions to finance the development of their crediting activity mainly from interbanking sources.

The changes at the level of the shareholding of the crediting institutions in 2011 and 2012 have not led to major mutations in the structure of the Romanian banking sector. As a result of the acquisition of the Anglo-Romanian Bank by BCR the number of the crediting institutions has been reduced to 41. The banks with a majority foreign capital have easily diminished their market share in the aggregated assets of up to 83% on 31 December 2011 and 82.5% at the end of the first semester of 2012, mainly on the basis of the immobilized and non-performing sales of assets. From the perspective of the percentage in the aggregated assets, the banks with Austrian capital keep holding the majority position with a market share of approximately 38%. The group of banks with Greek capital decreasing by 13.0% on 31 March 2012 (13.3% at the end of 2011) has witnessed a repositioning within the banking sector as an effect of the restriction of the local deposit basis in the context of the negative perception of certain deponents induced by the events in Greece being surpassed by the banks with Romanian and French capital holding a share of 17.5%, respectively 13.1% on 31 March 2012.

The degree of financial intermediation measured as a balance of the net banking assets of the GDP (61% on 31 December 2011) has remained under the European average with a level much lower in comparison with the one in 2010. The degree of concentration of the Romanian banking system (reflected by the balance held by the first five banks after the amount of the assets) has lightly increased until 54.2% on 31 March 2012 (54.6% at the end of 2011). A similar evolution manifested itself with respect to the credits and deposits held by the first five banks in the banking system which have reached 53.1%, respectively 53.1% on 31 March 2011 (the corresponding levels on 31 December 2011 have reached 52.3%, respectively 58% on 31 December 2011).

A special attention has been paid to the credit granted to the private sector which has risen in real terms to 3.3% on 31 December 2011 and by the end of the first semester of 2012 the annual dynamics has accelerated by 4.1%. The most dynamic component has been the short-term credit. The main segment

of the credit destination has been that of the companies whose balance in the total assets has increased by 30.2% on 31 December 2011, a superior level by 4% to that registered by the credits granted to the population; the same structure has been maintained in the first semester of 2012 [5].

Even if the crediting in the national currency has been recommenced since the last semester of 2011, the crediting stock in foreign currency granted to the private sector has remained majority holding approximately 64% of the total credit portfolio on 31 March 2012 (63.4% at the end of 2011), especially on the basis of the financing directed towards the companies.

In the period under discussion, the manifestation of the disintermediation phenomenon as well as its impact upon the real economy has become a preoccupation at European level. At the level of the crediting institutions in Romania the process of disintermediation can materialize through the following channels:

- the reduction of the external financing as a result of the deterioration of the macro-economical conditions with effect upon the liquidity of the crediting institutions;
- the tendency of the foreign banking groups to diminish the exposure of the branches towards the non-governmental sector as a strategy to reduce capital demand at the group level (by diminishing the balanced exposure to risk taking into account the fact that the elements regarding the credit nature granted to the real sector have a high risk rate);
- the measures oriented towards the development of the exploitation activity (for example, the reduction of the exposure to certain sectors or categories of debtors, the sale of credit portfolios, the redimensioning of the expenses directly neglected by the earnings or even the restructuring of the territorial network).

Throughout 2011, the disintermediation phenomenon has substantially affected the Romanian banking system, the rate between the assets of the crediting institutions and the actual capital determined by the aggregated level registering a non-significant change (11.1 on 31 December 2011 in comparison with 11.2 on December 2010).

3. The perspective of the financing sources

From the perspective of the financing sources of the balance assets one can notice the following tendencies:

- the positive trend of the dynamics associated with the banking savings of the population in the second part of 2011 after the contraction in the previous four semesters;
- the ascendant trajectory of the inherent financing sources which ensure 17% of the financing demand on 31 March 2012 (16.2% at the end of 2011);
- the diminishing in real terms of the external liabilities. This category has preserved its second position in the classification of the financing sources (with a rate of approximately 26% of the total liabilities), the largest part of the financing of the banking assets (approximately 48%) being ensured by the internal deposit basis (resources attracted from the companies and the population).

The resident non-banking clientele [6] (companies and population) holds its net debtor position towards the Romanian banking system for the fifth consecutive year, the credits significantly surpassing the deposits. The structure of the aggregated balance keeps raising problems from the perspective of the correlation on maturity of the assets and liabilities but the same vulnerability is decreasing. The capitalization of the Romanian banking system has preserved a comfortable level throughout the entire period under discussion. The solvability indicator was 14.9% on 31 December 2011 and 14.6% on 31 March 2012, superior levels to the prudential level of 10% recommended by the central bank together with the effects of the international financial crisis. The cost of the credit risk has represented a challenge for the maintenance of an appropriate capitalization compensated by the new infusion of capital exclusively got by the shareholders.

The actual level of capitalization ensures good conditions for the implementation of the new demands stipulated in the Basel III regulation during the following period. In addition, from the stress testing analysis periodically made by the central bank a level covering the capitalization of the banking sector has resulted in spite of the diminishing capacity of generating profit from exploitation against the background of the

increase of the percentage of the instruments carrying a fixed interest with lower effects.

The National Bank of Romania ceaselessly makes evaluations of the crisis. According to the officials of the National Bank of Romania, this crisis will not affect Romania directly not because our country has a primitive financial system, but because Romanian banks have avoided the toxic crediting products and the crediting norms of the National Bank of Romania have been more drastic. The Governor of the National Bank of Romania has explained that Romania has a financial and banking system which has continuously evaluated from simple to complex, from weak to powerful and which at present has not by far those vulnerabilities specific to other countries.

4. Conclusions

The National Bank has an important role in the management of the effects of the crisis, its direct responsibility targeting two markets of major importance: the monetary market and the foreign currency market. It is certain that the measures of monetary policy have a positive or negative effect upon the entire economy. From this reason, the National Bank of Romania operates on a large scale. If alarming rumours invade the market it intervenes to calm the public. When the consumption demand dramatically exceeds the internal bid of goods and services it interferes in order to balance the market. As far as the two afore-mentioned markets are concerned, the monetary and the foreign currency market, all measures are taken in order to avoid any kind of side-slip from a correct evolution.

Abstract

In the pages of this article, we shall present a study whose main objective is to reflect how financial period result is influenced by policies and accounting treatments applied within companies. To achieve this objective we considered the financial statements and audit reports for the financial period 2009 and 2010, 2011, of the following companies listed on Bucharest Stock Exchange : Alro SA Slatina; Alumil Rom Industry SA; Azomures SA; Transilvania Constructii SA; Mechel Targoviste SA; Prodplast SA Bucuresti; Mecanica Ceahlau SA Piatra Neamt; [1].

Keywords: accounting treatments, accounting policies, tangible fixed assets, evaluation, fair value.

J.E.L. Classification: M 41

Introduction

When applying accounting regulations compliant with European Directives, entities must develop own accounting policies which must be approved by administrators according to the law. For entities which do not have administrators, accounting policies must be approved by people who manage the entity. The accounting policies are not uniform or "standardized" because they must be adapted to the company's activity.

