Most of the current economic software solutions are based on distributed Web technologies. This fact has led to a new world of business, full of opportunities. Businesses can benefit now from faster communications, advanced methods of data collection, electronic chains of suppliers and other benefits offered by this new era of information processing. So, it is required a better level of security of the economic data, reason for what the role of cryptography is becoming increasingly higher. This paper reviews the progress in this area and points out some existent problems in digital chaotic ciphers. As a comprehensive solution to these problems, a novel pseudo-random bit generator based on a new couple of chaotic systems is presented. Detailed theoretical and statistical analyses show that it has perfect cryptographic properties, and it can be used to construct stream ciphers with higher security. Some experiments are made for confirmation.

Key words: chaotic systems, pseudo random, cryptography, stream cipher.

J.E.L. classification: C22

1. Introduction

In the last decade, the relationship between chaos and the classic cryptography has been highlighted and intensely analyzed because a lot of the properties of the non-linear dynamic systems have a correspondent abreast of the encryption systems based on computational methods. Thus, characteristics of the chaotic systems such as ergodicity, the system's sensitivity to the initial condition or the parameters' values, the mixing property,

the deterministic dynamic and complexity are similar to the properties given by the diffusion to minor changes of the plain or in key text, the diffusion determined by a change of the plain text, the deterministic pseudo-randomness and the complexity of the algorithm from classic encryption systems [9].

Since 2000, based on these results, a series of chaos-based cryptosystems have been proposed. They are: block type symmetric systems based on the construction of the encryption keys from the system's initial conditions and their multiple iteration, the string type symmetric systems based on the generation of random sequences used to hide the plain text [5,7,8,9].

However, the vulnerability of these systems shouldn't be neglected. Some of the chaos-based cryptosystems didn't resist to certain types of cryptanalytic attack. The predictability of the generated values using the orbits of a single system and the little space of the keys, allow attackers' to extract easily the information about the system, which makes the chaos-based encryption system to be weak candidates for security applications of the information [7,8].

The article proposes a theoretical analysis of the random qualities of new chaotic maps, as well as an analysis of the statistical results of pseudorandom number generators which are based on new maps.

In the next chapter is presented a brief of the chaotic systems used in cryptography, as well as a brief analysis of the proprieties of this type.

2. Chaotic systems used in cryptography

The most studied map within the studies on dynamic and chaos systems is the *logistic map*, described by the recurrence:

$$x(n+1) = f_L(x(n)), \quad (1)$$

where $f_L: [0,1] \rightarrow [0,1]$ is defined through:

$$f_L(x) = rx(1-x), \forall x \in [0,1] \quad (2)$$

The behavior in time, of the logistic map, depends on the value of the parameter r as well as the starting point represented by the initial condition. In figures 1, 2 and 3 we have summarized the complete dynamical behavior of the logistic map using the bifurcation diagram, exponent Lyapunov and distribution probability of the logistic map trajectories.

Figure 1. Bifurcation diagram of the logistic map

Figure 2. Lyapunov exponent of the logistic map

Analyzing the bifurcation diagram and exponent Lyapunov, it can be observed that for values of the parameter r between the interval $(3.57, 4]$, the logistic map has a chaotic behavior. The distribution probability of the logistic maps trajectories is showed in figure 3.

Figure 3. The distribution probability of the logistic map

It has been shown analytically that for the logistic map with system parameter $r = 4$, the probability distribution is given by [1]:

$$\varphi_f = \frac{1}{\pi \sqrt{x(1-x)}} \quad (3)$$

Another category of maps preferred for the simplicity and performances given in cryptographic applications, is represented by *tent maps*:

$f_T(x): [0,1] \rightarrow [0,1]$, defined through relation:

$$f_T = \begin{cases} \frac{x}{p}, & 0 \leq x \leq p \\ \frac{1-x}{1-p}, & p < x \leq 1 \end{cases} \quad (4)$$

where p is the parameter of the tent map. It is a non-invertible transformation of unit interval into itself and contains only one system parameter p , which determines the position of the tent in the interval $[0,1]$. A sequence computed by iterating $F(p; x)$ is expansionary everywhere in the interval $[0, 1]$ and distributed uniformly in it.

Recently, it has been demonstrated that different chaotic maps such as $x_{n+1} = f(x_n)$ have exact solutions written explicitly under the form [3]:

$$x_n = P(\theta T z^n) \quad (5)$$

where $P(T)$ is a periodical map, z is a whole number, θ defines the initial condition $x_0 = P(\theta T)$, and T is the period of the function $P(t)$.

A particular case of the relation (5) is $x_n = \sin^2(2^n \arcsin(\sqrt{x_0}))$ (6)

which is general solution of the logistic map $x_n = 4x_n(1-x_n)$. Similarly, the tent map defined by the relation (4) has the analytic solution:

$$x_n = \frac{1}{\pi} \arccos(\cos(2^n \pi x_0)) \quad (7)$$

The exact solutions of the chaotic dynamic systems allow the rise of the accuracy and computing speed. Instead of iterating a function, it can be calculated a value of a term using the analytical expression of the solution, avoiding in this way the numerical errors which can appear during iterations. Also, this procedure allows the calculation of the value x_k , avoiding $k-1$ iterations of the system.

The disadvantage of these number generators is given by the system's predictability. A remedy for this disadvantage is to use chaotic dynamic systems with no solutions. Such an idea was proposed by Gonzales and Pino. Another possibility to assure or at least to improve the construction of the chaotic dynamic systems with no solutions is to increase the space of phases S[3].

Thus, for the construction of a pseudorandom number generator we'll propose two one-dimensional maps whose analysis is presented in the next chapter.

3. The analysis of the proposed maps

For the construction of a pseudorandom number generator we'll propose two new one dimensional maps with a single parameter. In the beginning it is analyzed the map defined by the relation:

$$x(n+1) = f_N(x(n))$$

Where $f_N(x): [-1,1] \rightarrow [-1,1]$ is defined through:

$$f_N = \frac{2}{\pi} \operatorname{asin} \left(\cos \left(\pi \left(\frac{1}{2} - x * r \right) \right) \right) \quad (8)$$

and r is the parameter of f_N .

The behavior of the map f_N in time depends on the value of parameter r , as well as on the starting point represented by the initial condition. The bifurcation diagram is presented in figure 4.

Figure 4. Bifurcation diagram of f_N

At the value $r = 0.5$ the only attractor starts to split in two. After the value $r = 1$, the attractors split in four, eight, etc. Thus, for a value of a parameter r greater than 1, the map has a chaotic behavior. The conclusion is sustained also by the value of the Lyapunov exponent, represented in figure 5.

Figure 5. Lyapunov exponent of f_N

In figure 6, there are represented the distribution probabilities of the trajectories of the type (8) map which start from different initial conditions ($x_0 = 0.2$ and $x_0 = 0.7$), with the system's parameter $r = 5$. Here, the interval $[-1,1]$ has been split in 100 subintervals and for each trajectory a total of $N = 10^6$ points has been used.

Figure 6. The distributions probabilities of f_N

It is obvious that the two distributions are identical; therefore, the map keeps an invariant density for values of parameter $r \in [1,10]$.

In order to determine the invariant density of the map f_N the following result it is used: the logistic map and the tent map which keep an invariant density $\varphi_T(x) = 1$, are topologically conjugated through map:

$$C(x) = \frac{1 - \cos \pi x}{2} \quad (9)$$

which supposes that the relation $f^{\circ} C = C^{\circ} T$ is verified. Also, it can be verified if the map f_N confirms the relation:

$$f_N(x) \circ C(x) = C(x) \circ f_N(x),$$

therefore the invariant density kept by the map f_N is

$$\varphi_f = \frac{1}{\pi \sqrt{x(1-x)}}$$

In the previous chapter we noted that the logistic equation has the following solution $x_n = \sin^2(\theta\pi z^n) = \frac{1 - \cos(\theta\pi z^{n+1})}{2}$.

If we transform the logistic equation in polar coordinates, it can be observed that the following equation is obtained:

$$\varphi(\theta) = r(1 - \cos\theta), \quad (10)$$

where $r = \frac{1}{2}$.

Figure 7. Polar representation of logistic map

From figure 7, it can be observed that the equation (11) describes a curve known under the name *cardioid* (described by Etenie Pascal and studied in detail by Gille Roberval).

Having this result, we intend to analyze another map that comes from another flat curve, such as *lemniscate of Bernoulli* (figure8).

Figure 8. Lemniscate of Bernoulli

This curve is described by the following parametrical equations:

$$x = \frac{\alpha\sqrt{2}\cos t}{\sin^2 t + 1} \quad y = \frac{\alpha\sqrt{2}\sin t \cos t}{\sin^2 t + 1} \quad (11)$$

Starting from the above relations, we create the one dimensional map f_B with a single parameter r , defined by the relation:

$$f_B(x): [-\sqrt{2}, \sqrt{2}] \rightarrow [-\sqrt{2}, \sqrt{2}],$$

$$f_B = \frac{\sqrt{2}\cos(rt)}{\sin^2(rt)+1} \quad (12)$$

The behavior of the f_B map in time depends by the value of the parameter r and by the starting point represented by the initial condition. The bifurcation diagram is presented in figure 9.

Figure 4. Bifurcation diagram of f_B

At a certain value of the parameter $r \in [0.4, 0.5]$ the only attractor value depending by r starts to split in two. After the value $r = 0.5$, the two attractors split in four, eight etc. Thus, for a value of a parameter greater than 0.5, the map has a chaotic behavior. The conclusion is sustained also by the value of Lyapunov exponent, represented in figure 10.

Figure 10. Lyapunov exponent of f_B

Figure 11 represents the distribution probabilities of the trajectories of the type (12) maps which start from different initial conditions ($x_0 = -0.8$ and $x_0 = 0.6$), with the system's parameter $r = 80$.

Figure 11. The distributions probabilities of f_B

It is obvious that the two distributions are identical, therefore the map keeps an invariant density for values of the parameter $r \in [60,200]$.

Based on the results described above, the maps f_N si f_B defined by the relations (8) and (12) have a chaotic behavior for a big range of values of the system's parameter and keeps an invariant density making this one to be successfully used in realizing strong pseudorandom number generators from the cryptographic point of view.

In the next chapter is presented the analysis of the statistical results for the pseudorandom number generators based on the proposed chaotic maps.

4. The analysis of randomness for keystreams generated using the proposed functions

The experimental testing of the randomness for keystreams generated using both of the new proposed function was performed using the automated system designed by authors and presented in [2]. The automated system is based on DIEHARD, a very well known battery for statistical testing of randomness of a PRNG, developed by George Marsaglia. For a certain input stream, DIEHARD performs more statistical tests to measure the quality of randomness of it and provides as output a set of 215 *p-values*. If a *p-value*, corresponding to a test, lies in the interval [0.001, 0.995], we can conclude that the input stream passed that test. For our experimental analysis of randomness, we used, for each of the two proposed function, three methods for keystream generation, which will be described below. For each method and each new proposed function, we have generated 1000 keystreams and we plotted the obtained results as a histogram of total number of passed tests versus number of keystreams which realized that number.

The first method used for generation of a keystream consisted in the writing of the real number $x(n+1) = f_N(x(n))$ or $x(n+1) = f_B(x(n))$ as an unsigned integer in the keystream. The obtained histograms are shown in the figures 9 and 10.

Figure 9. Histogram for f_N

Figure 10. Histogram for f_B

The second method consisted in the writing of a bit of 1 in the keystream if the current value of the function, i.e. $x(n+1)$, was greater than a threshold (equal to 0 for both proposed functions) or a bit of 0 otherwise. The obtained histograms are shown in the figures 11 and 12.

Figure 11. Histogram for f_N

Figure 12. Histogram for f_B

The third method compared the outputs from two functions of the same type, but with different seeds and parameters, and wrote a bit of 1 in the keystream if the current value of first function was greater than the current value of the second function, or a bit of 0 otherwise. The obtained histograms are shown in the figures 13 and 14.

Figure 13. Histogram for f_N

Figure 14. Histogram for f_B

Analyzing all the three histograms of f_N , we can conclude that at least 97% from the generated keystreams, regardless of the method we used to generate them, have passed over 210 tests from a total of 215, in other words - over 97% of them. This entitles us to say that function f_N has a very good randomness.

Analyzing in the same way the histograms of f_B , it's clear that the first method used for generation provides keystreams with a very good randomness. Anyway, the next two methods are still feasible, maybe with some minor adjustments.

5. Conclusions

In the third chapter we theoretically have demonstrated, using instruments of the theory of nonlinear dynamic systems, that the proposed map has a good chaotic behavior. From the analysis of the experimental results, presented in chapter 4, we can conclude that the randomness of the sequences obtained using the PRNG, based on the proposed map, raises the level requested by the current standards for the construction of type string encryption keys.

Abstract

The financial crises that have occurred in recent decades, affecting the entire international financial system and beyond, have highlighted the existing gaps in the models of country risk analysis, models that cannot provide, in most cases, an anticipation of the collapse. The crisis multiplication caused important mutations concerning the different features of country risk, the crises manifested worldwide creating new forms of risk, and making its assessment more complex. If Country risk is shaped by the crisis, it, in turn, may influence the manifestation of the crisis. A current example is the sovereign country risk component, which meets the characteristics that make it able to prolong the depression. What we propose in this brief paper is a “radiography” of the country risk in a crisis context, paving the way for future studies aiming to establish specific risk indicators, in order to facilitate the anticipation of crises.

Key words: economic crisis, country risk, sovereign risk, external debt, warning indicators.

J.E.L. classification: F31, F34

1. Introduction – Risk and crisis

Undoubtedly, the notions of risk and crisis are in close contact. The crisis is a turning point, regardless of its character, and also an unstable condition, which involves an abrupt and decisive change. The crisis involves a manifestation of the risk, while the risk, in turn, influence the crisis, and often explains it. Regarding the form of risk that we intend to study, the country risk, it is clear from the beginning that economic developments caused by the global financial

crisis that started in 2008 had a significant impact. Although, in general, degradation of the country risk was lower than expected, it is certain that there were major changes concerning it: for example, a number of developed countries, considered before as foreign to country risk, became the subject of its specific analysis.

The global crisis has created a new configuration of country risk, different from case to case:

- A focus on the sovereign risk and on the transfer one for developing states that have little progress in terms of governance [1];
- An orientation towards credit risk and market risk in the emerging countries successfully integrated into the process of globalization, states that have effectively implemented structural reforms – Brazil, India, China, etc.;
- A focus on the various components of country risk in the developed countries considered "safe" so far: sovereign risk, primarily, but also credit risk, market risk and even political risk.

2. Country risk and economic crises

The relation country risk – crisis emerged as evident and close when the debt crisis of the 1980s occurred. In the late 1970s and the early ninth decade of the last century, commercial banks, especially American ones, were noted by the frenzy with which they have been competitive in their efforts to take over the *huge surplus of liquidity of the oil exporting states, and namely the petrodollars resulting from the first oil shock – 1973-1974* [2]. This helped developing states in obtaining credits, their governments taking full advantage of this “cheap” funding. Of course, a logical consequence was a significant increase in external debt in

developing countries, a trend that has not entailed any concern (one of the reasons why banks have borrowed heavily, without taking into account the still vague notion of country risk, was the fact that specific growth rates in developing states were higher than interest rates and, on the other hand, export prices for these countries had a favorable trend). Following the second oil shock (1979-1980), industrialized countries have adopted a deflationary monetary policy, which led to an increase in real interest rate on short and long term, and lower prices of products exported from developing states. One of the indicators that showed a significant degradation has been the *external debt / exports* ratio; despite these signals, the conditions offered by commercial banks continued to improve. After 1980, the situation of developing States experienced a marked deterioration. Consequently, the interests and debt repayment has become problematic, the need for new credits, oriented towards debt servicing, being more and more intense.

The next period was characterized by the multiplication of the cases where developing states have not been able to pay its arrears, initiating wide cycles of debt restructuring and renegotiation. In this context, country risk deteriorates significantly, boosting the debt crisis. We can say that, basically, the debt crisis has first brought to public attention the country risk, the early '80s being the moment when representatives of commercial banks realized the importance of its systematic study.

If the '80s were the years of indebtedness problems, it should be noted that the subsequent decade brought important new aspects as regards the crisis. A new category, from this point of view, is represented by the *crises without indebtedness*. These are crises that occur in the absence of an overall indebtedness of the states. In the absence of the concern raised by the values of the classical indicators of indebtedness, they are primed by increased liquidity risk; high short-term debt, accompanied by a low level of reserves, are among the main factors of collapse. Several cases of this kind can be evoked in this context:

- Mexico, in 1995 – of course, are many and complex causes of the crisis, with debt having the main role, however;

- Korea in 1997;
- Ukraine and Russia in 1998;
- Pakistan in 1999, Turkey in 2000, etc.

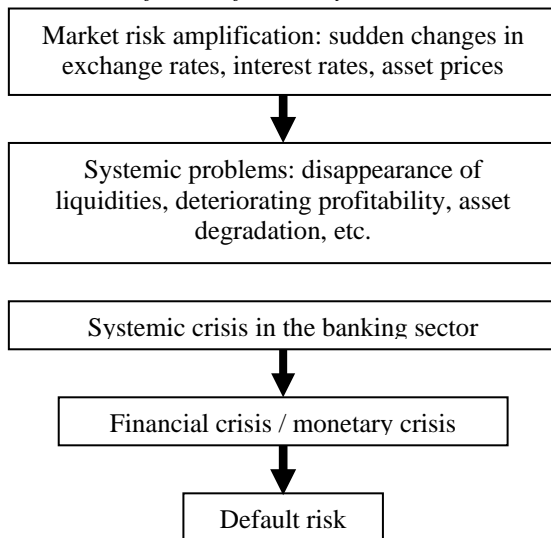

At the same time, the crises acquire a composite character; we cannot talk anymore of "pure" crises, but of multiple ones; for example, the 1998 Russian crisis combined several characteristics, assuming currency devaluation, the financial sector crisis and the sovereign one.

New crises have led, naturally, to a "new" country risk. This must be addressed by focusing attention towards various fragilities, potential sources of imbalance. They can be found both in the macroeconomic and microeconomic sphere, as well as in the political or social ones. It is also essential to identify *factors that may cause the transition from latent vulnerability to crisis* [3]. The new crises show, on the other hand, the fact that not only the fundamental imbalances are important in the study of country risk, but also the stability of the economic sector performances. It depends largely on issues involving several nations, *the specific combination of economic events* [4].

For the country risk analyst, market risk analysis is a serious challenge, this type of risk being more difficult to assess than, for example, the risk of default. This is explained by the higher number of indicators to be studied and correlated, and the many possibilities of interaction between them. In Guy Longueville's vision, market risk is an extension of the *generalized country risk* defined by John Calverley [9] in the late '80s. Located on the border of micro and macro spheres, systemic risk largely explains why some crises become general, sometimes leading to the collapse of an entire economy. Information asymmetry contributes significantly to this risk, which includes situations in which rational agents' reactions to the risks they perceive, instead of leading to better allocation of risk, increase the general insecurity [5]. Systemic risk claims its membership in the country risk class, its analysis involving economic, financial and political variables, of the same kind as in the case of sovereign risk, market risk, etc. Vulnerability to systemic risk depends not only on the financial system, but also *the complex institutional arrangements, the history of societies* [3]. Of course, all forms

of country risk are closely related, more cause-effect relationships can be identified:

Figure 1: Relations between different forms of Country Risk

Source: Authors conception.

Crises manifested during the last decade of last century were favored by pre-existing vulnerabilities. Taking a look at the situation of emerging markets at the end of the twentieth century, we might ask, rightly, if only countries that have achieved this status officially have experienced a sovereign crisis; the answer is not simple because, in theory, sovereign debt crisis involves the cessation of debt (principal) and interests payment at the maturity, this approach thus neglecting states that have avoided insolvency with the help of the International Monetary Fund, or due to a restructuring of debt; countries such as Mexico in 1995, Brazil in 2001, Turkey 2000, were assisted by the IMF, while in Ukraine in 1998 and Pakistan in 1999, the international community and the International Monetary Fund have proposed a debt restructuring.

In the same time, lower confidence contributes to the deteriorating nature of the situation; the "vicious circle" of events is inevitable: *Exiting capitals* → *Liquidity crisis* → *Acceleration of capital exit*.

The dynamics, the rapid spread of crises is overwhelmingly influenced by spillover effects. Based on the analysis of Obstfeld (1986), Nicolas Meunier (2005) identifies three types of contagion: *Monsoonal Effects* – which assume that a single significant

shock causes important crises in several states simultaneously, *Spillover Effects* – the result of economic interdependence, of strong commercial ties; the Asian case is a good example. Among the most exposed areas to this effect, we can include Central and South-East Asia. Treating this issue, Nicolas Meunier remembers the Hungarian Stock Exchange meltdown in 1998, in the context of the Russian crisis, a phenomenon explained by the importance of the Russian market for the Hungarian pharmaceutical industry. *The pure contagion*, the third type, is explained by factors of subjective nature (agents behavior, general climate, etc.), but also of objective type (cost of information issues, etc.).

In conclusion, we can say that events and crises of the past 15-20 years have generated new models of country risk analysis, requiring institutional diagnosis and studies related to the economies outlook.

3. Country risk in the post-crisis landscape

The year 2010 has brought positive developments in the world economy, at least in general terms. Of course, these improvements are differentiated in size, between the developed and emerging economies [6]. Several phenomena are clearly outlined, however, and have major implications for the global conjuncture and contemporary country risk:

- the increasing *financial decoupling between the developed and developing countries* [6];
- the global increase in commodity prices;
- the implementation of restrictive monetary policies, particularly in developing states;
- the decision of maintaining the policy of "Quantitative easing" by Fed;
- the progression of bond spreads of the States situated in the "periphery" of the Euro area (we are referring to countries such as Greece, Ireland, Portugal);
- the economic growth in emerging markets, over 7%, five percentage points higher than in the developed countries;
- the contraction, at the end of the last year, of industrial production, influenced by

the decline in exports (the increase of 15.4% in the second quarter of 2010 has left the place to an increase of only 2.4% during the third trimester). Another positive development that we note is the fact that the issue of bonds in foreign currencies of emerging markets have reached and exceeded the before-crisis level. Monetary policies implemented in 2010 were generally of restrictive nature; in the same time, currency appreciation in emerging markets presents a general nature, and it is present even a slight risk of overvaluation [6]. The world environment was characterized in the last year by a revival of trade; so, *world trade volume increased by 11.4% during 2010 and for 2011 it is expected a growth of 7%* (IMF, World Economic Outlook, October 2010). In addition, net private capital flows directed towards emerging countries have exceeded 820 billion dollars, in comparison to only 581 billion in 2009. Growth forecasts are also positive for emerging markets:

Table 1: Growth forecasts (%)

	2011	2012
Global economy	4,2	4,5
G3 + UK	1,9	2,4
Emerging economies / (without China and India)	6,3 / 4,2	6,3 / 4,4
Latin America	4,0	4,2
Emerging Asia	7,9	7,8
Emerging Europe	3,9	4,3
Africa and the Middle East	5,2	5,1

Source: IMF [10], 2010.

The year 2010 will remain, however, primarily related to the sovereign debt crisis in Europe. From the beginning, it should be noted that the budgetary situation in the euro area, despite some degradations, is not the most serious.

Figure 2: Budget balance evolution (%GDP)

Source: OCDE, 2010, in D'Arvisenet, Philippe, 2011.

According to some authors [7], the sovereign debt crisis manifested in the euro area is a consequence of one of the European construction weaknesses: *the joining of the common monetary policy and decentralized fiscal policies, lacking coordination – lack of budgetary federalism*. At the same time, we might mention the too low political integration, or the lack of structural reforms.

The reduction in interest rate by the European Central Bank has boosted borrowing significantly, particularly of private nature, in countries like Ireland and Spain, and especially of a public nature in Greece.

Figure 3: Public debt evolution

Source: Longueville, Guy, Faure, François, 2010.

It should be added here that the rating agencies have ignored the developments, the absence of spreads can be observed until the onset of the crisis.

Largely a consequence of internal imbalances, translated into excessive debt, the increase in external deficits is, however, concerning. Some plans, unimaginable just a few years ago, were made and even implemented; we mention here are already well-known "rescue package" to Greece in a joint European Union and International Monetary Fund effort, or the acquisition of sovereign bonds by the European Central Bank, etc.

Figure 4: Evolution of the current balance (%GDP)

Source: OECD, in D'Arvisenet, Philippe, 2011.

For Greece, it can be said that the economy is in a recession period. Despite reductions in wages and the incentives for exports, exiting this situation it is not expected in a time shorter than two years, and uncertainties remain high for all states that have a fragile public finances sector.

The skepticism regarding the possibilities of governments to reduce deficits and to manage indebtedness control is confirmed by the actions of rating agencies, translated in the degradation of sovereign ratings for the mentioned countries.

The overall situation described above presents a considerable impact in terms of country risk. Thus, several remarks can be made:

- In emerging economies, although progress is not uniform, the sovereign risk and the credit risk and reduced their intensity;

- Currently, political tensions seem to develop at a global scale. The events at the beginning of 2011 in Tunisia, Egypt or Libya, are testimony to this, and many other similar risks concern: Bangladesh, Morocco, Algeria, Iran, Nigeria, etc. In Egypt, for example, despite good economic performance in the years 2009 and 2010, the fragility of the structural fiscal imbalances, the social tensions and governance problems have led to a rapid and unexpected deterioration in country risk, enhanced by the revolt that began in late January;

- Country risk has become a reality even for developed countries, where until recently there was no question of such an analysis, this development is not foreign nor the euro area, in the light of new realities;

- Forecasts for improving sovereign ratings – but also those "corporate" – are more optimistic for emerging countries than for developed countries;

- The prices evolution of industrial raw materials and agricultural products can generate inflationary pressures, but also leads to improved external balances; in this regard, the influence on the country risk has a positive character [6];

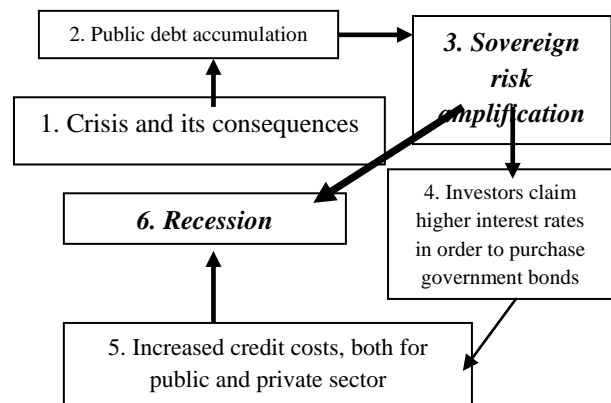

- In the European Union, despite the taken measures, there is no significant improvement in country risk, especially concerning its sovereign component; credit risk and even political risk are present, although their materialization seems unlikely.

4. Concluding Remarks

Undoubtedly, the crisis impact on country risk is extremely broad and difficult to grasp in its totality and complexity, which is why we intend to study this relationship during the next period. One thing we want to emphasize here is that, if country risk is shaped by the crisis, it, in turn, may influence the manifestation of the crisis. A current example is the sovereign component of country risk, about which we can say that it meets the characteristics enabling it to prolong the depression.

The tensions associated with sovereign issues are likely to lead to the prolongation of the crisis, despite the improving condition of the international financial system, induced by the global economic recovery. A possible degradation of sovereign risk would severely affect both the national banking system and economy. Chain reactions could occur as a result of these developments:

Figure 5: Sovereign risk and crisis extension

Source: Authors conception.

Therefore, strengthening public finances and sovereign risk monitoring should be the priority for national governments. At the same time, the banking activity presents a particular importance, their capitalization being in particular a delicate issue; the quality of the balance sheet and the own funds level are equally essential, banks around the world facing large financing needs – about U.S. \$ 5000 billion over the next 2-3 years, according to IMF data. The research literature has tried, especially in recent years, characterized by the multiplication and diversification of crisis, to reproduce the actual phenomena theoretically, in order to identify key factors and to develop forecasting tools.

Although it is noted that there is a general consensus regarding the determinants of crises, the particular impact of each of them remains difficult to quantify, as well as the values for warning thresholds; so, the forecasts for the possible sequence of events are still outside the possibilities of the scientific apparatus. A special aspect is the opportunity to develop theoretical models able to determine the optimal level of sovereign borrowing, given that, at least at the present time, no international coercive mechanisms that ensure the sovereign debtor payment exist.

On the other hand, we must stress here the importance of the political factor. Linkages between political and country risk are present, and debt restructuring issues have a special importance, being a prime concern for the financial community. The belief that the "default" risk for sovereign bonds is minimal has proved erroneous in recent years; it has been put into question even the issue of "bankruptcy" of a state [8], yet impossible because of the specificity of the sovereign. The anticipation of crises in the context of country risk is an ambitious objective, a real challenge; the understanding of the root causes and transmission channels is essential, in order to identify an early warning indicators system; this will be the subject and the goal of our next study.

5. Acknowledgment

The authors wish to thank for the financial support provided from the program co-financed by THE SECTORAL OPERATIONAL PROGRAM FOR HUMAN RESOURCES DEVELOPMENT, Contract POSDRU 6/1.5/S/3 – "Doctoral studies, a major factor in the development of socio-economic and humanistic studies".

Abstract

The problem of ethics in the financial/accounting activity permanently generates controversy. Starting with the options of certain famous specialists in the financial/accounting field, the paper presents beforehand the ethics concept and the characteristics of an ethical decisions, focusing after that on the ethics and creativity issue in the financial/accounting field, since the provided information is destined for building an accurate image with purpose of correctly informing different types of “actors” of the business environment and not only.

The study was based on a scientific research, investigation type, applied on a 110 organizations` sample. The essential objectives consist of knowing the level in which financial-accounting professionals apply the professional ethics` standards; outlining the managers` opinion regarding the estimation and usage of creativity and innovation in the financial-accounting activity. Based on the things presented in 5th paper, it can be noticed that the financial-accounting creativity practice and its effects depends on what managers wish to offer with the information they provide and implicitly what they want to get from the decisions adopted by using this information.

Key words: creativity, ethics, financial-accounting activity, fraud

J.E.L. classification: M10, M40

1. Introduction

One problem in the ethics of financial/accounting activity is related to creativity and innovation. Most of the people view this activity as a rigid one that doesn't allow the possible use of imagination.

This aspect has been contradicted by a multitude of situations which proved that imagination in the management of financial-accounting could have a very important role when the distortion of reality becomes a fundamental necessity.

Thus a question may rise:” Do financial-accounting innovation and creativity represent a fraud?”

This study is aimed to answer the following questions:

1. Do financial-accounting professionals obey the standards of professional ethics?
2. How would you appreciate creative and innovative performance with financial-accounting personnel?”
3. Is financial-accounting activity being put into practice within the framework of organization?
4. If it is put into practice , what is the purpose of this practice?
5. If it isn't put into practice , then what is the cause of this lack?

We consider this an up-to-date study under law circumstances influenced by economic crisis. It is this influence that transforms the creative temptation in a negative way into an inherent quality.

Opinions regarding ethics and creativity in financial-accounting activity

Owing to its characteristics, financial-accounting activity, control and audit are in close connection with ethics, morality and religion.

Moral, ethical and religious concepts are close, connective and complementary. Ethics is a rational theory on the origin of the good and the evil and of morally and wisely ordered values. Based on already structured principles, ethical values render morality religious connotation with restrictive character. Ethics can be defined "as a systematic reflection of the moral consequences of decisions. Moral consequences can be drawn in terms of damage potential of each beneficiary of decision. Ethics is a code of conduct that applies to every day life and deals with correctness or incorrectness of individual decisions. It is estimated that an ethical decision has the following cumulative characteristics:

- it is a competent decision, based on accumulated knowledge and experience
- it is a decision taken in the context of a clear identification, in a particular situation of interested persons, of obligations of each part involved and of specific problems;
- it is a balanced decision; it allows identification and hierarchy of relevant ethical principles in a particular situation
- it is a pertinent decision; it is based on determination and estimation of all relevant action and decision options
- it is a pragmatic decision; it allows action based on partial, clear, objectives that are achievable in an objective and responsible way until the formulation of conclusions.

The frequent ethical dilemmas of categories involved in financial-accounting activity and of those that are not involved in it could be the result of different reasons. The most common of these reasons are the conflicts of interests, the security of

information and the practice of making gifts. Conflicts of interests are usually due to competition among similar firms but this is not the only case. The practice of making gifts is perceived as a delicate problem in the business world. In our country gifts are made in order to obtain something. This is considered to be a form of "bribery" paid to encourage business. The security of financial-accounting records is a dilemma that appears when some information do not have a secret character. Most of managers believe that it is dangerous for any firm/company to reveal any kind of secret information because they do not understand that some of them are of public interest.(financial records)

Among the causes of unethical behaviour could be mentioned the following:

- the earnings, because we must admit the role of temptations in unethical behaviour, especially when the process of motivation within the firm /company is not appropriate or does not even exist.
- competition both among firms and among its members
- personality influences the degree of morality of each person; those who are economically oriented to a greater extent or are interested in leading positions make use of unethical behaviour to achieve their purposes.

The problem of ethics in financial-accounting activity appears when it is aimed to create an image of reality in order to inform various beneficiaries who depend on the judgement of those involved. The ethics of these people plays a special role in searching for truth, because they are those who observe the economic reality, interpret and formalize it and eventually construct financial situations which should reflect reality truthfully. If the temptations are great, it is only the professionalism and the conscience of those involved in financial-accounting activity that can guarantee the search for truth through the formalization of a specific economic reality.

The financial-accounting professionals do not live in isolation, they work on a market where the supply and demand of financial-

accounting information confront each other. Financial "performers", accountants and auditors want to sell their merchandise and will offer an image of performance for the countries in which investors bring great pressure, an image of stability for the countries in which bankers have a dominant position and a fiscal image for the countries in which the public plays a significant role in the financial-accounting field. (we consider this to be our country's case). Talking about financial-accounting ethics and morality under such circumstances entails great suspicion as long as the front-page topic is the "financial crisis".

We tried to offer those interested an image of what financial-accounting ethics means.

The importance of this knowledge lies also in the fact that "Ethics in business" represents a compulsory discipline not only for economic qualifications but also for other qualifications. (according to ARACIS standards). Thus we consider that there is an increasing public awareness regarding the informing of the future professionals, accountants, managers or financiers or auditors and the importance of the principles of professional ethics. Actually the most professional organizations have an elaborate and adjustable ethical code. International financial-accounting and audit The Ethics Committee elaborates and issues standards and statements on professional ethics useful to accountants and audits of its present or potential members. The Commission of Ethics also promotes debates of international level on ethical issues that its members confront with. But the process cannot stop at this stage: there is a necessity to ensure that both present and potential members of this profession understand and put into practice the regulations in a proper, adequate and honest way. Moreover there must be emphasized the fact that perfect professional ethics requires self-training.

The Romanian National Code of Ethics of the professional accountants has been elaborated according to The International Code of Ethics of professional accountants reviewed by IFAC in which conduct standards and fundamental principles such as integrity, objectivity and professional

competence have been formulated. These must be obeyed by all those involved in financial-accounting.

Willingness, professional attitude, confidentiality, responsibility, professional and technical guidelines in order to substantiate the managerial decisions, to fulfill the objective, for good information of all those who are interested in the fundamental, financial-accounting news, to offer a true image of any entity

For auditors, the principals considered to be fundamental is independence this being the "touch stone" of the profession. Usually the situations implying the adoption of some ethic decisions are the ones in the "grey zone" in which there isn't a predefined way of actioning. Without an unchallenged professional independence, the auditor's opinion can't be but suspect. Theoretically the factors that determine the degree of independence are the auditor's integrity and objectivity.

A problem related to the ethics in the financial accounting activity refers to the creativity and innovation. Most of us consider the financial-accounting activity as being rigid, with one accepting imagination. This fact was contradicted by many cases in which it was proved that the financial accounting activity can have an important part when the distortion of reality becomes highly important. That's why the concept of "creative financial-accounting" appeared, being used as a rule to describe the process in which the financial-accounting professionals use their knowledge in order to manipulate the figures. We consider that the creative financial-accounting activity might be defined as it follows

The process in which the accounting figures are manipulated and profiting by the teribility and only those practices are selected which permit the transformation of the financial reports from what they must be into what the managers want to be.

Most references papers often present the creative financial-accounting activity through its negative side, being considered as a preres of manipulation the financial-accounting figures so that the financial and economic performances to be influenced in

the direction wished by the company 's management , or even by the employer.

Using creative and innovative polices and techniques in the financial-accounting activity might have many consequences: increasing on decreasing the debts and active, manipulating the information presented in the annex.

These appears the following questions are the financial accounting creativity and innovation a fraud? Using creativity doesn't mean the breaking of the law, but it is rather a matter of interpretation utility and not last ,the ethics. We still don't deny the fact that with the creative financial accounting actability the image of the company's financial position and of the financial – economic performances are adorned. In fact , our opinion is shared by the most managers of the companins included in the research study.

Speaking about the creative financial – accounting activity and the possible chances to step using the negative Techniques, Sir David Tweedie ,A.S.B president said : “We are all like a crossed eye javelin athlete who takes part in the Olympic Games; maybe we won't win, but definitely, we keep the people breathlessly. This assertion must warn as speciality the external users of the financial-accounting information. The efforts that had been doing in order to stop using the creativity techniques of the financial-accounting ,did have the expected result; this still doesn't mean giving up, on the contrary ,even if extra effort is required ,the competition goes on.

2. The Research Methodology

This study intends to bring under attention the perception of the economic regarding the fraud and the financial-accounting creativity.

The investigation included two successive researches : a qualitative scanning type research and a descriptive type research.

The qualitative scanning type meant the production of some hypotheses which were then included in the descriptive type research, the establishment of the next research priorities

The methods used in this preliminary research stage were: the analysis of the secondary data which supposed the use of available data from different sources, trying to find out some problems, ideas, solutions related to the costs and the price policy; the interviews with some specialist meant to get suplimentary information in the financial-accounting field, the group meetings or focus group that were a good opportunity to debate this topic.

With the quantitative research descriptive type, whose results are presented in this paper we intended to know the managers perception regarding the fraud and the financial-accounting creativity. We consider that the results we got have a great importance especially under the present conditions in the economy during the “financial crisis”.

Depending on the place of development the research was a practical one ,the colleting of the data being made at the companies included in our sample.

To establish the sample we used the aleatory sample method which had a basic fix sample (considering the organizatory restrictions, it was established a number of 110 responders ,societies in Sibiu judet/county, 9.4% error for a trust level of 95%)with restrictions. We can say that the samples method consists of combining the multilevel sample method with the non-proportional aleatory layer sample method. The program SPSS for Windows was used to process the data.

We'd like to underline the fact that this research study could be extended(the interest in a possible extension has already been expressed)the present information and results being a real good starting point in this respect.

As to the field of activity that makes up the sample of the research study are organized like this:45 companies out of 110 respectively 40.9% are included in the commerce area,37(33,6%) belong to the industrial area, and 28(25.5%) activate in the services field. Reffering to the dimension, it is found out that out of 110 companies,17(15.5%) microindustrial unit, 52(47,3%) are small companies,29(26.4%) are medium size, and 12(10,8%) are big

companies. We noticed the dependence of the company category on the field of activity. Thus as for the micro industrial units, these are distributed as follows : in the commerce area(47.1%) and services (52.9%).No such company activate in the field industry. For the small companies, the distribution is the following one:61.5% have commerce as their field of activity,13.5% industries 25,0% services. The medium size companies activate mostly in industry(75.9%) being approximately equal to the distribution ,in the offer two fields of activity :commerce (10,3%) and services(13.8%). As concern the big companies most of them activate in industry(66.6%) and services (16.7%).

Depending on the form of property,3 companies (2.7%) out of 110 have an integral state capital,106 (96.4%),private capital and only one (0.5%) has got a mixed capital. It is found that most of the analyzed companies have a private integral capital, these being in fact the general characteristic of the companies in Sibiu county, but in the country as well , regarding the way of forming the capital

Depending on the type of company the information I got show that 89 of the analyzed companies depending on the type of information I got show that 89 of the analyzed companies, respectively 80.9% are organized in societies with limited responsibility (SRL) and 21(19.1%) are S.A

Most of the respondents(43.6%) have the function of general principal, being followed by those who are the head of financial-accounting department ,financial-accounting compartment in chief(11.8%) accountant professional with a performing services contract(16.4%).

Another aspect taken into consideration refers at the educational level of the respondents out of the presented data it is obvious that the highest amount is given by the university training, in this category being included 96 respondents out of 110,that is 87.3% followed by those with medium training(9, respectively 8.2%)and those with postuniversity training(5, respectively 4.5%).At the same time the research study had in view the respondents specialization. of the data it is evident that most obtained responses have an economical university

training(66.4%) being followed by those who graduated much further university studies in other fields of activity engineering(13.6%),computers(1.8%) filology (1.8%) law(2.7%) medicine(0.9%).The respondents with medium training graduated a highschool (2.7%) and an economical posthighschool (5.5%).Those postuniversity training graduated a master program (2.7%) as a PH degree in the economic field

As a conclusion we can observe that most of the respondents have an economic university training, means they know or should know the economic language

3. Conclusions on the research

One of the first objectives of the performed financial-accounting professionals respect the standard of the professional ethics. Resulting from the working data we calculated the score for every standard of professional ethics alone and the global score as well, the information being presented in table 1.

The analysis of the information leads us to the appreciation that in the case of the majority firms it is considered that the standards of the professional ethics are respected either to a extend professional who work in the financial-accounting domain , or to a very large extend.

It is to be noticed the fact that neither of the firms in question consider that there is a standard of professional ethics to be respected to a little extend.

The performed analysis brings to attention the fact that the score for every standard of professional ethics is approximately equal (4.26-integrity, 4.32 , 4.26 -objectivity , 4.25-behavior ,4.37 – confidentiality,4.39-responsibility) all the characteristics being in this way respected in a large extend.(from 1-to little extend , to 5-to large extend)

This ,the general score obtained (4.39) confirms the hypothesis forwarded before the research. The standards of ethics are respected to a large extend.

As we have mentioned in the theoretical aspect of the study, a problem of ethics in the

financial-accounting activity is connected to creativity and innovation.

The majority of us see the financial – accounting activity as being rigid, not allowing the use of imagination. This idea has been counter acted by a multitude of cases in which the result was that imagination may have a very important role in the financial – accounting domain when the distortion of reality becomes a main necessity. In this context, another general objective of the research is to bring forward.

The managers opinion regarding the appreciation and the use of the creativity and innovation in the financial – accounting activity. To reach the objective we have introduces 3 question in the questionnaire as:

- Is the financial-accounting innovation and creativity a fraud?

- How to do appreciate the performance of the staff from the financial-accounting activity to be creative?

- In your organization, are there practices of creativity and financial-accounting innovation used?

That in the opinion many managers (over 73%) creativity and financial-accounting innovation isn't considered a fraud disagreement in this respect disagreement, or the total disagreement and a percentage of 15,15% the managers have neutral opinion regarding creativity and innovation. Only approximately 10% of those interviewed consider that by creativity and financial-accounting innovation fraud is created. Generally, taking into consideration the calculated score for this question of 2,05 (from 1 – total disagreement, to 5 - total agreement) we can appreciate that the managers don't agree with statement made, the hypothesis given at the beginning of the research. In fact this was our conclusion, too.

It is stated that the reasons why the companies use methods of financial-accounting activity are separated in this way: creative 32% from the firms have the wish of avoiding fiscality; 43,1% from the questioned firms are interested in obtaining supplementary financial resources; 36,1% use creativity and innovation when they are obliged to offer financial-accounting information to some external users and 51,4% of the interviewed firms which use

financial-accounting creativity and innovation mention also other reasons.

In the category "other reason" there have been mentioned law contradictions, law interpretations, personal professional judgements; the decrease of the work load; the manipulation of the financial result for not paying the dividends according to the stock owners wish.

By analyzing the reasons why the firms use the financial – accounting creativity and innovation, must often there is the need to obtain supplementary source of finance, the need (there urge) to avoid fiscality and law ambiguity. From the research there can be emplasized the main reasons why the firms don't use the financial-accounting creativity and innovation: correctness, fear, the existence of major risks, the existence of internal and financial auditors, foreign stock owners, etc.

In conclusion, the forwarded hypothesis before the research (the majority of the firms use creativity and innovation in the financial – accounting activity)is confirmed. We can also conclude that most of the organizations use these kinds of technigues witen negative intend. All that remains us to do is to ask ourselves to what extend the accounting principles are respected, if we can still talk about a real image or about "users, watch out!".

These questions find their answers in another research. Following the conclusions brought out/ forward from the present study, we considered that the financial – accounting creativity and its effects depend on what the managers want to offer king the information that they provide and consequently on what they want to obtain the decisions that the users adopt with this information. This dependence should create a certain responsibility to act ethically, not taking into consideration the interests for offering equal chances of information.

The Balanced Scorecard – System of Indicators for the Assessment of Intellectual Capital

Dicu Roxana-Manuela
„Alexandru Ioan Cuza” University of Iasi
rm.dicu@yahoo.com

Abstract

The Balanced Scorecard is a management system that enables organizations both to clarify their vision and strategy and translate them into action. It is not only a measurement system, it is a complex instrument which provides feedback around both the internal business processes and external outcomes in order to continuously improve strategic performance and results. When fully deployed, the balanced scorecard transforms strategic planning from an academic exercise into the centered point of an enterprise. Working through the balanced scorecard process enables management to define those key perspectives that will drive the business to success, as well as to define how to measure their impact on the performance and the results of the enterprise. Since intellectual capital is intangible and influenced by complex economic, social and political factors, using this system to assess and measure knowledge management provides suitable indicators.

Key words: balanced scorecard, strategy, indicators, intellectual capital, knowledge.

J.E.L. classification: J24, L21, L25, M12, O15.

1. Introduction

Balanced Scorecard (BSC) is a tool for strategic planning and management system, used extensively in business and industry, government and nonprofit organizations worldwide to align their activities to business strategy and vision, to improve internal and external communication and to monitor the performance of the organization in the context of achieving strategic objectives. It was created by Robert Kaplan (Harvard Business School) and David Norton as a

framework for measuring performance and it evolved over time, adding indicators of strategic non-financial performance to the traditional ones and providing to the managers balanced information about the performance of the organization. Although the term was imposed only in the 1990s, the roots of this approach of the performance and strategy are deep, including General Electric's methodology for reporting financial performance in the 50's, and reporting the results of the enterprises from France under the name "Tableau de bord" in the first part of the twentieth century.

2. The Balanced Scorecard – definition and composition

The Scorecards with strategic orientation are systems of indicators that seek to measure the overall performance (and evolution) in different sizes constituents [1]. They allow clarifying the strategic objectives and their expression in *specific target values*. They also provide a general development policy within the organization and a return to strategy for the gradual completion of it. There are three possible system analyses:

- Balanced Scorecard, imagined by R. Kaplan and D. Norton. This instrument remains focused on the financial performance and on the shareholder's value. Operational evaluations are based on customer satisfaction, experience and organizational development. Once the relationship is established, one can identify correct means to measure those business drivers in order to achieve desired economic and financial performance [2];
- A scoreboard that focuses on the intangible capital of the company (experienced by L. Edvinsson) envisages the development of individual and organizational competences. This

technique is based on four types of indicators. These are the human resources indicator, infrastructure indicator, innovation indicator and structural capital indicator. The changes in intellectual capital indicator as a total reflects changes in market value of the company [3];

- A system which is based on the criteria used to accomplish the ISO standards, or to compete for the awards which promote quality (Malcolm Baldrige Award, the European Foundation for Quality Management Award). It is aimed at providing more value to the customer.

Next we will focus on the model of the Balanced Scorecard. To obtain the highest possible global outcome, it is first necessary to provide quality services that will be reflected in a series of indicators. They are reporting to key strategic issues and are focusing on four strategic axes.

Financial indicators depend on the adopted strategy (withdrawal, growth or maintenance). For example, a growing industry will indicate the increase in turnover according to the percentage of sales from new products or new markets [4].

Customer indicators are relatively classics: the market level of satisfaction and the loyalty of customers, number of new customers, profitable customers by category. Monitoring indicators are given treats attributes: those relating to product or performance (functionality, price, and quality), the relationship with customers, and those related to brand image and reputation. The selected criterion depends on the strategy of prices and quality service.

Indicators of internal business processes are limited to key processes. For example, if the speed of innovation is essential, the company may choose to follow the development and expect the percentage of sales achieved with new products. It will be taken into consideration the processes of product development and after sales service, because they have an increasingly important role in the current competitive context.

Indicators of organizational experience, innovation and development refer to the level of satisfaction and competence of the staff, level of functionality and performance of information and quality management systems. The decisions generate a training

exercise, a change in the payment system and making available to officials a tool to access information in real time.

Monitoring indicators are deviation between the level of competence and the current situation, the percentage of customers' expenditures, whose remuneration corresponds to the new rules and the appropriate IT equipment.

They allow the identification of practical indicators for measuring the outcome (lagging indicators) whose output intervenes after completion of the action and advanced indicators (leading indicators), located further upstream in time, which play an alarm signal before the performance gets to lower. For example, if the result is the satisfaction of customers, according to the criteria and the rates of error or response time to customer requests, the company can react more quickly to abatement.

By using these indicators, the Balance scorecard is a tool that provides an operational representation of the overall company performance, while enabling guidance and evaluation of the strategy.

3. The strategic maps – adjacent instruments for BSC

The Balanced Scorecard offers a model of consistent performance. But he turned from a simple system of measuring performance into a complex system of strategic management is the year of 2001, when Kaplan and Norton published their paper "The Strategy-Focused Organization". They proposed the creation of adjacent instruments, called strategic maps. These are diagrams that describe how an organization creates value by connecting in explicit cause-and-effect relationship with each other in the four BSC objectives (financial, customer, processes, learning and growth), using the cause-effect relationship [4].

Following the information contained in the map, the financial perspective looks at creating long-term shareholder value, and builds from a productivity strategy of improving cost structure and asset utilization and a growth strategy of expanding opportunities and enhancing customer value. These four elements of strategy are supported by cost, price, service, quality, functionality, etc., which internally is being translated into

improved attributes of products / services, or into an improved brand image of the organization. All these processes are based on the exploitation of human capital, information capital and organization capital.

In this way, the Balanced Scorecard facilitates the implementation of the strategy and allows a reflection on the relevance of options [5].

4. The intellectual capital – the input-process-output relationship

By working with indicators and using organizational tools, the balanced scorecard allows better communication between strategy units. Managers often limit their messages to their strategic intentions. This attitude is insufficient to transmit clear guidelines. The BSC indicates the strategy by using specified objectives and cause-and-effect linkages between them [6].

Being given the complexity of BSC, we consider that it is a good system for the assessment and measurement of intellectual capital. Before explaining this, we have to present a compound of intellectual capital.

One is people or *human capital*. We can define human capital as the amount of skills, abilities, talent, knowledge and expertise of employees.

The other component is what is surrounding people in an organization and that is *structural capital* – all those intangibles left behind, when people go home, internal processes and structures, patents, databases, all documents certifying the know-how of a company.

As third part, there are external processes and relations, customer relationships and company's image, called *social capital* [7].

A closer analysis reveals though the necessity to include in the definition above any type or transformation of any intangible assets which are under some control of an organization and contribute to the general process of creating added value for that organization. So, from this point of view, intellectual capital must be more than pure intellect, but include intellectual action. It is the move from "having" knowledge and skills to "using" them [8]. The "using" of knowledge implies that relationships (social capital) and intangible assets and processes (structural capital) are needed to transform

knowledge, abilities, skills and expertise (which are owned by the employees – human capital) into a product or service that is of value to the firm and its stockholders.

Analyzing the intellectual capital though *the input-process-output relationship*, we may consider that *the input is the knowledge, expertise and skills of the employees. This input is transformed by the processes reflected in the structural and social capital (the know-how of a company combined with its image and relationships with the economic and social environment). The output is the added value for the stakeholders and the company itself.*

Being interested in performance, the organization will manage these resource suppliers and will be preoccupied by the management of intellectual capital, in order to add value to the business. The quality of intellectual capital management within the organization and the strategy related to that can be included in business strategy plan. Such a plan is reflected in the Balanced Scorecard.

Next, we will consider a sum of indicators that could be included in the BSC and monitored through this instrument.

5. The assessment of intellectual capital using BSC

Knowing that the BSC aims to evaluate the strategy and the objectives of a company, we will consider in the following the four previously presented axes of this instrument, and we will include, in each of them, indicators related to intellectual capital, which will be helpful in defining a strategy and, of course evaluate it.

In the center of *financial axis* is the profitability and operating income, value added and the income from invested capital. Here there may be included ratios that describe human capital effectiveness and performance. In order to do that, measures like Revenue ratio, Turnover ratio, Net income ratio and Gross income ratio could be included. Those are basic measures of human capital effectiveness and are calculated by taking the financial indicators (revenues, turnover, gross and net income) and dividing them by the total headcount of the organization. Of course, these ratios are possible to be computed using full-time

equivalents instead of headcount, which would be more precise, but significantly more difficult.

Establishing targets for these ratios and the correlation between financial indicators and the headcount of a company is very important to be included in the BSC, with a notice: to correlate these ratios to the indicators reflecting the planned structure, number and expertise of the employees, included in learning and development axis.

The *customer axis* can be considered as fully dedicated to social capital. Having as main indicator, in our opinion, the market share, this area must specify the customers and/or markets that the business wishes to serve and establish appropriate targets and objectives, as customer satisfaction index, number of customers, customers' rating, annual sales per customer, medium size of customers, average time to answer customers' solicitation, lost customers, medium time of the company-customer relationship, etc. Here we may add the number of clients per employee, which is an indicator that establishes a relation between social capital and human capital. Those are few indicators to be included in this axis and be proper in order to assess the social capital of an organization, from the customers' point of view. They enable the monitoring of customers' satisfaction, customer retention rates, the attraction of new customers, profitability on the types of customers and targeted market segment obtained.

The *axis for internal business processes* examines how the organization uses various tools to create value. Because this axis is partially referring to products development, we consider that we can include here the know-how and the patents and we can establish as targets revenues from usage of patents/software/databases, number of processes ended without errors, investments in IT, etc.

Finally, *the innovation and development axis* is dedicated to factors as employee skills, organizational alignment, strategic partnerships, employee competence, infrastructure, etc. This area is often the most difficult to develop appropriate measures. However, the examples may include employee motivation, employee skills profile, number of employees who left or came in the company, analysis of the reasons

for which employees have left the company, and many other indicators which can be related to employee motivation, can be targeted and, of course, can be related to human capital, in order to help assessing the intellectual capital. This axis has also a learning component, which can be related to training planning, number of hours of training per employee, the allocated time for training (hours per year). *The objective is to identify determinants of growth and progress on long-term undertaking.* This is another reason to consider employee indicators as suitable for this axis. By using the proposed indicators, managers will be able to monitor employee's competence and the progress made in the relationship company-employees.

6. Conclusions

The Balanced scorecard provides a framework to focus on key perspectives that will lead to success, and to constantly assess performance against targets. *It helps align key performance measures with strategy.*

By connecting such elements as shareholder value creation, customer management, process technology, employee motivation, organizational design and learning in one graphical representation, the Balanced Scorecard helps greatly in describing the strategy and to communicate the strategy among executives and to their employees. In this way alignment can be created around the strategy, which makes its successful implementation easier. No small thing, bearing in mind that often, the implementation of a constructed strategy is the biggest challenge.

Although the BSC provides management with a comprehensive picture of business goals and strategies at all levels of an organization, there are limitations of this instrument. The distinction between indicators of action and the ones of result is often ambiguous. Also, the implementation of the strategies implies some difficulties [9]: the strategic objectives are insufficiently expressed in operational objectives; the resources are not always allocated according to strategic objectives; managers are concerned with short-term objectives against strategy (e.g. the obligation to maintain a price of stocks to meet investors' interest).

As an instrument used in the assessment of intellectual capital, the BSC can include financial and non-financial indicators, related to all three components of intellectual capital: social, structural and human. In our opinion, these indicators should be presented separately in the BSC of a company. Or, if possible, if the company acknowledges the nowadays importance of intellectual capital, it should create and develop a BSC especially for intellectual capital, focused also on financial and non-financial indicators, part of them presented in this paper. This last possibility, the creation of an "intellectual capital BSC", can be related to the core operations of a company. If a company bases almost extensively its activity on knowledge (IT, laboratories, public relations etc.), then, in these cases, a BSC created especially for intellectual capital should be recommended.

The BSC provides a common language for enterprise's business partners. The future will validate its priority by way of relevance, efficiency and potentiating the performance of the organization.

Theoretical Approaches Regarding the Management of Museum Resources

eduapa92@yahoo.com, andreea.vivi@yahoo.com, depopescu@yahoo.com

Abstract

By their nature management the issues of cultural institutions, show that these units, beyond their specific aims, are broadly like all other organizations. They have a separate organizational structure, a specific internal process, using their own resources and deposits (inputs) performing cultural "products" and "services" (outputs), that they are interested in promoting and specializing in etc.

The institutional system designed and developed in the cultural area is a complex instrument, used by a given human community, in order to solve specific problems and needs of a spiritual nature.

Key words: management, museum, resource, culture

J.E.L.classification: M00

1. Introduction

The cultural organization can not ignore, unless with serious risks, the concepts, the symbolic paradigms and the qualitative judgments that re at the basis of the entire management system. In a culture organized institutionally, the management becomes a functional requirement, an indispensable condition for the system to survive and be able to work.

2. Cultural institutions

The main cultural agent acting in the big socio-modern human communities, the cultural institution, is the "body" that materializes into a specific form of

structuring of social relations of a particular nature and represents a relatively simple organizational entity, usually funded on grants and sponsorships specialized in combining "inputs" whose primary cultural function is the development and/or propagation of "goods and services" (values) designed to meet the cultural and artistic needs.

The defining landmarks of a cultural organization are [8]:

- The group of people with the technical and material system and funding mechanism;
- The ensemble of representative purposes or its spiritual, artistic, aesthetic goals etc.

- The legal status which sets out the role and the existential framework. In the light of theories known so far, cultural institution, like any organization, moreover, may be analyzed using different versions.

As a socio-human opened system, the institution of culture develops in the center of a gear with several other relations in its environment: the upper level and socio-cultural units which are in contact with banks, sponsors, suppliers, distributors, customers, public, cultural, elites, media, etc.. Between the organization and its environment takes place an intense and continuous exchange between people, ideas, money, material goods, etc. The largely operational dimension of a cultural organization determines, above all, a flexible and adaptive behavior, and secondly, a continuing concern for a self-regulatory system, based on its primary purpose - the spiritual, aesthetic, artistic values etc. and its circulation in society. Alternatively, self-regulation requires a permanent relocation of

the relationship between internal departments.

Thereby the cultural institution is revealed as dependent on its environment, with which there exists a constant interaction and inter conditioning.

As an organizational structure, the cultural organization is emerging based on its scope and nature of its internal processes. The functionality of an institution of culture is deeply influenced by its organizational setup, the links established between the compartments, the informal structure and, last but not least, the quality of management. The acute need for flexibility often requires the design of organizational interventions created to support the internal and / or the adaptation process to the environment. The organizational structure is the "anatomy" of a cultural entity, its inner "architecture" and also one of the main management tools designed to support efforts to achieve the preset objectives.

As an agent, given the current operational activities, the cultural organization is, in fact, an instrument of socio-cultural goals that make up its mission, its reason for existence. Oriented towards an end (all of its fundamental goals), the cultural organization is deeply interested in the selection, throughout its decision-making fund management, of the most reasonable and appropriate means to achieve its goals. The cultural agent (organization, administration, foundation ...) is, in fact, an "invention" that allows the people interested in culture to express their creativity, vocation and thereby enriching the heritage of spiritual values in society and their movement in the environment.

Goals of cultural institutions are marked by a clear bipolarity. On one hand, its purpose mainly aesthetic, artistic, spiritual, moral, etc. is target for the refinement and virtuosity, but on the other hand, material matters that are related to the survival of the organization as a whole, can not be neglected, as well the realization of income and resource management etc. Viewed from this angle, the cultural organization is a hybrid that blends the aesthetic, artistic, spiritual, elements etc. with the economic ones. By its nature, this symbiosis requires a two-headed management, dominated by two

major categories of commands (fundamental purposes).

3. Management of the museum's resources

The museum's resource management consists of the management of human resource and as well the management of the technical, material and financial resources. The three components are inter-conditioned, influencing one another. Each category of resource specifically contributes to a successful managerial approach.

Human resource management is the one that animates the museum's staff to acquire professional rated satisfactory results. Quality, staff training and motivation are important factors that follow the interests and desires of the personnel (personal/institutional) and that may lead to performance. Ensuring an eased working climate, encouraging employees, improving working conditions and proper salaries are elements to be taken into consideration at all times. In the museum a large number of personalities are working, leading experts on cultural heritage, which - once treated according to their status - can rise to high levels of professional achievements. The manager is subject to a continuous effort to establish, not only cordial relations and an efficient communicational system, but also to use the most appropriate methods to deal with the work climate. The manager, because of his hierarchical position, is prone to encounter unforeseen difficulties, especially in winning respect and strengthening its authority when promoting changes, when the reforms must justify his approach. His competence in leading small groups, strongly personalized, will become apparent precisely throughout the change strategies that he will promote.

The management of material and technical resources ensures the completion in good conditions of the projects and programs. Technical and material resources, their ability to support the museum's demanding requirements, are very important aspects for the organization. The precariousness or the backwardness of different facilities, the lower level of the quality of the equipment and services, failure, degradation of space and of the furniture that

is displayed or storage issues, lower maintenance and equipment protection, reduced operational resources (transportation, vehicular, etc.), low development techniques for laboratory research and field work, chaotic supply, all these can produce adverse effects diminishing the quality of labor and also the managerial efficiency.

The rationing of material and technical resources should not be opposed to insuring certain requirements regarding the equipment functioning properly and also achieving high quality products. Administrative functions and technical working groups are of great value in ensuring material and technical resources and so the prices have a reasonable cost.

The annual procurement program established in time, with attention to detail and justification, provides the museum with consumables and technical facilities at high level and also ensures the use of equipment and facilities according to standards and regulations, providing rational energy consumption.

Financial resource management is focusing primarily on budgetary and extra budgetary financing requirements. The presence of a well organized budget, insured and balanced, harmoniously sized and distributed to meet the objectives proposed, represents a mean of evaluating the manager. Frequently, the initial budget proposals are different from those approved by the competent bodies. The museum's philosophy budget includes salary expenses, a major part (between 60-80% of the budget), followed by the expenses in other budgetary areas (research and development, investments, costs of materials and technical equipment, with a much lower percentage. Local environmental factors, financial possibilities and politico-administrative decision differentiate the museums budgets. Visionary foresight and the decision-making bodies may substantially increase the amounts allocated to investments, endowments and museum acquisitions. Currently, the museum's strategic efforts are concentrated towards restoring permanent exhibitions, upgrading the facilities and the equipment, work automation, computerization, etc.

The budget is divided into regular intervals, the manager having a permanent control:

- Rational expenditure of allocated resources;

- Identifying and obtaining extra-budgetary funds by providing services (advice and expertise, renting different facilities, special public services, etc.)

- Outsourcing of different service categories (security and protection, maintenance and production of museum presentation materials, etc.)

- Ensuring proper management of resources and internal financial audit; preventive control of financial transactions.

Extra-budgetary funding sources are becoming increasingly more important, as they tend to occupy a significant place in the economy of the museum. To those already used, are added different international collaborative projects, financially ensured by third bodies. Preparation, drafting and documentation related to planning, payments and work operations, management and technical control are of an exceptional importance.

The gradual increasing trend of self-management skills significantly increased the efforts to reduce the budgetary funds allocated. The museum's financial resources are usually limited, so each museum is concerned with supplementing funds through specific marketing activities. In recent years, museum marketing managers have become especially important.

The marketing in museums has in mind primarily the commercial stand (shop, store): this is meant to create an income, to guide the public, to promote the authenticity, the excellence, the good taste and the cultural value. Contemporary artists, craftsmen and artisans, producers of audiovisual materials, publishers must be enticed to sell their products through the museums. In all cases the offer will be guided by the museum's profile, trying to make it as specific as possible.

An important place is occupied by parking spaces, cafeterias, snack bars, restaurants. They also generate high revenues and have an important position in the process of socialization.

Another important place is occupied by marketing research that involves the identification of senior producers, beneficial products, stimulating the market and refining the categories of supplies. From this point on

the production phase starts throughout presentation and distribution. Quality and price of purchase / sales are important components of managerial policy. The association between several museums in the system of museum poles may lead to a substantial increase in revenues. The correlation of copyright, is a responsibility assigned to the financial management. At this point, the manager will join or will use the most qualified legal counsel team. The manager and the staff policy has the role to maintain and support the specialized workforce in the museums, creating a balance between the scientific, technical, administrative and financial elements. The manager himself, in most cases arises as a result of staff training. Its selection implies an optimal framework of quality assertion, the promotion is recommended to be made gradually: first in a secondary position (at age 30-40 years) giving the staff a chance to perfect their managerial skills. Specific activities of the museum can be performed only by persons qualified to perform them; the specializations start to become a must and require systematic efforts from both the individual and the institution: in the preparation of a graduate specialist a lot of time is invested in order for its results to be efficient. The manager is the one guiding these efforts, identifying areas that need specialized staff, creating optimal conditions - through courses and graduate programs, master's, doctoral fellowships, internships documentaries - and ensuring, of course, the proper funding. The improvement of these specialists is mandatory coming as an immediate consequence is the use of their abilities. The auxiliary, technical and economic staff, does not have to be underestimated in terms of its professional training, its abilities depending on the proper functioning of the museum. Its components must be well selected and their performance will be followed at all times, maintaining a proper running of the museum's infrastructure falling in their duties. As well there is going to be an effort to retain this staff in the museum. The way that the specialized staff, behaves, reveals an evident managerial blatant negligence. The state of the facilities, of the exhibitions, the equipment and the working materials of inferior quality, the low cohesion and

motivation of employees, is evident and reflects a lack of professional skills of auxiliaries, a direct consequence of management failures. Such defects are often encountered in financial and administrative departments, with a negative impact on the image of the institution or producing unintended consequences in the management, in the completion and utilization of funds, in the reputation of the museum's services.

In the museums of France, the public relations department has installed security cameras in order to permanently have control on visitors and their behavior [5].

The ability to understand what visitors want to see is the most important task that the museum has to take into account [4].

A rated museum manager does not ignore any segment of the staff, seeking to harmonize the working climate and human relations between people, seeking a good continuous functioning. In the internal organization of professional micro groups life the manager will always seek to achieve harmony and respect. Table spaces, the dressing and recreational areas, the working conditions alleged by the museum's schedule, with its specific restrictions and requirements, the planning of holidays and vacations, must be organized very well in order to meet the requirements of both the staff and the public. The incentives, rewards and sanctions will take into account the quality and the performance of the specialists. Therefore, the manager has also the role of training the specialists, identifying the special qualities, allowing, in perspective, a general view of the person that would best qualify as a successor.

Encouraging competition arises from the role of continuous performance incentives and a good working climate. Any bias and ignorance, the directorial bias against employees may result in damage to work and climate relations, severely affecting the image of the museum.

A fundamental mistake of many museum directors, is not organizing the working time with those inside the institution: heads of departments and employees with responsibilities or outside of it: officials, delegates, collectors, donors, etc.. A functional secretariat also corrects deficiencies, scheduling and ordering the manager's working time.

As such, the organization and the administration of the managerial work, of the meetings and the protocol, has to be regarded and treated with great care and deliberation, avoiding loss of time and lack of courtesy in their dealings with others.

There is no control of a museum without a minimum involvement of employees [1].

To a large extent, the success of a public museum is provided by its "friends". In Italy, in 1992, there were 5.9 museums per 100,000 inhabitants, their number increasing day by day [7].

4. Managerial decisions in a museum

The managerial decision in a museum is presented in the museum's everyday life, in all its functions and in the smooth running of activities [6].

The idea of a museum's management team has progressed, this concerns the existence of two managers: administrative and "artistic", so increasing the competences will lead to an increase of the museum's negotiation policy with potential suppliers and to competitive differentiation [3] etc.

As the museum's management is a set of concepts, methods and techniques, we can deduce that the management is accomplished through the manager's decisions. Implementation of decision-making in daily practice involves a laborious process that implies the association of several factors. Leadership involves communication skills, advanced knowledge in museums, because the existence of small and medium groups, implies the existence of a good manager, who plays a key role in harmonizing them, animate and lead, as decisions are required to be clear, justified and reasonable. For this purpose a few elements are necessary:

- Gathering information on a certain issue that needs a resolution;
- Construction of different settlement options;
- Optimal solution;
- Communicating the decision to those who are responsible for putting it into practice;
- Enforcement of the decisions and findings;
- Reporting the completion of the decisions.

The informal circuits and the climate of working groups, are factors to be taken into account by the manager, seeking to ensure appropriate conditions for action. The cultural team may have the impression that it has a marginal place and its involvement can not change anything in the museum, that is why it is important that the manager involves the whole in cultural projects [2].

5. Performance evaluation criteria of management in museums

Establishing criteria for performance evaluation of management in museums has become possible - though always relative outside of precise rules - by recent legislation [9]. They seek to quantify and clarify without making a gradual distinction - the criteria for assessing the management of the museum. Among the specific operational objectives, in terms of management, we can mention:

- The efficient and optimal valorisation of the museum's heritage, as well as the museum's offer in terms of products and services;
- Diversifying and adapting the offer, responding to higher quality and efficiency requirements;
- Offering services to meet higher standards as present in certain museums both in Europe and as well at an international level, in agreement with the local cultural environment;
- Continuously promote collaborations and partnerships with various cultural operators;
- Designing the museum's offer to the real demands and needs of the public, attracting new categories of visitors and increase audience loyalty by its co-participating in the cultural act;
- Identification of complementary and alternative sources of financing: accessing national and international projects and programs, increasing donor gestures, sponsorships and patronages;
- Identifying and vigorously pursuing new ways to streamline efficiency throughout saving material, financial and human resources of the museum;
- Providing material resources and ensuring an ideal climate for the qualification, specialization and professional development;

- The creation of strategic projects and programs of development of the museum on short, medium and long term.

6. Conclusions

Each museum can be defined specifically with reference to a "ecosystem of the museum" (national and international) where activities interact. Each museum - has a part involved in the ecosystem, which the museum can not ignore - is free to decide its future, also their choice of objectives, means and criteria for evaluating the quality of achievements and developments.

Bureaucratic work trends for standardization and modernization may be opposed to forces of differentiation, even fragmentation, likely to resemble to the museum's environment - a world full of initiative and sometimes contradictory directions.

The Impact of Globalization about Capital Market

Din Alina Valentina
"Lucian Blaga" University of Sibiu
alinavdin@yahoo.com
Meghișan Flaviu
University of Pitesti
marketing_mf@yahoo.com

Abstract

The paper intends to identify elements which nowadays naturally bind the Romanian capital market to external financial circuits and to evaluate the dynamics of these one into a world of multiple conditionings in which the juxtaposition of influences may generate the intensification or disruption of the effects, and their reproduction in different circumstances may lead to results situated beyond anticipations.

Key words: globalization, deregularizations, capital markets, financial crises, financial volatility

J.E.L. classification: G

1. Introduction

Globalization of capital markets the direction of internalization of stock exchanges and development of a global financial market may have negative consequences.

In Felix Rohatyn's opinion "global financial markets are a greater danger today to world's stability even more than atomic weapons".

The succession of financial crises in the '90s starting with Mexico and finishing with South Korea, Russia or Brasilia is an argument used by globalization's opponents. The main factor of financial crises in the last decade is also the factor of globalization of capital markets, which speeded the capital movements.

Unlike previous decades, nowadays national economies integrated in global economical circuit must be prepared anytime

in order to face eventual shocks from the exterior. The isolation from the global economy is not a solution in order to escape from the dangers implied. A strong economy with a solid financial compartment, open and transparent may face successfully the provocations brought by changes on the international level.

The reduced degree of regulation of international market enhances the opportunities of speculations[1] and thus may affect the stability of national capital markets.

A globalized financial system where hundreds of milliard dollars may circulate simultaneously as a reaction to the latest news and eventually only on the grounds of some psychological factors, may become an unstable system.

The speculative movements represent a significant perturbant source which attempts to the stability of financial markets. The overwhelming financial power of private investors may create problems even to the most powerful governments.

A familiar example which shows the potential source of instability generated by globalization is the one of Rarings Bank.

Nowadays, on a global market with global investors the international flows of capital may affect the whole system with the risk of being a source of instability. The intercorrelation of national financial markets allows the more rapid transfer of wave shocks and the consequences of a domino effect generalized at global scale are hard to imagine. The technological revolution reduced the autonomy of national markets and increased their volatility.

2. Globalization and financial volatility

The financial crises of the second half of the '90s threatened the globalized system of capital markets and brought spectacular reductions of production on a short term. The volatility of capital flows measured as a standard deviation to the mean of admissions –exits of financial resources placed under doubt the capacity of markets to actuate increases on a long term and thus the development of national economies.

In a reciprocal sense one intended the influence of financial globalization to the macro economical volatility – measured as a standard deviation of the consumption and production to the mean.

In spite of the fact that the volatility of capital flows inhibits the development, recent evaluations show the fact that countries learn to manage more and more better their volatility. Thus, the rather harsh process of global financial integration offer – if well-managed – the possibility of some economical growths.

The volatility of capital flows, measured either as a standard deviation to the mean of admissions –exits, or as a deviation to the average proportion between the flows and the internal brute product may be the result of an internal cause as well as of an external one:

- The changes in the internal financial politics, for example, may determine reactions of the capital flows when these kinds of modifications are frequent and unpredictable. In this situation, the volatility is considered a symptom of the deficiencies of politics rather than a risk.

- On the other side there are the opinions according to which the movements of capital flows are almost independent to the fundamental economical balances of the states – the volatility of the flows is thus owed to the state of global liquidities and 'contagious' conduct of investors.

An intermediate vision binds internal weaknesses – especially in the financial sector – to the imperfections of global allocation of capital flows. The relation affects especially the countries which liberalize their financial sectors in the same time with the opening of the economies to the external capital.

This perspective led to the general accepted importance of consolidation of internal financial sector in the same time with the financial integration with the rest of the world.

During the last years the volatility on a long term of capital flows, though even increased or increasing in some countries has recorded deflations in the group of state in development. The signs of reducing of volatility as well as the perception of the fact that some countries got in shape relatively soon from the crises determined the observers to conclude that the countries succeeded to ameliorate the ability to manage the volatility of capital flows by such means as:

- diversification of the structures of production
- introduction of flexible rate of exchange
- preservation of a higher levels of currency stores
- consolidation of the observation of the financial sector
- rating of capital admissions in order to maintain under control the most volatile flows.

3. Regulation and observation of national capital markets

The national organisms of observation of capital market have as their main mission to ensure the protection of the investors who placed money in value titles, permanent information of the investors, authorization of the creation and observation of the course of activity for the institutions implied in the field and the well functioning of the markets organized in movable values.

They have also the task to examine if there are persons who benefit from privileged or confidential information. One of the antinomy of the exchange: knowing of the reality previous to the 'market' is a source of benefit but the confidential piece of information is, theoretically, unusable.

In more countries one can observe the tendency to unify the whole responsibilities of regulation and observation of national capital market in the hands of a single institution.

The existence in more and more countries of the preoccupation of agglomeration of tasks of observation has the disadvantage of a lack of responsibility.

The tendency to reunite all the responsibilities of regulation and observation of national capital market in the duty of one institution do not have to be mixed with that of unification of observation for the whole financial market but can represent a first step in this direction.

In the attempt to fulfill their objectives, the role of the 'peace officer of the exchange', the organisms of observation of the market are invested with powers of executive and judicial regulation:

- powers of regulation with the view to the possibility to promote regulation, instructions, recommendations, etc;
- executive powers which refer to the activities of notifying of public offers, of observing of the market;
- judicial powers in accordance with the possibilities to proceed to investigations if one observes the break of the laws in the field or of proper regulations, the cases being able to be sent to the law court or being directly executed by penalties or administrative measurement to the society of movable values.

In the future, the problem of a unique authority of observation and regulation for the whole financial market will be one of actuality, one taking into account the tendency of sending to the banks the implication on the capital market.

4. Tendencies of deregularizations of capital markets

The concept of deregularization does not imply the renouncement of regularizations. Capital markets continue to remain regularized.

The tendency of deregularization manifested internationally has in view a phenomenon of liberalization of the markets, of opening of national capital markets. In this sense the deregularization must be regarded also related to the phenomenon of accelerate globalization of national capital markets.

5. The embryos of financial crises and global finances

The problem of the imperfections of the market arises when there appear frictions between the capital movements and the fundamental indicators and when the discipline of the market proves to be weak. This is the case, for example, when capital flows refer to countries with unsustainable politics or, on the contrary, when financings on the external capital markets are either unavailable, or too expensive for countries which otherwise have correct politics and perspectives on the capital markets.

"In the battle between nations matters not so much the different divisions or ideologies as the capacity to attract and hold the investors"[2].

According to the hypothesis of the arbitration between financial politics, the differences in the quality of the management of economical politics represent important determinants of the volume, terms and direction of capital flows. Thus, these flows tend to come from countries with relatively instable economical politics to countries with healthy economical politics and good perspectives.

Any conflict which can appear in this way between the national and international interests refer not so much to the direction of the capital movements, as to their volume. If an economy receives a volume of capitals bigger than its capacity of absorption, the admissions of capital will destabilize the fundamental balances and rise problem to the monetary politics and the one of the rate exchange.

The management of financial crises resides in the arbitrary of the two opponent realities which governs the national markets: the control of capital flows which assumes a certain degree of economical planning on the one hand, and the pressure of group of interests, on the other. The judgments are aggravated by the psychology of the regular intervenient on the capital market.

6. The simple cause of a financial crises

Inventions – Emergent Markets – Economical Boom

These tendencies are increased by the fact that any economical 'boom' is the carrier of a great inflationary potential.

The expansion of the crisis is an attribute of these ones which raises question marks and accentuates the urgency regime of the problematic of financial crises. One notices that the impact of the crises in the decades IX and X to the group of countries OECD was insignificant and that the losses registered in the countries in crises would equal only 2-3 years of economical growth.

Moreover, the innovation and the financial intermediation facilitate the circulation without furrows of some immense capitals – inclusively of the 'black money' – with evident effects to national economies[3].

7. Conclusions

Romanian capital market develops, in its turn, a process of evolution, exceeding the phase of the emergency of system but remaining at the stage of searching and partial and sometimes painful consolidations, taking its proper rhythms of internal economy and aspiring to the statute of a delicate instrument.

In order to circumscribe the Romanian capital market within the international financial space it is necessary the identification of the broad cadre of the influences of the globalization to the markets and capital flows but especially to the ones of economies in transition with a higher degree of vulnerability.

Regional initiatives and commune plans of action which sustain them determine the profile of many of the transformations which Romanian exchanges and other financial systems operated or have to operate soon. The new European economical geography, the problems of monetary and financial union, internal sectorial bets and even those

social of European community seem distant subjects but they actually have the capacity to significantly influence and on a long term the integration of the Romanian market – as well as of some other markets – in the European financial arena.

In the presence of global structural forces which determine the movements of the capitals, the role of internal fiscal ropes becomes crucial. These one avoid the costs associated with different types of politics of sterilization and represent a substitute for the flexibility of the rate of exchange. Nevertheless, few countries have relied so far on the fiscal politics in order to control the admission of the capital due to its inflexible character

Fiscal contraction can play a benefic role as an instrument for the stabilization of the capitals on a short term and the conservative fiscal position should occupy a central role in the control of the countries which are in a phase of growth of the financial integration.

During extensive financial integration the direction and size of the capital flows become very sensitive to the perception of the investors on internal public solvability and limit fiscal flexibility. Moreover, during volatility of capitals the preventive tightening of fiscal politics may help the protection of important capitals of incomes and expenses. Even if the fiscal position has to be consolidate in front of the volatility of the great capital flows, the necessary modifications will be less important if the government has already consolidated the fiscal politics. This will help the govern to avoid the eventual significant adjustments of fiscal programmes.

The conclusion, as well as the way of approaching are certainly perfectible and deserve the effort of a future ample research. In addition, the legislative initiatives and the structural changes for the capital market in the near future will generate new elements of analysis and will reconfigure dynamically one of the youngest sectors of Romanian economy.

Combating Tax Evasion Between Legality and Illegality in Romania

Abstract

Humans are always tempted to put general interest after the personal one, thus being inclined to consider taxes more as the ones who try to diminish their heritage.

The phenomenon of avoiding to pay taxes towards the state namely tax evasion is especially characteristic to a free market economy and less to a directed, centralized economy or an economy controlled by the Government.

Tax prejudices and not as legitimate contributions to public expenses, furthermore to see as being evil evasion is not only the image of fiscality, but also of a political and social climate, of nationality and religion. Human condition is responsible for the generalization of this particular phenomenon, together with the feeling of forfeit without receiving the equivalent back. There is a way of thinking in the minds of contributors that consists in not paying anything but only the absolutely necessary.

Key words: tax, evasion, fraud, law, illegality.

J.E.L.classification: G

1. Introduction

Growth in our civilization level leads to an amplification and diversification in human needs, thus higher demands for public and quasi-public assets. This way, the financial effort claimed by fulfilling these needs registers higher levels from one period to another, leading to a very high demand of public financial resources, which either way have a limited and often insufficient nature. In this context, identifying efficient solutions

to obtain larger public financial resources poses problems. A so-called solution might be the uncovered monetary issue, but considering the harmful medium and long term effects of this extreme measure on the stability indicators in macroeconomics, we appreciate that this is not a healthy measure. Could it be that state loan contracting or augmentation of the general fiscality rate is the best solution? Considering that state loans are often assimilated to "held taxes" it is obvious that in both situations the basic effect is the same: increasing tax burdens for contributors (either immediately, or in a future period). Although the effect caused by the two directions is an unpopular one, it certainly is better than using uncovered monetary issue. There is one amendment: the public authority should apply them only when the disproportion between supply and demand in public financial resources is obvious, furthermore when public expenses have been reduced to a minimum level so that there is no chance of "margining".