However, the rules and accounting treatment cannot be unitary or „standardized” because they must be provided in accordance with accounting regulations of the Fourth Directive of the European Economic

Communities, approved by the Ministry of Public Finances by Order no. 3055/2009.

Given the possible implications of the accounting treatments under IFRS, the tax value determined under the provisions of these standards proposes the introduction of separate accounts highlighting elements such as impairment of intangible assets, derivative transactions, the value of assets, impairment of goodwill.

Also it has been brought some clarification regarding the accounting of the cost of consumption of stocks, property depreciation, interest expenses, personnel expenses, etc.. and which according to IFRS are included in the value of assets.

Accounting treatment regarding the initial recognition of tangible fixed assets

Tangible fixed assets recognition

Tangible assets are recognized as assets and included in the financial statements of a company (ie balance sheet), if they correspond to the definition of assets and fulfill the following conditions cumulatively: the possibility for the company to generate future economic benefits corresponding to these assets, the cost of the assets can be determined as fair as possible.

The first criterion is accomplished when a company establishes a certain degree of reliability by obtaining economic benefits as a result of asset holding. In addition, the company must take both benefits (future economic benefits which result clearly from destinations that these elements may have: direct or indirect) and asset risks. What do you think about security systems? Can they be considered tangible assets? (Since they protect production systems, they contribute indirectly to the achievement of future

economic benefits and thus they are considered tangible assets with useful life longer than one year. Let's think to losses which will occur during their absence).

The second criterion of recognition is usually achieved since at the time of tangible fixed assets purchasing, the cost can be clearly identified with the help of supporting documents showing the purchase. It is more difficult to determine the cost of tangible fixed assets produced by the entity, because not all costs can be capitalized and then we have to resort to the application of professional judgement for the correct capitalization of costs.

In terms of tangible fixed assets identification, if the components of an asset have different useful lives or provide benefits to the enterprise in a different way, they are accounted for separately, using different depreciation rates and methods. It is about the so-called "component approach" which IFRS requires for depreciation. For example: aircrafts and their engines, construction and heating systems for buildings or lands and buildings where these are located (the useful life of lands is unlimited, so that only buildings are subject to depreciation).

Evaluation of tangible fixed assets

Tangible fixed assets are valued at cost at the time of their purchase, that means the entry value (accounting value).

Accounting value has different names, depending on the purchase way of tangible fixed assets, such as: acquisition cost for purchased goods; production cost in case of personal labor; contribution value for goods supplied to the capital stock; fair value for goods received free of charge and for those which are exchanged. In addition, tangible fixed assets can be purchased also by leasing, when the determination way of book entry value presents some peculiarities, as it is shown in IAS 17 "Leasing".

Regarding tangible fixed assets, the main problem which arises in this category is related to the fair value.

Fair value was considered the "trigger" of the financial crisis. Most specialists believe that such a serious crisis like the current one is not and can not be caused by a single involved party, but it involves the inefficiency of a whole ecosystem which

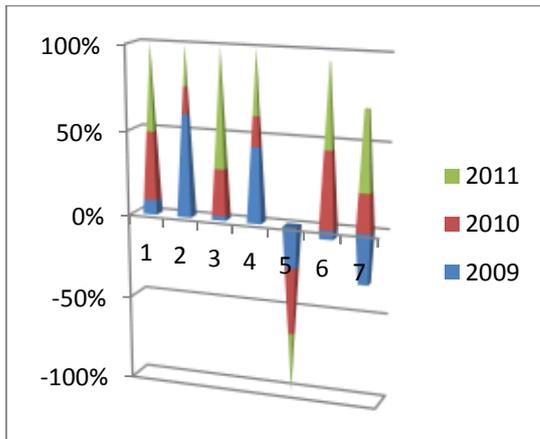

failed to assess the risks implied by the fast growth of structured risks of mortgages, the other side of the coin in the increase of real estates prices and a lack of market liquidity without precedent. [3] Therefore, all these factors brought up an inappropriate behavior from the part of lenders, borrowers and investors, making them to ignore what the simple common sense would have indicated, that is never to forget to assess at fair value the true risk involved.

The support for the fair value concept didn't result from the belief that this is a perfect one, knowing that there will be a series of amendments to current standards which will be achieved in the future, as the IASB president suggested himself recently [2]. Nevertheless, the purpose assigned to the fair value accounting and market-based assessments does not seem exaggerated, however if we integrate it in the picture which presents the characteristics of financial markets in an emergent world, a picture which reflects also the lessons learned from past crises. A restriction of the fair value would not only heal the wounds of the current financial crisis, but on the contrary, would be likely to worsen them, reducing the level of confidence that investors and others, have in the financial statements of financial institutions [4].

We shall present further the evolution of the operating result, financial result, as well as the gross result during the period 2009-2011. The data have been taken from the financial statements of economic entities. In order to realize the charts more easily we assigned a number to each entity as follows: Alro Slatina - 1, Alumil Rom Industry -2, Azomures - 3, Transilvania Constructii - 4, Mechel Targoviste - 5, Prodplast Bucuresti - 6, Mecanica - 7.

In the diagram No. 1. it is shown the percentage evolution of the operating result. As can be seen from the chart, the company Mechel Targoviste is the entity which has the negative values of this indicator in the analysed period. At the counter pole, Alro recorded the highest increase of the operating result.

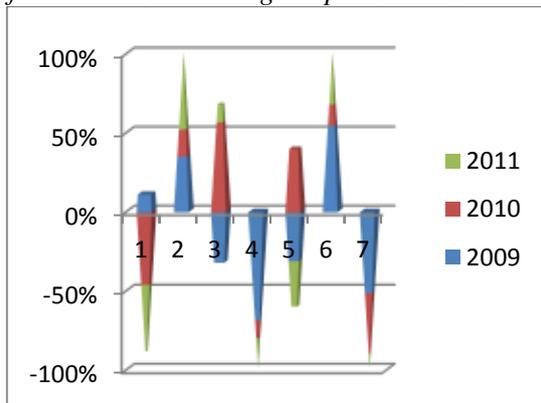

Diagram No.1 Evolution of the operating result during the period 2009-2011

Source: author's projection

The evolution of financial activity result is shown in the Diagram No 2. In this case we can see the effect of the financial crisis, the significant decrease of this indicator in most analysed entities. Transylvania Constructii and Mecanica registered a significant decrease of the financial result during the all analysed period. Alro Slatina and Mechel Targoviste managed to achieve a slight increase of the indicator in one of the three periods. Regarding Azomures, it seems that the financial crisis affected the financial result only in 2009 and then the entity registered a growth of the indicator in the subsequent years, the greatest evolution being in 2010.