Many times, when the public authority takes into account the increasing fiscality they bet on fiscal illusion phenomenon (also known in the economy's doctrine as fiscal anesthesia). This implies a boost in taxes without this being actually perceived by the simple contributors through their tax burdens. Regularly, the fiscal illusion phenomenon does not imply any change in tax portion or the introduction of new taxes, but it might involve changes in the structure (sometimes even perception) of already existent taxes. Obviously, this phenomenon is encouraged by an even more complex (or ambiguous) fiscal structure that does not allow the contributors to gather exact information regarding their taxes. When the intention of increasing fiscal burdens becomes

perceptible to a larger range of contributors, the public authority will try and minimize the political and elective costs of this measure so that it will be possible to generalize countervails induced by the increase of tax burdens; as a consequence there will be justifications regarding the fact that only this particular fiscal rate is able to insure the public financial resources needed to finance a larger number of public assets, thus better satisfying the collective needs of society. Starting from defining tax as "necessary evil", fiscality has been approached, without a doubt, as a constraint to the average contributor, especially when the respect for the law together with the level of culture in this particular domain, are quite low. Regardless of the contributor's fiscal civism, tax burdens will be perceived as being more uncomfortable and unjustified as the fiscal pressure becomes higher or as the management of public financial resources becomes assimilated to political decisions that are discretionary and incoherent. The phenomenon of "avoiding taxes" or tax evasion is based on the issues presented above together with the suffocating fiscality situations.

2. Tax evasion

Tax evasion constitutes at this point a complex economical and social phenomenon. Tax evasion is one of the most complex and important social and economic phenomena confronted nowadays by all states and whose negative consequences are fought with more and more, but also keeping in mind that the eradication is practically impossible. The statistics confirm the fact that this phenomenon has a wider spread in developing than in undeveloped countries where governments objectively encounter difficulties in monitoring transactions in their economy. Tax evasion is the best studied chapter in fiscal law, as well as by technicians, ideologists and even journalists. However, in spite of all that is written about causes, ways, spread, control and sanctions regarding tax evasion, the words describing it are not precise and the exploited domain is uncertain. Thus, this notion is difficult to shape up, but unanimously recognized, because there is no legal definition of tax evasion that has mostly illicit evasion acts at

its base. As a result there are vague differences between tax avoidance and evasion. Regarding the vagueness of words used to describe tax evasion this comes from the diversity of words used to enlighten, more or less the same phenomenon: willing unfulfilment of legal tax obligations by the contributor. The Romanian Dictionary defines tax avoidance as: "avoidance of tax obligations". The Oxford Dictionary defines tax avoidance as "minimizing tax obligations legally but also through ways of full uncover towards fiscal authorities; the arrangement of financial business with the purpose of reducing obligations within the law". The same source defines tax evasion as the minimization of fiscal obligations illegally, usually by not revealing the obligation of paying a tax or duty, or through providing the authorities with fake information. Romanian jurists at the beginning of this century have been preoccupied by the definition of tax evasion. Oreste Atanasiu considered it as being represented by "all licit and illicit procedures with the help of whom the ones interested tamper totally or partially with their fortune from the obligations settled by fiscal laws". Tax avoidance is the contributor's action to elude the law, drawing upon an unforeseen law combination thus "tolerated" through incaution. The legal support of these contributors is given by the principle: "what the law does not forbid is allowed" [1]. Illicit tax avoidance can be defined as a willing action from the contributor that violates a legal prescription in the purpose of unfulfilling the proper fiscal obligations. To achieve this purpose, he appeals to: the diminishing of the tollable object, under evaluating the quantum of ratable mater or the use of other ways of avoidance. Tax evasion presumes, above a violation of the law and legislator's intention, a direct and deliberate trespassing of the rules imposed by the law for establishing taxes and tax payment for the contributor. University professor D.D. Şaguna defines tax evasion as "a logical result of the effects and inadvertences of an imperfect legislation, of vicious applied methods, as well as imprudence and incompetence from the legislator, whose excessive ficality is as guilty as the one committing the evasion". Some authors appreciate that, by the way the effects of fiscal regulations, there are legal

tax evasions and the illegal ones [2]. When avoidance of the fulfillment of budgetary obligations is created by interpreting fiscal laws in favor of the contributor, then we find ourselves in the area of tax avoidance which does not constitute malfeasance. As an example this shapes up when a certain part of the incomes of some individuals or social categories is taken hold of from the actual taxes because of the way fiscal legislation elates the establishment of ratable objects. When an income is settled by the law depending on certain standards or rules and determines a ratable income that is inferior to the real one it is called tax avoidance. In case the ratable object is counterfeited with an under evaluation of tax quantum or with the help of other ways of avoiding tax payments, we find ourselves dealing with tax evasion. So we can clearly observe that the connection between legality (avoidance) and illegality (evasion) is actually not a rupture, but continuity. Thus there is an "interference area" between the legal and the illegal compartments. This area is quite easy and frequently used and the contributor is due to slip easily and deeper from the error of using fiscal options, the simple abstinence from breaking the law to actually breaking it and qualifying for abuse and fraud. If we are indeed talking about fraud we are also talking about: legal or legitimate fraud, illegal fraud, international evasion, legal evasion, illegal evasion, tax obligations by withholding the income information, the falsification of evidence documents, even through the simple fact of not elaborating fictional documents [3]. Concluding upon the diversity of opinions towards legal and illegal tax avoidance, legal and illegal tax evasion, we consider that there is only one phenomenon that affects income taxes depending on the relation to the law of this particular activity and that can be called licit tax avoidance (allowed by law) and not legal tax avoidance (because legal implies that there are laws upon it exists, it is foreseen by the law, according to the law), as well as illicit tax avoidance (illegal), which is a synonym of tax evasion. The actual ways this phenomenon takes place, either in a situation or another, only aggravate the severity and seriousness of this phenomenon, rather than defining it. The definition is only one: avoiding the obligation of imposing the

taxable situations without contravening with the present laws or by the contrary contravening with them.

The imposed taxes determine more and more countries to act within the underground economy, as long as there is not a proper offer of public goods and infrastructure.

In his study, Vito Tanzi indicated as the main cause of the underground economy the level of taxes. [4]. He adds the instability of the legislative framework, legislative restrictions imposed within certain states, corruption and bureaucracy.

It is found that the 20-25 percents which represent the increase of taxation in the European states within the last decades were annihilated by the 12 percents of the GDP in the same countries, representing the percentage of the underground economy within the states member of OECD at the end of the last century.

The increase of the taxes imposes, even if not proportionally in all the cases, the increase of prices. This affects everybody, especially the final consumers.

This way, the underground economy registers supplementary profits because:

- *it offers cheaper products of lower quality, because by avoiding the taxes, the clandestine producer can ask prices which fraudulently compete with the prices within the real economy;*
- *it attracts new activities to its domain because many tax payers overwhelmed with supplementary taxes, choose the underground economy as an exist option;*
- *it creates the possibility of illegal work, of obtaining different non-taxable incomes.*

Numerous specialists have studied the impact of taxation increase on the level of the underground economy, stipulating different increase figures, as a consequence of increasing the taxation by a percent. For example, the results of a study carried out based on the data regarding the underground economy in the USA show that for the increase by a percent of the marginal rate of the income tax the increase of the underground economy is of 1.4 percents [5]. In another study it is shown that the value of the undeclared incomes increases by 0.05% only, for each increasing percent of the value of the incomes from taxes, drawing up the conclusion that, it is questionable whether the increase of incomes achieved by reducing

evasion could be high enough in order to cover the loss generated by tax reduction [6].

With regard to the relationship existing between the level of the pressure of taxation and the one of the underground economy, Norman Loayza, a well-known analyst of the underground economy phenomenon, demonstrates in a recent study for countries within Latin America that in the economies where the pressure of taxation is higher than the optimum one, and the application of regulations has a low level, the increase of the relative dimension of the unofficial sector leads to a reduction of the economic growth. [7]. His results indicate the following: for an increase of the underground economy by a percent of the GDP a reduction of GDP by 1.22%.

3. Combating tax evasion

It is extremely necessary for all the countries to limit the harmful effects of this phenomenon so it will become less spread, for it is well known to us that it cannot be eradicated. Tax evasion has an early and direct effect on the levels of fiscal influx leading to disturbed balances in market mechanisms and unlawful enrichment among those who practice this deceiving method that affects the state and last, every contributor.

One of the most important Romanian institutions that prevent, combats, traces and sanctions fiscal evasion is Financial Guard. Financial Guard, a public control institution is financed from state budget, organised as a special authority of public central administration subordinated to Economy and Finance Ministry – National Agency of Fiscal Administration, with a juridical personality, exerts operative and unannounced control concerning prevention, founding and combating of any documents and acts in the economic, financial and custom field, that has as an effect fiscal fraud and evasion.

The measures have been taken for:

- Combating illicit trade with taxed products, having checks during which, an important, permanent objective was represented by actions concerning illegal spaces where took place illicit commercial activities (production, storing, trading etc.)

- Combating the introducing and trading illegal cigarettes proceeded from smuggling

and from illegal internal production, these acts in this field recording spectacular results, mainly in the 4th trimester

- Impose the compiling to OUG no>28/1999 concerning the compulsory owning of fiscal electronic marking devices targeting that economic agents which proceed retail trade to own and use the fiscal electronic devices.

- Respecting the fiscal law by importers of consumption goods, also food and other products.

In this field have been organised thematic actions for checking for complying with law by the vegetable and fruit importers, where has been founded serious disfunctions concerning praising and the payment of VAT and profit tax. Also, has been effected checking to meat and meat products importers, and to rice, sugar and coffee importers. The proceeded verifying activities to importers and construction material users has emphasized that some economic agents has formally recorded fiscal duties to state budget, omitting the payments.

Founding economic agents from trading field with technical plants, cereals, milling and bakery products which did not praised all proceeded commercial operations or use phantom firms to justify the origin of the wares or to rise the expenses recorded to abate the profit as a subject to taxation and the VAT to be paid diminish the illicit transactions in the field of exploitation, financial administration, processing and trading wood. The verifying activities have shown the procedures of selling wood on the black market which has been exploited and surreptitiously processed Discouraging illicit procedures in the domain of offals that can be recycled, by which economic agents, using fictive identities of garbage disposals, encourage the acquisition of diverse stolen materials from energetic or railway sector, with major consequences for national economy.

There are numerous ways of avoid paying taxes, but those who use these methods can be separated into two categories: those who exploit the flaws of the rules in this domain and those that use licit procedures. In market economy, the fiscal authorities are confronted with an evasion phenomenon that has been taking proportions as a result of the tendency to tamper with

higher amounts of money from under the law. "To cheat the revenue authority is considered to be a proof of ability, not of dishonesty, to pay what the revenue authority claims, is a proof of simple-mindedness, not of integrity [8]. According to specialists in the field, tax evasion holds the first place in underground economy, its' ways varying and being extremely ingenious:

- unapproved merchandise production;
- purchasing companies in debt;
- deceitful bookkeeping and balance sheets;
- accelerated multiplications of forms and procedures used in money laundering, so on and so forth.

4. Conclusions

Tax evasion creates "images", "realities", "histories" parallel to reality on a certain tax generating situation so that it will become less ratable. So, tax evasion will generate parallel realities on a certain economical phenomenon so that it will lead to a reduction in tax payments. In order to achieve its objectives, tax evasion appeals to information regarding the law, personal funds, public funds, economy and finance administration, management, marketing etc. Tax evasion is born in the simplest game of interests whatever the tax share, all this reflecting human greed and selfishness.. Tax evasion is one of the most complex and important social and economic phenomena confronted nowadays by all states and whose negative consequences are fought with more and more, but also keeping in mind that the eradication is practically impossible. The statistics confirm the fact that this phenomenon has a wider spread in developing than in undeveloped countries where governments objectively encounter difficulties in monitoring transactions in their economy. Tax evasion is the best studied chapter in fiscal law, as well as by technicians, ideologists and even journalists. However, in spite of all that is written about causes, ways, spread, control and sanctions regarding tax evasion, the words describing it are not precise and the exploited domain is uncertain. Thus, this notion is difficult to shape up, but unanimously recognized, because there is no legal definition of tax evasion that has mostly illicit evasion acts at

its base. As a result there are vague differences between tax avoidance and evasion. Regarding the vagueness of words used to describe tax evasion this comes from the diversity of words used to enlighten, more or less the same phenomenon: willing unfulfilment of legal tax obligations by the contributor. The Romanian Dictionary defines tax avoidance as: "avoidance of tax obligations". The Oxford Dictionary defines tax avoidance as "minimizing tax obligations legally but also

Describing licit and illicit (illegal) tax avoidance is necessary and useful because it gives us the at least theoretical possibilities of estimating the size of this phenomenon based on its two ways of manifesting. This dissociation helps sensitize different political and administrative decision factors towards finding and establishing adequate ways of limiting and controlling tax evasion as a whole. During the last decade has been a growing tendency of law, agencies and intergovernmental organisations to focus upon international evasion and fraud phenomenon. This subject has an increased importance as a direct result of climate of economical recession, which determined the increasing of the tendency of a part of tax payers to reduce their taxes as a source of a new finance, in the same time, for other reasons the governs has continued to retrieve missing tax by fighting against fiscal fraud, by avoiding tax burdens and by modifying national fiscal policies.

Teliceanu Viorel Gabriel

Chiriac Marius

“Dunărea de Jos” University of Galati, Doctoral School

Abstract

Individual career planning defines a complex and customized process, run in parallel on two temporal axes. The management of developing a career management is a challenge to every individual because the levers used are not standardized and can be adapted to any employer from the labor market

An optimal behavior in short-term career management requires both deep knowledge of active methods for career development and their efficient handling. Professional success can be ensured by a correct correlation of the individual compatibilities with the values and needs of labor market.

Long-term career planning represents a desideratum for the development of basic skills, which are valuable and useful at any level of career.

This paper presents the most effective methods for the optimal development of a career.

Key words: employer, personal marketing, management, career.

J.E.L. classification: M 59

1. Introduction

Career planning is a long term process which includes choosing an occupation, employment, workplace advancement, possible career changes, and finally, retirement.

Career success depends largely on the care and seriousness with which we are preparing a career plan that we intend to follow.

In order to ensure success in career planning we should take into consideration the development of two plans:

- Short-term career plan
- Long -term career plan

2. Short-term career planning

A short-term career plan should focus on a period of minimum 1 year and maximum 3 years. The key feature around which this plan should be developed is to create realistic goals, objectives that can be achieved in the very near future.

As we begin short term career planning we should focus on removing certain career barriers that are of several kinds:

- Personal barriers - lack of motivation, apathy, simple and trivial disgust

- Pressure from family - parents waiting for us to continue working in the family business, following a career that is desired by our parents or avoiding a career that is considered by our parents to be a familial prejudice

- The strong influence exerted by the group we belong to, especially in adolescence, to have the same goals in life as the other group members do.

1.1. Identifying prospective employers

Before we start looking for a job we need to develop a search strategy or a personal marketing strategy in which each of us to play a product. Any product on the market, no matter how good, can not succeed without a strong marketing strategy.

First we must establish to whom we address for employment. We need to identify the market employers who are looking for employees with our qualifications. We should inquire whether they belong to certain industries or if our qualifications and skills are in demand in many industries. Career advice services can facilitate our activity

direction based on the establishment of our skills and talents as a result of a complex and fair individual analysis.

1.2. Ways of approaching the prospective employers

Having identified industries in which we could develop a career, we will identify the method through which we can get in touch with them, meaning that we must decide on the sources that we use to locate prospective employers.

The majority of those who seek a job are prone to choosing the passive search method. This is a method that involves:

- Applying for jobs found on the recruitment websites;
- Searching for jobs in print media;
- Searching for jobs among acquaintanceship;
- Sending resumes via e-mail to companies they would like to work for;
- Sending resumes via e-mail to various recruiting companies.

I believe that these applying methods are little or no effective in a market with constant rising unemployment because nothing makes us different from other candidates.

The inefficiency of these methods is outlined by the poor results obtained by recruiters. They will end up with many resumes that do not meet basic job requirements. They are poorly structured, generalist and do not give the recruiter the opportunity to have a clear impression on the profile of the person who applied. Under these circumstances, the recruiter's inclination is to analyze resumes superficially and, therefore, he risks to overlook the well structured ones.

These types of applications currently prevail because of our desire to save time and because we do not want to leave our comfort zone and undergo any risks.

We must discover and use active methods of finding a job because the search results can be much higher. These could be:

a) Job Fairs - actions that are present mainly in large cities with developed industry. Here we have the opportunity to meet representatives of employers and find out details about the company, jobs available and employment criteria. We can discover the existence of some jobs that are not

published, find out what the market trends are and make our professional contacts. Here we can leave our CV and make ourselves known to prospective employers physically

b) Networking site - requires us to identify and participate in various events in order to know and build relationships with different people. The idea is to get beyond the circle of relatives, friends, colleagues and neighbors and have the initiative to meet people who hold relevant positions in companies operating in our sectors of interest. In time we need to build a network of people who can tell us about the various employment opportunities.

c) Placing the resume personally - once we learn about the availability of a job, we have to bone up on the company characteristics, adopt a proactive attitude and go to the company to leave a resume and show our interest in the job. The objective of this approaching method is, above all, to know closely the organization and not necessarily get the job.

Active methods of searching for a job involve the possession and use of skills such as: ease of networking with strangers, clear communication, the ability to win someone's trust, etc.

1.3. Employer Selection

Following the training processes that we experience at preorganizational level, we will have to find an employer whose development directions are consistent with our career plans. To select the organization we are going to be part of, we must discover inside it aspects that would motivate us as human resource. These could be:

- ensuring that possibility of advancement through training opportunities and strategies of motivating and rewarding employees with potential;

- the prestige of an organization can increase a resume value, which is why we should choose companies with experience and economic performance that are representative for our field of interest. Working for such a company can significantly increase our chances of career advancement.

- the employer's respect towards the work done by us, as an integrated human

resource, can boost our performance and the desire to climb the professional career.

- the working hours are an important factor in choosing a company. The careerist level at which we are at that moment counts equally. At the beginning of our career we easily opt for a longer working hours and once we advance we would rather respect working hours and keep our leisure time unaltered.

- the benefits offered by employers – in choosing the organization we are going to work for, facilities such as: private health insurance, rewards in the form of time off, bonus schemes, bonuses and payment of costs for training courses conducted in our field of interest will play an important role.

We can get knowledge of all these aspects regarding the employer through direct queries directly to the employer when we have the interview . And in this case, personal networking can help us discover all these aspects prior to filing our resume, thus avoiding accessing a job in a company that does not correspond to our needs.

1.4. Personal marketing through resume

Resume is one of the most important marketing tools that a prospective employee can use to persuade an employer. Because this is the first contact between the individual and the organization and has the power to decisively influence the existence of future contacts, we can conclude that this has a strategic role, as well. Our CV is an opportunity to impress a prospective employer because it may create a first impression about the professionalism, intelligence, accomplishments and attributes that recommend us. A well structured CV can provide further participation in the interview, the representative of the prospective employer having already formed a favorable first impression.

Assuming that the CV is the first step in our presentation as a human resource and that currently in Romania, this is the main method of selecting the prospective employees, we should take the CV writing very seriously. Due to the wide range of CV models we have available, we must choose a model, but most often we tend to choose the European CV, filling it in hoping that it will impress the reader. This model was developed to respond

to all candidates' requirements, regardless of the profile. It should be adjusted according to the job they apply for.

A well - thought out personalised resume should permit the employer to easily find the potential of each applicant and to select those whose abilities and skills correspond with the company's requirements.

The most important elements a resume should contain, are:

–the details about the responsibilities we had in our prior jobs (as employee or self-willed) as well as the relevant results obtained in that position, corresponding with the requirements of the job we apply for. The actual trend of each candidate in Romania is that of mentioning in the resume any occupied position, even if they are irrelevant for the job. For this reason, the resume turns out to be full of useless information and difficult to run over by the headhunter.

–details concerning our training, training that has direct connection with the job we apply for.

–detailing our abilities, considered to be essential elements that increase the value of the resume. Because university studies have become so common, this list of abilities has become, along with the experience, a basic criterion in selecting the abilities. A complete resume should also include the modalities of achieving these abilities.

1.5. Purpose and importance of the letter of intent

While most of the applicants do not attach a letter of intent to the resume, those who do, present a standard letter of intent. They modify some information and then send it to all companies. The letter of intent is an important presentation element and it's personalization for each job may assure us an advantage before the headhunter. The composition of a letter of intent offers the possibility of pointing out the connection between the organization's needs(mentioned in the employment notice) and our abilities that may recommend us for the job(mentioned in the resume). Also, the letter of intent may include a career plan, that overlaps with the evolution of the company.

Due to the importance that we personally give to the letter of intent, I consider very useful the composition of a post-interview

letter of interest. This should be mailed after the first interview, considering that we have concluded that the organization's development axis coincides with our career plan. This letter should be composed as a thank-you letter through which we mark out our interest, motivation and enthusiasm for the job and company.

1.6. The role of the interview in the individual career

All the activities developed at pre-organisational level, achieved experience and intuitive spirit must correctly prepare us for the interview. We must not consider the interview an interrogatory, but a free discussion where both us and our interlocutor find short, medium and long term important information.

The interview should be seen as having a double role:

1. The representatives of the company find skills and characteristics that recommend us for the wanted job.

2. We, the applicants, may decide if the organization is convenient for us, considering our skills and expectations.

During the interview we must find the moment to take over the control, changing roles with our interlocutor. The employer will appreciate our interest and the capacity of changing the interview in a pleasant and natural way into an information source. Definitely we will win at image if our discrete and pertinent questions reflect the interest in the company and attention for how we can contribute to the achievement of its objectives.

The actual reality of the Romanian economy, mainly characterised by an acute lack of jobs and continuous growth of the unemployment rate, predisposes to the perception of the interview as a stress factor, diminishing the applicant's abilities and intimidating him.

Finally, I affirm that the right and early choice of the job, basing on criteria of compatibility with the values and requirements of the working environment, invariably takes us to professional fulfilment.

2. Long term career planning

Long term career planning is made for a period of at least 3 - 5 years and should be defined by a complete set of perfection and orientation programmes. Taking into consideration the actual mobility of the labour market as well as the continuous evolution of the business environment, there is the risk that the skills achieved at the beginning of the career may not be required in the future. Therefore, the long term career planning should concentrate on identifying and developing the basic skills, always appreciated by employers. These transferable skills are represented by:

- verbal or written communication
- critical and creative thinking
- team work
- team building
- listening
- concentration
- capacity of taking decisions and assuming the role of project manager
- capacity of organization and planning
- computer skills
- capacity of accommodation with the new technologies
- continuous learning ability

Considering the fact that the career planning and decision process regarding the career are fundamental aspects for success in the professional life, must assure us that the pressure they exert on us will not influence us in any way in taking the best decisions. Finally, the individual career planning, is an evolutive process, always changing, therefore, we must have a well developed capacity of accommodation.

The Role of Risk Management in Banking Institutions Activity

Dinculescu Elena – Silvia

Buican Monica

“Constantin Brâncoveanu” University of Pitești

nataliadinculescu@yahoo.com

Abstract

The development of the concept of risk management has a relatively recent history, progressing rapidly in recent decades. In the past, most banking institutions did not consider risk management to have an active role in daily operations. Risk monitoring should encourage banking institutions to take risks commercially and financially; resulting in development and increased profits.

Key words: risk management, banking system, performance

J.E.L. classification: G22, G32.

Since ancient times, risk and uncertainty were the two phenomena with which people and organizations interacted. The economist Aaron Wildovsky mentions: “the greatest risk to people and organizations is the effort they make to avoid risk.” Risks are seen both in people's daily lives and organizations; virtually all decisions and strategic planning of any activity involve the occurrence of certain categories of risks.

The risk was always assessed by credit institutions as a key objective in development strategies. This was reflected in their managerial plans by creating and developing tools for monitoring and continuous management of categories and subcategories of risks that are inevitably exposed due to the nature of the activity [1].

Behind the concept of credit risk lies a typical conglomerate, which involves a more complex approach in each category of risks. The risks associated with banking activities are of financial nature. However, the aspect of mutual determinations and inherent interconnections should not be overlooked because they tend to increase if they are ignored or poorly managed.

In the current economic conditions of imbalances and structural failures, banks are becoming increasingly affected by changes in economic and financial conditions. This includes globally registered banks as well as the countries in which they operate. Therefore, commercial banks that are considered a center of the financial system, are forced to assume all risk categories and provide proactive, preventive, and responsible management in order to reduce and neutralize any adverse effects.

Risk management process requires the existence of a systematic vision. This means identifying risk profiles specific to various offers of banking products and services addressed to the customers. This includes configuring the risk profile for each component of the branch network.

Because of the wide variety of banking products and services of these banking organizations a certain kind of comprehensive approach is required. An approach to reduce overall costs by reducing the likelihood of adverse effects which may manifest risks, regardless of their form of expression is required.

For a banking company, the ultimate aim of any risk management process is to identify and minimize all risk categories. All involve some costs which must be correlated with the total benefit, reflecting the banking institution's ability to improve financial performance.

It is vital for the image of any bank for risks to hold a key position. Risk identification and assessment should be part of the strategic planning process, in order to provide executive managers the opportunity to forecast and quantify the consequences determined by these risks.

The development of the concept of risk management has a relatively recent history, progressing rapidly in recent decades. In the past, most banking institutions did not

consider risk management to have an active role in daily operations. The starting point in the development of risk management was the failure of Barings bank in 1995. It brought to the public's attention the negative effects caused by lack of effective control in operations conducted by the banking organization.

The alarm surrounding that occasion led to recognition of the importance of risk management function at all levels; both among banking institutions and the regulatory authorities.

The concept of risk management can not be assigned to a universally accepted definition. Risk management can be defined as a set of policies and procedures in place for managing, monitoring and controlling the banking organization's risk exposure [2].

Risk management is a management process that encompasses the techniques and methods used in analyzing and assessing risk categories. It is applied using measured actions, control, and reporting. This results in decisions designed to eliminate as many risk categories as possible.

Risk protection measures are common elements for any management policy. Defining banking management from the perspective of risk involves measures that the banking organization apply in order to protect the bank against situations of potential loss [3].

Due to the uncertain nature of banking operations, risk management is fully justified since any decision from the banks cannot simply be assumed. Therefore, risk management should provide a more comprehensive view on the image of the future, the policies, and strategies that are undertaken based on this vision.

In the absence of a risk management it would be impossible to produce estimates on the potential fluctuations that directly affect the results of commercial banks. At the level of any credit institution applying risk management involves the following steps [4]:

- knowing and understanding the nature of risks;
- identifying emerging risks;
- measuring the effects determined by the triggering of certain risks;
- monitoring and controlling risks;
- risk communication process at each managerial level;

- analysis of costs involved in the efforts to eliminate the risks;
- action to implement strategies to eliminate risk;
- evaluation of performance resulting from the implementation of these strategies.

It is well known that the profit of commercial banks is amended continuously according to changes registered in the business sectors or indicators registered on the banking market. In this respect, the role of risk management is to provide an overall projection on the magnitude and potential deviations from the expected results that may be recorded.

Nowadays, in our country most of the commercial banks operate centralized risk management, both administratively and conceptually. Risk management is carried out consistently, in a single command center. Such a center is usually located at the central office, which is responsible for risk management throughout the bank or whole group. Banking organizations that have a developed organizational structure are organized by lines of business (Business-lines). One of these lines that is risk related, is led by a vice president (senior risk officer) that also holds the function of president of the Risk Management Committee, which is required by the banking legislation.

In the banking sector we can identify four main types of risks that a banking organization may be faced with:

The market risk, also called the risk of variation of financial assets, appears in forms of interest rate risk and currency risk. It expresses the probability that a change in market conditions may negatively affect the profits of the banking institution. The effects of these risk categories consist of losses that appear in balance sheets and are best reflected in the conduct of business activities (sale and purchase of foreign exchange, capital transactions, or other direct transactions).

Credit risk, also known as, risk of defaulting of debtors, default risk, or risk of deterioration of bank assets, is the most important category of risk that the bank may face in terms of size and losses caused to the whole business. This type of risk has the largest share in the balance sheet of the credit institution and consists of the probability to

record losses from not respecting contract terms made by borrowers.

Reputation risk occurs as a result of losses of attributes specific to the activities run by the banking organization. It is ultimately reflected by partial or total loss of reputation on the banking market and among its customers, for which it is continuously monitored by stakeholders (shareholders, managers, employees, customers, business partners and the bank in generally). Cases of this type of risk are numerous; the reporting of poor financial results, the assessment made by specialized institutions, a rating drop, and the launch of negative rumors about liquidity. All have an immediate consequence that would decrease the bank shares' quotations on the stock market.

Operational risk, or the risk of assignment, is shown by the inability of the banking institution to ensure proper functioning of business relations with customers [5]. As a result, both the service offerings and the management team's ability to evaluate and control costs are important. Manifestations of operational risks may be the result of losses caused by staff error, attempted fraud, failure to timely perform a transaction, or the likelihood of compromising the interests of the bank due to inappropriate activity of personnel or faults in the information system products.

A necessary step to ensure the success of a coherent risk management program is the design, implementation, and maintenance of a management information system (MIS) designed to provide excellent performance and response times.

The information system developed by the banking organizations is usually associated with indicators to measure individual performance. This enables the convergence of individual objectives and the banking company with global banking strategies and objectives thus ensuring that the principles and rules of the banking system are respected.

Quality and consistent information are essential for correct management decisions at the highest level. The information system is organized in a pyramidal style in terms of quantity of information. It starts from the base and works its way to the top, in a filtered and summarized form, concentrated in a few key indicators to form the so-called "dashboard" of the top-manager.

Information flows are conducted in a double sense, both from the bottom toward the top and vice versa, and horizontally, where we find intense flows between departments located on the same chain of command.

Information in a banking organization can determine the effectiveness of management. Protection and confidentiality are vital, so the information system should be accompanied by a powerful computer system designed to operate in real time.

Risk monitoring should encourage banking institutions to take risks commercially and financially; resulting in development and increased profits.

Benefits of implementing a risk management system proved to be sufficiently large. They help guide development and implementation of policies at a managerial level within the banking system and justify this new measurement and control of banking risks.

Descriptive Study of the Promotional Communication Systems Successfully Applied in Banking Institutions

Dindire Laura

Munteanu Andreea

„Constantin Brâncoveanu” University of Pitesti

lauradindire@yahoo.com

andreeadumitrache2000@yahoo.com

Abstract

The present communication aims, without any pretense of an exhaustive research, to highlight the need for a strategic communication and promotion in such a competitive environment, by presenting some corporate communication strategies applied in the banking sector. The paper was founded, as a main instrument of scientific research, on a case study of the identity reconstruction and rebranding programme of CEC Bank, the oldest bank in the Romanian financial-banking system. From the examples provided by practice, as well as from the researches conducted in this area of expertise, it results the major importance of the direct and powerful impact the corporate identity has on an increasingly more specialized and selective audience. In this context, banks should understand the consumers' different communication preferences and to adjust accordingly, by means of specific methods of communication and differentiated promotion.

Key words: promotional communication, brand, visual identity, rebranding activity.

J.E.L classification: M37

1. Introduction

The theme proposed to be discussed within this communication represents a stage objective of a personal scientific research programme, whose ultimate goal is drafting a conceptual model in order to optimize the promotional strategy, based on researching the phenomenon of promoting the economic affairs, both from a theoretical and a domestic and international practice point of

view. Along with the profound theoretical, scientific, doctrinaire and specific comprehensive procedures framework, the ultimate goal is the scientific investigation of the corporate communication and promotion strategies successfully used both internally and internationally. These strategies can contribute to the enhanced capitalization of the comparative, strategic or competitive advantages of the organizations using them. In this regard, the output of this stage objective aims to analyze efficient promotion strategies and methods used by the domestic and international banking system and a case study: CEC development strategy for 2007-2011, a reconstruction strategy of the CEC brand.

2. Branding, rebranding and corporate identity in the financial-banking sector

The need for business opportunities exploitation and meeting the bank customers' needs when you seek to improve corporate communication processes and promotion of the banking system is assessed in terms of the performances that can be obtained. Great achievements in promotion are inspired by understanding how brands interact with consumers [1], and setting advertising objectives must be consistent with the target market segments. There is a wide range of positioning strategies available in advertising, as follows: by product characteristics or customer benefit; by quality and price; by use and application of the product; by cultural symbol [2]. We further present corporate promotion and brand strategies successfully applied by banking – financial institutions or for banking products, internationally. Thus, in 2009, Visa launched its first global advertising campaign entitled

„More people go with Visa”, based on a radical change in terms of the communication mix: moving towards digital media, including social networks, as opposed to using traditional media in a proportion of 95%, prior to this campaign. The main idea of this campaign was not about spending more money, but about using Visa for those things that are important for each consumer every day. Carefully chosen, in order to overcome communication and language barriers, which can interfere on an intercultural level, the name Visa is pronounced the same in all languages. Promoting brand identity and international reputation are parts of a long-term strategy, including public relations events and sponsorships, such as: exclusive partnerships with a series of world-class sports organizations, such as FIFA or the International Olympic Committee. The FIFA partnership provides exclusive rights to a wide range of activities, such as FIFA Women’s World Cup Germany 2011 and FIFA World Cup Brazil 2014, thereby associating with the world’s favorite sport. The IOC partnership dates from 1986. Visa is the international Olympic partner, being the only official payment card and financial payment service of the Olympic Games until 2020. This includes the 2012 Olympic Games in London, the 2014 Winter Olympic Games in Sochi and the 2016 Olympic Games in Rio de Janeiro. Since 1995 Visa has also sponsored the National Football League (NFL) in the U.S. and a number of NFL teams, having access to the most important competitions until 2014 [3]. In order to provide the scientific grounds of the specific public relations and advertising actions used to promote the Visa brand, we find rather important to present a number of representative models. A special model mainly used to solve system problems belongs to John Marston, entitled Race: R = Research; A = Action; C = Communication; E = Evaluation. Based on this model, Jerry Hendrix drafted the ROPE model: ROPE: R = Research; O = Objectives; P = Programming; E = Evaluation [4], [5]. Another public relation strategy model is that proposed by specialists Scott M. Cutlip, Allen H. Center and Glen M. Broom. It consists of a four-step process: 1) Definition of public relations problems; 2) Planning and

programming; 3) Act and communicate; 4) Programme evaluation. [6]. We agree with Anne Gregory’s opinion, according to which public relations can best play a role in developing successful campaigns, when all other elements of the marketing communication effort are present and integrated with them [7].

Although author Oyvind Ihlen points out that those companies which decide to use a strategy focused only on the mark risk losing sight of other aspects of the advertising strategy, of the company’s identity [8], we further present another representative example of a successful strategy centered on building a strong brand identity. Upshaw considers that the identity of a brand is largely formed from the confluence of its positioning and strategic personality also adding other defining elements - brand name, marketing communications, promotion, product/service performance, selling strategies, logo/graphic system. Thus, in her opinion, the identity is a brand’s DNA configuration, a particular set of brand elements, mixed in a unique way, which determines how the brand will be perceived in the marketplace. In this sense, choosing the name, for example, can determine the faith of a business. *Bank of America* is, probably, the best brand name of a bank in the country. But it was not always like that. The founder of the bank, A.P. Giannini, changed the name of his Bank of Italy in 1930, when he foresaw huge opportunities for interstate banking. That name change helped Giannini transform a medium-sized bank into an extraordinary financial services brand, with a much more powerful brand identity. Interstate banking system is now a reality. As the Bank of America seeks to become the first nationwide American bank, it already has a head start by the name itself, which best represents the American country and its people [9]. A market research conducted by Mintel Comperemedia, a service which provides competitive direct marketing information to the banking sector, points out that the bank should take into account that each customer has different communication preferences and the bank should offer multiple points of communication, Americans preferring to contact the bank personally instead of online[10]. In Romania, as an effect of the

economic-financial crisis, the banking system completed the last year, for the first time after 1999, with a net loss of 304 million Romanian lei, compared to 2009, when a net cumulative gain of 815 million Romanian lei had been recorded [11]. In this context, along with implementing prudent banking strategies for reducing the cost of risk, speculating the opportunities of the macroeconomic environment and other bank – specific methods to improve its activity, the management of corporate communication and integrated promotion is more and more required in order to face such a competitive environment. The specialist G. Belch noted the companies' need for using all the promotion tools, based on the strategy, so as to convey a unified message to the consumers [12]. Further more, we chose to present the promotion of the corporate revitalization of the single state-owned Romanian bank, 3rd regarding the assets, holding a market share of approximately 6.4%.

3. Analysis of the identity and brand rebuilding of CEC Bank

CEC achieved one of the best financial results in Romania last year, the banks incomes raising by 30.16% and the interest income by over 24% compared to 2009 [13]. In May 2007, CEC shareholders approved and made public "The CEC development strategy for 207-2011", a CEC brand rebuilding strategy. For this extensive rebranding process they chose the CEC President, Radu Gratian Ghetea, a prominent personality of the Romanian banking system and, at the same time, President of the Romanian Bankers Association. He made a priority from promoting the corporate revitalization by rebuilding the corporate identity. The development strategy for CEC includes three phases which will further blend together: efficiency by 2009, development by 2010, consolidation by 2011. Given these strategic objectives, CEC shareholders agreed that the name of Deposits and Consignments House is not suggestive enough anymore and that the institution is a Bank in an ongoing process of modernization and efficiency, thereby changing its name into the CEC Bank on May, 6th 2008. The new name combines the

traditions and aspirations of the institution that wants to be a leading player in the Romanian banking system. The new visual identity has colours that symbolize the rebirth of an institution as green symbolizes the rebirth of nature each spring and the oak leaf in the CEC Bank logo, placed on a shield, suggests continuity and tradition, authenticity and power and also safety and protection. Since the launch of the new brand, CEC Bank has won several awards [14]:

- At the 6th Effie edition in 2009, gold in the „Financial Services” category, with the spot image „The Boxer”. The same case study won bronze in the „Renaissance” category, and was also nominated in the Grand Effie category.
- At the 7th edition of the PR Award, CEC Bank won “Golden Award for excellence” in the Internal Communication category.
- At the Rebrand 100 Competition in the United States in 2009, it won a prize in the „Merit” category for the CEC Bank rebranding.

The structure of the Marketing and Communication Direction of CEC Bank meets the needs of the institution, consisting of the Marketing Service which has nationwide coverage and is responsible for organizing campaigns and various events, promoting products and maintaining the relation with the advertising agencies they work with; the Network Marketing office, which maintains the liaison with the national network, organizes participation to events and local tactical actions, maintains relationships with the call center, with the mystery shopping firm, and manages the brand; the Communication and Public Relations activity, which maintains contacts with the media and the customers. The general goal of the promotion policy of CEC Bank is to influence the consumers' behaviour. In this sense, the following promotion forms are used: TV, radio, printed press (newspapers and banking and financial magazines), OOH, web. The corporate communication strategy also integrates campaigns for the steps made in the rebranding process from the launch of the new institutional image to the present. As concrete actions we can mention: integrated campaigns to promote products, with the careful choice of media channels, increased

use of the web in the advertising campaigns by including sites with maximum traffic on that particular category, as well as informal communication through campaigns carried on social networks, maintaining and developing the existing outdoor network in order to support the advertised products. Public relations are evidenced in sending press releases each time a new product is launched or for important events, organizing press conferences. Research specific to the public relations activity is also reflected in the daily monitoring of articles related to CEC Bank and its competitors, from local and central media. Other methods of data collection are: observation, the mystery shopping survey and also the qualitative research by means of discussions with the people involved or organizing focus groups. CEC Bank has defined a public relations strategy focused on the customers' needs. Thus, the bank has tried to apply an approach inspired by the "reversed pyramid" which focuses on the customer, by implementing a policy having as a fundamental goal to provide the quality the customer expects. Control and assessment processes are carried out during the course of each campaign, the brand indicators and the bank customers' degree of satisfaction being measured, annually, by an external company, specialized in market research. The rebranding activity of CEC Bank was based on the unified promotion of the global image composed of social image, financial image, technological image, commercial image and public image.

4. Conclusions

In conclusion, we consider that by the present communication we tried an analytical and descriptive study of promotion strategies successfully applied, nationally and internationally, in the banking system. We presented typical examples of promotional communication for the Romanian banking system. Using the deductive method, we shall try to extrapolate the phenomena specific for optimizing promotion strategies used for the Romanian banking institutions, starting from real data, existing or potential. We consider that the potential future research directions may focus on the assessment of the promotional communication systems applied

to the entire Romanian banking system. The main research method used in this sense is the direct selective research based on questionnaire applied in the banks operating in the Romanian economic space. Later on, you can find the main deficiencies, errors and irregularities in the promotional activity, and you can thus develop proposals to improve the systems of promotional communication of the banking institutions, based on analysis and scientific research.

Global Trends in Advertising Campaigns – Integration of Social Media

Dindire Laura

Munteanu Andreea

“Constantin Brâncoveanu” University of Pitesti

lauradindire@yahoo.com

andreadumitrache2000@yahoo.com

Abstract

The paper does not aim to provide practical solutions but only to raise, within the academic community, the following questions: Are the current paradigms of promotional communication still valid? Does a crisis of knowledge intervene in this field? Are new paradigms necessary for instating new research customs able to provide new theories, models, research methods and a new image of this field? The paper thus aims to present the aspects which have determined us to raise these questions: the admission of new concepts, as Through the Line advertising, necessary due to communication hybrids which make the division of some promotion forms into the classical typology – ATL/BTL – impossible; the important mutations on the media market worldwide; the social media revolution, with spectacular results reflected in numbers and statistics; the emergence of global virtual communities with hundreds of million members worldwide, which generated an unprecedented interest of advertising investments in social media.

Key words: social media, TTL advertising, brand awareness, word-of-mouth effect.

J.E.L classification: M37

1. Introduction

As an expression of its increased complexity and importance, the advertising activity has become an essential factor of the mass-media functioning and development. Thus, advertising is the forwarder force, the prior condition of qualitative and quantitative mass-media development.

In order to divide the promotional media which convey the advertising message, the

profile specialists and researchers use concepts such as ATL (*Above the Line*), BTL (*Below the Line*) and TTL (*Through the Line*), “the line” being considered the imaginary line between using payable media and commission-free media [1]. The concepts have their origins in accountancy methods, where they simply drew a line: for methods above the line, the advertising agency received a commission and for those below the line it worked on a fee-base. What is above the line are methods which use classical ways of mass communication, as printed press, television, radio etc. The promotional instruments below the line consist of techniques using promotions, communication by organizing specific events etc.

Above the Line (ATL) advertising uses, as media:

- the television, radio and cinema advertisements;
- newspaper ad prints;
- advertising display, billboards (meshes, banners, street signs etc.), mobile media, transit (buses, trolleybuses etc.) for outdoor advertising;
- flyers, letters, mail, e-mail, brochures, direct mail posters;
- promotional items: lighters, matches, T-shirts, caps etc.

Advertising messages adapt to these channels and are organized depending on their technical constraints. This type of communication also leaves the message hearing/viewing up to a broad audience, consumers being targets of a persuasion without direct pressure.

On the other hand, *Below the Line* (BTL) advertising refers to the “unconventional” communication media that prove more inspiration and originality. It is mainly about organising events:

- meaningful calendar days;
- visits of major personalities, foreign or domestic;
- book launches, fairs and exhibitions;
- sponsorships of some public interest events;
- organisation of receptions, balls, concerts, fund raisings.

Through the Line (TTL) concept developed due to communication hybrids, which make the division of some promotion forms into the classical typology – ATL/BTL – impossible. Thus, according to some authors, TTL represents the *integrated marketing communication*, because it combines both ATL techniques and BTL [2]. The new concept originated from the need to convey the same message through more media, without making any distinction according to the advertising channel used.

The main elements that characterize Above The Line advertising are the following:

- advertising forms used to promote the **company**;
- the main objective is to **increase sales' volume**;
- communication forms addressed to the **masses**, by using the mass-media;
- the messages conveyed have an **impersonal** character;
- **slow** or even **no feedback** at all.

The main elements that characterize Below The Line advertising are the following:

- advertising forms used to promote the **brand**;
- the main objectives are **consumers' awareness** and **strengthening the brand image**;
- communication forms addressed to **small-sized target groups**;
- the messages conveyed have a **personal and punctual** character;
- **direct** and **instant feedback**.

The advertising strategies and objectives didn't change over the years, but they evolved and adapted to new realities, new markets, new media and channels and new consumers' behaviour. Thus, the ATL and BTL concepts are still in use, but advertisers should keep in mind the fact that the 21st century advertising is not only about TV commercials and coupons anymore. What

changed is that companies must keep up with how and where consumers want to receive information about brands. This doesn't mean that the mass-media are dead, but they are being supplemented by all sorts of new ways to reach consumers. Thus, *consumer preferences and new technology are reshaping the communication environment* [3]. A new advertising and brand communication order is being instated, one where Through the Line advertising is more and more the key to success. The technological global village, where hundreds of millions people are connected at any time and space, anywhere in the world, gave birth to an **advertising global village**, that means increased worldwide visibility at less costs.

2. The global media market in numbers

The worldwide media and entertainment market, has known, for the last years, according to a number of studies conducted in this field, significant mutations that advertisers should pay attention to when projecting advertising plans and budgets. Thus, according to the *Global Trends of Digital Media Yearbook*, published by the World Association of Newspapers in 2010, the whole global media and entertainment market, valued at \$1.17 trillion in 2005, grew to more than \$1.32 trillion in 2009 and it is expected to exceed \$1.69 trillion in 2014 [4]. In 2005, the newspaper publishing segment held the leading market share – 15.2% - or \$153 billion value. TV advertising, as well as TV subscription and license fees accounted for 12% market share each, or \$146 billion and \$142 billion, respectively. Studies show an increased shifting in the market share ranking segments by 2014. Thus, internet access, wired or mobile, is forecast to be a market leader, with a growth from 11.7% market share in 2005 (\$137 billion value), up to 20.4% in 2014 (\$351 billion value) in 2014, the newspaper publishing market losing more and more ground, up to 9.3% in 2014. Within this new configuration, internet advertising is also expected to grow from 2.2% market share in 2005 up to 6% market share in 2014.

3. The social media platform

In the light of what we have stated earlier in the paper, that companies must know how and where to reach consumers, and the worldwide shifting of media market segments, the social media are one of the answers. Social media are the modern version of the prior industrial media paradigm. If the traditional media, mostly ATL advertising, generates a one-way communication, impersonal and complex in its development, social media advertising allows, primarily and most important, a maximum degree of consumers' approach, bidirectional and very easy to manage. The simplest definition comes from researcher Lon Safko, in the sense that *social media are the media we use to socialize* [5]. The social media platform consists of a wide range of communication forms, from which eight have been globally imposed: blog, microblog (Twitter), social networks (Facebook, LinkedIn), media-sharing sites (YouTube), voting and sharing sites (Digg, Reddit), review sites (Yelp), forums and virtual worlds (Second Life). Though different in approach and presentation, the element these social media have in common is creating a communication binder between people all over the world.

Social media definitely caught the attention of both the global business community and the academic world, as a subject of study and research, when an intranet network has become the largest global virtual community ever, with hundreds of millions members worldwide. Thus, since 2004, from the Facebook network development, initially launched by Mark Zuckerberg as a private network of Harvard University students and publically extended in 2006 and since the development of Twitter in 2006, the online advertising has gained a new relevance, with a spectacular (r)evolution.

The social network community has reached spectacular levels. From its 600 million members, 250 million are active users of the Facebook social network. More than 346 million people read blogs and more than 184 million are bloggers themselves. Twitter has more than 14 million registered users and YouTube registers 100 million views per month. In this context, the

Canadian specialist Zarella is very much entitled to state that million of consumers are connected more than ever and every second a company is not engaged in social media is a wasted opportunity [6]. If prior to 2008 this promotional channels were taken lightly by companies and advertisers, the increased interest shown by consumers in these social networks, consequently attracted the interest of the business environment. And the results are reflected in numbers and statistics. If in 2008 the amounts invested in these media reached several million Euros, the forecast places advertising budgets in social media at €4.26 billion in 2011, with over 70% growth than in 2010 [7].

4. The social media revolution

Much like in every other field, there are also pioneers and one of the companies which fully felt the effects of this type of viral marketing was Evian, by its "Live Young" campaign, having as a main promotional tool the "Roller-Skates Babies" commercial. The campaign started with two viral teasers posted on YouTube, which registered 13 million views in just a couple of days. The campaign was officially launched in the stratosphere, live on YouTube, on July, 3rd 2009, in six key territories: France, UK, USA, Canada, Germany and Japan, generating over 62 million views in 9 months. This made it **the most viewed advertisement in history**. Among the effects it generated, the following facts and numbers are worth mentioning:

- the first ad to be included in the Guinness Book of World Records as the most viewed online advertisement of all times, with 45,166,109 views by November, 9th 2009;
- 120,000,000 views on YouTube in 12 months from its official launch ;
- 500,000 Facebook fans;
- 130,000 online comments;
- 35,000 blog posts;
- 7% raise in sales in France;
- 13% raise of market share in the UK;
- 7% raise in sales in Canada;
- within the first 24h from its broadcasting it became the most talked about advertisement in the world, gaining the interest of worldwide

mass-media. *Time Magazine* declared it the **Advertisement of the Year** and ranked it 1st in "The Top 10 of Everything in 2009" [8];

- 12 million views of the remixes of the original advertisement;
- 7 million views of the making-of and interviews with babies clips.

During the last year, 80% of the companies worldwide included the social media in their marketing mix, assigning budgets from a couple of hundreds to a couple of hundred of thousand million Euros, depending on their target. Both globally and in Romania, the Facebook social network is ranked 1st among the consumers' preferences, with 1.5 million users in Romania at the middle of 2010. According to Agerpress' forecast, the advertising revenues of Facebook grew up to \$1.285 billion in 2010, with \$835 million just in the United States, as opposed to \$665 million in 2009. The study considers that they will reach \$1.760 billion by 2011 [9]. Large companies, such as COCA-COLA and P&G invested \$740 million last year, but the largest share of Facebook advertisement revenues (about \$1.12 billion) was generated by small companies [10].

In Romania, Facebook registered users reached 3 million, and will keep on growing up to about 5 million by the end of 2011. Among the Romanians' preferences we also find the Hi5 network, accessed by over 600.000 users every day, Tpu.ro with almost 2 million visitors per month or Neogen with 750.000 unique visitors. Among the largest Romanian companies which chose to be a part of the social media, we find Dacia, ProTv or Arctic.

5. Conclusions

Given these up to date facts, numbers and statistics, the newly comers to the advertisement industry, the social media, are impossible to ignore. The profile literature has also largely enriched itself for the last couple of years, adding studies, researches and, mostly, attempts to define and theorize new strategies and tactics to implement social media campaigns, but without outstanding results up to now. The main issues those who dedicated themselves to the new communication wave, placed under the

Facebook sign, have encountered are focused on how to measure the effects generated by such a campaign. Without having identified any high-end qualitative and quantitative parameters to assess results yet, they reached, though, a certain level of conclusions related to an increased level of **word-of-mouth effect**, by the generated traffic, and of what the profile literature names **brand awareness**. Another conclusion could be a high demographic and geographic segmentation, based on the information provided by the potential consumers' profile pages. An example which perfectly illustrates this is offered by the Facebook Ad Service page itself [11]. According to it, the Facebook Ads service provided CM Photographic Company the possibility to target its demographic segment – 24-30 years old women, whose status on the Facebook profile indicates they are engaged. Within 12 months since placing the ad, CM Photographic gained revenues of almost \$40000 out of a \$600 investment on Facebook.

Without giving any scientific-research-based answers to the questions raised, we can firmly state that, in the years to come, the advertising industry, both in practice and theoretically, will postulate new theories and, especially, new tactics on how to approach consumers in order to optimize the communication process and achieve advertising, brand and sales goals. One of these tactics becomes clearer and clearer for all companies: insert yourself in all aspects of the consumers' life and always try to keep up with it.

The Process of Data Preprocessing for Web Usage Data Mining through a Complete Example

Dinucă Claudia Elena
University of Craiova,
Faculty of Economics and Business Administration
clauely4u@yahoo.com

Abstract

Nowadays, using data mining techniques to extract knowledge from web log files has become a necessity. The behavior of Internet users can be found in the log files stored on Internet servers. Analyzing data obtained from web server logs is rapidly becoming one of the most important activities for companies in any sector as most businesses become e-businesses. Web log analysis can improve business firms that are based on a Web site through learning user behavior. This understanding can then be utilized for improving customer satisfaction with the web site and the company in general, yielding a huge business advantage. Before the actual analyzing of the data, it must have a specific format. This paper describes the effective and complete preprocessing of access stream before actual mining process can be performed using an example.

Key words: Web logs, clickstream analysis, Web usage mining, Data Preprocessing.

J.E.L. classification: C8.

1. Introduction

Web mining can be divided into three categories: Web content mining, Web structure mining and Web usage mining [1]. Web content mining is the process of extracting knowledge from documents and content description. Web structure mining is the process of obtaining knowledge from the organization of the Web and the links between Web pages. Web usage mining analyzes information about visited Web page saved in log files of Internet servers in order to discover interesting patterns previously unknown and potentially useful. Web usage

is described as applying data mining techniques on Web access logs to optimize web site for users.

Preparing data requires between 60 and 90% of the time data analysis and contribute to the success of the entire process of extracting knowledge with rate of 75-90% [2]. The target of data preparation is to select relevant information from the available data while the data mining finds significant patterns. In this study, we present all necessary steps to preprocess data to be able to be used for Web Usage Mining.

2. Data Collection

Data preparation phase starts with data collection. Usually, the analyst does not participate in the process of data collection, so his goal is to select from existing data those that best fit the analyse it wishes to perform. Variables and records used depend on what it is desired to obtain. The primary source used for web usage mining are logs files of the server. The data used to analyze web usage mining may come from two sources: the period of testing and web logs. The log files from the testing periods are rarely used because of the large time required and high cost. Web log files consist of information which track web users work in their interaction with web servers. Logs files can be located as follows: on the web server, a proxy server or client computers. Logs available on Web servers are most often used because they contain accurate and complete data on site usage

3. Fields Extractions

Log files are created by web servers and filled with information about user requests on a particular Web site. They may contain

information about: domains, subdomains and host names; resources requested by the user, time of request, protocol used, errors returned by the server, the page size for successful requests. There are several formats for web logs, among which common logs format (Common Log Format) and large logs format (Extended Log Format). In the example presented the logs are extended, the database logs information belongs to NASA Kennedy Space Center log available online at <http://ita.ee.lbl.gov/html/contrib/NASA-HTTP.html>. Example of logs from this file can be seen below:

```
199.72.81.55 - - [01/Jul/1995:00:00:01 -0400] "GET
/history/apollo/ HTTP/1.0" 200 6245
unicomp6.unicomp.net - - [01/Jul/1995:00:00:06 -0400] "GET
/shuttle/countdown/ HTTP/1.0" 200 3985
199.120.110.21 - - [01/Jul/1995:00:00:09 -0400] "GET
/shuttle/missions/sts-73/mission-sts-73.html HTTP/1.0" 200 4085
burger.letters.com - - [01/Jul/1995:00:00:11 -0400] "GET
/shuttle/countdown/liftoff.html HTTP/1.0" 304 0
199.120.110.21 - - [01/Jul/1995:00:00:11 -0400] "GET
/shuttle/missions/sts-73/sts-73-patch-small.gif HTTP/1.0" 200 4179
burger.letters.com - - [01/Jul/1995:00:00:12 -0400] "GET
/images/NASA-logosmall.gif HTTP/1.0" 304 0
```

Web log file set contains the following fields:

- remote host (IP address of the computer user).
- date and time field.
- HTTP request.
- Field of status code.
- Field of volume transferred.

We specify that all fields are in text format, because the log file is a text file. Some fields may contain data on several variables, such as field date / time specifies the date and time. HTTP request data field encompassed the method used, the page requested protocol version used, and optionally other information. Before making the log analysis, these masked variables must be extracted.

4. Data Cleaning

The data cleaning process is depending on the pages type. This step removes all data which is not relevant to the problem. This removes from the flog files all registrations that are created by human users. A first step in cleaning and filtering of data is the extraction of variables. For this process we use existing string handling functions in the program used for preprocessing. This example uses string processing methods from Java. This will remove the elements that

separates fields within a single log record, we remove "--", "-", "]", "[", " " and quote. Using the method to separate strings, the following fields are saved in the database: remote host (IP or DNS address of your computer), date and time, HTTP request, status code, the volume of bits transferred. When the user requests to view a Web page it results more records in the log file as there are loaded and graphics and additional scripts to HTML file[4]. Since the main interest of clickstream analysis is to extract patterns of user behavior, it makes no sense to include in the review pages that were not explicitly required by the user. In this respect, it will remove all entries with the type extensions: gif, GIF, JPEG, JPEG, JPG, JPG. There are four classes of status codes: success (200 series), redirect (300 series), failure (400 series) and state error (500 series) [3]. The most common failure codes are 401 - identification failed, 403 - banned from a subdirectory and 404-file not found. All entries which have different series status code different from class 200 are removed. After removing irrelevant information is obtained the log files table that can be seen in the figure below:

Fig. 1. The table with the logs obtained

ID	ID_SOLICITANT	DATA_ORA	METODA	PAGINA	PROTOCOL	CODE	NR_BITS
1	129.12.103.49	01-Jul-1995:00:00:11	GET	/history/apollo/	HTTP/1.0	200	12945
2	199.72.81.55	01-Jul-1995:00:00:06	GET	/shuttle/countdown/	HTTP/1.0	200	3985
3	199.120.110.21	01-Jul-1995:00:00:09	GET	/shuttle/missions/sts-73/mission-sts-73.html	HTTP/1.0	200	4085
4	199.120.110.21	01-Jul-1995:00:00:11	GET	/shuttle/countdown/liftoff.html	HTTP/1.0	304	0
5	199.120.110.21	01-Jul-1995:00:00:11	GET	/shuttle/missions/sts-73/sts-73-patch-small.gif	HTTP/1.0	200	4179
6	199.120.110.21	01-Jul-1995:00:00:12	GET	/images/NASA-logosmall.gif	HTTP/1.0	304	0

5. Session Identification

Records of logs belonging to the same user are grouped in one session. Users are identified by IP address or DNS. Two or more records which have the same IP address are considered to belong to the same person. A session contains a unique session ID and a set of pairs (id_solicitant, t), where id_solicitant is an identifier of the page and t is the time spent by users on that page. To determine the end of a session, a time limit defined max_idle, so if the same IP address is not met in this period, the current session is closed and the next requests from the same IP address will be treated in a new one. To find the time spent on a particular page we create

a timestamp variable that represents the difference in time to a fixed date, in our case the first day of registration, so we defined start date to 01/Jul/1995/00: 00:00 .

The time spent on a Web page is determined as the difference of time between two consecutive requests. The introduction of the variable max_idle, the maximum time, was done by conceptual and practical reasons. From conceptual point of view, it helps to limit the session to a single visit. Thus, if a user buys a magazine and returns the next day to look for a book, his activities are divided into two sessions.

Fig. 2. Table with sessions obtained

#	ID_SOLICITANT	ID_SESSiUNE	TIMESTAMP	DATA_ORA
1	129.121.119.19	155	2002-01-24 09:00:24.42	
2	130.121.119.19	145	1975-01-24 09:00:28.11	
3	147.31.204.131	295	9515-01-24 09:00:50.05	
4	147.31.204.131	295	2047-01-24 09:00:50.17	
5	147.31.204.131	295	3081-01-24 09:00:50.21	
6	149.171.160.182	149	1712-01-24 09:00:28.33	
7	149.171.160.182	149	1026-01-24 09:00:28.36	
8	149.171.160.182	149	1423-01-24 09:00:28.43	
9	153.64.25.131	219	2384-01-24 09:00:30.14	
10	156.151.176.30	181	1794-01-24 09:00:28.14	
11	156.151.176.30	181	964-01-24 09:00:11.04	
12	156.151.176.30	181	407-01-24 09:00:11.07	
13	156.42.141.49	376	4823-01-24 09:01:00.23	
14	163.208.78.13	213	2297-01-24 09:00:30.12	
15	166.79.67.111	26	1896-01-24 09:00:10.36	
16	166.79.67.111	26	1798-01-24 09:00:29.58	
17	166.79.67.111	26	1652-01-24 09:00:27.32	
18	192.112.207.81	276	3189-01-24 09:00:52.39	
19	198.4.9.2	250	2004-01-24 09:00:46.44	
20	199.120.110.21	130	9112-01-24 09:00:00.09	

6. Conclusions

In any data mining application, an important step is to create the appropriate data to apply data mining methods and statistical algorithms. Especially in the clickstream analysis process the preprocessing stage is very important because of the complexity of web logs. The process of data preprocessing in Web Usage Mining is time-consuming and often requires special algorithms. Preprocessing is not a standard process, it depends on the type of data processing and structure of needed data. For these reasons, the analyst overseeing the whole process is a necessity.

E-Business, a New Way of Trading in Virtual Environment Based on Information Technology

Dinuță Claudia Elena
University of Craiova,
Faculty of Economics and Business Administration
clauely4u@yahoo.com

Abstract

The age of Information technology with lots of services is upon us. Nowadays, using computers to do all sorts of daily tasks has become a necessity. Internet technology is changing faster, and the pace of it's innovation and adoption is truly staggering. Apart from sharing or transacting data/information, all types of business transactions are frequently done through Internet. Over time people prefer staying in front of the PC and doing any business transactions for convenience and saving time. Hence, E-business is the key to make life easier for the people. Knowledge of e-business environment is essential for doing business in this century. New technologies for extracting knowledge from data must be understood and applied.

Key words: e-business, B2B, B2C, e-commerce, Internet

J.E.L. classification: M1

1. Introduction

E-business, electronic business, refers to the organization of transactions, communications and information, as well as business planning and control, using the full potential of information technology. E-business is therefore on the border between computer technology, artificial intelligence and business. The term e-business was first used by IBM in 1997 in order to define the use of Internet technologies to improve and transform key processes within a business. E-business is actually new ways of doing business, new ways to use technology and a new way to create companies. The Internet has revolutionized the business world that is constantly trying to adapt to the changing

needs of the digital market. Given that the Internet has become an integral part of society developed countries, this new medium could not escape the attention of traders. The Internet was originally created for the exchange of information and e-mail, and then it becoming the most dynamic business environment. In a few years, e-business concept became a reality. It works for everyone: customers, business, government. Today, large companies rethink their business using the Internet to improve business. Business carried on the Web offers the opportunity to potential customers or partners where our products and specific company can be found. Presence through a company web site has several advantages as it breaks the barrier of time and space compared with the existence of a physical business office.

2. Benefits of E-Business

Among the main advantages of electronic business development:

- The ability to sell and make known their products globally, geographical constraints are removed, customers can significantly increase the number.
- Communication with suppliers and customers of the company is much faster, involving a low cost and is more efficient, thus satisfying their requirements and expectations.
- Compared to a traditional business, starting a successful online business requires minimal investment.
- Helps companies save time and effort.
- Organizations can use the chat as a mean of electronic technical support and customer support.
- Ability to quickly launch new businesses keeping old customers.

- Reduced costs for personnel.
- Make it easier to inventory operation.
- Elimination of time constraints, the non-stop activity.

• Improved company image, because they contain accurate and complete data on site usage

Benefits to consumers are numerous, of which the most important are the following:

- Possibility of making permanent trading.
- Give consumers the choice of multiple possibilities.
- Lowest price for a product or service can be determined easily.
- Delivery of products or services can be done quickly in some cases.
- Relevant information for consumers are received in a short time. They need some seconds, not days or weeks as with traditional business.
- Possibility to participate in virtual auctions.
- Facilitates competition, which leads to lower prices of products and services.
- Allows consumers interact with other clients through virtual communities with the opportunity to exchange impressions and compare experiences.

3. Disadvantages of e-business

There are some disadvantages for business conducted over the internet.

- Hacker attacks that can cripple business with viruses.
- Attempts to defraud.
- The need to decrease the maximum prices or services leading to lower profits.

Customers can hit the following problems:

- It can be difficult, especially for those less familiar with using the Internet to find the best deal.
- There are many sites out of date due to lack of maintenance.
- Sites that try to find out details about individual accounts to fraud.

4. E-business Domains

As the number of Internet users is growing at a continuous pace, and due to increasing online transactions, electronic businesses make their presence felt in various fields and

are divided into several categories, of which the most important are:

- e-commerce - electronic commerce through online stores (www.amazon.com, www.dell.com, www.walmart.com, www.emag.ro, www.dol.ro). Online payment solutions (www.paypall.com, www.epayment.ro).
- e-auctions - online auction (www.ebay.com, www.okazii.ro).
- e-banking - online banking transactions (accounts, money transfers, checks, payments, consulting).
- e-learning - online education (www.brainbench.com, www.online-learning.com, www.cursurionline.ro).
- e-directories - virtual catalog (www.yahoo.com, www.dmoz.org, www.paginiaurii.ro).
- e-brokering - buying and selling shares online.
- e-leasing - leasing online (www.leasing.ro).
- e-gambling - online gambling (www.gamebookers.com, www.party poker.com).
- e-working - virtual companies.
- e-mailing - mail.
- e-marketing - online promotion of products and / or services.

The basic idea of electronic business is to translate physical, material business in the website. Thus, the company presents its catalog of products and services over the Internet.

E-business is the use of the Internet and the Web by organizations, households and individuals in order to do business. The business means: acts of sale, purchase or exchange of products, services and information, providing customer services, collaboration with partners and conducting electronic transactions. A definition of e-business in terms of functions that satisfy the business process is presented below.

As commercial techniques, e-business results from the application of advanced knowledge management based on the rules of e-business system components that are infrastructure technology, electronic applications and virtual products.

Given the multidisciplinary dimension, e-business can be considered a business strategy, a work technology, a system, a

separate business, a sales channel, a phenomenon or a combination of them.

5. E-business platforms

When it comes to online business development, it must be decided which is the best suited e-business model to achieve goals. An e-business model is defined as the organization of products, services, information flow, and source of income and benefits for suppliers and customers. Types of e-business models are very numerous. According to some authors such diversity can be limited only by human imagination.

Applications of simple web sites. Today, most large companies have websites. At first these websites were simple and static set of HTML pages that you load your browser and read them. Today, the sites contain links to company databases, applets, ActiveX or CGI, so you can save information from users. The information gathered through forms and questionnaires can be used for users to customize the site for individual use or to make improvements to customer satisfaction.

Applications to access and share information. Such applications are the intranet applications that companies have developed to allow employees to share applications and databases. These types of applications are also found as the Business-to-Employee (B2E).

Applications Business-to-Business (B2B). B2B includes all transactions that are made between two or more business partners, suppliers. These transactions are based on systems extranet partners using the Internet using names and passwords for their Web pages. All participants in the transaction are companies or organizations.

Supply Chain Integration Applications. Once companies automate supply chain process can quickly evolve into a very sophisticated system. Initially, only companies create plans, programs or commands to allow providers to anticipate needs. Provider integrates its manufacturer system with the final producer one. Providers need to learn about new materials being directly linked to inventory and manufacturing system of the manufacturer. Once the supplier meets manufacturer requirements, accounting entries are created and payment is made automatically. The

whole process requires trust and quality control.

Applications Business-to-Customer (B2C). B2C refers to the relationship between dealer and end consumer, being considered as retail e-commerce. The difference between developing a web site or an application to access and share information and B2B, B2C, supply chain is big enough. While the first can be developed with relatively simple techniques and tools, the three latter requires very sophisticated techniques to be implemented. B2C e-commerce is a model in which companies offer individuals a range of products and services similar to traditional trade through online stores: information about products / services, discounts, special offers, electronic payment products purchased. Virtual stores are based on a Web site. It contains a catalog of products or services related to each position description. The catalog is managed by a DBMS (Database Management System), here are stored and updated information on products or services. These stores include functions for searching and viewing products, taking orders and payments.

6. Conclusions

E-business helps organizations conduct business online but also connects the organization with all its external and internal components of the value chain: the components supply chain, logistics providers, distributors, service providers and buyers. E-business creates integrated network of relationships with channels, end users, suppliers and rivals that were not possible before. E-business solutions make customers available in almost all industries. Customers can buy non-stop and companies can offer self-service applications and distribution of products and services to customer. E-business offers new forms of market conditions which radically change the game. Through electronic business is redefined every process in the traditional business: from the development of new products and customer relationship management to purchasing human resources and materials and components procurement. The goal of e-business application is to provide necessary information to the end user, and also attract clients to come later. The services provided

to users on the functionality, ease of use (navigation and organization easier to understand) and response strength of the application, integrity of information is critical to user perception. If the user finds application useful then it is a chance to return to make new business. The Internet and e-business is an important key to future success of any organization, offering huge opportunities and market outlets worldwide. E-business projects are doomed to failure because of misunderstanding the new rules of e-economy environment, thus failing to step into the competition. To differentiate into the Internet economy, companies must realize that winning e-business means more than simple transactions of purchase/sale, the appropriate strategies being the key to improving competitive power. This can be done by using data mining techniques and other statistical analysis on historical data from e-business activities. To conclude, some directions may be taken depending on the e-business contents that were discussed here conducting further research on those particular areas.

Training of Eco-skills for Development of Sustainable Business

Dionisie Cristina

"Petre Andrei" University of Iasi, Faculty of Economics
cris_dion@yahoo.com

Abstract

The paper illustrates the important role of managerial skills acquisition for sustainable society and design requirements based on the use of non-conventional energy business.

Thinking sustainable is now changing the way we live, work and does business. The paper illustrates which skills are today in training and education system and which are necessary for the creation of "green-collar" jobs in both skilled and semi skilled occupations, in hands-on jobs in industries like renewable energy, water and energy efficiency as well as placing trainees into entry level positions who have sustainability embedded into their training package with employers who want to embrace climate change.

The study also reveals the necessity of training for green skills in the three courses of study tailored to future business. The paper studies environmental perception skills students acquired currently upon completion of the first cycle, eco-skills necessary to develop sustainable business.

Key words: green skills, ecoskills, green jobs, green collar workers, sustainable economy,

J.E.L. classification: M5, M53

1. Introduction

In higher education system, programs of management have a key role in training future managers' skills, to develop sustainable business. In the future position of decision-makers, managers must be prepared so as to be able to develop managerial skills including the three sides of economic efficiency, social and environmental situation and to adopt practical solutions or make decisions that simultaneously combine the three types of efficiency [1]: economic

efficiency, social equity and ecological sustainability which means treble efficiency.

Nowadays, to create green jobs is a necessity of our economical system and a consequence of applying the treble efficiency but this it's not possible without support of trainers for green carrier. Green jobs are all the jobs that have a benefit for the environment. They may include jobs in public transport, in building and construction, in primary industries and manufacturing.

The approach made attempts to answer two basic questions: Why should managers trained in line with the principle of treble efficiency? What are the main managerial skills would be developed so that managers can respond positively to the challenges of the sustainable and knowledge society? How could provide training of managers so that the principles of sustainable development can be applied to achieve treble efficiency after graduation?

At the level of education system and managerial practice changing the approach of educational strategies in line with treble efficiency is particularly important and necessary for several reasons [2]:

a. First, it corresponds to the major trend of rallying the current economic theories outlined management and sustainable development of the knowledge society. Theorists and practitioners, such as David Korten, Peter Drucker, Walter Trux, Michael Lester Brown, Francisc Fukuyama stressed the need to use a single model in training managers, linking together economic, ecological and social.

b. Secondly, it corresponds to major trend of rallying to the existing systems of sustainable development on the global market. In managerial practice from developed countries was created green jobs and green collar workers who were capable to apply system solutions that combine the three principles in order to achieve sustainable development. Green Jobs include

jobs in public transport, in building and construction, in primary industries and manufacturing: Community Sustainability Manager, Land Management Officer, Save Water Manager, Waste Sustainability Officer, Sustainable Vegetation Tradesperson, Waste Water Treatment Plant Operator s.a. Green collar workers include professionals such as conservation movement workers, environmental consultants, environmental or biological systems engineers, green building architects, solar energy and wind energy engineers and installers, nuclear engineers, environmental lawyers, ecology educators, and sales staff working with these services or products. Green collar workers also include vocational or trade-level workers: electricians who install solar panels, plumbers who install solar water heaters, construction workers who build energy-efficient green buildings and wind power farms, construction workers who weatherize buildings to make them more energy efficient, or other workers involved in clean, renewable, sustainable future energy development. [3]

c. Thirdly, it corresponds to the major trend of rallying to the current education system performance. The European education systems, including private education, not only focus on the assimilation of specialist knowledge and skills to specific, but also the acquisition of training systems and skills derived values, which correspond to a profile manager called to built the sustainable economy.

d. Promoting treble efficiency principles in educational programs and managerial economics means to find mechanisms and appropriate solutions that meet the interests and current issues of sustainable society. It's also about recognizing the truth that the aim of any approach would be to meet human needs in his unit being bio-psycho-social-historical. [4]

2. Managerial and green skills - consequences of the educational process

Competencies are defined as structured sets of knowledge and skills acquired through learning, identifying and solving specific problems in various contexts. Education Act,

considers that the main purpose of the current education system is skills training. [5] The competencies are defined in art. 4 of Law of Education as a "multipurpose assembly and transfer of knowledge, skills / abilities and skills required to: a) fulfillment and personal development through the achievement of their goals in life, each according to their interests and aspirations and desire to learn throughout life; b) social integration and active citizen participation in society, c) job employment and participation in the operation and development of a sustainable economy, d) forming a conception of life, based on humanistic values and scientific, on national and universal culture and fostering intercultural dialogue; e) education for dignity, tolerance and respect for human rights and fundamental freedoms, f) growing sensitivity to issues human, moral and civic values to and respect for nature and the natural environment, social and cultural"

Competencies translate into **useful knowledge, the ability to apply that knowledge acquired** (skills, abilities, practical skills) and in **behavior** (positive behavior and attitudes) to achieve something with their practical / useful. Depending on the degree of generality and complexity have been identified general skills that can be applied to many fields of study and specific skills that define a particular field of study. Managerial skills are part of specific skills that can be acquired by studying disciplines in management.

Managerial skills must to meet the current requirements of management experience, both folded on solving economic problems and those social and environmental.

The management's competencies are determinate with the corresponding relationship management skills:

$$Cm = c^1 + c^2 + c^3,$$

Cm - management's competencies

*c*¹ - economic competencies

*c*² - social competencies

*c*³ - ecological competencies

Economic competencies enable professionals and managers to achieve performance excellence in the profession. Social competence involves knowledge and ability to collaborate, communicate and align

their goals with the desires and needs of others.

The term social competence was introduced by M. Argyle meaning 'social behavior patterns that give individuals from socially competent, able to produce the desired effects on other individuals'. In the category of social skills, which are included in the profile of successful managers, the literature states: communicative, sociability, networking skills, empathic ability, assertiveness, anomicitate, diplomacy, teamwork, spirit of collaboration, self-management skills [6]

Starting from the presentation logic of the concept of social skills can define **ecological competence as given by the knowledge, skills and behaviors that will ensure effective and beneficial consequences of environmental protection and ensuring sustainable economic systems according to the principles of sustainable development.**

In ecological skills training, environmental education or ecological education has a critical role. In 1970, following the IUCN meeting in Nevada, environmental education has been defined as "the process by which values are known and clarified concepts in order to develop skills and attitudes necessary for an understanding and appreciation of human relations, culture and environment". [7] Ecological education also includes environmental education, practice and a decision formulating their own code of conduct on environmental quality.

The ecological competencies might include three categories of skills derived, including knowledge, skills, abilities and specific behaviors:

1) Expertise on environmental knowledge formed the basis of continuing education about the environment, providing a better understanding of natural phenomena, the natural environmental components and systems. These skills allow exploring the environment, to adopt certain attitudes based on critical thinking, environments decisions (C_{dm});

2) Skills manifested in the environment, gained from working on certain types of environmental knowledge, a certain environmental experiences, which have formed habits and skills of collecting investigation, action, the environment, in

which any professional would be to "manage" in various media (C_{im});

3) Environmental education skills for preparing managers for decisions and actions that contribute to environmental improvement (C_{pm}):

$$C^3 = C_{dm} + C_{im} + C_{pm}$$

Among the three categories of specific skills included in determining the relationship of environmental competencies, the most complex concerns the third category, the skills regarding environmental education because it involves the creation of skills necessary actions on the environment.

Development of the cross and ecotourism arias requires the creation of managers and specialists able to work actively so that after visiting the cross, they look better than the stage where they were found. However, such skills require capacity building to address a lifestyle compatible with the concepts of sustainable development, contributing to good management of natural resources.

Skills training through the educational process involves going through repeated, on different subjects in the field of management learning stages:

- 1) Reproduction of knowledge;
- 2) Linking them with those already acquired;
- 3) Theoretical resolution of problems or situations with knowledge gained;
- 4) Application and enforcement of the knowledge in economic life. [8]

3. The Main Eco-Competencies needed to develop environmentally friendly Eco zone

The skills managers need, based on questionnaires filled in a survey, conducted among students from Petre Andrei University, of the Faculty of Economics have identified a set of ecoskills necessary for managers to apply the principles of ecological sustainable development. Results of the survey took into account responses from the 100 questionnaires distributed to students from the 2nd and 3rd year, concerning the skills acquired through existing environmental curricula, environmental skills which would be desirable to form in order to conduct business and sustainable

development and skills that are expected to be necessary in view of business development that will use non-conventional energy.

A percentage of 73% from the students surveyed were selected among 18 types of environmental competence skills from a list with 130 skills: knowledge of natural phenomena, the natural environmental components and systems; the ability to analyze systemic problems at the local and global environment; the ability to think in terms of natural systems theory of optimal processes; understanding the impact of pollution on the BIOS having origins; understanding changes in the biosphere natural and man; understanding the fundamental phenomena of the dynamics of land cover; capacity of synthesis and interpretation of a set of information on environmental changes and make any conclusions; ability to apply theoretical knowledge and experimental skills in case studies in the field of environmental protection; the ability of independent analysis of problems; capacity of reasoning and communication solutions concerning environment problems; the capacity of using methods and measuring equipment for measuring and monitoring and control quantities determined in a process that occurs in the environment; the ability to address complex problems specific environmental strategies using the most appropriate approach; ability to develop a diagnostic environment; knowledge and design development of agriculture, forestry and services in the context of environmental and sustainable development requirements; the ability to formulate credible and sustainable business projects; initiative and effectiveness in addressing and solving environmental problems using both scientific knowledge and scope of environmental legislation, economic policy, management, quality management; ability to design and implement sustainable tourism facilities; assessing the effectiveness of ecotourism farm; pollution assessment in the domestic environment based on professional tests that can be made available to customers.

In the three groups of competencies, the students identified in the first five skills, the following ecological competencies of managers:

1) Knowledge and skills about environment (Cdm):

- Knowledge of natural phenomena, the natural environmental components and systems;
- Ability to analyze systemic problems at the local and global environment;
- Ability to think in terms of natural systems theory of optimal processes;
- Understand the impact of pollution on BIOS
- Understanding changes in the biosphere, with natural and anthropogenic origins;

2) Skills manifested in the environment (Cim):

- Ability to synthesis and interpretation of a set of information processing and phenomena found in the environment and to draw conclusions;
- The ability to apply theoretical knowledge and experimental skills in case studies in the field of environmental protection;
- Ability to independently analyze problems, specifying the reasons and solutions;
- Ability to use measuring equipment and methods for measuring and monitoring and control quantities determined in a process that occurs in the environment;
- Ability to develop a diagnostic environment;

3) Environmental education skills for preparing managers for decisions and actions that contribute to environmental improvement (Cpm):

- Knowledge and design a strategy based on the development of agriculture, forestry and environmental services and requirements in the context of sustainable development;
- Ability to formulate credible and sustainable environmental projects;
- Ability to design and implement sustainable tourism facilities, eco homes, private farms;
- Evaluate the effectiveness of farm tourism;
- Evaluation of pollution in the domestic environment under professional tester that can be made available to customers.

On the question of ecological skills that students consider that they hold a license upon completion of the first cycle, - specialty trade economy, tourism and services -, a percentage of 52% students have selected 7

of the proposed types of skills: knowledge of natural phenomena, components environment and natural systems; the ability of synthesis and interpretation of a set of information on environmental changes and to draw conclusions; ability to apply theoretical knowledge and experimental skills in case studies in the field of environmental protection; the ability of independent analysis of problems of reasoning and communication solutions; the ability to formulate credible and sustainable business projects; initiative and effectiveness in addressing and resolving environmental problems using scientific knowledge in the field as well as environmental legislation, economic policy, management, quality management; ability to design and implement sustainable tourism facilities; assessing the effectiveness of farm tourism.

4. Conclusions and implications

In conclusion, to develop business management ecoskills to design sustainable environmental education should be focused on the formation of the three dimensions of power. Environmental education is an essential dimension of basic education involves personal and social development. This type of education seeks to induce a social dynamic, encouraging a partnership approach to environmental issues and seeking creative solutions to independent and relevant environmental protection.

Results for sounding sentiment survey students about environmental skills training need has resulted in the selection set of skills that could be included within the scope of environmental skills, establishing the necessary ecoskills would be included in existing curricula with a view to sustainable business conduct and skills necessary to conduct business in the future using non-conventional energy.

Consistent with the fundamental pedagogical principle "learning by" the competencies are not merely ecological learning outcomes, but the consequences of the educational process, observable and measurable form of performance. In determining the ecological skills, managerial skills cause social skills that ultimately translate into the green skills. Determining

the ecological relationship skills is given as algorithm:

$$C: e^1 + \rightarrow e^2 + \rightarrow e^3)$$

The education system must develop the skills and attributes that correspond to social order. Only negative consequences of excessive orientation towards economic efficiency and social efficiency by neglecting environmental education system itself affects the economy as a whole, but primarily students, on completion of a particular course of study will be faced with some difficulties in its efforts to achieve and sustainable business design: slow adaptation to the requirements and principles of sustainable development, ignorance of environmental issues, excessive consumption of traditional energy.