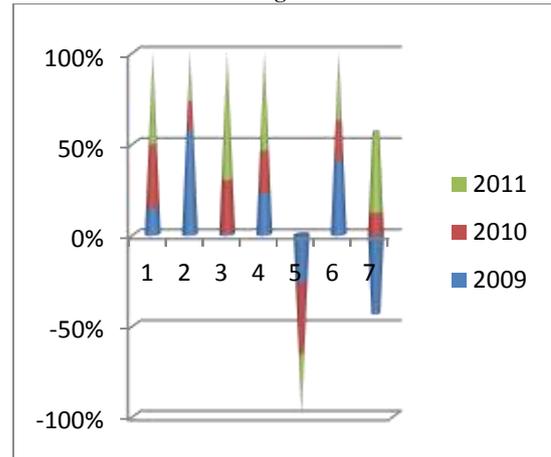

Diagram No.2 The evolution of the financial result during the period 2009-2011

Source: author's projection

In the diagram number 3, we present the evolution of the gross result during the period 2009-2011. Five entities from those analysed showed an upward trend of the indicator, while Mechel Targoviste showed a strong decrease of the indicator during the all analysed period . We can say that this entity has been the most affected by the global crisis from all analysed entities.

Diagram No. 3. The evolution of the gross result during 2009-2011

Source: author's projection

These results have been influenced mainly by policies and accounting treatments used by those companies.

Usually the fair value is determined through a reassessment made by an A.N.E.V.A.R. member appraiser[5].

According to the Tax Code, Article 54 paragraph [1] "building tax owed by legal entities which have not made the reassessment in the last 3 years previous to the fiscal year of reference, shall be calculated on the basis of the rate set between 5% and 10%, applied to the building inventory value recorded in the accounting of legal entities by the end of the month in which the first reassessment was made. By the first reassessment we understand the nearest reassessment to the fiscal year 2002. " All firms from the test object reassessed the tangible fixed assets in order to avoid this provision of the tax code. We shall present in the table below the year in which reassessment of tangible fixed assets was made to the following companies:

Table number 1. The year in which reassessment was made

Company	Year when reassessment was made
Alro SA Slatina	31.12.2008
Alumil Rom Industry SA	31.12.2009
Azomures SA	31.12.2010
Mechel Targoviste SA	31.12.2009
Mecanica Ceahlau SA Piatra Neamt	31.12.2010

Source: Financial Reports for 2010 and 2011

All companies which were subject to the study reassessed the tangible fixed assets, namely lands and buildings at a period of three years, only to identify themselves with the rules of the tax code[6]. The issue is also due to the financial crisis of the real estate market, since if this reassessment was done only every three years, there is a risk that in this period the fair value at the end of these years not to be close to reality. There are companies which have tangible fixed assets, namely, lands and buildings which are otherwise encumbered in the sense that they are mortgaged in favour of different credit institutions in order to guarantee certain loans. Usually these institutions update the values of mortgaged tangible fixed assets and prepare a reassessment report, which can be

harnessed also by companies in order to reflect the value of these categories of tangible fixed assets as closer to the real value(fair) in the annual financial statements[7].

Another aspect worth mentioning is that of the valuation method used, namely the gross value method or net worth method[8]. The result of the financial period is affected by the revaluation method used in the sense that if we use the gross value method ,both the entry value and accumulated depreciation will be updated, affecting downward the financial period result and if we use the net worth method to reassess the tangible fixed assets, the result of the financial period will not be affected. The effect on the balance sheet is the same.

Table number 2. The depreciation method used

Company	The Method used
Alro SA Slatina	Gross value method
Alumil Rom Industry SA	Net worth method
Azomures SA	Net worth method
Mechel Targoviste SA	Gross value method
Mecanica Ceahlau SA Piatra Neamt	Net worth method

Source: Financial Reports for 2010 and 2011

Conclusions:

Accounting treatments and policies used by companies influence the result of the financial period, leading many times to a result which can be determined by the needs of the companies.

Tangible fixed assets accounting policies directly affect the result of the exercise. Some companies have adopted a policy of acquisitions of tangible fixed assets. This will affect the operating result in the next period, especially in companies which do not have as main activity the manufacturing, decreasing this indicator.

Also all the companies which were subject to the study used the linear method of depreciation, although it could use a depreciation method that reflects the proportional utilization of equipments, for example the digressive or accelerated depreciation method.

According to many specialists in the field, the fair value evaluation of the balance sheet would be justified only for the elements which are meant to sale, marketing while those which are to be preserved, should be evaluated at the historical cost.

An important aspect worth mentioning is that information users must consider not only one indicator, but many indicators: turnover, operating result, total assets, net assets and every ratio that can lead to a real value of the company.

Abstract

Economic entities have a very important role in our daily life and for this reason performing companies are a key element for the development of a nation. Thus, many economists consider economic entities as an engine – in determining economic, social and political progress. In the context of the current economic and financial crisis it is highly important to know the factors generating success and how it can be measured. Changes in economic and social environment, technology improvement, need for relevant, reliable, timely and effective information in decision making in order to achieve performance goals have led us to think about performance measurement as a consequence of fair assessment.

Keywords: fair value, performance, market, financial position.

JEL classification: M41

1. Introduction

The goal of general financial statements is to provide information about: *financial position; performance and cash flows of an economic entity, useful for a wide range of users in economic decision making.* Financial statements also show the results of company's management of the resources entrusted.

Applying the *fair value in accounting* “seems” to enable the development of financial statements that give others better information on current and future performance of the company and therefore the possibility of substantiating their decisions. *By making such a statement we feel obliged to ask about the relationship*

between accounting results, in the broad sense of the term, and the company's market value. Amid the exponential growth of financial markets, some foreign experts ask themselves the following question: *Is the recognition of balance sheets and past results likely to generate information on the evolution of future results?* [1].

2. Concept of performance

The meaning of the concept of performance has changed over time becoming a polysemous term with various meanings depending on the areas in which it is used. The word performance comes from Latin word “performare” and means “giving form to something entirely”, but its meaning comes from the English verb “to perform” which means “to achieve something that requires a particular skill or aptitude” [2].

In the local literature we meet the noun “**performance**” which basically translates the manner with which an organization achieve the goals that have been proposed. [3].

Other meanings referred to in the literature [4] are common without reaching a universal definition of performance.

Performance means success. Performance does not exist by itself, being dependent by the representation of the success of the different categories of users of accounting information.

Performance is the result of the action. Opposite to the preceding, this sense does not retain the value judgment of external users. Performance measurement is understood as the “ex-post evaluation of the results obtained”.

Performance is action. In this sense, the performance is a process, not an outcome that occurs at a time. If we refer to all of these

meanings we can say that performance can be defined by the users of accounting information in relation to their own goals.

Bunea Stefan, in his attempt to define this notion so “sweet” as meaning but “bitter” in its complexity, from the economic perspective, distinguishes three major guidelines [5].

Definition of performance based on the achievement of goals: from this perspective an entity can be considered efficient only if it achieves the goals set. In other words, the performance depends on a purpose, a goal originally set or a reference. Since purposes may be multiple - depending on the one setting this reference and the reason why it is set, performance becomes multidimensional. A performance itself is not poor or good, it can be appreciated as a good performance when the goal is modest or as poor performance, if we are dealing with an ambitious goal. [6].