Demands in Educational Management Strategies for Management Skills Training

Dionisie Cristina
Diaconu Mihaela

"Petre Andrei" University of Iasi, Faculty of Economics
cris_dion@yahoo.com

Abstract

The study is a plea for educational strategies to rally real trends emerging in economic and social practice real economies of developed countries, marked the formation of society based on information and knowledge and the foundation of a sustainable economy.

Emphasizing the main trends in modern educational systems in developed countries, the study outlines the main requirements of educational management strategies based on social order parts on the training of managers in line with triple optical efficiency.

The evolution towards the so-called information society has given rise to a series of challenges that must be considered, echoing long-term changes in society. Educational actors should identify specific changes in cognitive and cultural ecological problems and the accelerated development of digital technologies will bring the entire company.

Finally necessary courses of action are drawn to meet the strategic requirements specified

Key words: educational management strategies, requirements of educational strategies, sustainable economy, managerial skills,

J.E.L. classification: M5, M53

1. Introduction

National Education Law, considers that the main purpose of the current education system skills training. In this regard, Article 4. states: "Education and training of children, youth and adult skills training are the main

purpose, which is defined as a" multipurpose assembly and transfer of knowledge, skills / abilities and skills required to: a) fulfillment and personal development through achieve their goals in life, according to their interests and aspirations of each and willingness to learn throughout life; b) social integration and active citizen participation in society, c) job employment and participation in the operation and development of a sustainable economy, d) formation of a conception of life, based on humanistic values and scientific, on national and universal culture and fostering intercultural dialogue; e) Education for dignity, tolerance and respect for human rights and fundamental freedoms; f) growing sensitivity to human issues, with moral and civic values and respect for nature and the natural environment, social and cultural"[1].

Management skills training should be done in the spirit of triple efficiency and sustainable economic development. [2] However, this can not be achieved without harmonizing the actions of educational policy makers at the macroeconomic level, with universities and policy makers at mezo-economic with the media, materializing in the end, the actual implementation by processes of education and training courses and seminars.

2. Current Challenges

Management skills training should be correlated with the current data trends and challenges in promoting a sustainable economy and knowledge society:

- Sustainable development is inextricably linked to the shift to a green economy, which finally prints the education system that prerequisite skills necessary training and skills in environmental management skills.

With the development of unconventional energy sources, environmental skills required beach managers will increasingly widen more. In unconventional energy sources, the EU has increased its efforts to develop wind energy, which in addition to combating global warming; the sector can ensure European energy independence. In 2009, according to a study by the European Wind Energy Association shows that by 2020, the European Union wind energy industry will double to reach 330,000 jobs. Due to the need for states to boost economic growth necessary to build and develop managers to lead companies or companies that will invest in this area. Wind energy jobs involve a complex set of environmental skills required to develop wind farm, wind farm construction, manufacture and maintenance of wind turbines [4].

- The formation of society based on knowledge and information print system formatted a multidisciplinary, managers need to develop specific skills and abilities of IT. In this respect, developing the necessary infrastructure for implementing the electronic payment system, electronic signatures and electronic management of the current operation involves complex data bases in real-time. A number of universities will have to increase its offer training in the IT program and dedicated active dissemination of knowledge (embedded web). Digital skills training could alleviate the differences in the use of digital technologies and even equitable access to information. A pressing need for the current period, with the transition to knowledge-based society and information to students is the development of critical reasoning to digital media, digital cultural awareness, knowledge and understanding of virtual learning environments and their ability to improve processes learning.

- Expanding global educational networks that use high technology. Educational networks are used for: communication via email and forums, documentation, collaboration and projects. Through educational portals universities and training institutions are in constant communication, sharing their latest knowledge. The use of such platforms Kennisnet, which uses a single login system can be developed teaching and learning processes by building themed sites, offering online learning

services, providing teaching materials and teaching, helping to develop a new generation of educational communities.

- The widening gap on the quality of educational processes, costs, organization, sustainability education systems. School systems are in strong competition, universities are strongly differentiated mainly in terms of quality human resources, material resources and access to different information. The institution is rated much better chances of success on the employment of graduates are higher.

3. Highlights of the social order on the training of managers

To enable managers to ensure appropriate training should be developed a set of measures that have performed actions of educational policy makers at the macroeconomic level, with universities and policy makers at mezeoeconomic, materializing in the end, with actual implementation, through the process of education and training courses and seminars. [3] This conclusion is reached based on assumptions and possible answers to the question: Who dictates the performance and skills they need to become future professional manager?

A first answer is social control, with both internal component but also including the international context, the isolation can no longer accept a state and to remain behind. Performance and skills they need to get specialist manager's future would be dictated by social order. The order follows a professional profile of social, ethical and moral future managers. Profile management emerged from renowned European universities is already folded optics and the principles of sustainable development and ensuring efficiency triple. For this reason, results and many benefits to society in these countries. The development of attributes such as reliability, punctuality, honesty, conscientiousness, ability to work together and cooperate, education for work well done, organizational spirit, still a student, complete - with the expertise - future moral and civic profile manager asked by XXI century. Shaping a profile focused on both economic powers and the social and environmental skills reveal new qualities of the manager,

along with the need for extensive ecological knowledge: inventiveness, insight on changes in the environment, the ability to generate change in the environment, the ability to prevent and response to environmental changes, initiative and courage to design and implement business based on the use of no conventional energy.

Profile would be required, further, to find and meet nationally-developed standards of occupational and professional - in which economic model will be rolled manager specialist skills, required by society today.

Normally this new educational reform, incorporating triple efficiency would have been useful to be adopted on the three cycles: bachelor, master and doctoral studies. Further, the faculties and departments, reorientation training content managers through training and education strategy in line triple efficiency must be reflected in the following:

1) Curricula that ensure the subjects covered the whole range of activities designed to develop, a fund of general knowledge, expertise in a new vision, the creation of practical skills to achieve triple the efficiency;

2) Subjects contained in the plan, which would have to extract them belong powers to carry out the performance of these skills and training to students, proposed syllabi for each subject;

3) Innovative Teaching Methods should not promote the technology first and then investigate whether they are sorted by skill profile manager asked for the twentieth century.

4) In different specialties should be selected according to the specificity of each set of environmental competencies that could be provided in addition. It also requires a series of measures at national level:

a) Action to improve the dissemination of existing studies, policies and practices in education;

b) Comparative studies on European methods in education trainers skills training aimed at implementing ecological models;

c) The establishment of relevant indicators to assess the results of introducing policies and practices in environmental education skills in various European countries. [5]

4. Requirements of educational strategies for training of managerial skills appropriate sustainable society and knowledge economy

Based on current challenges and strategies should be applied in education, in educational strategies to be followed a set of requirements:

1) Preparing for the digital economy requires the mandatory inclusion of training in IT, digital literacy and employment development in the university curriculum. Achieving a consensus on delimiting the set of skills would be desirable. Currently some educational policies focusing on skills in using computers, others include education on all media, media expertise (Germany). In the field of media educations in France were 20 projects funded European e-Learning.

2) Recovery of better results by learning processes by encouraging flexibility in curricula and market orientation of applied research. In many areas of Romania lacks an effective interface between research and industry. It is important to increase the share of extra-curriculum activities and better recovery results obtained from these activities. In many European countries, about 30% of the curriculum is defined locally, based on extra-curricular activities aimed at cross-curricular or extra-curricular issues, or may be related to the development of new partnerships.

3) Training human resources consistent with the current requirements of the competitive educational environment, and enrich the knowledge necessary to adapt in line with triple optical efficiency and training throughout their working lives. In this respect, it requires rethinking of education as a coherent system of training of human resources for a sustainable society based on information and knowledge;

4) Adoption of mechanisms and bodies to ensure creation of an adaptive processing system in accordance with the dynamics of knowledge society. Promoting relations with the socio-economic universities, increasing the contribution of universities to sustainable development of regions would be a better adaptation to social and economic dynamism.

5) Stimulate students and teachers for transmission and transfer of knowledge and capacities. The Creation of science parks and

technology transfer at each university should become a priority strategic objective in education. Establishment at the university management of specialized centers for the management, transfer and dissemination of knowledge, harnessing creativity and innovation should be preferred. It is desirable to perform as many actions to drive real talent for developing innovative programs in multidisciplinary teams.

6) Operation with new environmental indicators related to skills training and use of digital technologies. Indicators should consider both the investment in equipment and teacher improvement, software and educational resources. Consistent with the approach of integrating digital technology is preferable to use a composite indicator that is based on an overall analysis of the progress of schools in specific environments: teachers, students, programs of study. It should also create a database of operational data to provide information necessary for calculation of aggregate indicators, including data input on: how to offer education programs, or traditional conference, the active use of IT by student learning on-line or integrated activities based on education platform. Platform must operate also with the output data: number of teachers trained in IT and use these technologies effectively in their work, the variety of learning situations involved.

7) Development of new assessment procedures appropriate education for a sustainable society and using IT. Traditional methods for assessing cumulative can not be used to assess the formation of organic and digital skills. Current programs and examinations are often seen as an obstacle because the content subjects are inconsistent with the approach already applied interdisciplinary. Formative evaluation can contribute to the quality of the learning experience. There is a great need to carry out research activities focused on learning processes, enhanced by the introduction of materials for environmental education and information technology to inform players and analyze educational experiences that take place in the group of students.

5. Lines of action for educational strategies for training of managerial skills appropriate sustainable society and knowledge economy

1) Stimulation of research and innovation involves the adoption of a set of concerted action to ensure competitive financing mechanisms to increase capacity and exploitation of results. Encourage inventions and innovations in strategies and educational processes should become a priority. In this respect should be corrected a number of bureaucratic procedures concerning intellectual property rights legislation and stimulated recovery of domestic inventions and scientific creation. Promoting local brands and intellectual property in all areas including IT would be desirable.

2) Encouraging policies that accesses additional educational resources. Thus, strategies to encourage on-line access to public domain information or particulars that may be considered part of the national heritage and treasures of human civilization are desirable. In some European universities have signed agreements with owners of patents to allow students to use those resources protected by intellectual property law. Resources freely available on the Internet have led to the formation of policies best links or resources to create closed environments, as a remedy against the influx cognitive syndrome resulting from the explosion of information portals on the Internet. However, this expansion of information may lead to a reduction of investment in educational software or production of items related to knowledge and resources more e-learning, development belonging to public agencies or private publishers of multimedia content.

3) Formulating policies and strategies with long-term educational prospects. It is important that educational policies and strategies are determined by long-term educational goals. The possibility of taking up a job to be seen in a long term perspective, aimed at linking educational strategies as long-term professional development and job opportunities in the short term. Implementation of new educational methods takes time and it is important that the forecasts for employment

should not be done short term to be overcome when implementing new methods and education schemes. In areas such as using digital technology for science education, policy must address two needs: 1) to prepare students to choose careers in science; 2) to educate them to act as citizens in a society that gives rise to scientific challenges. Cognitive tools for processing and analysis will play a key role, as well as learning processes based on collaboration which will allow a better understanding of science, technology and social interaction. This also requires an update of educational objectives in the acquisition of knowledge and cultural appropriateness. It is obvious that the perspective of lifelong learning will underpin the long-term development policies and lead to the integration of education with other learning environments.

4) Ensure new support services for education. It should set specific services, agencies, competence centers, help desks for assistance and educational technology. Such services will involve training and advice for teachers, teacher trainers and managers of the education system. They will focus on customization and better methods of learning, tutoring and counseling services to the learners and to provide new means of validation and certification. A key recommendation is to encourage open learning environments by providing flexibility in the policy so that the different territorial levels are involved at their full potential in the integration of digital technologies in education. Establishing a service can be made closer to what can be done at each level and the number of users that can exist in a neighborhood or a village. In a city, region or country can develop services based on common languages and cultures, taking into account the development of specific resources and lesser-used languages. The best use of local resources can be made on the spot by specific services designed to enrich the learning experiences of students or school environment with resources that may be provided by other actors such as universities, art and science museums, research centers, companies or local industries.

5) Creating opportunities for developing new competencies needed to implement change trainers, who must to operate with the

new challenges. Educational policies relating to initial and continuing education of teachers and trainers must go beyond technical skills and to enable all educational stakeholders to develop new skills to master digital technology and media to form their own skills and to integrate environmental education into everyday contexts. A basic framework for environmental education modules for integrating digital technology in education will lead to a better understanding of changes taking place in the educational processes of the global economy. New possibilities open to be explored by setting up learning centers for continuing education. Managing change requires institutional flexibility and therefore a new vision, while promoting creativity and inventiveness.

6) Develop research, establish new indicators and access to results. Research and technological development is often given precedence over social sciences and applied educational research. Pilot experiments should lead to a complete analysis of the contribution of environmental skills and digital technologies to educational outcomes, taking into account different learning styles, different target groups, socio-cultural contexts and size groups. Examples of innovative practices to be studied and documented best to provide important information. New indicators can be defined only when the specific educational objectives of environmental education and digital technologies have been stable. Digital skills training module can be assessed in relation to their contribution to achieving educational goals. From this perspective, were highlighted in the European countries, seven educational areas: information skills, communication and media for students, teachers use educational technologies, educational technologies for teaching quality assurance processes, language and arithmetic skills training, active involvement in civic activities for communication and collaboration skills, technical and scientific culture. Should be targeted and increased risk of social exclusion because of poor social conditions existing educational uses of digital technologies. Access the results can be generated and the learning from pilot and research projects present or past. In the reports, information projects and publications can be found an important body of

knowledge to be synthesized and made easily accessible.

6. Conclusions

In conclusion, the strategies of the educational system must always have in mind that education goals are personal development, social development, development of relationship with the cultural, economic environment, the natural environment and technology to be included in a coherent systemic vision;

- The current education needs are focused on a) the continued development of skills and competencies, b) building a knowledge base necessary to identify and accumulation of information, motivation and execution of cultivating a task to complete properly.

- The local education policy should be appropriate to the design of local programs, the design of means of assessment of local programs, design programs of social integration of students, design of strategic niche development programs, encouraging the cultivation of social skills programs, the local cultural programs and volunteer action and social responsibility.

- Human contacts and social interaction remain basic principles on which the new educational methods should start. A relevant example of the use of clean technologies and digital technologies in the EU countries shows the importance of critical dialogue and exchange of experience at the same level.

- In the context of major transformation of society, educational actors must meet new training requirements raised by the knowledge society and sustainable development of economy. They must adapt to new categories of students and cognitive styles. Therefore, we need a new way of approach to training teachers and trainers.

- The role of open universities as centers of learning will increase with the emergence of other complementary services to assist in education and social organizations, economic, cultural or scientific will provide opportunities for open learning.

- Innovative learning methods should not promote the technology first and then to identify the educational problems could be solved by it.

Public Indebtedness in Developing Countries: Romanian Case

Dobranschi Marian

"Alexandru Iona Cuza" University of Iasi, Doctoral School of Economics
dobrica_3@yahoo.com

Abstract

In this paper we concern about the unsustainable level of public indebtedness of developing countries, due the fragile and undeveloped national economy, under different impact factors that may lead to a debt crisis and government insolvency. We analyze the ratio between GDP annual growth rate and public debt annual growth rate as an important indicator able to measure the economic situation at a given time. In addition we consider that public debt composition matters since the external public loaning leads to an export of capital abroad that is affecting growth and economic development of national economy.

Key words: Public debt sustainability, crowding-out effect, level of indebtedness, sovereign debt crisis, current account deficit

J.E.L. classification: F31, F32, H12, H62, H63, H68

1. Introduction

According to the literature, public debt is one of the important economic variables that measures and describes a nation's economy.

Governments have to often borrow to cover their public budget deficit, in order to finance certain types of public expenditures. In all countries, either developed or developing states, governments tend to rely the surplus of public expenditures that exceed tax revenues, on the public loans. Even so, public debt is another way to increase expenditures, that are covered finally through taxes. According to David Ricardo, public loans are nothing but delayed taxes.

In comparison with taxation, that are compulsory levies, nonrefundable, paid by the taxpayers, public loans constitute a different financial relations, based on the

market rules. Once the government decide to borrow, he must comply a sort of conditions that govern public borrowing, first one is the requirement of repayment at maturity and the second one is interest payment.

2. Public debt composition

An important feature is the public debt composition, taking in consideration domestic public debt and external or foreign public debt. Domestic public debt, may be considered as a internal method to supplement budgetary resources, when government borrows from internal capital market, through specialized financial institutions or directly from financial resources holders. Over domestic public debt, Milton Friedman sustain, that this method to finance public expenditures generates and supports the crowding-out effect that has a negative influence over economic growth and development. The rationale is simple, if government tend to exaggerate with internal public loans, it will increase interest rate and it will make credits more expensive effecting investments in private sector. We are partially agree with this point of view, this effect may occur only in certain conditions are accomplished. Crowding-out effect occurs and negative affect national economy when, all the internal inputs are used at full level, in which case public indebtedness is unjustified and harmful.

But this rule does not apply in most of the developing countries, where the inputs are not fully used, and where public intervention even through public loaning is useful, using the latent financial resources, to finance public investments in project like social infrastructure. In this case, the crowding-out effect does not apply or in other words do not adversely affect growth and economic development.

The other component of total public debt is the external public debt, that involves a different set of effects over national economy. Called in literature the "original sin" or the impossibility to borrow in own currency, that leads in majority of the cases to negative effects over national economy.

Due the insufficient development of financial markets, many developing countries, have difficulties in borrowing domestically long-term and are unable to borrow abroad in terms of they own currency, consequently they need to borrow in foreign currency in order to acces foreign capital markets. The first negative effect appears when at maturity the debt has to be repayed at foreign currency, repayment that is financed through domestic currency. So a depreciating domestic currency leads to debt crisis and finally to insolvency, situations where governments are unable to service their foreign currency debts.

Foreign borrowing has, according to some econonists, both benefits and costs.

The benefits that a country may have from borrowing foreign may include buying advanced equipment and technology and investing in esential projects where private sector is incapable or are unwilling to support, such as infrastructure. With better technology and improved infrastructure, the debtor country can raise the efficiency of the production process, creating more added value and it may reach self sustainable growth, that will cover the repayment of borrowed financial resources at maturity. The costs of foreign borrowing according to is the interest payment on the debt. To cover repayment and the interest, are needed future tax revenues raises, and a given tax revenue must be allocated and diverted from other productive destinations that may affect economic growth and social welfare.

Concerning about the manifestation of negativ effects over national economy, we consider that they are more costs than benefits when governments decide to borrow from abroad. A condition to limit asociated costs of public debt is to increase the level of efficiency of public debt management and more important is to channel the borrowed resources to productive expenditures. If the borrowed financier resources ar used efficiently and the interest rate is not high, only then foreign debt is likely to stimulate

economic growth. But, if the funds are used to finance nonproductive public expenditure corroborated with high interest rate, the foreign public debt has a negative impact over growth and economic development.

Governments in most of the cases, borrow to cover cash gaps that result from differences between receipts and payments, also government loans are intended to cover the budget deficit, and in some cases the state is borrowing to finance various public investment projects. Moreover, a situation characteristic developing countries, in a global economy, government are forced to borrow from abroad important financial resources to cover current account deficit of balance of payments.

Underdeveloped capital market and also precarious economic situation of the Romanian economy in transition that has become more a consumer economy, far from being a functioning market economy, has forced the Romanian government to increase foreign public debt, not only to finance the budget deficit but also to support foreign exchange reserves, thanks to a trend of current account deficit that we recorded in the last 20 years in Romania.

Table 1. Current account deficit evolution

Net current account	2006	2007	2008	2009	2010
mil. Euro	-1,298	-1,804	-858	-726	-414

*Statistical data from NBR anual reports

Debt composition matters, so if we analyze the composition of total public debt in Romania, we observe the atypical nature of public debt, where more financial resources are purchased from international creditors.

Table 2. External public debt evolution in Romania

Items	2000	2001	2002	2003	2004	2005
External Public debt (mil. EURO)	7,371.70	8,708.50	9,167.50	9,637.60	10,270.00	10,947.20
- percent in GDP (%)	22.10%	20.80%	21.10%	20.10%	16.50%	13.90%
Total public debt, GDP(%)	31.40%	28.70%	28.80%	25.90%	22.40%	19.50%

After 1990, Romania as a developing state, gain acces to the international capital market, by default the risk of sovereign debt crisis has increased considerably. To avoid debt crisis, the government must ensure that the level of purchased debt is sustainable, or in other words, the external financial situation of a country where foreign exchange resources are beyond the external debt service payment obligations.

Given the positive macroeconomical evolution between 2000-2008, this situation favored adoption of a set of expansionary fiscal and budgetary policies, confirming the orientation of developing countries to pro-cyclical policies. The obvious result was a strong commitment to projects and government expenditures over the national economy ability to finance them.

Figure 1. Public debt growth rate and GDP growth evolution between 2000-2010

*Source: Eurostat and annual reports of NBR

Once Romania has become a European Union member state in 2007, among many politic and economic condition to meet, Romania in order to adhere to European Monetary Union, must guide her fiscal and budgetary policy according to the limits set by the Stability and Growth Pact, that are 60% public debt of GDP and 3% limit of public deficit of GDP. Even if Romania was

characterised as an low indebted country, compared to the other EU member states, the economic situation of Romania has rapidly changed once financial and economical crisis stroke

worldwide and and also romanian economy.

The imediate effect of the financial crisis, was the negative impact over real economy

wich can be observed in falling of GDP growth rate in 2009 to -7.1% level, in comparison with 2008. In this hostile environment, the financial situation of Romania has rapidly deteriorated, firstly under the pressure of the state budget widening due the diminished tax revenues and secondly the rising public sector expenditures on social protection like unemployment allocations and pensions, and third point of view a important factor to worsening the economic situation in romanian economy was the decline of foreign exchange incomes due the falling of exports.

In these conditions, romanian government decided to meet this economic challenges by concluding a financial agreement for two-year loan of 20 bilion Euro with IMF, EU, EBRD and World Bank, under the condition of reducing the budget deficit and freezing wages in the public sector. The main cause that triggered and conducted to public loaning was the increasing macroeconomical imbalances, particulary the current account deficit, the savings-investment balance, and the pressures on the external balance of payment emerged in recent years due the trade deficit.

The 20 bilion loan was regarded as a "safety belt", the loan was intended to finance the budget deficit and economic activity, and to support the euro-lei exchange rates at sustainable levels for the economy and population, and to ensure the boost of growth and economic development.

Economists like Van de Ploeg (2005), Breben and Bronsen (2008) sustain that the limits imposed by the Stability and Growth Pact must be chabged or revised due the actual situation of most of the EU member states that are not meeting the Pact's limits of 60% public debt and 3% budget deficit reported to GDP level. On the other hand, Dvorakova (2008) sustain that the main purpose of these limits is that they provide a sustainable debt policy and economic balance. But if we analyze the actual situation of Romania, after 2008, even if romanian state comply the Stability and Growth Pact conditions, the negative evolution of GDP in last two years corroborated with an increased growth rate of public debt, we are concerning about the sustainability of the romanian economy, or the ability to meet all her financial obligations at maturity. If

Romania continues to borrow with the same rate it risks a sovereign debt crisis, in wich the romanian state will be unable to meet his financial obligations.

Public loans represent financial relations that generate costs, and if the government borrows to spend on nonproductive destinations (bills, wages), the scenario case reply to a unique solution, namely that of contracting new public loans, more expensive in order to repay the older public credits that have reached maturity. In that case government will be forced to raise taxes to increase tax revenues and to cut public expenditures on public investment and social protection due the neccesity to repay acumulated public debt.

3. Conclusions

To avoid public debt crisis and cases of insolvency of the public sector, we must take in consideration not only the limits set by EU, through Stability and Growth Pact, but also the government must keep under control the growth of debt ratio, in order to ensure a sustainable level of indebtedness. Debt sustainability is one of the most important conditions that can limit the excesive public indetebtedness and also it can be avoid hte vicious circle of borrowing supported by the incrazed debt burden and high interest rate, which generates new public debt because of the lack of financial resources to repay loans at maturity.

Regarding to te ratio between annual GDP growth rate and annual growth of the public debt rate, we consider to be an important indicator to be considered in the public debt management and public policy.

Merger Trends and Assessment in the Midst of a Financial Crisis

Dobre I. Claudia

"Ovidius" University of Constanta, Faculty of Economic Sciences
dobre_claudia@yahoo.com

Abstract

In this paper, we analyse data on global M&A deals for the last four years, from 2007 to 2010 to understand what are the trends and to answer the question - does a global financial slowdown increase the number of mergers or decrease it? We find that the number of mergers across the globe has gone down, while the average size of a deal has seen only a minor dip. However, as the economy picks up, we expect that companies are looking to M&A as a way to rapidly add to revenue growth in the coming years.

Merger assessment in the midst of a financial crisis is highly challenging. We consider that EU merger control instruments allow for appropriate application in circumstances of economic crisis, whilst ensuring effectiveness of competition policy. The analyse that follows in this paper upon the number of notifications of concentrations at EU level, during the recent financial crisis, reveals a reduction in the number of cases but not in their complexity.

Key words: merger&acquisitions, merger control, competition policy

J.E.L. classification: F02, K21, L40

1. Introduction

While companies combining forces (referred to below as mergers) can expand markets and bring benefits to the economy, some combinations may reduce competition. Combining the activities of different companies may allow the companies, for example, to develop new products more efficiently or to reduce production or distribution costs. Through their increased efficiency, the market becomes more competitive and consumers benefit from higher-quality goods at fairer prices. However, some mergers may reduce competition in a market, usually by creating

or strengthening a dominant player. This is likely to harm consumers through higher prices, reduced choice or less innovation. Increased competition within the European single market and globalisation are among the factors which make it attractive for companies to join forces. Such reorganisations are welcome to the extent that they do not impede competition and hence are capable of increasing the competitiveness of European industry, improving the conditions of growth and raising the standard of living in the EU.

During the crisis, M&A deals were still being done, but the focus was more on taking advantage of competitive weaknesses and building out the bottom line rather than on strategic growth. Post-crisis, companies are seeking more strategic growth opportunities, particularly in markets such as Asia and Latin America.

2. M&A trends from 2007 to 2010

In 2007, Mergermarkets estimated the global M&A market to be doing around US\$ 3,600 billion worth of mergers in about 15,700 deals. Over the next three years, as the financial markets in the West melted and many industries and geographies witnessed negative growth, the number of mergers as well as the total value went down, to hit \$1,800 billion in 9,400 deals in 2009. In short, the total value of deals struck globally halved, while the number of deals came down by 40 percent, indicating that value per deal or the price paid per acquired company has more or less stayed where it was and had not come down dramatically from where it was in 2007, even as the number of deals came down to half.[1]

The world economy has been witnessing some significant geographical shifts away from Europe and to a lesser extent from the Americas, towards Asia. And the M&A scene has not been immune to these. While valuations in Europe more than halved in

2009, Asian economies actually registered growth in valuations. America had already

seen almost an equal decline in 2008 to what Europe saw in 2009.

Figure 1

Source: Nimesh Sharma , *Mergers and acquisitions in times of financial crisis* , in "Dare" - business magazine, 01 March 2010

The impact of the recession has not been uniform across sectors. In 2009, the pharma sector saw the highest increase of 103 percent in actual values over 2008-09, largely because of a giant deal of \$63 billion (Pfizer buying Wyeth). Three out of the top five deals based on value of 2009 came from the pharma sector, adding a total valuation of about \$150 billion.

In energy, mining and utilities, just two deals involving Rio Tinto-BHP Billiton and Exxon Mobil-XTO Energy added a combined price tag of \$98 billion. No wonder energy deals had icing on the cake in terms of best pricing.

In 2008, in comparison, it was the consumer sector that witnessed two of the biggest deals in history, with Altria Group selling off Philip Morris and InBev buying Anheuser Busch Companies for a combined total of \$165 billion. In keeping with the theme of the times, in 2009, in terms of average deal size, the consumer sector was the worst affected if you ignore the miniscule contribution of the defense industry, with deal sizes halving.

The financial services sector saw average deal size lowering from \$477 million to \$287 million (40 percent down). Consumer and financial services make up about 24 percent of total volume of M&A.

Against all expectations, the world in 2010 enjoyed a surprisingly benign economic climate. In 2010, corporate merger and acquisition activity made a huge comeback. Most of the M&A activity involved North American companies, but activity has also increased around the world, and in various market sectors / industries.

Companies have stashed away a record amount of cash, which they have hoarded since the height of the financial crisis when cash was considered king. Acquiring companies have been spurred on by record low interest & lending rates, as well as a North American economy which has been considered as "stabilized". Risk in general, has been perceived to be lower than during financial crisis, and there has been an increase in corporate and investor confidence. Even though stock prices were a lot higher in 2010 than in 2008 or 2009, the

market value of companies have still remained relatively low due to a weak global economy.

The value of deals in the 12 months through November 2010 rose 9% from the same period ended November 2009, to \$786 billion, according to Thomson Reuters. However, the number of deals was flat, and there were few megadeals, owing to uncertainty and perceived levels of risk in the global economy. M&A activity significantly increased during the second half of 2010 especially for large sized (multi-billion dollar) takeovers. Late July and the month of August were notable for heavy merger & acquisition activity. Those months were highlighted by the announcements of :

- 7/29/2010 – Sanofi-Aventis – Genzyme (\$18.5 billion)
- 8/14/2010 -BHP Billiton – Potash Corp (\$40 billion)
- 8/19/2010 – Intel – McAfee (\$7.7 billion)

M&A will continue picking up steam this year as companies aim for top-line growth. Plus, after the extreme cost-cutting exercises of the past few years, in order to grow—or at least maintain—profitability, it will require top-line development that can only be achieved through greater scale, some form of vertical integration, greater geographical coverage or increased products and- services offerings.

The biggest wild card for the year ahead is that ongoing concerns about the economic health of Europe could make banks reluctant to lend and could affect confidence in global capital markets and the ability of sovereign governments to prop up their financial systems.

3. EU Merger Control and the Economic Crisis

In assessing mergers between firms, competition authorities examine whether the merger is likely to result in a lessening of competition. The exercise involves considering the possible effects of a merger against an estimate of what might have happened in the absence of the merger - the so-called counterfactual. It is particularly difficult to determine a plausible counterfactual if expectations surrounding the future competitive dynamics of the market are changing on a daily basis. The

potential for one or both of the merging entities to receive state support further complicates the analysis. In such circumstances, the counterfactual scenario could include the likelihood of government support in the absence of a merger. This could lead to the rather circular scenario of a competition authority speculating that the counterfactual to an anti-competitive merger would be a government bailout that would preserve the existing level of competition. Such a scenario could result in the competition authority blocking the merger, while the government itself may judge that a merger would preserve financial stability at a lower overall cost to society.

EU merger control instruments allow for appropriate application in circumstances of economic crisis, whilst ensuring effectiveness of competition policy. [2]

Generally, economic context can be taken into account to a sufficient extent (cases *Microsoft/Yahoo*, *KLM/Martinair*). However, uncertainty and instability in some markets can pose challenges in terms of predictability of future market developments & assessment of counterfactual.

In EU merger control, the failing firm defence has not played an important role.

Here, we must notice the specific case of the banking sector - rescue mergers. Following the onset of the 2008 financial crisis, governments throughout Europe have intervened in the merger approval process in a number of cases to enable banking consolidation in the interest of financial stability. These interventions raise the question of whether competition regulators should be allowed to follow their standard merger approval processes during times of systemic crisis, or whether special procedures are indeed justified.

It is important to recognise the substantial size of the potential costs and risk to the state of measures associated with systemic financial crisis. As an illustration, the governor of the Bank of England, Mervyn King, stated in a speech on 20 October 2009 that: "The sheer scale of support to the banking sector is breathtaking. In the UK, in the form of direct or guaranteed loans and equity investment, it is not far short of a trillion (that is, one thousand billion) pounds, close to two-thirds of the annual output of the entire economy." [3]

The unusual public cost and widespread scale of the impact of bank failures means that exceptions to standard merger regulation may be required during a financial crisis. In circumstances where it is perceived that a merger may substantially reduce the cost to society of dealing with a banking crisis, the system needs to be flexible enough to allow such an intervention by central government. This can be seen as providing the basis for governments to maintain a financial stability public interest test in the merger framework which may, on occasion, allow anti-competitive mergers to take place.

This need for flexibility in extreme circumstances is reflected in many competition law frameworks. An OECD report on Competition and Financial markets in 2009 noted that the European merger regulation lists prudential rules as a

legitimate interest that can be taken into account meaning that "at least in merger control, stability considerations may override competition concerns". The report noted similar provisions in Canada and Switzerland. In the UK in 2008 a new public interest ground of preserving financial stability was rapidly introduced into UK merger control in response to the proposed merger of Lloyds and HBOS.

The new EU Competition Commissioner Joaquin Almunia noted that mergers and acquisitions play an important role in a competitive and healthy Europe and, for this reason, he said that the Commission should only intervene on the merits of a contemplated transaction where the proposed merger creates competition problems leading to higher prices or less innovation on the market.[4]

Figure 2

Source: author (upon dates available on European Commission, DG Competition)

During the recent financial crisis, we can observe a reduction in the number of cases but not in their complexity.

As we can see in the chart, in 2010, the Commission received a total of 274 notifications of proposed transactions meeting the EU thresholds. In 2009, the volume of EU notifications was roughly the same. The busiest year thus far has been 2007 ("pre-crisis"), when the Commission reviewed more than 400 proposed mergers. EU merger control constitutes, in a way, an economic bellwether. [5]

The year 2010 was marked by consistent and stable merger enforcement by the Commission despite the reduction of notified transactions due to the financial and economic crisis.

For just the 21st time in the 20-year history of EU merger control and the first time in more than three years, the European Commission has prohibited a proposed merger outright. On January 26, 2011, the Commission prohibited, on the basis of the EU Merger Regulation, a proposed merger between Greece's two largest airlines: Aegean Airlines and Olympic Air. The

Commission considered that the merger would have resulted in a quasi-monopoly on the relevant air transport market since, together, the two carriers control more than 90% of the Greek domestic market. [6] This is the first prohibition decision since the *Ryanair/Aer Lingus* case in 2007, which also concerned the air transport market.

Trends that were emerging in the second half of 2010, including increased M&A activity in the middle market, the availability of attractive debt financing, and stronger valuations for corporate assets are likely to extend into 2011. The growing middle class in emerging market economies is expected to play a pivotal role in driving demand for consumer products at a time when food-and-beverage and consumer product manufacturers are seeking growth amid slow economic recoveries in developed countries. We must remember here the PepsiCo's announcement that it would buy a 66% interest in Russia-based dairy products and juice maker Wimm-Bill-Dann Foods for \$3.8 billion put the focus on the consumer sector in emerging markets. Plus, Russia's biggest retailer, X5 Retail Group, agreed to acquire the Kopeyka grocery and discount-store chain for \$1.65 billion. The transaction was the biggest acquisition ever in the Russian retail sector. [7]

Demand for raw materials in emerging markets also is likely to remain strong in 2011, thanks to rapid development in China and India. In the biggest M&A deal globally that was announced in November 2010, Caterpillar, the world's largest construction and mining equipment maker, agreed to acquire Bucyrus International, a Milwaukee, Wisconsin-based manufacturer of surface-mining equipment, for \$8.6 billion. China is continuing to make acquisitions around the world to secure its energy supplies. In November 2010, China National Offshore Oil Corporation (CNOOC) and its joint venture partner, Bidas Energy Holdings, agreed to buy BP's 60% stake in Argentina-based Pan American Energy for \$7.06 billion. Pan American Energy is Argentina's second largest oil producer, and it is stepping up development of the country's biggest oil field, known as Dragon Hill.

4. Conclusion

One interesting fact after our analysis is that in spite of the economic depression, at global level there has been no apparent decline in the average valuation when all geographies are considered as a whole. The decrease in the average valuation of a deal is only a miniscule \$1.3 million. But, at the European level, the analysis indicates valuation losses.

Plus, it was 2008 that had seen a major decline in valuation, of an average of \$42 million per deal, which means that the big impact in the M&A market had already happened in 2008.

We can expect that will be a substantial increase in mergers and acquisitions in 2011, as companies have plenty of cash to spend on strategic acquisitions, particularly in fast-growing emerging markets. Demand for commodities from developed nations, and especially from emerging markets will contribute to the huge increase. Larger companies (both public/private and state-owned) from BRIC nations (Brazil, Russia, India, China), especially Russia, China, and Brazil, will likely be ones that will acquire smaller companies, rather than be acquired.

More, crisis has not affected all sectors (e.g. continuity in energy & pharma vs worsening in air transport sector) and companies equally. It is important to mark the changes in the type of concentrations and underlying rationale (less financial investment-driven / more industrial consolidation; less expansion-driven / more defensive transactions).

Performance Management of International Reserves National Bank of Romania in Actual Crisis Period

Dobre Elena

„Ovidius” University of Constanta, Faculty of Economic Sciences

Abstract

2008 was a year of financial crisis - the world economy has slowed down growth and financial markets have become volatile. Crisis hit in full both private sector and the public.

In this context, National Bank has carried a successful management of international reserves in order to ensure the liquidity necessary to carry out external transactions of the state and the objectives of central bank monetary policy, ensuring adequate foreign compositions, and realizing the availability of gold and currency risk under control. NBR strategy paid off.

Conservative approach in managing foreign reserves and prudence shown, have been translated into a profit amounting to 3,338,305 lei, seven times the 2007 profit. In 2008, to prevent and mitigate the risk of central bank invested in the safest tools on the market, and issuers such as governments turned to other states and government agencies, always watching their rating of their financial statements. Finally, greater importance in achieving this result have had transactions with currencies of NBR to secure liquidity in the market and exchange rate stability.

So, as a result of careful observation and good economic environment anticipation of its development, National Bank acted prudently in the public interest and the results have resulted in yield. In this paper, we try to surprise how the central bank acted to obtain these results, since the institution's role and the means used and ending with the performance achieved in a period with poor expectations .

Key words: Synthesis crisis-performance gold currency reserves return

J.E.L. classification: G20

1. Status and functions NBR

National Bank of Romania (NBR) is the central bank in the financial system in Romania.

Founded in 1880 as a credit institution, National Bank had the exclusive right to issue currency, the leu. Over time, the NBR has enjoyed uninterrupted right, even if its role in national economy, property regime and its institutional dimensions have seen important changes.

If in 1880, only one third of the capital belonged to the state central bank in state ownership in 1929 dropped to 10% of the share capital of the NBR. After the war, the establishment of the communist regime has made important changes in the organization and powers of the NBR. Law in December 1946, from January 1, 1947, passed the state-owned National Bank in 1948 became the Romanian People's Republic Bank, State Bank, subordinated to the Ministry of Finance. Only after 1989, the central bank was reorganized as a modern central bank. During 1991-1998, the National Bank business was regulated by Law no. 34/1991, and from 1998-2004, the Law no. 101/1998. Currently, it is reglementată by Law no. 312 in June 2004 on the Statute of the NBR.

National Bank of Romania is headed by a management board consisting of nine members appointed by Parliament upon the proposal of the standing committees of the two rooms. Appointments are made for a period of 5 years, with possibility of renewal. BNR chief executives exercised by the Governor, Senior Deputy Governor and two Deputy Governors. Both board members and employees of National Bank of Romania are obliged to observe professional secrecy regarding any information not intended for publication, they learned during their duties, including after termination of the bank, any infringement being punished by law .

According to Law no. 312/2004, NBR is the central bank, having legal personality and has the goal of providing and maintaining price stability.

NBR tasks include:

- the development and implementation of monetary policy and exchange rate policy;
- licensing, regulation and prudential supervision of credit institutions, promote and oversee the smooth operation of payment systems for ensuring financial stability;
- issue banknotes and coins as legal tender in Romania;
- exchange arrangements and supervise its observance;
- manage the official reserves of Romania.

Although the NBR supports the general economic policy of the state, its primary objective remains to ensure and maintain price stability.

In its monetary policy, the National Bank of Romania using specific tools and procedures for money market operations and lending to credit institutions and the minimum reserve.

NBR may perform reversible secondary market transactions, purchases / sales or take as security for loans collateralised by claims on the state or its securities, credit institutions or other legal entities may conduct foreign exchange swaps, issue certificates deposits and deposits from credit institutions, under such conditions as it deems appropriate to achieve monetary policy objectives. In lending operations, according to NBR status, it may grant loans in terms of repayment, collateral and interest. Deadlines that may be granted may not exceed 90 days. Lending by the central bank overdraft is prohibited.

In foreign policy, National Bank develop and apply the exchange rate policy and supervises the implementation of the exchange rate regime in Romania.

In managing the exchange rate regime, the central bank responsible for:

- regulate operations with foreign assets and gold, to protect the national currency;
- balance of payments;

- setting exchange rates for their foreign exchange transactions, and average exchange rates for calculating statistical authorization and revocation;
- authorization of legal entities which are authorized to conduct foreign exchange transactions;
- setting ceilings on foreign asset holdings and transactions in gold and foreign assets for individuals and legal entities;
- set the ceiling and external borrowing requirements of businesses and individuals falling exchange arrangements; maintain and manage international reserves.

2. International reserve management

Assets included in international reserves are managed by the central bank that any balance of payments imbalances are mitigated, and the state to maintain its credibility. This function of international reserves is supported by the principle that the currency composition of international reserves should reflect the structure of external debt, while allowing protection against currency risk.

Monetary gold, the bank guarantee issue banknotes in gold convertibility in the past, is the oldest active reserve currency. Over time, coins frequently used international economic transactions (such as the German mark, pound sterling, U.S. dollar, SDR and later the euro) have been incorporated into the structure of state reserves.

So, today, Romania's international reserves managed by National Bank include:

- gold holdings stored in foreign country;
- external assets in the form of banknotes or in accounts with banks abroad;
- other reserve assets internationally recognized, including the right to make purchases from the IMF reserve tranche and holdings of SDRs (special drawing rights);
- bills, checks, promissory notes, bonds or other securities negociabile or bills issued or guaranteed by non-resident legal persons and payable denominated in foreign currency;

- Treasury bills, bonds and other bonds issued or guaranteed by foreign governments or intergovernmental financial institutions denominated and payable in foreign currency.

Over time, foreign reserves have met several functions:

a) were used to cover the movement of banknotes into gold during the gold standard;

b) increase the credibility and the country's external creditworthiness - thus ensuring a good rating by international credit market and favorable credit conditions could get if the country wanted to contract foreign loans;

c) sources of balancing the balance of payments current deficit when foreign money is not covered from other sources (such as foreign investment inflows and loans from abroad);

d) absence of other sources, part of the reserve can be used to pay debt service, including past due installments of loans and interest on public external debt with remaining maturities of future payment;

e) is a condition for transition to current account convertibility of the currency (domestic) and - especially - to achieve full currency convertibility;

f) a means by which central bank intervenes in the currency market (the sale-purchase of foreign currency), to maintain currency exchange rate of national economic policy objectives within the state;

g) strategic monetary reserves to cope with exceptional situations and monetary claims (trade embargo, a state of force majeure, etc.).

h) obtain income from foreign exploitation of these stocks through their investments in bank deposits or negotiable securities and safe.

Regulations governing the administration of international reserves are contained in the Statute Law nr.312/2004 National Bank, Art. 30 and Art. 31. According to these articles, to

maintain liquidity and sound management of banking risks, the National Bank of Romania shall establish and maintain an optimal level of international reserves.

To manage international reserves, National Bank may purchase, sell or conduct other transactions: bullion and gold coins and other precious metals; currencies; treasury bills, bonds or other securities issued or guaranteed by foreign governments; securities issued by foreign central banks.

Also, the central bank is authorized to open and maintain accounts with central banks and monetary authorities, banking or other international financial institutions but also to open and hold accounts and transactions of correspondent financial institutions, central banks and authorities monetary, banking and financial institutions, intergovernmental financial institutions abroad, and foreign governments and their agencies.

3. Performance management of international reserves

National Bank of Romania shall ensure that the policies they undertake to ensure and maintain price stability. Unlike commercial banks, central bank does not seek fulfillment of performance for commercial reasons, such as profit maximization, but only seeks to limit its operating expenses.

However, in 2008, the central bank failed to record a gross profit of 3.34 billion lei, seven times higher than the yield in 2007. It has been used to cover losses from previous years. In addition, with the yield in the first three months of 2009, losses from previous years were fully covered, and in April to resume tax profit NBR with a 80% share. The question arises: How did the National Bank performance in the economic crisis? NBR analysis of financial statements we may provide the answer.

Table 1 Result financial year 2008 (thousands)

Activity	Revenue	Expenditure	Financial Result
Monetary Policy	110.023	1.220.129	-1.110.106
Management of international reserves	6.572.736	1.073.887	+5.498.849
Currency issuance and settlement of payments	144.392	158.407	-14.015
Other operations including operating costs	35.792	331.718	-295.926
Subtotal - operating activities	6.862.943	2.784.141	+4.078.802
Revaluation of assets and liabilities	-	740.497	-740.497
Total	6.862.943	3.524.638	3.338.305

Source: NBR Annual Report for 2008

Profits made by the central bank to obtain a result operating profit of 4,078,802 lei, three times higher than that obtained in 2007 as higher revenue and expenditure by 68% to 3% (Table 1). Profit increase in 2008 contributed 19% reduction from 2007 expenditures unfavorable revaluation differences on foreign currency net assets. Reasons offered by the NBR Annual Report 2008 were profitable growth of international

reserves management operations and reducing losses from monetary policy operations (Table 2). Also NBR's annual report, profit growth of international reserves management operations has been determined, in turn, increases the average volume of foreign reserves and increasing efficiency resulting from administration of international reserves in terms of their performance management.

Table 2 Operational Financial Result financial years 2007 and 2008

Total operating result	+1.375.745	+4.078.802	+196

Source: NBR Annual Report for 2008

Over time, changes in foreign assets of central bank followed a trend ascentent (Fig. 1), reaching the end of 2008 amounted to 116,394,294 lei, by 14.8% higher than in 2007. This increase was driven by increasing international reserves, but currency depreciation against the euro. In 2008 economic crisis turned into financial crisis, leading to annual growth slowdown of the economy. Thus, according to data

published by the IMF, developed countries (USA, Canada, the euro area, Japan, UK, etc..) Recorded in 2008 an average growth of 1% to 2.7% in 2007. Meanwhile, average growth emerging economies and developing countries (such as those in Central and Eastern Europe, China, India, Brazil, Mexico etc..) Was 6.3% in 2008, down 2 percentage points in 2007.

Figure 1 The evolution of foreign assets of the NBR
- end of year values adjusted to inflation - 31.12.2008

Source: NBR Annual Report for 2008

In setting its objectives, according to the NBR Annual Report, National Bank took into account both the global economic slowdown and the decline in interest rates in international markets (the U.S. Federal Reserve lowered interest from 4.25% to 0,25%, European Central Bank from 4% to 2.5%, Bank of Britain to 5.5% to 2%), but also dampened the U.S. dollar depreciation. Thus, for the period April 2008 - March 2009, the Management Board of central bank established two main objectives:

- maintaining a share of 55-85% of total foreign exchange reserves to euros, 10-40% of all U.S. dollar foreign reserves for up to 10% for other currencies;
- portfolio of bonds separation in two tranches:

- A medium term investment tranche (approximately 3.2 years) amounting to 3.1 billion equivalent;

- Liquid portion (with a duration of 0.8 years) amounting to 21.3 billion equivalent;

- NBR can take exposures: U.S. government and government agencies or U.S. government sponsored; EU member governments and government agencies or sponsored by European Union member governments; Other governments receiving AAA; Supranational institutions; Private entities issuing bonds guaranteed assets;

• exposure limit private Setting entities issuing asset-backed bonds to 10% of international reserves (over 15% in 2007).

Figure 2 Currency reserve structure (%)

Source: NBR Annual Report for 2008

Management Committee of international reserves (quarries) in the central bank constantly reviewed developments in financial markets and their impact on targets. Lower interest rates has increased the price of government bonds. These are the main

component of the NBR's international reserves, hence the development of bond portfolios than expected. Therefore, the central bank chose a conservative position and prudent management of foreign exchange reserve.

Figure 3 Foreign currency reserve composition of Romania

Source: NBR Annual Report for 2008

International Context - resounding failures (such as that of Lehman Brothers), Merrill Lynch acquisition by Bank of America - created panic in financial markets and investors were facing financial securities had a lower risk (such as government bonds short term) to the detriment of assets perceived as having high risk (such as corporate bonds). International reserve management committee decided to reduce exposure to asset-backed bonds through reinvestment amounts falling due only oligatiuni government. Thus, the end of 2008, the share of government bonds in total foreign exchange reserves amounted to 50% versus 31% in 2007 (Fig. 2).

NBR has issued bonds in the portfolio and Freddie Mac and Fannie Mae (two institutions supported by the U.S. federal government and faced with significant problems of solvency in 2008) but have matured and were not renewed. Also changed and the currency composition of foreign reserves of Romania (Fig. 3.). Thus, share the euro fell to 69.51% in 2007 to 63.02% in 2008 while the share of U.S. dollar increased by approximately 7 percentage points to value of 32.55%. The share of other currencies has fallen from 5.01% in 2007 to 4.42% in 2008.

Figure 4 The evolution of international reserves in the period January 2008 - December 2008

Source: Processed on the basis of press NBR presented at www.bnro.ro/Comunicate-de-presa-1004.aspx

National Bank of press releases, we can see that in late 2008 took place an increase in foreign reserves managed by the central bank. Thus, they peaked in October 2008 when they reached 27,318 million euros (Fig. 4). Also, the monthly releases of the NBR are presented and the main inputs and outputs affecting international reserves. Thus, the outputs were represented by changes in

reserve currency created by commercial banks, income from international reserve management, supply accounts to the European Commission. Also, in June of 2008, some entries were the equivalent of Eurobonds issue of MEF. In addition, in the last three months of 2008 were recorded and entries representing transactions in the interbank market. Exits are the payments and

interest rates due to direct external debt guaranteed by the Ministry of Economy and Finance, European Commission payments and changes in foreign currency reserve up by commercial banks. During October to December 2008 were also recorded output as a result of transactions in the interbank market.

Thus, the result of international reserve management was influenced primarily by increased market value of bond portfolios and increase international reserves. They have increased revenue to the record level of 1.45 billion euros, with 330 million euros more than in 2007. However, National Bank Governor said that BNR was the source of profit international reserve management, but the sale price of approximately EUR 4 lei, while the euro central bank acquired in 2005-2008 at a rate of approximately 3 lei. The aim of NBR in the foreign exchange market was monitoring liquidity, although dealers have made speeches on behalf of banks NBR intention to maintain the exchange rate.

4. Conclusions

Acting in public interest, National Bank made a profit in 2008 due to expectations of good economic development, the prudent and efficient management of international reserve management, but also as a result of currency market intervention required to ensure market liquidity and stabilize the exchange rate.

However, the central bank profitability should not be judged in the same way that a commercial bank - National Bank objective remains to ensure and maintain price stability, while commercial banks seek to maximize profit.

Ethnicity Discrimination in Romania`s Labour Market

Dobre Mihaela Hrisanta
Academy of Economic Studies, Bucharest
mihaelah.dobre@gmail.com

Abstract

By discrimination one understands any distinction, exclusion, restriction, preference, different treatment that puts a person or a group to disadvantage when compared to other persons /groups in similar situations. Discrimination is a general feature of social life and it is rooted into preconception. By preconception one understands rejecting the "other" as member of a group which is invested with negative feelings.

In this article, we analysed the main ethnic groups from Romania (Romanian, Hungarian and Rroma) based on the data provided by the population census (2002), by the Discrimination among employers Survey (2010) and by the European Union Minorities and Discrimination Survey (2009). Rroma population shows the highest level of vulnerability on the labor market in Romania, because they are discriminated both by the employers and by the dominant population as a consequence of the way they are perceived.

Key words: labour market, wage, region, discrimination, ethnicity

J.E.L. classification: J01, J15, J16

1. The study of specialty literature

Modern economic theory of discrimination started with Becker [1] and was later developed by Arrow [2]. They consider that people have certain attitudes towards their co-workers, towards people they supervise and also towards people they buy things from. Consequently they demand some sort of compensation for working with the members of the discriminated group.

Narol [3] defines an ethnic group as a unity that carries culture, namely a social group whose members share a life style

which is going to pass on to the next generation. Barth [4] considered that each ethnic group has its very own culture. In this context we define culture a sum of behaviours, values, specific attitudes that are passed onto the next generations. An ethnic group identifies its own culture as different from the ones of other groups. The markers of a cultural group are: language, religion, origins, etc, and in the case of many populations, as for instance the Rroma, the life style. Marushiakova, Popov [5].

In any society people are categorized starting with the traits (be those stereotypical or not) that are believed to be common to all members of the ethnic group. These traits are usually established on the stereotypes about ethnic groups, Goffman [6] The traits can be mainly positive (see the example of German ethnics of Romanian citizenship who are known to be serious, honest, and rigorous) or mainly negative (the Rroma population: each individual will be seen as a thief, as a dirty person, unreliable, etc. Starting from such discriminations certain social groups like the Rroma population is more discriminated against than other populations [7].

McCall [8] suggested that discriminating against minority groups leads to an increase in the costs brought about by the constant search for jobs. Sloan [9] considered that the probability for a worker to be rejected increases with the duration of looking for employment, and the opportunity cost is lower for the minority group than for the majority one, since the potential earnings of the first group are smaller. The circumstances in the labour market can influence the activity ratio of the workers while the discrimination can lead to unemployment and to the appearance of discouraged work force.

The analysis of the costs related to the discrimination process was done by Amsden and Moser [10] who studied the discrimination based on gender and race. The two authors maintain that legislation against

discrimination will lead to a cost increase in order to find the discriminated groups and then to another type of increase on the part of the employer if the law forces him to interview candidates from the minority groups, candidates whom he will not want to hire anyway.

Carneiro, Heckman, Masterv [11] study ethnicity discrimination in the labour market and explain that this type of discrimination exists because of the difference that exists among ethnicities regarding the specific skills that each ethnicity has. The level of skills is related to the level of education. The above mentioned researchers have shown that in most cases there is a connection between the educational level that the parents have and the one that their children are going to receive.

Bertrand and Mullainathan [12] conducted a field research by sending fake CV-s with names that had several ethnic connotations. They concluded that the applicants with names that suggested minorities were less contacted than the other ones.

Bursell [13] analyses ethnicity discrimination in the Swedish labour market. He conducted some field research (testing by means of mail), which look at the level of discrimination on the part of the employer. In order to establish the degree of discrimination on the part of the employer several CV-s were sent, some of them had a Swedish names and some had foreign names. The results indicated that there is discrimination in all the professional fields where CV-s were sent and that the extent of ethnicity discrimination is related to specific fields.

2. Romania's population according to ethnicity (Romanian, Hungarian and Rroma)

The data provided by the latest census indicate that the main ethnic groups in Romania (as a percentage of population structure) are: Romanians, Hungarians and Rroma (Figure 1). Over the 1930-2002 period of time, the population of Hungarian origin decreased from 10% in 1930 to 6.6% in 2002, whereas the Rroma population recorded an upward trend since 1966 from 1.7% to 2.5%.

Figure 1: Ethnic structure of Romania's population, according to census data from 1930 to 2002

Source: www.insse.ro

At regional level, there is an uneven distribution of the population of Hungarian origin and they are found mainly in the Central Region (29.9%) and in the Northwest Region 19.31% (Figure 2) as they are more attached to the place and community in which they were brought up/raised.

Figure 2: Distribution of the population of Hungarian origin at the regional level

Source: www.insse.ro, Population Census, 2002

In contrast, Rroma are better distributed in the whole country, because they can move easily from one region to another, are more flexible, and the majority of them are found in South and Central Region (Figure 3).

Figure 3: Distribution of the population of Roma origin at the regional level

Source: www.insse.ro, Population Census, 2002

If we analyse the economically active population by professional status based on the three ethnic groups, we notice that there is a large discrepancy among the Romanian and Hungarian workers, respectively, Roma. Hungarians occupy mainly the position of employees, while Roma are comprised in the category entitled other situations in a rather high percentage (18.9%), than those shown above (Figure 4).

Figure 4: Economically active population by professional status according to ethnicity

Source: www.insse.ro, Population Census, 2002

At the Central Region level, where resides the majority of the Hungarians, the discrepancies are not so high anymore, therefore: 28% of Hungarians are employees, 40% work in agriculture, 34% work in their own household and 35% have others occupation (segment of which records the lowest gap between Romanians and

Hungarians concerning the economically active population, Figure 5).

Figure 5: Economically active population at Central Region level by professional status according to ethnic

Source: www.insse.ro, Population Census, 2002

In the South Region, the gap between Roma and Romanians is maintained as recorded at the level of the whole country, because no huge differences are recorded among regions regarding the distribution of the Roma population, compared to the Hungarian population which record 30% in the Central Region. Another explanation of this discrepancy is related to the fact that many Roma do not declare their nationality, in order not to be discriminated against on the labour market. This situation is not common in the case of Hungarian, because these are better perceived by the majority of the population. According to a study made by the RCED (Resource Centre for the Ethno-cultural Diversity, 2003), Hungarians are seen by the Romanian as being: diligent, united and civilized (Figure 6).

Figure 6: Economically active population at South Region level by professional status according to ethnicity

Source: www.insse.ro, Population Census, 2002

3. Ethnicity discrimination in Romania's labour market

According to the Euro barometer of the European Union (2009), 16% of respondents considered that ethnic discrimination was the most widespread and 46% fairly widespread. However, there are many differences at the E.U. level, thus, in Netherlands, France, Hungary and Sweden it is believed that this type of discrimination is very widespread (their percentage ranges between 78% and 80%), while in Lithuania, Poland and Latvia only 4 of 10 respondents share this opinion. In Estonia, Bulgaria and Romania this form of discrimination is fairly widespread (41%, 40% and 46%).

The survey conducted by the European Union concerning minorities and discrimination (EU-MIDIS, 2009), showed that, on average, one of two Roma asked had been discriminated because of his ethnicity in the last 12 months. EU-MIDIS had examined the following cases of discrimination: when looking for work, at work, when looking for a house or an apartment to rent or buy, by healthcare personnel, by social service personnel, by school personnel, at a café, restaurant or bar, when entering or in a shop and when trying to open a bank account or get a loan. Based on the nine cases mentioned above the average rate of discrimination was determined for the last 12 months in:

Bulgaria, Czech Republic, Greece, Hungary, Poland, Romania and Slovakia (Figure 7).

Figure 7: Average discrimination rate (%)

Source: EU-MIDIS

In the Czech Republic was recorded the highest rate of discrimination (64%), but we must start with the presumption that very few discriminated people report their situation to the authorities. According to the same study 79% of the Roma questioned in the seven countries did not report their experiences of discrimination. The reasons behind such a behaviour are related to: distrust that something can be changed (78%), lack of knowledge of the law and of the procedures in case of discrimination (52%), the banality of it (it happens all the time, 44%) and a too much bureaucracy (23%).

In Romania, discrimination against Roma is manifested mainly by the housing agency (14% which means: at a café, restaurant or bar, when entering in a shop and when trying to open a bank account or get a loan), by social service personnel (11%) and when looking for work or at work (9%) (Figure 8).

Figure 8: Specific discrimination experience

Source: EU-MIDIS

Discrimination in the private services for Roma people occupied an important place in all other countries surveyed (Czech Republic-42%, Greece-30%, Hungary-41%, Poland-48%, Slovakia-24%) with the exception of Bulgaria, where working place or looking for a job presents the highest level of discrimination.

According to EU-MIDIS study it was observed a spatial segregation among Roma in the following countries: Bulgaria (72%), Romania (66%), Slovakia (65%) and Greece (63%), which means that they live mainly in areas populated only by Roma. This fact indicates us that they experience high levels of discrimination from the dominant population.

4. Conclusions:

Romania's population consists mainly of three ethnic groups: Romanians, Roma and Hungarians. The latter are largely located in the Central Region and they are perceived by the dominant population in a very good manner (hardworking, civilized, united, etc.). Not the same perception occurs for the Roma population, which is distributed throughout the country, being dominant in the South Region (lazy, lax, etc.).

Discrimination based on ethnicity is widespread, both at the E.U. and at Romania level, especially against Roma population. According to the study made at the European Union level (*European Union Minorities and Discrimination Survey*, 2009), the countries populated mainly by Roma (Greece, Bulgaria, Hungary, Czech Republic, Romania, Poland and Slovakia) have an average discrimination rate of 47%, Romania

recorded a level of 25%. This level of discrimination must be examined in accordance with the number of the persons who declare that they are discriminated, as on average 79% of respondents said they do not report the cases of discrimination they face because they believe they cannot change anything and that the authorities will do nothing in this respect. The Roma population in Romania is mainly discriminated by the housing agency, by social service personnel and when looking for work or at work.

Currently, there are a number of projects which aim at insertion of the Roma population in the Romania's labour market and at reducing discrimination but this remains primarily a problem of perception of the majority population (as we emphasized above, the Roma are perceived in a negative way). There is on the Romania's labour market a spatial segregation of Roma, as they usually live on the outskirts of town, only in Roma communities.

The Knowledge Based Organisation – A Major Challenge of the 21st Century

Dragomir Lucia Mariana

Varga Melinda

Dragomir Constantin

„Lucian Blaga” University of Sibiu, Faculty of Economic Science

lucylucyda2005@yahoo.com

Abstract

The present context, in the opinion of most specialists, is characterised by “the knowledge based economy, organisation and management”. The novelty of these concepts resides in the transition of the issue of organisation capitals from the tangible to the intangible ones, as the performance of a company is nowadays reflected by the proportion of intangible assets in the total of assets. Adapting to the requirements of the new economy requires an organisation which is knowledge-based, sustainable, simpler and with a lower number of hierarchical levels, a flexible and intelligent one. The transition to the knowledge based organisation generates extensive changes in all the areas of the company, especially in its functions and mission. These aspects need a conceptual and pragmatic solution, supported by scientific research.

Key words: knowledge capital, knowledge based organisation, knowledge function, scientific research.

J.E.L. classification: M10, M21, D83

1. Introduction

Peter Drucker stated, in the past decade that “the one thing we can be sure of is that the world that will emerge from the present rearrangement of values, beliefs, social and economic structures, of political concepts and systems, indeed, of world views, will be different from anything anyone today imagines; in some areas, and especially in society and its structures, basic shifts have happened. That the new society will be both a non-socialist and a post-capitalist society is

practically certain. And it is certain also that its primary resource will be knowledge” [1]. We would like to focus in the following part on certain elements of novelty, from the point of view of management science and company economy, elements which point towards the new type of knowledge based organisation. The specialists in economy and management hold the belief that mankind is evolving rapidly towards a new type of economy, of company and management, and according to the opinion of the renown management specialist, Ovidiu Nicolescu, and others, this new type should be called *the knowledge based economy, organisation and management*, an approach that we are also in full support of. “The fundamental characteristic of the new concept resides in assimilating the top progresses of science and techniques and transforming them into a competitive advantage”. [2]

2. Concept and characteristics of the knowledge based organisation

According to the new theory, the organisation is defined as a market structure whose resource is knowledge and main activities focus on creating, purchasing, protecting, learning, sharing, integrating and capitalizing upon knowledge in order to obtain economic and social performance [3].

In the opinion of the specialist P. Drucker [4], the knowledge-based organisation represents the organisational model of the 21st century, and its main components can be foreseen as follows: composed mainly of specialists, a low number of intermediate hierarchical levels and coordination is insured by non-authoritative means (standards, norms, cooperation rules etc.) The knowledge based company presents

characteristics which are different from the common company of our times. The most relevant are [5]:

- changing the ratio of the assets used, with a view to increasing the intangible assets;
- outsourcing the activities non-essential for the company or those very specialized, and insourcing the complementary, highly specialized ones, influenced by the knowledge of the company, which can ensure its competitive advantage;
- adopting, as a general strategic attitude the knowledge based strategies;
- adopting the internal organisation model analogous to the human cognitive model, which is a model reconfigurable due to accumulated knowledge;
- directing knowledge through training more to the top than to the lower levels, which would leave the lower level managers prepare by themselves;
- raising the measures aimed at increasing cohesion within teams;
- integrating the knowledge managers in the company;
- remodelling the entire managerial behaviour in order to create the organisational and motivational framework necessary for capitalising on knowledge;
- restructuring the system for motivating the employees, in terms of performance rewards, using global, group and individual incentives and promoting exclusively on basis of performance;
- simplifying the hierarchical levels;
- transforming the company in one that teaches change and promotes learning how to learn, continuous learning in obtaining and using knowledge.

We will assist to an increasingly complex variety of organisations, aimed at offering adapting solutions to the requirements of the knowledge based economy, a variety that must be adapted to the specific needs of people, knowledge and opportunities. Therefore, one must not search for an ideal company, but a combination of advantages offered by the intelligent company, the

flexible company, the circular company, the reconfigurable company, the multi-cellular organisation, the virtual organisation, the organisation as a living organism, the satellite organisation, the front-back organisation, ambidextrous or sense-send-respond, etc. Following these elements, the knowledge based organisation will become simpler, having a lower number of hierarchical levels, and the acquired flexibility and intelligence become determining advantages in ensuring its functionality and sustainability.

3. The knowledge capital – the strategic resource of the knowledge based organisation

While the industrial revolution in the previous centuries relied on steam power and financial capital, and the role of knowledge was limited, in a modern market economy characterised by intense globalisation process, intellectual resources and knowledge capital are determining requirements for wealth and power in the 21st century. Knowledge is defined by specialists as cumulative stocks of information and abilities generated by the receiver's usage of information [6]. A particular issue that sets apart knowledge from information is the difference in perception, reception and usage. Only knowledge has the ability to generate added value. Without diminishing the importance of the other resources – technical, material, human, financial informational, financial, in the context of the knowledge-based economy, the knowledge resources have a significant impact in the functionality and performance of the company. Knowledge is the defining element of the company of the future. It is, at the same time, raw material, essential production factor, but also basic finite product of the company. Knowledge capital becomes the most important component in the general economy of the organisation's assets. Due to the fact that the specialised literature often refers to the concepts of intellectual capital and knowledge capital, we would like to present the correct manner of approaching the two. The relationship between the two concepts is one of ratio between total and part, because the intellectual capital includes the knowledge capital and the people who own

it, the economic equipment and networks that take part in the product and service creation processes [5].

An issue of great complexity, which has not received a proper enough solution in order to be implemented and monitored in practice, is the assessment of the intellectual capital. Scientific research must provide realistic methods for calculating the value brought by intellectual capital in the knowledge based organisations.

4. The impact of knowledge on the functions of the organisation

Acclaimed management specialists who analysed the role of knowledge in the organisation of the future, on the one side, and the complexity of the activities generated by the general issue of knowledge in the life of companies, on the other side, have identified the following changes in the functions of the company [6]:

a) changes that affect all the traditional functions of the company, determined by :

- the intellectualisation of work processes at the level of each function;
- the transformation of knowledge in "raw materials" essential for all the activities of the organisation;
- the increase of the creative dimension of work processes within each function and activity;
- the outsourcing of some activities and insourcing of others, on a basis of competitive advantage, which alters the content of the functions where these transfers are operated;
- the transition of the emphasis from work processes to the knowledge involved and their owners;
- informationisation, following the bringing to the foreground of knowledge;

b) the ascent of certain traditional functions and activities following the sharing of new and different knowledge, with an impact in :

- the Research and Development function which becomes primordial, especially in the activity of technical design, through inventions and innovations.

- the commercial function and especially its marketing component register a slight increase in importance, in the context of client orientation, of market globalisation and organisation internationalisation;
- the personnel function, which means the fact that the company cannot fulfil its mission in terms of labour force in its traditional sense, but needs the person from a global point of view (mind, commitment, attachment etc.); the new concept of employee motivation and continuous learning raise considerably the importance of these functions and bring about the separation of a new function – the training function;

c) the necessity of determining new functions for the coordination, protection and integration of knowledge, in short the knowledge function, which would comprise the following activities:

- the commercial function and especially its marketing component register a slight increase in importance, in the context of client orientation, of market globalisation and organisation internationalisation;
- identifying the necessary knowledge;
- purchasing knowledge;
- learning and assimilating knowledge;
- creating knowledge;
- stocking knowledge;
- sharing, using and protecting knowledge;
- capitalizing on knowledge.

We believe that it is necessary to study and define the transformations that must take place in the current functions, taking into consideration the role and importance of knowledge in the organisation. The vital importance of knowledge in the contemporary world requires a new function of the organisation, one that ensures the unity in thinking and action, which is "the function of establishing the necessary knowledge, the areas of available knowledge and the way of ensuring, consolidating and capitalizing on the acquired knowledge". This function will need to have established the component activities, methodology and instrument for achieving and evaluating results. [7] The knowledge based activities take place in the

organisation under two directions, generating functionality and sustainability [3]:

- independently, without overlapping with the daily activity of the company, for example the learning processes within certain training or knowledge creation programs in the creation and design departments;
- integrated in the development of other activities in the company - production etc.

Therefore, it is necessary to add to all the traditional functions a component derived from the knowledge based economy, organisation, management; this is the activity to decide the necessities regarding knowledge in order to accomplish the function, to decide on the areas of available knowledge and of the manner of ensuring, consolidating and using the acquired knowledge. It is necessary to restructure the mission of the organisation, for which knowledge has a double role: new knowledge, derived from the requirements of the knowledge based economy and organisation, as well as from the role of the mission to acquire and use knowledge as a competitive advantage. Acquiring top knowledge in order to transform it into competitive advantage can be done only from two sources: one is the latest in scientific research, which must be identified through documenting and purchasing by means of commercial contracts; the second is personal creation (inventions, innovations), as creation is a dominant component in the activity of the organisation of the future [7] These are requirements that grant a new structure and dimension to the mission of the organisation.

5. Conclusions

In the general opinion of specialists, opinion which we also fully support, we do not need to prepare for the organisation of the future, we are already in it and we must adapt quickly or we run the danger of missing the chances and opportunities. It is a chain reaction and if we disregard it we assume high risks and losses, which cannot be evaluated, anticipated or imagined at this time. The organisation of the 21st century will be a chameleon and, like this animal, will survive through capitalizing on the advantages of change.

We believe we managed to point out certain issues generated by the mutations of the knowledge based organisation, which are still unresolved at a conceptual level, and even less on a pragmatic level, and for which scientific research must find proper solutions.

Tax Evasion and Underground Economy: Challenges of the Contemporary World

Dragomir Lucia Mariana

Varga Melinda

Dragomir Constantin

„Lucian Blaga” University of Sibiu, Faculty of Economic Sciences

lucylucyda2005@yahoo.com

Abstract

This paper aims to present the dimensions, causes and consequences of negative phenomena such as tax evasion and underground economy. The present economic context, generated by the financial-economic world crisis aggravates these phenomena, which have a bad influence on the degree of taxation, amplifying the effects of the crisis.

Key words: globalisation, tax evasion, taxation, underground economy.

J.E.L. classification: H26;E62

1. Introduction

It is well-known that human nature always has the tendency to place the personal interest before the general one, just like the tax payers try from the earliest times to reduce the fiscal obligations. For this aim, they resort to the most varied and ingenious methods. In the 21st century, which could be generically called “the century of globalisation”, the effects of the interactions among national economies are of great diversity and complexity. Internationalisation and globalisation are phenomena which have amplified the correlation, interaction and interdependence among national economies, creating business opportunities.

It is unmistakable the fact that globalization is a process that has raised and continues to raise a great interest. The opinions of the specialists in the field are divided: some see globalization as a myth, a completed process; others consider it is only in an incipient phase, one that gives birth to a new state of globality the traits of which are far from being fully comprehended. It has

become obvious that globalization represents the inexorable faith mankind is heading towards, as we all are affected to a greater or lesser extent by its irreversible unfolding. [5]

However, unfortunately, these effects, generated by globalisation, are not always positive. We are witnesses to one of these effects: the economic-financial world crisis. In the context of globalisation, the structures in the global economic environment have become more complex, facilitating the formation of financial bubbles and the faster spread of crises at a global level.

The transmission of the unfavourable effects of the crisis from a country the size of USA to other countries, larger or smaller, is based on the increasing independences of the national economies within the framework of the globalisation of markets, including the financial ones.[12]

The economic-financial crisis has spread with a great speed at a global level, and its pace and amplitude show how interconnected it is to the world we live in. The main fiscal effect of globalisation resides in the fact that the control of the tax evasion phenomenon, a disturbing but thriving phenomenon of the contemporary world, which is becoming more and more difficult to achieve.

2. Concept, forms, causes and consequences of the tax evasion phenomenon

Tax evasion is one of the economic-social events of the greatest importance with which all the states are confronted, to a greater or lesser extent. Tax evasion is the main cause for the decrease of fiscal revenues. It is a negative economic phenomenon, present in all the world economies, at different, but high, levels, determined by a range of factors,

which include the psychological ones.[1] Unfortunately, the only thing that can be effectively done in this area is to limit the consequences of the phenomenon. Eliminating tax evasion is an impossible objective. The specialised studies [9], define tax evasion as the licit or illicit procedures with the help of which those interested avoid submitting their taxable matter to the obligations imposed by the fiscal laws.

According to the criterion of legitimacy, tax evasion can be legal, licit, and illegal or illicit.

Legal tax evasion means that the tax payers find certain means and dodge paying taxes, completely or in part, due to some shortfalls of the law. Therefore, this form of tax evasion is only possible when the law either has gaps or presents inadvertences. The tax evader, therefore, uses legal means under the form of gates left open by the lawmaker himself. This fiscal reality can be regarded as an exception from the principle of tax neutrality. In an analysis of the principle of tax equity, C.I.Tulai [11] believes that this principle refers to equality in terms of taxes. V. Bârle [3] shows that equity is a principle of ethics and that it will always have a certain degree of subjectivity, depending on the way in which it is interpreted by the ones targeted – it can be economic, social or fiscal. The actors of this process are the state and the taxpayers.

Illicit tax evasion refers to the action of the taxpayer who breaches the legal prescriptions with the aim of not paying the due taxes. Tax evasion is illegal when the tax payer who is obliged to supply in support of his or her declaration certain justifications, establishes them in a random way with the aim to mislead the authorities or when the revenues undeclared are by their nature materially justified but their insufficiency is to such a degree that the will of the evader becomes obvious.[8]

Illicit tax evasion is an event permanently active in the economy, characterised by a high degree of adaptability to the changes in the economy and materialised in various forms of manifestation, such as:

- submitting false declarations;
- providing fake payment documents;
- creating fake accounting records;
- not declaring the taxable matter;

- declaring lower revenues than the real ones;
- keeping of a double set of books: a real and a fake version;
- sales without invoice;
- issuing invoices without a real sale, which hide real taxable operations;
- manipulating the balance sheet;
- not paying the taxes that are already imposed.

Tax evasion has always been ethically and also legally condemned. From a legal point of view, committing these deeds leads to applying certain responsibility measures, depending on the manner they are done, the subject of the crime and the damage produced.

As for the causes of tax evasion, they are multiple and complex. We believe that one of the first and maybe most important causes is the fiscal burden. From this point of view, one can even speak about a real vicious circle because, the higher the fiscal pressure is, the more extensive tax evasion is, and the more extensive tax evasion is, the more will fiscal pressure weigh on the shoulders of disciplined taxpayers, who fulfil their legal obligations. In this context, establishing limits of fiscal pressure is an issue that has preoccupied specialists even from the end of the 18th century, when economists and legal experts claimed that taxation should be as loose as possible. The increase in fiscal pressure in the past two centuries is based on an expansion of the economic and social role of the state; consequently, taxes and fiscal pressure present the same upward tendency as public expenses. In the category of subjective causes of tax evasion, we would like to mention the possibility to assume the risk or the existence of the phenomenon of corruption of the fiscal authorities.

We believe that the activity of inspection represents a decisive factor in administering the phenomenon of tax evasion. In this context, in order to exert the functions of tax inspection it is necessary to have specialists selected based on criteria of professionalism, also to have an efficient management, with well motivated and high morality implementers.

3. Concept, causes, forms of manifestations and implications of the phenomenon of underground economy

Underground economy exists in all countries of the world, in various extents as compared to the GDP. Defining the notion of underground economy, as well as its most severe component, money laundering, a nuisance on all levels, has been and still is the subject of various studies in the field. They are justified by the need to know their dimensions and size in society, as well as establishing the most efficient prevention and counteraction measures.

The underground economy raises major problems and is a challenge for international organizations as well as for national public authorities. The latter must find solutions for preventing or at least limiting the effects of such a phenomenon on the national and international economy.

The names under which underground economy is referred to in the specialized studies are:

occult economy;

- concealed economy;
- hidden economy;
- parallel economy;
- adjunct economy;
- phantom economy;
- invisible economy;
- informal economy;
- dual economy;
- cash economy;
- grey market;
- unregistered economy;
- secondary economy;
- counter-economy etc.

As for the participants to the activities that form the underground economy, two categories of people can be identified:

- those who obtain revenues exclusively from the underground economy ;
- the people who receive incomes from the legal, but also from the underground economy.

There are multiple forms of manifestation of the underground economy. Among these, we would like to mention:

- tax evasion and fraud;
- the black labour market;

- more severe practices, such as corruption etc.

There is an extensive literature concerning the possible causes of the underground economy, among which we would like to mention the following types:

- fiscal pressure exerted by taxation[4];
- pressure from the regulations imposed by the state[6] ;
- fiscal morality: the attitude of the citizens towards the state[10].

The social impact of underground economy is a strong one and is tightly connected to a series of phenomena such as: different types of crimes, among which we would like to mention:

- drug abuse;
- mafia-type organisations;
- work exploitation through the black market;
- money laundering;
- violating human rights;
- environmental pollution, etc.

The most dangerous structural element of the underground economy is represented by its criminal sector, more particularly the totality of illegal economic activities that refer to the production, fabrication, accumulation, change, redistribution of merchandise, activities and goods outside the civil circuit, as well as other criminal activities oriented towards obtaining a certain part of the product of the legal economy.

For a long time, economic analysts have considered corruption as a cultural and political issue, whose decrease or elimination would be impossible to achieve [2] Thus, corruption suppression was not regarded as an objective of the development reforms, but as a natural component of a country as exogenous as, for instance, its geography. [7] Corruption is a phenomenon that appears in the most varied areas, under different and complex forms and interactions, however, in terms of number and dimension of cases, it dominates the fiscal and budgetary area. Corruption is present in emerging countries as well as in well developed ones. Although the corruption potential is specific to each country, it has been noticed that the types and spread of fiscal and budgetary corruption are influenced by the general fiscal structure of the country and of the fiscal management systems used by the respective country.[7]

As for the black labour, another element of the underground economy, its causes are diverse and usually have a pregnant economic side. Clandestine work allows the one that performs it to increase his or her resources, and the one that uses it to reduce the expenses and, therefore, both avoid fiscal and social expenses.

An important aspect of the underground economy is the negative effects of the decrease and reducing of the development of the official economy. A study by AT Kearney in collaboration with Friedrich Schneider, economy professor at the Linz University, shows the fact that the proportion of underground economy in Romania's GDP reached 35% in 2005; in 2010 it totalled up to 40-50 billion Euros. "When global economy goes through a recession, more and more people will be tempted to act outside the legal framework. This is why it is important to understand the phenomenon so as the states could take the necessary decisions for recovering the lost income and protecting the workers ", said Schneider.

4. Conclusions

The underground economy and tax evasion are major problems of our society, even more so in the context of the present economic-financial world crisis. At the basis of these negative phenomena is the human desire to accumulate money, goods or other values. In the economic life at the beginning of the third millennium, these phenomena are more and more present. We believe that in order to accelerate the overcoming of the crisis, it is important to monitor and limit these phenomena.

Activity Based Costing versus Traditional Technique

Dragomirescu Simona Elena

Solomon Daniela Cristina

"Vasile Alecsandri" University of Bacău, Faculty of Economic Sciences

symonna21@yahoo.com

solomon_daniela@yahoo.com

Abstract

One of the current methods of management is Activity-Based Costing (ABC), method that allows the company to understand more clearly how and on what activity/product profit is achieved. In essence, the method involves identifying all specific activities of a product or service and distribution expenses to achieve them with greater accuracy than with traditional accounting methods. This involves not only costs determining closer to reality, but a better understanding of the factors that determine costs.

Key words: ABC method, traditional commands method.

J.E.L.classification: M41 - Accounting.

1. Conceptual approach on the ABC method

In small production industrial enterprises, a typical situation involves "the existence of good products or services, from a technical point of view, and delivered on time; customers are satisfied; productivity is around or above the industry average." And yet, after the first years of operation and development, profitability reached an unacceptable level because, by using traditional methods, "one may not know for sure what products bring in money and what products spend it." Therefore, it must move towards a new computer system that provides information about the "true cost".

The concept of the ABC method assumes that not the products consume resources but activities do. In other words, **activities consume resources and products consume activities**. After developing this method it was found that the traditional methodology of

calculation of costs may create significant differences in the costs of final products due to the allocation of indirect costs. The difference "may obstruct the final price of outputs and, also, may lead to erroneous management decisions" - say the promoters of this methodology applied today, particularly by large companies alert to any possibility of reduction and cost control.

From those above presented, the **ABC cost calculation model** can be schematically presented as follows:

Figure no 1. ABC Calculation model

(Source: Caraiani C., Dumitrana M. (cord.), „Management Accounting and Management Control”, InfoMega Publishing house, Bucharest, 2005, p. 235)

In contrast, traditional technique can be schematized as follows:

Figure no 2. Traditional technique of costs damage

2. Comparative study on ABC method versus commands method

Industrial enterprise "ALFA" manufactures and sells "slewing rings"- "L" type, articles 20101, 20102 and 20103 (coded SRL.20101, SRL.20102 and SRL.20103), according to received orders, for

which production cost is established through the **traditional commands method**.