Definition of performance based on value creation: for the economic entity, performance is what helps to improve value-cost relation and not just what helps to reduce costs or increase value. Creating value should be considered from the perspective of all those parties involved in the activity of the institution - shareholders, employees, customers and not least the environment in which the institution operates.

The concept of value creation is based on a worldwide admitted truth, regardless of geographic or economic boundaries: companies create value as long as provides remuneration of capital at a rate of return that exceeds its cost. In other words, it is not enough that an entity is recording accounting profit for it to create value. The concept of *value created* is linked, directly or indirectly, to the profit, but a profit, even very large, has no value in itself, but it must be judged in the light of efforts made to obtain it and in terms of resources used, which have a cost, even if we consider it virtual or of opportunity. Today, all economic entities responsible face the problem of value creation under the pressure of internal management aspirations, oriented either to increase the value or under pressure from financial markets that require a higher and faster yield.

Definition of performance based on profitability and efficiency of the economic entity: According to this vision, an economic

entity is theoretically efficient if it is both profitable and effective [7].

Performance is the degree to which an entity manages to meet both the internal environment and the external environment requirements, through an optimal combination of effectiveness and efficiency.

According to Professor Maria Niculescu, performance “is a company’s state of competitiveness reached by a level of effectiveness and productivity (efficiency) that ensures its sustainable market presence” [8].

You cannot win a race without knowing where you are going and under what conditions, without defining your path and resources you need to support the race, without being trained and motivated to win it! Without proper management, there cannot be performance, effectiveness. Therefore performance has its cost. Normally, costs should be lower than the results obtained, otherwise the economic entity does not generate a positive value.

Therefore, if effectiveness is a measure of what is being done, efficiency is a measure of how it is done. It is not the same thing if in achieving its objectives an economic entity generates a lower or higher value, and this value is manifested in many forms, sometimes tangible and other times intangible and it is provided to customers, shareholders, employees and partners. The entity will produce more value, the more it will have more resources available to invest in long-term competitive fight. It can be created a definition of performance starting from the following elements: achieving something for a given purpose (create value); result (which can be defined in different ways); achievement potential (creative ability, customer loyalty); comparing a results to a reference (internal or external, chosen or imposed); competition (applying the concepts of continuous improvement, doing better than last time); judgement; comparison.

3. Implications of using fair value on financial performance

Fair value represents one of the forms of assessment that make increasingly more presence felt both in the accounting language and accounting standards. Adopting fair

value as assessment basis in the financial statements has generated numerous disputes being considered one of the main triggers of the crisis [9].

In this respect, the arguments consist in his pro-cyclical nature and the insufficient information provided by the setters, for the assessment of financial instruments on inactive markets.

Regarding the fair value Gilbert Gélard, IASB member and representative of the French profession, interviewed by SIC magazine in March 2003, stated the following: *“The stake is changing the model of accounting from cost to value, having as corollary the volatility (...) is a major conceptual change facing many obstacles: habit, fear of systemic risk, absence of reliability – of fair value – (sometimes internally calculated without the possibility of being controlled too much), a management divorce...”*.

Dudian Monica and Huru Dragos stated that at the basis of the concept of *fair value* is the presumption that economic entities have an ongoing activity (the principle of continuity) without any intention or need to liquidate the business, significantly reducing the scale of its operations or undertaking a transaction on unfavourable terms [10].

Therefore, the fair value will not be the amount that the entity would receive or pay in a fortuitous transaction, forced liquidation or forced sale. However, the entity may be forced to consider its economic situation or current operations to determine the fair value of its assets and liabilities.

For example, the management’s plan to sell an asset on an accelerated basis to meet specific business goals may be relevant for determining the fair value of that asset. Disclosure of assets, liabilities and specific components of equity may arise from both the original records of transactions and as a result of subsequent modification of values.

Assessments and disclosure of fair value are not assertions themselves, but may be relevant to specific assertions based on the applicable financial reporting framework. Many assessments based on estimates, including fair value assessment are inherently imprecise. In addition, there are some evaluation practices and disclosure requirements for fair value in specific sectors.

The best fair value impact on a business performance measurement is provided by IAS 39 *“Financial instruments: recognition and measurement”*. Certain assets and liabilities are included in the balance sheet at their fair value, meaning at the market price. Any change occurred in the fair value of recognized assets and liabilities is taken to income statement. This changes the nature of profit and loss account and requires rethinking performance measurement process as net income before tax is no longer the economic activity of the company, but it also includes the profit generated by the growth of the fair value of assets.

In other words, changes in market values will lead to changes in the results reported in the profit and loss account and under these conditions it will be difficult to attribute the performance to internal changes or external conditions (market).

If the use of fair values lead to a market price impact on revenue, and hence on the performance, then the income will become more volatile as a result. Using fair value involves a change in direction of profit and loss account towards a global income statement, as does the one developed by the United States.

There are two views outlined in this regard, namely:

Arguments against:

1. It is difficult for shareholders to assess the effectiveness of resource management by the company’s management;

2. Profits arising from changes in fair value could be unrealized and the recognition of unrealized gains is inconsistent with the traditional conservative approach to accounting.

The pros:

1. Acquisition of assets whose value decreases is a clue of poor management that should be recognized in the income statement.

Reporting overall income in financial statements will involve the presentation of all the changes in the assets and liabilities arising from transactions other than with shareholders. This project intends to combine into a single statement called *“overall income statement”* all the currently elements recognized in the profit and loss account or the statement of changes in equity: *revaluation of fixed assets,*

investments in properties, goodwill, gain/loss on disposal of assets and net investments, fair value or cash flow covering etc. But this project has not yet been finalized and therefore we can say that the use of fair value in the absence of an overall income is not beneficial, especially in assessing performance. Currently, however, the fair value is trying to reduce the negative effects of historical cost. Once with the ever more powerful development of financial markets, fair value will have an *increasing* role.

4. Conclusion

Although international standard setters have wanted and still want to extend the practice of fair value of all balance sheet items, regardless of the scope of the entity, fair value assessment remains a very controversial topic.

The impact of assessment in fair values is significant, some authors considering that assessing the fair value of all balance sheet items leads to a result three times higher than the net result [11].

Therefore, the fair value assessment of balance sheet assets represents a risk of manipulation of the result as fair value is only an accounting estimation which leads to behaviours such creative accounting.

In addition, some experts believe that, in times of crisis, the fair value should not be determined based on the market value, but according to future estimates of cash flows to be generated by that item. Current experience related to capital markets falling provisionally stopped the trend of fair value assessment of balance sheet items. However, the fair value is considered to be the best method available to establish financial instruments and to reflect the financial position of an entity.

The European Social Charter (Revised) and the Protection of the Human Rights

Mititelu Cătălina,

maryanaradu@yahoo.com

Abstract

Between the moment of Convention for the Protection of Human Rights and Fundamental Freedoms (Rome, 1950) and The Treaty establishing a Constitution for Europe (Lisbon, 2007), the human rights - which have been the subject of numerous approaches and evaluations along the centuries, most of them considering the philosophical, juridical, and socio-political aspects - were taken into account in the pages of the documents elaborated by The Council of Europe. The texts of such documents are legally binding for all European Union members. One of these texts is also that of the European Social Charter (revised) published in Strasbourg in 1996, which contains general principles and norms of the European Union legislation on the juridical protection of the human rights. The output of the hermeneutic analysis of this Social Charter reveals that the member states of The Council of Europe, which included the protection of the human rights amongst their major preoccupations, brought an important contribution to the creation of the juridical framework for the affirmation and protection of the human rights.

Key words: Protection of Human Rights, Council of Europe, European Code on Social Security, Human Dignity

J.E.L. Classification: K33

1. Introduction

The European Convention, especially The European Social Charter, certifies that so far we can only speak about legislative reforms

in the social construction and reconstruction of Europe on European and international level, not on national one, although these two documents enforced as obligatory juridical documents have been ratified by Romania as well. Therefore, we intend to present within the pages of this study – even it is a brief presentation – the provisions stated as principles in the text of The European Social Charter (Revised) with the hope that such provisions will not only remain in the ratified texts as “Pium Desiderium” (Pious Wish), but by contrary it the near future they will become real and translated into practical and effective measures, and into the day-by-day life of the Romanian citizens.

2. Analysis of the subject

The European Convention on Human Rights (ECHR) (formally the Convention for the Protection of Human Rights and Fundamental Freedoms) is an international treaty to protect human rights and fundamental freedoms in Europe[1]. Drafted in 1950 by the then newly formed Council of Europe, the Convention entered into force on 3 September 1953. The Convention, which established the European Court of Human Rights (ECtHR), it is still the only international human rights agreement providing such a high degree of individual protection.

On 6th April 1964, the member states of The European Council have signed The Code on Social Security [2], to which Protocol to the European Code of Social Security has also been attached ten days later on [3].

The text of The European Social Charter enforced in Turin on October 18, 1961 has been revised in Strasbourg in 1996, and

afterwards published as *The Revised European Social Charter* [4]. Romania ratified The Charter in 1999 (The Law n. 74, Published in The Official Gazette n. 193/04.05.1999).

In line with the provisions of Article 7 of the Code on Social Security, each State “... must guarantee the medical care of curative nature to the protected persons under prescribed conditions when they need preventive or curative medical care ...”. The Code also enforces the obligation of the Parties to guarantee “unemployment support for the protected persons” (Article 19), “old-age benefits” (Article 25), “work accidents and occupational disease benefits” (Article 31), “medical care in case of maternity” (Article 49), “survivor’s benefits” (Article 59), etc.

As regards the protection of the human rights the 1st Part of The European Social Charter (the revised version enforced in Strasbourg) includes numerous basic *rights and principles*, e.g.: the opportunity of any person to earn his living in an occupation freely entered upon; the right to just conditions of work; the right to safe and healthy working conditions; the right to a fair remuneration; the right of all workers and employers to freedom of associations for the protection of their economic and social interests; the right of all children and young persons to “a special protection” against the physical and moral hazards to which they are exposed. The children and the teenagers have the right to a fair social, juridical, and economical protection; the right of the woman workers to “a special protection” in case of maternity; the right of any person to appropriate facilities for vocational guidance; the right of any person to benefit from any measures regarding his sanitary situation; the right to social security; the right to social and medical assistance; the right to benefit from qualified social welfare services; the right of any disabled person to independence, social integration and participation in the life of the community; the right of the family to social, juridical, and economical protection; the right of any European citizen to engage in any gainful occupation in the territory of any one others Party that signs this European Charter, on a footing of equality with the nationals of the latter, “subject to restrictions based on cogent economic or social reasons” (Article

18); the right of migrant workers who and their families to social protection and assistance; equal opportunities and treatment in matters of employment and occupation without discrimination on the grounds of sex; the right of the workers to be informed and to be consulted, including the procedures of collective unemployment and to take part in the determination and improvement of the working environment; the right of the every elderly person to social protection; the right of all workers to protection in cases of termination of employment; the right of all workers to protection of their claims in the event of the insolvency of their employer; the right to dignity at work; the right of all persons with family responsibilities to be employed; the right of workers’ representatives in undertakings to protection against acts prejudicial to them; the right of any person “to protection against poverty and social exclusion” (Part. I, Article 30); the right “to housing” (Article 31).

For the effective implementation of the above-mentioned rights, the Charter has also stipulated the obligations the Parties should be considered themselves as bound in. For example, with a view to ensuring the effective exercise of the right to work, the Parties must “recognize as one of their primary aims and responsibilities the achievement and maintenance of as high and stable a level of employment as possible,” (Part III, Article 1).

With a view to ensuring the effective exercise of the right to just conditions of work, the Parties undertake – amongst others – “to provide for public holidays with pay”; to provide “for a minimum of four weeks’ annual holiday with pay”; to eliminate “risks” in inherently dangerous or unhealthy occupations, etc. (Part II, Article 2).

With a view to ensuring the effective exercise of the right to safe and healthy working conditions, the Charter provides that the Parties are under the obligation in their policy to have “as primary aim to improve occupational safety and health and to prevent accidents and injury to health arising out of work,...” (Part II, Article 3, paragraph 1).

With a view to ensuring the right to a fair remuneration, the Charter provided the obligation of the Parties to recognize “the right of all workers to a reasonable period of notice for termination of employment” and

“to permit deductions from wages only under conditions and to the extent prescribed by national laws or regulations or fixed by collective agreements or arbitration awards” (Part II, Article 4, paragraphs 4 and 5).

With a view to ensuring and to protecting the union right, the Charter provided the obligation of the Parties to maintain this right unprejudiced by “their national laws and regulations” or the way this legislation is enforced (Part II, Article 5).

With a view to the right to bargain collectively “employees and employers” (see Part I, n. 6), the 2nd Part of the Charter provides the obligation of the Parties to promote “the establishment and use of appropriate machinery for conciliation and voluntary arbitration for the settlement of labour disputes” (Article 6, paragraph 3).

With a view to ensuring the effective exercise of the right of children and young persons to protection, the Charter provides the obligation of the Parties “to provide that the minimum age of admission to employment shall be 15 years” and “to forbid the employment of the children that are still included in obligatory educational process...” (Article 7, paragraphs 1 and 3).

With a view to ensuring the right of employed women to the protection of maternity, the Parties undertake amongst others to consider it “as unlawful for an employer to give a woman notice of dismissal during the period from the time she notifies her employer that she is pregnant until the end of her maternity leave...” (Article 8, paragraph 2).

In order to ensure the effective exercise of the right to vocational guidance, the Parties undertake “to provide or promote, as necessary, a service which will assist all persons, including the handicapped...; this assistance should be available free of charge, both to young persons, including schoolchildren, and to adults” (Article 9).

As regards the right to vocational training, the European Social Charter (Revised) provides the same obligation of the Parties to provide or promote “the technical and vocational training of all persons, including the handicapped... and to grant facilities for access to higher technical and university education, based solely on individual aptitude...”.

With the same view to ensuring the effective exercise of the right to vocational training, the Parties undertake “to provide or promote, as necessary, special facilities for the retraining and the reintegration of the long-term unemployed persons” and to ensure, “through adequate supervision”, the efficiency “of adequate protection of young workers” (Article 10).