Data on production, sales prices and costs for the three products manufactured by the company in June 2010 are the following:

Table no 1. Data on production, sales price and costs for SRL.20101, SRL.20102 and SRL.20103 products

Products	Produced and sold output	Unit selling price	Unit cost
0	1	2	3
SRL. 20101	300 pieces	1135.00 lei/ piece	945.86 lei/ piece
SRL. 20102	300 pieces	1813.00 lei/ piece	1510.76 lei/ piece
SRL. 20103	250 pieces	1562.00 lei/ piece	1301.37 lei/piece

Company management is concerned about the costs of the three products, especially of SRL.20101 product, because, at an increase in raw materials costs, as projected for the near future, its manufacture will involve expenditure that will exceed the average market price, which will make it uncompetitive. (According to studies made on the market, there was a slight increase in purchase prices of raw materials (from all known domestic suppliers) and it is expected that the next period, 3-5 months, their prices will continue to grow.)

So, to see which of these three products contribute more to income growth and, therefore, to which the company would have to increase production volume, a request was made for more detailed analysis, using newer ABC system methodology for determining total cost and compare obtained results with those resulting from the application of internal costing system, respective the commands method.

In this regard, supplementary information was collected. The cost of direct labour hour is 12.5 lei. The products are manufactured in batches of 10 pieces.

Table no 2. Data on direct costs incurred for SRL.20101, SRL.20103 and SRL.20102 products

Elements	SRL. 20101	SRL. 20102	SRL. 20103
0	1	2	3
Direct costs on raw materials	160 lei	300 lei	245 lei

Elements	SRL. 20101	SRL. 20102	SRL. 20103
0	1	2	3
- slewing rings balls (lei/piece)	75 lei	150 lei	125 lei
- steel bar 42CrMo11 (lei/piece)	85 lei	150 lei	120 lei
Direct labour (hours/piece)	16 hours	22 hours	20 hours
Equipment operation hours/product	4 hours	6 hours	5.5 hours

Indirect costs are absorbed in the cost of products according to the number of orders manufactured for sale and there were identified on **activities** as follows:

Table no 3. Data on indirect costs

Activities	Costs	Cost Inductors
0	1	2
Indirect production costs	321013.40	
- Equipment maintenance	110466.40	equipment operation hours
- Release manufacturing	67979.30	number of manufacturing orders
- Receiving material	50984.50	number of produced orders

108000.00	172500.00	123750.00
197048.10	265975.90	195053.40
305048.10	438475.90	318803.40
1016.83	1461.59	1275.21
1135.00	1813.00	1562.00
118.17	351.41	286.79

Analyzing the full costs of products, determined by the ABC methodology, and comparing them with prices of sale (competitive), it is noticed that all three products are profitable, SRL.20103 and SRL.20102 products being the most competitive.

For SRL.20101 product, however, although they succeeded in producing it at a lower cost than market prices, the situation is not very favourable under the conditions in which, as mentioned, a grow of raw materials in the near future is forecast.

Comparison of unit costs determined by traditional method and by ABC method

Examining the two sets of results, the company management can notice the difference between the results offered by the two approaches: ABC and the internal used system:

Table no. 7 Comparison of unit costs determined by commands and ABC methods

Products	Full unit cost (lei/piece) determined by	
	ABC method	Commands method
0	1	2
SRL.20101	1016.83	945.86
SRL.20102	1461.59	1510.76
SRL.20103	1275.21	1301.37

Products	Differences	
	in absolute value	in relative value
0	3	4
SRL.20101	+70.97	6.98 %
SRL.20102	-49.17	-3.25 %
SRL.20103	-26.16	-2.01 %

Figure no. 3. Comparison of costs unit determined by commands and ABC methods

Comparing the costs established by the two methods, we find that when costs are allocated on the developed activities, SRL.20101 product becomes more expensive than initially considered, its cost increasing from 945.86 lei/piece to 1016.83 lei/piece meaning with 70.97 lei or 6.98%. How the market price is very close to cost price, any increase of expenses with making of this product or with reducing its production volume will make the product not competitive for business any longer. (The decrease in production volume, fixed costs allocated on fewer made products, will lead to increased production costs/complete)

SRL.20103 and SRL.20102 products are competitive for the firm and, therefore, should be held in the portfolio of products manufactured by the company. To these, we find that by applying new ABC calculation method, costs are lowered as compared to those established by the traditional method, with 49.17 lei/piece, meaning 3.27%, for SRL.20102 product and respectively, 26.16 lei/piece, meaning 2.01%, for SRL.20103 product. In addition, market prices exceed "reasonably" production costs (complete).

In conclusion, based on relevant results and taking decisions based upon analysis provided by the new ABC system, the management company should decide to exclude SRL.20101 product, while they still can maintain its cost below competitive market price, and turn its attention to increasing production volume for SRL.20103 and SRL.20102 products. Even if it would keep manufacturing the first product, the department "Supply" cannot reduce the cost of raw materials needed (as originally leadership thought), and in addition, an increase of production cost/complete or a decrease in market selling price will make the product impossible to sell.

Energy Efficiency Contracts – A Challenge for Public Institutions

Dragu Gabi Georgiana
"1 Decembrie 1918" University of Alba Iulia
georgiana.dragu@yahoo.com
Marinescu Desiree
Academy of Economic Studies, Bucharest
desiree_marinescu@yahoo.com

Abstract

This research contributes to the understanding of the barriers and incentives on the energy efficiency market.

We may say that the universe tends from a chaos towards an organized status, in other words from predictability to uncertainty, if we look to the second law of thermodynamics. Energy is continuously available as unavailable energy until completely disappears. This is commonly referred to as entropy, that in all energy exchanges, the potential energy at a certain state will always be less than that of the initial state, if no energy enters the system.

The aim of this paper is the practical application of a solution meant to increase the quality of the accounting information delivered to the users. Particularly, there was a need to highlight the necessity of adapting the chart of accounts of public institutions, the budgetary classification, to the evolution of contractual relations of public institutions, including energy efficiency contracts. The prospect of approaching the partnerships subject is new in this field.

From the epistemological point of view, the paper provides a mixture of normative research and constructive accounting. The research strategies used included documentary and analytical research, formulation of opinions by benchmarking and case studies.

Key words: European System of Accounts ESA95, partnership contracts, energy efficiency contracts, the second law of thermodynamics

J.E.L. classification: M41

1. General Accounting Framework

According to Ishikawa's observation, the traditional accounting systems have proved to be unable to keep pace with change.

Lately, in literature new models of financial reporting, including an integrated perspective of all the mechanisms that generate and consume value – natural, social, information environment etc. are provided.

Accounting guideline normalization efforts are mainly directed towards convergence and tackle only briefly social and environment reporting issues. These are taken into account by the legal methodologists, who show some opening, but only for financial reporting purposes out of the financial statements.

The accounting practice is in constant motion, according to Professor M. Ristea "presently, by generalization in accounting only one principle can be known, the one of change." [1]

The interdisciplinary nature of the decision determines as an inevitable consequence the multidisciplinary nature of accounting.

2. The General Framework Regarding the Energy Efficiency Contracts (EEC)

2.1. The EU General Framework regarding the Energy Efficiency Contracts

A compressive framework of directives and regulations to improve energy efficiency in energy, using products, buildings and services is in force within the European Community laws. These include the Eco-Design Directive, the Energy Star Regulation, the Labeling Directive and its 8 implementing Directives, the Directive on

Energy End-use Efficiency and Energy Services and the Energy performance of Buildings Directive. The European Commission encourages Member States towards an ambitious implementation and enforcement of these instruments to ensure rapid services and a long-lasting market transformation. Where there is scope for additional legislative and supporting measures to be taken to strengthen and accelerate the development of this market, these measures will also be given priority. [2]

Recently, European Commission (under the Intelligent Energy Europe Programme) initiated two projects that look into energy service market in the EU. The first one is commissioned by the Berliner Energieagentur (Berlin Energy Agency) and is called EESI – European Energy Service Initiative. It aims to broadly promote the implementation of Energy performance contracting in Europe. The second one is commissioned by the Wuppertal institute and is called Change Best Program. It aims to promote the development of an energy efficiency service market. [3]

Buildings have an impact on long-term energy consumption. Given the long renovation cycle for existing buildings, new and existing buildings that are subject to major renovation should therefore meet minimum energy performance requirements adapted to the local climate. As the application of alternative energy supply systems is not generally explored to its full potential, alternative energy supply systems should be considered for new buildings, regardless of their size, pursuant to the principle of first ensuring that energy needs for heating and cooling are reduced to cost – optimal levels. [4]

2.2 The Romanian General Framework regarding the Energy Efficiency Contracts

“We will leave a steam engine free of charge to you. We will install these and will take over for five years the customer service. We guarantee you that the coal for the machine costs less, than you must spend at present at fodder (energy) on the horses, which do the same work. And everything that we require of you is that you give us a third of the money, which you save.” [James Watt, 1736-1819] [3]

Public private partnerships (PPPs) are developed as a way of fulfilling public tasks in partnership between a public sector authority and a private enterprise. The agreement shares the risk of the project while, generally, the public entity retains the ownership of the project and the private entity transpose the project into practice. This approach develops new dimensions in the new global era. The partnership shows the common interest of the parties involved, joined efforts, understanding of the each limitations. The PPPs are mainly established for infrastructure related projects and represent a key element for delivering modern, high quality, more competitive public services. For example, the PPPs developed by UK Government have three broad objectives in mind, namely:

- to deliver significantly improved public services, by contributing to increases in the quality and quantity of investment,
- to release the full potential of public sector assets to provide value for the tax payer and wider benefits for the economy,
- to allow stakeholders such as the users of the service, tax payers and employees to receive a fair share of the benefits of the PPP.

A new approach is the PSPPs as a development PPPs, referring to public social private partnerships. We can say that it represents an extension of the PPPs in social and educational services. For the public side of the partnership this means that solutions are found for public tasks of the common good or welfare provision, firstly through a cooperative form of outsourcing (including financing) and secondly by involving additional partners from private and social entities in doing things which the state has responsibility for. For the private side of the partnership it provides possibilities for new kinds of business activity through the cooperation with the state and social entities. In this way, social entities have the opportunity to act in their ideal role of intermediaries between the state and private sectors. [5]

3. Transposing of EU Provisions into the Romanian Legislation

In 2008, the Government Ordinance no. 22/2008 transposed into the Romanian legislation the EU Directive 2006/32/CE8 regarding the energetic efficiency to final users and energetic services.

The Government Ordinance 22/2008 defines the energetic services that constitute the foundation for the energetic performance contracts.

The same ordinance also defines for the first time in the case of Romania the energetic services companies (ESCOs).

Figura 1. Energy services – definitions

Source: after Beyl & Schinner 2008

4. National Strategic Framework

Romania has engaged in reducing the energy consumption with 13.5% by 2016, relatively to the medium level of energy consumption between 2001 and 2005.

The National Strategy for Energetic Efficiency (approved by Government Resolution no. 163/2004) and the National Action Plan for Energetic Efficiency (approved by Government Resolution no. 1661/2008) presents specific measures for the achievement of these objectives.

In 2010 an updated framework of the Directive was adopted, strengthening the energy performance requirements aiming to reduce the carbon footprint of public buildings to an energy standard of nearly zero by 2018, and for this to be extended to all buildings by 2020. It is expected that this will reduce the overall EU energy consumption by 5-6%, resulting in a 5% drop in emissions.

These studies show there is a huge market potential for ESCOs within Energy service contracting.

The increase of energetic efficiency within the public institutions will have a socio-economical impact. According to the current legal norms, the impact upon public institutions is of approximately 40 years, sometimes longer. The potential reduction of energy expenses for these buildings is very high.

In July 2009, the European Commission adopted a set of measures aimed at simplifying the management of the Cohesion Policy. Local authorities aiming to improving local energy management can receive financing for:

- construction or renovation of buildings for disadvantaged groups
- creation of "green" jobs and training sessions (e.g. energy managers, technicians, architects, builders, counseling services etc.) 100% funded by the European Social Fund
- development of specific financial instruments (urban funds, financial incentives for loans etc.).

In the future the biggest impact will be done by utilization of Structural Funds. In this context the funds for educations units rehabilitations process are included in Regional Operational program 2007-2013, Priority Axe 3 "Improvement of Social Infrastructure, chapter 3.4", "Rehabilitation/ Modernization/ Development and equipment provision for education infrastructure in primary, secondary, university and continuous professional training sectors education infrastructure". Official call for projects launched in April 2008. The program is managed by the Ministry of Regional Development and Tourism. [6]

Total available budget is 284.91 Meuro, from which 85% from EU funds and 15% from national contributions.

The project has 3 major target groups:

- primary, secondary and university units: 130 units;
- creation and development of pre-university and university campus (complex of buildings): 30+35 units;
- centers for contributions professional trading: 15 units;

A specific point in projects eligibility criteria is "utilities modernization" which, probably, can be a subject for increasing energy efficiency

Eligible project initiator:

- local authorities as defined in Public administration Law no.215 from 2001;
- public universities certified according to the Law no. 88 from 1993;

Due to the many legal, financial and organizational barriers, a Green Card on this subject has not been developed yet.

5. Financing Mechanisms

Energetic efficiency contracts may include, in addition to the energy supplier and the beneficiary of the means of improving the energy efficiency, a tertiary that provides the capital for the certain measure.

The German energy efficiency contract model stipulates that the payment of the capital provider is made from the savings obtained from the reduction of energy expenses, as a direct consequence of the implemented measures for the improvement of energetic efficiency.

The owners and legal administrators of public commodities subjected to some CPE projects may take commercial loans to finance the investment and the operational and maintenance expenses or they may resort to private financing by signing public private partnership (PPP) or concession agreements.

Based on the legal provisions in place, the most important principle of public finance is that it is mandatory to spend public funds according to their destinations mentioned in the budget. All the financing activities of programs and projects at the level of public institutions should comply with this basic principle.

Making of payments directly from the collected income is forbidden too, except for the cases in which the law stipulates otherwise. No expenditure from the local public funds can be engaged, ordered and paid if there is no approval according to law and do not have budgetary provisions and financial sources.

However, the local public administration authorities may contract or secure loans according to the law in effect, only with the permission of the commission for the authorization of local loans.

In accordance with the law of local public finances, the local authorities "are forbidden access to loans or to secure any kind of loan

if the total annual debts representing the outstanding installments of contracted and/or secured loans, the reprises and afferent commissions, including the ones afferent to the loan pursued for that year exceed the limit of 30% of the total revenues."

The contracted or secured loans that ensure the pre-financing and/or the co-financing of projects that benefit from pre- and post-adherence EU funds are excluded from the rule of 30% of the total revenues of the particular authority.

6. The Accounting Operations Applied to Concessions

According to ESA95 regulations, when the assets (in the form of constructions or other structures) are counted as governmental assets registered in the State Balance sheet, the capital expenses are registered into the accounting the moment they arise, not at the end of the restoration period. The pay in installments of the constructor may establish the moment in which the accounting registration is made.

However within Romanian accounting, the economic agents from public institutions register the assets that come from private sources after the concession contracts expire and the commodities are amortized.

7. The Role of Local Authorities – Examples of Associations

The association "Energy Cities Romania" is a nongovernmental organization, established in 1994 under the Phare Programme with support of the Energy Cities network. Since 2006, the association headquarters moved to Brasov.

"Energy Cities Romania" meet the 31 municipalities interested in improving energy efficiency in urban public services (heating, public lighting, water and gas supply, storage and transportation of waste etc.) and the promotion of renewable energy sources and protection of environment.

Main activities:

- Participation in regional, national and European projects;
- Organization of conferences, seminars and other meetings at regional, national and international level;

- Establishment of a database at local and national level;
- Support to local authorities in elaboration and monitoring of a sustainable energy policy;
- Dissemination of information about experiences, technologies and energy efficient equipments;
- Representation of members at national and European level.

8. Study Case – Brasov City

- Vice-President of the European Network "Energy Cities" – European Association of Local Authorities for Sustainable Development in terms of energy;
- President of National Network "Energy Cities Romania" – Support structure at national level of the Mayors Convention initiative;
- "Action Plan for Sustainable Energy" (SEAP) approved by the County Council in August 2009.

In 2010, The Energy Programme of Brasov City for 2010-2012 was prepared and submitted for approval to the Local Council. The programme was approved by the Local Council Decision no 157 / March 2010.

The priorities for Brasov City included under the program are:

- Administrative buildings,
- Public Lighting,
- Under graduate educational institutions,
- Public transport,
- Residential sector.

Premises:

- Analysis of annual consumption along with the measures considered in selection of the energy rehabilitated buildings;
- Benchmark year for monitoring is 2008;
- Analyses and comparisons were made by type of activity: nursery, primary and high schools;
- The monitoring was made monthly on each institution – 2008/2009/2010;
- During the year 2010 have been closed or merged 15 kindergartens, 3 primary schools and 4 high schools;
- The general level of comfort in educational institutions has steadily risen during the period analyzed;

- Prices of utilities increased constantly during the period under review, and additionally VAT increased from 19 to 24% - in 2010.

Figure 2. Success Story: Kindergarten no. 19 – Barbu Lautaru Street

Savings in kWh 58%
Savings in RON 79%

Measures: central heating installation (disconnection from district heating), building the attic

Figure 3. Success Stories: High Schools "Sfintii Voievozi" and "N. Titulescu"

Savings in kWh 52%

Measures: central heating installation (disconnection from district heating), energy rehabilitation building B

Figure 4. Evolution of total energy consumption in educational institutions during the monitored period

Consum total în kWh (grădinițe+școli+licee)

Consumption reduction 11%

Total savings 12.286 MWh/year

Local authorities have a key role in mitigating climate change. More than half of the emissions of greenhouse gases are

generated in and by cities.

At the same time, 80% of the population lives and works in cities, and consume up to 80% of energy. [7]

9. Conclusions and Recommendations Regarding the Accounting of Energy Efficiency Contracts in Public Institutions

The question that was raised during the research about the validity of the instrument could be explored in the further research.

Since the economical operations in accounting are registered the moment they arise, the accounting cannot include future operations whose value is unknown.

Complicated administrative procedures and non-compatible accounting rules are also among the most frequently mentioned regulatory barriers.

Since the main objective of this kind of contractual relation is the economical efficiency not the technological solution and is necessary for the implementation of an accounting model that can highlight the value of the reduction in the energy invoice of the institutions as well as in the payment of services provided by different companies from the value of energy saving, we recommend that in order to monitor the efficiency, a extra-accounting evidence must be developed in which the amount of energy to be reduced is estimated for each period as a consequence of the restorations together with the amount of energy that was effectively saved during that period.

Moreover, the introduction of a budgetary-economical classification assigned to a code that reflects this type of economical efficiency contracts is recommended.

For now, Romania has a legal framework regarding the energetic efficiency services that follow the EU requirements through the adaptation of European Directives.

However, an authority that desires to implement CPE models will confront with practical difficulties associated with the modes of applying these regulations. There is a need for an institutional framework that can

assist in the implementation of first CPE projects in Romania. [8]

Perspective for the Development of Romanian Cultural Events

Dridea Catrinel Raluca
Romanian-American University of Bucharest
dridea.catrinel.raluca@profesor.rau.ro

Abstract

This paper analyses the importance of events as a major component of the tourism industry. Among its characteristics, the cultural events have grown to represent a special method to attract tourists all over the world. More than that, the leisure activities have become sophisticated with various opportunities to enjoy free time.

In this context, it is important to identify positively influence of cultural events for increasing the Romanian tourism.

Key words: tourism, cultural events, development

J.E.L. classification: L83

1. Introduction

Over the years, the tourism industry has turn into a major player on the global economic market. Its basic sectors are more and more important, as tourists have become especially demanding. The change of tourist desire from a passive vacation to an active one has determined the tourism firms and operators to reevaluate their offers and conceive new and unique ideas for an enjoyable holiday.

The lodging facilities, the food and beverage ones, and the transport system were considered the main framework for producing and commercializing the tourism products.

The globalization process has deeply impact all economic fields, including also, the tourism activities. Competition between small or large tourism organizations has accentuated and therefore it appeared necessary to anticipate the tourists' needs and wants and to offer a new and different product. As a result, the leisure facilities and services have represented a method to diversify the offer by surprising with the

variety they encompasses: sports, events, cruises, theme parks, marinas, etc.

The events sector influences the tourism circulation, stimulating the lack of dependence from sezonality, with perspective in any period of the year. But the development of the event industry must be connected to the general and tourism specific infrastructure, in order to obtain the proper positive response. In this circumstance, the growth of tourism represents the basic strategy for the development of other sector component, like the event one.

2. Cultural events

The events spectrum is a large one containing activities such as [1] : *business and corporate events; cause-related and fund-raising events; exhibitions, expositions and fairs; entertainment and leisure events, festivals, government and civic events, hallmark events, marketing events, meeting and conventions events, social events, sport events*. This allocation offers a detailed perspective over the events' diversity and also possibility to be appealing to different kinds of tourists.

Other authors present the events by underlining the main contents [2]: *cultural events, sport events, and business events*.

Regardless of the way event activities are explained, the fact that there are a multitude of theme and there are several possibility to fructify theme make this one of the most important aspect of tourism growth.

More than that, the events must contribute significantly to the development of a destination, by enlarging the number of tourists received, by promoting the destinations' attributes, and local communities particularities, the tourism attractions, and so on. Hence, the events activities offer important benefits, and a strategic planning event has the ability to

determine representative outcomes like [3]:

- Generating the possibility to enhance the attributes of a destination, and to determine important benefits, but also to be known as a tourism destination;
- Influencing the importance of the destination by efficiently attracting tourists that are interested in returning and also profit by word of mouth;
- Developing the competitive position as a major destination, for the tourism market;
- Producing an increase number of tourists, and therefore increasing the revenues obtained;
- Generating interest for all activities and facilities offered by the destinations;
- Improving the proper marketing activities of the local tourism organizations, by using special promoting ideas, attract media, and others; Etc.

Media	6

Society at a Glance, 2009: OECD Social Indicators, OECD Publishing 2009;

International survey presents different countries regarding the free time activities. Among the main activities specific for leisure are watching TV and listening to radio, sports, visits and socializing activities but also, event participating as usually spectators. The percentages are very low in rapport to 100%, the higher position been occupied by Germany, Norway, Spain, UK and Italy.

The cultural events has a significant importance as it usually marks local community events, particularly festivals with themes like: art , music, film, food, science, religion, wine and others. It also refers to spectacles and leisure events as fairs.

These events are generally interesting for both the foreign tourists and the local ones because of the rich content in cultural community values and traditions. The main purpose of the festivals is to celebrate the locals by electing a theme that represents their social view and ideology and cultural heritage.

Over the time, tourism has grown these local event have become more well known and shared with a variety of travelers. This context resulted in international tourism events, providing a unique insight into a society's traditions, their culture, religion, music, customs, and language.

Cultural events are now perceived joined to the destination they occurred in, as a symbol to the notoriety of the city or country. For example:

Munich, Germany – Oktoberfest, India - Holi Festival, New Orleans, LA - Mardi Gras, Brazil - Rio de Janeiro Carnival, Dublin, Ireland - St Patrick's Day, France, Cannes - Cannes Film Festival, Pamplona, Spain - Running of the Bulls, Montreal, Canada - International Jazz Festival, Berlin, Germany – Love Parade, are just a few of the most popular events that captivates tourist all over the world.

Based on the research of specialists a structure of cultural event can be developed, based on the purpose of the event [2]:

High-profile general celebration of art generally tries to reach higher standards, and obtained increased levels of incomes.

Festivals that celebrate a particular location – there aim is to bring people together to celebrate their local destination. The difference of size is strictly connected to the organizations, which are volunteer groups or the local authorities.

Art-form festivals remark specific form of arts, focusing on the special audience appealed by this segment, offering the possibility to realize unique events.

Celebration of work by a community of interest refers to categories of people such as seniors, young, or disabled.

Calendar takes into account the religious and cultural festivals.

Amateurs art festivals attracts a variety of people, with accent on the competitiveness degree and has no particularities explained.

Commercial music festival has an important role due to the large number of participant.

3. Romanian cultural events and perspectives

Romanian tourism has always taken into account the importance of tradition and heritage. Promoting the cultural resources and objectives has been an essential element in presenting Romania as a famous tourism destination.

The tourism sector has increased its importance by accentuating the traditional characteristics of popular art, of handcrafting and famous artistic creations like [4]: *crafts and cottage articles* – Horezu, Curund, Marginea, Vama, *dance, music, traditional clothing* –Tara Motilor, Tara Maramuresului, Tara Zarandului, *local architecture and technique, traditional events* – Samba Oilor, Targul de Fete, Festivalul Narciselor, Cocosul de Horez,etc.

Beside this, there are cultural events that are well known, offering some examples such as: *music festivals* – George Enescu Festival, Cerbul de Aur, Artmania Festival, Sibiu, Transilvania International Guitar Festival, Jazz Spring Festival, Bucharest, Europafest, Peninsula, Bestfest and others; *cinema festivals* – Dakino Buharest International Film Festival, Comedy Cluj, Alternative international Short Film Festival, Astra Film Festival, Anim'est Animation Festival, etc; other festivals – Sighisoara Medieval Festival.

Despite the various forms of cultural display and marketing activities the number of tourists has declined, indicating a lack of a general policy that can be orientated to different types of tourism. For instance, the main event facilities are in limited number as the figure below can demonstrate:

Romanian Spectacles-Events Institutions

Fig. 2

Event institutions	units		
	2003	2004	2005
Legitimate Drama	57	57	59
Puppets' Drama	25	24	24
Opera	7	7	7
Musical theatre, music hall	9	8	
Philharmonic and symphonic orchestra	18	17	18
Traditional Orchestra	8	7	6
Folklore groups	22	24	24
Circus	1	1	1
Total Units	147	145	146

Sursa: Masterplan pentru turism –partea I, www.mdlpl.ro

The image is a poorly described one, for more than half of the institutions have provided the same number of units, and some of them have registered lower positions. The results are determined by the little interest in the spectacle – cultural activities of the local residents and also the reduced number of tourist with little or less knowledge about them.

Regarding the participation as spectators, in the analyzed period, per total it can definitely, be observed the reduction of participant, taking into consideration the same reasoning that underline the necessity of the tourism promoting activities.

An interesting cultural aria is represented by folkloric groups that attract the highest number of participant, even though, in the course of the three years the evolution is a negative one. It can be concluded that this cultural event of folklore is more appealing by the Romanian specific character that offers an image over the historical ideology and social and cultural life.

Participation in Romanian spectacles

Fig. 2 thousand pers

Event Institutions	2003	2004	2005
Legitimate Drame	1.188	1.249	1.121

Sursa: Masterplan pentru turism –partea I, www.mdpl.ro

Therefore it is necessary to formulate a set of priorities for the development of general tourism and extra for the cultural event domain.

On one hand tourism is strictly dependent of the equipment or *infrastructure*, so the restoration and creation of lodging, food and beverages, transport and leisure infrastructures. On the other hand, the activities related to the *tourists' information* accessibility must be reorganized in an efficient way. For instance, there must activate tourism information centers that provide a variety of information and can be easily reached. Also, creating a national database with the major information about tourism event can definitely influence the degree of transparency to the consumer and their choices.

The *state* involvement it's a priority because it generates important investments by offering the legal context and production deductions.

Another important part is *the marketing* of the destination, or the activities. On relating to this, first it should be the realization of marketing studies, based on accurate numbers, influencing the necessary actions to be used. Also a marketing tool, a special measure is the collaboration of the public sector with the private one to unify the destinations' perfect image. More than that, it is imperious to create a notorious country brand, using a strategy to promote Romania's

best features but in concordance with the development of all tourism facilities and services.

At an international level, cultural events determine billions of tourists, not only because of the nature of event, but also stimulated by the facilities offered. In conclusion, the cultural events can positively influence the development of Romanian touristic potential by different improving actions:

- Fructifying in a superior mode the historical landmarks, with special attention to the restoration and preservation of heritage buildings and museums;
- Creating and improving a diversified touristic equipment for event purposes;
- Promoting the cultural events within a long period of time and permanently investing in the promoting activities;
- Attracting well known event celebrities that have a special impact on tourists demand- famous DJ, Sportsman, etc.;
- Investing in new cultural event activities, with a large spectrum and future perspectives;
- Accentuating the traditions and costumes in offering a unique event product;
- Providing special amenities and facilities for the display of festivals, and for accommodating and serving local and foreign tourists;
- Educate the mentality of local residents toward tourism and event; etc.

Financial Performance and Social Responsibility: Romanian Scenario

Duca Florinița

Academy of Economic Studies, Bucharest

florinitaduca@yahoo.com

Abstract

The form and content of the capitalist world economy is fast evolving and we find capital being increasingly concentrated and centralised as the battle of market competition intensifies. Companies have to keep running just to stay in the same place so intense is the competition. One of the factors that make the critical difference between the companies is the public perception of a business's value systems that are best exhibited by initiatives in discharging its Corporate Social Responsibility (CSR). This study explores and tests the sign of the relationship between corporate social responsibility and financial performance.

Key words: Corporate social responsibility, financial performance, correlation, companies

J.E.L. classification: C10, M14, G34

1. Introduction

Corporate social responsibility (CSR) is now seen as an integral part of corporate strategy.

The field of corporate social responsibility has grown exponentially in the last decade. A larger number of companies than at any time previous are engaged in a serious effort to define and integrate CSR into all aspects of their businesses. An increasing number of shareholders, analysts, regulators, activists, labor unions, employees, community organizations, and news media are asking companies to be accountable for an ever-changing set of CSR issues. There is increasing demand for transparency and growing expectations that corporations measure, report, and continuously improve their social, environmental, and economic performance.

The definition of corporate social responsibility is not abstruse. Corporate social responsibility, it is usually described in terms of a company considering, managing and balancing the economic, social and environmental impacts of its activities (PJC 2006). The notion of corporate social responsibility as a part of the core business operations of a company, rather than a separate "add on", distinguishes it from corporate philanthropy which may be funded out of operations that are damaging to the communities in which business is conducted. McWilliams and Siegel (2001) describe CSR as "actions that appear to further some social good, beyond the interest of the firm and that which is required by law." [1]

Social responsibility is an ethical or ideological theory that an entity whether it is a government, corporation, organization or individual has a responsibility to society at large. This responsibility can be "negative", meaning there is exemption from blame or liability, or it can be "positive," meaning there is a responsibility to act beneficently (proactive stance). Businesses can use ethical decision making to secure their businesses by making decisions that allow for government agencies to minimize their involvement with the corporation. Corporate social responsibility (CSR), also known as corporate responsibility, corporate citizenship, responsible business, sustainable responsible business (SRB), or corporate social performance, is a form of corporate self-regulation integrated into a business model. Ideally, CSR policy would function as a built-in, selfregulating mechanism whereby business would monitor and ensure its adherence to law, ethical standards, and international norms.

2. Empirical studies of csr and financial performance

In academic circles, extensive research has been conducted to assess the empirical association between CSR and corporate financial performance under diverse geographical contexts. Theoretical ideas on the impact of CSR practices on firm profitability appeared in the management science literature as early as in the beginning of the 20th century (Crane et al., 2008)[2]. The discussion later developed both in the economic literature with a focus on the cost and revenue implications of CSR practices as well as in the financial theoretical literature where simple stock return implications for investment carried under environmental, social, and corporate governance considerations were put forward.

The results of previous studies, however, are largely indeterminate. According to Margolis and Walsh (2001), one hundred twenty-two published studies between 1971 and 2001 empirically examined the relationship between corporate social responsibility and financial performance.[3] The first study was published by Narver in 1971. According to “instrumental stakeholder theory”[4], companies with superior social performance tend to perform better financially by attracting socially responsible consumers (Bagnoli and Watts, [5]), alleviating the threat of regulation (Lev et al., [6]). A notable source is a meta analysis undertaken by Orlitzky et al, who integrated 30 years of research from 52 previous studies and used meta analytical techniques to support the proposition that corporate social performance and corporate financial performance are positively correlated and statistically significant. Interestingly, the meta analysis found a higher correlation between financial performance and a company’s management of its social impact than between financial performance and a company’s management of its environmental performance.[7]

As commented by Dowell et al. the majority of empirical works about the theme has been completed using samples of corporations from U.S.A. and Europe[8]. We consider the concentration of the research in well-developed markets as an additional factor in the determination of caution against

generalizations of the findings and also as a motivator to new research in other markets. Besides economic development, the institutional framework may also interfere in CSR [9].

3. Objective of the study

In this paper we have examined the relation between corporate social responsibility (CSR) and financial performance. And compare the dependency of corporate social expenditure on financial performance.

Hypothesis

H1-CSE(corporate social responsibility) and FP (Financial Performance) is an independent from each other and CSE does not depends upon FP.

Methodology

The study is descriptive in nature because the study is a comparative analysis of expected with actual expenditure incurred and an attempt has been made to explore the relation between CSR expenditure and financial performance. We examined the relationship between financial performance and corporate social responsibility across the companies for the 2008 financial year. Data was gathered from publicly available information, as well as information from CSR Romania. Data has been analysed by using correlation and regression.

Results

It is being observed under various studies that there is a positive relationship between financial Performance and Social expenditure. To validate the same has been applied on financial performance (FP) i.e, NPAT and Corporate social expenditure(CSE). By applying the Pearson correlation at 0.01 level , the correlation coefficient for the same is 0.516 which rejects the Hypothesis-I.

4. Conclusion

The analysis reveals that there is a positive relationship between CSR and financial performance and the descriptive and inferential measures shows that Corporate social expenditure depends upon the financial performance of the Company. But at the same time we can conclude that most of the top roumanian companies are spending nothing on part of their social responsibilities.

The roumanian companies are not providing detailed information about their spending upon the social projects rather we are following the descriptive measures for reporting and just specifying in the report, the area where company is having its projects. No specific annual spending, budgets and details of social projects are disclosed by companies. By promoting and partaking in environmental conservation, the company profits in the long run. Corporations have realized conserving the environment is a vital aspect of the well-being of a company in the long run. If all resources are used up and destroyed, future success is not feasible. The company should focus on improving ways to better the manufacturing process of the goods so as to reduce air pollution as much as possible. It should also play an active role in the community and sponsor projects for the betterment of society and those less fortunate.

Coordinates and Approaches in the Practice of Internal Audit

Ducu Corina Maria

Mărăcine Mihaela Simona

„Constantin Brâncoveanu” University of Pitești

Faculty of Management Marketing in Economic Affairs

corina_ducu@yahoo.com

mihaela.maracine@yahoo.com

cameliachirila2004@yahoo.com

Abstract

Internal audit contributes through its processes to achieve the best working conditions within an entity and to reach the proposed objectives. Increasing the entity's performance requires an effective coordination between the internal audit department and its risk management processes and internal control.

Key words: internal auditing, internal control, risk management.

J.E.L. classification: M42

The effective functioning of an entity refers in practice to the existence of various internal audit departments whose objective is to plan and develop audit missions.

Planning an audit mission requires the elaboration of an audit strategy regarding the nature, duration and determining the methods and techniques to be used during the audit process. [1] For a better mission planning, the auditors should take into consideration some issues regarding: the business objectives, the risks associated with the developed activities, the system of risk management and the internal control system.

The development of internal audit firstly requires the collection of the information and then their analysis and assessment. The documentation of the information is an important step in accomplishing the mission. Reporting the results of the audit mission takes the form of an audit report. This should include recommendations and measures on the proper functioning of the activities within the entity.

The practical coordinates of internal audit highlighted some features already established such as:

Universality of the internal audit function

Internal audit operates in all entities, whatever their field of activity and monitors most of their activities.

Internal control is considered to be its main object of activity. Due to the fact that internal audit aims to improve the internal control system with the recommendations made to the managers, and how internal control is universal, it results that this function can be the feature of universality.

Internal audit is a function of managerial assistance through which auditors help managers to increase the entity's performance in accordance with the monitored activities. Given that managers are everywhere, the internal audit assistance has consequently expanded in all areas, which allows us again to mention the universality of this function.

Independence of the internal audit function

To understand the internal audit function is essential to start from the existence of the internal audit department within the entity. This department operates independently of other departments and aims to supervise all activities in order to increase performance and achieve goals.

This is possible by:

- risk assessment activities;
- according to the results of risk assessment they establish the effectiveness of internal controls;
- management reporting of findings;

- advice given to improve the management activities carried out within the entity;
- how to implement oversight recommendations.

According to these responsibilities, internal audit provides an independent and objective opinion on risk management, internal control and governance of the entity.

Frequency of the internal audit function

The internal audit function aims to increase the value added within the entity. This can be achieved through effective audit aimed at reducing risks that are subject to activating a system by implementing internal controls to identify areas of inefficiency and increased performance.

The audit work is an ongoing activity but also a regular activity. Audit departments can always work in an entity, but there may be situations where the conduct of audits is related to risk assessment activities.

Auditors may audit an entity for 8-12 weeks and then return after a period of 2-3 years depending on the risks to which the entity activities are subject to. Thus, the internal audit activity is regularly scheduled, held on the basis of standards, based on a running program, and all mentions, ideas and recommendations are presented in a report assessing the entire activity within an entity.

The measures undertaken by internal audit are constantly changing, they are measures adapted to the new field regulations, to the available financial resources, and to the social and economic environmental influences. The effects of the economic crisis may have negative influences on the internal audit activity on a long term, so it is necessary to refocus and reorganize this function. Here are some attributes that maximize the internal audit function in these conditions [2]:

- focus on risks;
- aligning all operational processes;
- technology;
- quality and innovation;
- culture oriented to the client;
- efficiency in terms of cost.

We believe these attributes are beneficial in improving the internal audit activity. But to develop activities in accordance with the new trends/attributes, entities should allocate substantial financial resources to audit departments. Large entities allocate resources in order to implement a risk management

department, and internal auditors participate in courses and training to acquire different abilities.

The problem occurs in small and medium-sized entities that do not have sufficient financial resources to keep pace with these trends. Moreover, internal audit is seen as a structure that evaluates the internal control environment.

Therefore, we need first a reorganization of internal audit at the level of these types of entities, which do not only cover internal control but also risk management and governance entity.

The reorganization of these departments will make entities improve their activities and adapt to new trends.

Conclusions

Internal audit by its characteristics, scope and pursued objectives contributes to the improvement of the activities adding value to the entity. The proper planning and implementation of internal audit will contribute to the smooth running of the entity even in conditions of economic crisis. Moreover, taking into account the reorganization of internal audit according to the attributes that maximize this function we observe that this fact brings various benefits to the entity.

The Importance of Sovereign Rating for Romania in the Crisis Context

Dudian Monica

Trașcă Daniela Livia

Academy of Economic Studies, Bucharest

monica.dudian@economie.ase.ro

trasca.daniela@gmail.com

Abstract

The sovereign credit risk rating for Romania had significant changes in the 1996 – 2008 periods, from category B- with negative perspective, as the lowest level, to BBB-, with positive perspective. The objective of this paper is to explain the importance of sovereign rating for Romania in the crisis context. The first part of the article is a short presentation of the sovereign rating literature regarding the concept and the risk sources. The second part highlights the relation between foreign currency long-term sovereign rating, foreign direct investment and debt cost. The paper find evidence that sovereign rating influences capital inflows and debt cost.

Key words: sovereign rating, rating agencies, foreign direct investment, credit spreads

J.E.L. classification: G24

1. Introduction

Our paper aims to answer to the following questions: What country risk means for rating agencies? What is the relationship between the sovereign rating and the volume of direct foreign investment? What about the relationship between the risk grade and the cost of debt? How did sovereign credit rating influence the inflow of direct foreign investment in Romania?

The first part of the work briefly presents the main concepts and the reference literature on the relationship between the risk grade and the international assignment of financial capitals. The second part presents the evolution of sovereign rating of Romania during the years 1996 – 2010. Also, it is emphasized the influence of sovereign risk on the direct foreign investment and the cost of

external debt. The statistics about Romania suggest, similarly to the hypotheses validated into the reviewed bibliography, a negative relationship between the sovereign credit rating and the direct foreign investment. The main conclusion of the work is that the degradation of the sovereign rating negatively affected the inflow of direct foreign investment and the cost of debt.

2. Theoretical references

Country risk is a synthetic indicator on the quality of business conditions within a country. On the global risk assessment market there are various tenderers that can be classified in accordance with the nature of activity as: rating agencies (Standard & Poor's, Moody's, Fitch and others), professional companies (P.R.S. Group, Euromoney, Institutional Investors and others) and big banking groups (Citibank, Credit Lyonnais, BNP Paribas and others). The country risk does not encounter a unitary methodologic approach, being surrounded by many conceptual confusions. The risk grade meaning is not the same for all the mentioned organizations, being strongly influenced by the assessment objective. Thus, the professional companies have as main activity the consulting services for banks, private non-banking companies, governments and international multilateral institutions. Therefore, the country risk grade mostly shows the general country risk, understood as a complex indicator covering the total risks inherent to capital investment abroad. In case of banks, the analysis of country risk drives at reflecting the credit conditions, and the country risk indicator is not disseminated to the public. Rating agencies have as main activity the risk assessment, completed by the issuance of risk grades. In accordance with the rating agency Standard&Poor's,

“Sovereign credit ratings reflect Standard & Poor's Ratings Services' opinions on the future ability and willingness of sovereign governments to service their debt obligations to the nonofficial sector in full and on time.”(Standard & Poor's, 2008). Fitch uses for the same concept the term of sovereign issuer default ratings, and Moody's the term of government bond ratings. In this work the reference is to the sovereign risk assessed by rating agencies. The meaning of risk classes is the following: AAA – extremely powerful capacity of a debtor to take up its obligations, AA – very powerful capacity, A – powerful capacity, BBB – appropriate capacity, but sensitive to potential changes within the business environment, BB and B – speculative bonds with low vulnerable capacity, respectively more non-payment vulnerable, CCC and CC – currently vulnerable bonds and very non-payment vulnerable, C – very vulnerable bonds or debts involving contractual restructuring, SD (selective default) and D – payment cease.

Ratings, including the sovereign ones, are important signal for the world investors, subjects of the system of internationally capital allocation, due to financial disintermediation and globalization. The recent world financial crisis has once more emphasized the importance of credit risk grades, as it is demonstrated by the official investigations conducted by the regulating authorities from the European Union and USA (European Securities Markets Expert Group report to the European Commission, 2008, Stability Forum Financial Report (FSF), 2008, Report of the International Organization of Securities Commissions (IOSCO), 2008, Annual Report on the Nationally Recognized Statistical Rating Organizations (NRSRO), Securities and Exchange Commission, USA, 2009). The conclusions to these reports show that investors take into account the rating when making decisions and rating agencies have contributed through their grades to the cumulation of tensions on the financial markets, inducing insecurity. There must be mentioned the fact that the assessment of sovereign risk by agencies is estimated as satisfactory in terms of accuracy. The financial crisis has been worsen mostly by the too high credit risk grades associated to the derived instruments.

Besides the official reports, there are other studies concerning the relevance of sovereign risk for big international investors, financial market and economic growth. A synthesis of the reference works for this article is displayed into the following table:

Table 1. Influences of the sovereign credit rating

Study	Conclusion
Cantor and Packer (1996)	92% of the variation in credit spreads can be attributed to ratings, and the effect is more powerful in case of rating degradation against upgrading.
Erb, Harvey and Viskanta (1999)	There is a strong relationship between country risk and sovereign bond yield spreads for emerging markets.
Kaminsky and Schmukler (2002)	Modification of sovereign rating affects both the assessed instruments and other instruments of credit from the country referred to. The modification contributes to contagion, and the contagion effect has regional nature.
Cantor and Mann (2003)	There is a positive correlation between the ratings assigned by Moody's and the cycle indicators.
Setty and Dodd (2003)	Credit rating agencies influence credit spreads and the flow of capital to developing countries.
Reinhart and Rogoff (2004)	Sovereign default risk, measured by sovereign rating, affects capital flows.
Kim and Wu (2007)	Sovereign credit ratings affect capital flows.
Borensztein, Cowan, and Valenzuela (2007)	High country risk increases the financing cost for the private entities and reduces the volume of private capital flows.
Altman et al. (2008)	Rating influences the bonds margins. The weaker the risk class, the higher the margins, and the relationship is a long term one (more than 20 years).

Source: personal adaptation in accordance with the mentioned studies.

In conclusion, sovereign rating influences the cost of bonds and the volume of external financing, and the influence is more powerful for developing countries and emerging markets, characterized by weaker risk grades.

3. Romania's case

The sovereign credit risk rating for Romania incurred significant changes during the years 1996 – 2008, from category B- with negative perspective, as the lowest level, to BBB-, with positive perspective. In 2005 Romania entered for the first time the investment grade category, but in 2008 it was degraded to speculative grade by two big agencies out of three that dominate the world market: Standard & Poor's and Fitch. The evolution is the following:

Table 2. Sovereign Rating, Romania, 1996 - 2008

Period	Mar. 1996	Apr. 1997	Jan. 1998	May 1998	Oct. 1998

*FCR=foreign currency long-term sovereign rating.

Source: Standard&Poor's, 2008

From October 2008 to 2011 Romania held BB+ category, turning to stable outlook in 2010. To observe the relationship between the sovereign rating and direct foreign investment (ISD) in Romania, the risk grade was turned into numbers. Thus, the best grade held by the country under survey, BBB-, positive outlook received the score of 20, then the score was increased by a ranking of 5, up to the highest sovereign risk into the reviewed period, B-, negative outlook (which received 120 points). Referring to ISD, the investment volume was divided by 100 to ensure compliance with the assessment scale. Further to these

adjustments, the following relationship resulted:

Figure 1. Sovereign rating - Foreign Direct Investment (ISD), Romania, 1996 - 2008

Sources: Eurostat and Standard&Poor's, 2008

The chart points out the reverse relationship between rating and ISD flow, relationship which appears also into the works from table 1.

Besides ISD, external financing can take the form of the external debt. In accordance with the reviewed works, when rating improves, the cost of debt decreases, fact leading to the hypothesis that the debt volume should increase. Therefore, holding the transformations applied to rating and dividing the total external gross debt by 1000 to assure comparison, the following chart resulted:

Figure 2. Sovereign rating and total external debt 2001 – 2009

Sources: Eurostat and Standard&Poor's, 2008

The chart shows the fact that the external debt increased gradually as the risk diminished and the rating improved up to the year 2007. Beginning with 2008, the risk grade lowers but the external debt grows as the financing need increases within the context of ISD diminution having as background the international financial crisis. Therefore, the reverse relationship sovereign rating – total external debt is doubtful.

In respect of the debt cost, the analysis checked whether the improvement/degradation of the risk grade determines the decrease/increase of the debt cost. Therefore, the following chart is relevant:

Figure 3. Impact of FCR to 3-Month Money Market Rate Spreads against the Euro Area

Sources: Standard&Poor's, 2008 and Bloomberg, 2009

The above chart emphasizes the fact that Romania's entry from investment grade to speculative grade in November 2008 was accompanied by the immediate abrupt increase of the interest margin. It is thus confirmed the direct relationship between the debt cost and sovereign rating, mentioned into the reference literature.

4. Conclusions

The Romanian sovereign risk grade has been generally ranging during the last fifteen years within the speculative class, except September 2005 – November 2008. During

those three years, the Romanian state was considered an investment grade debtor, but on the low threshold, the limit of this category.

Statistics referring to Romania, in chart form, show a reverse relationship between the sovereign rating and ISD and a direct relationship between the risk grade and the external debt cost. It appears that sovereign rating influences Romania's conditions of access on the international financial market.

Factoring, a Financing Alternative for Romanian Exporters During Crisis

Dugan Silvia
Pepenel Madelaine-Lorelai
"Constantin Brâncoveanu" University of Pitesti
dugan_silvia@yahoo.com

Abstract

Factoring, a product used in dynamic business environments worldwide, is a quick solution for the issue of working capital locked in the loan provider, ensuring a productive use of financial resources. During the economic crisis and given the very limited access to traditional financing schemes, factoring may be a suitable alternative for some companies in Romania, particularly those operating in the provision of goods or services. Factoring is therefore a solution to short-term finance company unsecured debt on assignment for specialized factoring company. As an alternative to standard loans, factoring is a low risk way of financing increasingly requested by Romanian companies.

Key words: factoring, factor, adherent, debts.

J.E.L. classification.: G21

1. Introduction

In current conditions, when the economy is showing signs of weakness, banks are increasingly hard to credit, capital market is moving slowly, companies do layoffs, people are very careful with their money and consumers pay their bills late. New more stringent risk policy applied by banks, with low liquidity on the market have made many SMEs no longer qualify for a bank loan or facilities extensions are no longer taken, which eliminates chances of development or even survival in the market (4).

Due to current market constraints (mainly depreciation on real estate, which limits access to traditional forms of borrowing), the factoring may be an alternative for those

companies that have significant amounts earned from sales of goods and services to the third parties who want to gain quick access to financing their businesses. According to several statistics available to the public, the potential development of this alternative financing is indeed significant.

2. General considerations on factoring operation

2.1. Definition of factoring

Factoring is a commercial credit contract involving a company specialist (banking company or a specialized financial institution) called factor and a company supplying products or services known as the adherent. The adherent seeks to charge the bills before the deadline and the factor seeks for a benefit, usually a percentage of the invoices he settled in advance. In other words, factoring is a financing solution to short-term unsecured company, based on assignment of claims in favor of specialized factoring company (8).

Debtors' insolvency risk and the risk of failure to pay on time (risk of cash) are the factor's responsibility, without any possibility to return against the adherent as an appeal. If the factor does not accept the bill, it can be cashed within a term contract, without assuming the risk of failure to pay, while the adherent is obliged to notify customers about the factor's overtaking, to which they must refer their payments.

Factoring companies also deal with customer management and billing management, and bring insurance against default risk of debtors (full-service factoring).

2.2. Advantages and disadvantages of factoring for the adherent

The main **benefits** of the factoring transaction for the adherent are as it follows:

- A company that chooses the factoring transaction as a financing alternative will assign the claims arising from invoices for goods and services provided to third parties, to the company, in return for factor's prompt payment of the value of these receivables, less an amount representing the factoring fee. There are variants of factoring in which payment is made in several tranches. Therefore, factoring allows adherent to dispose of the necessary capital to continue trading, to reduce the cycle of rotation of the working capital by only a single financial institution immediate payment of bills, to focus their attention on the real trade and, finally, to realize an increase in turnover and profits. The period for obtaining cash is much shorter than for a loan, without having to comply with a specific destination as in the case of a loan. In addition, the number of documents necessary to obtain financing through factoring is much reduced compared with the documentation necessary to obtain a loan (7).

- Generally, the factoring is regarded as a sale of receivables, inside which the full risk for paying claims by the borrower belongs to the factor, the last one having no right of recourse against the adherent in case of borrowers payment default. All income costs and loss account of the risk involved insolvency are thus eliminated for the adherent. However, some factors also provide a right of recourse financing, which means that the risk by failure of payment of claims goes to the adherent. By taking over the "clients" area from the adherent's assignement and by taking advantage of the current account system, the factoring helps simplify adherent's accounting and reduce its functional tracking device for receiving financial and accounting bills, ensuring the reduction of funds for its daily business being also able to use funds for other purposes. The factor performs all operations related to the adherent bills, processes them by inserting them into the system or information, along with their collection. At the end of each month it prepares reports on complex financial transactions performed. Also, the

factor becomes the adherent manager and adviser in selecting both customers in terms of their trustworthiness, and in its commercial trade policy guidance, the adherent thus losing a part of its economic and financial autonomy. Factor's involvement in its client's business management -the adherent- is accompanied by a wide range of services, as well as aspects of modern methods of management and accounting studies and analysis of external market situation, legal services, intended to make the adherent more operational, to enhance safety and expanding market by establishing relationships with partners of an obvious ability to pay.

- Given that the factoring is essentially an assignment of receivables, the factors, having obtained all debts from the adherent, generally do not require any other warranties.

- Factoring does not require a change in the company's ownership structure. This means that shareholders are not expected to give up their share capital or to accept new partners.

- There are no geographical limits on factoring operations. A factor can work in any area and the customer can have trading partners from all over the world;

- The adherent takes full advantage of discounts and sales granted for early payment discount, as well as of those granted for volume discount. If a business can save between 2-5% of the cost of raw materials needed for production by the mere fact that the adherent has the money to pay for them within 10 days, this significantly reduces the real cost of financing through factoring;

- Bu using factoring the adherent ceases to offer discounts for immediate payment. As long as exporters cash their debts immediately, they will not have to give discounts for immediate payment. The adherent is able to offset the cost of factoring by obtaining these savings and taking advantage of the discounts received for immediate payment.

- Factoring is not a loan, but a special form of mobilization of outstanding debts in the future. Therefore, the exporter may, apart from mobilizing the factoring of overdue debts, to resort to bank loans and cover other additional needs.

Factoring disadvantages for the adherent are as it follows:

- Overdue debts usage takes place at more than 80% of the total debt, the rest being reinvested at the payment deadline imposed by the importer, after deducting the interest and commissions due to the export factor;

- The exporter may use factoring only for short-term debts (usually up to 120 days and exceptionally 180 days);

- The operation can be carried out with recourse to the exporter. – The exporter may have obligations to deliver/import and to provide over the credit limit set by the import factor and can thus be concerned with seeking other funding sources;

- All financing expenses are the exporter's responsibility, together with the fees imposed by the export factor.

2.3. Types of factoring operations

Depending on the method of debts financing, factoring transaction can embrace two forms (1):

- **traditional / old line factoring**, when the factor pays the bills when they come into his possession, giving credit to the adherent till the payment deadline, so that it holds an interest (discount rate);

- **maturity factoring**, which occurs when the factor pays the bills at the deadline.

Depending on the business settlement, there are the following types of factoring (5):

- **national factoring** –it is estimated that 80% of the global factoring operations are internal ones, which imply that the factoring agreement is concluded between the factor and the adherent for invoices issued for goods and services supply inside the adherent's residence country;

- **international factoring**, which currently has a faster development than that of the national one, especially because of the fact that it is dealt with export financing activities, which significantly increased in the last ten years. External financing can be a direct import or export factoring, inside which the factoring company maintains business relationships with foreign buyers or suppliers, or with a two-factor system, where an export factor uses the services of the import one, in the buyer's residence country.

3. Romanian Factoring Market

Factoring operations in Romania are briefly covered by legal stipulations in certain incidents and regulations issued by The National Bank of Romania, generally in connection with activities undertaken by commercial banks and non-bank financial institutions. The applicable law issued by NBR includes factoring operation for the general credit activity, which can be performed only by commercial banks and non-bank financial institutions (NFI), without providing a definition of factoring operations. In the absence of specific regulations, the legal status of these operations is represented by the general rules applicable to debts transfers.

Currently, the factoring market in Romania is concentrated in the hands of the ten strongest players, mainly of commercial banks. Only three larger companies are separate entities dealing strictly with only factoring: Sterling Factor, Factoring Company and ING Commercial Finance.

Factoring IFN SA Company is the first company in Romania specialized in factoring services, whose shareholders are Transylvania Bank and Intermarket Bank Austria AG, a leading Central and Eastern Europe factoring services. Factoring IFN SA Company is a member of Factors Chain International (FCI), one of the largest global professional services. It provides bills funding services, debts and debtors management and collect debts at maturity. It represents the perfect option for companies that need money. It secures payments of 80% of the total amount of goods in less than 48 hours after delivery together with external customers checking and processes handled by specialist companies or banks (9).

Sterling Factor Company is a non-banking society specializing in providing factoring services for international and national factoring, the only one of its kind in Romania. Sterling Factor is a group of Romanian-American joint venture, with a real partnership with over 40 countries including Australia, Canada, France, Hungary, Great Britain, Spain, USA, Turkey, Italy, Greece, Germany, etc.. Moreover, compared to other banks from Romania, Sterling Factor Company has also covered Russia. The services provided by the

company are default insuring risk, bills collection and cash advances. Sterling Factor deals with collecting bills, watching as they are paid on time and will report on the bills to be collected. Cash advances stand for a percentage of 60-80% of the bill value, 48 hours from goods delivery.

In the past years, banks have been seriously involved in providing factoring offers for small and average companies. The top four players in the factoring market, BRD Groupe Société Générale, BCR, Raiffeisen Bank and ABN Amro gather together 85% of the market. In addition, the top players, BRD and BCR, are proving to be the most aggressive in the field, the tending market of the first sharing this year to 42% while the second goes for 30%. The competition which takes place between factoring companies often focuses on large retailers, which bring along dozens of suppliers who serve them. For example, the BRD holds as main customers the supermarket chains Carrefour and Auchan.

By using factoring services in national and international currencies offered by BCR, customers benefit from immediate funding for the delivered goods or services, collection monitoring, bills registration and foreign borrowers default risk covering. The financing represents 80% of invoice value at the time of purchase and 20% upon invoice, the cost for companies being profitable.

BRD - Groupe Société Générale, besides financing debts, also deals with the debts management service, consisting of their administration, collection and, if necessary, cover the default risk of borrowers. Through this service, BRD-Groupe Société Générale aims to develop and improve payment behavior of companies by respecting the contractual maturities.

Raiffeisen Bank offers this product in several versions, intended for business: factoring with recourse (no pay, no risk covered), non-recourse factoring, national and international factoring. Over 80% of Romanian factoring volumes come from small and average companies and 95% of the customers also come from the mentioned area.

Factoring has been on the Romanian market since 1994, but came to the attention only in the last five or six years, as small business developed. Till 2005-2006,

factoring market players focused more on companies with export activities.

If the turnover was of 20 million Euros in 1999, there was in 2004 a substantial increase in volume, reaching 420 million Euros. After steady increases over 100% of the activity recorded in 2004 and 2005, factoring market in Romania reached 750 million Euros in 2006. Factoring in Romania market value was 1.7 billion Euros in 2008, representing a significant increase of 63.64% over 2007 and put Romania on the seventh place in a market ranking which recorded the strongest growth in 2008. In 2009 the factoring market volume decreased to 1.4 billion Euros from which 1.05 billion Euros came from national factoring, while 350 million Euros were issued by the external one.

However, Romanian factoring services remains quite small (0.52%) compared with the average EU level (7 to 7.5%) and global (3.45%), which theoretically means that Romania has great potential for development of these financial activities (2).

In 2008, in Romania, factoring market represented only 1.5% of the National Product, compared with 3% EU average or even 9-10% of NP in developed countries. In Poland, the share of factoring in NP slightly decreased to 2.2% last year, while in Hungary has remained constant to 3.2%. The biggest factoring market is in the UK, where business players in this area exceed 10% of NP.

According to several specialized companies, Romanian factoring market has high growth potential, taking into account the fact that its share in NP is about half from the European's average and more and more companies are choosing to assign invoices in order to obtain cash, in a time when access to traditional lines of financing from banks is limited.

In 2009, the Romanian volume of factoring transactions as a share of NP is 4-5 times lower than in Slovenia, Hungary and Poland. According to data presented by Next Capital Company, even Bulgaria has overcome Romania from this point of view.

EU funds absorption in Romania through Sectorial Operational Program for Human Resources Development between 2007 and February 2011 – an analysis

Duhnea Cristina
Ghiță Mitrescu Silvia

„Ovidius” University of Constanta , Faculty of Economic Sciences

cristina@duhnea.net

silviamitrescu@yahoo.com

Abstract

One of the opportunities to finance succesful projects represents the european funds that Romania can access through the Operational Programmes implemented for 2007 2013 period. After more then three years the absortion level of these funds remains very low and the projects aproved to be financed face many difficulties during the implementation process. In this paper we try to indentify the state of the financing process for the most accessed operational programme – human resources development.

Key words: European funds, human resources development, projects.

J.E.L. classification: G01

1. Introduction

EU funding represents, at this time especially, one of the best ways to fund ideas that most often do not have another chance to turn into viable projects that will support the achievement of overall goal of increasing the living standards and the competitiveness of the Romanian economy so as to exceed the minimum criteria required by European Union for its members so that they no longer come under the Community policy to mitigate disparities.

Fresh EU member state, Romania prepared in compliance with EU cohesion policy its own development strategy for the period 2007 to 2013.

Framework documents for the implementation of national development policy basically refer to three elements: the National Development Plan, National Strategic Reference Framework and

Operational Programmes.

Romania's National Development Plan for the financial period 2007-2013 is the strategic planning document for multiannual financial programming, approved by the Government and developed into a broad partnership that would guide the socio-economic development of Romania under Cohesion Policy European Union.

NDP is the document upon which were developed the National Strategic Reference Framework 2007-2013 (NSRF), which was agreed with the European Commission strategy for the use of structural instruments, and the Operational Programmes which will implement these funds. The development strategy of the NDP for 2007-2013 is a reflection of Romania's development needs in order to reduce the gaps compared to EU as soon as possible. NDP 2007-2013 strategy focuses both on communitary strategic guidelines on cohesion, as well as the Lisbon Agenda and the Gothenburg objectives.

Romania's National Development Plan for 2007-2013 provides six national development priorities for 2007-2013 as a result of the SWOT analysis made by the authorities:

1. Increased economic competitiveness and development of the knowledge-based economy
2. Development and modernization of transport infrastructure
3. Protect and improve the environment's quality
4. Human resource development, promoting employment and social inclusion and strengthening the administrative capacity
5. Development of rural economy and increase productivity in agricultural sector
6. Reduce development's disparities between different regions of Romania.

National Strategic Reference Framework (NSRF) is the strategic reference document for programming Structural Funds and Cohesion Funds in Romania. This document is prepared by each EU member state, according to the new *acquis* on Cohesion Policy.

This document will not serve as a management tool, but as a strategic document setting out the priorities of intervention of the Structural and Cohesion Funds in the reference period.

The NSRF explains how they will be implemented Structural Instruments in Romania between 2007 and 2013.

NSRF creates the links between national development priorities set in National Development Plan 2007-2013, and priorities at European level - the Community Strategic Guidelines (CSG) for Cohesion 2007-2013 and the Integrated Guidelines for Growth and Jobs 2005 -2008.

The basis for the development of this strategic planning document in the medium of the Structural Funds and Cohesion was the National Development Plan 2007-2013, approved by the Government in December 2005.

The main purpose of the NSRF strategic objective is to strengthen the economic, social and regional cohesion in Romania, as well as fit and proper to establish links with European Commission policies, particularly with the Lisbon Strategy, which underpins the policy-making economic development and create new jobs.

NSRF has been prepared based on the National Development Plan (NDP) 2007-2013 and is implemented through Operational Programmes.

2. Sectoral Operational Programme for Human Resources Development (SOP HRD)

One of the most accessible operational programmes is SOP HRD which represents the strategy for human resource development through the intervention of European Social Fund in Romania.

The general objective of SOP HRD is the development of human capital and increase competitiveness by linking education and lifelong learning with the labor market and providing increased opportunities to

participate in a modern labor, flexible and inclusive market for 1,650,000 people.

The general objective of SOP can be divided into several specific objectives: promotion of education and initial and continuous training, including higher education and research; promoting entrepreneurial culture and improving quality and productivity; facilitate labor market insertion of young people and long-term unemployed; development of a modern, flexible and inclusive labor market; promote insertion / reinsertion into the labor market of inactive people, including rural areas; improving public employment services; facilitate the access of the vulnerable groups to education and the labor market.

SOP HRD funds seven areas of activity, known as "priority axis". Each of these priorities is in turn divided into several subdomains, called "areas of intervention."

SOP HRD strategy includes 6 priority and a dedicated technical assistance priority axis, as follows:

The financial plan of SOP HRD was elaborated in accordance with the financial plan of the National Strategic Reference Framework 2007-2013. SOP HRD will be financed from European Social Fund. ESF allocation for SOP HRD is 3.476 million euro, representing 85% of the total value the Programme. National contribution is estimated at 613 million euros.

Priority axes set for the human resources development in Romania are supported by the proposed financial allocations, indicating the importance given to each of the three main areas of intervention of ESF in Romania through SOP HRD:

1. Promoting lifelong learning and the adaptability of labor force and enterprises (AP 2 and 3), accounting for 38.37% in financial allocation;

2. Promoting active employment measures for the inactive population, especially for people living from the subsistence agriculture, youth unemployment and long-term unemployed and the labor market integration and social inclusion of vulnerable groups (AP 4, 5 and 6): 34 , 21%;

3. Education and training in support of growth and development of the knowledge-based society, aiming at modernizing the educational system and initial and ongoing professional training, including university

education and research support (AP 1): 23.55%.

The financial allocations for each priority axis have considered the extent of the problems identified in the SWOT analysis performed for creating the National Development Plan. Figures and indicators in the time of analysis were compared with the revised Lisbon Strategy objectives in terms of the knowledge society, mainly the participation in lifelong learning, adaptability and the promotion of scientific research in the economic sectors with high added value. For these objectives has been taken into account the in order to achieve equilibrium allocations of Lisbon and the Community Strategic Guidelines on cohesion, proposing the active employment measures and intensified action to promote social inclusion of persons belonging to vulnerable groups. For this purpose, have been proposed and priority key areas of intervention that addresses these two complementary directions of development of human resources and targets that will be achieved by the end of 2015 were set .

Financing the projects under SOP HRD started in 2007 and, in theory, should represent an opportunity for those ideas that come to solve identified weaknesses in human resources in Romania. In practice, however, the rate of financing is still very small. To see the funding situation for the SOP HRD we did an analysis of the projects submitted and accepted for funding under this operational programme.

3. The project financing activity through Sectorial Operational Program for Human Resources Development between 2007 and the end of February 2011

To evaluate the level of financing of the projects from European funds available for Romania through structural instruments between 2007 and 2013 we conducted and analysis regarding the projects submitted and financed by the SOP HRD starting from 2007 and until the end of February 2011.

The analysis performed takes into account both the quantification of contracted projects and focus on each key area of intervention in one hand, and the values of these contracts

on the other hand. The database used for the analysis was provided by the Management Authority of the Sectorial Operational Programme for Human Resources Development and regards the period 2007 february 2011 which represents aproximatively the half of the entire period set to implement the communitary policy from 2007 to 2013 and use the financial allocations from European Union.

The first goal of our analysis is to identify how many projects were contracted for each priority axis of the programme.

Figure no. 1

Number of contracted projects for the seven axis of the SOP HRD

Source: data processing by author

From the chart above it appears that most of the approved projects were contracted under Axis 3 (Increasing adaptability of workers and enterprises). In this context, it is noted that only 3 axes, 1 (education and training in support of growth and development of knowledge-based society) and 5 (Promoting active employment measures) exceed the 400 projects.

The underlined situation leads us to the conclusion that these are the lines of action in which the beneficiaries of the projects identified more opportunities. Not far from leading positions we find axis 2 (correlation of lifelong learning and the labor market) that the 370 projects with exceed 4 the axes (Modernising public employment service), 6 (Promoting social inclusion) and 7 (Technical) together.

Axis 6, although numbers less than 200 projects, it clearly exceeds the last two grades. If for priority axis 7 is somewhere normal that the number of projects to be lower than in other cases, the same could not be said about the axis 4 which reflect the lack of efforts to increase the efficiency of the Public Employment Service. Remains to be

seen to what extent, in the upcoming period, the number of projects approved for each axis will increase.

Figure no. 2

Source: data processing by author

The graph above shows the distribution of the contracted projects on each key areas of intervention (KAI) for the 7 axes. Thus, within the priority axis 1, which refers to five KAI, were contracted 430 projects in total. Most of them (141) concerns KAI 3 respectively human resources development in education and training.

Also in the axis 1, 134 projects were contracted in the KAI 5 (Doctoral and post-doctoral programs to support research). Each of the others DMI have less than 100 projects approved, the order is as follows: KAI 2 (Quality in higher education) - 80 projects, KAI 1 (access to initial education and vocational training) - 58 approved projects and KAI 4 (Quality in continuous professional training) - only 17 projects.

Within the axis 2, which includes three key areas of intervention have been contracted a total of 370 projects. Among these 149 concerns KAI 3 (access and participation in CPT). The other two KAIs are relatively close, namely: KAI 1 (transition from school to work) - 131 projects and KAI 2 (Preventing and correcting of early school leaving) - 90 projects.

The priority axis 3 also has three major areas of intervention, the number of approved projects amounting to a total number of 502. Here it is noted that KAI 2 (Training and support for businesses and employees to promote adaptability) recorded a greater number of projects than KAI 1 (Promoting entrepreneurial culture) and KAI 3 (development of partnerships and encouraging initiatives for social partners and civil society) together. Thus, the order is: KAI 2-315 projects, KAI 1-118 projects and KAI 3-69 projects.

The two key areas of intervention under Axis 4 recorded in total only 33 projects. Under these conditions on the KAI 1 (Strengthening Public Employment Service to provide employment services) were contracted 21 projects and on KAI 2 (training personnel of the Public Employment Service) 12.

In the axis 5 is observed a significant difference between the two major areas of intervention which together account for 472 projects. Thus, under KAI 1 (Developing and implementing active employment measures) were contracted 385 projects, while KAI 2 (Promoting long term sustainability of rural areas regarding the human resources development and employment) have only 87 projects approved (four times less).

The four major areas of intervention of the axis 6 projects summarize 181 approved projects. . Thus, the hierarchy of the axis is: KAI 2 (Improving access and participation of vulnerable groups in the labor market) - 61 of projects, KAI 1 (the development of social economy) - 58 projects, KAI 3 (Promote gender equality on the labor market) - 55 projects and KAI 4 (trans-national initiatives for an inclusive labor market) - only seven projects.

In the axis 7, which has two major areas of intervention have been contracted a total of only 23 projects, distributed as follows: KAI 1 (Support for implementation, overall management and evaluation of SOP HRD) - 15 projects, KAI 2 (Support for SOP HRD promotion and communication) - 8 projects.

Another element analysed is the percentage allocated for each axis of the programme from the total financed value (the value of the finance agreement which can be different from the final value of the project depending on the capacity of the beneficiaries to make expenses from its own funds before reimbursement. At the end of february the total value of the the contracted projects was about 3.3 billions EUR.

Figure no.3

Percentage from total financed value for each axis

Source: data processing by author

The graph above shows, in a detailed manner the percentage distribution of the values of contracted projects on each priority axis of SOP HRD. Thus we note that axis 1 (education and training in support of growth and development of the knowledge-based society) aggregates the most consistent amounts contracted through projects developed by the beneficiaries, reaching the threshold of 32% of the total value approved.

Axis 3 (Increasing adaptability of workers and enterprises) includes projects whose the total value is 20% and is closely followed by axis 2 (correlation of the lifelong learning and the labor market) by 18%.

The values resulting from projects related to axis 6 (Promoting social inclusion) and 5 (Promoting active employment measures) are close. The difference between the two is only 1%.

Under axis 4 (Modernizing Public Employment Service) contracted projects account for 2.70% of the total value of the programme under this axis being situated only 7 (Technical) with 0.30%.

4. Conclusions

The Human Resources Development Operational Programme is the most accessed operational programme for the period taken into account for our analysis as the situation of the submitted and also the approved projects to be financed under the seven operational programmes for Romania for 2007-2013 period prove.

Figure no.4

Submitted projects

Source: data processing by author

Figures reveal that the total projects submitted most were within the Human Resources Development Operational Programme SOP HRD (37.40%). Increase of Economic Competitiveness Operational Programme SOP IEC and Regional Operational Programme showed similar values in this regard, each exceeding the threshold of 28%. Romania's other operational programmes together account for 6.22% of all projects submitted.

Figure no.5

Source: data processing by author

Human Resources Development Operational Programme has the largest share of the total approved projects reviewed by 28/02/2011. SOP Increase of Economic Competitiveness ranks second in terms approved projects, only 6 percent apart. Well below expectations, we find the projects approved in Regional Operational project totaling only 19% of the total. In the other operational programmes chart illustrates the delicate situation closely facing our country on the line absorption of EU funds.

Figure no.6

Source: data processing by author

The analysis showed that the number of rejected projects is very high, clearly exceeding the total number of approved projects. This leads to the conclusion that there were numerous deficiencies in the drafting. Most affected have been the Sectoral Operational Programme Human Resources Development, Sectoral Operational Programme Increase of Economic Competitiveness and ROP.

In conclusion regarding the financing process through the SOP HRD we can consider that, even the number of rejected projects was relatively high, this operational programme is the most accessed of the all operational programmes and within the programme the priority axis 3 represents the leader on terms of contracted projects.

Communication Analysis for a Tourism Enterprise

Dumitrașcu Elena
Mărunțelu Liliana
„Ovidius” University of Constanta
elena_mam2006@yahoo.com
liliana_maruntelu@yahoo.com

Abstract

The implementation of a global communication strategy does not stand for a measure that could be put into action one day or another, but it requires a long way which is often blocked by obstacles or in danger of being lost. For such risks to be prevented, the establishment of an elaborated system of communication assessment (in its various forms, and also at a global level) is crucial (and unfortunately non-existent even in the incipient forms at SC THR “Black Sea” in Eforie Nord). The global communication strategy implies an agreement between the internal communication strategies and the institutional and commercial ones. On the one hand, a separation between those strategies cannot be done accurately, and on the other hand, it may affect the approach that led us to debate the theme of global communication.

Key words: global communication, strategy, objective, institutional communication, logo.

J.E.L. classification: D83, M14

1. Introduction

Effective communication is the key to success in modern organization. Inside the company, this effective communication strengthens the employees' confidence in the organization's mission and vision, connects the employees to the reality of that particular business, fuels the company's development process and helps facilitate the change in employee's behaviour. On the outside, the company image, the discovery of new business opportunities and the relationship with the society depend largely on how well this continuous process of communication is designed and managed.

In other words, companies communicate increasingly more, however - taking into consideration the technological progress – they prefer the more modern and faster ways of sending and receiving information. Measuring the communication process becomes thus mandatory in order to design, apply and modify – where necessary- the communication strategy of a company or organization with the purpose of increasing its profit.

Communication plays an important role in the enterprise activity, while implications of the communicational process are like waves propagation at the level of all organization functions. Of course, some might wonder how the separation of communication process from other factors that lead to the development of a company succeeded. The answer is simple: communication stands for the foundation on which other factors that depend on the company are built: investments, advanced management, human resources and the intelligent use of HR, brilliant ideas, tenacity.

Designing and implementing the communication strategy (both external and internal) may not be easily achieved, while global communication involves extremely complex phenomena regarding both the content and the required stages. Therefore, the elaboration of a communication strategy should be made rigorously on the basis of a well founded plan while taking into account the features that define each component of the global communication.

The communication strategy should under no circumstances be detached from the enterprise overall strategy; instead it should be integrated first in the overall strategy and afterwards at the managerial levels. Therefore, the communication strategy stands for a factor which conditions the implementation of the overall strategy,

representing at the same time a component of the enterprise's strategy.

2. Communication Analysis for S.C.THR "Black Sea" S.A. in Eforie Nord

For the communication analysis, we started with the exploration of the following strategy: S.C.THR "Black Sea" S.A. in Eforie Nord. Speaking of this society, unfortunately, strategic planning is not given the worthy importance. However, analysis activity, as well as the exploration of some internal documents and of information provided by the society, make possible the identification of some strategic coordinates for the S.C.THR "Black Sea" S.A. Starting with 2008 (until 2012), the company has opted for a reorganization strategy, attainable by selling many assets of the company while rehabilitating the others (conversion to three and four star objectives).

Sales of assets should be made by means such as public auction, direct negotiation or real estate leasing. For the 2008-2012 period, the touristic company has developed an investment program, amounting to 67,43 million Euros, to modernize the assets that remain part of the patrimony.

Regarding the internal communication within S.C.THR "Black Sea" S.A. in Eforie Nord, we have noticed the following applied methods:

- internal communication methods by means of printed materials: internal magazines, newsletters, flyers etc¹;
- oral communication methods: informational meetings, open discussions, direct informing from the head of the organization, committees and working groups, conferences, seminars and speeches;
- electronic methods of communication: internet, e-mail and videos;
- communication methods by means of display units: fixed display panels, notice boards, banners;
- training and improvement courses for the organization's staff inside that organization.

In regard to the external communication, the most important methods used by S.C.THR "Black Sea" S.A. are:

-external communication methods for establishing mass-media relationships: news releases, press releases, articles for specialty magazines, announcements, press photos, press briefings and press review – national press speeches at the national press regarding the HORECA sector and forwarded by the Directorate of Marketing by e-mail;

-external communication methods for developing relationships with customers: e-mail mk@efonet.ro;

-training and improvement courses for the organization's staff outside the organization.

Out of the two external communication components at S.C.THR "Black Sea" S.A., the institutional communication is somehow neglected or 'obsolete', the commercial one being more developed.

For the commercial communication analysis at S.C.THR "Black Sea" S.A. we began with the organization's marketing plan for 2008. This analysis intends to emphasize the fact that unlike the configuration of the internal and institutional communication actions, the marketing communication is much more rigorously designed, following closely the theoretical points regarding the strategic development.

The first section of the marketing plan aims at *defining the organization's offer*. Thus, it is divided into two categories: *basic services* (accommodation, meals, entertainment, therapy) and *additional services*. These are themselves divided into two categories: **for money** (phone, fax, selling items of immediate necessity, beach items rentals – deck chairs, sun umbrella, iron hire – parking, fitness room, pool, air conditioning) and **free of charge** (touristic information – sport events programs, entertainment programs, organized tours programs, public transport timetable, sending and receiving messages – mail distribution, publicity touristic materials, reception press, baggage handling and storage of baggage in special arranged places, keeping valuable belongings in safe deposits, keeping forgotten objects and announcing them, waking up tourists on demand, shoe cleaning, hair dryer, first aid medical kit, booking seats at shows, concerts and in public transportation, special activities – folklore evenings, wine tasting – emergency call).

Furthermore, the organization has proposed to attract a social category represented by middle-income youth, including high-school students and university-students. Attracting this new market segment depends mainly on the diversification of services and products offered to young people, as well as on both the improvement or modernization of the existing entertainment places and the creation of new ones addressing this segment of people (modernization of day and night bars, discos and summer terraces etc.). This attraction depends also on the general level of development and maintenance of each and every resort.

Analyzing this organization's touristic market, we have sketched a *profile of the actual customer*, as well as of the *potential customer* for each unit belonging to S.C.THR "Black Sea" S.A. In our opinion, for the next period of time, the potential customer will remain the traditional one, while the actual client is represented by the Romanian tourist with middle income and by the foreigner tourist with low income.

The marketing specialists within S.C.THR "Black Sea" S.A. have identified the so-called 'crucial factors' for each category of touristic unit, that is criteria which decisively influence consumer's choice, directing him/her towards one of the locations or another.

Starting with these elements, but also taking into consideration the particularities of the touristic sector in Romania, the Marketing and Sales Director has established some main objectives for the year 2008:

- to increase the quality of the offered services;
- to improve the contracted structure by reducing the predominance of CNPAS with about 5% for the benefit of the travel agencies;
- to develop the touristic product by introducing the 'all inclusive' system in the Cleopatra complex of Saturn;
- to develop the market, as well as entering new market segments, and reaching both the business segment and the events segment by arranging the places designed for the involved category;
- to provide with adequate tools/equipment (the Bran-Brad-Bega and Cleopatra complexes), as well as to enter new

markets abroad (Czech Republic, Ukraine, Moldova, Belarus, the Russian Federation);

In addition to this realistic goals, the Marketing and Sales Director has also established some more general objectives that are divided into eight domains (positioning, product policy, price policy, distribution policy, promotion policy, environmental policy, process policy and personnel policy), being also accompanied by some strategies.

Regarding the promotion policy, the following objectives have been established:

- promoting the SC THR " Black Sea" SA. Brand;
- promoting the new touristic complexes that will be reintroduced in the touristic circuits after modernization (Cleopatra and B-B-B);
- promoting complexes that have therapeutic bases within, such as: Sirena, Balada, Cerna, Hora.

At the same time, two stars hotels and restaurants of great importance in the company's offer will be also promoted: Venus Hotel, Minerva Hotel, Aqua Park Cleopatra, Balada (the leisure and entertainment centres are one of the 'magnates' that attract clients), Lidia Hotel, Măgura Hotel, Capitol Hotel.

In order to implement these objectives, the following methods have been chosen:

- registering in catalogues, magazines, presentation guides, specialty works;
- presentation of the organization and its services in national and local newspapers, radio and TV, internet;
- manufacturing and distributing publicity materials (flyers, leaflets, brochures, maps, catalogues, posters, personalized matchboxes and sugar bags, banners);
- participation in trade fairs, scholarships and travel fairs.

By following these plans we can say that just as in the past few years, actions have been approximately the same, with few minor changes. Moreover, during 2004-2007, actions categorised as 'communication related' (commercial or institutional) can be mentioned:

- promoting the main touristic locations (primarily www.infoturism.ro.) (The action (operation) was included in the

2007 plan, but was only partially achieved. The main hotels in the company's portfolio have been included on the website, however without details concerning facilities, payment or entertainment possibilities. Furthermore, there is no direct connection between the company and the hotels registered on the site).

- organising international nights in restaurants within three stars hotels (Turkish, Italian, German and Spanish nights- music and dishes specific to each nationality)(The goals of such an action are related to promoting the image, improving the quality and diversifying the touristic product. The action was included in the plan for 2007.)
- hosting some TV Shows, located in S.C.THR "Black Sea" S.A (2007)
- opening Eforie Club (the Union Complex and the "B's") as well as offering loyalty cards to club members (2007);
- providing personalized uniforms for pool personnel- lifeguard, waiter (2006);
- including "Menu of the Day" (Day Speciality) in all company's nourishment units;
- establishing a "Happy Hour" program, especially during the periods previous and subsequent to the peak season - May, June and September (2007);
- promoting Romanian specific evenings at "Nunta Zamfirei" (Zamfirei's Wedding) Restaurant (2007);
- selling spaces for advertisement such as the inside and outside walls of one and two star hotels (in my opinion, this action has unfavourable results for the company's image. The spaces used by third parties could be designed in such way to offer elements of distinction);
- increasing the entertainment activities in front of the "Vraja Marii" (Sea Spell) bar by employing a DJ and an animator (entertainer) as well as including various contests (2008);
- participating at various culinary salons (2007).Although these actions were undertaken, the impression left is that the marketing and institutional communication is slightly chaotic, but it is possible to be only a subjective perception. However, no

counterarguments that things would be different have been brought by the organization, considering that at the organization's level there is no concern for the assessment and quantification of communication effects.