Amongst the measures the Parties should undertake in order to effectively promote the right to health protection, the Charter provides: the removal of the causes of “ill-health”; the creation of “advisory and educational facilities for the promotion of health and the encouragement of individual responsibility in matters of health”; the prevention “as far as possible of epidemic, endemic and other diseases, as well as accidents” (Article 11).

In order to ensure the exercise and protection of the right to social security, the Charter provides, amongst others, the obligation of the Parties to establish and maintain “the social security system at a satisfactory level at least equal to that necessary for the ratification of the European Code of Social Security...”, and to apply for the citizens of each Party “equal treatment with their own nationals of the nationals of other Parties in respect of social security rights, including the retention of benefits arising out of social security legislation, whatever movements the persons protected may undertake between the territories of the Parties...”.

With a view to ensuring the effective exercise of the right to social and medical assistance, the Charter requested the Parties “to ensure that any person who is without adequate resources... be granted adequate assistance, and, in case of sickness, the care necessitated by his condition...”, and to provide that everyone may receive “by appropriate public or private services such advice and personal help as may be required to prevent, to remove, or to alleviate personal or family want...” (Article 13, paragraphs 1-3).

In this respect, the public institutions as Mayoralties, Social Assistance Organizations, Hospitals, etc. are under the obligation of providing both the needed social and medical assistance, and the

adequate material support to the persons with personal or familial needs.

The Charter provides also that in order to fairly apply the right to social and medical assistance the Parties should apply the equal footing with their nationals to nationals of other Parties lawfully within their territories “in accordance with their obligations under the European Convention on Social and Medical Assistance, signed at Paris on December 11th 1953” (Article 13, paragraph 4).

With a view to the right to benefit from social welfare services, the Charter provided the obligation of the Parties to promote or provide services, which would contribute “to the welfare and development of both individuals and groups in the community, and to their adjustment to the social environment” (Article 14, paragraph 1).

With a view to ensuring to persons with disabilities the effective exercise of the right to independence, social integration and participation in the life of the community, the Charter provided the obligation of the Parties to take “the necessary measures to provide persons with disabilities with guidance, education and vocational training...” and “to promote their full social integration and participation in the life of the community...” (Article 15, paragraphs 1, 3).

The Parties are also under the obligation to promote as well “the economic, legal and social protection of family life by such means as social and family benefits, fiscal arrangements, and provision of family housing, benefits for the newly married and other appropriate means” (Article 16).

With a view to ensuring the effective exercise of the right of children and young persons, the Parties engaged themselves to ensure: a) “...the care, the assistance, the education and the training they need”, obviously “taking account of the rights and duties of their parents”; b) the protection of the children and young persons against negligence, violence or exploitation; c) the protection and special aid from the state for children and young persons temporarily or definitively deprived of their family's support; d) the free primary and secondary education to children and young persons, as well as to encourage regular attendance at schools.

The European Social Charter provides the obligation of the Parties to ensure both the right to engage in a gainful occupation in the territory of other Parties (Article 18), and the right of migrant workers and their families to protection and assistance on the territory of other Party (Article 19). The Parties should also “secure that such workers lawfully residing within their territories are not expelled unless they endanger national security or offend against public interest or morality” and “promote and facilitate, as far as practicable, the teaching of the migrant worker's mother tongue to the children of the migrant worker” (Article 19, paragraphs 8 and 12).

With a view to ensuring the effective exercise of the right to equal opportunities and equal treatment in matters of employment and occupation without discrimination on the grounds of sex, the Parties should ensure: a) “access to employment, protection against dismissal and occupational reintegration; b) vocational guidance, training, retraining and rehabilitation; c) terms of employment and working conditions, including remuneration; d) career development, including promotion” (Article 20).

The Charter has included the obligation of the Parties to ensuring the effective exercise of the right of workers to be informed and consulted within the undertaking. Based on this right, the workers should “be informed regularly or at the appropriate time and in a comprehensible way about the economic and financial situation of the undertaking employing them...”; and “be consulted in good time on proposed decisions which could substantially affect the interests of workers, particularly on those decisions which could have an important impact on the employment situation in the undertaking” (Article 21, paragraphs 1-2).

The Parties have engaged to promote measures aiming at: a) “the determination and the improvement of the working conditions, work organisation and working environment; b) the protection of health and safety within the undertaking; c) the organisation of social and socio-cultural services and facilities within the undertaking; and d) the supervision of the observance of regulations on these matters” (Article 22).

The signatory Parties of the Convention have also engaged themselves to ensuring and promoting the right of the elderly persons to social protection [5], in particular by means of “adequate resources enabling them to lead a decent life and play an active part in public, social and cultural life...”; at the same time, the Parties should enable elderly persons “to choose their life-style freely and to lead independent lives in their familiar surroundings for as long as they wish and are able...” (Article 23)

The Parties undertake to recognize the right to protection in cases of termination of employment (Article 24); to ensuring the right of workers to the protection of their claims in the event of the insolvency of their employer (Article 25); “to promote awareness, information and prevention of sexual harassment in the workplace or in relation to work and to take all appropriate measures to protect workers from such conduct” (Article 26); to ensuring the effective exercise of the workers with familial responsibilities to equal opportunities and treatment (Article 27); to ensuring the right of workers' representatives to carry out their functions, to guarantee “an effective protection against the facts that could lead to prejudice, including against unemployment procedure” and to create adequate possibilities to enable them to quickly and efficiently carry out their tasks...” (Article 28); to ensuring the workers' representatives the right “to information and consultation in collective redundancy procedures...” (Article 29); to ensuring the effective exercise “of the right to protection against poverty and social exclusion...” (Article 30); to ensuring the right to housing, hence “...to make the price of housing accessible to those without adequate resources” (Article 31).

Finally, the 5th Part of the European Social Charter restricts *expressis verbis* any kind of discrimination. “The enjoyment of the rights set forth in this Charter shall be secured without discrimination on any ground such as race, colour, sex, language, religion, political or other opinion, national extraction or social origin, health, association with a national minority, birth or other status” (Article E).

3. Conclusions

This specific Article of the European Social Charter (Revised) aimed to the reaffirmation of the principle according to which the affirmation and protection of the human rights involves the restriction of every single kind of discrimination[6] on any ground like race, colour, sex, language, religion, philosophical and political opinion, etc. Indeed, for the Party States of the European Council that ratified the Charter, the ethnical and social origin, the health status or the national extraction, the association with a national minority, etc. cannot represent grounds or conditions leading to the violation of the human rights. By contrary, the Charter provides the compulsoriness of ensuring the compliance all human rights recognized within its text.

The brief analysis of the Revised European Social Charter reveals that the Member States of the European Council put the legal protection of human rights on the first place in the list of their major preoccupations. Undoubtedly, through the enforcement of the human rights legal protection the States have reaffirmed the right to “*dignitas humana*” (human dignity) of each person, as expressly provided by the text of The Treaty establishing a Constitution for Europe (see Article 6).

Abstract

The phenomenon of globalization we are witnessing today determines the development of interstate relations by enhancing collaboration between them. If in the past globalization was achieved through force, violence and terror, nowadays we all realize that, without the strong cooperation between countries in certain areas of social life, there would be no guarantee for sustainability.

Through the long and sinuous globalization process that underlies the international cooperation, states have imposed laws that have governed their relations, reaching an agreement on the means and instruments of establishing the relations between them. Of course, the aforementioned cooperation entails vast advantages, but, sometimes, there can be a number of problems and difficulties that should be regulated and granted mandatory force.

Key words: globalization, cooperation, criminal, regulatory harmonization

J.E.L. Classification: K14

1. Introduction

The European countries, as the whole world, are witnessing a major transformation. But what are the reasons for these changes? Since the beginning of the millennium, a sense of awareness emerged according to which, without permanent changes consistent with all the requirements of social life, there cannot be any achievement of full protection and safety within the community we live in. These changes refer to finding new ways to counterattack the nuisances of society. We

address here the contemporary criminality as a phenomenon threatening the system of social values as states pillars [1].

It goes without saying that, in the fight against national and international crime, the best results cannot be obtained without the special cooperation between states.

The fight against crime is a major concern of all States and, above all, it is a priority over many other demands that society requires at a certain time. In these circumstances, states are forced to render mutual legal assistance, thus cooperating in the discovery, apprehension and conviction of all those who disobeyed in any way the criminal law [2].

This disturbing presence of crime in the international life entailed solidarity among the states aware of the need of cooperation, in order to prevent and fight against this phenomenon. Because of its scale, of its area of distribution and of its organized nature, it is obvious that international crime exceeds the states' capacity of response, and that a solitary fight cannot be carried out effectively.

Moreover, the Romanian legislator's concerns are to harmonize our legislation with that of European countries: the adoption of Law no. 302 of 28 June 2004 [3], amended by Law no. 244 of 01/06/2006 [4], demonstrates the awareness of the need for close cooperation between States in order to prevent and fight against acts hindering the rule of law.

In this respect, Romania has concluded several bilateral and multilateral agreements with a large number of states, entailing reciprocal assistance in criminal matters. The legal system is perhaps the most demanding area of social life, which has often raised issues for Romania at an international level.

Agreeing or harmonizing legal thinking is, at present, an element that requires great attention and concern for the deciding actors.

The globalization phenomenon we are witnessing is unfortunately fuelling the dimension of antisocial acts of repression, which exceeds the scope of a single state reaction. It is therefore imperative that the fight against crime states grants mutual aid.

This reciprocity requires similar or even identical perspectives on their reaction when faced with crime. We cannot speak of international aid since the two countries have very different legal backgrounds for sanctioning aggressive acts.

The parity of legal instruments against international crimes increases the state's reaction when confronted with a threat. The similarity of legal systems determines agreeing upon the legal and political aspects, so that we are now witnessing the emergence of a unified legal system at the continental level, and even at the global level.

From this point of view, Romania is making serious efforts in order to build a sustainable and well grounded system of legal rules which also meets international requirements. Of course, this transformation of the legal system is not easy to achieve in terms of the plurality of views, but many laws enforced after the events of 1989 and the fast changing rhythm of the Romanian legislative reveal the legislator's concern in harmonizing the Romanian legislation with the European and global ones.

Law 302/28.06.2004 on the international judicial cooperation in criminal matters is undoubtedly one of the most complete and modern settlement so far in this area, being also in line with the European legislation. The adoption of this legal instrument was strongly determined by Europe's critical attitude and it is inspired from the laws of other EU Member States.

The emergence and development of international cooperation was imposed not only by positive events but also by negative ones, entailing the need to find solutions to the problems that exceeded the singular capacity of a state. At the current stage of development, the contemporary international cooperation between sovereign and equal international actors is a reality imposed by objective needs [5]. The principle of cooperation is now widely accepted in the

international relations among states, contributing to the mutual understanding among nations. The fundamental premise in the development of international relations must remain the respect of national sovereignty and independence [6].

International cooperation is thus a way of showing the existence of states in international relations, of respecting the national sovereignty and independence, based on consensual agreement and granting mutual trust in order to promote and protect common interests.

2. Institutions empowered in the international judicial cooperation in criminal matters

2.1. Romanian central authorities

According to article 13 of Law 302/2004, the Romanian central authorities must submit the requests in the areas covered by Titles II (extradition) and IV-VII (transfer of proceedings in criminal matters and the recognition and enforcement of judicial proceedings, transfer of sentenced persons, legal assistance in criminal matters) of this Law and transmit them through the following central authorities:

a) The Ministry of Justice, if they concern the extradition and transfer of sentenced persons or if they refer to the activity of judgment or to the stage of the enforcement of criminal court decisions;

b) The Public Prosecutor's Office attached to the High Court of Cassation and Justice, if they refer to activities from the stage of investigation and criminal prosecution;

c) The Ministry of Administration and the Interior, if they refer to the criminal record.

Most of cooperation forms require the appointment of one or more central authorities for the submission of requests and performance of other tasks. In Romania, as in most states, the Ministry of Justice is the central authority in the following matters: extradition, transfer of sentenced persons, transfer of proceedings, recognition of judgments and legal assistance during trial. The requests for mutual legal assistance during criminal investigation and prosecution are dealt with by the Prosecutor's Office from the High Court of Cassation and Justice; however, there are treaties (such as

the one with the U.S.) requiring, at this stage, the submission of requests through the Ministry of Justice. The Ministry of Interior is the central authority for all requests concerning criminal records.

On 1 December 2000, there was established the National Focal Point – a body subordinated to the Ministry of Administration and Interior of Romania, its main task being to ensure the operational cooperation between the structures with attributions in this field, from the Ministry of Interior and the Ministry of Finance – the National Authority for Customs and the corresponding agencies from the states part in SECI [7].

2.2. Foreign central authorities

The concern for the problem of international crime is relevant not only to states, but also to some important international organizations such as the United Nations Organization (now UN), the International Criminal Police Organization (INTERPOL) and the Council of Europe [8].

The idea of cooperation in the field of judicial investigation was, at the first, the subject of sporadic and isolated concerns, resulting in some agreements with a bilateral nature. In 1914, in Monaco, there took place the first International Congress of the police force, whose main concern was the centralization of documents related to the identification of criminals, the international research facilities to be provided and the procedure for extradition.

The contribution of the United Nations and of the Council of Europe in the fight against crime is not limited to drafting conventions, protocols and agreements, as these actors also give resolutions, directives and recommendations setting the major lines of action in the matter; they are also completed by the joint declarations of Heads of State and the Government. The role of cooperation coordinators in Southeastern Europe is also played by several organizations including the Council of Europe, SECI, OSCE, UNICEF, and the Pact for South Eastern Stability by the European Task Force on Trafficking in Human Beings.

Good cooperation is achieved not only by Interpol but also by ENFOPOL (for central and Eastern Europe), by the National Anti-

Mafia Directorate in Italy, and by the institutional twinning programs and by Romania-US Strategic Partnership (since 1998).