In our opinion, the institutional communication at S.C.THR "Black Sea" S.A. has several shortcomings, some of them having quite relevant justification.

Under these circumstances, the issue of building a company's image which may function at the same time as an umbrella for all these subdivisions is a difficult thing to do. Analyzing the means used in the institutional communication, we stopped first at the institutional publicity. The local mass-media components are used as channels in the institutional publicity. From our point of view, the society having a target audience across the country should have a much more aggressive publicity in the national mass-media.

The company has a logo that you can tabulate as a mixed one, resulting from the association of the logotype with an icotype. (Fig. 1) The logotype contains an acronym (THR – Tourism, Hotels, Restaurants) and also the society's name "Black Sea". The icotype (stylized waves), together with the blue colour, refers to the company's activity object – coastline tourism. The symbolism in the logo is not a metaphorical one and does not refer to a specific positioning of the company or to some privileged values.

The S.C.THR "Black Sea" S.A. Eforie Nord logo

Finally, we make an analysis of the company's site, emphasizing the main characteristics. Thus, the website of S.C.THR "Black Sea" S.A. offers a substantial informational content. The information is well structured and organized into links that have clear names and that appear on the website's first page.

The first/main page of this company contains the following links: "About Us", "Resorts", "Treatment", "Entertainment", "Prices", "Photo Gallery", "Special Offers", "Contact", "Reports", "AGA", "Auctions", "Announcements", "Hotels", "Restaurants", "Villas".

The site also provides with useful current information which is not related to the organization's services, such as the weather forecast and the currency exchange rates. This information is daily updated. The website is designed both in Romanian and English, a fact which is necessary as long as the company aims at foreign customers also. The graphic is not overloaded, but it remains constant on all links. The main colours used are blue and red, the former being presented in the company's logo as well.

Given its configuration, the website can be considered a tool of communication with the media thanks to the information published in the "Auctions" and "Announcements" links.

The main methods by means of which the website can be promoted are: exchanging links (with Transilvania Travel agency), registering in many more tourism portals and introducing the site in many search engines (www.google.com, www.altavista.com).

Besides these arguments, it is fair to recognize the website's weak points as well. First of all, in some links we may find 'dull' expressions which are unable to arise interest in the potential customers and which don't have a counterpart in reality: *"the clear, competitive strategy which is based on the quality of services and the entire organization's focus on client is what makes S.C.THR "Black Sea" S.A. to be recommended"*, *"the recreational possibilities on the Romanian coastline are multiple and varied"*; *"Tourists who choose those truly unique destinations spend unforgettable moments"*; *"pools can be also considered oasis of relaxation and tranquillity"*.

Comparing the website of the S.C.THR "Black Sea" S.A. with sites belonging to hotels abroad, one may observe the lack of some elements that are otherwise presented in quasi-all similar websites that I visited: a statement of the company's vision and mission, a link that allows a virtual verification of accommodation possibilities in a given period or a virtual system of

booking, a link that allows making a virtual tour, or a link that facilitates cost calculation of a certain package tour.

We have discussed about a diffused image, about a slightly suggestive logo, about a slogan having no impact, but all these are conclusions of an empirical analysis. These judgements which are poorly substantiated should not mislead to the idea that everything regarding the institutional communication at the level of S.C.THR "Black Sea" S.A. is inappropriate.

This is why, a study of the perceived image is truly necessary. Moreover, one should add studies regarding the organizational culture, the competitors' image and the potential target audiences.

Depending on these, one could re(position) the enterprise's image, taking into consideration both the external environment elements and the supporting elements in the internal environment. Once this positioning is achieved, we may have a framework that includes not only all institutional communication actions, but also some internal and commercial communication ones.

3. Conclusions

To conclude with, we would like to emphasize the fact that the implementation of a global communication strategy implies research between all communicational strategies, i. e. internal, institutional and commercial. On the one hand, a separation between them cannot be done accurately and on the other hand it may affect the approach that led us to debate the theme of global communication. Furthermore, imposing a global communication strategy is not a process that could be achieved in a few days time; on the contrary it consists of a long track, often liable to be blocked by obstacles or to become lost. In order to prevent these kind of risks it is essential to implement an elaborated system of communication evaluation (in its diverse forms, but also at a global level); unfortunately, this implementation is non-existent even at its incipient forms at SC THR "Black Sea" SA.

The Efficiency of Internal Public Audit Activity for the Local Public Administration

Dumitrescu Adelina

National School of Political Studies and Public Administration

adelinad@snspp.ro

Abstract

The public administration is subject to major changes, due to major changes within the Romanian society and ever growing requirements of efficiency, effectiveness and economy. Given a certain conflict between support activities which are at times most expensive and these requirements, a race is on for optimizing these activities from a financial point of view.

This paper is the result of a research that has taken place in the years 2009 and 2010, and proposes a way to reach a better state regarding the internal public audit.

Key words: Internal public audit, centralization, decentralization, rural communities, correlation analysis

J.E.L. classification: D73, H21, H72, H83, M42, R51.

1. Introduction

Economic, political and social transformations in our country after 1990 have confirmed clearly that local public administration management compliant to today's growing demands isn't possible without a profound knowledge of the economic realities in all their complexity. From this perspective the acknowledgement of the economic reality of local communities is an objective necessity of their management, a major and indispensable dimension for exactly identifying the development stage and the way in which the administration must respond to the needs of its subjects.

One of the main demands for the public administration, and one of the main problems of the local administrations at the same time

is the efficiency of public funds spending (Matei, 2009: p. 35, 36), especially for such activities that do not constitute primordial preoccupations. Such an activity is the internal public audit, whose organization is mandatory for each and every public institution from Romania. The efficiency of support activities in Romania's public administration thus is not only a desiderate, but also a necessity, given the budgetary restrictions on the rural level. Public auditing, which is meant to insure the efficiency of public institutions activity is actually interfering with its own object of study.

2. Statistical considerations

According to the Romanian Statistic Yearbook 2008, Romania had on July 1st, 2006 a population of 21.584.365 inhabitants, of which 9.765.435 rural inhabitants. Romania is thus demographically, a strongly rural based country, with 45,24% rural inhabitants. Excluding Bucharest, with a registered population of 1.931.236, the quota of rural inhabitants rises to 49,69%.

Romania has 2823 rural communities in 41 districts, an average of 69 communities per district. The most rural communities can be found in the districts of Dolj and Olt with 104 communities each, while the fewest communities are located in Ilfov (32) and Salaj (39). The 2823 rural communities count 12.144 villages, meaning an average of 4 villages for each rural community. The most villages can be found in the district of Alba (658 villages), and Arges (577 villages). The fewest villages are in Tulcea (51 villages) and Ilfov (102 villages).

We can thus ask ourselves, can be the internal public audit in rural communities made more efficient? Is the existence of at least one internal public auditor in rural administrations efficient? Can another organization of the internal public audit be a

more efficient and economical solution, which could bring substantial economies to the local budgets?

In order to answer these questions and to guarantee the opportunity of taking some variables into account, a series of states of facts must be determined based on some calculated indexes:

- Urbanization degree of the district: meaning the ratio of the urban population to the total population of Romania;
- Weight: the weight of the population of one district in the total population of Romania;
- Villages per community (*Vill/Comm*): the ratio of the number of villages in a district to the number of communities in the same district;
- Inhabitants per community (*Inh/Comm*): is determined by dividing the amount of rural population of a district to the total population of that district.

However, for the final conclusions not only statistical data but also qualitative factors like the relief of the districts or the possibilities offered by the existing infrastructure have been taken into consideration. Also, the research did not concentrate on each district, but on specific groups of districts, which have been built according to historical criteria. Thus, the following regions have been built: Banat, Transilvania, Muntenia, Moldova and Dobrogea.

This grouping has been chosen for the easying of the data analysis for the following reasons:

- Historically, the districts in these regions have known similar economic and demographic developments;
- Statistically, the standard deviations (*StDev* in table 1) of the mentioned indexes have shown mostly lower values than the standard deviations for the whole statistic population.

Table 1. – Standard deviations for the historic regions

	<i>Urbaniz.</i>	<i>Weight</i>	<i>Vill/Comm</i>	<i>Inh/Com</i>
StDev Banat	0,0626	0,0077	0,2188	642,62
StDev Dobrogea	0,1521	0,0152	1,5202	592,45
StDev Moldova	0,0370	0,0076	2,4994	388,32
StDev Muntenia	0,0921	0,0077	1,5330	776,03
StDev Transilvania	0,1203	0,0068	2,0774	378,34
StDev Total	0,1107	0,0077	1,8988	740,31

source: <http://www.comune.ro>, accessed on Aug. 9th 2010

In table 1 the values of the standard deviation that exceed the national value are shown red. It can be observed that these values still lie around the national values. This confirms the hypothesis that the historic regions have known similar developments. The grouping in five regions has been proven to be statistically sufficient.

Table 2. – Grouped demographic data

<i>Region</i>	<i>Urbaniz.</i>	<i>Weight</i>	<i>Vill/Com</i>	<i>Inh/Com</i>
Banat	56,57%	6,72%	4	2.774
Dobrogea	59,99%	4,49%	2	3.196
Moldova	42,35%	19,11%	4	4.256
Muntenia	44,67%	34,15%	4	3.601
Transilvania	55,06%	26,59%	5	2.996
BUCURESTI	100%	8,95%	0	0
Nat. Values	54,68%	100%	4	3.127

Source: <http://www.comune.ro>, accessed on Aug. 9th 2010

3. Correlation analysis

In order to draw the right conclusions about the gathered data, the degree of to which these variables depend of each other must be studied. This offers information about certain states of fact that can influence the qualitative analysis. Thus data interpretation will differ according to the different correlations between data sets. In this case, the finding of a deterministic link between these variables is not important, but the mere determination of its existence.

For this a correlation analysis has been carried out. This kind of analysis refers to the calculation of one or more correlation coefficients between different data sets. For our purpose the Bravais-Pearson Correlation coefficient has been used, to determine the linearity of the dependence of two variables, and is calculated according to the formula below (Bourier, 2005):

$$r_{xy} = \frac{\sum_{i=1}^n (x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum_{i=1}^n (x_i - \bar{x})^2 \cdot \sum_{i=1}^n (y_i - \bar{y})^2}}$$

(Formula 1.)

Where:

r_{xy} = Bravais – Pearson correlation coefficient

x_i, y_i = data from set X and Y, corresponding to index position i;

\bar{x}, \bar{y} = average values for X and Y data

i = current index between 1 and n;

n = sample size.

The calculated main coefficients are shown in table 3.

Table 3 – Main correlation coefficients for calculated indexes

Correlation	Value
Vill/Comm – Inh/Comm	-0,14393
Inh/Comm – Urbanization	-0,38214
Urbanization-District population	0,30009
Urbanization – Vill/Comm	0,09266
Rural pop - Urbanization	-0,34461

4. Qualitative analysis

The major step forward made by Romania after 1990 for the modernization of the public administration was the transmission of competency at the communal, urban and district level, and implicitly, the creation of a new organization and coordination form for public policies. Law 215/2001 for the public administration stipulates the founding of public services in the main activity fields of the city or community, according to the local note and needs, legal terms and allocated budgets. There is however a distinction

between the different categories of services (Profiroiu, 2010, p. 153): public services and comminatory services of public utility. The result of these actions was the decentralization of power, authority and decision. The decentralization process has also imposed the need for verification and control in the public administration and the need to extend the preoccupation areas up to the rural public administration. This is also stated in Law 672/2002 regarding the internal public audit, which specifies that every public institution must organize internal public audit.

Yet, as an activity organized within the public administration, internal public audit is subjected to the same performance requirements as the public institution in whose ranks it is organized in. Here we observe a first conflict between the formal legal demands and the economic requirements for one and the same entity. Starting from the idea that 2823 communities have the need for at least 2823 internal public auditors, we ask the question of efficiency of a completely decentralized verification and control system at the level of rural authorities. Without taking into account the all expenses, only salaries, material costs and basic investments, we can say that the yearly amount necessary to organize internal public audit at the rural level is of about 150 million Lei. Although at the level of the national budget 150 million Lei are not an impressive amount, these savings must be regarded upon from the perspective of local communities. For each of the 2823 communities, savings of 150 million Lei represent an average additional income of 53.000 Lei, which can be used to finance other activities.

A possible way of making this domain more efficient is to conduct the internal public audit at a district level. Thus the control degree of the local councils on the rural administrations is increased by centralization of the audit activities at a district level. This is also stipulated as an „escape hatch” for those public institution that cannot for various reasons organize the internal public audit, and in internal regulations of public institutions as well. Clearly, a public institution which cannot organize the internal public audit, must be audited by the organization that is hierarchically superior. Such a measure

would have a few negative effects, but would be mostly beneficial. The negative implications are:

- Growth in transport expenditures;
 - Growth in auditors workload;
 - Possibility of increased procedure errors.
- The advantages of such a measure are more important. From these we enumerate:
- A unified audit methodology;
 - Compliance with the reorganization plans of the public sector;
 - The need to optimize the auditing process and procedures;
 - Independence of the auditor towards the audited entity;
 - Reduction of the demand for highly trained workforce;
 - Increase in transparency of the internal public audit.

5. Conclusion

The modernization process of the Romanian public administration must take place under the sign of permanent change in the sense of optimizing all processes that take place within it. The decentralization process is in this regard one of the essential steps that have to be completed in order for the public administration to respond to the needs and requirements of the statute of an EU member state.

In this regard, the fact must be mentioned, that a decentralized public administration is more susceptible to errors of procedure or operational errors, than a central one, errors which must be prevented and avoided in order to insure a coherent and efficient administrative process. Thus it is imperative that the control and prevention system is a national one, meaning central. We grab the idea that a central system of control and prevention (e.g. internal public audit) can guarantee the efficiency, economy and effectiveness of a decentralized public administration.

Opportunities for Upgrading the Local Community Budget

Dumitru Franca

"Tibiscus" University of Timișoara, Faculty of Economic Sciences
francadumitru@yahoo.com

Abstract

Financial decentralization, along with financial globalization, are currently two of the phenomena that concern professionals involved in reforming the local government finance and accounting systems, that are trying hard to become a language of communication for those interested in knowing the position and financial performance of local communities in Romania, as well as internationally. To meet the need of informing the taxpayers interested in knowing the methods of incorporation and usage of resources, of training financial creditors in administering their capacity for repaying any loans, as well as all the interest parties (including central government), local communities have turned to instruments they have at hand: budget and accounting.

Key words: budget, accounting, loans, transfers, local community

J.E.L. classification: M41, M49.

1. Introduction

Pressures on the balance of local budgets began to raise, local authorities being forced to choose from two possible alternatives:

- to **use loans** as a result of budget deficits recorded, the initiative of the legislature to impose restrictions on their use is laudable, debt financing being provided only for public investments only for local interests and local opportunities for refinancing debt.
- to **receive transfers from the state budget**, and thus to show an increasing reliance of central governments. The consequence is limitation of the financial autonomy of local communities, transferred grants being conditional or unconditional, as central authorities'

intention is to support certain policies or strategies in certain areas or to fund certain categories of expenditures of local authorities.

Faced with such alternatives, local authorities search for those tools based on modern financial management that reflects best:

a) **financial position** as an expression of net worth available to the community at a certain time, reflecting that part of the public assets that are not encumbered by debt;

b) **financial performance** as a result of the "profitability" confirmation to the activities of the local community in the delicate, complex and lengthy process for the formation of public financial resources and their allocation by destination;

c) **cash flows** as a consequence of receipts and payments transactions conducted at the administrative-territorial unit and as an expression of financial creditworthiness to ensure the creditors of financial loans that local communities have called them, determined in time the existence availability of cash "kept" in the treasury accounts or covered shortages most often by fund working capital or cash loans.

The first area of analysis was the local budget (of local communities) often defined as a financial planning tool where resources are mainly from taxes, while their maximum allocation is determined by the structure of the budget appropriations approved by the budget law year.

The financial[1] mechanism of functioning of public institutions is relatively simple, taxes and fees collected from the local budget are depersonalized and finance public spending categories that coincide with the structure of public services, despite the fact that it is approved annually by the budget law (as mentioned above) is still defined by the extensive process of decentralization of public services and their proximity to citizens.

The ordered structure of public managers known as primary, secondary or tertiary credit officers are doomed to meet the rigors of public expenditure execution so that ultimately services can be provided under maximum quality and permanence.

Results soon appeared because of the various implications that they have primarily on increasing revenues consisting of: increasing revenue from the tax on buildings, increasing land tax revenues, increased income from shares deducted from the income tax, registration of income from the construction authorization tax.

Although these are revenues specific for local communities and by following the rigors of law, some facilities may be granted to investors finally representing an investment that local authorities can do, we established a function name "extra income local budgets function" which will help local decision factors to quantify the additional revenue that foreign investments can generate.

Analysis[2] of skills' transfer regarding costs, based on principles of efficiency, equity, accountability and macroeconomic balance, led to the following conclusions:

1) sharing public services between levels I and II is based on the administration of public services closer to citizens;

2) public services is entrusted only to those authorities which have full management and financial capacity to manage them;

3) criterion of territoriality is a key criterion used in the sharing of responsibilities between the local government I and II.

Skills transfer regarding income is based on subsidiary principles, the connection of income with the assumed responsibilities, equity, predictability, neutrality, objectivity and conditioning transfers, and dedicating two methods in literature:

1. Method of custody / allocation
2. Revenue sharing method

2. Method of custody / allocation

Method of custody / allocation, led to the delineation of a new sphere of public finances belonging to the local communities, thus making the concept of public finances known as local government finances. Studied

in countries like Poland, Hungary, Czech Republic, Estonia, the method led to the system resources assigned to two categories of income:

- own revenues that the authorities can manage in conditions of limited fiscal autonomy, with the tax base and/or tax rate determined at central level;
- additional shares (piggy back), in which local authorities can add to the national tax rate some additional flexibility, the tax base and tax administration is under the responsibility of government. The relatively simple method has not led to the expected results, sometimes responsibility transfer is not fully covered by resources.

3. Revenue sharing method

Revenue sharing method, designed to solve the problem of financing public services, studied for the same countries Poland, Hungary, Czech Republic and Estonia is that both base and tax rates are set centrally, while funds are shared between central government and local authorities based on certain criteria.

Revenue sharing, in international practice takes place on two ways:

- on a derivative base (the origin of collection);
- as transfers divided on the basis of a formula, cost reimbursement of public services provided or based on ad hoc decisions.

The combination of methods of determining the volume of inter-administrative transfers to local authorities with the methods of allocating the transfers between the local authorities, in international practice, new types of transfers have resulted:

- Type A transfer - contributes to local authorities with a greater fiscal capacity being considered anti-equalizer;
- Type B transfer - provides horizontal balance, is used to reduce discrepancies between the administrative-territorial unit;
- Type C transfer - is allocated between local authorities, is a conditional transfer based on the reimbursement cost of public services;
- Type D transfer - is allocated between local authorities based on an ad-hoc decision, with regard to discretionary criteria. It can be conditional or unconditional;

- Type E transfer - is a central transfer, with general purpose, the amounts are allocated based on a principle of derivation;

- Type F transfer - is based on the fact that the amounts are apportioned between local authorities using a formula, by a general purpose;

- Type G transfer - comes from the central level based on ad hoc decisions, and between local authorities are the amounts are reimbursed by the reimbursement amounts;

- Type H transfer - is based on the same ad-hoc decision on central to local level, division between the administrative-territorial units being achieved on the basis of that ad hoc decision. It is the central transfer;

- Type K transfer - is a special-purpose transfer, it is based on both the situation at the central allocation amounts to the local level and between the administrative-territorial cost-based reimbursements.

Financial decentralization will lead eventually, both for Romania and internationally, in the community, regardless of the type of transfer sought, to issues of balancing local budgets.

Financial resources are the most important wealth available to local communities at a certain time, being a means of financial support of the public services for citizens.

Because most of local revenues are represented by tax revenue, we conducted a review of international taxation, and got to the following conclusions:

1. The level of local taxation is determined primarily by the level of expenditure that are the local authorities' responsibility;
2. Correlation tax - liability means that where local revenues are a small percentage of total revenue and the responsibilities of local authorities is also reduced;
3. In federal countries, the relative importance of taxes and fees are generally lower than in unitary countries, since the federal government collects income countries while the unitary countries are the area of interest of local authorities;
4. In countries where local revenues are compared higher as the percentage of GDP and total revenue, local authorities have more confidence in local income taxes;
5. Local authorities in some countries have access to only one tax (property or

income) while local communities from other countries have access to two or three local taxes (fees).

As most local taxes are usually formed as a product of the tax base and tax rate, an important issue in local taxation is the limited fiscal autonomy, determined by local communities' possibility to establish:

- a) tax base without restrictions at national level;

- b) tax rate;

- c) tax base and rate, consequence of a full fiscal autonomy.

The analysis of fiscal autonomy situation, at international level, highlights the following trends:

- local authorities set the tax rate and base in very few countries;

- revenue division between central government and local authorities is different: by setting division conditions under the law, by changing revenue division agreement with local authorities or the determination by the central government division arrangements.

Two indicators are representative for local communities, who are represented by:

- 1) *feasibility of local taxes* - new indicator that came at the reform table, which will help local communities to assess the profitability of maintaining a tax or an entire tax system, after deducting all expenses in income tax administration or local tax system as a whole, two forms are identified:

- a) *feasibility of uniform tax*, expressed as the average taxpayer unit;

- b) *feasibility of aggregate tax*, set at the whole tax system.

- 2) *tax depreciation* - the second indicator will be useful to local authorities to determine the number of years, on account of tax increment, they will recover their public investments made especially in infrastructure.

It is necessary to use a new model in which both the tax base and the tax rate to be determined independently (for property taxes), to be based on:

- determining the amount of tax on the market value of goods determined by the Tax Assessment Office functioning under local authorities;

- setting the tax rate as a ratio of budgetary resource requirements (determined on the basis of budget planning) and the tax value.

Of particular importance, is to clarify the situation of a new source of income which will find its rightful place with the completion of a delegation of public service management, whose essence is to ensure the operation of public infrastructure to service operators, for a known monthly amount known as a monthly fee.

The models available for feasibility and tax depreciation, along with community fee (thought at least monthly at depreciation level recorded in the linear regime) together with the new model of assessment for local taxes will be useful for authorizing credit officers called to provide the best management for financial resources.

At the opposite, and not insignificant, is the consumption of public resources, which ultimately gives life services for citizens in terms of efficiency, effectiveness and economy.

The next analyzed area, based on functional classification of public expenditure, is based on studying the effects of decentralization on the financing of public services provided by the local government expenditure.

Although the reform in the university education system is quite advanced, based on core funding from the state budget and additional funding from local budgets, crossing to financing on the standard cost of the current phase is a necessity to improve the rendered quality of university education.

The health reform soon appeared, the task of local communities is truly optional, which is to finance the costs of maintenance, household repairs and investment in buildings where health care facilities, medical and social assistance and nurseries, as they operate.

Capital expenditures were in turn examined separately, in addition to the presentation of important issues arising from the establishment of the capital investment program (CIP), the financing of public investment - analyzing the scenario from their own sources of financing versus borrowing and financing sources prioritization of investment objectives, we believe that the real benefit to local authorities will be the mathematical model that will help them plan the amount of financial resources that involves a public investment.

After a rigorous scientific foundation of the principles of the budgetary procedure - the principle of universality, publicity, monetary unit, annual, budget specialization and budget balance, known in literature, the schedule and budget policy statement due to macroeconomic changes they have made has enjoyed a special attention.

While macroeconomic policy statement sets out the macroeconomic indicators on which the local budget will project future budget years, the budget calendar has been much simplified in terms of work, presenting the disadvantage that it ignores the real needs of local authorities.

Financial foundation of the local budget was another area where traditional methods of analysis - automated method, the increase/decrease method, direct evaluation method with modern methods - the method of planning, programming, budgeting, management by objective method, method of zero budgeting contribute to the projection of budgetary indicators.

Another method based on time series analysis involves understanding the revenue system, the forces and events that have affected revenues in the past, obtaining information in a timely manner and implementing a sound judgment.

Applying the method involves the following steps:

- establishment data series and its graphic representation;
- calculating the slope and level of the central year;
- establishment of the right trend and forecasting for years N and $N + 1$.

Approval, execution and control of local budgets, as known in the literature was the subject of this paper, trying to debate and bring some improvements in the current budget process established forms, but we believe that a special attention should be given to the budget standards that will "win", we hope, more "ground", making his place in the everyday concerns of specialists.

Another[3] concern regarding the modernization of the local budget was the identification of specific modern financial management tools to help support establishment and resource allocation decisions of credit officers, in this category there are:

- **consolidated local budget**, which is a summation of each credit officer's budget, financed wholly or partly from the local budget equivalent of a consolidation, in order to ensure an overview of financial performance in each local community. Together with local budget, annex budgets are emerging for those public institutions that have provided the link with the local budget subsidies and government budgets for those service operators whose capital is wholly owned by local authorities.

- **budget programs** - the second instrument of financial management including as a "required" budget in official documents of the European Union, is defined as a coherent set of actions that relate to the same main budget, designed to achieve a defined goal or set of goals and indicators that are established by the program, to evaluate results achieved within the approved funding. We consider useful in the budget programs, to determine the average cost of capital when used as sources for funding their own and borrowed sources. We appreciate that the budget for programs will be a useful tool for developing investment programs and those of major repairs.

- **costs financing plan** - is another tool for financial management, being a preliminary step for developing the operating budget and "connected" capital without respecting the true principles of the budget, local budget revenues with allocations of resources in conditions of legislation.

- **operational budget and capital budget** - are based on connecting the income grouped in current income and capital with the consumption part of budget resources structured by the same criteria, resulting in: functional budget - the current work of local communities, whose final balance if surplus can constitute its own source of investment financing, capital budget - a characteristic development work, is a tool for quantifying the financial resources necessary to support public investment.

- **budget as an economic variable** was analyzed in terms of links between the budget surplus and taxable income, the relationship between local government gross domestic product and the links between the budget surplus and tax rate.

- **multi-annual budget** is the last form of financial management tools studied, which includes phasing financial resources over several budget years, to pursue investment policies formulated by local authorities. The American humorous metaphor about the camel getting his nose in the tent, to be followed by the rest of the animal in the coming years is a good illustration of the problem of multi-annual budgeting.

4. Conclusion

Presenting the budget as a financial plan, budgetary standards ensure that the scheme of consolidation and reconciliation of all transactions of receipts and payments are presented in a consolidated statement. In keeping with the idea of this budget as an operations guide, the second standard aims to compare data from the past with the present and tries to explain the relationship between capital and operational expenditure. The third standard presents the budget as a means of communication that must be understood by the ordinary reader, to be accompanied by the mayor's report and to highlight key policies and strategies supporting tax data. Finally, the last standard requires the budget to be presented as a public policy, to be explained major modification of existing policies, as well as new ones. Budget standards aim to transform the budget from a play with "voiceless" actors in a means of communication with stakeholders.

The Specifics of Expenditures' Execution at Public Institutions of Culture

Dumitru Franca

"Tibiscus" University of Timișoara, Faculty of Economic Sciencea

francadumitru@yahoo.com

Abstract

According to public finance legislation, budgetary credits approved by the state budget can be used at the request of the principal credit officer, only after opening credits or supplying funds by the Ministry of Finance, by opening accounts on their behalf.

The Minister of Culture allocates budgetary credits approved by the state budget for the own needs of its' institutions, by drawing up the application for opening credits (two copies) to the Ministry of Economy and Public Finance and for the current and capital expenditures of the subordinated institutions, in relation to their tasks, based on the available budget on credit allocations.

Key words: expenditures, public institutions, culture, budgetary credits, allocation

J.E.L. classification: M41, M49.

1. Introduction

At the request of granting funds from the state budget, the Minister of Culture, as chief credit officer shall consider the following:

1. funding request will not exceed the budget appropriations and according to approved destination - current expenditure and capital expenditure in relation to their use of resources made available earlier;
2. ensuring efficient use of funds allocated from the budget for expenditures necessary to fulfill its own actions and the ones of the strictly subordinated institutions;
3. budget expenditures based solely on documentary evidence produced, endorsed and approved by authorized persons in the department of economics, finance and administration.

Application for opening credits is used to opening credits in the principal credit officers' level. It includes the nature and purpose of the loan requested and the breakdown of the loan to the budget classification structure and overleaf there is a separate summary statement for their own activities and its separate subordinated institutions from open budget appropriations, the ministry retains the amounts necessary for their own expenses which have been entered on the other side of the demand and distributes within three days the appropriations budget based on budgetary provisions, compiled and submitted to the Treasury in four copies:

- an approved copy returns to the chief officer (Ministry of Culture);
- an approved copy shall be sent to the central treasury;
- an approved copy shall be sent to the local treasury, the county or the sector in Bucharest that institution in the field of culture has opened accounts;
- an approved copy serves to the institution in the cultural field which is funded for registering the distribution of loans in its own accounting.

2. Execution of expenditures in public cultural institutions

After the promulgation and publication in the Official Gazette the budget becomes operational, moving to its execution, this is done during the budget year. Budgetary provisions for income represent the minimum limits to be achieved, excluding revenues from loans that represent the reached maximum limits. In turn, budgetary expenditures approved by the law represent the maximum limits that can not be overcome, public institutions are obliged to respect the budget runs just destinations for each budget allocation.

Cash execution in cultural institutions is carried out by treasuries where they have open accounts. Cash execution in the Ministry of Culture is made by the city treasury of Bucharest. Cash execution of budget in the culture county, and cultural institutions under the Ministry of Culture and local government is done by local treasuries to which they are subordinated. Treasury seeks framing costs in the budget approved by the credit officer.

The stages of expenditures' execution are: commitment, expenditures' liquidation, spending authorization, payment of expenditures.

Commitment[1] is the decision that generates the obligation of the Ministry of Culture for Culture county, cultural institutions under the Ministry of Culture and subordinated to local administration to pay a certain amount.

Commit to make expenditures. The commitment to any expenditure takes two forms: legal commitment and budgetary commitment.

a) **Legal commitment** means any legal act which results or could result in a liability to the cultural institutions of a person, a "service rendered" on public funds. Legal commitment may take the form of a public contract, purchase order, agreement, contract work, act of control, loan agreement etc. Therefore, at the conclusion of a legal commitment the credit officer is required to check the provider's "capacity" to perform the service that is subject to legal commitment and good faith on the one hand and secondly to ensure that the institution has the necessary budgetary resources available to honor obligations under that commitment.

b) **Budgetary commitment** is the act that amounts from the budget reserves needed to cover expenses. Therefore, budgetary commitments can not exceed the approved levels of the budget appropriations approved. Budgetary commitments are:

- individual budget commitments
- overall budget commitments.

Uncommitted budget appropriations and budget appropriations committed and unused at the end of the budget year are void of law. In individual and provisional legal commitments and in individual and global commitments, the subdivisions of the approved budget have to be specified.

Expenditure's liquidation is in the budget execution phase which verifies the existence of commitments, the reality of the amount due is determined or verified, the conditions in which the legal commitment are checked based on documentary evidence of the transactions. Expenditure's liquidation operations are conducted by the credit officer.

Credit officers of cultural institutions will check:

a) existence of commitments and conditions in which the performance of the obligation is fulfilled;

- if an approved legal commitment exists
- if an approved budget commitment exists
- if the deadline for payment of the obligation corresponds with data contained in legal commitments.

Documents proving the existence of commitments are contract, order, provisional legal commitment and budgetary commitment.

b) the reality of the obligation to pay if the goods were delivered, work performed and services rendered, or - if there is a way to justify payment: enforcement, loan agreement, etc. Documents certifying the goods delivered, work performed and services rendered are tax invoices or bill and for salaries and allowances collective payrolls are used, prepared by the specialized department, unless an individual liquidation is required.

c) reality of the amount due - if the requirement is stated in the invoice matches the data recorded in the institution stating "service performance" (minutes of the reception, for fixed assets; note reception and finding the differences, for material goods other than fixed assets).

The credit officer or person empowered to make liquidation personally checks supporting documents and confirms that this check was performed.

If all conditions relating to liquidation expenses are met, the credit officer will apply to documents evidencing the obligation of payment (invoice, payroll state) the "Good to pay" visa. Granting the "**Good to pay**" visa shows that the service was properly made by the supplier and that all items in the bill have been checked. In this way it is confirmed that: the goods supplied have been received, specifying the date and place of receipt, the

works were performed and services rendered, goods supplied have been registered in accounting and management, and accounting note specifying the recording; other conditions stipulated by law are met.

If all conditions relating to liquidation expenses are not met, the authorizing officer does not register on the documentary evidence of payment (invoice, payroll wages) the "Good to pay" confirmation.

The documents certifying completion of the expenditures' liquidation phase underlay the registration of asset in the accounts of cultural institutions to reflect the services provided and the obligation to pay creditors against third parties.

3. Authorization of expenditure and payment authorization

Authorization of expenditure is the phase in the budget implementation process which confirms that deliveries of goods were made or other claims have been verified and that the payment can be made.

Authorization of payment is the internal document by which the credit officer instructs the head of the financial-accounting department to prepare the payment instruments for expenditures.

The document used for payment of expenses authorization is "authorize payments". It contains data on: the financial year in which the payment is recorded, the budget division to which the payment is recorded, the payment amount (in figures and letters) expressed in national currency or foreign currency, as appropriate, information identifying the payee, nature of expenditure, method of payment (bank transfer or cash), date and signature of the credit officer or the person delegated with such powers; visa of authorized persons in specialist departments, which confirms the correctness of the amounts of payment, delivery and receipt of goods, works and services implementation, existence of another title that justify the payment and, where appropriate, the institution's record in managing property and its accounts.

The original supporting documents are sent to economic and financial departments so that the documents for payment to be prepared. Authorize payments by the target person entitled to exercise the preventive

financial control are void and of no value to the head of the economic-financial department.

Payment of expenditures is the final phase of budget execution by which public institution is released from its obligations towards third parties-creditors. The payment shall be made in lei, and according to the destinations within budget appropriations approved under the laws, through treasury and public accounting units that they have open accounts. Payment is provided by the coordinators of economic and financial departments within the open and unused budget appropriations or availability in accounts, as appropriate.

The payment instruments used by cultural institutions, the cash check and the payment order for the state treasury are signed by two persons authorized to do so. The payment instruments must be accompanied by supporting documents, which certify the accuracy of payment amounts, receiving goods and services performance, closed under legal commitments.

Materialization of budget management is carried out by drawing up the budget execution account at the end of the budgetary year. It reflects the purpose of executing operations of revenue and expenditures and leads to the determination of the observance of budgetary provisions mode.

The budgetary account shall cover the revenue receipts and payments for expenditure actually incurred during that budget year regardless of the financial year to which they relate.

The operations remaining outstanding in a year budget are reflected in the executive account of the following year.

The preparation of the budget execution account is done centrally by the Ministry of Finance based on the balance sheet and cash accounts on the implementation of the budget, prepared by each public institution. These documents accounting reports are centralized, vertically, within each government agency (chief credit officer) then submit to the Ministry of Finance, the budget implementation situation in the field of activity.

Public cultural institutions are required to conduct double entry accounting with the accounts provided in the general accounts.

The correspondence functions each account established under the rules are not limiting. They can be developed within each institution, in compliance with the economic content of the operation, accounting requirements based on the principle of rights and obligations and the legal provisions in force.

In this respect, the credit officer may development accounts with the development plans in the analytical accounts and monographs containing specific operations in the area of activity.

Public institutions of culture usually organize and lead their accounting in separate compartments, led by chief financial officer, chief accounting officer or other person empowered to perform this function. These individuals have higher economic studies and together with subordinated staff respond of the organization and management of accounting.

Economic and financial transactions accounts are held in the Romanian language and currency. Accounting for foreign currency operations is made both national currency and foreign currency, according to regulations issued in this regard. The operations of foreign currency receipts and payments shall be accounted for in the daily appreciation communicated by the National Bank of Romania.

Documents supporting the underlying accounting records of the liable persons that have been prepared, endorsed and approved, and those that were recorded in the accounts as appropriate.

Public institutions record economic and financial transactions at the time in supporting documents which make journal entries, accounting records and other documents as appropriate.

Documents underlying accounting records may acquire only a supporting document quality that provides all the conditions lay down by laws. Documents supporting the underlying accounting records of the liable persons that have been prepared, endorsed and approved, and those that were recorded in the accounts. The forms that are specific to economy that don't have a special enrollment and numbering requirement on financial and accounting activities can be adapted to the

characteristics and needs of public institutions, with the condition of providing the minimum information content and standards of preparation and use.

In public institutions accounting, records are made, mostly, on those documents common to all industries (invoices, bills of consumption, receipts, payroll wages, etc.). However, specific documents are used such as:

- request for opening the budget appropriations;
- the budgetary provision for the allocation of budgetary appropriations;
- the budgetary provision for the withdrawal of budgetary appropriations;
- the budgetary provision for repayment of budgetary loans
- daily food record.

In order to open budget appropriations, credit officers draw request to open the budget appropriations for each chapter of expenditure approved by law, with breakdown: expenses (personnel expenses, expenditures for goods and services, etc.) and capital expenditures. This document is required for any quarter credits necessary expenses (both for costs and expenses of the principal subordinate officers). The application will be presented to competent Directorate of the Ministry of Finance until day 20 of the last month of the quarter.

4. Conclusion

In the event of termination of business, public institutions give their documents to state or military archives, as appropriate. The computer system of automatic data processing in each institution in the cultural field is used to ensure data is recorded in the accounting processing in accordance with applicable accounting standards, testing and maintaining their technical supports.

Performance Audit and its Role in Improving the Management

Durdureanu Corneliu

Cîdea Moise

„Petre Andrei” University of Iasi

corneliu_durdureanu@yahoo.com

cindeamoise@yahoo.com

Abstract

If we are to give a definition to the attention of managers, the audit is what a responsible should do in order to ensure that it has control over his business if he had time and if he knew how to act [1]. The internal audit activity has three basic functions: it is a leadership position because it primarily concerns the responsible of the company, it is a job that needs to be learnt and in which improvisation cannot be accepted and in the implementation of which time is required, from where it arises the need to seek experts in order to perform this task.

Key words: Concepts, postulates, reliability, performance, review, preliminary investigations, collecting evidence, performance audit.

J.E.L. classification: M40, M42.

1. Introduction

Auditors often use to call themselves practitioners, starting from the point that they seek practical solutions to practical problems. For this reason, there is the danger that some practitioners believe that they do not need theories to explain what they do or what they should do.

Audit theory is largely a descriptive theory and, in a lesser degree, a normative theory, as providing guidance on how auditing practices should be. Thus, audit theory should provide a logically coherent and conceptual framework for determining audit procedures necessary to achieve the audit objectives, respectively for assessing current practices and procedures in order to improve them.

2. Theories ad concepts regarding the audit activity

Some authors believe that postulates are essential for the development of a discipline and represent the fundamental structure for formulating any theory. This is compounded by the fact that the postulates can be regarded as hypotheses that cannot be proven, but which represent the basis of the inductive process, while likely to be modified by virtue of science. Thus, Mautz and Sharaf have developed a list of audit postulates based on a rigorous study of nature and audit activities. Although formulated over 40 years ago in the form of the proposed postulates and, despite the changes occurred in the economic life of the companies which determined the evolution and the improvement of audit practices, their postulates seem equally valid nowadays.

These postulates are:

- audit bases on the idea that both the financial statements and the financial information are verifiable;
- objectively, there is no long-term conflict between auditors and company management or audited institution;
- functional control structures reduce the possibility for fraud or irregularities to occur in the course of an patrimonial entity;
- applying the generally accepted accounting principles (national or international accounting standards) lead to a true image in the summary financial situations;
- where there is no evidence to the contrary, it assumes that what was true in the past will be true in the future (by extension, what lead to a particular result in the past, as long as there is no evidence of changing conditions, will lead to a similar result in future, too);

- financial statements don't have fundamental errors;
- to examine financial information undertaken in order to issue an independent opinion on these, the auditor operates exclusively within the powers delegated to an auditor;
- professional status of an auditor requires certain professional obligations.

David Flint made seven postulates. For centuries, Flint noted, delegation of responsibilities and assuming responsibilities for the accountability in managing money and other resources represented tasks for which unloading responsible persons was made only by the audit. Thus, audit postulates made by Flint have as central element concepts of responsibility and accountability through which the audit finds its justification.

These postulates are:

- basic requirement in an audit is the existence of relations of accountability;
- accountability is too complex and / or of a too high importance so as the discharge of responsibilities can be made without an audit;
- essential features of an audit consist of independence status and the exclusion of any relationships that may constitute constraints of reporting and investigation;
- the audit object is likely to be evidence-based verified;
- responsibility standards, such as standards of behavior, performance, achievements, quality of information may be established for those who assume responsibility;
- the significance, the importance and the purpose of audited statements are clear enough so that the credibility attributed to them through the audit can be clearly expressed and communicated;
- audit generates positive economic and social effects [2].

Audit concepts held by Mautz and Sharaf are: audit evidence, audit diligence, fair presentation, independence and ethical behavior. Over time, they have added new ones, such as objectivity, materiality, reasonable assurance, audit risk, etc.

Gray and Manson propose a systematic structuring of the concepts of auditing into four distinct categories, determined by the fundamental audit principles contained in the

Code of Auditors from the UK, presented in Table 1:

Table 1. The structure of the audit concepts

Category	Concepts
Credibility	Competence
	Independence
	Integrity and ethics
Audit process	Risk
	Audit evidence
	Reasoning
	Significance level
Communication	Reporting
	Fair image
	Association
Performance	Audit diligence
	Standards
	Control of quality
	Strictness

Source: Gray I., Manson S., *audit process: principles, practice and cases*, London, Thomson Learning, 2008

Credibility is the extent to which users trust the auditor and, in his opinion, has as main direct impact the fact that auditors should ensure that it is perceived as a competent, independent person, having an honest behavior and appropriate ethics.

The audit process refers to how the audit engagement is carried out. Auditors seek to obtain evidence to prove the statements (made by management) regarding the issues presented in the financial situations. Moreover, during the audit process, auditors assess the risk of failing in detecting elements that affect the image presented in the financial statements. They use professional reasoning to continually assess the events that may have a significantly enough impact on the financial statements to alter the image of the company, its activities and performance.

Communication: Reporting can be regarded as a component of the communication process of opinions by all those interested auditors (external users). On the other hand, the communication may involve contacts with the management company auditors, shareholders etc. The concept of fair presentation, originally concept of accountancy has also a major importance in the audit, being very closely

related to materiality and professional reasoning.

Performance: The last category captures the qualitative aspects of the work of an auditor, all efforts in meeting the audit, with the utmost care in accordance with professional standards. In other words, auditors should have their own quality control procedures to ensure that services are appropriate for them.

Although they are structurally presented, the relationship that exists among different concepts is obvious. Thus, for instance, legitimate assumption that the process of obtaining evidence is achieved with full professional care, by applying all diligence audits, emphasizes the relationship which exists between the concepts of audit evidence, diligent audit respectively.

According to several authors we can define the audit activity as '*the professional expression of information in order to express an independent and responsible opinion in relation to quality criteria, in terms of reliability, privacy and performance*' [3].

3. Performance in audit activity

As shown above, performance captures the qualitative aspects of audit activity, in meeting all efforts to accomplish all diligent audits with the utmost care and rigor in terms of quality and in accordance to professional standards in use.

We often talk about performance. But is the meaning of that term known? The term performance is rarely defined even in works in which performance is the central subject matter. Everything happens as if the meaning of the word performance were so clear that its definition would be trivial. However, the meaning of performance is not the same.

Michel Lebas notes the difference which exists between: 'a performance', 'performance' and 'being performing'.

'A performance' is generally attributed to a measured result, higher than the one following the previous results. Therefore, 'performance' always indicates a positive connotation. 'Performance' can be both positive and negative and refers to past results. The adjective "performing" tends to be rather used to talk about future, future results, so it is an indicator of potential, of dynamic.

Annick Bourguignon identifies three major meanings of the word performance:

- Performance is *success*. Performance is not in itself; it varies depending on 'successful' representations of firms, on 'actors'.

- Performance is *the result of the action*. This meaning contains nothing but value. Performance measurement is understood as the evaluation of the results obtained from the execution of a process, an activity.

- Performance is *action*. In this sense, performance is a process and not an outcome that appears at a particular time [4].

The concept of performance is defined differently by the business partners, according to their interests: managers are focused on the overall performance of their business; present and potential investors are interested in the profitability of their investments; employees are interested in the business stability and profitability; lenders are interested in the creditworthiness of the company; customers, in the business stability. Therefore, performance measurement can be done differently depending on users' objectives. But what interests us is the definition of performance which can satisfy all users.

In the diversity of definitions there are three major guidelines that are not divergent: the definition of performance based on the level of achievement of its strategic objectives; the definition of performance based on creating the value; the definition of performance based on productivity and business efficiency of the company.

Performance measurement is a system of control techniques designed to ensure that the achievements of various responsibility centers of the company are in accordance with the rules established for each of them and to impose positive or negative sanctions if the fulfillments deviate substantially from the rules chosen. The determining standards constitute an important issue to be questioned.

Measuring performance goes beyond simple observation; it aims to enable better decision-making performance conditions. Management control, performance management system should therefore highlight the indicators of performance measurement and guiding.

4. The concept of performance audit and its importance in improving the management

In Romania, this concept has been restored to its legal rights with the entry into force in early 2003 of the law no. 672/2002 regarding the public internal audit.

The performance audit examines whether the criteria established for implementing the objectives and tasks of a public entity are correct for assessing the results and whether the results are in accordance with the objectives [5]. The performance audit evaluates the results, analyzes the economy, the effectiveness, the efficiency and the relevance of the indicators (optimizing the means in accordance with the objectives, the relevance of the structures, of methods, the quality of management and its results).

The performance audit is an objective and systematic examination of the program, activity, function, management systems and procedures of a public institution in order to assess in what extent that entity, in the attempt of achieving the predefined goals, has used its resources in an economical, efficient and effective way.

Although the performance audit can be very extensive, in broad terms, it will apply:

- To those activities involving a high level of resources;
- To projects which may not achieve its objectives;
- To issues of interest or that concern the top management.

The performance audit is the independent assessment of the level of achieving the economy, efficiency, effectiveness and fulfilling the desired results.

The main objective of performance audit is to provide information to the top leader, insurance and independent views about the organization in order to achieve the desired results with economy, efficiency and effectiveness (in fact, to optimize the use of resources), as well as proper accountability of resources used in its efforts to achieve those results. Independent performance reviews indicate whether the entity's management, using resources to achieve organizational goals, has achieved its policies, principles or standards in an economic, efficient and effective way.

A secondary objective of the performance audit is to identify ways of improving the organizational performance and to optimize the use of resource and to help the management to take action in order to improve the control systems and tools.

Audit performance goals can be summarized in:

- The examination and the evaluation of assurance approaches of an optimizing process that uses resources in an entity receiving public funds;
- Signaling major losses, extravagant attitudes or other examples of poor performance. The auditor's role is to assess on what level and how well the resources are managed in that organization.
- Helping the managers in their efforts of:
 - Rising the level of incomes/collections;
 - Reducing the costs or outgoings;
 - Improving the efficiency;
 - Strengthening or improving the management, administrative or organizational processes;
 - Improving the quality of the services;
 - Achieving the organization's goals and objectives in a more effective way in terms of costs;
 - Developing an effective policy;
 - Increasing the level of being aware of the importance of accountability and of transparency in the use of resources.

5. Performance audit planning and its connection with successful management

A performance audit program should be rigorously planned if you want it to be effective. Planning is the way in which we are identified, ranked and included in the overall program objectives of the audit activity in order to assess the potential structure and to estimate the audit activities to be developed. The planning process leads to fair decision regarding the nature, the extent and the timing of the performance audit to be conducted.

Strategic planning process for internal audit units must be concretized into specific performance audit programs covering all four major types described above in a period of three years.

This program must be based on risk assessment. In evaluating risks, the following criteria are taken into account:

- the importance of the activity performance in achieving the general objectives of the organization;
- the complexity of success indicators and their measurement instruments;
- the level of interdependence with other systems/activities in order to achieve success;
- the volume / amount of resources used in activity and the potential for wasting.

The aim of the strategic planning is to establish the future program of the performance audit, the priorities and the necessary resources to be carried out. Strategic plans are way ahead, for a period of three years, in order to identify the opportunities for long term and they may include more detailed proposals for short-term audit. Plans involve identification procedures, prioritization and selection of potential areas for performance audit. They must be reviewed and updated whenever it is necessary and especially in situations where management plans are modified.

Therefore, an appropriate strategic planning performance audit can provide accurate determination of priorities through an optimal distribution of resources to areas of maximum impact in order to establish an effective, complete and well structured program of the performance audit for a better efficiency in each mission.

6. Conclusions

The performance audit is an examination or a planned, independent and objective evaluation measure in which a program or activity of a public entity operates efficiently and effectively while respecting the economical part.

As a function, performance audit pursues the following aims:

- to act towards management in an independent and objective process to complete the activities of insurance and consulting;
- to add value and to improve the organization's operations;
- to assist the organization for its achievement of some objectives by bringing a systematic and disciplined approach to improve management.

The audit is an activity with an advisor role for the organization's management not being similar to the control. It follows the respecting of internal standards and rules applied to operational processes of the organization highlighting the critical points of the activity for shaping the program of measures, recovery and normalization.

In some cases, auditors' interests may be the same with the interests of managers in reducing risks linked to the reputation and the image of the entity, to prevent illegal conduct or failure, transparency, effectiveness and reliability of internal communication, basing the approaches of risk assessment and prevention.

The basic role of performance audit in its relationship with the management should be the provider of information and risk management solutions through a good collaboration among auditors, board of directors and managers.

The Aesthetical and Utilitar Categories in the Consumption Society

Duțu Mihaela

„Constantin Brâncoveanu” University of Pitesti

elamica67@yahoo.com

Abstract

In this paper, I wanted to present several aspects about the consumer's behaviour nowadays, influenced by the relationship between utilitary and aesthetical categories. This behaviour is conditioned by the nature of needs and wishes, by the way of their materialization, as the results of economical activities. So, the link between production and consumption was determined, over the times, by the evolution processes, focused on passing from the manufactured to the big seria products, as a result of the big industrialization.

There are also included aspects with reference to durability, repetability and authenticity, like major characteristics of the consumption goods, in the context of the new interdependences between culture and civilization. I also mentioned the impact of the underground provocations and the actual global problems from our society.

As a conclusion, I brought references over the fact that the modern consumption society must help us to identify the veritable values of our existence.

Key words: Consumption, Prototype, Standard, Authenticity, Unicat and seria goods

J.E.L. classification: M0

The consumption approach as a way of satisfying the needs in the actual economic context, in which the success dynamics seems to be more and more linked to the money, needs considering the complexity of the people's life which finally is imprinting both the level of living and on the actual lifestyles. We may talk about an economical-social determinism submitted to a continuous evolution which is conditioning aspects linked to the people's education and their

level of training, the socio-professional mobility, the motivation and the sensitivity – all of these being constituting as the points of reference which are establishing the interdependence between the aesthetical and the utilitar categories. The goods created in the actual consumption society must gain a new existential status, influenced by the growing rythm of their social recognition and validity, but also by the moral erosion which is following.

In this context, Victor Basch (1863-1994)[1] appreciates that the individus are manifesting four types of attitudes over the surrounding reality with different weights and roles, depending on everyone's personality adapted to the existing economic-social standards.

a) **practical-utilitar**, by which is conditioned the adaptation of the resources valorifying the needs satisfaction which is conserved into the biological integrity of the individuals;

b) **moral and religious**, as the references by which the individus are being reported to the society;

c) **intellectual**, by which are established the rationality and the finality of all the displayed activities;

d) **aesthetical** which, by distinguishing the others, are supposing a desinterested reporting to the surrounding world, this being a simple adhering to shapes motivated by a sympathy without ideas.

In the modern societies, all these attitudes are valorified and manipulated by the specialists in economy and communication, by the designers and creators. The premises of these tendencies are having their origin in the prosperity assumed by the industries developing, by the mass production, by the development of marketing, publicity, credit, phenomena which began to be extended from the second half of the XXth century.

So, in its dynamics, the industrial production influenced also the other types of activity, because of its main characteristics, of which the more relevant are the following [2]:

- a) it's the result of same mechanical forces led by the man, but yet extra human;
- b) it includes the seriability notion, by producing the same good in many copies;
- c) its finality has an utilitar character, a feature which cannot be attributed to the artistic creations;
- d) it's linked to individual particularities of different categories of consumers, by which are determined the market segments.

By these presentations, we may conclude that the industrialisation process, determining the immediate efficiency, the productivity and the quantity to be the main criteria of appreciating, by putting prioritizing the utility and functionality. Nowadays, the complexity of the human being existence involves a dynamicity of needings with different priorities, which are putting the individus in front of more and more opportunities of choosing. For example, it is easy understanding that the necessity of buying a house or a car is more stringent than the wish of growing an unique object or a masterpiece, a reason by which the utility, the functionality, the constructivity are generating from an economical perspective our possibilities.

In this way, the industrial production of utilitar shapes becomes more and more comprehensive and, conforming to its specific, the shape is initially conceived and then included to the matter, in a just moment, only at the level of the unique item, under the name of "prototype".[3] Once recognized as good and accepted, the prototype will be reproduced in many identical exemplaries, and the result of multiplying the prototype by the industrial technologies, at a big scale, is constituting the product.

So, the new paradigm of the relationship between the utilitar and the aesthetic cathegories are necessitating the consideration of the differences between art, skill and industrial production. For instance, the agricultural production didn't need a distinction because the shapes resulted by working the land were imposed as industrial shapes. But the industrial production needs a distinction, talking about the shapes resulted

from the man's action over the raw materials and the technologies, nature having no contribution and the shape is not the result of every item. On the contrary, it is imposed as a discovery only at the prototype level.

On the other hand, "the standard"[4], a concept introduced by the English people during the XVII-XVIIIth centuries signifies just copying the prototype in big series. In their running after more and more profits, the economic agents are oriented towards producing the goods with an ephemere commercial success for an easy substitution and the daily life begins to be dominated by the standardization phenomena with all the consequences (the tastes aplatisation, the depersonalization an falling into an unvalued existence)[5]. We may also add the promotional system conceived in a more refined way, which is pushing the individuals into the situation of buying more and more goods much over his needs and wishes, a tendency recognized as the main reason of the actual economic crisis.

We must also admit that the industrialization extension[6] generated many social mutations in the sense that more and more workers are today living better than the high-classes with only a century ago. On the essence of that "welfare mediocrity", is also maintaining a social satisfaction, generated by a complex of factors (occupation, incomes, fortune, education, system of values) which are influencing the perception over the goods and the consumption mentalities. In these conditions, it is more and more evident the dilemma after which the functional and beautiful goods, obtained by the industrial processes are having a very big weight in consumption and are presenting a new big social importance, a tendency generated by the next factors[7]:

a) **Economical**, by the rations generated by scale savings, by means of industrial production, are being satisfied nearly all the needings. As known, in the middle ages, there were transmitted from one generation to another the furniture, the family objects or just the clothes. But, from the middle of the XIXth century, the status from the utilitar goods is changed, the preferences are manifested for the big series produced goods destined to the same needs and delivered by the industrial factories.

b) **Technological**, generated by the big science discoveries, they created phenomena with profound implications in the private and collective behaviour of the people. By the machinery inventions, the psychological impact was strong, passing from fear to getting used to, with influences also over the aesthetical categories. This phenomenon generated a new concept, called the "industrial aesthetics"[8] which, step by step, began to be considered "a beauty science" in the field of industrial production, of the working place and ambiance of the production tools and the final goods.

Under the impact of the same factors, at the confluence between the TV technology and the performative experiments (image, sound, moving), is created the video art. After its influence, the homes are invaded by the "publicity clips"[9], like strategies of forming and manipulating the consumption attitudes. At the end of the 80th years of the XXth century is imposing also the computer capable to manage the multimedia installations. In the meantime, by increasing the capacity of stoking on CD – ROM and DVD-ROM facilitated the individual creations and their spreading to more and more users. They became serial creations, transformed into goods which may be traded together with these destined to the mass consumption.

Under the impact of cultural factors, is appearing the aesthetical wearing phenomena of industrial goods which, after a using period, they become uninteresting from a visual point of views. This phenomenon is determined by the fact that the origin of their production is not based of authenticity[10], as a veritable value creation, capable to generate progress by the continuity of becoming. Being aware of this aspect, in the developed industrial countries, there are always added aesthetical improvements, but with consistent increases of prices.

So, it becomes a necessity to create an interdependancy between technological and cultural factors because, as we can easily observe, promoting the consumption goods by mass-media, determines the people to define their life-style not by what they are, but what they want to become. Using the "image message"[11] eliminates the psychological possibility of cristalizing, by interior collection, the artistic emotion and

being rapidly annihilated by the avalanche of images and information. As a contrast to the utilitar shapes, the artistical ones, characterized by originality, must not be changed for the reason that they are old, they are unuseful or they are not corresponding, on the contrary, they are resisting in time, they are discovering a permanent "actual value". Considered to be the best synthesis between spirit and matter, they are detaching by the world of the utilitar goods by the fact that, on the one hand, they are not reproducible, and on the other hand, they are expriming the talent, the emotions and the innovations of their creators. Asking us in a rethorical manner if the repetability means the veritable destiny of beauty, we must be aware of the fact that, nowadays, any object wins or loses their own "beauty"[12] not function by what is it, the social coordinates which are determining the way of looking and perception. So, the aesthetical values circulation for their trading is conditioned not by the preferences and by the consumption society perceptions which begin to manifest alarming tendencies (the cities and houses depersonalization or the preferences for the big serial goods). These are the reasons why the cultural goods creators are proposing to cultivate promoting the aesthetical values, to educate the culture consumes, for raising them as the veritable scale of human values. The economists and, obviously, the specialists in management and marketing are interested in aesthetic by means of visual advertising for a certain product, its content or shape being treated only as a "support".

Considering that imitation means civilization, we may easily explain why nowadays society facilitated passing the art from culture to civilization, a phenomena which generates the aesthetics of the quotidian life, in which the need for beauty may be satisfied not only by art. As a reverse, these tendencies attired also the underground trends, the hippie movies, the drug consumption, the sexual and feminist liberties, preceded and accompanied by the big protestatary waves from USA and Europe from the last 60 th century. We must not neglect the big planetary problems (aids, pollution, the green house effect, the industrial rests, the city of natural resource) reflected in the creations of contemporary artists who, always by their manifestations,

proved to be in the avangarde of the big economical and social problems. The economical globalisation tends to attire, in the cultural fields inclusively, the occidental hegemony tendence, manifested by the localization and delocalization of markets, exhibitions, the big centers of sales. The of XXIth century is more and more confronted with the disappearance of a "globalised"[13] world, but characterized by the historical and cultural specificity which is nourishing the identitary searchings. The capital accumulation, as a purpose, has generated the growth of discrepancies between the material potential of different social cathogories and their cultural level, phenomenon which generated the perpetuation of bad taste, culminating with the sharpening of economical and moral crisis.

We may appreciate that, the modern society, dominated by major contradictions, must also administrate the material and human resources in the direction of a better valorization the interdependences between the aesthetical and utilitar aspects, between the production and the consumption of big serial and unique objects, between global and national.

Brief Analysis of Financial Architecture of European Union and Romania from Single Market Perspective

Enescu Roxana

Voroneanu Constantin-Bogdan

„Alexandru Ioan Cuza” University of Iasi,

Faculty of Economics and Business Administration

enescu.rox@gmail.com

bvoroneanu@yahoo.com

Abstract

The European integration is an event that impacts in every economy and in every financial field of European Union. The purpose of this study is to underline the main steps made in the integration process and to analyze the impact of an economic, monetary, financial union both on microeconomic and macroeconomic field. What are the main steps that Romania should follow in adopting the single currency? What are the consequences of a single currency? What can Romania learn from other countries experience? Those are some questions that we tried to answer. In this study, section 1 presents the evolution and implications of European system of Central banks. The second section underlines the main contributions of TARGET and SEPA and the last two chapters analyze the main indicators before and after the integration process in European Union and Romania.

Key words: European integration, central banks, financial market, Romanian banking.

J.E.L. classification: E58; G21; D53

1. Introduction

The last decade and not only had a main topic in European Union, the European integration process and all the implications that had come from this: financial liberalization, single currency, European System of Central Banks centered on European Central Bank, new regulators, the elimination of barriers in many sectors and not only that.

This study contributes to the literature by extending the analysis of the implications and consequences of European integration process to Romania. We analyze the evolution of European integration process from the beginning until today with the direct implications in financial sector.

In the same time, we analyze the direct impact of single currency and the connection between its implementation and some financial indicators and tried to underline the advantages and benefits to be applied in Romania case.

2. European System of Central Banks – evolution and implications

In the last 10-15 years, the banking consolidation in Europe led to increase the size of European banks within national boundaries rather than borders, despite European rules that encourage expansion of banks within the EU by deregulation of banking and other financial services and by elimination of the controls of interest rate, capital or barriers between banking system, insurance and stock exchanges.

European banking system is highly segmented, while capital markets are characterized by a high degree of integration mainly due to the single European currency and to the fact the process was also stimulated by the American investment banks which operate on UK markets with extension to the continental side of Europe.

One of the reasons that the banking system has expanded beyond the national level was reflected in the strict regulation of the sector by governments in order to protect individual consumers. (*Economic Tribune*, no. 9, February 2007, pp. 93)

For many countries in the euro area, the introduction of the single currency led to new conditions consisting in a low rate of inflation and macroeconomic stability. According to experts, this is effectively guaranteed, because the euro area is supervised and coordinated by the most independent central bank in the world, namely the European Central Bank. Research in the field of European Union countries show that a more independency of the central bank is also reflected in lower inflation. Experience has shown that countries where central banks were not immune to political influences (Italy, Spain) were faced with higher inflation.

Figure 1. Evolution of inflation rates in the EU - 1991-2011

Source: www.ecb.int

For this reason, the Euro would represent an important advantage for long-term regional economic stability, whereas the ECB is the first central bank in history with whom there is no government to influence its policy. Although the high level of independence of the ECB will bring little benefit to countries known for their low inflation (Germany, Austria, Netherlands), it still allows for a more stable economic future for other countries, who consider price stability as one of the main advantages of the Euro.

3. The evolution and advantages of Single Payment System

The major importance of the clearing's efficiency deeply interested in the international banking community and imposed extensive studies of groups of experts appointed by the prestigious international associations, whose conclusions

were stated in the banking world as a stronger reference source authority

Single European Payments Area (SEPA)

On the single European market there are still considerable differences between national payment systems. European Union tries to remove these barriers and to reduce border costs for consumers by creating a single payment in the Euro Area (SEPA). European Payments Council (EPC - European Payments Council) was formed to create standards in this area and a common infrastructure.

SEPA involves the creation of an area for the Euro or any currency whose member state wishes to notify participation in which all electronic payments are considered domestic and where a difference between national and intra-European cross border payments does not exist.

This system improves the efficiency of cross border payments and turn the fragmented national markets for euro payments into a single domestic one: SEPA enables customers to make cashless euro payments to anyone located anywhere in the area using only a single bank account and a single set of payment instruments.

SEPA has advantages for all categories of participants.

For traders: Cards are one of the main instruments of payment for consumers. To accept these payment cards merchants must sign a contract with the bank to "get" this right.

SEPA will allow card use overseas. Merchants can choose any bank to sign the contract to accept payment cards, which will increase competition and reduce costs. SEPA will push the standards of POS terminals in the euro area. Traders will be able to accept a wider range of cards from one terminal, and competition will also lead to lower costs.

For companies: SEPA will help companies to simplify the management of pan-European business; all financial transactions will be made from one bank account using SEPA payment instruments. Payments will be simplified considering that all have the same format. Also, the companies that have activities in the euro area will even save money and time by consolidating management of payments.

For banks: Promoting new payment instruments and common infrastructure, SEPA will lead to an effective single market. This consolidation of facilities will boost competition and the banks will be able to negotiate better prices for settlement.

SEPA payment instruments will allow banks to expand business and compete on a pan-European level, also any bank can offer its services to anyone in the euro area, without the submission of an effort or additional costs

TARGET (Trans-European Automated Real-time Gross settlement Express Transfer)

TARGET is the RTGS (Real Time Gross Settlement) for the Euro, offered by the EUROSYSTEM. This system is used for settling transactions of the central banks, large-value transfers and other types of payments. It is based on real-time transactions with immediate finality.

TARGET was created by linking the national RTGS systems with the European Central Bank payments system. It began on January 1, 1999. The launch of a single currency needed a real-time payments system Euro area: to ensure payment procedures necessary to implement the single monetary policy of the European Central Bank and to promote an efficient system for euro payments.

TARGET2 became operational on 19 November 2007 (replacing the TARGET) and provides with increased efficiency in terms of recovery costs harmonized basic services and single technical infrastructure. Also, the system was designed to be easily adapted to any subsequent amendments, both technical and Euro-system extension process based.

TARGET2 represents: backbone of the financial system in euro, because through it there are finally settled all the euro payments in the euro area, both national and cross-border, including payments related systems (either payment, clearing or settlement) and also basic instrument for the Euro-system's single monetary policy, given that TARGET is the only system which settles Euro-system monetary policy operations.

Regarding Romania, taking into account that payments for Euro-system monetary policy operations will be settled only through TARGET2, the connection to this cross-

border payments system is optional before joining the euro area, but will be mandatory with the adoption this currency. (National Bank of Romania, Annual Report 2008).

4. The evolution of European banking system

European financial integration is an important issue both in terms of regional and global implications. One of the main objectives of the European Union is to build a single market for financial services. Since the financial system is important in allocating economic resources, a single market for financial services has the potential to significantly improve the investment's efficiency and to ensure the economic growth by removing barriers and frictions.

Despite the measures taken over time for increasing the financial integration in the European Union, it continues to be characterized by fragmentation due to technical, regulatory or administrative barriers that still exist in different national financial systems.

The introduction of the Euro and the measures adopted through the FSAP (Financial Service Action Plan) has contributed to increased financial integration, but the specificity of the national economies, the diversity of national laws have delayed the full integration of financial markets.

The EU Action Plan for financial services, which was launched during the period of 1999-2005, aimed to create a single market of the financial services designated for the industrial consumers basing on a single legal framework for securities and derivatives markets, mergers and acquisitions and to integrate and give access to all consumers to a European financial market for individual consumers, which would imply a reduction of differences in charges between EU countries, the harmonization of prudential rules, especially in case of insurance and reinsurance domains. The regulatory areas had included the statute of European investment companies, taxing savings, banking activities privacy, pension funds, acquisitions, communication in distance financial services.

According to the White Paper of financial services policy (2005-2010), the inefficient payments system and the absence of a EU model of financial integration represent the main obstacles to integration of European financial markets. Studies made by the European Commission show that financial services policy should be in strictly concordance with the other policies such as competition, consumer protection or taxation. The main obstacles to cross-border merger can be found in insecurity of the rules related to taxation and in the discriminatory character of it.

Intensity of financial integration in the European market depends on the specific segment of these markets. A fully integrated market is the inter-banking market because of the launching of the Euro and of the European Central Bank's coordination of the monetary activity.

Another integrated market is the bonds one (especially bonds issued by governments), which is sufficiently large to compete with the markets listed in U.S. currency. Transparency and liquidity in this market segment have improved and the market integration was also sustained by the transformation of secondary market infrastructure and by the developing of electronic trading platforms.

Less integrated markets are the markets of securities and certificates of deposit, the stock exchanges and the markets of financial derivatives.

As regards banking markets, the degree of integration also varies depending on the specific financial services segments: bank lending and securities trading have registered a relative increase while the segment of banking services for individual consumers have not progressed.

Further, the focused areas are banking services for individual consumers and segments of consumer credit, mortgage loans and payment services. What could be done in the future would be a greater harmonization between the various financial products, increasing of solvency, encouraging of mergers and acquisitions, eliminating of barriers to conducting cross-border payments. Financial services to individual consumers are highly fragmented.

A key role in European financial market integration was played by the achieving a

single monetary market, which helped some steps forward in finance domain, with a different intensity depending on specific financial segments. It should be noted that the advance was not very ambitious having in view the persistence of obstacles to cross-border actions. Generally, there have been removed the technical obstacles reflecting in a better offer and cheaper access to capital for entrepreneurs.

However, there are still different degrees of integration in different markets, although there is progress on integration process in all areas. Retail market and the dividends one are still considered to be fragmented, while large amounts of money and bonds markets tend to be well integrated.

The integration's degree of EU banking system started to grow in a particularly way since 1999 (when Euro was introduced). Uninterrupted strengthen the EU banking sector may change the conditions of competitiveness and even more may improve the efficiency and diversity of EU banks. When the EU retail banking sector is compared with other financial sectors, it appears that it has evolved relatively slowly and this is reflected both by the price and quantitative indicators.

Number of credit institutions has decreased since 1997, and in 2004 also fell by 2.8%. In 2004 the total number of EU credit institutions was 8684.

The number of mergers and acquisitions has dropped since 1999 and this trend continued in 2004 and during the first half of 2005. This suggests that the consolidation process going on even if a decreasing rate. This downward trend can be explained by a slowdown in merger and acquisition activity internally. In contrast to this, cross-border mergers and acquisitions have increased by comparing with period 1993-1998, by 30% respectively 24% in number and value of transactions. It also increased financial market integration, national competition and concentration limits, as the euro currency introduction and they are seen as a possible explanation of this development.

In 2005, just as in the year 2004, data shows common trends in the EU banking sector development. However, national conditions still differ considerably from one country to another. This is reflected for instance in various structures of the retail

market where the main members differ from one EU member to another.

But in 2005, after four years of decline, the number of branches started to increase again reaching the same level as reaching almost 201,259 in 2002. The number of branches of credit institutions increased in 16 countries, mainly in Spain.

Analyzing the total share held by top 5 largest institutions in total banking sector assets, it can be seen that many countries, especially the small ones, are still characterized by a high concentration of the banking sector. Anyway, the concentration remained relatively low in Germany, Italy, Luxembourg and Britain. In Germany and Italy, this can be also attributed to the double bank structure (with both types of banks, commercial and cooperative), while in Luxembourg and United Kingdom the concentration of banking for residents increases due to the presence of many foreign banks. In 2005, the concentration in the banking sector further increased. In 2001, the five largest credit institutions reached 37.8% while in 2005 it reached 42.3% (from 39.1% to 43% in the euro area).

There are still significant differences in the EU banking sector from country to country. Population employed in the banking sector varies from 20 (in Luxembourg) to 447 (Lithuania); banking unit population: between 797 (in Cyprus) and 7511 (in Poland). However, in 2001, the dispersion which characterizes these indicators decreased, possibly as a result of the strong competition in the integrated markets.

5. Evaluation of Romanian' ascension to the Euro zone

European integration is not a goal in itself, but rather a means to promote the highest values of European culture: respect for fundamental human rights, pluralist democracy, prosperity for major part of society and economic competition. One of the main objectives was a political union, the peoples of Europe more than ever in need of a united Europe, including in this regard. Reiterating the bases of Political Union involves a greater effort for members by connecting to the common objectives.

EU enlargement strategy aims to integrate new members in parallel with the harmonization of domestic and foreign policy objectives in all countries (members), by compliance and consistent application of common basic principles.

Joining the European Union was undoubtedly an important step forward, but the process of reduction of disparities still continue. Joining the euro will be the second major step in this process. In this respect, the moment of the introduction of euro currency must be weighed carefully to see what are the advantages and limitations that this approach entailed.

To adopt the euro currency must be taken measures in the following directions: first, inflation should be reduced in a time when massive capital inflows will continue and there will be a convergence to income and prices. Thus, a monetary policy to reduce inflation will have to accept a continuous appreciation of the national currency and a possible erosion of competitiveness. But at the same time, in terms of tax should be increased the expenses with infrastructure, mentioning that the fiscal deficit should be kept under control due to the explosion of the external deficit. Under these conditions, the solution can only be widening the tax base or increase the main taxes.

Regarding the Romanian banking system, it should be noticed the fact that it represents a subset of the national economy that has worked consistently and clearly evolved over the last decade towards modern structures in accordance with relevant European and international levels. The importance of the banking system for the national economy is now so pronounced due to the technical and informational progress and to the new monetary and financial instruments that banks use in achieving the three main functions (financial intermediation, transfer and implementation of monetary policy central bank)

6. Conclusions

The introduction of euro currency in our country will be based on a number of common elements with those countries which have gone through this process. Furthermore, Romania has the great advantage that it can

learn from the experience of those countries that have switched to the single currency.

Thus, the main lessons from the experience of the previously processes of entering within euro area are the follows: careful and active preparation gives the best results. Countries that invested early in training were rewarded for their efforts by the speed of change, easy public acceptance of the new currency and smooth transition. Investing in information and communication has also been rewarded. The need for accurate and timely information remains as important as in the past; lack of information could lead to reactions of fear or hostility.

A long transitional period is not recommended for further countries to join the euro area because public authorities will had to resume efforts in order to persuade again the companies and citizens to prepare in time to change money. Furthermore, using the euro "scriptural" remained rather limited during the transitional period. However, since countries try to make shorter transitional periods, the complexity of using two currencies (euro and national currency) will be reduced simultaneously and the transition will be easier to explain and understand. The introduction of euro banknotes and coins must be swift: a gradually introduction of the euro currency creates complications for citizens and businesses. Instead, a quick introduction gives benefits to all parties involved because it is carefully prepared; also the dual circulation period is preferably to be short. As it was demonstrated by the countries currently in the euro area, a rapid introduction of the euro needs to be based on an extensive network of flights to all ATMs and the ability for customers and non-customers of the banks to change the current currency legally and without any cost. In this case, the importance of card-based payments and online payment must be emphasized. Such payment methods contribute significantly to a smooth transition: removing of the national currency requires careful preparation: the expertise shows the main efforts were focused too much on the introduction of euro banknotes and coins while the consequences of the national currency restitution have been underestimated. Measures must be taken to avoid any impact on prices. Prevent is clearly

better than cure. The risk of abuse during the change of prices is a very important reason for citizens to have fear about this process. Changing the "mental" perception take considerably more time than the physical change. Results of surveys show that 30% of customers think most often in national currency when doing their daily shopping, 46% think in euro currency for higher values (house or car), however, most citizens in the euro area calculated mentally most often in national currency (54%) while a small fraction calculated in euros.

Abstract

The subject of the present paper is consistent with the current developments in marketing theory and practice, referring to a managerial change of priorities from isolated and short term transactional exchanges towards more stable business relationships, with positive consequences on the company long term profitability and competitiveness. Relationship marketing has been promoted in the literature as a natural reaction to technological, economic and social changes occurred in the global business environment. Increased customer migration rates have been a strong argument for many companies for adapting their marketing strategies to new business realities and to understand the value of loyal customers. However, the relationship marketing approach is not equally applicable to all fields of activity, being best implemented in organizational markets and services economic sectors.

Key words: customer relationships, stakeholders, business to business market, services sector.

J.E.L. classification: M31-Marketing.

1. Introduction

In the academic world, relationship marketing has been a well debated topic for more than twenty-five years. Many definitions and perspective have been stated and a vast scientific literature was developed.

The controversies concerning the status of the concept did not lack. Thus, relationship marketing has been considered by some authors an economic paradigm, while others, in contrast have not found its clear evidence of novelty.

The present paper aims to highlight the main conceptual approaches that can be found in the literature, to clarify relationship marketing meaning and fundamental principles and to prove its applicability in different economic areas of activity.

2. Evolution of relationship marketing concept

Relationship marketing literature began to develop in 1983, with Berry's scientific contribution. The author proved the need for more closer and long term business relationships between services companies and their customers. He stated that relationship marketing aims "to attract, maintain and (in multi-service organization) to develop relationships with customers" [3]. Although it is recognized that the acquisition of new customers has been and will remain one of the marketing responsibilities, the definition highlights the need for a relational approach which emphasize the importance of customer retention and relationships development.

Two years later, Jackson is trying to prove the complexity of inter-organizational relationships and the benefits of buyer-seller collaboration [14]. In organizational markets, customers are considered to have a

continuing value over the period they stay in business with a specific company. Thus, the focus should be on developing customer relationships and not on single and isolated transactions.

The duration of the exchange is a core element in making the distinction between relationships and transactions.

A transactional exchange involves a single, short time exchange with a distinct beginning and ending. In contrast a relational exchange involves multiple linked exchanges extending over time and usually involves both economic and social bonds [8]. In other words, a relationship can be conceptualized as one or more exchange activities between a buyer and a seller, which are perceived by the customer as being related to past and future exchanges.

A much broader characterization of the term has been given by Dwyer, Schurr and Oh who state that relationship marketing is "longer in duration than transactional marketing, reflecting an ongoing process" [7]. The authors emphasize, therefore, the continuing character of exchanges that occur between business partners, collaboration not being limited to simple transactions.

Morgan and Hunt also define relationship marketing from a general perspective, without highlighting a sectoral view or explicitly mention the need for a customer relationship to exist. They state that "relationship marketing refers to all marketing activities directed toward establishing, developing and maintaining successful relational exchanges" [16].

Gummesson defines relationship marketing as "marketing seen as interactions, relationships and networks" [11]. The author identified a number of thirty-two relationships that can be developed by an organization in its internal and external business environment.

These are further classified into three main categories: market relationships, mega relationships and nano relationships [12].

The first take place between the company and the key stakeholders from its micro environment, including customers, suppliers, competitors and distributors.

The second are relations that occur between the organization and a heterogeneous external public that have a potential influence on the company long term

performance and market position: public authorities, mass media and the civil society.

And the third refers to the company internal relationships, involving groups such as: employees, investors and shareholders.

The widely accepted definition of the concept in question belongs most probably to Christian Grönroos, according to which relationship marketing aims "to establish, nurture and enhance relationships with customers and other partners, at a profit, so that the objectives of the partners involved are met" [10]. The author goes on to explain that this objective is achieved by a mutual exchange and fulfilment of promises.

An analytical view on the above definition emphasizes the following key elements: the vehicle role of the relationship in creating value for customers, the importance of properly managing relationships with other members of the supply chain, and also the profitability goals underlying the elaboration and implementation of relational strategies.

Moreover, it is suggested that the success of the marketing activities can not be assessed only through monitoring a company market share. Thus, satisfaction and retention indices have to be defined and properly measured in order to determine customer loyalty.

Another prestigious author who stated the need for a change of focus in the marketing philosophy is Philip Kotler. He promotes the advantages of a relational business approach by repositioning the marketing mix as a set of tools for understanding and responding to the requirements expressed by all significant stakeholders from both internal and external environment.

In this context, Kotler propose an additional alternative of the marketing mix, which represents in his opinion the customer perspective on the value received in the business relationship.

Known under the name of the "4Cs", these are translated as follows: customer needs and desires, costs for customer, commodity for customer and communication with the customer [15]. According to this conceptual model, companies have to meet customer needs economically, in a convenient manner and by using efficient communications.

Organizations that have adopted a relationship marketing orientation wish to establish long term relationships based on

commitment, trust and cooperation, and characterized by openness, genuine concern to deliver high quality products and services, prompt response to customer questions or suggestions, and fair businesses [5].

They shift from attempting to maximize profits on each individual transaction towards the establishment of solid, dependable and, above all, permanent relationships with the people they serve. In Bennett's opinion, relationship marketing "is the organizational development and maintenance of mutually rewarding relationships with customers achieved via the total integration of information and quality management systems, service support, business strategy and organizational mission in order to delight the customer and secure profitable lasting business [2].

The natural development of the marketing strategic objectives and activities towards a relational approach is also highlighted by The American Marketing Association (AMA) in its marketing definitions developed after 2000.

Thus, the definition of AMA specialists from 2004 states that "marketing is an organizational function and a set of processes for creating, communicating, and delivering value to customers and for managing customer relationships in ways that benefit the organization and its stakeholders" [6]. The same definition is reformulated in 2007, as follows: "marketing is the activity, set of institutions, and processes for creating, communicating, delivering, and exchanging offerings that have value for customer, clients, partners, and society at large" [6].

As we can see, the focus of both definitions is on customer portfolio management and also on developing relationships with other influential stakeholders, the latter aspect being frequently omitted in the initial conceptualization of the term in discussion. Moreover, marketing is not viewed strictly as a matter of a single functional department, but customer orientation is necessary to be adopted throughout the entire organization and become a corporate culture, highlighting the beliefs of each employee.

As a synthesis of the above mentioned definitions, relationship marketing literature has evolved and developed on two main levels or directions.

The first is a macro level that defines an organizational strategic objective to develop profitable relationships with all relevant stakeholders, including: employees or internal customers, shareholders, investors, suppliers, distribution intermediaries, partners from strategic alliances and so on.

The second is a micro level, which purpose is to attract and retain valuable customers. This is also known as the primary aim of customer relationship management, a concept developed in close connection with the relationship marketing theory and practice.

3. Relationship marketing adoption by economic sectors

Although relationship marketing principles have gained widespread popularity, in the literature certain economic areas or industries were considered to be favorite fields of implementation.

In this context, many researchers proved that the business to business market and the services sector present specific features that facilitate customer relationships development and stakeholders' partnership creation.

Business to business markets are considered to be very complex in nature, due to specific needs which underpin the organizational buying behavior.

Market structure is significantly different from what it is known in the business to consumer field of activity and this is related to reasons such as: the small number of customers and the derived demand, the concentration of purchasing power and the interdependence between buyer and seller, the greater complexity of products purchased, etc. [13].

In inter-organizational markets, the number of customers and prospects is much lower than the situation encountered in consumer markets. Organizational buyers are usually recorded in official statistics, having a clear demographic profile, which helps seller companies to more properly estimate their specific needs.

Due to the great volume and value of individual transactions, business to business customers are considered to have a high buying potential, some of them being of strategic importance for the supplier business stability.

Within many business to business domains there is a high concentration of demand. Most time, the aggregate market share of the first three or four buyers tend to reach values of 70 or 80 per cent of their total market, which translates into a high concentration ratio and dominance by a few firms.

Those companies that control large shares of the customer market are also the largest customers for suppliers to the industry [4].