A specific form of cooperation between states in order to suppress certain categories of offenses is achieved by establishing several international courts, to prosecute the most serious crimes against humanity. Thus there were established:

- The Nürnberg International Military Tribunal for the prosecution of war crimes in Europe;
- The Tokyo War Crimes Tribunal for crimes in Asia;
- The International Criminal Tribunal [9] in Hague, whose jurisdiction is limited to crimes committed in the former Yugoslavia since 1991; it covers four categories of crimes: serious breaches of the Geneva Conventions of 1949, breaches of the laws and customs of war, genocide and crimes against humanity[10];
- The International Tribunal for Rwanda, in Arusha (Tanzania), which prosecutes the crimes of genocide, the crimes against humanity and the breaches of the Geneva Conventions, committed by Rwandans in neighboring states[11];
- The International Criminal Court, established on 17 July 1988 at Rome, by which there has been established the Statute of the International Criminal Court [12] in Hague; this court may exercise its powers in the territory of any State Party regarding: crimes of genocide, crimes against humanity, war crimes and the crime of aggression.

As part of the third EU pillar (the international cooperation in criminal matters), there are three agencies:

1. The European Police College (CEPOL) [13] aims to support the training of border police and of senior officers, by improving and strengthening the cooperation between institutes and national professional organizations;
2. EUROPOL;
3. EUROJUST.

At EU level, there are two institutions empowered in the field of international cooperation, namely Europol and Eurojust. An important contribution to the international cooperation was brought by the European Council [14], under which there were adopted, so far, over 160 agreements and

numerous recommendations that establish common action in economic, social, cultural, scientific, legal and administrative fields and that govern, among other things, a system of coordination between the European countries in the fight against crime[15].

I. Eurojust [16]: It was created by EU Council Decision of 28 February 2002 no. 2002/187/JHA OJE L 63/1, 6.3.2002, as amended by Council Decision of 18 June 2003 no. 2003/659/ JHA (OJE L 245/44, 29.09.2003). Since 1 March 2001, it provisionally operated in Brussels and, in December 2002, it moved to Hague.

Eurojust is the European body that serves to enhance judicial cooperation and coordination between Member States, by adopting structural measures at the EU level, in order to facilitate the optimal coordination of actions in the investigation and indictment of suspects in the Member States, while fully complying with fundamental rights and freedoms. The main objectives are: to boost the coordination between the competent authorities of the Member States in the investigation and prosecution in the Member States, to improve the coordination between the competent authorities of Member States, particularly in facilitating mutual legal assistance and the implementation of extradition requests, to support the competent authorities in the Member States in order to streamline investigations and indictments.

Eurojust (European Judicial Cooperation) is a new European Union body established in order to increase the efficiency of Member States' competent authorities when dealing with serious cross-border and organized crime.

The legal doctrine states that Europol and Eurojust are the third pillar in police and judicial cooperation in criminal matters. Europol and Eurojust are decentralized bodies of the EU. Eurojust and Europol signed an agreement for close cooperation on 9 June 2004. The cooperation between Romania and Eurojust started in 2002, by the resolution of complex cases of transnational crimes of human trafficking or drugs.

II. Europol (European Police Office) [17]. The idea of a European Police Office was first launched at the European Council in Luxembourg, on 28 and 29 June 1991. The

plan had in view to establish a new body in order to provide a framework for developing police cooperation in the EU Member States, to prevent and combat international organized crime, including terrorism and drug trafficking. The Convention whereby the Europol was set up was signed in July 1995 and entered into force on 1 October 1998.

Coordinating the work of various national police service, Interpol does not intervene directly, as it has an operational service. Intervention takes place at the request of national central offices and it shall be made by the dissemination, in other national offices in the affiliated countries, of records on the wanted individuals, whose refuge is not known [5]. The scope of Interpol is limited to common law offenses [18]. Interpol's activity is not only procedural, but also informative, as it monthly publishes tables on the traffic of narcotic drugs and crime statistics.

The Treaty of Amsterdam gives Europol a number of tasks such as: coordinating and implementing specific investigations undertaken by Member States, developing specialized skills in order to assist Member States in their investigations into organized crime, establishing contacts with prosecutors and investigators specializing in fighting against organized crime.

From the perspective of its mission, Europol is the organization in charge of law enforcement in the EU, which operates with information about crime. Its objective is to improve the effectiveness and cooperation of the competent authorities of the Member States in preventing and fighting against serious forms of international organized crime and terrorism. Europol's mission is to make a significant contribution to EU action law enforcement against organized crime and terrorism, concentrating its efforts on criminal organizations.

Europol supports law enforcement activities conducted by Member States, in particular against: drug trafficking, illegal immigration networks, terrorism, counterfeiting money (euro counterfeiting) and other means of payment, human trafficking, including child pornography, trafficking in vehicles, money laundering. European officials acknowledge that the changes made in terms of policies, institutions and security instruments adopted

by the EU, and which are in the process of quickly adapting to the new challenges of the contemporary world, affect personal freedoms. But, at the same time, improving security measures at European level and achieving a safer environment fully justifies some shortcomings caused by the “freedom of movement”.

Given that the activities related to international organized crime do not stop at national borders, Europol has improved its international law enforcement cooperation through the negotiation of bilateral or strategic operative agreements with other states and international organizations such as: Bulgaria, Colombia, the European Central Bank, the European Commission, including the European Anti-Fraud Office (OLAF), Eurojust, the European Monitoring Centre for Drugs and Drug Addiction, Iceland, Interpol, Norway, Switzerland, Turkey, the United States, the United Nations Office on Drugs and Crime, the World Customs Organization, Romania and Russia.

3. Difficulties of international cooperation in criminal matters

The overview of the concept and scope of international cooperation in criminal matters reveals the importance, needs and justification in the present context of international relations.

The aim of cooperation in criminal matters is very precise, contoured, many years ago, by those who became aware of the advances and perspectives of globalization. The international cooperation in criminal matters did not reach maximum maturity because, in practice, there are many problems that hinder cooperation activities. Among them, there are: the existence of different languages, of diverse judicial systems, the existence of different laws and of different criminal laws, the slowness of the mechanisms for the transmission of requests, the lack of monitoring and control practices regarding the requests for legal assistance, dual criminality, the defense of own citizens, the fact that the authorities control the State requested to respect procedural safeguards and the establishment of different ways of appeal: distrust, cooperation limits due to diffuse causes such as national interest or public order.

4. Conclusions

As we can notice, the activity of international cooperation in criminal matters is a major concern of competent state organs and, therefore, the Romanian legislator has made positive steps in order to ease international relations. On this occasion, we welcome the enforcement of Law 302/2004 (and of its subsequent amendments) on the international cooperation in criminal matters, which, by its content, brought an added value to the concept of interstate cooperation.

It is true that, at present, we cannot say that the laws in force have covered all the aspects of cooperation among states; however, we believe that, in the near future, all cooperation shortcomings or difficulties will be removed. The fact is this: without unions, states taken in isolation cannot cope with the new wave of international crime.