This situation is a very good justification for sellers to adopt relational strategies in order to keep these customers and to capitalize on their high profitability potential. The aim will be to develop mutual beneficial partnerships, based on trust and commitment, which will enhance customer investments in the business relationships and thus will be created natural switching barriers.

For business to business marketers, adopting relationship marketing strategies will certainly involve a very good understanding of the customers' demographic and behavioral profile, which will underpin all future decisions and actions. This will frequently involve the development of tailored solutions to individual strategic customers rather than implementing standardized marketing mix strategies.

The services marketing literature, was similar to the business to business sector, one of the first area for the development of relationship marketing research [9].

The growth of the services sector in many international markets has favourable influenced the development of specific marketing mix tools in fields such as: banks, assurance, tourism, health, etc.

In marketing literature there is a great acceptance of the need to differentiate business strategies depending on the nature of supply.

The main differences that can be identified between goods and services are: the intangible elements that dominate value creation, the fact that service product cannot be inventoried, the variability in the operational inputs or outputs and the inseparability of services consumption from the contact personnel, which means that customers may be involved in the production process [8].

Due to these specific features, Bendapudi and Berry stressed that the practice of relationship marketing is most applicable to a

service company [1]. They argue this theory through three main reasons.

First, many services require a continuous nature of the delivery process, which involves supplying the service over several contacts with the customer.

Second, services intangibility and increased difficulties of assessing the quality of services before consumption leads customers to seek ways to reduce perceived risks by engaging in business relationships.

Third, customers will most probably want to form relationships with other people (employees, first-line staff) rather than with products or objects.

Relationships development is favoured in this case by the inseparability characteristic of services, both the service provider and the buyer having a specific influence on the outcome of delivery process.

Moreover, some kind of services such as health, banking or educational services are very complex in nature. Thus, the customer has difficulties to evaluate them, even after their experimentation.

In these circumstances, the confidence in the service provider will be a key factor in reducing buyer anxiety and perceived insecurity, leading to increased customer commitment to the supplier.

Regarding the consumer goods market, most researchers believe there are some obstacles in the adoption of relationship marketing principles, given the existence of a high number of customers with a low or fragmented purchasing power, whose profile is not always easy to identify at an individual level.

4. Conclusions

As described in the present paper, relationship marketing is a popular subject that has remained the focus of marketing specialists for more than two decades. It highlights an ongoing process by which a company creates value, based on the individual needs of targeted customers and business partners.

Relationship marketing involves a win-win business strategy which integrates information technology and quality management systems into specific internal processes, with the aim of better understand and adapt to customer behaviour and to the

requirements of other relevant stakeholders.

From a company perspective, this new marketing orientation is expected to lead to increased customer loyalty, higher economic performance and a better competitive position.

However, relationship marketing strategies are not applicable in all situations, sectors or market contexts. Its main economic fields of implementation are considered to be the service sector and the business to business market.

Abstract

Each discipline of the law implies the scientific knowledge through the identification of some basic notions, as, through those notions to it's reveal te essence of the investigated phenomenon. Each notion represent the investigation of an specific characters of it's content, which it's ordonate in a concret and logic way, delimit in this way, in the abstract thinking plane, not only the borders of the phenomenu and of the process which recall, but this essence it self.

The scientific knowlwdge is not enything else in a metaphorical wording, but an permanent process of language improvement, to recall much more profound essences.

In the administrative traditional law the meaning of the public administration notion was different and extensive analyse, both in the interwar juridical literature, and in that after the second world war. Sometime, the the sphere of the state administration, and other time the administration accomplished by the state organisms was concern just like an dimension of public administration, making the difference between the state public administration and the local communities public administration.

Key words: administrative law, public administration, centralization, decentralization, local autonomy

J.E.L. classification: K23

1. Introduction

In any state, regardless it's structure (unitary or federal), regardless the shape of government (republic or monarchy) or by the political regime (democratic or dictatorial) it's put in the debate the problems and the aspects which regard the centralization,

decentralization and the local autonomy in the public administration, the aspects which present a special, theoretical and practical importance for the good organisation and performance of the state.

All over in the world in any state will prevail, at a time in some stage, either the centralization side, either the decentralization one because the state will not govern only in a exclusive centralized regime or exclusive decentralized. This problem necessitate a right understanding for the insure of an optimum balance between these sides of the structure and the statal activity, necessary to all the states darkling in the process of transition through an decentralized system ground on the principles of the law state.

So, the local autonomy represent an fundamental of organization and founction principle of the local public administration.

2. The local autonomy – the fundamental principle of organisation and performance of the public administration

Under the article 120, al. 1 from Romania's Constitution from 1991, recence in 2003, „The public administration from the administrative-territorial units it's base on the principles of the centralization, decentralization, local autonomy and deconcentration of the public services”[1]. Other consecrations of the local autonomy principle we fiind in the Law no. 215/2001 article 1 – The Local Public Administration Law – and in The European Charta of The Local Autonomy adopted at Strassbourg october, 15 1985 and ratify by Romania in 1997 [2].

The article 1 from 215/2001 Law specify that: „(1) The present law it's settle the general regime of the local autonomy, and

the organisation and the working of the local public administration", and the article 2 from the same law stipulate that: „(1) The public administration in the administrative-territorial units it's organise and operate on the ground of decentralisation, local autonomy, deconcentration of the public services, eligibility of the authorities of the local public administration, legality principles and citizens consulting in the solving of the local problems of special interest"[3].

The European Charta of The Local Autonomy adopte dat Strassbourg at october,15 1985 define the local autonomy like an „principle establish through the Constitution or through the part-states laws, which confer to the local collectivities the right and the capacity to resolve and gestion, in the frame of the law, under it's own responsibility and in these population interest, an important part from the public affairs". This document recognize the necessity of exertion of an administrative control from the state on the local collectivities, the control which regard only the legality of the deeds emissived by their representative authorities.

The content of this principle arrise from the assembly of the settlements comprised in the law's regulations and represent the essence of the hole activity of public administration from the administrative-territorial units. It's right understanding present an special importance on the plan of the practical actions and emphasise the achievement of an apart independent character of the local public administration authorities and the concept of the selfgovernance which should mean an contraset of the local public administration to the central administration through which it's accomplish the executive power of state.

The local autonomy does'n mean the right of an collectivity to govern it's self in any problems, without allowance of the bearings with similar collectivities or situate dat the superior levels, or at the centre.

The principle of the local autonomy is not only a theoretic concept and it's does'nt have an abstract content. It had un material holder, which it's express through the practical, concrete actions. The local autonomy had like economic foundation the it's self patrimonial base on which the local

collectivities it's administrate like an genuine owner, in the law's conditions.

The local collectivities held in propriety or administration, the material goods – form by the lands, buildings, differents equipements and others – like financial means, making the public or private domain of those, which it's administrate regarding of the inhabitant's interests, but in conforming with existant regulates. Otherwise, the local autonomy without the existance of this material foundation and without freedom to administrate it suitable of the personal needs could mean just the affirmation of an principle pure theoretical, without an content and without relcatlessness on the practical action plane.

The patrimony that dispose each collectivity from the administrative-territorial units constitute, in fact, the spring of it's development and prosperity, of the solution, at the superior level, of the requirements and of the affair of the inhabitants.

In the intention of ensure of the local autonomy, The 215/2001's Law anticipate that the public administration authorities from the villages, cities and districts, elaborate and approve the budgets of income and expenses and had the right to institute and perceive duties and local taxes, in the law's conditions[4].

3. The characteristics of the local autonomy principle

The Law 215/2001 contain other disposals too which are directly legal and give juridical expresion of an elements which regard the pntinciple of the local autonomy.

The law specify the juridical nature of the local autonomy and it's statuare that this is administrative and financial and it's exercise only on base and the limits predict by the law. An similar stiplulations is by nature to interrupt any tendency or action to distort the meaning and the exactly content of these principle, to advance or to put in opera „the local autonomies" on the „ethnic", „linguistic", „territorial"(regionals) criterions etc.

The Law 215/2001 also specify that the local autonomy „represent the right and the effective capacity of the local public authorities to resolve and administrate in the name and in the personal interest and under

their responsibility an important part of the public affairs of the local collectivities which it's represent, in the law's conditions". In the similar way this text it's fiind again also in Tha European Charta of The Local Autonomy, and the romanian legislator undertake it because this is in the complete concordance with the stipulations and the spirit of the Romania's Constitution.

From all these exposures by legislative order we detach some essential characteristics of the concept of the local autonomy, such as:

- ✓ The local autonomy represent not only an right but an obligation (responsability) too for the representative authorities of the locale collectivities, to resolve and administrate the problems of those collectivities;
- ✓ This right and this obligation it's exercise in the name of the local collectivities and only on the base of the mandate given by the collectivities (like an sucesion of the assignation deed through the scrutiny);
- ✓ The exercition of the rights and obligations confere it's made only in the interest of the collectivities which it's represent;
- ✓ The authorities of the local public administration representiveness rejoin political (in a front of those which it's represent) and juridical (in a front of the state) by the way in which they exercise the right and obligation regarding the reslove and administrate the problems of the local collectivities.

The Local Public Administration Law define also what it's mean through „local collectivity”, specifying that means „the total amount of the inhabitants from the administrative-territorial unit”.

The Local Public Administration Law also anticipate that „the application of those principles enunciated can not bring touch to the character of the national, unitary and indivisible state of Romania”. These stipulations represent a juridical guaranty of understanding and mostly of the assertion in the practice of those principles, but mostly of the local autonomy principle[5].

As much as develop could be the local autonomy and the decentralization, these mustn't affect neither the state suzerainty and

neither the national and unitary character, the state being even the factor that assure and guaranty the local autonomy, being directly interest both in the resolving of the local interest and both of those national, keeping them in a optimum equilibrium and creating the adequate conditions of cooperation between the local public authorities and those central authorities, in the intention of an good performance on the whole society.

Which in Romanian is call *administrative decentralization* or *local autonomy* is designate in Franch *decentralization administratif* and *auto-administration*, in English *self-government* or *local government*, and in German *selbstverwaltung*.

The state is not longer the only one territorial collectivity recognise, but, beside this, also the local territorial collectivities are moral persons of public law political-territorial, having the capacity of the personal public law and personal public interests different by the public interests of the state. They dispose by the personal administrative authorities for the satisfaction of these public interests, and also by the material, finacial and human resources means[6].

The local autonomy it's manifeste on multiple plans. On the juridical capacity plan, the local territorial collectivities are distinct subjects of the law, having personal public interests. On the institutional plan, they dispose by personal administrative authorities, exterior of the administrative statal labor. On the decisional autonomy, these personal authorities had personal abilities and take the decision in the interest of the collectivities which administrate them. At last, the autonomy could not be real, efective, without the presence of the autonomy in the plan of human, material and financial means, the local collectivities disposing by the personal civil servant, by the personal domain (public and private), by financial autonomy, especially under the aspect of establishment and collection of the personal duties and taxes and of the existent of an personal budget.

The local administrative authorities are autonomous, but not sovereign. Therefor, on the hand, the autonomy is exclusiv at the administrative level[7], but not legislative, by governance or judicial, it not being an political autonomy (like political

decentralization), like in the case of federalism[8]. On the other hand, the local autonomous administrative authorities, though unservient to the state administration authorities, are highly placed to an peculiar administrative control, the administrative tutelage control, from the central or territorial state administration. It visa the protection of the state public interests, and the observance of the laws being, therefore, by general regulation, an legality control, and not one of opportunity control.

The administrative tutelage control is an special control, which can exercise only if the law express institute it and only in the forms, with the procedures and with it's effects express assign by the law.

The administrative tutelage it's exercise on two dimensions: the tutelage on the existence of the tutelary organs and the tutelage on their activity.

The tutelage on the existence of the tutelary organs knows a tough forms, in which the tutelary organs has the right to dispose or to dissolve protected organs, and a liberal forms, in which the tutelary organs not dispose than by a disciplinary action, so by the right to inform an jurisdiction, for the demission or dissolve of the protected organs, the decision revert to the independent, impartial and irremovable judge. The literal forms could be harden through the setting-up of the right suspension of the organ against which it's exercise the disciplinary action, through the tutelage organ right to dispose the suspension of the protected organ against it's exercise the disciplinary action or only through it's right to ask the adjournment to the instance.

The tutelage on the protected organs activity regard, as a rule, the deed in regime by the public power of the autonomous authorities, such as the administrative deeds and the administrative contracts. It's exclude the deeds in the private right regime, which the local territorial collectivities made exclusively in the ground of the private right capacity, without the usage of the public power prerogatives, for what this special administrative tutelage control wouldn't justify and it could be appear like excessive.

The administrative tutelage it could exercise by an organ of the central state administration (Government, Internal Ministry) or territorial (Prefect).

In the case of the local autonomy administrative regime, the state remains an unitary state, but an complex unitary state, recognizing the existence of others subjects of public right invest by a command power on the population from a certain territory and disposing by the personal administrative authorities.

It is to remark the fact that the doctrine emphasize, both in France and both in Romania, that the base, common organization, with her autonomy, it is anterior of the state[9], it being placed at the crossing between the state and the civil society.

The local autonomy exist both between the local territorial collectivities and both between the local territorial collectivities themselves, whatever of the level they are situated. Beside, the administrative tutelage doesn't exist than in the reports between the state and the local territorial collectivities, and not between the local territorial collectivities themselves. One local territorial collectivity situated at an superior level couldn't exercise neither kind of tutelage on the inferior local territorial collectivities, darkling on the it's territory. In France, the tutelage between the local territorial collectivities are express forbidden by the law, but, even if, juridical formal, does not exist neither kind of the tutelage, in the reality does exist sometime the relationship of dependency, which could arrive until a authentic tutelage, mostly from the financial and technical point of view.

Abstract

Each individual must have a membership. And it is not about political membership (so popular in the last few years) , but a intrinsic right acquired by the human being since birth. It's about citizenship, a right sanctioned by the constitution of any country, as important as the right to life. Practically, the both rights coexist and combine in a harmonious suite which does nothing but gives a special value to the man, the citizen.

The citizenship is an indissoluble legal report regarding the human being. The citizenship report is lasting in time, begins with the birth and, virtually, disappears, once with the physical disappearance and absolute in space, it exists everywhere there is a person , in the provenience state, in another country, on the sea, in the air or in cosmos.

The citizenship is basically submitted to a legal system of internal regulation, the states having an exclusive part in establishing in its own legislation both the manners of acquisition and losing the citizenship, and also all the rights and obligations which flow from the political and legal reference of a state's membership. As a rule only the citizens of a state can have political rights and can get access to public, civil or military jobs.

The international law doesn't restrict the state's freedom to establish through its internal legislation the legal system to its own citizens, but can decide upon the conditions under which the established legal system is opposable to other states.

Key words: expulsion, extradition, the right for asylum, statelessness, double Statelessness, citizenship.

J.E.L. classification: K 33

Along the establishment of the European Union appeared extensive discussion in the doctrine of international law vis-à-vis the issue of citizenship. It is a completely natural problem if we do not lose sight of which were the reasons for the establishment of a European Union. Turning back in time, we could remind the desire of the Union's "parents" Union respectively Winston Churchill, Jean Monnet, Robert Schuman and Marshall to protect the citizens of Europe divided by the scourge and the chaos caused by the two world wars. Obviously the ideas of European unity are more deeply rooted in history, but space does not allow us here a comprehensive analysis of this phenomenon.

Beyond the internal aspects of the term of citizenship, after the unification of Europe emerged the concept of European citizenship. EU citizenship is the same for all citizens of EU Member States, regardless of when they joined, the economic development of the states or their size. Being a relatively new concept it should be noted that European citizenship does not come to replace the national state citizenship, but a complement, thus giving the citizens of the Member States some advantages, such as: free movement of persons in Europe, the right to settle in other countries, the benefit of diplomatic and consular protection from some other Member States, access to work opportunities in other EU member states, namely a working law without discrimination and restrictions.

As a conclusion, the European citizenship is nothing else but equality of rights of the European citizens and thus representation in all European institutions.

Concept of citizenship - Citizenship is not a concept invented overnight. We can not talk about citizenship without taking into account aspects of the emergence and

development of states and hence their component elements. It's about people and the territory of a state, elements conferring sovereignty. Population is nothing but all the natural and legal persons that coexist within a well defined territory, people who are subject to state jurisdiction. These individuals and legal entities that make up the population of the state are divided into several categories, with different legal status established by national laws of each state. Otherwise meet:

- citizens of that state;
- foreigners (i.e. people who have foreign citizenship);
- stateless persons (persons without citizenship);
- double citizens (persons who have acquired dual citizenship).

We must not forget that besides these groups there are some categories of foreigners who live within a state, but not under its jurisdiction. It's about the members of diplomatic missions of other states, state's representatives of intergovernmental organizations, their officials and members of foreign armies.

Not only the national laws of each state determine the legal status of such categories of persons, including their own nationals. The rights and obligations of each category of persons are stipulated by international treaties and a number of customary rules, however, all these are the result of international cooperation between states, due to respect and implementation of basic principles governing international law.

The term "nationality" can be defined as that political and legal bond that always exists between an individual and a state that produces a variety of rights and mutual obligations between that person and the community or the state he belongs to [2] .

Among the documents which provided a clear definition of the concept of citizenship may be recalled the International Court of Justice which defines citizenship as "a legal relationship based on a social fact of attachment, a genuine connection of the existence of interests and sentiments, together with the existence of legal rights and duties " and for The European Convention on nationality sealed on November 6, 1997 in the Council of Europe, citizenship means "the legal bond between a person and a state

and does not indicate the person's ethnic origin."

International law stipulates that this relationship between the citizen and the state always occurs and continues wherever that person might be, either in his/her state or in another state or in locations where there is no sovereignty of any state.

In other words, nationality is expressing the person's adherence to the state in question. Under these rules of international law and the principles enshrined in it, a state may not challenge another state law in determining the legal status of its citizenship by means of its own internal laws, and can not be bound to recognize or accept the consequences arising from such rules.

Citizenship issues shall be governed by the national law of each state, but, because its international implications, the concept of citizenship is at the point of interference between the national and international law.

For example, the national law provides all citizens have rights and obligations under that state's active laws and for people who are not citizens, they enjoy political rights and diplomatic protection from the state to which they belong to, and the state whose citizen one is can not refuse the return , whether it's a wish or by reason of expulsion from another country.

There are several factors that can lead to deprivation of the nationality of a person in addition to other penalties provided by the law. These situations aim at, inter alia, citizen's breaching of loyalty duty, enrolling in a foreign army or committing grave acts against their country.

In international law a set of rules have been imposed that undertake states to apply certain rules in solving problems related to citizenship. The state is the one which establishes the conditions of acquiring the citizenship and because of that, other states can not challenge its decisions and are not obliged to accept the consequences of the decisions taken on the nationality of a person [3]

Means of acquiring citizenship

There are some general rules on how a person can become a citizen of a state. These rules are established by national laws of some states and international conventions. Thus, acquisition of citizenship is made:

1. by birth, after two legal systems:

➤ *jus sanguinis* (Latin countries from Europe and Scandinavian countries) - the right of blood, through which the newly born receives his/her parents citizenship regardless the country of birth;

➤ *jus soli* (specific to the United States, England and some Latin American countries) - the right of soil, according to which the child will receive the citizenship of the state where he/she is born, regardless the parents' nationality.

2. by naturalization (conditioned or determined by the person's will and the fulfilment of the conditions provided in the domestic law of the state):

▪ *by affiliation or adoption* – case in which the adopted child shall acquire the citizenship of the person who adopted him, obviously respecting the national legislation in the state where the adoption occurs. Regarding the rules of private international law, specifically in cases of conflict of laws between the adopter's state law and the adopted state law, it's applied the law of the territory where the child is, thus acquires the citizenship of the state where he/she is situated;

▪ *by marriage* - the state law applies where the marriage was terminated, but the international law states the common domicile of both spouses law, in accordance with the active national laws ;

▪ *by recovery or rehabilitation* - situation referring to the relapse to the previous citizenship for people who have emigrated or have lost their citizenship by marriage to a foreigner from whom they divorced;

▪ *transfer or relocation of the population* - problem which appears with populations moved to other areas and under agreements sealed between states which granted the citizenship of the territory where the movement was held;

▪ *the option* - a problem that arises when the transfer of territory from one state to another is made, for people living in that territory. These people have the right to choose either the previous citizenship or the citizenship of the new state that received the transfer of territory. The population has this right in virtue of the right of peoples to self-determination, which is nothing else but a

fundamental principle of public international law and the principle of nationalization;

▪ *by granting (or naturalization)* - is a way which implies that the acquisition of citizenship is made at the request of the person interested in this aspect. Citizenship is granted by a competent state organ to which the application for citizenship is addressed[4].

All laws of all the states of the world also contain a set of conditions which compete for the acquisition of citizenship, and I recall here some of them, namely: a required period of establishment (residence) in that territory (the extension of the period is different from one country to another, more or less), good character, proof of livelihoods, namely employment, housing space, etc.. There is also the term "honorary citizenship" that is conferred to a member of another state only for humanitarian honors or for brave, heroic acts towards the state which confers this title.

Loss of citizenship

But there is also a reverse, in the citizenship, acquiring it also supposes losing this status.

There are two ways of losing the nationality under the domestic laws of the states and the international conventions. These two cases are:

✓ through waiver - which occurs following a specific request made in authentic form, generally by the interested persons in acquiring foreign citizenship;

✓ through withdrawal - when applying a domestic law of a state on the basis of a decision taken as a sanction against a citizen who had inappropriate conduct for which the law requires such a penalty.

Reasons for withdrawal were stipulated in the Universal Declaration of Human Rights in 1948 (which provides that no person may be arbitrarily deprived of his/her nationality) and the Convention on reduction of cases of statelessness in 1961 (which provides some reasons why not arbitrary).

These reasons may be considered: the repudiation or the proof of willingness to renounce at the allegiance towards another state, providing an oath of allegiance to another state, making services to other state - seen especially in espionage, conducts causing serious harm to the important interests of a state [5].

European regulations on citizenship

The desire to unify the European countries and therefore their legal systems has led to the adoption of the first multilateral agreement in 1963. It's about the Convention on the reduction of the multi-citizenship and military obligations in this case, convention based on the idea that acquiring a new citizenship will inevitably lead to the loss of the first, and military service should be performed only within a state, not in both in case of dual citizenships.

Another European document that addressed the issue of citizenship is the EU Treaty of Maastricht from 1992, entered into force in 1993 which established for the first time the union citizenship, stating that all citizens of the member states are citizens of EU and every citizen has the right:

- to move and to establish their domicile freely across the member states;
- to vote and stand in municipal and European elections which take place in the state of one's domicile;
- to be protected by diplomatic or consular authorities of any state;
- to address the Parliament and the public official charged with checking public opinions (mediator).

The Council of Europe European Convention on Citizenship was adopted on 6 November 1997, the Convention establishes general rules according to which the national laws of each state should be planned. If the internal laws of a state shall be adopted in accordance with the general principles of the international law, of the customary international law and applicable international conventions, then they must be respected and accepted by all the other states, taking into account the nature of public international law, in general, which is a coordinator and not a subordinate law, and its rules based on sovereign equality of states establish a voluntary international jurisdiction, different from the general law that is general and compulsory.

The European Constitution stipulates in Article 10 that: "1. Any person holding the nationality of a member state is a citizen of the Union. The Union citizenship adds to and does not replace the national citizenship. 2. The EU citizens enjoy rights and have obligations under the present Constitution. They have: - freedom of movement and

residence within the member states; - the right to vote and be elected in the European Parliament and in the local elections in the member state where they reside, in the same conditions as the nationals of that state ; -the right to benefit, in a third country where their member state is not represented, of protection from the part of the diplomatic and consular authorities of any member state, in the same conditions as the nationals of that state ; - the right to present petitions to the European Parliament ,to address the European Ombudsman or to address to the institutions and advisory bodies of the Union in one of its languages and to receive an answer in the same language. 3. These rights are exerted in the conditions and limits defined in this Constitution and in the provisions for its application [6].

Conflicts of citizenships

Conflicts of citizenships appear as a result of differences in national laws regarding the means of acquiring , respectively, loss of citizenship. Thus, regarding the legal status of the foreigners, international practice has identified several forms / types of legal regime applied to foreigners. It is about :

1. national scheme - which grants the same rights as to their own citizens, except the political ones;
2. special rules - are granted only certain rights;
3. regime most favorite nation clause - which means that foreigners receive a treatment as good as that applied to the foreigners from other countries through international treaties [7].

The international status of foreigners is currently a mixture of customary and conventional rules that has known a great development as a result of the continuous processes regarding the fundamental human and citizen rights and the extension of the concern regarding their protection.

It requires some clarification on certain categories of foreigners who enjoy special legal regime. These categories are:

- a) **Stateless persons** - persons who have no nationality. This occurs either due to the loss or waiver of the citizenship of a state and the failure in acquiring the citizenship of another state, either a person who marries a foreigner losses his home state citizenship

and has not yet acquired the citizenship of the spouse. Stateless persons have reduced rights compared to the rest of the citizens of that state and even to foreign nationals of other countries. The United Nations International Law Commission developed in 1954 a series of projects on which the Convention regarding the status of stateless persons was adapted and in 1961 The Convention on the reduction of cases of statelessness.

b) **Double citizens** – persons who possess the nationality of two or more states. The double citizenship usually occurs in two ways:

- whether the citizenship has been acquired by birth within a state that applies *jus messengers*, i.e. the right of soil from parents belonging to another state on the ground on which *jus sanguinis* prevails, ie the right of blood;

- whether the situation of naturalization, if a person keeps the old nationality.

The causes of double citizenship can create complications in the relations between states and therefore the issue about solving the conflict between laws regarding citizenship has come up. In this regard, there were established a series of bilateral agreements through which a series of rules for avoiding dual citizenship.

c) **Refugees** - are people who because of war or other causes have been forced to abandon their home country on good grounds of race, religion, nationality, affiliation to a particular social group or political one and seek for the protection of another state. In 1947 The International Organization for Refugee was set up besides The United Nations which has as consequence the creation of the UN High Commissioner for Refugees in 1951. By offering a person the status of refugee the state grants a right to entry and establishment on its territory of a foreign tracked in his country for political activity, i.e. grants political asylum.

d) **Political asylum** - is a sovereign state's right to grant the establishment on its territory of displaced foreign people , pursued in their home country for political, religious or scientific activities, which are in accordance with the law of that state. According asylum is actually refusing extradition. Asylum is an exclusive right of the state and not of the person requesting it.

Asylum is not considered a hostile action in the relations between states as it is done for purely humanitarian reasons, and the right to seek asylum is considered a fundamental human right provided by the Universal Declaration of Human Rights in 1947.

e) **Expulsion** - is an act whereby a state compels a foreigner who has become undesirable after committing acts that violate the laws of the state of residence , who is on its territory, to leave in a short a time as possible. According to the International Covenant from 1996 on civil and political rights ,a foreigner which is legally on the territory of another state can only be expelled by court order.

f) **Extradition** - is the act whereby a state at the request of another state, hands over a person from its territory, who allegedly committed crimes, for trial or serving a sentence to which he/she had been previously convicted. The institution of extradition has emerged as a form of support in criminal law to ensure the transfer from the territory of a state of people who have broken the law. Nationals can not be extradited.. According to art. 19 from the 2003 revised Constitution of Romania, Romanian citizens can be extradited on the base of international conventions to which Romania is part of, respecting the law and the conditions of mutuality . The treatise of extradition establish a set of mutual rights and obligations of the states which are parts, and also the conditions and manners of performing it. The European Convention from 1957 provides that the acts for which extradition is sought to be punishable under the domestic laws of the requesting state with a custodial sentence or detention order of imprisonment for at least one year.

Some Aspects Concerning the Statement of the Cash-Flow Within the Public Entities

Florea Gheorghe
"Petre Andrei" University of Iasi
geluflorea@yahoo.com

Abstract

On the level of the enterprises, neither the balance sheet nor the results account have proved to be enough to serve as basic elements to professionals, especially to financial analysts, this being one of the main causes for the appearance of the treasury flows variability. As we all know, the Romanian rate setters have decided to translate this traditions on the level of the public sector, too, where the concept of result has been submitted to acerbic criticism

However, the absence of a lucrative purpose does not spare public entities from focussing on their liquidities, but on the contrary we daresay that they should be constantly concerned with providing liquidity. Which is more, supplementing the balance sheet and the results account with a report of the changes that have occurred in the financial situation will help to further the interpretation of the values encompassed in the two annual/quarterly reports.

Key words: cash-flow, public entities

J.E.L. classification: M41

1. Introduction

In the private sector neither the balance sheet nor results account presented in the classic format have shown to be sufficient to serve as the basic professional elements to the business world, especially to financial analysts.

"The limits of the balance sheet and of the result accounts underline the interest in a document to show all the uses and flows of resources embedded in the operations, all operations that affect the outcome, and especially to allow the analysis of the incidence on the financial balance and on its treasury. This document usually referred to

as financial-picture or picture of funding and uses of resources, achieves in a particular way the «crossing» between two successive balance sheets" [1].

As a result of this fact, the origin and use of funds has emerged, logically, as a fundamental complement, especially because it allows the understanding of certain financial transactions that could be "hidden" [2] by applying accounting principles.

2. The concept of fund. Statement of cash flows

Since 40s of last century were the first attempts aimed at gradual financial accounting information based flows, financial analysts were those who urged such initiative now become tradition. As a result of those initiatives, some standardize accounting entities, such as Accounting Principles Board, have begun to issue rules in this regard, that, at the beginning, declared it optional (the APB 3), and then set it mandatory (APB 19).

It was the beginning of polemics centred on the substitution of the idol accounting, the benefit, by other financial means, based on it, considered to have a richer information content. In this context, the financial surplus based on the exchange ratio could emphasize within the financial report some fundamental issues regarding the liquidity and solvency of a company, issues considered as important as profitability, based on the benefit.

In this context, Anthony [3] believes that *"the balance sheet must be accompanied by a report that reflects the origin and use of funds and must take into account these concepts during the accounting principles ... The principles taken into account in order to establish the content and format of these reports will be exactly the same that were given to commercial enterprises now in APB 19"*. On the same line were other authors

that: Holder (1980), Henke (1986), Greenall (1988), etc.

Generally, any report which aims to highlight the modifications produced on the financial situation of an entity seeks to explain the entries of funds produced during the year, their use and their destination, as well.

However, we cannot speak of the existence of a single type of changes in financial position; in fact, every report will depend on the financial variable chosen to be presented, and, accordingly, we will face an almost endless polemics concerning what type of variations of the funds would be more useful to explain.

The term "fund" has been largely used in the accounting area, and especially in the public accounts, with different signification.

If, however, focusing only on the main concepts used in emphasizing a change of statement in the financial position, one can notice different concepts that have been defined and accepted within the financial accounting.

First, one can conclude that all the external financing sources are funds, in which case the picture of origin and use of funds will reflect changes made in each post of the balance-sheet, meaning that certain items of assets or liabilities will increase or reduce, *the positive and negative variations between two successive balance-sheets* being considered as a "*differential stock*".

Another basic concept is the current assets; in this case the fund approach signifies net current financial resources available to the entity. The picture of origin and use of funds would explain the variations produced in the current assets as a result of transactions between the entity and outside, this concept being mostly met by the end of the '80 in the private sector.

A restriction only to monetary assets and liabilities is the third basic concept, identified with the financial assets.

Finally, in some situations the term "fund" is identified only with cash and its equivalents, in this case the picture of origin and use of funds being converted into a report which reflects the variation of treasury and its cash equivalents.

Moreover, in the public entities one can use and explain in the picture of funds-flow as a variable the remnant treasury, due to its importance in public sector accounting.

3. The Statement of cash flows

Facing such a diversity of situations regarding the origin and use of funds or variations in the state of financial accounts, this question naturally raises: What picture should be adopted by public entities?

Most important authors and public accounting standards organizations declined their preference for the solution adopted by the national rules applicable to the private sector. CIPFA, GASB and CICA used to recommend the elaboration within the public entities of the same paintings of variations regarding the financial accounts that were in force for commercial entities.

However, Holder [4] agrees that the concepts described above are neither relevant nor significant for governmental entities and added one last concept called "financial supplies", that includes those components of the working capital of the public entities that can be converted into treasury and are available to be spent. Also in his opinion, the concept should be applied especially for local public entities which are best adapted to the budgetary regime and to the economic reality through information on the financial resources available for future consumption.

Subsequently, and Henke [5] subscribes to this idea, stating that public entities should draw up a picture of the flows expressed in terms of available resources.

These authors' suggestions could equally be assimilated to our accounting and budgeting standards, in a report which in order to reflect cash remaining variation, because it properly indicates the amount of resources available to be used next year.

If by the end of the '80 vehement debates had as object the identification and the agreement on the type of financial variable that had to explain the origin and use of the resources' painting, today one observe that the cash flows painting replaced the picture of the financing or the report of working capital variation.

Specifically, GASB notes that statement of cash flow, along with related disclosures and information in other financial statements, can be useful in assessing the following [6]:

- Ability of an entity to generate future cash-flow;
- Ability of an entity to pay its debt as the debt matures;

- Need to seek outside financing;
- Reasons for differences between cash flows from operations and operating income;
- Effect on an entity's financial position of cash and non-cash transactions from investing, capital, and financial activities.

These assessments can be made when statement of cash-flows is prepared in a manner that summarizes:

- Cash flow from operations;
- Noncapital financing activities;
- Capital and related financing activities;
- Investing activities.

In addition, noncash transactions that have an effect on the entity's financial position should be presented. Finally, there should be reconciliation between operating income and net cash flow from operating activities.

The format of statement of cash flows adopted by GASB provides for four main categories (table 1), un-like FAS-95 which requires three main categories [7].

Table 1. Statement of cash flows

I. Cash flows from operating activities
Receipts from customers
Payments to suppliers
Payments to employees
Internal activity – payments to other funds
Claims paid
Other receipts (payments)
Net cash provided by operating activities
II. Cash flows from noncapital financing activities
Operating subsidies and transfers to other funds
III. Cash flows from capital and related financing activities
Proceeds from capital debt
Capital contributions
Purchases of capital assets
Principal paid on capital debt
Interest paid on capital debt
Other receipts (payments)
Net cash by capital and related financing activities
IV. Cash flows from investing activities
Proceeds from sales and maturities of investments
Interest and dividends
Net cash provided by investing activities
A. Net (decrease) in cash and cash equivalents
Balances – beginning of the year
Balances – end of the year
B. Reconciliation of operating income (loss) to net cash provided (used) by operating activities
Operating income (loss)
Adjustments to reconcile operating income to net cash provided (used) by operating activities:
Depreciation expense
Change in assets and liabilities:
Receivables net
Inventories

Accounts and other payables
Accrued expenses

Source: GASB no. 9, pp. 230-231.

In this sense, the teacher Feleagă Niculae made a nice plea seeking arguments pro paintings Flux "in financial accounting: "As is known, the balance-sheet provides a static view on the financial structure, and the profit-and-loss account, a dynamic one. In other words, the balance-sheet describes at a certain date (usually at the end of the exercise) the various financial resources of the enterprise (liabilities) and their manner of use (assets). It is a representation as "stocks" (existing), of the physical or financial elements that characterize an enterprise, emphasizing the effects that the past decisions continue to exert on the present situation. As for the profit and loss account, it includes the balance flows generated by business operations, which have a bearing on the outcome of a given period (the accounting exercise). It enables establishing the capacity of self-financing ...

But neither the balance-sheet nor the profit and loss account does not allow, a priori, obtaining a dynamic view of the financial structure, that is, upon the evolution of this structure. Such a vision is subject to interest, both the financial analyst, foreign to the enterprise and its managers. A business leader is often led to question and to find answers on the location of the benefit in economic structures (treasury stocks, fixed assets etc.). Perplexity occurs when he finds a discrepancy between the increased production and turnover on the one hand, and the treasury, on the other. Finally, he attaches a special interest in investment opportunities and means that he can put into work. In all of these requirements, and many others, theory, doctrine and worldwide practice have responded by creating a very interesting instrument: painting funding. The specialty literature proposes several terms to designate the financial situation's summary: panel funding, panel uses and resources, the flow pattern, the picture of Treasury)" [8].

4. Conclusions

If the above elements were the main causes of the occurrence of variable cash flows, in our view we are happy we get to know that the Romanian standards issuers decided to adapt this tradition to the public sector, where, as is known, the concept of result was subjected to intense criticism.

However, the absence of lucrative aim does not exempt public entities from the attention of their liquidity, but dare to say that they should be permanently preoccupied with assuring liquidity.

Given that the financial surplus was conceived precisely for such purposes, especially in the early years, it should be an element of great utility for the Romanian public entities. In fact, this utility is highlighted by the accounting rules related to the aims of the public financial-accounting information, which recognizes the user's interests upon the changes of the financial accounts, upon the origin of financial resources and their use, including the way of financing its activities.

As such, although the entities operating in the public sector mind a tradition less developed regarding the elaboration of the picture of the flow, due mainly to delays in accounting standards issuing for this sector, since the moment of elaboration of the financial statements, one recognize the importance of completing the balance-sheet and of the profit and loss account with a report of the changes of the financial status, considering that such a situation will help to explain more detailed the values comprised in the two annual/quarterly reports.

Measurement and Appraisal in the Accounting System of the Economic Entities of Romania

Florea Gheorghe
"Petre Andrei" University of Iasi
geluflorea@yahoo.com

Abstract

Since current accounting of the business and financial operations, as well as the centralization and the generalization of the patrimonial holdings data, is achieved in pecuniary terms, we can positively state that accounting, as it is seen today, cannot be achieved without assessment. Under the circumstances of the market economy, pricing, on grounds of the rapport between supply and demand leads to the appearance of a flexible price system that turns the appraisal of the accounting entities patrimony into a complex task which sometimes proves to be pretty difficult. There are three criteria usually taken into account from the standpoint of the accounting theory and practice, which have been accepted for the appraisal of the assets and liabilities flows and inventories, of the incomings and outgoings, namely: the utility value or the real value, the market value and the time.

Key words: measurement, assets, liabilities
J.E.L. classification: M41

1. Introduction

In order to record accounting information on the existence and movement of assets and cash expressed physically, one should treat and evaluate them using a uniform standard, in this case the monetary standard.

Since the current accounting of economic and financial operations and centralization and generalization of patrimonial data units is money valued, one can certainly assert that, on its modern meaning, accounting cannot be made without assessment.

By accounting assessment one understands a procedure of the accounting technique that consists in quantifying in monetary expression of the existence, movement and

transformation of the economic patrimony in order to be reflected through book-keeping.

On the doctrine and practice of accounting, three criteria were considered and accepted for assessment of stocks and flows of assets and liabilities, income and expenditure, namely: the utility value or the real value, the market price and time.

Thus, the utility value assumes that the value reflects the "cost" or "sacrifice" made by a person or entity to bring an asset or assets in the patrimony which is what the asset would bring if it was used or were sold on the market, while liabilities, regarded as debts, reflect the amounts allowed to be paid in exchange for the obligation created or the amounts expected to be paid to satisfy tax obligations [1].

In turn, the market price represents the price resulted/paid from direct transactions achieved on an active market characterized by: the relative homogeneity of the assets on the market, availability of sufficient quantities of assets traded allowing anytime finding potential buyers and sellers; prices are available to the public knowledge.

Finally, the criterion based on the time factor takes into account the moment of placing the assessment in the past, present or future, that "by virtue of the continuity of the business entity slips over past, passes through the present and takes care of breeding the economic values in the future" [2]. In these circumstances, the assessment of transactions and events is done at present, based on historical cost at the moment of purchasing and the selling price at the exit, while for the deductions or stops materialized in assets and liabilities the assessment is done in the present time and glides from past and future time when the assets and liabilities will exit from the patrimony. As such, the evaluation process is carried out at present time and regards the patrimonial elements of the

economic entity that is the means, resources and economic processes.

2. The assessment basis in book-keeping

The basis of measurement is monetary attributes of the items that comprise the financial statements [3].

Depending on the assessment criteria outlined above, around the world one have outlined four conventions or assessment basis: historical cost, current cost, the achieving value and the present value, a schematic is shown in Table 1.

Table 1. The assessment basis used in book-keeping

Basis of measurement	Definition of assessment	Accounting evaluated according to the envisaged:	
		Patrimonial Assets	Patrimonial liabilities
Historical cost	- Is the real cost in the moment of the entry of assets and debt creation, meaning the sacrifice which was agreed to bring the item into the patrimony;	- As to the historical cost, they are valued and accounted at the equivalent of cash or treasury paid, or at fair value at the time of their acquisition corresponding to their buying date;	- The value of benefits received in exchange for the obligation, or in certain circumstances, the amount of cash or cash equivalents for paying off an obligation;
Current cost or the reposition cost	- Is the cost which the entity agrees to pay in order to acquire another asset at the current value, similar to the asset that makes the object of the assessment	- Are assessed and accounted at the level of liquidities or cash equivalents which the entity should pay the same if the asset or a similar one would be purchased or produced at present.	- Are assessed and accounted at the nominal value of the amounts which would be needed today to pay the obligation.
Realisable settlement value	- Consists of the value that the entity would receive if it sells the asset or it pays the debts.	- Reflect the level of cash or cash equivalents that could be obtained today through a normal sale of these goods.	- Represent the out dated value, in cash or cash equivalent that should be paid for paying off the liabilities at their settlement value.
Present value	- Is estimation at present, of the value depending on the flows of future benefits that	- At the present value of net cash flows which are expected to be generated by these assets during its	- Are updated to the value of output or the net cash flows which are expected to be required to pay off obligations

	arise in the normal course of business entity.	normal business;	in the normal course of business.

3. The rules of assessment as a reference system in formulating the accounting policies

Assessing the patrimonial elements of an accounting entity should consider the moment of the assessment, the nature of events and the sense of the movements affecting the patrimony, these factors determining the rules and forms of assessment [4].

In this respect, the Romanian accounting law inspired by The IV European Directive and more recently the International Accounting Standards, aims to four main moments involving the assessment operations: the entry into heritage; during inventory, closing the year, and the out coming of assets, determining in this respect the following rules:

a) *At the date of entry into heritage property* the assets are assessed and recorded in the accounts at the purchasing value, called the carrying value (or historical cost) established on the documents, customized according to the possibilities of entry:

- cost of purchase for goods purchased for valuable consideration, it shall consist of the purchase price, unrecoverable fees, transport and supplying expenditures and other expenses necessary for the state utility and entry into the asset management respectively;

- cost of production for goods produced in the unit, it includes the cost of raw materials and supplies, other direct costs of production and share of indirect costs rationally allocated to production, related to the cost of goods produced;

- fair value for goods obtained free of charge, which is the amount for which an asset could be exchanged freely between the two parties in a transaction, in which price was objectively settled;

Other patrimonial elements shall be assessed as follows [5]:

- claims and liabilities at nominal value, representing the amount recorded in a document, which will be paid or cashed in their exchange;

- claims and liabilities denominated in foreign currency cash, comprising a double reflection in foreign currencies and in national currency, by converting the foreign currency using the exchange rate;

- securities, valued at the purchase price to which they were acquired or the one established in the contracts.

Using the historical cost as the basis for economic evaluation of the elements in the moment of the entry in the unit, is justified by the principle of prudence, representing the most undisputed in-coming value, in terms of objectivity.

b) During the inventory, the elements such as the patrimonial assets and liabilities are always assessed at the present value of each item, called inventory value and established according to the good's utility, its state and its market price. As to claim and obligations, their inventory value is settled according to their potential value which can be cashed or paid. The assessment of the patrimonial elements at the inventory value results from the fact that the information that contains the in-coming value (historic cost) can be altered by any significant change after the assets had entered the patrimony.

c) Assessment at the close of the financial year (the balance) the property is assessed and reflected in the annual accounts at the in-coming value or the carrying value resulted by the inventory, respectively. In this case, one may proceed to a comparison of the two values and, according to the principle of prudence, one will retain as assessment the lowest one, if the element represents an asset and the highest, if the assessed element is a liability, and there for:

- as concern the elements of assets, the positive differences found between the inventory and the carrying value are not recorded into accounts, considering they are still at the in-coming value;

- the negative differences found between the less inventory and the in-coming value are registered as write-off expenditures in the case of the depreciable assets (depreciation in this case is irreversible), and by adjustments

for depreciation, if outstanding assets (if the impairment is considered as reversible);

- the negative differences between the inventory value and the carrying value for the liabilities are not recorded in the accounts, being maintained at the in-coming value;

- the positive differences are recorded as adjustments/provisions expenditures, this solution being only theoretical for the moment [6].

The monetary items denominated in foreign currencies (other items available and assimilated, such as bank deposits, debts and claims in foreign currency) should be assessed and reported using the exchange rate notified by the National Bank of Romania valid for the last day of the reporting period. Differences in exchange rates, favourable or unfavourable, between the exchange rate at the date of registration of claims and liabilities in foreign currency and the exchange rate at the end of the financial exercise are recorded as income or expenditures, as appropriate;

A step towards achieving the requirements of fidelity imposed to book-keeping and to the financial statement's drawing up is made under these regulations by taking into account the significant events that occur after closing the financial exercise and may provide additional information to those known on December 31, if the financial statements have not been approved at the moment of identification. As such, the financial statements are not based only on information obtained in the preceding stages of their issuing and they also can be modified in order to reflect additional information after the financial exercise's closing, to allow users to acknowledge the special events with a decisive impact upon decisions, such as: changes regarding the main customers and suppliers (for example, declaring bankruptcy), any disputes arising between the date of closure of the year and date of publication of financial statements; events that led to changes in the assets held by the unit (natural disasters, the possibility of significant losses to financial fixed assets or investment securities), etc.

d) At the moment of coming-off the patrimony or allotting for consumption the elements shall be assessed and subtracted from the financial administration at their carrying value or their in-coming value.

The rule is not applicable to all categories of goods. Thus, in the case of fungible or interchangeable, like inventories, securities, etc. one admit exceptions to the general rule, the evaluation being possible by specific methods, such as the average weighted cost method, the "first in-first out" method or the "last in, first-out" method, the choice of the method being left to the managers' means, who should aim the relevance and credibility of the assessment and not obtaining tax advantages.

If we relate to the signification of the concept of assessing in book-keeping, then a fifth moment of the evaluation could be represented by the reassessment. Moreover, the assessment and reassessment present no differences of substance, but aimed different moments of the existence of items subject to these operations [7].

In book-keeping, the *re-evaluation* is a "process of amending the carrying value of a real item and bringing it to the present value" [8]. As a rule, are subject to the reviewing operation especially the elements considered fixed and financial assets, but also some liabilities may be subject of the re-evaluation. Technically, reassessment may be free (the present value of each element is established at the economic entity in the utility function of it) or regulated (when the actual value is determined by applying coefficients of indexation set by law, which is weighted by the amount of input items subject reassessment).

In the operation of the revaluation, the entity's level one may result in increased value, which will lead to increase in equity (net assets), or a reduction value, which will be treated as an exceptional expense, thus affecting the result.

4. Conclusions

In the market economy's conditions, the setting up of the prices based on the supply and demand ratio leads to a flexible pricing, which makes assessment of the accounting entity to become a complex task and sometimes very difficult.

Although the historical cost is the basis of measurement the most often used for the preparation of financial statements, one can say that none of the bases of evaluation has any general application and is not satisfactory

to the absolute, so, from country to country, or from case to case, one require an option for an assessment base or a combination thereof.

However, in the developed countries, where inflation does not have strong effects on monetary assets, one accepts the accounting model based on the historical recoverable cost and on the concept of maintaining the level of financial or physical capital.

Entities operating in areas with high inflation, use as an assessing basis the current cost, and the fair value, and combinations of these bases of evaluation as well, in order to answer the needs of users related to management.

The Role and Importance of the National Civil of Social Insurance in Romania

Florea Ianc Maria Mirabela

Florea Ianc Maria Claudia

"Constantin Brancusi" University of Targu-Jiu,
Faculty of Economics Science and Business Management
florea_mirabela@yahoo.com

Abstract

The essence of insurance is to spread on a particular community organized for this purpose. The process of identifying, quantifying, responding to risk research, reducing the likelihood of the risk occurs, the implementation of measures and decisions to limit the damage to limit the damage production is now defined as a transfer of risk.

Key words: social insurance, insured, consumers

J.E.L. classification: A1

Socio-historical and cultural evolution of man and brought a diversification of individual and group needs in this respect there is a specific logic and dynamics of the system needs, their functional connectivity. Society has become a binding framework of fulfillment of needs and promoting human resources to meet them. For any individual and any society where life, health, property, safety of people and material goods are core values and priorities.

The social security – is that part of the social –economic relations with that money in the gross national product form distribution, dispense, manage and use the funds necessary for the compulsory care of employees and retirees of the national companies, autonomous administrations, companies of consumer cooperatives and credit network, members of handicraft cooperatives and agricultural establishments, lawyers, agriculturorilor, craftsmen in their workshops, private entrepreneurs, the ministers of religion, the domestic staff employed individuals, persons blocks serve

residents, temporarily or permanently incapable of work, in case of old age and in other cases provided by law. Also social security and family members caring for people above.[1]

In a democracy, social protection is a fundamental element of state policy, because by its implementation id done to prevent, reduce or eliminate the consequences of events considered as “social risks” on the living standards of population.

The specific conditions and needs to be covered are as modalities of implementation of social protection to be different. Such programs are based on differing assumptions for social-insurance coverage for personal needs due to temporary or permanent loss of working capacity or the protection of workers at work (environment, work conditions), needs to be transferred the costs of production and whose satisfaction is included in the price of the product.

Social security guarantes is one of the means for achieving the constitutional rights of the people , they represent only part of the complex of measures taken to achieve a decent and civilized life of the Romanian people.Government social insurance system in Romania is of particular importance for the protection of people and their family members illness prevention, rehabilitation and strengthening of employment, temporary loss of working capacity in case of maternity, for the growth and the care of child until the age of two years (a handicapped child up to age 3). Also, be granted protection in the event of disability, to reach a certain age limit, when man can no longer work with the plenitude of its forces.

The role of government social security resulting from the new nature of its underlying principales and the woy it is and

use the funds in question. As the national economy, have expanded and perfected and social security. Along with this improvement, have increased their role and importance.

Social security involved in the distribution part of the gross national product, providing a means to control the formation, distribution and its use when supplies are distributed and use social insurance funds. It also stimulates the production of social insurance social progress of national economy and contribute to the development of socio-cultural. [2]

Social security includes a set of rules for carrying out an even better occupational safety and hygiene, disease prevention, health restoration and strengthening of citizenz and their families, which results in maintaining the capacity of employees and using it wisely.

The social insurance system is comprised of care and protection to help active citizens, retired, referrals to rest, spa treatment and other gratuities, in the period in which they are temporarily or permanently unable to work or in other cases when help is needed.

The special role of social insurance is to safeguard citizens in all cases of loss of working capacity, also by granting allowances and restrictions apply, they act against simulants and busybodies joins.

Social Security is a State that uses leverage and strengthen labor discipline. By the way they are covered by income received and set restrictions, social security and contribute to the streng

By the way they are covered by income received and set restrictions, social security and contribute to the strengthening of labor discipline, with positive effects on labor productivity, the achievement of economic and social indicators. The benefits granted and the restrictions imposed, fosters social security staff qualification improvement, quality improvement work, the stability of employees in the same unit, making a bigger seniority at work, fighting justified absences from work, reducing the number of unused days of work.

Social security plays an important role in public education in civic development, promoting social equity, thei grow attitudes responsible to work, to family, traits contributing to etical and spiritual traits submitted inoculation of each citizen, to respect the rules of convention and the

development attitude of public and private property protection [3]

Social security is called to play an important role in maintaining and raising the people's welfare.

The supervision on the occasion of the performance of revenue collection and expediture on the payment of pensions, allowances, aids, etc., contribute to the efficient organization of production and labor , the rational use of labor and money to strengthen economic and financial discipline, to respect and the strengthening of legality.

Practical implementation of social policy has contributed to the crystallization of the Romanian state and national level to improve the national social security system.

It includes all forms of organized social security shirts keep individuality, depend on each other, thus resulting in the appearance of totality and completeness that workers are protected from state units, mixed private meșteșugoești members of cooperatives, farmers, lawyers, ministers cults, domestic staff and care residents blocks, retirees and their family members.[4]

In the current period in Romania, government social security system has as component: the state social insurance, social security system handicraft cooperatives and artisans with their own workshops, social insurance of agricultural enterprises, social insurance for farmers own household, social security lawyers, social security ministers of religion

The current structure of government in Romania social security system is the result of deep and revolutionary changes of a long process of economic and social development.

The establishment of national public insurance has created a unified framework for the implementation of legislation, human and material resources are saved, it creates flexibility in the redistribution of available resources, depending on the requirements for certain benefits, strengthens controls on formation and use resources and quality services.

The Insurance Risk Transfer as a Tool

Florea Ianc Maria Mirabela
"Constantin Brancusi" University of Targu-Jiu,
Faculty of Economics Science and Business Management
florea_mirabela@yahoo.com
Florea Ianc Zaharica

Abstract

The essence of insurance is to spread on a particular community organized for this purpose. The process of indentifying quantifying, responding to risk research, reducing the probability of the risk occurs, the implementation of measures and decisions to limit the damage production is naw defined as a transfer of risk

Key words: risk, insurance, social instruments

J.E.L. classification: A1

Both individuals and legal entities, they provide multiple opportunities to transfer risk, one of the most important being the transfer of risk to insurance companies

The risk transfer can be done through and social instruments. (1)

Financial instruments are used on four markets:

- Cash market
- On the futures market
- Optional markets
- Futures markets.

The social transfer instruments are represented in the general insurance, however, that with all such tools are limited companies, investment clubs, and even state investment contracts.

The **joins stock** companies as well as with other types of businesses feel the risks its own funds. The risks are passed on to shareholders who ultimately bear them, and they may even lose the amount invested in shares.

Investment clubs are groups of investments that common investment decisions. When it adopted the decision to invest each member of the club shares with members of the financial consequences of the

expected investment risks. Talk to you soon and to share risks, decâtda a transfer, but at the macroeconomic level clubs can be seen as instruments of risk transfer.

The state in its investment plan in the broader social and economic life, a whole array coordinates (a class of measure) sharing tools, or transfer of risk such as health insurance, unemployment insurance or indemnity payments from the budget for natural disasters.

Contracts are instruments of risk transfer because when parties to include a contract may have the motivation and desire to transfer the risk to someone else entirely or in part. For example, a firm provides media distribution contract with providers in return unsold newspapers, since one company would not cover this risk and has no alternative risk transfer instruments, such as for example an insurance policy.

Insurance contracts are instruments for risk transfer characteristic.

For companies that have a choice between risk retention, self – financing, risk transfer instruments and insurance and benefits and providing financial risk transfer instruments have several **advantages:** (2)

1. is preferred by business managers under their aversion towards risk. They want to transfer risk asigurări company, which may affect the risk of financial indicators whose evolution accountable to shareholders.
2. avoids the risk of insufficient capitalization and liquidity crisis, self-insurance retention or risk of catastrofing risks in particular, can cause serios damage when there are strong and anduring effects on the level of own funds. Lack of coverage of such risks reduces the present value of cash flows available as weighted average cost of

capital increases the possible insolvency of the firm's prospects.

On the financial theory of the firm, self-insurance increases the likelihood of major risks that the company can't finance the aftermath of a serious damage, thereby decreasing the value of the company in terms of shareholders.

3. provides services in insurance risk assessment, prevention and liquidation of claims. Because the specific activity of insurance companies are able to offer such services at a competitive cost. Risk identification and assessment are made more powerful by the insurance company than the firms themselves in this important factor is experience.

And in whose production involves risk of civil liability of the company responsible for the damages, insurance companies offer competitive services in the liquidation of damages in civil lawsuits

For example, a firm has a contract rope washing windows in a building for offices, damage by climbers (inadvertently breaking windows, or exterior panels) are compensated by insurance companies if the company is climbing liability insurance.

4. can lead to a mediating effect on self-insurance tax risk if the company is calling it using firm dedicated reserves, which are not deductible as expenses on income tax, while insurance premiums are treated as deductible expenses, so decreasing taxable income

Buying an insurance company receiving a tax benefit, which creates a tax mediating effect. These benefits possibility effects the demand for insurance.

Buy an insurance company that enjoys a tax advantage, which creates a tax mediating effect. These benefits positive effects the demand for insurance companies, but there are negative factors influencing the process of transferring risk to insurer, thus affecting the insurance market offer. Thus, competition in the insurance market falls by more risks to be insured is either very high or very specialized. In these cases, the insurer's own funds required size increases, thereby decreasing the number of insurance companies to get involved in providing such risks and thereby reducing competition. (3)

Lack of competition may increase insurance rates, which can cause a light cost

of providing and retaining some of the economic agents. At the same time, the size of transferable risk, especially for large companies, the insurance market reaches capacity. For example, the risk of developing (liability of company for adverse effects arising from the use of its products) for very large sums assured, is absolutely impossible to obtain a greater coverage of \$ 1 billion from the insurer.(4)

Insurance plays a well-established among the elements of risk transfer. His position is not inflexible in their assembly, it is subject to various influences. Evolution of insurance will be determined by present and future mutuality regarding:

- Guarantees required by policy limits (are growing)
- Insurance condition
- The emergence and development of new techniques to ensure

No matter how much care taken to avoid problems or protection of personal and family risk exists in our lives, bringing financial and material losses. The risk, the basic element from which insurance is used to start a negative sense of the events we do not want.(5)

The Corporate System in Some European Countries – a Comparative Approach

Frunză Ramona

“Alexandru Ioan Cuza” University of Iași

ramona.frunza@uaic.ro

Abstract

In corporate governance, through its specific mechanisms, some measures can be taken to strengthen institutional development (against corruption, administrative shortcomings, favouritism) and to promote market values. These values include accountability, transparency, primacy of law, equity, property and protection of minority shareholders. It should be considered in this context the fact that, as good would be the regulatory framework, if shareholders (owners) are not active and get involved, things can not move towards an optimal way.

Based on these aspects, in the present paper we intend to emphasize which is the effectiveness of the corporate system in some European countries, compared with the specific Romanian one.

Key words: corporate governance, principles, efficiency, ownership structure

J.E.L. classification: G30, G34, M14

1. General aspects of corporate governance

Many specialists have tried to define the corporation and we mention the most edifying approach, the one of O. Williamson, who argues: “modern corporation is a product of a series of organizational innovations that have had the purpose and effect the realization of savings in the transaction costs” [4]. Experts speak of different models of corporate governance. For example, the German model investors are institutions (banks) which control the activity of company and its management. In other countries, is significant “the minority shareholder protection”. But, whatever the approach, the essence remains the same: the

governance structure is determined by property rights. Thus, laws that imposed, lets say, diffuse ownership have created so-called “corporate Berle-Means”, in which the fragmented ownership change the power in the company in favour of managers [2]. In modern terminology, the argument presented by A. Berle and G. Means is as follows: for shareholders the organizational, monitoring and control costs of management tend to be high compared to benefits, especially when ownership is dispersed and the cost of collective action is high. According to the Berle-Means thesis, corporate managers were considered masters of their own and not those who take materials advantage of their own actions, they would be prepared to allocate resources for uses that do not seek to maximize the capital value of firm. For this reason, the economic results of production in corporations may reflect excessive consumption for the held activity, limited incentives for introducing and adapting new technologies etc.

The central issue of corporate governance system of modern corporations has been made in the famous article of M. Jensen and W. Meckling, *Theory of the firm: managerial behaviour, agency costs and ownership structure* [3], one of the most cited articles in economics literature on how to structure ownership in various organizational arrangements. The authors sought to demonstrate that an owner-manager, who shares ownership of a company with shareholders that are not managers, not lead company with the intention of maximizing profits. Moreover, they showed that this would happen in a hypothetical world where the costs of monitoring foreign owners regarding business management, are zero. But, hypothetical worlds are not relevant alternatives. Recognition of this fact contributes to increased interest in identifying those situations (institutional and

organizational arrangements) that can mitigate the agency opportunism so that human behaviour in business management to became more predictable, especially at an entrepreneurship level. This approach represent the problem of the way of how entrepreneurs, business owners, shareholders are anticipating the behaviour of the decision-makers in the company, i.e. the problem of predictability of the managerial decisions, which nature should be in concordance with the requirements of owners.

2. Corporate system in Romania. Comparison with other European countries

The majority of the companies in Central and Eastern Europe are conducted by the owner but the management is realized only by professionals. In what is concerning the corporate governance, the main compromise is the one between the assuring of the incentives for the majority owners and the protection of small investors [1]. First, measures to protect small businesses are extremely important in combating fraud and reducing financial costs and secondly, to protect small investors by maintaining in function or in taking the leadership of an organization could discourage strategic investors and inhibit restructuring where appropriate. As majority owner distances himself from day to day management ceasing the responsibility to professional managers, corporate governance is changing the nature of the problem. Managers need to be monitored and only the majority owners have enough incentives to carry out this task. Therefore, in the implementation of existing laws in EU countries, efforts are made to preserve incentives for active shareholders. Few states provide a better legal system for minority shareholders. They face substantial problems and the actions they take can easily be blocked by majority shareholders.

Because in Romania, as in other countries, the interests of shareholders and managers can often divergent, corporate governance may become a factor that brings interests through active intervention, according to a detailed code of doing business, of the boards, which provide the interests of

shareholders, regardless of the percentage share they hold, exercise permanent control over the executive leadership of the company and are responsible for the transparency of the transactions concluded, to the General Assembly of Shareholders (GAS). Property rights theory starts from the assumption that corporate efficiency depends fundamentally on the quality management but also exercising a rigorous control by shareholders on managers.

In Romania, there are many companies that have minority shareholders. To highlight their activities are used a series of indicators:

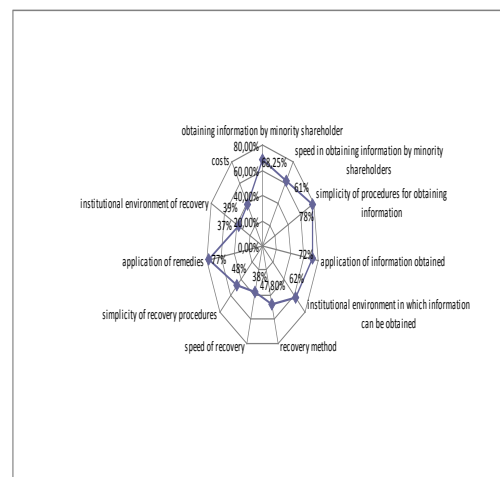

- *ability to obtain information about their company* (speed in obtaining information, simple procedures for obtaining information, applying information obtained, the institutional environment in which information can be obtain - refers to a country's legal framework to implement and enforce corporate governance legislation);

- *recovery method* - refers to the remedies which are available to a minority shareholder whose rights have been broken (speed of recovery, simplicity of recovery procedures, application of remedies, institutional environment of recovery);

- *costs* - estimated costs to be paid by a minority shareholder to have legal action.

In our country, these indicators record the following values:

Figure 1. Efficiency of minority shareholders in Romania

Source: after EBRD, Legal Indicator Survey, 2009

Making the average of the 11 indicators is obtained an average efficiency of the activity of minority shareholders of 57%.

Concerning the quality of laws in corporative governance system, our country is not so well positioned.

Figure 2. The quality of laws in corporate governance system, year 2009

Source: own representation after Corporate Governance Report, 2009

Note: 1: very low; 2: low; 3: medium; 4: high; 5: very high

We see that level five (very high quality of laws in corporate governance system) is not reached by any of the analyzed countries. Romania fall at the second level, which means that in the field of corporate governance, the quality of laws is low. In the same position are countries like Bosnia-Herzegovina and Georgia.

Referring to the efficiency of minority shareholders to obtain information about their company (first indicator), in the year 2009, the situation is represented below:

Figure 3. Efficiency of minority shareholders at European level

Source: EBRD, Legal Indicator Survey, 2009

Note: The score for each country is calculated on a scale of 1-10, where 10 represents maximum effectiveness.

Leaders in this chapter are Poland, Slovakia, Czech Republic, Slovenia, Estonia. Romania received 6.5 points (having thus a medium efficiency) and Albania, Montenegro and Ukraine occupies the bottom of the ranking. But who are the shareholders in the European corporations? The answer to this question is found by analyzing the figure 4:

Figure 4. Shareholders in European corporations

Source: FESE, Nestor Advisors, 2009

The foreign investors are major shareholders of the corporations (33%), followed by private financial firms (24%), private non-financial companies (16%), domestic individual investors (15%), etc. Referring to the level of compliance with OECD principles of corporate governance, the situation is as follows:

Figure 5. Compliance with the OECD principles on corporate governance, 2009

Source: after <http://www.waset.org/ijhss/v1/v1-1-2.pdf>

In figure 5, we observe that the principle which was adopted the most, according to OECD criteria, is the one concerning the fair treatment of shareholders. In Central Europe and Baltic countries it is found in a proportion of 83% and in South-Eastern Europe of 78%. The principle which is less respected refers to the transparency of corporate governance (62% in Central Europe and Baltic countries and 32% in Southeast Europe). Here is the big problem, especially in Southeast European states. Therefore, appropriate measures should be taken on this line.

To have a clearer view on levels that characterize corporate governance the South-Eastern Europe, we present the following situation:

Figure 6. Levels that characterize corporate governance in some South-Eastern European countries in accordance with international standards

Source: after EBRD, Report on Insolvency Office Holders in South-Eastern Europe, 2007

Note: **1.** qualifications to become a majority shareholder; **2.** availability to establish meetings depending on various cases (bankruptcy, special situations, etc.); **3.** removal / the retirement of a majority shareholder; **4.** replacement of the majority shareholder; **5.** compliance of discipline code; **6.** remuneration of the majority shareholder, **7.** obligations / the responsibilities of the majority shareholder.

International standards refer to The World Bank Principles for Effective Insolvency, Creditor Rights Systems and The 2005 UNCITRAL Legislative Guide on Insolvency Law.

Analyzing the figure 6, we see that Macedonia (with the best score), Bulgaria and Slovenia fall into the category of countries that have high levels of corporate governance in accordance with international

standards. Romania has medium levels. Greater efforts should be made to the chapter concerning the availability to establish meetings depending on various cases (bankruptcy, special situations, etc.) and also to the chapter about the replacement of the majority shareholder. Albania and Bosnia-Herzegovina have low levels (especially in terms of the compliance of discipline code in Bosnia-Herzegovina and the qualifications to become a majority shareholder in Albania). These differences can be largely explained by the fact that there is no permanent harmonization of national laws comply with EU legislation on corporate governance. Do not forget that after the improvements in this area since 2004, Romania passed from a low to a medium level, maintaining this position until now. During 2007 year, some regulations have been adopted in the field, in line with European legislation, so that in 2011 it is expected to have a high level of corporate governance implementation.

We point, in the following table, the legal basis of the corporate governance in some countries in Southeast Europe:

Table 1

Countries	Sets of rules that serve as national code for corporate governance
Albania	Company Law (1992)
Bosnia-Herzegovina	Laws on banks and Laws on business companies
Bulgaria	Law for the emission of bonds
Croatia	Company Law
Macedonia	Code of company and the rules of trading company shares
Serbia & Montenegro	Law on enterprises and Law on security and other financial instruments of the market
Romania	There is no specific national code of corporate governance. It is regulated by Company Law, Security Law

Source: after <http://www.waset.org/ijhss/v1/v1-1-2.pdf>

Concerning our country, the Group of Applied Economics conducted in June 2007, a survey on the principles of corporate governance at the level of 153 manufacturing firms. In their choice have been taken into account the turnover, number of employees and regional distribution. Thus, it was found that:

Figure 6. Information degree of Romanian managers about the principles of corporate governance

Source: after <http://www.euractiv.ro>

We observe that from the firms surveyed, 77,8% do not know the principles of corporate governance, 15,7% know these principles and 6,5% do not know / do not answer. In addition, it was found that 79,7% do not apply these principles. However, it is possible that more firms to apply these principles without know them. Also, the survey reveals that 34,7% of companies do not have a written code of conduct setting, which to establish formally rights and responsibilities of the General Assembly Shareholders (GAS) members and the type of management, the way of communication between managers and shareholders. In the case of 31,3% of the companies, shareholders do not receive in advance the documents to be discussed at GAS and for 26,2% of the company minority shareholders have no access to accounting records.

To see which the implementation level of corporate governance is, Heidrick & Struggles International has conducted a comprehensive analysis on the 294 large companies in 10 European countries: Belgium (19), Switzerland (20), France (40), Germany (30), Italy (40), United Kingdom (50), Netherlands (23), Portugal (10), Spain

(35) and Sweden (27). Were selected only top companies, according to market capitalization, based on national indexes (eg the Financial Times Stock Exchange 100 Index (FTSE 100), 40 Cotation Assistée en Continue (CAC 40), Iberia Index 35 (IBEX 35), Deutscher 30 Aktien Index (DAX 30).The test results highlighted:

Figure 7. Corporate governance (in accordance with governance criteria) – country scores

Source: after Corporate Governance Report, Heidrick&Struggles International, 2009

Note: Each company was evaluated individually (on a scale of up to 16 points) and finally a score for each country was calculated on which it was generated a European average.

We see that there is a relatively small disparity between the countries in which is prevailing the corporate activity: the difference between best and lowest score, achieved in 2008, is 3.3 points versus 9.5 points in 2002. Improvements were made in each country, indicating the fact that a general and continuous process is manifesting in increasing corporate governance standards. It appears that above the European average for 2008 are situated Great Britain, Holland, Switzerland, France and Sweden. We state that Portugal has made most progress in this field in recent years: from 4.9 points in 2002 rose to 13.2 points in 2008.

3. Conclusions

Corporate governance is useful as a concept that can be the basis for restructuring the Romanian economy, but it will have a real impact only in the condition in which the private companies will decide to become open entities, to address capital market to procure the necessary funds for development. Until then these companies will be leaded only by the decision-making of business owner; state-owned companies with lack of working capital, will be able to apply only in a small measure, and more declarative, the principles of corporate governance, different interests as their market position being determined in a larger proportion by extra-economic decisions. State-owned companies may have poorer conditions of action because of lack of development funds which can not be obtained without the main shareholder support, which is the state.

Finally, we conclude that is necessary that the public and private sector to cooperate to develop a set of rules, compulsory for all. Business associations, chambers of commerce and industry should try to encourage their members to develop governing norms for the protection of shareholders and of social responsibility for all the parts involved.

Cultural Influences on Management Ethics

Gavrilescu Liviu

Romanian Academy, Iasi Branch, Postdoctoral School

liviu.gavrilescu@yahoo.com

Abstract

Managerial ethics, as a branch of applied Ethics, is a relatively recent approach to the management of the organizations, as an interference of the Philosophy with Economics, due to increasing awareness of the need of connecting managers' behavior and actions to the rules and moral values of society. These values differ in the human communities within society, the differences being caused by various factors of influence. The most important factor determining managers' behavior is the cultural factor, religion being the main provider of moral values and norms.

The paper presents an analysis on the influence of major religions of the West and East on the characteristics of major economies - the U.S., Europe, Japan, also a comparison between the main features of the philosophy of management in these regions.

Also, the ethical differences determine different views on the role and rationale of businesses. Classical approach, the idea of maximizing profit, precludes an approach to social responsibility of the company, that gain more ground, due to cultural interference and challenges of the modern business environment.

Key words: ethics, management, values, culture, religion

J.E.L. classification: M14

1. The concept of managerial ethics

The last decades have strongly imposed into the public consciousness the importance of taking into account the ethical dimension of organizations' lives. Codes of ethics, ethics committees, ethics audits, ethics education for staff, techniques for creating an moral institutional culture - all these have become more and more widespread realities -

among others for being politically imposed and, in many countries, they have received a formality and a legal force. It is true that their inclusion in the habits of people has not reached a spectacular level, but the process is in progress. "Institutionalization of ethics" is a new reality which is required to be analyzed, in order to find influences and models.

The ethical problem deciphered by the modern moral philosophy is the human satisfaction / dissatisfaction in the industrial and post-industrial society and also the problems of humans surviving in disadvantaged societies, struggling with underdevelopment, material and cultural poverty. Ethics and moral philosophy do not hesitate to reveal adverse effects on humans caused by fighting and fierce competition, by the spiritual and physical isolation and insecurity of peoples, and by international terrorism that threatens people from different corners of the world.

The term „ethics” has a dual sense: a) a scientific discipline of study covering rules of conduct governing relations between people, i.e. the science of morality, of right and wrong, b) the ensemble of rules governing human behavior in society - rules to be applied in life to practice good as opposed to evil - rules whose observance is imposed by force of habits established in society [12].

In management literature the term „ethics” is used in both above-mentioned directions, the distinction being made according to the context. Thus, ethics is understood either as "study of morals and rules of conduct" [10] or as "rules and principles that define good or bad behavior" [20].

Management ethics is a form of applied ethics, which refers to the conduct and actions of people with leadership positions in private and public organizations [11].

In the case of management ethics, too, cultural norms are values enshrined by

tradition and education, their compliance being imposed by the normal requirements of social life, as they are perceived by public opinion.

Managerial problems in which ethical issues may arise are: pricing, promotion of products on the market, conditions of work offered, product quality, reducing labor, relations established with suppliers, relationships that exist with the local community, environmental pollution, advertising ; promotion of staff (motivation), relations between employers and trade unions [9].

2. Religion, a cultural factor of managerial ethics

Most analysts and experts converge to highlight the crucial importance of environmental influences on the development of an organization. There is no doubt that between the ethical aspects of the social environment and various business concepts, management styles, education systems for leaders and followers and organizational culture in companies there is a close interdependence [8].

The most important factor in determining the ethical behavior of managers, the values on which it is based, is undoubtedly the cultural factor, influenced largely by the religious spirit. This criterion has an essential contribution to coherently explain the differences in the important economies of the modern world, the Western (which joins Europe and America) and the Oriental, especially Japanese, but more and more the economies of China and India.

Great ancient and medieval philosophers have stimulated the philosophical and moral meditation in Europe and Western space, which has never been totally separate from the Asian, Oriental space, marked by several current and ethics as important as those of famous Greek: Brahmanism and Buddhism initiated by the ancient Indians and, then, expanded in various countries of Asia, Lao Tzu Taoism and Confucius in ancient China. Good and evil are fundamental ethical values also for these philosophical and religious currents, conceived in the perspective of enlightenment (Nirvana), achieved by switching off any desire and by experiencing pain the whole way, when the soul acquires

its full peace.

The ethical evolution mentioned above can be traced in the Bible, too, respectively, in the three religions intertwined: Judaism, Christianity and Islam.

Islamic moral philosophy is a rational synthesis between pagan philosophy (Plato and Aristotle in particular) and Muslim religion, linked to two other, Jewish and Christian religions.

The East remains a source of moral values stemming from contemplation and speculation, thus completing the moral values of Western characterized by activism and domineering spirit

For the issues addressed in this paper, the interest is accorded to the Christian religion and the religious philosophies of the Pacific Arc, especially in Japan. As regards Christianity, we will put an emphasis on Catholicism and its reformist currents that dominate the capitalist world. The Orthodox religion, perhaps the most tolerant and impregnated with mysticism, has never exercised a decisive influence on the economic development, since poverty on earth was considered the supreme virtue and condition of happiness in the eternal world. This attitude is reflected, in general, in all Christianity, but in time, both in Catholicism and (especially) in the reform currents have occurred new ideas and experiments of adaptation to the socio-economic developments.

In the West, the notions of "ethics" and "business" have been associated over time in different ways. If money remained suspect for medieval Catholicism from an ethical point of view, a moral businessman seeming a contradiction in terms, Protestantism has made it possible to reconcile ethics with business. Moreover, the Protestant work ethic has helped, according to Max Weber, the affirmation of capitalism [21]. He showed that Protestant asceticism is characteristic for the rationalistic spirit of Western capitalism. This asceticism consists of the cult of labor and of condemnation of laziness, begging and parasitism of any kind, and the moderate cult of wealth and money.

Catholicism is oriented towards the „other world”, the eternal paradise, considering life on earth as an intermediate stage for the eternal existence. According to the Catholic teaching, Jesus Christ has established that the

pope is the head of the Christian church, as the successor of Saint Peter. After the ideology of Jesus, the poor and the disadvantaged were privileged in the next life, while the rich were not admitted into paradise. To a faithful Catholic it is generally undesirable, and not in God's grace to accumulate excessive wealth.

Beginning with the nineteenth century, a stream came known as social Catholicism, aimed at promoting economic and social reforms in the spirit of the Gospel. Currently, all European Catholic countries are in favor of social market economy, a social capitalism with a strong concern for the disadvantaged.

Lutheran Protestantism, following Martin Luther's reform (1488-1546), gives more importance to life on this world. Luther gave a high value to concepts like hard work, vocational pursuits, sense of duty and seriousness that are pleasing to God and make access to paradise, into the next world. Moreover, these concepts underlie the Protestant ethic. Many modern scholars see Luther's ideology in a fulcrum of modern capitalism.

The seriousness and hard work of the Germans and "The Dual Professional Educational System" are rooted in their Protestantism. The same qualities are specific to the Nordic countries (50% of the population of Germany and almost 100% of the Scandinavian embrace the Lutheran religion). Consideration to the underprivileged and the social component of capitalism are values of Catholicism.

Calvinist Protestantism, initiated by the French reformer Jean Calvin (1509-1564) is a solemn affirmation of the sovereignty of God, the only savior of men through predestination. According to the Calvinist ideology, human beings are - fundamentally - weak, helpless and they can not do anything against this evil and its consequences: non-admission to paradise. God alone, arbitrarily selects and predestines certain individuals to paradise. During the earthly life, those chosen by God achieve economic success and the others not; the predestinated are rich and the others poor.

Undoubtedly, the "ideology of predestination", resulting from the reformist ideas of Calvin, is the basis of hard capitalism in some western countries, especially the U.S. This ideology seems to be

the philosophy of greed and selfishness, but some individuals' inclination towards unlimited accumulation of wealth should not be attributed only to the Calvinist reform.

Religions in Japan are four in number: Confucianism (in fact, not a religion), Buddhism, Shinto and Christianity, whose influence is split, without totally dominate the Japanese business environment.

Confucianism, with approx. 200-250 million followers worldwide, is more a philosophical and moral concept, due to the Chinese writer and philosopher Kong-fou-Tse (551-479 BC), which emphasizes the importance of morality and loyalty to others and believes that the answer to world problems is in the order, personal change for the better and development of a sense of human solidarity.

Buddhism, with approx. 450-500 million followers worldwide, is the name that designates the founder of this doctrine, Gautama, after he received the enlightenment in 525 BC (Buddha = the enlightened). Buddhist doctrine is a response to pain, which is identified with existence itself. To exit from the cycle of births and deaths (reincarnation theory) and to reach "nirvana", one should start by releasing the causes of suffering, that are the desires that press us every day.

Some fundamental concepts of Confucianism and Buddhism, like "harmony" and "self-improvement" have, even today, a strong influence on the population, including the industrial and business companies. They manifest through the spirit of cooperation, social responsibility, self-discipline, respect for others, especially to the elderly, mutual trust, meditation etc.

Shinto is Japan's own religion, dating before Buddhism (introduced in the late sixth century), which honors the deities - personifications of the forces of nature, the ancestors and the Emperor. Since the fourteenth century, Shinto turned into a nationalist movement. Separated by the state, in 1946, Shinto remained very influential in Japan.

A key characteristic of Japanese social climate and their specific culture is paternalism. Essentially, it consists of the Japanese tendency to focus on the group they belong, in the sense of protection, affection, discovery of its proper functioning needs,

and engagement for life.

Psychologically, most Japanese have two families: one at home, the classical one, the other being the collectivity within the company. Both have a vital importance to form a balanced universe in which their lives are conducted.

In Table 1 are compared (West vs. Japan) the behavioral criteria and the managerial attitudes towards them.

Table 1. Comparison between Western and Japanese management philosophies

Criterion	West	Japan
Objectives	Profit (quarterly)	Customer satisfaction (long term)
Company Results	Maximizing financial profit (short term)	Profit is a consequence, not an end in itself
Organization	Hierarchical, military style	Teamwork, self-organizing network
Employing staff	With experts, tough-type, winner	Multidisciplinary, team-oriented
Staff Dismissal	Easy, fast, without problems	Almost inconceivable
Management Development	Vertical	Extended in all directions, rotation of professions
Professional education, continuing education	As needed, short-term	Extended; provided long-term
Job description	Precise, detailed, limited	Vague, general, partial
Suggestions, proposals from staff	Trivial	Singular importance, the top priorities, incentives, motivation and reward
Wages, compensation, pay staff	Based on the work, by functions	Based on qualification, performance and skills of each individual
Motivation	Money, company status	Joint Vision (team, company, nation)
Planning	Either nothing or very sophisticated plans	Long-term strategic planning, but not detailed

Projects, strengths	Additional tasks in relation to the current	High prestige, quality, sufficient long-term resources
Collaborators assessment	Individually, depending on momentary interests	Especially in the group, in a spirit of assistance, in relation to team
Quality Control	Q.C. Department's responsibility	Priority no. 1. Each member of the company feels responsible for quality
Handling errors	The responsible (guilty) individuals are searched to be punished	Inquire about the causes of errors. Efforts to eliminate these causes. Opportunities for future lessons.

3. Differences in business philosophy

Undoubtedly, cultural differences, including religious, present in Eastern and Western economies, and mutual influences manifested especially in recent decades due to globalization, lead to two opposing views about the rationale of the firm: to one extreme the ultimate goal of the company is considered as to maximize profit (the classical approach), to the other, it is alleged that the company exists to promote the welfare of society (socio-economic approach).

Classical approach supports the thesis that companies exist to bring benefit to the owners (shareholders) or to reduce transaction costs. Among representatives of this approach is included, for example, Nobel laureate Milton Friedman. He assumes that currently most managers are employed as professionals, i.e. they do not own the business (separation between property and management), as such, their main responsibility is to manage the business so as to maximize the benefit of owners, the shareholders. And shareholders have, as Friedman, one concern: financial results.

After the same author, when managers decide to spend discretionary resources for "social goods", they undermine the market mechanism. Distribution of assets resulting from social activities will be ultimately paid, either by the shareholders (if profits are reduced, following additional costs with

"social goods") or by the employees (if wages are reduced) or by consumers (if the company's products prices increase, in the latter case, sales may decrease and, in extreme cases company will not survive).

Socio-economic approach considers that "profit maximization is the second priority of a company, the first is to ensure business survival." This involves the pursuit of broader goals than just maximizing profits. In this sense, several arguments are brought:

First, corporations are legal persons registered in a country and must comply with the legal and business climate in the country of operation. They are therefore not independent entities, responsible only to shareholders.

Second, the existence of the firm is not the short-term, as would result from the classical approach. Supporters of the socio-economic concept consider that managers must ensure the maximization of financial results on long-term, in which case they must accept certain social obligations (as non-polluting, non-discrimination, fairness to customers, etc.) and their associated costs.

Thirdly, the practice of modern companies stated that these are no-longer 'pure' economic institutions: they are involved in politics (lobbying), cultural and sports activities (sponsorship), supporting national and local authorities, etc., enriching the managerial ethics with the concept of "social responsibility".

One of the most famous businessmen in Japan, Konosuke Matsushita (b. 1894, author of the Panasonic brand, founder in 1980 of The Institute of Matsushita School of Government and Management) speaks not of responsibility, but of the social mission of the company and show that: "The industrialist's mission is to defeat poverty, to liberate the society in general of poverty and bring wealth. Business and production are designed to enrich not only the respective company stores or factories, but the whole society "[14].

Empirical studies [20] show a positive correlation between the degree of social involvement of a firm and its economic performance, and the explanation of this result seems to be that social involvement brings a number of benefits that cover and exceed costs induced by it.

Moral Norms in Management Ethics

Gavrilescu Liviu

Romanian Academy, Iasi Branch, Postdoctoral School

liviu.gavrilescu@yahoo.com

Abstract

The culture and values of a community shape its behavior with the support of all the norms, rules and institutions created for this purpose. Business environment is focused on the responsibility to company success. This philosophy is the base of business ethics, of specific rules systems, supplemented and not replaced by legal regulations. However, responsibility for business can come into conflict with the common morality of society, the public in general, creating an "ethical paradox". The harmonization of these interests creates a moral organization, based on an identified set of principles, values and challenges. The introduction of ethics in the business routine requires a coherent program and tools, of which the easiest to use is the code of ethics. These codes are particularly useful for resolving moral or interest conflicts, guiding in a practical way the conduct of managers and employees. Called either codes of ethics or codes of conduct, they are adopted by many major companies in the world. This paper presents the functions and objectives of ethical codes, present increasingly more in the business environment, and propose a model for such a code that addresses the full range of issues and potential conflicts.

Key words: Business, ethics, management, values, ethical code

J.E.L. classification: M14

1. Ethical Culture and Behavior

Culture and ethos of a community are vectors and sources that supply the behavior. They define, in the area of maximum objectivity of the economics, the limits and freedoms, the acceptability and unacceptability, the desirability and undesirability. Therefore the quality and usability of norms and values that regulate

the community environments support the production and reproduction of a particular model of business conduct and behavior. Naturally, in a society are created structures and institutions, norms and rules, especially of legal nature, required to promote those existential values that are compatible with the human expectations.

Professor Dimitrie Gusti wrote in his work "Ethical ideal and personality" [3] that many of us do not possess the necessary virtue of a moral point of view, to wait in an honest and dignified manner what they deserve, according to their education and work. Legal and social provisions, which actually are meant to guide the way of the things, seem for them unnecessary obstacles or forms.

An understanding of ethics is critical for us as individuals, because a healthy ethics is the essence of the civilized society. Ethics is the foundation upon which all our relationships are built. It means the ensemble of our relations with the community we belong to. Ethics does not refer to the links we have with others – we all have ties to each other - but to the quality of these links.

2. Responsibility and Ethics in Business

Business Ethics defines a system of principles, values, norms and codes of perception and behavior, based on a philosophy of the company, which impose themselves as moral imperatives inducing the obligation of their expression. For good measure, the cognitive and behavioral codes integrate their moral values as such, although they are functional and credible only if they are associated with socially valid business objectives. The features of the expression of moral values in business derive from the assumption, as principle and practice, of accountability to the company's success. In a business that fails there can be no responsibility, except in extreme situations, completely independent of employers and

management. Refusal of responsibility denies any reference to the moral principles and values. In other words, in business, the imposition of moral rules requires the definition of the desirable values for the business and their expression.

Business Ethics delimits its issues at the level of the rules of ethical behavior, indicating, employees and managers, the dos and don'ts in their specific activity. Business ethics is also determined by the legal status of the company. Private organizations are characterized by an entrepreneurial culture open to the market, customers, innovation, and performance. Public organizations have a bureaucratic culture, are less adaptable and inert.

The distinction between moral norms and legal requirements is of utmost importance in the world of businesses. Many believe that the only obligation of an honest business man is to respect the laws in force, the corollary being that any management decision which seeks to maximize profit within the law is not only legitimate but even morally binding.

3. Business Ethics Dilemma

Managers have always two priorities, which sometimes can be contradictory: the public and their organization. These priorities create ethical dilemmas for, many times, what is moral for one manager may be considered immoral by the other actors. The ethical area of businesses is as more sensitive as the aim is to obtain larger benefits, without being impaired the public confidence in the overall benefits brought by the business world: the reward of labor and better social services to the community. In essence, ethical behavior in business can be both a matter of survival of the organization as a responsible living of individuals.

"Ethical paradox" means for businessmen to take the responsibility and the economic risks inherent in their actions, or to remain to moral judgments, abstract and devoid of responsible commitment. This dilemma - responsibility / morality itself - moves the discourse on businessmen conduct from "morals" to "ethics of responsibility". For, in business, a number of common moral values (compassion, altruism, love for the neighbor, philanthropy, etc.) can lead to collapse, bankruptcy, with all the moral consequences to be derived from an organizational disaster.

Business philosophy must harmonize moral with purpose.

Niccolo Machiavelli's phrase "the end justifies the means" is specific to the business, to the extent that it does not go beyond a regulatory model proposed by the company. In reality, any business is subject to norms-rules that define "the game". Respecting the "game rules" when they are rational and incentive is sufficient to define the responsibility in the coordinates of business ethics.

Overcoming the limits set by economic and legal norms alters behavior and questions the responsibility of the businessman.

4. The Moral Organization

A "moral organization" is the one which meets at least the following four principles:

1) It interacts naturally with various beneficiaries and its basic rules consider the good of the beneficiaries as part of the good of their organization.

2) Its members are extremely sensitive to the fairness issue: their basic rules stipulate that the interests of others matter as much as its own interest; deception and exploitation of clients is their nightmare.

3) Responsibility is seen as individual rather than collective; you can not hide behind the organization; its members must be individuals who assume personal responsibility for the actions of the organization; its rules state that individuals are responsible for themselves.

4) They regard their activities in terms of objectives, the objective is a mode of operation which is highly valued by the members of the organization and it links them to the external environment.

Obviously, all these things belong to an advanced stage of development of ethical management in organizations.

David Murray, in his book "The seven core values, SMEs and their beneficiaries" [6] identifies the core values that a company should consider, with its managers and employees, for a more ethical conduct of its business, namely:

- consideration of our neighbors;
- vigilance in maintaining ethical standards;
- creativity in saving resources and environmental protection;
- better customer service;

- fairness to suppliers, customers, employees, partners, community;
- transparency - the elimination of lies in communication with partners, customers, suppliers, employees, state institutions;
- interdependence with the community in which we live and operate;

also 12 moral challenges in business life: appreciation of the dignity of work, good business relationships, impeccable customer service, morality in purchasing, morality in the conduct of the competition, treating staff with dignity and respect, fair remuneration for the staff, complying with the laws, protect environment, the conclusion of businesses without bribery, maintaining honesty in business, survival in the event of major changes.

Even if a worker is honest and has a high morality, the bad example given by its managers may lead him to overlook the unethical practices of others or even to adopt them.

Top-managers have the power to dictate policy to an organization and tone the morality. They have a great responsibility to use this power judiciously, they can and should serve as models of ethical conduct for the entire organization, not only through their daily behavior, which must be the embodiment of high ethical principles, also by communicating throughout the organization the similar expectations from employees, and by encouraging positive results.

It turned out that regarding the conduct, it must not only be above any reproach, but it should also look without reproach. In other words, the appearance of integrity is almost as important as integrity itself.

5. Codes of Ethical Conduct

To raise the level of business ethics, ethics should be institutionalized, intertwined with the activity of the company. This, in fact, means the introduction of ethics, in principle and explicitly, in the everyday business.

Particularly relevant for those who are receptive to questions of responsibility are some ways that can be used to encourage ethical behavior:

- publishing an own ethical code, according to recognized standards and social values;

- designing and implementation of a management development program that included ethics;
- development of ethical conflicts resolution programs;
- institutionalization of committees monitoring ethical behavior;
- providing appropriate rewards and sanctions.

Company codes are the simplest means of institutionalizing ethics and they are found in many organizations. Most responsible organizations actually combine these methods, thus encouraging and supporting ethical behavior in their relations with the exterior.

Most times, the levels of enforcement of managerial ethics are clearly specified in the codes of ethics. Even if they have not finalized codes of conduct or ethical codes, yet now more than two decades many large corporations have established ethics programs and assigned officers to monitor ethical behavior in organizations.

Initially, codes were developed by professional groups in the form of deontological rules and then there was an explosion of such codes in organizations. Experts assert that this was possible because without any formal activity or program, ethical practices can not be encouraged. Consequently, the ethical codes try to solve conflicts of interest in the internal environment and in the external relations of the organization, namely, to establish principles and requirements that would make managers more sensitive to ethical issues. They do not contain purely theoretical precepts, but set practical significances, useful for everyone in the organization. This does not mean that a code of ethics automatically ensures a moral behavior, or can cover all situations encountered in organizational life. The limits of the ethical codes can reside in their formulation in general terms, because the top managers and their subordinates are unable to identify all ethical issues that may arise. The way an ethical code is translated into practice remains, ultimately, at the discretion of managers and subordinates. The ethical code remains valid if all the members of the organization comply with it: if the manager gives no importance to it, certainly neither the employees will not follow its provisions.

The existence of a code of ethics is not a

guarantee for a company that its employees will adopt an ethical behavior, but it may reflect a company culture of appreciation and reward for ethical behavior.

Ethical codes have certain functions, which explain why they have enjoyed so much interest from managers and, also, members of organizations:

- conduct and inspiration - codes offer a positive incentive for ethical conduct and guidance on key requirements;
- support - code provides positive support for those looking for elements of ethical behavior;
- discipline - the codes might constitute legal form for the investigation of unethical behavior;
- education and mutual understanding - ethical codes can be used in schools or other places to promote discussion and reflection on the moral issues;
- create the public image of the profession - codes may present a positive image to the public on a profession;
- protection of the status of the profession - the codes can stop certain disagreements that may arise at the level of exercising a profession;
- promoting interest in business.

Concerning the objectives of a code, there is a consensus of opinion that, by formalizing the ethics, it is attempted the promotion of virtues and professional values. In addition to this, Samuel Mercier noted other objectives:

- conclusion of a moral contract between the beneficiaries and organizations, respectively between those belonging to the same organization;
- organization protection against dishonest or opportunistic behavior;
- promotion of a positive image of the organization;
- provision of means of regulating the staff adhesion and commitment;
- creation (and organizational culture) sense of uniqueness and belonging to group members;
- shows a commitment in principle of the managers;
- correlation of purely contractual relationships with trust and responsibility;
- guides the behavior in the case of ethical dilemmas.

For example, we present one of the world's most famous ethical codes: a code created by

the British Institute of Management, called the Code of Conduct (Code of Conduct) - always quoted in the literature as a template for a fair managerial conduct and a responsible way of doing business.

1. In the pursuit of personal interests, must also be taken into account the interests of others.

2. Managers should not be vindictive and not harm reputation of others' persons or businesses.

3. Managers must immediately and fully declare the personal interests that may be in conflict with company interests.

4. Managers need to show interest in the health, safety and welfare of those they lead.

5. Managers must respect the confidentiality of information, if so requested by consumers or suppliers.

6. Managers must not give or accept gifts or favors for the purpose of bribery or corruption.

7. Managers must be convinced that all public information provided is true.

Since 1961, NORTON multinational company has developed a code called "Politics and Business Ethics", which has been continuously improved. It includes a series of rules concerning the conduct of the company in its relations with "the law" and society, having as guiding principles the following requirements:

- Honesty and integrity are characterized by sincerity and exclude deception and fraud.
- In our perception, ethical behavior must be dynamically sensitive to changes in the values and habits that will surely occur in time, as well as those concerning cultures.
- No code of conduct can hope to define the moral and ethical behavior appropriate for each situation we face.
- One of the most important principles of our policy is openness.
- We should not be afraid of inspection.
- We see no contradiction between profit focus and attention to ethics. In fact, both should go hand in hand.

Some codes are just general policy statements which set a specific ethical behavior for all employees. Others give detailed rules for appropriate behavior in business and launch explicit procedures for monitoring and rewarding such behavior. However, simplicity is one of the best

features of a code of ethics: the more complicated it is, the more probable it will generate the opposite effects to those desired.

6. A Model of Ethical Code

The model of a professional ethics code:

A. All members of an organization (company) will act with:

- responsibility and fidelity to public needs;
- fairness and loyalty to associates, customers, suppliers and owners of the company where they are employed;
- competence and devotion to high ideals of personal honor and professional integrity;

B. All members of an organization (company):

- will always maintain their independent thinking and actions;
- not express their opinion on contracts or on the company's financial statements, until they first have a relationship with their client to determine whether to expect that their opinion will be considered independent and objective by someone who knows all the data;
- when preparing financial reports expressing an opinion on the company's financial position for the company's management, will provide all material information they know, in order not to omit information that might mislead; will gather enough information to guarantee the expression of those views and will report any errors or deviations from generally accepted professional principles;

C. All members of an organization (company):

- will not disclose or use any confidential information concerning the business owner or the client, only when acting according their obligations, or when such information is needed to be disclosed for their own defense or for the defense of any associate or employee in any legal process against any alleged professional improprieties, by order of the authorities or of the management or any committee of the company in the exercise of their duties, but only to the extent of the necessity for that purpose;

- will inform the employer or client of any connections or business interests that might interest;
- in carrying out their duties in the interest of the employer or client, will not keep, receive, negotiate, or acquire any fee, remuneration or benefit without the knowledge and consent of the employer or their clients;
- will follow all steps in arranging any commitment as a consultant to establish a clear understanding of the purpose and objectives of the works before their commencement and will provide the client with an estimate profitable cost before making a commitment, in any case, as soon as possible;

D. All members of an organization (company):

- will behave towards subordinates with courtesy and good faith;
- will not commit any act likely to discredit their employing company or profession;
- will not engage or will not advise any business incompatible with the company's view of professional ethics or morality of the company;
- will not accept any commitment to checking a subordinate employee other than with the knowledge of the subordinate or when the subordinate connection with the work was completed; an exception is when there is a nominal duty to check the work of others.
- will not try to obtain an advantage over other subordinates by accepting a commission for the conclusion of a contract or achievement of a service;
- will support the general principles of his profession;
- will not act with malice or another way to stain public or professional reputation of another employee or to impede the achievements of its obligations;

E. All members of an organization (company):

- will always maintain themselves to the standards of competence expressed by the education and experience requirements for their employment;
- will share with others in the firm or profession, the knowledge they hold on which the profession stands, and will promote the progress of the employer organization or its profession;

- will only undertake work for which they are authorized by training and experience, and when it is in the interest of their client or employer, will hire or will advise the employer or client to hire another specialists;

7. Conclusion

Looking at these examples, it is noticeable that a code of ethics formulates ideals, values and it addresses issues such as conflicts of interest, competitors, privacy of information, giving gifts, etc. In essence, the ethical code tries to cover a gap that exists between a organizational community values and the laws that govern society.

The Normalization Process of Recognition of the Elements in the Financial Statements. The Credibility and Relevance of Information

Gâdău Liana

"Spiru Haret" University of Bucharest

lianagadau@yahoo.com

Abstract

The necessity of normalization process of recognition of the elements in the financial statements appeared at different levels of the accounting referential, and here we refer particularly at the two basic referential: the international and the American one, which will constitute the basis of our analysis on this paper.

Therefore, the result of the normalization process of recognition of the items from the financial statements has result in the establishment of the criteria for recognition, which contribute to proper positioning of elements in the financial statements, thus giving credibility and relevance of the information contained therein.

Key words: the financial statements, the process of recognition of the elements, the criteria for recognition

J.E.L. classification: M40, M41

The necessity of normalization process of recognition of the elements in the financial statements appeared at different levels of the accounting referential, and here we refer particularly at the two basic referential: the international and the American one, which will constitute the basis of our analysis on this paper.

Therefore, the result of the normalization process of recognition of the items from the financial statements has result in the establishment of the criteria for recognition, which contribute to proper positioning of elements in the financial statements, thus giving credibility and relevance of the information contained therein.

The Approach of the process of recognition of the elements in the financial statement through the various accounting referential.

1. The general framework for the preparation and presentation of the financial statements

The general framework for the preparation and presentation of the financial statements - defines "recognition" as the process of incorporation in the Balance Sheet or the Profit and Loss Account of an article which first meets the definition of an element, and satisfies the following criteria:

- It is likely that any future economic benefit associated to enter or leave in/or from the enterprise;
- The article has a cost or value reliably measured.

We observed that the requirement of probability of future economic benefits highlights the definitions of elements, which are circumscribed to the existence of these benefits.

It should be noted that, while respecting the definitions of elements is not considered a criterion for recognition as the American Framework, it still remains the essential condition in recognizing an element in the Balance Sheet or the Profit and Loss Account.

IASB also states that an element which possesses the essential characteristics, but that does not meet the criteria for recognition, can bring information in the Annex to the Financial Statements. Such information becomes relevant when knowledge of these elements is considered useful for assessing the financial position, performance and the evolution of the financial position.

At the same time, the criteria for recognition involves the interplay between an element that meets the definition and the criteria for an ascertained fact (for example, an asset) to automatically assume the finding

of another element (for example income or a liability). Also, IASB states that an element which at a certain moment does not meet the criteria for recognition in the financial statements can satisfy these criteria later, as a result of a subsequent events and circumstances.

2. The American conceptual framework

On the other hand, the **American conceptual framework** places a strong emphasis on the recognition process of the elements in financial statements, in this sense leaving a distinct structure within the conceptual framework, namely SFAC 5 "Recognition and assessment in financial statements of commercial companies".

SFAC5 defines recognition as the process of incorporating an element in the financial statements, an element that meets certain criteria for recognition, the incorporating of an item in the financial statements involving both a descriptive and numeric form, as in the case of IASB Framework.

It should be noted that the criteria for recognition of an element proposed by the FASB in the financial statements are far more detailed than those required by the IASB, but these criteria must be applied in the limits imposed by the relationship cost-benefit and materiality level.

The criteria for recognizing states:

- *The definitions:* an element to be recognized in the financial statements must first meet the definitions set out in SFAC6 "Elements of financial statements";

- *The assessment (measurement):* information corresponding to that item should be useful for decision making by users;

- *The credibility (reliability):* information relating to the item must be sincere (true), verifiable and neutral.

However, SFAC5 states that recognition process includes the initial recognition, the later modifications and the un-recognition (elimination from the financial statements of that element).

The IASB Framework establishes as first criteria for recognition - *the concept of probability*. It is used in conjunction with *the uncertainty level* in which the future

economic benefits associated with the item will affect the benefits or losses.

The evaluation of uncertainty level refers at the information available at the time when the financial statements are drawn up.

To understand the concept presented, *the correlation probability - uncertainty* present the following example:

when a claim is likely to be charged is justified, in the absence of any evidence to the contrary, (and therefore virtually no uncertainty) and the claim is recognized as an asset.

In the event that the number of claims is high, it is quite probable (so it feels a slight increase in the degree of probability) that some claims can not be cashed, so the appearance of a certain amount of not receiving the money (in conjunction with a slight increase of the uncertainty level), a situation where there will be reduced the economic benefits of recognizing.

On the other hand, the American conceptual framework does not defines a distinct concept of probability among the criteria for recognition, but this is induced by the definitions of the elements set by the framework for the following elements that will be recognized in the financial statements.

The second condition that an element must satisfy to be recognized in the financial statements, a condition which can be found in both referential, more or less detailed, is that the item must have *a cost or value that can be measured reliably*.

This concept is shown in more details in the American framework, through the following three characteristics of the referential: evaluation, relevance, credibility. The two quality characteristics (relevance and credibility) come to create the context in which the assessment takes place, in terms of both its nature, by finding the most appropriate basis for the item concerned, and in terms of its size, by finding a value that is representative for the company that presents that element.

In many cases the cost or value must be estimated. The use of reasonable estimates is an essential part of preparing the financial statements and does not influence their credibility. If it can not be made a reasonable estimate, the item will not be recognized in the Balance Sheet or the Profit and Loss

Account, but may be presented in the Notes Information about that item, especially if they are relevant to assessing enterprise's financial position, performance, or modification of the financial position.

The concept of probability used in the criteria for recognition, is accompanied by a degree of uncertainty about future economic benefits associated.

Therefore, we can say that *the assessment of probability level of generating future economic benefits has a significant influence in the recognition process and the correct establishment of an element in the financial statements.*

The best examples are the provisions, liabilities and contingent liabilities where the degree of probability makes the difference between these elements.

As a basis of analysis we will use the rules of IAS 37 "Provisions, contingent liabilities and assets", but also the Finance Order no. 3055/2009 regarding the Approval of the Accounting Regulations according to the European Directives.

The standard states that *the uncertainty* related to the chargeability and the size of the final amount is the one which makes the difference between reserves and debts.

According to IAS 37, *the provisions* are defined as *doubtful debts* in terms of chargeability moment, or the corresponding amount, thus having a probable character.

What interests us is their correct positioning in the financial statements for the information to be relevant and credible. This standard offers the necessary guidance, specifying that *the provisions are recognized in the balance sheet* - if these conditions are met:

- The entity has a present obligation (legal or constructive) resulting from a past event;

- It is likely that an outflow will affect the future economic benefits in order to honor the current obligation (there are more changes too happen than not to happen), meaning that the probability of generating future economic benefits is high, to be noted that this criterion of recognition is essential in positioning the provision in the balance sheet;

- The amount of obligation can be estimated reliably (IAS 37 specifies that only in very rare cases can not be a reliable estimate of the amount of the obligation).

A *contingent liability* is an *obligation likely* to emerge as a result of past events and whose existence will be confirmed only by the occurrence or non-occurrence of uncertain future events that may not be entirely under the control of the entity, or *an obligation incurred* in the current past events.

The question that interests us is whether the contingent liability can be recognized in the Balance Sheet, in the conditions presented above. Because it does not meet all the criteria for recognition, in the sense that:

- Even if it is a general obligation of past events;

- Is not likely that outflow of resources which would incorporate future economic benefits to happen, meaning that the probability of generating future economic benefits is low; and

- The amount of obligation can not be evaluated sufficiently credible, under these conditions in the Notes to the financial statements are given information regarding the existence of contingent liabilities, especially since the information generated by it are important in determining the financial position, financial performance and changes in the financial position.

3. The current national legislation on the approval of Accounting Regulation harmonized with the European Directives, the OMPF no.3055/2009

The current national legislation on the approval of Accounting Regulation harmonized with the European Directives, the OMPF no.3055/2009, defines in the same way these elements and their criteria for recognition in the financial statements.

Thus, the order defines the contingent liabilities in the same manner and states that they will not be recognized in the Balance Sheet, just off the Balance Sheet, being presented in the Explicative Notes.

The contingent liabilities are assessed continually to determine whether it has become probable an outflow of resources which incorporates economic benefits. When it an outflow of resources, generate by an event considered previously a contingent liability, is necessary, a debt or a provision

will be recognized in the financial statements for the period in which this change appeared.

The order clarifies the conditions under which contingent liabilities are distinguished from provisions, namely:

- *The provisions* are recognized as liabilities (and recorded in the Balance Sheet) as they are current liabilities on the Balance Sheet and it is probable that an outflow of resources will be required to settle the obligations;

- *The contingent liabilities* are not recognized as liabilities (related information appear in the Explicative Notes) because they are obligations *that must be possible* to confirm whether the entity has a present obligation that may lead to an outflow of resources, or they are *current obligations*, but do not qualify for recognition in the Balance Sheet.

3. Conclusion

Through the issues presented and analyzed, we wanted to highlight the overwhelming importance of the recognition process of the elements in the financial statements, resulted in the recognition criteria, more or less detailed, depending on the chosen normalization framework, but which helps to the accurate positioning of items in the financial statements and thus the credibility and relevance of the information contained therein.

Leasing versus Bank Loan a Comparative Analysis in Terms of Tax Effects

Geambazi Petris

Academy of Economic Studies, Bucharest

petrisgeambazi@yahoo.com

Abstract

Existing funding sources in the companys is vital for the functioning and development. Cost of funding sources may vary from one company to another, at least for their own funding sources. However, for external funding sources, the market has reached a level where the cost of financing and, thus gains tax, are influenced by fiscal policy of individual businesses and related tax regulations that operate in market. The aims of this article is to identify a funding source from which businesses can obtain tax benefits, the research being done on a total of 32 companies from Romania. The research started by analyzing financial statements, followed by the formulation of hypotheses that have been tested and whose parameters were estimated.

Key words: fiscal impact, internal funding, external funding, leasing, bank loan

J.E.L. classification: G18, G32, K34

1. Introduction

Sources of funding determines the company's financial structure, a structure that represents the relationship between its short-term funding and long-term funding. In order to adjust the financial structure of the company, is aimed financial policy of the company and its correlation with market conditions. Also take into account the company's ability to adapt to environmental changes, using controlled economic resources, but also with sources of funding. The main argument which must underpin the funding sources of training is to find a perfect combination between the source of funding, the use of money and how that investment creates future economic benefits suitable to enable repayment of amounts borrowed.

Neoclassical theory predicts that financial integration can foster growth in emerging markets because it permits capital from rich countries to be invested in economies with low savings but high growth opportunities. Thus far, empirical work has focused predominantly on the impact of equity market liberalization on growth. Henry (2000a,b, 2003), Bekaert et al. (2005), Mitton (2006), among others, show that equity market liberalization decreases the cost of capital, causes investment booms, and increases aggregate growth. Recent empirical firm-level evidence corroborates and extends these aggregate findings. Chari and Henry (2004), for example, document that companies with a larger free float and more liquid stocks tend to attract more investor interest and thus experience a larger decrease in their cost of equity than the other listed companies. [10]

Funding sources include several ways to procure the necessary funds, but we insist only on two of them: the leasing and bank credit, they are the most accessible.

2. Leasing concept

Leasing, by its relatively short history, is a product of market economy, as a result of the evolutionary process of identifying new forms of financing for the sale of products and services provided. Leasing is a special form of credit in goods and services (do not have a credit by offering money), hence the diverse nature of institutions engaged in leasing operations - from specialized institutions to banks and insurance companies. A more complete definition of the concept of leasing is: the trade form and financing by financial companies specializing in these operations, financial institutions or directly from producers or companies that carries out a specific, or do not have own or

borrowed enough money to buy them. On the other hand, leasing is a form of lease - performed by specialized financial firms - some equipment assets to beneficiaries who do not have own or borrowed funds to purchase their from producers.[6]

One of the reasons why leasing is a financial alternative so popular in the world is actually summarizing by the leasing "philosophy": Not the ownership of assets but their actual use is one that brings profit [14]. The key issue is the judicious use of capital resources: invest money in generating "business" and make profits, such as advertising, superior training staff, inventory, explore new markets, research, development, instead of blocking them by buying fixed assets.

Leasing is a step in the financing of companys wishing to acquire movable or immovable goods, but do not have money. This financing technique which involves a higher risk, comes to satisfy traders who can not obtain credit from banks, or do not want to encumber movable and immovable property mortgages or liens by setting tasks that affect specific dynamic commercial area.

Practical interest of leasing is to ensure full financing through borrowed funds, an investment without precautionary measures from beneficiary, by this leasing it differs from traditional investment lending, where the beneficiary undertaking bear part of the investment value. Therefore, leasing as a financing technique is primarily aimed at business enterprises that aim at broadening and raising performance, and more generally, ensure technical progress.

The mature markets show that leasing knew the most important development free of any regulatory constraints. For an emerging market like Romania, is deemed necessary regulation and oversight to avoid a poorly addressed at the concept. These rules are a continuous dynamic both legally and for tax and accounting. It should be noted that internal rules are sometimes more conservative than those of European Union countries, so it is recommended to be reconsidered levels of debt eligible for leasing companies to increase their, and relaxation of the provisions in the calculation procedure the degree of risk.

1.1. The preference for leasing

The ability of a lessor to repossessed an asset is an important benefit of leasing. This ability to repossessed allows the lessor to extend the loan compared to a creditor who claims securities for the same asset. Lending capacity of leasing is greater than the capacity given by a bank credit loan. So, leasing is preferred by companies with financial limitations. [14]

The main argument for leasing, offered by the leasing companies are to: conserve money, offer 100% financing or maintaining credit lines. The fact that the lease exceeds the borrowing capacity of credit borrowing capacity was considered an aberration in the academic literature [7].

Leasing offers almost "100% financing", and equity tenant needs to cover only a period of use. The issue of the contract for lessor is critical, involving amounts in advance for their best leasing contracts, which means that a capital leasing market improves security constraints, but does not remove them.

1.2. Fiscal leasing approach

Tax and accounting classification determines who treats asset as a capital and depreciate it for tax and accounting aims. There is a connection between the different classification. Operating leases are usually true leases for tax and legal purposes. Capital leases are often considered conditional sales contracts for tax purposes with two important caveats. First, a lease with a term exceeding 75% of the asset's economic life but not exceeding 80% will be a capital lease for accounting purposes but a true lease for tax purposes. Second, by making different assumptions about economic life, residual value, and so on for accounting and tax purposes, a lessee has some additional leeway to have a capital lease treated as a true lease for tax purposes. Importantly, whether a lease is considered a true lease for tax purposes or an operating lease for accounting purposes may affect how it will be characterized for legal purposes and hence may affect its treatment in bankruptcy.[8]

2. Bank loan concept approach

About bank loan we can say that is obtained under a contract whereby a bank (similar institution), called the lender undertakes to provide a natural or legal persons, called borrowed a sum of money (credit).[15] The analysis made by the bank for lending take into account the business, focusing on its economic and financial aspects, although, non-financial aspects are sometimes more important in lending decision.

Studies on capital structure attempts to explain how the company trains its funding structure. One can say that there is no universal theory on the structure, but may be mentioned that some of them are still marked and tested on various savings. Thus, the trade-off theory says that firms seek that level of borrowing to balance the tax advantages given by the ratio between debt and costs associated with financial difficulties or bankruptcy. This theory talks about the tax paying companies that have a moderate level of indebtedness.

Pecking order theory argues that firms will borrow, avoiding the issue of shares when their sources are insufficient to finance profitable investment opportunities. In these circumstances, a borrowed company forward, on the one hand, a signal failure of own funds, but also one of the existence of profitable investment projects it wishes to exploit.

Equilibrium theory developed by Modigliani and Miller (1963), indebted companies positioned in the opposite advantage not-indebted. Miller (1977) argues that these tax savings are lost as leverage of the Company indebtedness increase.

The existence of a positive correlation between leverage and size of turnover can be explained by: low bankruptcy costs, better diversification of business risks and therefore more likely that the firm could receive credits, which claims the applicability of trade-off theory in Romania.

When the presence of foreign banks is substantial, access to credit for small and start-ups can shrink, but the net impact of these must not be negative. Company size is a common measure by which the company has access to external funds. Small firms are expected to increase faster. If foreign banks

have difficulties in managing information or choose to focus on large firms, small businesses and increase their ability to increase the debt can be braked.[10]

3. The impact of indebtedness on income tax

Even if are measured very precisely, the tax rates are endogenous to debt policy, which can have important effects on tax research. When a company is indebt, the taxable income decrease, which causes a reduction in tax rate. The volume of debt grows, the more the marginal tax rate reduction. Therefore, if a debt ratio decreases on the marginal tax rate, endogeneity of corporate tax status can impose a negative bias on the tax rate. This could explain the negative tax coefficient found in some specifications [11].

There are two solutions to the problem of endogenous. Mackie-Mason (1990) proposed the first solution by looking at debt versus capital growth decision (rather than the debt) in the 1747 tests conducted between 1977 and 1987 [7]. The level of debt (such as debt ratios) are the culmination of many historic decisions that may affect the financial choice in light of the influence taxes. Detecting the effects of tax incremental approach requires the firm to make the appropriate choice of borrowing capital, given its current position and not necessarily return the optimal loan structure with each issue (as given in many studies the level of debt). To avoid making the endogenous debt marginal tax rate, Mackie-Mason used marginal tax rate to explain the financial decision for current period. He finds a positive relationship between increased borrowing and tax rates. Bianco (2006) argues that firms do not take into account the marginal tax rate when making incremental decisions, but rather take into account how far is the marginal tax rate of optimal marginal tax rate. Given the level of the tax rate constant, Bianco showed that firms with tax rates above the optimum level are those excessive indebt. The difficulty of this approach is that Bianco uses a optimal marginal tax rate taken incidentally.

If taxes exert a positive influence on each financing decision, then the sum of these decisions should appear in an analysis of current debt levels that could set a negative

effect on tax rates induced by the use of endogenous cumulative debt. A second approach to determining the endogeneity problem is to measure the rates of taxation for financing decisions. Graham and Tucker (2006) measured the tax rates before financing (based on earnings before interest deduction). They found a positive relationship between debt value (endogeneity corrected) and tax rates.

4. Research methodology

To highlight the tax effects of leasing versus bank loan financing have been examined 32 companies with head offices in Romania, from various economic sectors. Were analyzed each company's financial statements for the last two years (2009 and 2010).

Based on the actual situation of the last year, has made a simulation to see what financing options offer more favorable tax effects on society, taking into account the following assumptions:

- amount of funding required is 700.000 lei
- the cost of financing is the same
- funding period is 5 years
- depreciation is linear
- the turnover, costs of materials and services from third parties and staff costs remain constant,

I tried to observe the influence that one has the interest rate on loans to. From a practical perspective it was difficult, the lack of data forcing me to just summarize the analysis of the influence of the interest rate for loans recorded on the volume of bank loans. I only used data on the volume of loans to non-bank and non-governmental customers, both in domestic and non-currency, statistical data being provided by the National Bank of Romania.

5. Research results

In terms of taxation and the impact on the financial statements, bank credit is synonymous with financial leasing. The effect that has on the financial accounting of leasing as an operating lease rather than finance lease, the lessee's financial statements can be summarized as follows:

- accounting for operating leases relate to lease payments in the income statement as rent expense,
- to finance lease rental costs are lower and the depreciation are higher,
- operating leases recorded in the first 2-3 years, a better net result, therefore a better profit margin, then it drops under the finance lease, and finally averaged over the entire period to be equal,

- same situation happens in case of return of equity

- for operating leases, higher return on assets for the entire period analyzed, as well as in the case of rotational speed of the assets

Following interest rate calculations on the influence of the credit, I have less accurate results from a macro perspective, when the interest rate rises by one percentage point increase in loan volume 1180,523 millions lei (ROL for analysis) and decreases to 2731,881 millions lei (the analysis of currency). Economically, the credit is positive independently (with a very large amount) and interest rate developments affect different amount of loans.

In reality, the credit volume is affected by a variety of other factors, which in this model took into account only the residual variable, which leads to an incorrectly sized approach on real macroeconomic mechanisms.

6. Conclusions

The analysis undertaken was based on financial data from company accounts for 32 per 2009 and 2010 in accordance with the Accounting Law No. 82/1991 republished with subsequent completions and modifications, and with the order M. F. No. 1752/2005 on the approval of accounting regulations harmonized with the Fourth Directive of the European Economic Community.

Starting from the premise that the amount of funding required is 700.000 lei, the cost of financing is the same, funding period is 5 years, depreciation is linear, turnover, costs of materials and services from third parties and staff costs remain constant, there was no tax difference in results between the funding by through bank credit and financial leasing. Basically, in the analysis, the concept of bank credit has been assimilated by leasing, because there were no differences in results.

Going to different tax treatment of financial leases compared to operating leases have found differences in the results, differences at the end of the reporting period were eliminated each other. They were:

- at the profit margin, operating leases has resulted in higher expense in the early years because the rent was less than the total reported expense under finance lease method,
- at the rotational speed of the assets, operating leases has resulted in more active because there is no lease registered under the operational method,
- at the rate of immediate liquidity, operational leasing has had greater results because, under the operational method, in balance is not added any short-term debt,
- in the case of indebtedness, operating leases has resulted in lower because, as the operational method does not lead to the creation of debt. In the case of financial leasing is higher, but decreases over time because it decreases the obligation lease,
- at return on assets, operating leases has higher resulted in the early years because of higher profits and lower current. This effect can be canceled at the end, because in case of financial

leasing, while increasing return on assets based on an upward trend in the results, coupled with a decline in assets when are amortized,

- at return on equity, operating leases has resulted in higher early because the results were higher. Same as return on assets, and this effect is canceled at the end.

We can say that, from a legal perspective, there aren't favorable differences in the economic and fiscal results for a form of financing. The decision to choose for leasing or purchase a good by resorting to bank credit must be substantiated by comparing the costs of financing for the two alternative and to choice that sources of funding at lower cost. It also requires an analysis of the debt, borrowing impact that the financial return, so the final result to be to maximize enterprise value.

The study on the impact of interest rate of loans is noted that the interest rate does not affect the volume of loans, but there are other factors, not taken into account, that leading to a large extent its evolution.

The Usability of the Dashboard and of the Balanced Scorecard in the Context of Decision Making

Georgescu Cristina Elena

Asaloş Nicoleta

„Ovidius” University of Constanta, Faculty of Economic Sciences

cristina_georgescu95@yahoo.com

nicoleta_asalos@yahoo.com

Abstract

Managers are using a large volume of accounting data and information in order to substantiate their decisions-making. The dashboard translates the strategy of an entity into a set of performance indicators that ensure the frame for strategy implementation. The Balanced Scorecard provides managers with a process to describe strategy – both what the organization wants to accomplish and how it intends to realize its strategic outcomes. Taking all the objectives and measures together into a strategy map of cause-and-effect relationship across the four perspectives provides a comprehensive picture of the organization’s value creating activities.

Key words: dashboard, balanced scorecard, decision-making, strategy.

J.E.L. classification: M41.

1. Introduction

In today’s era, economical entities are continuously faced with changes generated by globalization, technical advancement, and access to information. Running such an entity and solving the various issues presented by the production and economical and financial activities, involves permanently enacting effective and scientific decisions.

In terms of management, the economical entity encompasses a chorus of subsystems: the decision making subsystem, the operational subsystem and the informational subsystem.

In essence, by decision making subsystem we define an ensemble of decisions, adopted and applied within an

organization, structured according to the total of objectives and of the governing hierarchy. It is necessary that, within the decision making subsystem, there be a performance analysis system, whose design commands the resolve of, mainly, the following issues:

- The assignation of organizational subunits that must receive information referring to achieved performances;
- Establishing centers for decisions and ways of presentation for information regarding activities being led;
- Coordinating organizational subunits that receive information concerning performances achieved in the operational system.

By using the dashboard and the balanced scorecard you can solve these issues, identify the relation between component subsystems and highlight relevant information that allow the decision making subsystem to achieve objectives.

2. The dashboard

The dashboard is a governing tool that encompasses a set of relevant and strategic information regarding the area being governed, presented in a set synthetic form, which provides for a very well conditioned need for information. The dashboard is recommended in the case of small and medium size enterprises and answers to the needs of operating managers in making decisions.

The role of the dashboard is that of ensuring fast, operational and complete information of the managers. The effect of applying this management technique is the growth in governing efficiency. The most important functions of the dashboard are:

- the information function: supplying information to the manager;

- the alarm function: reading situations that are out of the normal grid (the dashboard highlights the entity's alert points);
- the diagnosis function: evaluating the state of the system being governed;
- the decision making function: relevant information strategically sent to managers set in various hierarchical positions, allow the substantiation and enactment of adequate decisions that will eliminate negative aspects and generalize positive ones.

Structurally speaking, the dashboard should answer to some *specific demands*, such as:

- *consistency*: the dashboard must contain relevant, synthetic and exact information, about the areas being governed;
- *rigor*: by concentrating information in the dashboard on faithfully rendering phenomena and economical processes and transmitting them in real time;
- *aggregation*: inserting information with various degrees of adaptation based on the hierarchical level of the manager benefitting the dashboard;
- *accessibility*: a configuration of information that allows easy apprehension and fast and complex use;
- *balancing*: implies forming a structure of information that aptly reflects the proportion of various phenomena and processes;
- *emphasis*: implies a more suggestive presentation of information, using charts and tables;
- *flexibility*: refers to the possibility of adjusting the structure of information according to interceding changes;
- *economy*: the efforts of establishing the dashboard must be justified by the effects of its use.

Information concerning the results obtained in the governed area may be highlighted with the help of:

1) **Tables of values** that contain information about the provisioned level of the objectives, the level of results recorded in a given period, the differences between objectives and results, the achievement percentage of the objectives and the causes that generated negative or positive deflections. Objectives and results are expressed through indicators and the degree of achievement of these objectives is determined by relating the result to the provisioned level (highlights the percentage by which the objective was

achieved). The incidents that may endanger the achievement of the motioned objectives are presented in a precise and swift manner. Entities use several types of indicators: quantitative or volume indicators; effort indicators; production costs, permanent capital, personnel number, salaries, current assets stocks; effects indicators; profit, turnover, manufactured goods production, physical production, total income; quality or efficiency indicators: work productivity, medium salary, productivity rates, liquidity and solvency, treasury rate, the rotation speed of current assets.

2) **Charts** that illustrate some indicators' trends over a certain period of time. Information contained in the dashboard must be centered on concise and effective responsibilities, expressed in numbers and observed using the chart method.

3) **Mixed forms**: charts and tables of values.

The usability of the dashboard in managerial analyses and decisions may be synthesized as such:

- it integrates the information needed by management;
- by using it, managers establish immediate objectives, follow and validate achievements in relation to provisions;
- it is an instrument used to control the management of the entity and analyze economical and financial indicators;
- it is an instrument used to follow up on activities run by various responsibility hubs;
- it's comprised of indicators, information that attracts the respondents' attention toward the key points to follow;
- offers managers the possibility to focus their actions on several areas of activity and set objectives for these areas, entrusted to certain responsibility hubs;
- it highlights the alert points of the entity.

The advantages and disadvantages of the dashboard's usability

Among the advantages of this governing instrument we point out: the facilitation of a better foundation for decisions; saving the manager's work time; approaching information from a systemic point of view; offering valid criteria for personnel evaluation.

Among the disadvantages of the dashboard we mention: favoring redundancy in the informational system, by repeatedly recording the same information categories;

the relatively high use of time and resources for the development of the dashboard and implicitly a proportionally high cost.

3. The balanced scorecard

Management accounting offers reports that help managers follow the progress made in strategy implementation. Since the early 90's, American companies have been using a new steering and performance tracking tool: **the balanced scorecard**. Currently it is being adopted by companies worldwide, to manage the implementation of their strategies, as it is based on a concept according to which "strategy is transcribed into action".

The balanced scorecard transcribes the mission and strategy of an entity into a set of performance indicators that ensure the framework for implementing the strategy.

3.1. Strategy implementation

The strategy of an enterprise determines the way in which it harmonizes abilities with market opportunities in order to reach its objectives. When it formulates a strategy, an entity must make the most of understanding the particularity of the branch in which it activates, by analyzing five determining forces:

- competitors
- potential participants to the market
- equivalent products
- the customers' force of negotiation
- the suppliers' force of negotiation in supplying the production factors

The base effect of these forces influences such an entity's potential for profit. Generally, this decreases along with the growth of competition, the emergence of newer, more powerful companies, of similar products and more demanding suppliers.

The balanced scorecard focuses not only on reaching financial goals, but also on highlighting non-financial objectives that an organization must reach in order to fulfill its financial targets.

This situation balances the use of financial and non-financial indicators with the purpose of evaluating short term and long term performances in one single report. Thus, managers direct their attention on more than short term performances, such as quarterly

proceeds, due to the fact that non-financial and operational indicators measure the changes that a company can achieve on the long run. The benefits of these long term changes may not immediately be reflected in short term profits, but the solid improvements of non-financial indicators represent an indicator for creating future economical value. By balancing the percentage of financial and non-financial indicators, the balanced scorecard increases the management's attention on short term performances as well as long term goals.

At the beginning of the year, in a balanced scorecard, the enterprise must present its objectives, indicators, initiatives and actions that it must undertake in order to reach its objectives and target performances. The target levels of performance for non-financial indicators are based on reference-indicators in relation to competition. These indicate the levels of performance necessary to deal with customers' needs, in order to obtain efficiency on a competitive level and reach financial objectives; it is not enough for the entity to aim at obtaining better-than-before-results. The last column of the scorecard shows the real level of performances at the end of the year.

The balanced scorecard measures an entity's performances in four directions:

1. *The financial perspective*

This perspective evaluates the profitability of the strategy. The most commonly used indicators are: the exploitation profit, income growth, income obtained from new products, percentage marginal share, cost reduction in key areas, added economical value, investment profitability.

2. *The clients' perspective*

This perspective indicates the target market segments and measures the entity's success on these segments. In order to monitor development objectives, entities use indicators such as market share, the number of new clients, the customers' level of satisfaction, the level of customer continence, the time necessary to cover customer demands and the number of customer complaints.

3. *The perspective of the internal economical process*

This perspective focuses on operations that carry on the client's perspective by

creating customer value and financial outlook, increasing shareholders' value. The indicators used are categorized based on three sub-actions:

- *the innovation process*: abilities concerning production, the number of new products or services, development time for new products and the number of new patents.
- *the operational process*: efficiency, the number of defects, the time necessary to deliver the product to the customer, the percentage of real time deliveries, the average time necessary to realize production according to demands, the necessary time for assembly and adjustment and the actual production time.
- *post-sale services*: necessary time for replacement or repair of defective products, customer training sessions to show the proper use of the product.

4. Learning and growth perspective (expertise development)

This perspective establishes the abilities which the organization must excel in, in order to bring betterment to internal economical processes, which in return lead to a higher customer satisfaction and higher market shares and ultimately to superior financial performance. The indicators used here are employee training and qualification levels, numbers that indicate employee satisfaction levels, employee efficiency, the availability of informational systems, the number of advanced controls processes and the percentage of implemented employee suggestions.

The indicators used for performance evaluation in either of these directions must be a tightly linked to the strategy of the entity. Thus, assuming that the strategy is well planned, the entity focuses on actions that must be launched in order to achieve success.

The main characteristics of a balanced scorecard are:

- it presents the strategy of an entity through a series of consecutive cause-effect relations, meaning the connections between the various perspectives that describe the way in which the strategy will be implemented. Each indicator is part of a cause and effect chain reaction, starting with formulating the strategy and ending with financial results.
- it helps communicate the strategy to all the members of the enterprise by translating

the strategy into a coherent and well adjusted set of exploitation objectives, which is easy to measure and comprehend. With the guide of the balanced scorecard, managers and employees act and make decisions toward the implementation of the strategy.

- the balanced scorecard limits the number of indicators, only identifying the most important ones. The purpose is that of attracting managers' attention to the indicators that best affect the implementation of the strategy.

- in profit oriented companies, the focus lies on financial objectives and indicators. A balanced scorecard highlights the financial indicators as part of a program in order to reach future financial performances. When financial and non-financial performance indicators are tightly linked, most non-financial indicators serve as indicators for future financial performance.

3.2. Evaluating the success of a strategy

In order to evaluate the success of implementing the strategy, an entity compares the target performances with actual performances on the balance scorecard.

Some entities are tempted to highlight the success of their strategies by measuring the annual changes of the exploitation profit. This approach is not adequate, as the exploitation profit may grow either as a result of general development of markets, or due to other agents independent of the strategy. This is why managers and accountants must evaluate the success of a strategy by making the connection between the sources of the increase in exploitation profits and strategy.

The management accountant makes a thorough analysis of the exploitation profit giving managers more information in order to evaluate policies and thus, adds value to the management team in evaluating the efficiency of strategy implementation.

In order to realize this analysis, the modification of the exploitation profit can be divided as such:

- *the growth component*: measures the change of incomes and costs after the sale of a larger or smaller number of units, assuming that the prices, efficiency and production capacity remain unchanged;

- *the price recovery component*: measures the modification of incomes and costs as an effect of the change in the prices of production and production factors. An entity that has successfully implemented a strategy to differentiate the product will manage to up production costs faster than the production factors' prices, thus increasing the profit margins and the exploitation profit, recording a positive value of the price recovery component.

- *the productivity component*: measures the prices' decrease, as an effect of the production capacity reduction and the use of a small number of production factors. An entity that has successfully implemented a cost leader strategy will be able to realize a certain amount of production with a smaller amount of production factors, recording a positive value of the productivity component.

It is considered that an entity has successfully implemented its strategy when the value of the components apposite to product differentiation, the cost leader position and exploitation profit growth is regular to the strategy in question.

4. Conclusions

Even if financial situations are considered the main ways of transmitting accounting information to users, it is because they use professional term that are sometimes hard to process, complex accounting terminologies and formal business language that they lost ground to other instruments more accessible to managers

One instrument that is instrumental and more accessible to managers is the dashboard, which translates the strategy of an entity into a set of performance indicators that ensure the frame for strategy implementation. The dashboard synthesizes information needed for decision making and informs decision makers of the way in which

phenomena, (particular to the activities taking place) are evolving, and turns their attention to the key points to be followed. With the help of the dashboard entities establish immediate objectives, validate achievements in relation to provisions, measure the road covered, but also that left to travel in order to reach objectives and highlight the sensitive spots of the activity.

Unlike the dashboard, the balanced scorecard contains pertinent operational indicators that only follow the implementation of the entity's strategy, focuses on the strategy not control. The balanced scorecard is a complex instrument for measuring and managing performance, by ensuring balance between: short term and long term (it identifies the sources of long term success and leads to a short term decision), the outside and inside of the entity (considers external objectives – clients and internal objectives – the personnel, which it analyzes within internal processes), value and cost (leads to cost management from the perspective of generating customer value) and between the financial aspect and non-financial aspects of performance.

The Romanian Property Taxation System

Georgescu Maria - Andrada

Murgescu Dana Mihaela

National School of Political Studies and Public Administration

andradageor@yahoo.com

dana_akari@yahoo.com

Abstract

As the economic climate changes towards increased competitiveness within the public sector, the local public administration needs to identify its possible sources of own revenues and to decide on the best manner of collecting these revenues.

In the present paper, the authors critically analyze the taxation system employed nowadays in Romania, focusing on the tax on property. A brief empirical research is conducted, illustrating the evolution of the tax property shares in the national GDP, on the one hand, and in the local government own revenues, on the other hand.

The last part of the paper is reserved for the comparative analysis of the methodologies used in establishing the level of the property tax, debating with respect to the best methodology to be employed, concluding in favour of the value-based assessment.

Key words: local taxation, property tax, area-based assessment, value-based assessment.

J.E.L. classification: H71

1. Introduction

Typically, the following main types of local government revenues can be identified: tax revenues, including local taxes or shared national taxes; non-tax revenues and user charges; different types of grants (e.g. general and specific) made available to local government from the central government; and borrowing, e.g. for investment expenditure [11]. As fiscal constraints from the centre begin to harden, own revenue sources are becoming more important to local government [5]. Therefore, local governments begin to show real interest in

having access to their own revenue sources, *i.e.* income for which the level as well as the source are controlled or decided upon by local governments, who also have the liberty to decide their constitution. These are often connected with local taxes and different kind of user charges [7].

The Romanian law regarding local public finances (Law no. 273/2006) holds that own revenues to local budgets consist of taxes and fees and quotas from the Personal Income Tax PIT. These own revenues make up for almost half of the total income to the local budget (see Table 1), which highlights the increase of financial autonomy of a local public authority.

Table 1. Own Revenues as a % of Total Local Government Revenue

2007	2008	2009	2010
47.5	47.3	51.1	50.3

Source: our own findings based on data from the Ministry of Finance

The local taxes and fees are established by the Fiscal Code (Law no. 571/2003), which holds a special part dedicated to them; these are as the following: a) tax on buildings; b) tax on land; c) tax on means of transport; d) fee for the issuance of certificates, permits and authorization; e) fee for using means of advertising and publicity; f) tax on shows; g) hotel fee; h) special fees, and i) other local fees.

The most important own source revenues at LGU in Romania are the revenues from property tax. (A note: Property falls into two categories: immovable (or 'real') property (land, buildings, and other constructions or 'improvements' to the land), and movable property (which is subdivided into tangible and intangible property). This study will only deal with taxes on immovable property, or land and buildings.

The relative importance of the property tax, however, varies significantly across countries. In the US property tax revenues equal about 3 percent of GDP; 4 percent in Canada. For OECD countries, property tax revenues account for 2.1 percent of GDP, while in developing countries property tax revenue account for just 0.6 percent of GDP and in transition countries just 0.68 percent [3].

Romania, as a developing country, follows the same pattern (see table 2).

Table 2. Share of Revenues from Property Tax in Romania in GDP

2006	2007	2008	2009	2010
0.75	0.75	0.65	0.66	0.74

Source: our own findings based on data from the Ministry of Finance

Despite its relatively modest yield, the property tax is significant both from the tax policy and from the political perspectives. Above all, the property tax provides a high degree of fiscal autonomy for local governments because the amount of tax can be controlled by the local government.

2. Short overview of the Romanian Property Tax System

From the local taxes point of view, in Romania there are 6 ranks attributed to localities, as follows: rank 0 – the Romanian capital, rank I – municipalities of national importance; rank II – municipalities of county or inter-county importance ; rank III – towns; rank IV – locality residence villages; rank V – villages which are components of localities or belong to municipalities or towns. Therefore, ranks 0 to III refer to the urban areas, and ranks IV and V to the rural areas. The locations (zones) inside localities are established by the local council, according to the position of the land against the centre of the locality, to urban networks, as well as according to other elements specific to the administrative units, which

can influence the value of the land. The identification of the areas is done with the letters A, B, C and D.

A. Tax on land

Any person who owns land that is located in Romania pays the *tax on land*, and concessionaires, tenants, users or administrators of state-owned land pay the *fee on land*, calculated similarly with the tax on land.

The tax base is the area of the land, inside and outside municipalities' limits (for the land situated both inside and outside the built-up areas). (The Romanian term „intravilan” means within the built-up areas/incorporated area, and „extravilan” means outside the build-up areas / incorporated areas).

Tax rates are established by the central government as unit price per hectare. The tax level differs according to the rank of the locality, location (zone) inside locality, and/or use category of the land. Therefore, the ranking system may be represented in a 4×6 matrix, with location A-0 ranking highest and location D-V ranking lowest.

For land located in the intravilan and registered in the agricultural registry under the construction land use category, the tax ranges from lei 8,921 per hectare (EUR 2,124) for location A-0 to lei 153 per hectare (EUR 36) for location D-V.

For land located in the intravilan and registered in the agricultural registry for use other than land with construction, tax rates are determined first by use category and zone assignment, and then by a correction coefficient reflecting the rank of locality. Agricultural land breaks down into nine use categories (arable land, grazing field, hay field, vineyard, orchard, forest or other land with forest vegetation, land with water, roads and railways, unproductive land) and a tax rate is specified for each category associated with each zone. The correction coefficient for the rank of locality ranges from 8.00 to 1.00.

For land located in the extravilan tax rates are determined first by use category and zone assignment, and then by a correction coefficient reflecting the rank of the locality. The extravilan land breaks down into ten use categories (on top of the use categories stipulated for land located in the intravilan and registered in the agricultural registry for

use other than land with construction, construction land category is also stipulated) and a tax rate is specified for each category associated with each zone. The correction coefficient for the rank of locality ranges from 2.60 to 0.90.

B. Tax on buildings

Any person that owns buildings located in Romania pay an annual tax on buildings, and legal persons as concessionaires, tenants, users and administrators of state-owned buildings pay the fee on buildings. A building is any construction situated above ground and/or under ground, regardless of its name or use, and which has one or several rooms which can store people, animals, objects, products, materials, installations, equipment and others alike, as well as its basic structural elements, such as walls and ceiling, regardless of the materials they are made of.

Romanian property tax law faces a differentiation between natural (physical) and legal persons regarding the computation of tax on buildings.

Computation of tax on buildings for natural persons

The tax on buildings is computed by applying the rate of tax (de 0.1%) to the taxable value of the building. The taxable value of the building is determined by multiplying its built area by the taxable value per square meter; this value is then adjusted by multiplying it with a correction coefficient. The taxable value per square meter differs according to the construction materials used for the exterior walls, as well as according to the building facilities/infrastructure. For example, for a building with reinforced concrete frames or with exterior walls made of burnt bricks or any other materials resulted from a thermal and/or chemical treatment, which has electrical wiring, and water, sewage and thermal plumbing, (these are cumulative conditions), the taxable value is lei 806 per square meter (EUR 192), and for buildings with exterior walls made of wood, natural rock, un-burnt bricks, rolls or any other materials which have not been subjected to a thermal and/or chemical treatment and which does not meet at least one of the cumulative conditions presented above, the taxable value is lei 137 per square meter (EUR 33).

The taxable value of the building will be adjusted based on the location of the building. The correction coefficient ranges from 2.6 to 2.00 for urban areas and from 1.10 to 0.90 for rural areas. In the case of an apartment located in an apartment building with more than three floors and eight apartments, the correction coefficient will be reduced by 0.10. For a natural person, the taxable value of the building is reduced by 20% for buildings older than 50 years or by 10% for buildings older than 30 years, at the date of the 1st of January of the reference fiscal year. If the building used as a home has a built area larger than 150 square meters, the taxable value is increased by 5% for each 50 square meters or fraction.

The law provides for progressively higher tax burden to be placed on natural (physical) persons who own more than one building in the country. Therefore, the tax on buildings increases as follows: a) by 65% for the first building other than the address of domicile; b) by 150% for the second building other than the address of domicile; c) by 300% for the third and additional building other than the address of domicile.

Computation of tax on buildings for legal persons

In the case of legal persons, the tax on building is computed by applying a tax rate to the inventory value of the building. The inventory value of the building is the entry value of the building in the patrimony, recorded in the accounting system of the owner of the building. The tax rate is established by a decision of the local council and may vary between 0.25% and 1.50%, inclusively, but if the building has not been reevaluated in the last three years prior to the reference fiscal year, the tax rate may be between 5% and 10%. In the case of a building whose value was entirely recovered by means of depreciation, the taxable value is to be reduced by 15%.

After this brief overview of the Romanian (immovable) property taxation system, we can say that Romania has one of the most heterogeneous systems there are.

Therefore, in the case of the land tax, the approach adopted by Romania is the area-based assessment, regardless of the land owner's judicial form. In the case of the building tax, the assessed value is different according to whether the owner is a physical

or legal person. In the case of physical persons an area-based assessment is used, and in the case of legal persons a value-based assessment is used. The distinction may have more to do with policy objectives, such as preferential taxation of residential property, or with practical consideration (enterprises may have better records of their assets) [1]. Further more, in the case of the building tax, not only the assessment methodologies differ, but also the tax rate applied to these assessed values. In the case of physical persons, the tax rate is set by the central government by law, respectively 0.1%, and in the case of legal persons, it can be observed that the local council has the discretion to set the rate between the limits approved by law, respectively between 0.25% and 1.5%. This system gives local government the power to manage the distribution of the tax burden across property classes within their jurisdiction in addition to determining the size of the overall tax burden on taxpayers [6].

A common feature of the taxes on land and buildings owned by households is that they are based on area assessment. We have to observe that the area-assessment used is not in its purest form, *i.e.* it does not take into consideration any variation in the assessment base to reflect location, market condition, or quality of structures [9]. What is used is a hybrid form of area-based assessment, where the physical area is used as a key input in value mass appraisals [2].

In Romania two the government makes adjustments for varying characteristics of property in order to enhance tax fairness. Area valuation can be adjusted with rate differentials or adjustment coefficient. Rate differentials are based on categories of characteristics that have different rates for different characteristics. To calculate the tax owed for a parcel of land, the government multiplies the rate (amount per square meter) by a number of square meters the parcel of land covers. Adjustment coefficients are based on the same concept as rate differentials, *i.e.* variation according to characteristics, but are used differently in calculation. The coefficient for each characteristics act as a multiplier to a base value. The base value is the starting value per square meter of land or building, which is multiplied by coefficients representing

location, zone, infrastructure, etc. [8]. Romania uses both rate differentials and adjustment coefficient in the area-based valuation method. For example, in Romania 5 adjustment factors are used, meaning 4 rate differentials and 1 adjustment coefficient. It is interesting to note that, according to [8], total adjustment made average 5 per country and range from 0 to 30 per country.

Therefore, through the application of adjustment factors, the market value has an indirect influence on the assessment base [6]. These adjustment factors are derived from average values for groups of properties within each zone, but do not reflect the characteristics of each individual property. When the groups are defined narrowly enough, however, unit value begins to approximate market value [6].

Unit assessment requires both an initial determination of value per square meter and, as circumstances change, subsequent adjustments of this value [9]. How is this initial value to be determined and how will the adjustments be made? Is the determination to be made by a bureaucrat or is to be left to the market? If it is made by a bureaucrat, it may be arbitrary and unfair. If it is made by the market, why not simply use the market value of the property instead – as in market value assessment? Starting from these questions posed by [9] we will show the assessment methodologies used for property taxation, whilst trying to find the answer to another question: Which tax base is best for Romania?

3. Property taxation computation methodologies

In general, two distinct assessment methodologies are used for property taxation: area-based assessment and value-based assessment [2].

Area-based assessment (or non-value). Under an area-based assessment system, a charge is levied per square meter of land area, per square meter of building, or some combination of the two. The assessment rates may be the same for land and buildings, or they may be different. Simply, under area-based property tax systems, taxes are determined by multiplying a measurement of area by a rate.

Value-based assessment. When a measure of value is the basis for a property tax, there are several options: capital and rental value approach [10].

Market-value (or capital value) assessment estimates the value that the market places on individual properties. According to [6], market value is defined „as the price that would be struck between a willing buyer and a willing seller in an arm’s length transaction”. For estimating market value, the following methods can be used [6]:

- The comparable sales approach looks at valid sales of properties that are similar to the property being assessed. It is used when the market is active and similar properties are being sold.
- The depreciated cost approach values the property by estimating the land value as if it were vacant and adding the cost replacing the buildings and other improvements to that value. The cost approach is used when the property is relatively new, there are no comparable sales, and the improvements are relatively unique. The cost approach is also normally used to assess industrial properties.
- Under the income approach, the assessor estimates the potential gross rental income the property could produce and deducts operating expenditures. The resulting annual net operating income is converted to a capital value using a capitalization rate. This approach is used mainly for properties with actual rental income.

Under the rental value (or annual value) approach, property is assessed according to estimated (not actual) rental value or net rent. An argument in favor of rental value use is that taxes are paid from income (a flow) rather than from wealth (a stock) and thus it is appropriate to tax the net rental value of real property. In theory, however, there should be no difference between a tax on market value and a tax on rental value.

These two fundamental approaches to property taxation can be synthesized as follows: under an area-based approach, each parcel is taxed at a specific rate, per area unit of land and per area unit of structures; by contract, under a capital value approach, each parcel is valued at a specific rate, per area unit of land and per area unit of structures.

The area-based approach to property taxation in developing countries has caught on, and is now used in at least 38 countries [12].

4. Which tax base is best ?

According to [4], an are-based property tax

- Scores well in terms of revenue stability and predictability;
- May not generate adequate revenues to fund locally provided goods and services compared to the ad valorem property tax;
- May be somewhat more neutral than a market value based property tax with regard to the portion of the tax falling on structures;
- May be simpler to administer than a market value based property tax system, even if there is some level of self-assessment involved; and
- May be somewhat equitable from the perspective of the benefit received principle of taxation, while an ad valorem property tax is generally considered to score better on equity grounds from the perspective of the ability-to-pay principle of taxation.

A summary of the strengths and weaknesses of an area-based property tax, vis-a-vis an ad valorem property tax, are presented in table 4.

Table 4. Evaluation of Two Property Tax Form Under Traditional Criteria

Criteria	Area-based Tax	Value-based Tax
Revenue productivity	+, -	+, -
Neutrality	+, -	+, -
Simplicity	+	-
Equity	-	+, -

Source: [4], p. 369

The market value is generally regarded as a better tax base. First, the benefits from local public services are more closely reflected in property values than in the size of the property [9]. Second, market value has the advantage of capturing the amenities of the neighborhood, amenities that have often crated by government expenditures and

policies.

The dominant approach to property taxation in developed countries is based on the market value of property [12], but the area-based assessment is commonly used in Central and Eastern Europe [6].

Which is the Best Practice? There is no easy answer and certainly no general agreement among either analysts or policy maker. If the test for "best" is the most common practice in developing countries, then the preference would seem to be for a capital value system where both land and improvements are taxed [2]. However, a prerequisite of an ad valorem property tax is an open, active, and healthy property market for the full range of property types to be taxed and therefore valued. It is clear that Romania has not yet achieved such a property market, at least not across the entire country (such a market seems to operate in the capital and in some large cities). Another problem Romania faces has to do with retrocessions, if we take into account the fact that here, as opposed to other ex-communist countries, the property restitution process is still far from finished. The introduction of this "new" base of the property tax is not free from cost. There are major administrative hurdles to be overcome, in terms of responsibilities and professional training for assessment, valuation and collecting. The evidence on values and valuation experience are limited. The absence of reliable data on the sales value of properties is the issue that underlies the valuation problem.

Transport Time in Tourism... a Value or a Cost ?

Abstract

As a fundamental component of tourism, transport links between the tourist generating areas and destinations. Therefore, accessibility, who is determined by the quality of existing transport services, is essential in development of any tourist destination. Moreover, the tourism industry can have substantial benefits with increasing demand for a certain way to travel. In this context, travel time is one of the largest categories of transport costs, and time savings are often claimed to be the greatest benefit of transport projects. This paper examines the value of travel time and travel time savings. Various studies have developed estimates of traveltime values for different user types and travel conditions.

Key words: transport, cost, value, travel time

J.E.L. classification: L 83

1. Introduction

Transport services include both transport services for those which use an organized form of tourism, and services rendered to individuals traveling with their own means of transport (maintenance, repairs, gasoline bills granting lower prices, etc..). Therefore, about the level of development of transport and, especially, their organization depends the quality of tourism services and, therefore, the tourist traffic intensity.

Globally, according to studies conducted by the World Tourism Organisation, the period 2006-2008 is distinguished by a sustained development of international tourism receipts, and by increased revenue from tourist transport. However, the revenue

from this activity fell within the range analyzed by 16.8% to 14.7% of total revenue. This can be explained primarily by stronger growth in consumption of specific services, but also by the upward trend of the share of air transport (52% in 2008) of all types of tourist transport, as a result of increased competition and of transformation of low-cost airlines, in many cases, in direct competitors to traditional companies, which led to lower tariffs and thus, the share of transportation revenue.

2. Main categories of users of tourist transport

Tourist transport demand can come from three categories of users, and space for transport can be defined as the area of public and private transport access (including parking spaces, the spaces for cycling and pedestrian):

A. tourists, who can use specialized transport or not;

B. host community: area residents that are directly involved in the tourism industry, and have access to the same transport system as well as tourists and tourism employees;

C. employees in the tourism industry, which may come from the host community or from other regions or areas of the country or even from other countries; they may have special transportation needs because of the unconventional working hours.

For developing the tourist traffic people can rely on a variety of means of transportation: often the movement of tourists requires the combined use of several means of transport, depending on distance to destination, the itinerary features, the condition of communication and their technical infrastructure, the intensity and

seasonality of tourist traffic, the competitiveness of the prices charged for different forms of transport, speed and convenience of travel, etc.

Between the development of tourism and transport industry it is a good relationship: the growth of tourist traffic, and the emergence of various forms of tourism depends on the degree of development of transport and, consequently, the opportunities offered to tourists for the efficient, time and space the various means of transport.

3. Essential requirements for tourist transport

Looking at transport as a constituent and as a prerequisite of conducting business travel, it comes several essential requirements for shipments of interest:

- to ensure the safe, regular and comfortable travel for tourists, the number and the time limit, until the desired destination;
- it is important for travelers, and thanks to the tourism industry as the price of transport to remain as stable as possible;
- rational use of transport capacity, both for the needs of international tourism and domestic tourism and tourist activity during low (low season) the transmission capacity can be more wisely directed and other necessities to cover the national economy.

4. Place of transport services in the tourist arrangements

An important element relates to the relatively high share of transport services in the travel arrangements. In this regard, it is necessary to ensure the correspondence between content services and price levels, as well as their stability or in some cases, facilities / discounts during the low tourist activity. Cost reduction should not be made by reducing service quality, but through a rational use of transport capacity and advanced correspondence between the different modes of transport. Being a sensitive scientific and technical upgrades, improvements are expressed by increasing speed, the comfort, size, capacity, etc. means.

Domestic and international tourism can not thrive today without transport. As a crative element of tourism, transport, and it determines the volume of tourist traffic to its characteristic features prints.

Transport development pace is faster than other factors that influence domestic and international tourism, as, for example, hospitality, etc.. This explains the efforts to encourage companies to transport providers in the development of the material of interest. However, tourist transport is primarily quantified through time (ie the number of hours / days as a share of total travel time) and cost (or revenue).

5. Factors influencing the selection of means of transport

Among the most important factors influencing the selection of means of transport include: time, cost, distance, travel comfort. The total time of a tourist holiday can be decomposed into two components: transmission time (travel) and time of stay. This tourist is interested in rapid journeys, so with a minimum expenditure of time.

Increases in tourist traffic, the problem of achieving rapid transport occupies a special, first, the idea of superior quality to meet the travel needs for a growing number of tourists and, secondly, the effective exploitation of resources transport. Reduce travel time appears as a necessity and due to other tendencies in the development of tourist traffic that is increasing interest in traveling long distances and very long. Optimization of time-distance relationship is an essential element in sizing activity in the transport sphere, the main criterion for assessing the effectiveness and role in tourism development.

The trips must be taken into account the need to associate attributes quickly and conveniently. **Comfort** is an important aspect of tourist interest in stimulating movements, increasingly, tourists want to have, during the voyage, all the conveniences of modern civilization. Aims to offer comfort conditions inside the vehicles (the possibility of rest, relaxation, dining), but other elements of travel arrangements, such as providing transportation from the station to your accommodation destination and vice versa, transfer between different modes of transport,

carrying out additional operations (baggage transport, guide services), developing smoothly, even when the combined use of several types of vehicles. Poor quality of transport services and lack of amenities for tourism development act as brakes. However, during the visit is an important element in the decision to vacation in the option for a specific purpose, especially in international tourism.

Table 1.1. *Tendences in Transport Time Valuation*

Name	Description	Implications
Travel Time	Any time devoted to travel.	This is the least specific definition.
Clock Time	Travel time measured objectively.	This is how time is usually quantified.
Perceived Time	Travel time as experienced by users, which can vary greatly from clock time.	This reflects traveler comfort.
Paid (also called On-the-Clock or commercial)	When workers are paid for their travel time(for deliveries, traveling to worksites etc.).	This type of travel tends to have a relatively high value per hour.
Personal Travel Time	Time devoted to personal travel (commuting, errands, etc.).	This is the largest category of time value in most economic studies.
Generalized Costs	Combined travel time and financial costs.	This is how travel time is incorporated into traffic models.
Effective Speed	Total time devoted to travel and paying for transport equipment and services.	Higher costs for more expensive modes.

Source: www.climatechange.gov.au

Another problem of the relationship is underlined by the tourism and transport costs influence. Transport, as a tourism service, is not only the possibility of access to tourist

consumption, but also an important component of it.

Constituent part of the overall price of the holiday, with weights ranging between ¼ and ½ of the total, according to the type of tourism, transport type, the means used, season, distance from the place of origin and destination of tourists, the fuel market situation, etc., directly influences the cost of transport services and, in a great proportion, the general level of prices and indirect demand for vacation travel.

Thus, scientists have defined the value of travel time (VTT The Value of Travel Time) as the cost of time spent on transport, plus the waiting time of travel. Also, the reduction of travel time (The Value of Travel Time Savings VTTS) is the element that refers to the benefits obtained by reducing this time¹.

Time spent in travel is one of the most representative categories of transport costs, reduce it constituted an important benefit of transportation projects in the area (such as highways, transit facilities upgrading etc.). Factors such as passenger comfort or safety of travel can be quantified by adjusting the cost of travel time.

One can appreciate that time is an objective assessment of physical, cognitive unlike during which defines the way in which passengers travel experience (table nr.1.1.). Paid time costs are calculated according to the physical time, personal time and travel costs are calculated on the basis of cognitive time. Generalized costs and financial costs of incorporating the amount of time and the actual speed (also called social speed) refers to the total speed of travel, which includes both time spent in travel, but not for maintenance of vehicles and the value of travel expenses.

Costs of travel time can vary from one segment to another in the journey. Thus, walking to the bus station, waiting for the bus, traveling with a crowded bus or with the number of passengers is less than the seating means of travel segments which are treated separately in terms of cost.

Total travel time costs are dependent not least and passenger needs and preferences.

¹ Les Lumsdon, Stephen J. Page, *Tourism and Transport. Issues and Agenda for the New Millennium*, Elsevier Ltd, UK, 2004, p. 57.

Therefore, a plane trip usually involves a trip costs differ from the same route by train or other means of transport. It should be noted also that the uncertainty related to the journey of unexpected delays, cancellations, etc. scheduled flights. is always a factor in the additional cost and risk occurrence.

Numerous studies in recent years have quantified the costs of travel time per unit and the reduction of travel time, cost analysis based on the activity itself, a survey among passengers and measuring the behavioral responses of travelers, are reported in conventional units as: time and money.

6. Elements of travel time value

Consequently, the value of travel time elements can be grouped into categories in cost, time (duration), convenience, consumer preferences, encompassing both objective and subjective perception generated by passengers on various aspects of the trip:

A. The costs of travel

- **Business Costs**, including salaries and benefits driver / pilot / conductor etc.. time and amount of use of the transposed transport costs, reflecting the efficient use of the properties and ability to meet a predetermined schedule;

- **Travel Time Costs**, which are experiencing a trend proportional to individual income, so they are low in children and people without jobs and higher income for those who have a certain, well, they increase with variability and uncertainty of arrival at destination, and are especially high when unexpected delays in the activities with strict schedules, moreover, they are lower for the first segment of the movement, with an increasing trend as the journey time exceeds a certain limit;

- **Means of Travel Costs** (conditions pleasant walking, cycling or expectation may be positive or very low cost, while in bad conditions, costs can be 2-3 times higher).

B. Travel Time

- personal travel time is estimated as having a weighting of 25% -50% of total travel, but may vary depending on the type, the passenger or to the conduct of transport;

- between the physical time measured during cognitive and non-synchronization is often essential, which has the effect of congestion, discomfort and insecurity;

- in some cases, the journey may be associated with lower costs or a positive value, where passengers enjoy the experience itself and are not bound by a strict schedule (any cruise or special train journeys);

C. Travel Preferences can vary:

- journey time;

- the means used;

- Age and experience of tourists (some tourists associated higher costs of time spent in transit, while others believe that the time spent Sofandi is the most expensive).

7. Conclusions

With a complex and dependent on many factors (global market for fuels, infrastructure development, etc..) costs of transport have registered a decline over time, which was reflected in an increase in tourist traffic. Given the nature of the relationship between the two phenomena, and reduction of transport cost on the basis of the overall tourism products - are constant concerns. In this respect, enforce several requirements: conducting a rigorous correlation between price and quality of services (thereby reducing costs must be the result of technical progress, improving organization, rational use of resources rather than quantitative or qualitative reduction of services), ensuring A wide range of prices to levels appropriate for all potential customers and facilities of a system depending on the time, distance, group of tourists.

Therefore the premises creates a wider accessibility, and on this basis is stimulated tourist traffic.

The Financial Statements, Synthesis of the Compromise between the Accuracy of Enterprise Activities and the Handling of Accounting Information's

Gheorghe Dumitru

"Spiru Haret" University of Constanța, Faculty of Financial Accountancy Management
dumitru.gheorghe@spiruharet.ro

Abstract

All information presented in financial statements must reflect accounting reality in order to satisfy the needs of many different users, among whom there may be conflicts of interest.

Conflicts of interest, together with loopholes in accountancy law, room for maneuver in the creation of accountancy policies, and an accountant's freedom to choose his methods, can lead to managers massaging figures by exploiting so-called creative accounting techniques. The practice of creative accounting for the manipulation of final profit figures is known as outcome management.

These creative accountancy procedures may be restricted through international standardization as well as through the International's Accounting Standards Board (IASB) initiative, which seeks to reduce the number of alternative interpretations and introduce more rigid standards and increased uniformity to accountancy procedures.

Key words: financial statements, information users, accounting reality, creative accounting, outcome management.

J.E.L. classification: M

1. The need for global standardization in financial reporting

Financial accountancy began in Europe from the second half of the 17th century; the earliest known accounting system was launched in France in 1673, where the government introduced an annual audit,

based on true market values, to protect the economy from collapse.

From the 19th century, as a consequence of the industrial revolution, a large concentrated capital investment was required for a number of industrial projects (initially canals and railways), the risk for which was to be shared amongst many investors. In this context, the financial report represented a method of monitoring the activities of component businesses, and keeping shareholders informed regarding the ongoing administration of their investment.

The second half of the 20th century has been characterized by major changes in accountancy regulations. In the context of the powerful tendency towards an international capital market and the appearance of diverse regional accountancy regulatory bodies, representatives of the Institute of Chartered Accountants in England and Wales (ICAEW), and the American Institute of Certified Public Accountants (AICPA), launched the idea of creating an international organization to standardize accountancy, at the 1972 World Congress of Accountants. On the initiative of these two professional bodies, the International Accounting Standards Committee (IASC) came into being on 29 June 1973, in London.

According to its own documentation, the IASC's objectives were:

- To create and publish, in the public interest, accountancy standards to serve as a basis for the presentation of financial statements, and to encourage economic players, at an international level, to accept and respect these standards.
- To conduct business activities with a view to improving and harmonising legislation, accountancy standards, and

procedures relating to the presentation of financial statements.

In order to achieve these objectives, the IASC had by 2000 laid down 39 International Accountancy Standards and the framework for the preparation and presentation of financial statements, while the Standing Interpretations Committee (SIC) had released 17 interpretations of the International Accountancy Standards.

The organisational structure of the IASC as an international watchdog was until 2000 based on professional bodies.

The 1987 agreement between the IASC and the International Organization of Securities Commissions (IOSCO) aimed to create a set of core standards to serve as the minimum requirement imposed by all stock exchanges, this led to the reorganisation of the IASC's structure, in view of the fact that it was to become the recognised regulatory body of the world securities market

After the IASC Council's approval of these recommendations for reorganisation, IOSCO's adoption of IASC standards in May 2000, and the European Commission's announcement in June 2000 that it was to adopt IAS as a requirement for primary evaluation of all EU stock exchanges, IASC members voted in July of the same year to abandon the old structure based on professional bodies, and to adopt a new structure in which standards would be created by a professional council.

In April 2001 the International Accounting Standards Board (IASB) opened for business, its objectives being:

- To develop a single set of high quality universal accountancy standards in the public interest, which are understandable, applicable, and which impose high standards of quality upon information. This should in turn be transparent and comparable in all financial statements and reports, in order to support the economic decisions of participants in the world's capital markets, and other information users
- To promote the use and rigorous application of those standards
- To work proactively with national standards developers, in order to achieve the convergence of national accountancy standards with International Standards of Financial

Reporting, building high quality solutions.

The IASB meets its targets primarily through the creation and publication of the International Financial Reporting Standards (IFRS) and through the promotion of the role of these standards in general financial statements as well as in other more extensive financial reports, with an end to reaching efficient and informed judgements.

International Financial Reporting Standards cover accountancy standards and the interpretation thereof, as approved by the IASB, and formalise the requirements of recognition, evaluation, presentation and description in connection with the important transactions and events characteristic of general financial statements. International Financial Reporting Standards are based on the *Framework* conceived by the former IASC, which tackled the fundamental concepts of information handled in general financial contexts, and consolidated a basis for professional judgements in the resolution of accountancy issues.

International Financial Reporting Standards are intended for general financial statements, as well as the financial reports of profit-making institutions in commerce, industry, financing etc., regardless of the organisational structure of the operation.

2. The interests of users of accounting information and objectivity of financial statements

The principal line of communication between businesses and end users of accountancy data is that of information published in annual financial reports.

Annual financial reports are generated from information provided by accountancy, by way of which the activities of a given business are presented in a manner which enables users to take decisions of economic importance.

Ever since the tendency towards globalisation began to strengthen, and corporate interests began to dominate national economies, accounting systems have been obliged to serve diverse group interests. A hierarchy of priorities has developed in the interests of meeting the information requirements of end users, as fast as accountancy itself has developed. Hence, in

Anglo-saxon countries, investors represent the priority category of user, while in continental Europe accountancy serves a wide range of users in which creditors, and primarily the state, represent the leading categories.

This hierarchy of accountancy information users has brought about the need for harmonisation of practice and procedures through international norms adopted by the majority of countries.

The IASC's *Framework for the Preparation and Presentation of Financial Statements*, envisaged by the IASB, presents the following categories of user: current and potential investors, employees, creditors, suppliers and other commercial creditors, clients, government and governmental institutions, and the general public. According to the position of these users relative to the business in question, they may be classed as *internal or external users*. *Internal users* are principally management personnel within the company. They have responsibility for information release systems, and therefore have access to supplementary information. External users fall into the other categories mentioned in the Framework; according to their authority, they may be able to dictate the nature of the information to which they are privy, as is very much the case with governmental institutions (particularly the fiscal authorities) and banks, while others may be unable to have any say regarding the type of information to which they may obtain access, since they lack the necessary authority.

The divergent interests of these users - clearly identifiable from the privileged status of certain categories among them (e.g. managers, fiscal authorities and banks) - derive from their position and power, and give rise to doubt regarding the objectivity of accountancy information provided by annual financial reports.

Conversely, specialist literature in the field refers to *agency theory*, which relates to the conflicts of interest between users of accountancy information.

An agency relationship comes into being when one party, known as the *principal*, entrusts management of their private assets to another party, known as the *agent*, who has competence and knowledge inaccessible to the principal. The most common form of

agency is that in which a manager operates on behalf of a shareholder.

The conflict of interest between managers and shareholders, regarding data, is clear; since shareholders are principals who have empowered managers to operate on their behalf in the capacity of agents, the manager alone enjoys access to certain supplementary information.

Conflicts of interest surface where managers' remuneration is dependant upon profit and they may tend to push rashly for increased profits, or where they seek to maximise their own benefits at the shareholder's expense, through activity of which the business owner is unaware; perhaps in the form of loans to third parties in which the manager has a vested interest.

In other respects, the manner in which a business generates and releases accountancy data may be reduced to the goodwill and scruples of those concerned; internal users may take decisions on the basis of the differing interests of the various users of their accountancy data – managers may intervene in the application of accountancy methods and policies in pursuit of their own interests, thus compromising the quality of accountancy information.

3. Handling accounting information

Accountancy is a tool serving to represent the operational activity of a company, and has at its core professional principles, norms and rationality. Ultimately, a company's financial reporting should consist in the assimilation and presentation of financial data in a way which should afford the end user a *faithful likeness* of the operation's activity, on the basis of *accounting reality*.

Accounting reality derives from a set of principles, evaluation points, rules, conventions and specific practices, and marks the central compromise between the interests of data producer, financial auditor, and end user of the data.

Regardless of the accuracy of this transposition of operational activity into accountancy information, it is nonetheless unavoidably susceptible to the manipulation of information which derives from the instinctive and human perversity of the business person and the conflicts of interest between the end users. Thus, financial reports

tend to shift from the ideal to the desirable, from the point of view of those preparing them, such that the existing principles, rules and conventions of accountancy are exploited for personal benefit.

Specialist literature in the field has presented a series of case studies in which the manipulation of accountancy data has led to large scale financial scandals, such as the case of American energy provider Enron, which went bankrupt in 2001 following the exposure of irregularities.

The manipulation of accountancy data in the interests of providing a desirable operational image, as managers would like, does not necessarily imply a disregard for norms and regulations of accountancy procedure. On the contrary, this objective is often achieved without breaching the accepted standards, through the use of so-called *creative accounting*.

The expression 'creative accounting' is of Anglo-saxon origin and presupposes the use of legal accountancy practices which permit the company to present the desired public image.

Thus defined, creative accounting may be distinguished from accountancy fraud, in which data manipulation breaches accountancy rules. Creative accounting is in its turn however, also unacceptable, despite the fact that it respects the norms and rules of accountancy, since its ultimate purpose is that of distorting the perceived financial position and performance figures of a company, in order to mislead investors and other categories of end user of the accountancy information.

The creativity of accounting depends in principle, on the gaps in accountancy legislation, and the subjective judgements of professional accountants, which are made in the context of accountancy norms.

This last aspect is covered by IASB's Framework for the Preparation and Presentation of Financial Statements, according to which: *thus when the application of a norm detracts from the final outcome, this norm may be disregarded in order to achieve the closest possible reflection of real circumstances. The basis for such a decision being taken shall always be that of rational professionalism.*

The evolution of creative accounting makes assessment of a business' real position

impossible, and seriously affects accounting reality through the manipulation of figures. Such practice is facilitated not only by the existence of loopholes in the rules, but also by the flexibility of the rules themselves, which permit a certain degree of methodological choice which may yet be exploited to transform financial statements in a manner favourable to management.

The most frequent creative accounting practices target profit figures in order to give an inflated impression of company performance. Such practices are referred to as *outcome management*.

According to specialist literature in the field, "outcome management" is the manipulation of accounts in order to create an inflated impression of company performance. The desire to reach or exceed the company's estimated average share price represents an incentive for outcome management.

Conditions which favour outcome management are diverse, but generally relate to a lack of internal controls or management experience, or complexity in transactions.

The most common outcome management techniques simply exploit the flexibility inherent in the framework of accountancy norms and regulations.

The primary outcome management techniques, which may be employed in order to fulfil the objectives in question are as follow:

- changes to repayment regimes
- changes to the useful life expectancy of frozen material assets with an end to depreciation
- changes to residual securities, with an end to depreciation
- establishing the likelihood of debt collection failure for irrecoverable monies or frozen debts
- identification of depreciated assets;
- estimates of probability regarding fulfilment of contracts
- estimates of commissions
- establishing the demand on stock, and the depreciation thereof

Of all of these, the first three, which relate to changes relating to depreciation, may be considered discretionary in nature. These interventions in matters of depreciation may result from the modification of conditions affecting productivity, durability, or the state

of the asset market in question, and represent an ongoing issue in the field of outcome management.

Extreme cases of outcome management involve false declarations, or the omission of significant data from financial declarations. Such actions, intended to manipulate the end users of accountancy data, fall into the category of accounting irregularities or fraudulent financial reporting. In order to identify such procedures as fraud, one must prove that false declarations have been made for personal gain. Such actions indicate an abuse of profit figures which goes beyond the limits of the flexibility inherent in the norms and regulations of accountancy, and shows up above all in sales figures, outgoings, capitalisation of costs and the reduction of value in accountable assets.

The failure to acknowledge sales income, or the creation of fictional incomes, are among the most commonly encountered examples of misuse of outcome management. Examples of the aggressive application of outcome management strategies include the holding open of balance sheets in order to continue registering sales-related incomes which rightfully belong in later financial periods, or the entry of incomes connected to nonexistent sales.

Other examples of outcome management misuse include the underevaluation of company expenditure, capitalisation of costs, and the reduction in value of accountable assets whereby data is principally manipulated through:

- capitalisation which fails to reflect true costs with interest
- underevaluation of assets in order to reduce property tax
- overevaluation of stocks
- underevaluation of commercial and financial discounts.

The detection of outcome management scams is very difficult. Strategic discussions with the company management and auditors offer the greatest possibility of detecting the more blatant cases of corporate outcome management.

According to specialist literature in the field, outcome management detection techniques may be formalised as follows:

- *Employment of trend analysis*, which involves the comparison of quarterly

profit margins and financial statements with those of the previous year, review of previous income and expenditure patterns, and the identification of significant changes in the last quarter

- *Probability-based examination of circumstances*, i.e. examination of unusual or rare transactions, verification of any unjustified changes in accountancy procedures, examination of any changes or adjustments made in the last quarter, changes in accountancy policies, a focus on areas open to professional judgement, verification of debt history, the age of stock holdings and outstanding payments
- *Analysis of annotations*, which implies reading those notes concerning accountancy policies and the evaluation of stocks, and comparing them with those of the year preceeding, examination of notes regarding pensions and other post-employment benefits in order to identify changes in policy
- *Analysis of the correlation between predicted and actual profits*, through examination of financial performance trends, checking of profits against average share price estimates
- *Incentive analysis (motivating factors)*, which involves analysis of the climate in which the company is operating, with a view to identifying factors and motives which might inspire management to manipulate figures or disguise final profits.

Literature in the field of outcome management offers differing opinions on the issue. Certain authors feel that outcome management is detrimental to users, and investors in particular, since it distorts financial performance figures, artificially boosts share prices, and encourages short-term decisions to the detriment of long term performance. Others hold the 'whitewashing' of figures, within reasonable limits and within the parameters of Generally Accepted Accounting Principles (GAAP), to be acceptable on the grounds that the resultant reduction in volatility brings a growth in benefits; the market perceives lower risks, and the share price tends towards stability. We argue the case for honest and transparent reporting of financial outcomes, regardless of the end user in receipt of this data.

It may be seen from the above presentation that changes in accounting methodology can lead to alternative perceptions of the financial position and performance of a business operation.

Room for manoeuvre in the formulation of accountancy policies, and the freedom of accountants to choose their methods, have been the source of controversy in many papers covering the topic of accounting reality.

Aside from this room for manoeuvre in the framework of generally accepted accounting practice, which permits producers of financial-accountancy information to manipulate profit figures and present a desirable image of their operations and performance, there is another issue. The existence of alternative accounting systems with differing agendas leads to large discrepancies in profit reporting, which companies may find themselves obliged to reconcile in order to conform to the rules of others' accounting systems.

4. Conclusions

Thus, in order to assert itself in international capital markets, a multinational company must align itself with multiple financial structures:

- one set of principles conforming to national regulations
- another set conforming to European accountancy norms, where the company is based in a non-EU country
- a third set corresponding to international accountancy norms
- an additional set corresponding to US – GAAP standards where the capital market is located in the USA.

In such a situation, the most important aspects of financial statements compiled by companies under national accountancy legislation must be reconciled with, and presented under, the other legislative frameworks in accordance with European, international, and US-GAAP accountancy norms. This has repercussions upon profit figures, the discrepancies among which must be reconciled. International financial communications must therefore overcome significant difficulties, hence the need for assimilation of all current accountancy methods into one coherent system, a process

which may only be achieved through the standardisation and harmonisation of accountancy and its procedures at an international level.

We recognise that in order to limit the effects of creative accounting and outcome management, the IASB must reduce the number of permitted alternative methods available, in order to ensure a true harmonisation of systems whilst creating stricter standards to bring greater uniformity to global and international accountancy and financial reporting.

Development of the Romanian Legal Framework in the Field of Consumer Protection in the Context of E.U. Integration

Gheorghiu Gabriela

Gheorghiu Liviu

Inspectorate of Border Police, Constanta County

Anghel Ion

„Spiru Haret” University of Constanta, Faculty of Law and Public Administration

Abstract

This paper aims to demonstrate that, in fact, building a coherent national system of consumer protection in Romanian domestic market was achieved mainly due to the process of accession to the European Union, to harmonize its system with that prevailing in Europe, and especially in context of the conditions for turning the Romanian economy into a functioning market economy, able to cope with competitive pressures within the European single market.

Romania is just at the beginning in terms of consumer protection, and therefore, it is natural that there will not be possible to do in a short time what in the old European Union Member States has naturally been done in decades, as a result of the action of market economy objective laws.

Key words: consumer protection policy, harmonization, obligation, consumer regulation

J.E.L. classification: D18, F15, O52

1. Introduction

Since Romania has manifested, in the post-communist period, a near constant interest for the European structures, materialized by signing the EU Association Agreement, the activity of our country regarding the consumer protection focused in the following years on the harmonization of national legislation with the valid one in the European area. To this end it was expressly provided the cooperation between the parties regarding the exchange of information and experts, the access to EU databases,

completed by training activities and technical activities.

2. Romanian Consumer Protection - assumed obligation in the EU accession process

Over time, the consumer protection legal framework developed in Romania - whose foundation was the Government Ordinance no. 21/1991 on consumer protection - has been improved to some extent, without ensuring the complete harmonization with the existing *acquis communautaire* during the operation changes.

The most frequent *criticisms* that have been made in this respect were related to the content analysis of its text that reveals, on the one hand, the predilection assertion of the state role to protect citizens as consumers, by providing the necessary legal framework for their protection, and on the other hand, the omission of two of the main consumer rights recognized in Europe - namely the right to be heard, in the sense of audience's interest for the consideration of the full goodwill of its interests in the process of developing and carrying out economic policies, and the right to appropriate education (the first right is not mentioned in any legislative provision adopted so far, while the second, although mentioned in Government Ordinance no. 21/199, it was not developed further).

To these rights can be added another one, also not covered by the fundamental legal framework of consumer protection system, namely the right to basic needs satisfaction by acquiring goods and services designed to ensure consumer survival. In addition, the right to a healthy environment, able to improve the quality of consumer life,

although not recognized in its favor as a distinct right, is stipulated by the Romania's Constitution, namely in the 2003 revised version, as the fundamental right of "everyone to a healthy and ecologically balanced environment" on which "individuals have the legal duty to protect and improve the environment" (art. 35 of the Constitution).

So, the legal framework on consumer protection can be blamed to be confined to the vision that the State protects and consumers are assisted. This view is supported by the fact that most legal acts relating to consumer protection developed directly or indirectly during 1992-2007 period were adopted by ordinances or decrees of the Government and not directly by the Romanian Parliament, which shows a strong involvement of central authorities in the process of Romanian consumer protection.

Process improvement and development of new normative acts designed to protect the Romanian consumer was marked, therefore, by numerous *deficiencies* related especially to:

- superficiality of political authorities in the adoption of laws that were amended or withdrawn at short time intervals;
- insufficient and sometimes even lack of collaboration between central public administration bodies on drafting legislation affecting the consumer, which endangered the harmonization of legal provisions or, worse, has led to their mutual infringement;
- lack of provisions, in some laws, on cooperation between state institutions and civil society structures or the limitation, where they exist, of their access to the decision-making process;
- the delay in adopting the *acquis communautaire* in key consumer protection areas, such as consumer credit, insurance policies, etc.

However, the warnings came from the European Union periodic monitoring reports on Romania's progress towards accession, fired a warning about the shortcomings of the national legislation, imposing the speed up of its harmonization with the *acquis communautaire*. As a result, the majority of European consumer protection directives have been transposed into national law only since 1999, although some dating back even before 1990, making it finally possible to

temporarily conclude the negotiations with the EU in this area in 2003, without any transitional arrangements for Romania.

Moreover, to meet the assumed obligations, significant changes in the legislative framework for consumer protection came into force on 1 January 2007 (Law no. 296/2004 on "Consumer Code" as amended by Laws no. 363/2005 and no. 456/2006), the official date of Romania's accession to the European Union, and aimed as *new elements*:

- extending for the first time, the existing rules in this area also on services, including financial ones;
- highlighting the importance of indirect consumer protection exercised by the state, by initiating special programs developed in collaboration with schools at all levels, with operators and independent consumer organizations, to ensure the appropriate information and education of Romanian consumer, in order to enable him to operate separately, for a fair choice of goods and services needed, and be familiar with his legal rights and responsibilities;
- recognizing two more rights for the Romanian consumer, namely to reject the conclusion of contracts which contain unfair terms according to legal provisions, and not to be prohibited by an operator to obtain a benefit expressly provided by law. It can be noted that there are not included among the rights recognized to the Romanian consumer, the one to his education in the spirit of self-protection against the purchase and consumption of products which could endanger his health and even his life, or the right of representation of its interests in the development and conduct of economic policies at local and central level;
- providing for the establishment of a National Consumer Institute, organized as a public institution of national interest, with legal personality, as a center for research, information and studies on consumption, whose revenue is secured from legal budgetary and extra budgetary sources. We note however that, unlike the situation in the EU Member States, where such institute is a nongovernmental entity, according to the Romanian legislator view, it is designed to be an authority of the state, which increase the involvement of central authority to control the consumer protection process.

However, although on the Romania's official accession to the European Union, January 1st, 2007, the *acquis communautaire* in the field of consumer protection had been entirely implemented at national level, *a thorough analysis of the Romanian legal framework currently applicable in the field reveals several differences, and even deficiencies, of how it reflects the requirements of the European Union.*

First of all, the reported difference between the provisions that make up the *acquis communautaire* in the field and the normative acts (mostly government ordinances) by which they were internally implemented lies in the fact that Romania has called on various occasions, like many other Member States, a minimum number of clauses or exceptions allowed by Community rules in force. For example, the valid national rules regarding consumer protection in the negotiation and conclusion of distance contracts (as in Greece and Italy) establish his right to terminate such contract in 10 days, although the minimum rules laid down by Community law to exercise that right is 7 working days

Also, the law on selling goods and the associated guarantees, as established by the Romanian legislature shall not apply to "second hand" goods sold at public auctions in which participation is allowed for individual consumers (other countries that have turned to the exceptions provided for in Community legislation are: Bulgaria, Estonia, Finland, France, Germany, Greece, Great Britain, Sweden and Hungary). Moreover, national rules on contracts concluded away from business premises does not apply, under the exceptions allowed by EU rules, to some contracts, such as: those for the total amount to be paid by the consumer is less than the equivalent in lei of 30 euros calculated at the current rate of National Bank of Romania; contracts for the construction, sale and lending of immovable property, and contracts containing other rights relating to such property; contracts for the supply of household products for families, delivered regularly by an official dealer; contracts based on a trader's catalog; insurance contracts; contracts on securities (to these minimal clauses have also turned countries like Bulgaria, Ireland and the UK).

In addition to the provisions of the *acquis communautaire* in the field, according to Romanian law, contracts concluded away from business premises must be completed in written form, and their content to include at least the complete identification of the contracting parties, the object and the contract price, and the date and place of its conclusion (the same requirements are set by the legislation valid in Belgium, Greece, Malta, Netherlands, Portugal and Spain). Most importantly, only in Romania exist an explicit clause specifying on the consumer's right to terminate the contract away from business premises, and it must be stipulated in the contract with capital letters and right next to the place reserved for signature of the consumer, along with the name and the address of the trader to the consumer may exercise this right.

Secondly, there are certain situations in which the Romanian legislature proceeded to extend the Community provisions, but in the context of its permitted limits, such as the legal norms regarding the contracts negotiated and concluded away from business premises, which also applies to contracts concluded during a visit to any place where consumer can be found, even temporarily, for reasons of work, study or treatment, when the visit does not occur at his express request (such extensions did other countries such as Denmark, Italy and Lithuania). Also, additionally to the provisions regarding the effects of the contract denunciation, the Romanian legislature exempts the consumer from any obligation, except that related to the return of the goods delivered (similar provisions are found in the Danish, Maltese, Polish, Portuguese and Slovak consumer protection law), situation in which the latter, within 15 days of receipt of communication on consumers' decisions to opt out of contract, it must reimburse all amounts paid and any expenses.

Last but not least, can be also reported certain deficiencies in the transposition of EU rules in domestic consumer law, such as, for example, contracts negotiated away from business premises, for which the deadline deadline for exercising the right of consumer to terminate such a contract begins to run even when the dealer failed to inform him of his right of termination or if the information

was incomplete or wrong, so he would not exercise such a right (this deficiency can be also seen in how they translated into national legislation the consumer protection european law other countries such as Bulgaria, Italy, Lithuania, Poland and Slovenia). In the latter case, the time required by the Romanian legislation for giving up a consumer contract is extended by 60 working days to the seven days counted otherwise.

This approach may be criticized because the consumer that is not informed about his right to opt out of such contract or is not notified in writing, but orally, on this right, is not sufficiently protected. Also, the consumer may not be aware of the alternative of giving up the contract nor within 60 days.

3. Conclusions

In the field of consumer protection, under legislative terms, Romania has achieved in general its obligations under the full membership of the European Union, situation that contributes to creating an enabling environment for the development of consumer confidence in carrying out transactions on the national market, especially since prior to the transposition of Community provisions, there was no specific legal framework in force on the trade relations that could establish between the manufacturer / retailer and consumer, except for a few provisions of the Civil Code, also valid, within certain limits, for individuals as consumers.

Although there are some differences, and even "slippage" of the Romanian legislation with the *acquis communautaire* in the field, they can not be blamed only our country, since similar examples can be found in the legislation of other countries, mostly new members of the European Union, from the former communist bloc, where the transition to a market economy was gradually and liberalization of national economies and their opening to foreign competition automatically entailing the need to protect the economic interests of consumers. However, this situation does not exonerate the Romanian legislator for any inconsistencies to the Community rules, but most often they are the result of a process of adaptation to national specificities and, above all, to a mentality of conscious and active consumer in full

training, and are allowed, moreover, under the terms of the minimum requirements of relevant Community legislation completed by the principle of subsidiarity

The Permanent Development of the Human Resources

Gherman Liliana - Victoria

*"Constantin Brancoveanu" University of Pitesti,
Faculty of Management Marketing in Economic Affairs Braila
liliana.gherman@yahoo.com*

Abstract

The development of the human resources is a process of enriching the knowledge and skills through learning, in order to obtain higher performance.

Professional training is an investment in the organization human resources with immediate effect and perspective.

The high quality of education and training are essential for Europe to be developed as a knowledge-based society.

Key words: human resources, objectives, knowledge, performance, responsibility.

J.E.L classification: O15.

Generally, the human resources management is a responsibility shared between the line managers and the human resources specialists.

The specialists consider that the human resources have an important role in society, but also at a company level. [1]

In very small organizations, the owner is usually both the line manager and the human resources specialist. The person involved handles all or the majority of the human resources management activities. As the company grows, a human resources manager is assigned to take over most of the responsibilities. As growth continues, additional staff positions are added if needed.

Specific human resources management activities are designated to those who are in the proper position to perform them. The human resources planning and the job analysis are usually elaborated by the human resources specialists with input from the line managers. Also, the recruiting and selection process are generally handled by experts team, although the line managers are involved in the hiring decisions.

Orientation programmes are usually assigned to the human resources specialists and the orientation itself is carried out by

both the human resources specialists and the line managers.

The human resources development is a permanent process consisting in specific activities, as follows:

1. The human resources training with the aim to develop the key competences of the employees in order to be able to carry out the present and future specific job demand;

2. The careers management which means that the available jobs and the career strategy within an organization have to meet the career needs of the employees;

3. Organization development with the aim to ensure healthy relations between groups and to help them to anticipate, initiate and lead the change. The organization development means the implementation of a strategy and reorganization in order to deal with the accelerate rhythm of change.

Also, the human resources management takes into account the implementation of all activities related to the human resources procurement, training, motivation and retain in order to efficiently achieve the organization objectives and to satisfy the employees needs.

Today, the vision towards the human resources is totally different as it was several decades behind. So, it is mandatory for companies to change the own employees in a real strategic resource in order to face to a market which is becoming more competitive.

A company resists on a competitive market if the employees are transformed into a real strategically resource. [2]

Everyone knows that people are the most valuable and dynamic organization resource. A special attention it is needed to the employees in order to valorize their intellectual and physical potential, that is why the motivation, the employment procedure, the compensation, the professional training have to be included in the human resources procedure of the organization.

The professional training is situated in the middle of the changes and transition towards a knowledge-based economy and society. The main tool for an organization to meet the specific market demand is the human resources training. The professional training of the human resources is a planned process to improve the knowledge and the competences in order to achieve a specific level of performance in relation to the activities carried out³. During a professional training, the participants acquire theoretical and practical knowledge.

The human resources training should start with the staff induction process. An efficient staff induction can lead to a positive attitude towards the organizational culture and to obtain better results in a short period of time. The process has the aim to familiarize the employees with the new work conditions, the new team and to create a safety and confidential atmosphere. The specialists consider that the first six months are very important for the future achievements of the new employee. During this period of time, the employee realize if the new job meets his expectations and if the relations with the rest of the organization members make him to believe that is a part of the team. After this stage, the training of the employee follows other steps taking into consideration the employee level of knowledge and the organization training strategy.

The training need can be characterized as a gap between the actual situation and the desired standard, in other words between the present and the future. This gap can be removed/reduced using the training activities. [2]. This gap can be determined by the employee level of training, the organization development strategy (the development/downturn, the reorganization, the increase number of posts), the external factors (changes in the fiscal policy, rules in the activities organization, the technologies development, etc.).

The identification of the training needs must be seen as a necessary step in order to establish a training plan for the organization employees.

Compensation systems (including the benefits) are mostly often developed and implemented by the human resources management team. However, the line managers are those who recommend the salary increase and the promotions. The training and development activities are usually the connected responsibility of the

human resources specialists and the line managers. The performances evaluation is the responsibility of the line managers, although the human resources staff is likely to design the company evaluation system.

The human resources planning refers to the strategies development with the main objective to meet the future human resources needs. The starting point for this planning is the organization's overall strategic plan. The human resources specialists must determine whether the human resources needs are satisfied, they must forecast the supply of human resources within the firm. Finally, they have to take the steps in order match the supply side with the demand side.

The human resources strategy of the most European organizations provides training and development activities to improve the employees' skills and abilities.

These activities are usually differentiated as follows:

- training is a learning process for the operational or technical staff in order to carry out their jobs as efficiently can be;
- development is the retraining process of the line or middle managers or other employees from various organizational structures to assume increased responsibilities in both present and future positions.

The training and development are needed to increase the personal and organizational performances.

Generally, the employees want to improve their performances and compensation. The training and development are important aspects of the human resources management.

The competitive companies make great investments in training and development. These activities involve costs, therefore, the responsible managers should evaluate those efforts periodically.

At the end of the training period, the evaluators will measure the output of the trained employees. The results of the training evaluations should be made known to all those involve in the program – including trainees and upper management. For trainees, the results or evaluations can enhance motivation and learning. For upper management, the results may be the basis for taking decisions on the training program itself.

As a rule, in most of the companies, the performance evaluation represents the organization current evaluation and allow to

the managers to take objective decisions concerning the human resources. On the other hand, the performance evaluation provides an effective basis for distributing rewards such as: salaries raise and promotions. Also, performance evaluation helps the organization to monitor the employee selection, training and development activities.

If a high number of employees still register lower performances comparative with the expectations, the human resources selection process must be revised, or an additional training and career development program may be required.

The results should be discussed with the employee after the evaluation process is completed. The managers should explain the basis for the present reward and should let the employee know what he or she can do to be recognized as a better performer in the future.

The specialists in the human resources management analyzes the influence of the human resources management applied in the United States of America towards the European human resources practices.

As regards the characteristics of the American human resources management comparative with the European management, it is obvious that the USA is characterized by a low level of state interference and a stronger emphasize on individualism. Contrary, in Europe, the State and the European Agencies are very much involved and there is a huge organizational and managerial responsibility towards the employees. Also, the trade unions have a high social legitimacy in Europe compared to the USA.

Nevertheless, due to the cultural and institutional differences of the European Countries it is difficult to define a common Human Resources Management model in Europe.

Although, some European countries go to a directional convergence (whether countries share the same trend), the final convergence (whether countries are becoming more alike) is still far from being achieved. As a result, it should be assumed that neither the American human resources practices will significantly influence the European Human Resources Management nor that Europe will lead towards the convergence of a common model in the future. Countries will continue to be different in their human resources practices due to their unique cultural and institutional framework.

The human resources development is one the strategic option of the organization interested in its expansion. The organization capacity to adapt to the environment changes, to grow, depends in a great measure of the way in which the organization selects the employees, trains them, leads them taking into account their aspirations and potential.

The careers management or the human potential development within an enterprise points out the achievement of the best balance between the staff needs, expectations concerning the work, the potential and aspirations.

To set up a human resources development programme must be considered as an investment for the enterprise, the future results being measured in terms of labor productivity, improvement of the social climate, increase of the personnel stability, increase of the working efficiency.

The management of the employees careers must start from knowing these development steps and specific needs which in the same time are very different from one person to another. As a result, the elaboration and implementation of the careers development plan for the employees will have as a fundament an employee evaluation programme capable to offer a clear image of their potential and performances. Taking into consideration the evaluation results, the human resources development plans will be distinctive for each employee in close relation with the future company needs in the workforce field.

The long-life learning is a necessity and a solution for the actual changes from different activity fields of the contemporary society. One of the important characteristics is the rapidity of these changes comparative with the last decades when the social changes were characterized by a rhythm which assured a normal, slow, progressive development of values, things and ideas, people being able to easily adapt to the less or more constant life conditions. But, today, everything happens so rapidly then the people must go on this road of changes many time during the lifetime (jobs which disappeared or which were entirely transformed, appearance of new jobs, socials movements etc.)

The accelerate rhythm of globalization will also influence the labor force. It will increase the number of persons who will have to follow a long-life programme in order to comply with this situation, the educational system having the responsibly to answer to the changes on the labor force at international level.

It is the moment to „retrain” the labor force, a necessity which is becoming an essential job characteristic influencing the diversity and the flexibility of the educational services. The content of the educational offer, of the curricula is determined by the organizational interests, but also the participants who have the chance to choose what they want to learn. At this age, learning is related to the adult occupation, his job, the long-life learning becoming a vital component of a global competition.

All employees need to acquire and continually update their knowledge, skills and competences through lifelong learning, and the specific needs of those at risk of social exclusion need to be taken into account. This will help to raise labor force participation and increase economic growth, while ensuring social cohesion.

Any employee, organization or company must to engage into competition of the 21st century, must invest energy in the elaboration of a culture based on team, named culture of the success. [4]

These considerations are highly relevant to the EU's current reflection on the future development of the European social model. Europe is facing enormous socio-economic and demographic challenges associated, in particular, with an ageing population, high numbers of low-skilled adults and high rates of youth unemployment.

Nationally, reforms are moving forward. Many countries have established, or are establishing, their own targets that relate, to varying degrees, to the reference levels of average European performance for education and training.

Since 2000, as far as total investment in key sectors of the knowledge-economy is concerned, the gap has not narrowed between Europe and competitor countries such as the United States. What is more, some Asian countries, such as China and India, are catching up fast.

Nonetheless, public spending on education as a percentage of GDP is increasing in nearly all EU countries.

As regards lifelong learning strategies, many - but by no means all - countries have now developed policy statements, such as strategy documents or national action plans. Others have put in place framework legislation.

Too little attention is paid and too few financial resources are allocated to increasing access to adult learning opportunities. Older workers, whose numbers are set to increase by around 14 million by 2030, and the low-

skilled are particularly affected.

As for the reforms of higher education and vocational training, funding remains a key challenge and an obstacle to implementing the modernizations agenda for many countries.

Strengthening collaboration between higher education and industry is recognized by most countries as a basic requirement for innovation and increased competitiveness, but too few have a comprehensive approach to this issue. Part of the problem is that national innovation strategies too often do not incorporate higher education reforms.

Most countries concentrate on target populations in this context, in particular on young people, as vocational education and training programmes have a positive effect on reducing dropout rates. On the other hand, too low a priority is still placed on adults and older workers.

The professional development of vocational teachers and trainers also remains a real challenge for most countries.

With regard to the European dimension in the national systems, all countries consider it important to increase participation in mobility in education and training. However, despite some promising initiatives, for example as concerns quality of mobility, the national strategies are not enough.

Member States should in particular ensure that:

- education and training have a central position in the national Lisbon reform programmes, in the national strategic reference framework for the Structural Funds, and in the national strategies on social protection and social inclusion;

- mechanisms for coordinating the implementation of the work programme at national level are in place in all countries, involving the different Ministries concerned and the main stakeholders, especially the social partners;

- national targets and indicators should be further developed, taking account of these European references;

- the evaluation of policies is improved, to enable progress to be better monitored, and to create a culture of evaluation, making full use of research results. The development of high-quality statistical instruments and infrastructure is therefore indispensable;

- the various European agreements adopted in the context of the work programme are used as important reference points when designing national reforms.

The process of human resources development must be a permanent preoccupation both employees and employer.

The Relationship Between Productivity and Relative Prices in Romania (Balassa-Samuelson Internal Mechanism)

Ghiba Nicolae

"Alexandru Ioan Cuza" University of Iași, Doctoral School of Economics

ghiba.nicolae@yahoo.com

Abstract

During the catching-up process with the developed European countries, industrial productivity increased with higher rates than in services sector. The aim of the present paper is to test the influence of a growing productivity on relative prices as internal mechanism of Balassa-Samuelson Model. In reaching our purpose we used VEC methodology. Finally, we found a long-run relationship between variables and a weakly connection in the short-run.

Key words: Balassa-Samuelson internal mechanism, VEC model, productivity differential, relative prices

J.E.L. classification: F31,C32,E31

1. Introduction

In the last years, Romania witnessed a significant productivity increase, especially in industrial sector. A higher productivity rate in tradable economic sector against non-tradable sector generates a growing inflation and appreciation of local currency. These influences are known as Balassa-Samuelson Effect.

Balassa-Samuelson Model implies the following conditions:

- Labor productivity growth determines a higher relative prices ratio (internal mechanism);
- A faster productivity growth in Romania against the Eurozone leads to a higher relative prices ratio differential and therefore to an appreciation of exchange rate between euro and Romanian leu.

Testing the first condition involves checking for a positive relationship between labor productivity and relative prices. We'll use a VEC model to test the relationship between variables in short and long run.

2. Data description and methodology

We choose the Eurozone as benchmark, based on the followings:

- Euro is the reference currency since 2003;
- Exports to euro area represent almost 55% from total volume of Romania (74% are directed to European Union member states);
- Romania has already announced its intention to adopt the single currency in 2015;
- Most prices are euro denominated.

If over 10% of economic sector output is oriented to exports, we say that sector is tradable [4]. In Romania, the tradable sector is represented by industry, especially manufacturing, as we can observe from the following proportions of goods destined to exports for period between January 2010 – September 2010 (the main groups of products): machinery, mechanical appliances and electrical equipment (27%), vehicles (12%), textiles, leather, footwear (12%), metal products (12%), furniture, construction materials (10%), chemical and plastics (9%), food products (9%), mineral products (6%). The non-tradable sector includes activities that are not destined for international exchanges: transport and storage, post and telecommunication, trade, hotels, restaurants, financial activities, real estate transactions, renting, public administration, education, health and social assistance [6].

Given all that, we'll use as proxy for the relative prices the ratio between services and industry prices. Based on Eurostat data, we'll use as price index for Romania a fixed basis index for both sectors (I2005=100): tradable and non-tradable.

According to Dumitru [1], the productivity for both sectors can be calculated as ratio between gross value added and the number of employees for each case.

We use a VAR methodology for explaining the relationship between productivity differential (the difference between productivity in manufacturing and services) and relative prices (ratio between non-tradable and tradable sector). After testing variables stationarity, we'll proceed to a Vector Error Correction (VEC) if the variables are cointegrated. Finally, we'll find out if relative prices respond to a growing productivity in industrial sector. According to Balassa-Samuelson model, growing labor productivity in industry should lead to a higher value of relative price ratio [2].

3. Productivity and relative prices characteristics in Romania

The productivity, as ratio between gross value added and number of employees is higher in manufacturing than in services sector.

Figure 1. Productivity evolution of the Romanian economic sectors in 2003-2010 period (fixed base index, quarterly series)

Source: authorial calculation

Figure 1 shows a higher value of productivity in industry than in services. Since wages tend to be the same in both sectors, the employees will request bigger ones. Therefore, price increase in non-tradable area in order to cover the increased wages that aren't based on productivity.

In the last years, inflation level in industry was higher than in services sector.

Figure 2. Romanian price indices in industry and services for 2003-2010 period (fixed base index, quarterly series)

Source: [7]

Figure 2 shows higher growth rates in manufacturing sector than in services sector. Productivity growth in manufacturing leads to wage increases in both sectors and consequently, to price increases, in order to keep the same profit margins.

Figure 3. Relative prices in 2003-2010 period (fixed base index, quarterly series)

Source: authorial calculation

According to figure 3, relative prices have been higher in the last years, due to a bigger productivity in manufacturing.

4. Econometric analysis

In 1997, Engle and Granger identified a causal unidirectional or bi-directional relationship between variables, known as Granger Causality. They point out this causality for the cointegrated variables. Also, they found an Error Correction Model representation for the cointegrated variables. However, in practice, Johansen-Julesius methodology is preferred because:

- a change in the direction of regression may lead to wrong conclusions;
- difficulties in working with more than two cointegrating vectors in the case of multivariate analysis;
- it is a procedure with two steps and, therefore the series generated in the first step are used in the second.

We'll test the cointegration using Johansen procedure. Therefore, we'll estimate the relationship between productivity differential and relative prices using a VEC methodology. VEC is a special type of restricted VAR which can correct a disequilibrium that may affect the entire system. In order to remove heteroscedasticity problems from the model, both series are expressed in natural logarithm.

In the beginning, we verify both variables in order to assess their stationarity (a series is stationary if its mean and variance are constant). If stationary, a shock is temporarily and it is absorbed over time. Causality tests are considered sensitive to the characteristic of stationarity. Most of the series are non-stationary. Stationary series can be verified using Augmented Dickey-Fuller (ADF) and Phillips-Perron (PP) tests. The null hypothesis that will be tested, refers to a unit root presence. If the probability is over the classical relevance threshold of 5% (of be wrong in our presumption) the series has a unit root (is non-stationary). Test results are reflected in the table no. 1.

Table 1. ADF and PP stationarity test

Variables	ADF (<i>t</i> -statistic, [prob.])	PP (<i>t</i> -statistic, [prob.])
Productivity differential (natural logarithm)	1.988038 [0.9997]	-1.372119 [0.5824]
Productivity differential in first difference	-1.299294 [0.6110]	-8.235511 [0.0000]
Relative prices (natural logarithm)	-1.449834 [0.5451]	-1.449834 [0.5451]
Relative prices in first difference	-5.517583 [0.0001]	-5.580444 [0.0001]

Source: authorial calculation

Phillips-Perron stationarity test shows that both series are first order integrated with a unit root. If both variables are cointegrated, we use a Vector Error Correction (VEC) model, a special case of multivariate models of first difference (for that series which are level stationary and non-cointegrated we use a VAR test).

Table 2. Cointegration test for all possible assumptions

Data Trend:	None	None	Linear	Linear	Quadratic
Test Type	No Intercept	Intercept	Intercept	Intercept	Intercept
	No Trend	No Trend	No Trend	Trend	Trend
Trace	0	0	0	1	1
Max-Eig	0	0	0	1	1

Source: authorial calculation

According to table 2, for two of the five assumptions we found long-run relationship between variables.

Based on stationarity and cointegration tests, we use a VEC model to explain the relationship nature between variables. General equation for a VEC model with lag intervals '1 1' is:

$$D(Y_{g,t}) = A(g,1) * Coitg +$$

$$\sum_{k=1}^G C(g, k) * D(Y_{g,t-1}) + C(g, G + 1) + \mu_{g,t} \quad (1)$$

In order to study the connections in the short run between productivity differential and relative prices we'll perform a Granger causality test. The obtained results are reflected in table 2:

Table 3. Granger causality between variables

Dependent variable: D(L_PR_RO)			
Excluded	Chi-sq	df	Prob.
D(L_DIFERENTIAL_PROD_R)	3.636403	1	0.0565
All	3.636403	1	0.0565

Source: authorial calculation

According to table 2, the null hypothesis is rejected (probability is higher than 5%). Thus productivity differential is a Granger causality of relative prices in short run. However, the causality between variables is not strong.

The VEC Model results are presented in table 3:

Table 4. Productivity differential influence on relative prices in Romania using a VEC model

Cointegrating Eq:	CointEq1
L_PR_RO(-1)	1
L_DIFERENTIAL_PROD_R(-1)	-0.077172 -0.02887 [-2.67312]
C	0.021501
Error Correction:	D(L_PR_RO)
CointEq1	-0.187656 -0.08701 [-2.15668]
D(L_PR_RO(-1))	-0.001876 -0.20316 [-0.00923]
D(L_DIFERENTIAL_PROD_R(-1))	-0.01732 -0.00908 [-1.90694]
C	0.001901- 0.00278 [0.68340]

Source: authorial calculation

The relationship representation between variables according VEC is reflected in equation 2:

$$D(L_PR_RO) = - 0.19 * (L_PR_RO(-1) - 0.07 * L_DIFERENTIAL_PROD_R(-1) + 0.02) - 0.002* D(L_PR_RO(-1)) - 0.02* D(L_DIFERENTIAL_PROD_R(-1)) + 0.002. \quad (2)$$

Thus, productivity differential has a positive influence on relative prices.

If $|t_0| > 0$ or 1,96, the corresponding independent variable has a significant adjusted (partial) effect. The condition is verified for cointegration equation. Hence, relative prices are higher if productivity is increasing in industrial sector than in services sector. Considering the t-value, VEC model shows an insignificant relationship in the short run.

5. Conclusions

The present paper tests the relationship between productivity differential (the difference between productivity in industry and services) and relative prices (as ratio between non-tradable and tradable sectors). Our main conclusions are:

- the Eurozone is the most adequate benchmark for testing Balassa-Samuelson internal mechanism due the commercial, political and geographical connections between Romania and euro area;
- Romanian economy can be divided in two large sectors: tradable (industrial manufacturing) and non-tradable (services) using as criteria, their participation in international exchange;
- productivity can be properly reflected as ratio between gross value added and number of employees for each sector;
- our research found a higher productivity in the tradable than the non-tradable sector;
- in the short run the tradable sector productivity has a low influence on relative prices;
- using a VEC model we found a positive relationship between productivity and relative prices in long run.

As we highlighted above, Balassa-Samuelson internal mechanism is valid.

Credit Institutions – Actors on the Romanian Capital Market

Ghiță-Mitrescu Silvia

Duhnea Cristina

„Ovidius” University of Constanta, Faculty of Economic Sciences

silviamitrescu@yahoo.com

Abstract

Over a long period of time, it was thought that the banking sector and the capital market are two separate, constantly competing, components of a country's financial system. Lately though, this idea has been put aside and the direct involvement of the trust companies has increased on the capital market. After taking up the universal bank design for the organization of the capital market in Romania, credit institutions were granted access on the market as mediators. This particular paper's goal is to analyze the performances achieved by commercial banks functioning as intermediaries on the capital market in Romania in recent times.

Key words: credit institutions, financial intermediation, capital market.

J.E.L. classification: G10, G21

1. Introduction

No matter the way in which we define the capital market, as a component of the financial market or as a whole that integrates the financial market, it represents the place where the demand meets the supply through brokers.

The capital demand comes from entities in search for financial funding needed for carrying further with its activity or for investing in development (public and private companies, financial, banking and insurance institutions, public institutions, the government and local authorities, international financial and banking organizations). The capital offer comes from those entities holding financial funds exceeding their own needs and in search for a placement option that will bring future income.

Throughout time, economists have considered that commercial banks and the capital market represent two distinct segments of the financial system within a country and that they are in a constant competition to attract funds (Jacklin 1987, Diamond 1997, Allen and Gale 2002). Within the last few years it has been more clearly pointed out that the two systems coexist and are interconnected even. (Song and Thakor, 2010).

Several authors (Fama 1985, Diamond 1991, James 1987, Lummer and McConnell 1989, Best and Zhang 1993, Dahiya et.al. 2003) have emphasized the indirect role of banks on the capital market in respect to the dissemination of information concerning issuers. Thus, the privileged reports that the banks hand out to their clients grant the latter access to information regarding the financial situation of different companies. At second hand, capital market investors can orient based on the behavior banks display with regard to granting loans to companies for the investment in financial instruments.

Recently, banks have become directly active on the capital market, as issuers but also as investors and brokers.

2. Credit institutions acting on the Romanian capital market

The role of commercial banks on the Romanian capital market has increased sensibly over the last few years due to the modified legislative circumstances, as well as the attempts to expand their activity toward new sectors with the purpose of maintaining and increasing profits.

As exponents of capital demand, three of the commercial banks in Romania are presented in the capital market through the share offer listed in the 1st category of the Bucharest Stock Exchange: Transilvania Bank – since 15.10.1997; The Romanian

Bank for Development – since 15.01.2001; the Carpatica Commercial Bank – since 9.06.2004.

To these we can add the Erste Group Bank AG present in the international category since 14.02.2008.

The credit institutions' shares listed at the BSE are also support assets for derived financial instruments traded on the Sibiu Stock Exchange. In December 2008, BRD was admitted as participant on the derivatives regulated market at Sibiu, so becoming the first bank to trade on the Sibiu Exchange.

Currently there are 3 shares futures available for trading for credit institutions (BRD, Transilvania Bank, Erste Bank), 3 options on these futures and 2 CFD (BRD, Transilvania Bank).

As exponents of the capital offer, trade banks can acquire shares from commercial companies with non-bank object of activity, all the while respecting the regulations of the National Bank of Romania, regulations that do not allow the transgression of more than 20% of the issuer's social capital.

The defection from the principle of separation in 2002 in favor of the principle of the universal bank for the organization of the Romanian capital market, has allowed commercial banks to develop brokerage activities on the capital market.

The brokerage activity on the capital market is a countenance of the disintermediation tendency exhibited by the banking system, deployed by commercial banks in the BSE as well as Sibex, either through specialized departments, or through Financial Investment Services Societies, which are members of the banking groups.

At the BSE, in July 2011 there were 6 Romanian credit institutions acting as intermediaries, a credit institution and a branch of a credit institution from another state member of the EU and 3 FISSs members of a banking group (table no. 1).

Of all the credit institutions acting as intermediaries on the BSE, BRD recorded top trade values starting 2007 throughout the first semester of 2011 (data is available for this timeframe).(figure no 1)

On the segment of fund shares and holding units traded on the regulated market, BRD intermediated transactions, in the aforementioned time period, summing up to 2.121.965.986 Lei, representing market

listings with an annual growth, the highest point being in 2010 when the volume of intermediated transactions reached 661.110.078,65 Lei. Starting with 2009 BRD occupied the first position among mediators on the bonds segment, negotiating annual trades of 1 to 3 billion Lei. up to 2009 the first position in bonds operations was held by another credit institution, RBS Bank Romania, who in 2007 recorded a trade percentage of 79,18, respectively 29,31% in 2008.

First position on the two new segments of the BSE market, the structured, traded products on the regulated market and the alternative trading system, is occupied by another credit institution, BCR, who, in 2010,intermediated 46,18% of the trade value in structured products and 50,93% of the value of traded shares on the ATS market, respectively 40,26% and 47,65% in the first semester of 2011.

All this data leads us to the conclusion that credit institutions show a special interest in the expansion of their traditional activities toward new areas of the financial system and that these have the potential of becoming important pawns in the capital market game.

In respect to the role of mediator on the derived instruments market, in the short period of time since BSE introduced the futures products, two SSIFs members of a banking group and a loan institution have been active, with the following mediated trades values (table no.3)

Credit institutions and SSIFs members of banking groups are also present in the activity of intermediating derivatives trades on the Sibiu Exchange. One of the most active brokers at Sibex is BT Securities Cluj-Napoca, member of the Transilvania Bank financial group, of whose social capital the Transilvania Bank holds 95.5%, opposite to 75.4% which was recorded in 2001 (figure no.2).

In the period between 2005-2009, BT Securities was among the first 10 brokers at Sibex, the highest achieved intermediation volume being reached in 2006, with 722.857 contracts representing 16.93% of the total trades of the Stock Exchange. Since 2009 and until the first semester of 2011, the volume of realized intermediations dropped, a minimum was recorded in 2010(7.192 contracts representing 0,44% of the total). Even so, BT

Securities remains one of the most important brokers on the Sibiu Exchange, due to their accumulated experience and trust that they earned among investors.

The most important credit institutions acting as brokers on the Sibiu Exchange are, as in the case of the BSE, the Commercial Bank of Romania and the Romanian Bank for Development to which we add Piraeus Bank. These together with Romextterra finance, Unicredit CAIB Securities and Alpha Securities ,realized an average of 1,78% and 3.53% of the total volume of trades, in the period between 2006 and the first semester of 2011, as follows (figure no. 3).

BRD as well as BCR recorded maximum intermediated trades volumes in 2007, later having a decline in activity, a lot more visible in the case of BRD, who in 2008 intermediated 29.14% of the volume recorded in 2007, while BCR recorded a drop that was much slower up until 2010 when the intermediation volume reached 7.62% of the previous year's achievements. Unlike these two brokers, Piraeus Bank debuted on the Sibiu Exchange during a full financial crisis , increasing the volume of intermediations in 2009 31,4 times in relation to 2008, but ultimately finding the downward trend of the other analyzed banks.

3. Conclusion

We consider that the direct involvement of credit institutions on the capital market can be beneficial for both segments of the financial system. On the one hand the capital market can develop under the impulse of the involvement of the credit institutions as brokers because they command financial power but also a good reputation with investors. The double regulation and supervision of the banks' activities on the capital market by C.N.V.M. and B.N.R. is enough to increase stability and diminish the risks of a crisis being shared among systems. On the other hand, credit institutions can find new opportunities on the capital market to maintain profit and development in the context of the international disintermediation tendency.

We consider that commercial banks tend to become some of the most important actors on the Romanian capital market and that, at the moment; they hold all the necessary instruments to become the carriers of the development of the Romanian capital market.

Economic Versus Social - Economic Efficiency Assessment Criteria

Golea Pompiliu

Balogh Petru

petru_balogh@yahoo.com

Abstract

The paper aims to highlight the need to achieve a post-crisis economic growth that considers both economic and social objectives. Macro-economic efficiency assessment should be based on a set of indicators which quantify the positive and negative effects in developing appropriate strategies and policies.

Key words: Unpopularity index, Stability index, Inflation, Output-gap.

J.E.L. classification: E00

1. Romania's Overall Macroeconomic Coordinates

At the macroeconomic level any government advocates to achieve the following objectives:

- Achieve a sustainable economic growth;
- Inflation control and manage its relationship with GDP growth;
- Increase the degree of labor occupation, thus reducing unemployment at an optimal level;
- Establish the equilibrium between aggregate demand and aggregate supply.

It is known that in 2000-2008, Romania had achieved a Gross Domestic Product built on a basis that created further vulnerabilities. This created a relative wealth, but also hid the real current account deficit and thereby our economic inefficiency.

The evolution of macroeconomic indicators which will be analyzed are shown below:

Table no. 1 Evolution of GDP, unemployment rate and inflation rate in Romania during 2000-2010 – indices of the preceding %

Year	GDP- %	Unemploy- ment rate - %	Inflation rate - %
2000	2,4	10,50	40,70
2001	5,70	8,80	30,30
2002	5,10	8,40	17,80
2003	5,20	7,40	14,10
2004	6,20	6,30	9,30
2005	4,20	5,90	8,60
2006	7,90	5,20	4,87
2007	6,30	4,10	4,84
2008	7,30	4,40	6,30
2009	- 7,10	7,80	4,74
2010	-1,20	6,87	8,10

Source: National Bank of Romania, The Balance of payments.

The decrease in GDP in 2009-2010 to about 10% and the effects on social welfare has shown that development strategies and macroeconomic policies require taking into account all economic and social variables. We will review briefly two correlations.

A first correlation is between the **output gap** (the gap in GDP) and inflation.

Table no. 2 Evolution of output gap and inflation in Romania – indices of the preceding %

Year	GDP - %	Output-gap %	Inflation rate %
2000	2,4	-2,22	40,70
2001	5,70	-0,60	30,30
2002	5,10	-0,48	17,80
2003	5,20	-0,97	14,10
2004	6,20	1,04	9,30
2005	4,20	-1,09	8,60
2006	7,90	0,81	4,87
2007	6,30	2,17	4,84
2008	7,30	6,20	6,30
2009	- 7,10	-2,95	4,74
2010	-1,20	-3,92	8,10

Source: Statistical data from INSEE (National Statistical Institute)

Tests on the three macro variables of GDP, output gap and inflation rate, highlight the following:

- in 2000 – 2004: there is a trend of effective growth and we are witnessing an increase in the use of internal resources as a contribution to GDP; the disinflation in substance to attract foreign capital and currency appreciation is fast; in 2004 under the impulse of capital entry and to cover a domestic account deficit, we already have the first signs of excessive demand growth;

- in 2005 – 2007 we are witnessing an actual growth, except for a decrease in 2006, the excessive demand growth still has an increasing trend, but the inflation rate still has a lighter decrease trend;

- during 2007 – 2008 we have a new economic growth, but excessive demand increased substantially and therefore inflationary outbursts are introduced; actually the first signs of economic crisis appear in our country;

- 2009 – 2010 is the recession period and the time when the inflation rises.

We appreciate that sustainable growth should

be between 3-5% to close the output gap in 2014-2015.

We state that there is a need for a sustainable management of the disinflation process to minimize excessive demand deficit.

This year exports are intended to be the main economic growth engine, after that, it will give way to increasing domestic demand.

A **second correlation** is between the GDP and unemployment. We highlighted the intensity of this correlation using the statistical function Corell, in Excel, based on a statistical coefficient which is of the form:

$$r = \frac{n\sum x_i y_i - \sum x_i \sum y_i}{\sqrt{\left[n\sum x_i^2 - (\sum x_i)^2 \right] \left[n\sum y_i^2 - (\sum y_i)^2 \right]}}$$

We focused on the analysis of growth during 2000 – 2008.

Performing the calculations, results a correlation coefficient $r = -0.752$.

The data shows that between the two variables there is an inversely proportional relationship with an above average intensity. This indicator in conjunction with the previous correlation analysis reveals that the gross domestic product has grown primarily through the capitalization of imports of final consumer products.

Periods of crisis and recession and then again crisis must be the "purgatory" for a new economic model based on exploiting first the local resources.

However, still remains the problem of solving the contradiction between economic and social.

2. Evaluation Indicators of Economic Efficiency in Terms of Economic and Social Relationship

The recession that we hope to conclude soon, has generated many social disturbances, particularly in the form of unemployment. The basic problem that arises, in our opinion, would be solving the social side without sacrificing economic efficiency.

For a pro-domo plea to achieve this goal, we will use three indicators of economic performance that combines economic and social goals of macroeconomic policy.

Canadian Economists M. Parkin, L. Phaneuf

and R. Bade proposed three indicators – combinations between unemployment and inflation:

- a) Poverty index (I_S);
- b) Unpopularity index (I_{IP}),
- c) Index of stabilization policy (I_{ST}).

a) **Poverty index** (I_S) – is an economic performance index, calculated as the sum of unemployment (R_s) and inflation rate (R_i).

Calculation relation is as follows:

$$I_s = R_s + R_i$$

The following comments on the above relationship:

Poverty index shows how government management objectives have been met or not; the indicator give equal importance to the two rates, as follows:

- rising the unemployment rate leads to unsustainable GDP growth;
- increasing the rate of inflation affects exchange rate stability.

A decrease in inflation will lead to the existence of a lower real exchange rate:

$$CSr = \frac{1}{CSnom} \times \frac{Pmi}{Pme} < 1 \text{ where:}$$

CSr- real exchange rate; Csnom - nominal exchange rate; Pmi– the price of goods manufactured in the country; Pme – the price of goods manufactured abroad.

On short term between inflation and unemployment there is a relationship of balance: a lower unemployment can be achieved by a high inflation or inflation can be reduced by accepting higher unemployment. This relationship is called Philips curve.

However, Economists observations have shown that in the long term, under the impact of increasing prices of some basic products (such as petroleum products) the relationship is no longer valid.

b) Unpopularity index (I_{IP})

- the three above-mentioned economists have analyzed the unpopularity index established by R. Fair of Yale University:

$$I_{IP} = R_I - 3 \times R_{PIB}, \text{ where}$$

RPIB- growth rate of GDP

They compared the poverty index with this index and have established a link between the real GDP growth and unemployment.

In this way, the unpopularity index formula becomes:

$$I_{IP} = R_I + (9 \times R_s)$$

c) Index of stabilization policy (I_{ST})-

to determine this indicator, the above-mentioned economists have focused on the study of Okun's law:

$$R_{S+1} = R_s - 0,5(R_{PIB/t/t-1} - 3)$$

Unemployment in the current period will be higher or lower compared with the previous period, as the GDP will be higher or lower than the growth trend (3%).

Thereby, they established the following relation for the index of stabilization policy:

$$I_{ST} = R_I + (3 \times R_s)$$

The performed calculations give us the following results:

Table no. 3 Evolution of poverty, unpopularity and stabilization policy indexes in Romania - %

Year	I_s -%	I_{IP} -%	I_{ST} -%
2000	51,20	135,20	72,20
2001	39,10	109,50	56,70
2002	26,20	93,40	43,00
2003	21,50	80,70	36,30
2004	15,60	66,00	28,20
2005	14,50	61,70	26,30
2006	10,07	51,70	20,87
2007	8,94	41,74	17,14
2008	10,70	45,90	19,50
2009	12,54	74,94	28,14
2010	14,97	69,93	28,71

Source: Authors calculations based on INS (National Statistical Institute) statistics and National Bank of Romania.

It aims to reduce the values of these indices.

The evolution of GDP and the three indices is shown in the following figure:

Fig. no.1 Evolutions in GDP and the three indices in Romania during 2000-2010.

Source: Table no. 3

The graphics shows the evolution of the three indices in correlation with the evolution of GDP.

2000 – 2008 period is marked by a decrease of the three performance indicators in accordance with the Romanian economy. In 2009 and 2010, during the recession, the three indices increase in an inverse relationship with the gross domestic product. Romanian performance analysis shows a similar trend during the reviewed period.

It requires, in our opinion, a comparative analysis with the EU-15 countries, the core of today's European Union.

Table no. 4 Evolution of Gross Domestic Product, unemployment and inflation rates in the EU-15 between 2000–2010 – indices of the preceding %

Year	GD P-%	Unemployment rate -%	Inflation rate -%
2000	3,9	8,7	1,9
2001	2,0	8,5	2,2
2002	1,2	8,9	2,1
2003	1,3	9,0	2,0
2004	2,5	9,1	2,0
2005	2,0	8,9	2,2
2006	3,2	8,2	2,2
2007	3,0	7,1	2,3
2008	0,5	7,0	3,7
2009	-4,2	8,9	1
2010	1,8	9,5	2,1

Source: National Bank of Romania, The Balance of Payments

Calculations of the three indicators are embedded in the following table:

Table no. 5 Evolution of poverty, unpopularity and stabilization policy indexes in the EU-15 - %

Year	I _S -%	I _{IP} -%	I _{ST} -%
2000	10,6	80,2	28,0
2001	10,7	78,7	27,7
2002	11,0	82,2	28,8
2003	11,0	83,0	29,0
2004	11,1	83,9	29,3
2005	11,1	82,3	28,9
2006	10,4	76,0	26,8
2007	9,4	66,2	23,6
2008	10,7	66,7	24,7
2009	9,9	81,1	27,7
2010	11,6	87,60	30,6

Source: Authors calculations based on INS statistics and National Bank of Romania

Fig no. 2 Evolution of GDP and the three indices in the EU-15 between 2000-2010.

Source: Table no. 5

Also in EU, there is an inverse relationship between the three indices and gross domestic product.

A comparative analysis of the poverty index between Romania and the EU-15.

Fig no. 3 Comparison of poverty index between Romania and the EU-15 during 2000-2010.

From the graph, it appears that in the shown period, the indicators of poverty in EU-15 have values between 10-12%; in our country they have reduced from 51.2% in 2000 to 9.4% in 2007, after which, they increased to 14.97% in 2010. Analysis based on indices can be supplemented by other indicators. These could include: gross domestic product per capita, human development index.

3. Conclusions

The study of macroeconomic and macro-social variables in terms of these indices in relation to gross domestic product provides information for government management towards substantiation the strategies and economic policies.

Ensuring sustainable economic growth on medium and long term involves a series of painful reforms, but they must be permanently linked to social factors. High poverty shows not only lack of resources for subsistence, but also issues related to economic education.

Unpopularity degree shows the potential strength to reform measures.

The stability degree demonstrates the economic performances.

Therefore, to escape from the economic recession with the known social costs, means moving into a new phase characterized by partial crisis, which have to be managed to reach the final objective of any government – assurance of general welfare.

Services Cost Analysis Under Risk

Golea Pompiliu

Balogh Petru

"Dimitrie Cantemir" Christian University

golea_p@yahoo.com

petru_balogh@yahoo.com

Abstract

In this paper, an integrated approach based on Monte Carlo simulation and Six Sigma methodology is used to analyze the risk associated with a services cost. Monte Carlo simulation is applied to understand the variability in total cost caused by the probabilistic cost items. By Six Sigma methodology the range of variation of the service cost can be reduced by operating on the input factors with the greatest impact on total cost to cover the variation of 6s between the limits that were established in the design phase of Six Sigma.

Key words: Services cost risk; Six Sigma; Monte Carlo simulation

J.E.L. classification: C63, D24, D81

1. Introduction

In this paper it is shown how Monte Carlo simulation can be used in a Six Sigma analysis of the cost of a project. The underlying connection between Monte Carlo simulation and Six Sigma is the variability inherent in all business processes.

The Monte Carlo method of estimating project cost is based on the generation of multiple trials to determine the expected value of a random variable. There are a number of commercial packages that run Monte Carlo simulation; however a basic spreadsheet can be used to run a simulation.

In an increasingly competitive services, businesses are turning to new practices like Six Sigma, a structured methodology for accelerated process improvement, to help reduce costs and increase efficiency. Since its inception at Motorola in 1984 for measuring defect rates in manufacturing processes,

the Six Sigma initiative has changed the way people work around the world. Six-Sigma is a customer-focused, facts-based, data-driven, results oriented, project focused, project management approach to quality that can be used by any business, small or large. Six Sigma improves the process by reduction the variation.

The typical determining cost of services often overruns its cost estimates. This happens because cost estimating traditionally fails to take into account the risk that the service will actually cost more or less than provided by even the most competent estimate. The Six Sigma methodology can be used to identify the sources of the variability of the service cost and suggest ways in which costs can be reduced.

Six Sigma is divided into five distinct phases: Define, Measure, Analyze, Improve, and Control (DMAIC).

2. The Define Phase

The define phase is one of the most important phases because it sets the framework and goals for the service. In this paper, it is considered that the total cost of the service is determined by five major components: raw material, labor, equipment, other variable costs, indirects.

The cost risk analysis must answer some questions that include: what is the most likely cost, how likely is the baseline estimate to be overrun, what is the cost risk exposure, where is the risk in this service.

The Six Sigma team can define its goals as understanding and controlling the source of the variability of the project cost in order to reduce cost risk exposure.

3. The Measure Phase

During the measure phase, the Six Sigma team gathers data that describe the cost components of the service.

In Table 1 are presented the costs estimated in the traditional way by the specialists of the service. Of course, an example will consider only two components of cost.

Table 1. Estimated initial cost

Cost component	Estimate [ron]
Raw materials	180
Labor	88

Determining the risk associated with service cost can be achieved only by accumulating more information. The Six Sigma analyst must choose relevant persons to be interviewed. In many projects, it can appeal to engineers and business economists who have experience needed for these estimates, the project head and the other employees that are on the same hierarchical level and components of the project team, such as site foreman, etc.. It is possible and questioning of experts outside the organization, but only in a particular case, designated by the contracting authority or to the relationships established. When these people get into a room, the Six Sigma analyst asks about three numbers for each cost component: the pessimistic cost estimate, the optimistic cost estimate and the most likely cost estimate. Optimistic cost if it is deemed that all goes well and pessimistic cost is achieved in the worst possible case. Cost is usually the most likely price at which bidding the project, although, as will be seen this cost does not have the lowest level of risk. Usually, this price is quite optimistic as to be smaller but, in reality, it need a certain amount of luck to be gained.

Also, in the measure phase, the experts must be asked about a lower limit and an upper of the total cost of the project.

Also, in the measure phase, the experts must be asked about a lower limit and an upper of the total cost of the project.

4. The Analyse Phase

In the analyse phase, the team works to understand the variability of the service cost. Monte Carlo simulation can be used as a tool to help analyse the uncertainty of the project cost. Suppose that the expert interview has occurred and the estimates from Table 2 are obtained.

Table 2. The normal distributions of the service costs

Cost component	Estimate		
	Optimistic cost (a)	Most likely cost (b)	Pessimistic cost (c)
Raw materials	120	180	260
Labor	80	88	110

The Monte Carlo method involves the artificial generation of experience or data by the use of a random number generator and the cumulative distribution function being considered.

The normal distributions of the cost components will be used to run a Monte Carlo simulation.

This solution will be used to run Monte Carlo simulation with Microsoft Excel. The simulation results after 2000 iterations are presented in Figure 1.

The formula used for the simulation experiments are presented in Table 3.

Tabel 3

	Cell	Formula
Normal random number	B3	Data-Data Analysis- Random Number Generation- Distribution Normal
Raw materials	D3	$180+B3*C3$
Probability	E3	$NORMDIST(D5,181.96,23.58,TRUE)$
Labor	G3	$88+B3*F3$
Total	I3	$D3+G3$
Cumulative prob.	J3	$E3+H3-E3*H3$

Figure 1. Monte Carlo simulation results

Iteration	1	2	3	1996	1997	1998	1999
Normal random number	-2.9330	-2.9165	2.9219	3.0460			
(b-a)/3 or (c-b)/3	20	20	26.66	26.66			
Raw materials	121.3398	121.6701	257.8973	261.2065

Total Raw materials and Labor	201.5380	201.9122	367.3147	371.5338			
P=p1+p2-p1p2	0.0383	0.0392	1.0000	1.0000			
Average					23.58556	23.58556	181.9617
Standard deviation					5.1895	5.1895	89.7108

Figure 2. Probability distribution for raw materials and labor cost

Tabel 4

Cost	271	262	250	240	
Probability	0.75	0.6	0.4	0.3	
Number of services performed	1	0.75	0.6	0.4	0.3
	2	0.93	0.84	0.64	0.51
	3	0.98	0.93	0.78	0.65
	4	0.99	0.97	0.87	0.75
	5	0.99	0.98	0.92	0.83
	6	0.99	0.99	0.95	0.88
	7	0.99	0.99	0.97	0.91
	8	0.99	0.99	0.98	0.94
	9	0.99	0.99	0.98	0.95
	10	0.99	0.99	0.99	0.97
	11	1	0.99	0.99	0.98
	12	1	0.99	0.99	0.98
	13	1	0.99	0.99	0.99

When 2000 iterations are completed the results can be analysed using histogram presented in Figure 2.

The mean cost of raw materials and labor 271.67 m.u. with a standard deviation of 28.69 m.u. and the probability P (Total cost of raw materials and labor) can be determined with formula $P=p_1+p_2-p_1p_2$.

Depending on the number of services performed, you can set a lower average cost. For this we used the binomial distribution of results are presented in Table 4.

5. The Improvement Phase

After the understanding the effects of uncertainty on the service cost the Six Sigma analyst and project manager can try to make improvements to the process in order to increase the sigma level of the project.

In this paper the simulation will be used to analyze the effect of changing the suppliers of raw materials and the human resource management. It is expected that the pessimistic cost of raw materials and cost of labor will decrease from 370 m.u. to 271 m.u. where four services are performed, dedecreasing to 240 m.u. when the service is performed thirteen times.

6. Conclusion

Monte Carlo simulation has a crucial role to play in multiple phases of a Six Sigma analysis project. By moving to a probabilistic methodology, Six Sigma analysts can better quantify the effects of variability and can implement process improvements with greater insight and confidence.

In the case of applying the algorithm presented for calculating costs, companies can achieve competitive advantage by providing necessary affordable rates for customers without affecting profit.

Abstract

The article argues the theoretical concept of assessing the population's standard of living, which in conditions of globalization becomes a factor of competitiveness among countries. The authors show some of the methodological concepts used for assessing the quality of life (QL) from a worldwide perspective.

Using a wide range of theoretical and statistical information, they describe The Economist Intelligence Unit's Quality-of-Life Index (QLI). The authors argue that human development can be defined as an enlargement process of opportunities for people to choose from. From the perspective of human development, opportunities for people extend, in most cases, in three critical areas: life expectancy, educational level, and access to economical resources necessary for a decent level of living. All existing methodologies for assessing quality of life express the quality of life but from different perspectives.

Human development is both a process and a final result. From the perspective of human development, the authors argue the role and importance of subjective evaluation in public surveys. The article also analyzes the results of public polls conducted in European Union countries by „The Economist Intelligence Unit” during the years 2005, 2007 and 2009, the QL components and draws some conclusions.

Key words: quality-of-life index, assessment indicators, methodological concept, quality-of-life management, methods for quality-of-life assessment, life satisfaction.

J.E.L. classification: F

1. Human Development

In market economy conditions the quality of life in one country or another is a competitive factor. At the world level, quality of life (QL) is calculated by using the Human Development Indicator (HDI), the method proposed in 1990 by the United Nations, which includes monetary indices or measures of welfare and social indicators.

To measure the average achievements in a country is a challenge. As indicators of welfare, some monetary indices have been proposed - *income and consumption*, considered as important components of overall quality of life dynamics of the population. Income is one of the key factors which directly affects the living standard. If you assume that population's income generally viewed in terms of its use is manifested through consumption, that its surplus can be seen in savings, and that any increase in real income causes an increase in consumption, then this requires a parallel analysis of income and household consumption to assess welfare. It has been demonstrated that the main tool for measuring poverty is the poverty line, which allows the division of the whole society into poor and non-poor people. This is, essentially, the minimum allowable or critical life standard. The people whose welfare levels are below the poverty line, form the poor part of the population, while the rest are referred to as non-poor.

To characterize the quality of life, the authors consider that the most important income is the available income, known as *net income*, which means that part of income that remains available to people to cover consumer's spending and saving. The volume of expenditure in a given period depends on income levels in the same period, the

accumulation of income from prior periods as well as the use of anticipated income. As a rule, individual income of employees or their families are determined by the respective budgets. In addition to the factors listed above, a special place in the assessment of living standards is held by household consumption, which means all the consumed food and non food products, and the services used by population for non-productive purposes in a given period [3; 4; 5,11].

Each year the Human Development Reports (HDRs) make effective recommendations at national and international level. At national level, policy recommendations aim at human development priorities, the need to establish a new partnership between state and market, to promote new forms of alliance between governments, civil societies and institutions, communities and individuals. National, regional and global reports on human development have played a key role in promoting human development.

2. The Economist Intelligence Unit's Quality-of-Life Index (QLI)

The Economist Intelligence Unit's analysts developed a new QL index for the year 2005, which was based on the subjective opinion of respondents to the QL issues. The results of the research revealed surprising data: Ireland was ranked first comfortably. The United States of America, although ranked second due to its GDP per capita (after Luxembourg), according to the QLI ranked thirteenth, and the United Kingdom ranked the 29th. It was shown a long time ago that material wellbeing alone does not adequately measure the quality of life [12]. Money has its importance, of course, but polls have shown over time that substantial increases in income are not always translated into human satisfaction [14].

British Economic Analysis Division of The Economist Intelligence Unit proposed a new variant of QL index, variant based on a unique methodology that links the results of subjective life satisfaction surveys and the objective determinants of QL in several countries. This way, the QL index was calculated for 111 countries in 2005. We are going to present this methodology for calculating the QL index variant proposed by

The Economist Intelligence Unit [12]. According to some previous studies, material wellbeing, as measured by GDP per person cannot be the only explanation of the complex concept of QL in a country. Some of the literature has tried to adjust GDP by quantifying facets which are omitted by the GDP measure - as, for example, various nonmarket activities and social ills such as environmental pollution. But this approach has faced insurmountable difficulties in assigning monetary values to the various factors that comprise a wider measure of socio-economic wellbeing [12].

There have been numerous attempts to construct alternative, non-monetary indices of social and economic wellbeing by combining in a single statistic a variety of different factors that influence QL. The main problem is selection bias in QL factors and assigning weights to different indicators (measured on a comparable and meaningful scale) in order to find a single synthetic measure. GDP, despite its drawbacks, has at least one clear, substantive meaning, and prices are objective weights for the goods and services component. Some researchers have invoked the Universal Declaration of Human Rights to identify factors that should be included in a QL measure. But even if accepted as a starting point, they are not well defined and easy to weigh.

The starting point of the study conducted by The Economist Intelligence Unit for a methodologically improved and more comprehensive measurement of QL is subjective life-satisfaction surveys. In such investigations subjects are asked the question of how satisfied they are with their lives in general. Therefore, a typical question on a scale used in the EU's Eurobarometer studies is, "On the whole are you very satisfied, fairly satisfied, not very satisfied, or not at all satisfied with the life you lead?"

The results of such surveys have enjoyed growing attention in recent years. Despite initial criticism which is related to cultural differences, language barriers, and psychological factors distorting the answers, tests have disproved or mitigated most concerns. One objection is that responses to surveys do not adequately reflect how people actually perceive their lives; they report how satisfied they are expected to be. But the study conducted by the above mentioned

journal indicates that subjects know very well how satisfied they are. Responses are prompt and non-response rates are low. The simple measure of life satisfaction was found to correlate with more sophisticated tests. Survey results have proved more reliable than expected [8].

Another criticism of this type of investigation is that life-satisfaction responses reflect the dominant view of life rather than actual quality of life in a country. Life satisfaction is seen as a judgement depending on specific social and cultural frames of reference. But this degree of relativism is invalidated by the fact that people in different countries report similar criteria as being important for life satisfaction, and also that the majority of differences in life satisfaction across countries can be attributed to differences in objective circumstances. In addition, it has been found that the answers of immigrants in a country are much closer to the local population responses than answers in their motherland. Answers to questions on satisfaction in bilingual countries do not reveal any linguistic bias related to different meanings and connotations of the words "happiness" and "satisfaction."

There are several reasons why it is not sufficient to calculate the QL index of a country as the average life satisfaction score obtained from processing the survey results. First, comparable results for a sufficient number of countries tend to be outdated, while many nations are not covered by the survey results. Second, the impact of measurement errors on assessing the relationship between life satisfaction perception and objective indicators tends to cancel out when the research refers to a large number of countries. There might also be a significant number of errors for any given country. Thus, there is a bigger chance of error in assessing QL between countries, if we take a single average life-satisfaction score as opposed to a multi-component index. The last and most important reason – inter-country variation in the life-satisfaction surveys can be explained by objective factors.

3. Quality-of-Life Indicators

To calculate an objective index, the British specialists have used the survey results on life satisfaction as a starting point, and as a means for deriving weights for the various determinants of QL across countries.

The nine quality-of-life factors chosen by "The Economist Intelligence Unit" and the indicators used to represent these factors are [12]:

1) *Material wellbeing* (GDP per person, at PPP in \$. Source: Economist Intelligence Unit);

2) *Health* (Life expectancy at birth, years. Source: US Census Bureau);

3) *Political stability and security* (Political stability and security ratings. Source : Economist Intelligence Unit);

4) *Family life* (Divorce rate per 1,000 population, converted into index of 1 – lowest divorce rates to 5 – highest. Sources: UN; Euromonitor);

5) *Community life* (Dummy variable taking value 1 if country has either high rate of church attendance or trade-union membership; zero otherwise. Sources: ILO; World Values Survey);

6) *Climate and geography* (Latitude, to distinguish between warmer and colder climates. Source: CIA World Factbook);

7) *Job security* (Unemployment rate, %. Sources: Economist Intelligence Unit, ILO);

8) *Political freedom* (Average of indices of political and civil liberties. Scale of 1 – completely free to 7 – unfree. Source: Freedom House);

9) *Gender equality* (Ratio of average male and female earnings, latest available data. Source: UNDP Human Development Report).

A number of other variables were also investigated but, in line with findings in the literature, they had no significant impact on QL. These were: education levels, the rate of real GDP growth and income inequality (Gini coefficient). Studies have often found a small correlation between education and life satisfaction. A recent report by the ILO found that an indicator of schooling and training was actually inversely related to wellbeing when jobs were poorly attuned to people's needs and aspirations.

The British analysts have pointed out that GDP per capita explains more than 50% of the inter-country variation in life satisfaction and the relationship is linear. Surveys show that in rich countries high-income population is more satisfied with the level of living than low income people. In 24 of the 28 countries that entered the Eurobarometer survey, material wellbeing has been identified as the most important criterion for life satisfaction. However, over several decades there has been only a very modest upward trend in average life-satisfaction scores in developed nations, whereas average income has grown substantially. There is no evidence for an explanation. In The Economist Intelligence Unit's estimates, the level of income inequality had no impact on levels of life satisfaction. Life satisfaction is primarily determined by absolute status related to states of mind and aspirations. The explanation is that there are four factors associated with modernisation that, in part, offset its positive impact:

- a concomitant breakdown of traditional institutions is manifested in the decline of religiosity and of trade unions;
- a marked rise in various social pathologies (crime, and drug and alcohol addiction);
- a decline in political participation and of trust in public authority;
- the erosion of the institutions of family and marriage.

In personal terms, this has also been manifested in increased general uncertainty and an obsession with personal risk. These phenomena have accompanied rising incomes and expanded individual choice.

4. Quality-of-Life-Assessment in 2010

Since 2010 we have witnessed another period in the development of worldwide QL assessment. The new methodology for evaluating the global QL focuses on the following factors [8; 9]:

- cost of living in a country;
- people's culture and hobby;
- economic development;
- degree of cultural development;
- public health;
- infrastructure development degree;

- state security or stability;
- climatic conditions.

Some indicators previously used to assess QL are no longer in use. These are: GDP at PPP in \$, job security, political stability and freedom, family life, etc.

"International Living" Journal 2009 [14] published a top ten best countries in terms of QL, meaning the cost of living (15%), culture and hobbies (10%), economy (15%) environment (10%), freedom (10%), health (10%), infrastructure (10%), security (10%), climate (10%). France ranks first, then Australia, Switzerland, Germany, New Zealand, Luxembourg, the United States, Belgium, Canada and Italy. Australia, for example, is a place good for retirement, living a balanced life, enjoying a temperate climate, vast beaches and great landscapes. Also, people with college degree will find a job easily because of the Australian economy and the Asian boom. In Switzerland, everything works. There is reliability, quality, discretion, punctuality, safety and tranquility. Five languages are spoken in Switzerland. In New Zealand you can see the most beautiful scenery in the world. Moreover, for young graduates, New Zealand is the perfect place. There is a very low crime rate as well. Romania is flanked by the Cayman Islands and the Dominican Republic [2].

5. Drop in satisfaction with life and standard of living in the EU

In general, the most striking changes between 2007 and 2009 were seen in terms of satisfaction with life in general and with standard of living. Between the last quarter of 2007 and September 2009, the average level of satisfaction with life in general across the EU fell from 7,0 to 6,8, or by about 4%. This decline was more marked in the new Member States, where global life satisfaction had been increasing: here, the average score fell from 6,5 to 6,1, this decline of 6% being twice as great as the fall in life satisfaction in the EU15. The biggest falls were in Bulgaria (where average ratings of life satisfaction fell from 5,0 in 2007 to 4,4 in 2009), Romania, Malta, Estonia and Latvia, but also in France where the average life satisfaction rating fell from 7,3 to 6,7. So, in the Baltic States, for instance, the pattern of decline in life

satisfaction reflects the drop in GDP. However, it does not correspond to the relatively small declines in GDP in countries such as Malta and France [13].

There was no difference between men and women in terms of the drop in life satisfaction experienced between 2007 and 2009. However, a clear difference was seen between older and younger people: among people aged between 18 and 34 years, ratings of life satisfaction rating fell by only 1%, while they fell 5% among older people. The survey findings indicate that older people in the NMS-12 enjoyed fewer of the benefits of enlargement and are feeling exposed to the risks of the economic crisis. The ratings of life satisfaction among people aged 65 and over were, in 2009, on average of 7.0 in the EU-15 countries and only 5.5 in the NMS-12, which may in part be related to the poorer health of older people in the NMS-12.

Household income and material conditions have a consistent relationship with ratings of life satisfaction. Both the 2007 and 2009 surveys include a question on how easy or difficult respondents found it to make ends meet. In 2007, the average life satisfaction score for those who found it easy to make ends meet was 7.8; in 2009, this was 7.7. The corresponding ratings for people finding it difficult to make ends meet were 5.3 and 4.9. So, the fall in life satisfaction among people who reported difficulty in making ends meet was, on average, 8% between 2007 and 2009. However, this decline was greater in the NMS-12 – 15% compared with 6% in the EU-15, perhaps reflecting the greater depth of difficulties in the NMS-12. The average life satisfaction score for people who were unemployed at the time of the surveys was unchanged among people in the EU-15, but fell by 11% among respondents in the NMS-12 – from 5.7 to 5.0. A similar pattern of decline can be seen when people's satisfaction with their standard of living is compared. On average, in the NMS-12, citizens' satisfaction with their standard of living increased by 9% between 2003 and 2007. However, it fell by 6% between 2007 and 2009. In the EU15, the decline in satisfaction with the standard of living between 2007 and 2009 was less, at 4%. Moreover, the average rating of satisfaction with standard of living was 6.9 in the EU-15, compared with 5.8 in the NMS-12. The

biggest falls in ratings were in Romania and Malta, followed by Latvia and Portugal, France and Estonia, so the perceived decline in standard of living was by no means only in the NMS-12 or those countries most affected by the crisis.

In terms of social groups, older people in the NMS-12 would appear to have been most influenced by the economic crisis. Among people aged 65 and over, ratings of satisfaction with standard of living fell by 5% in the EU-15, but by 12% in the NMS-12. And older people in the NMS-12 rate their satisfaction with their standard of living at a lower level than their counterparts in the EU-15: in the 2009 survey, among people aged 65 and over, the average rating of satisfaction with standard of living was 6.9 in the EU15 as against 5.2 in the NMS-12. Not surprisingly, people who say that they are finding it difficult to make ends meet are much less satisfied with their standard of living than those who find it easy.

As table 1 shows, around twice as many people in the NMS12 as in the EU15 find it difficult to make ends meet. In 2009, the proportion of citizens having difficulties was highest in Bulgaria, Greece, Hungary and Latvia (more than 30% in each country, and more than 40% in Bulgaria). The pattern was little changed from 2007; the greatest increases (of more than 5%) were in Greece, Ireland, Latvia and Lithuania.

Table 1 Elements of economic strain, EU-15 and NMS-12, %

	EU-15		NMS-12	
	2007	2009	2007	2009
Difficult to make ends meet	10	11	26	22
Cannot afford meat	4	6	20	21
Cannot afford a holiday	24	28	55	55

Source: Trends in quality of life in the EU: 2003–2009

Two particular indicators from the deprivation index were used to identify changes in relatively severe hardship: being *unable to afford meals with meat, chicken or fish every second day*, and being *unable to afford a week's annual holiday away from home*. Table 2 shows that the proportions

unable to afford these items are much higher in the NMS, but that there was relatively little change overall between 2007 and 2009. The biggest increases in deprivation were found in Hungary, where the proportion of citizens who said that they were unable to afford meat rose from 32% to 42% between 2007 and 2009. Meanwhile, the proportion unable to afford a holiday rose from 61% in 2007 to 73% in 2009; the only other country in which people reported comparable levels of deprivation in 2009 was Bulgaria.

While between 2007 and 2009 there were noticeable falls in people's satisfaction with their lives, and their standard of living, there was less change in their satisfaction with other aspects of life. Between 2007 and 2009, satisfaction with family life and health fell somewhat more, but job satisfaction remained remarkably stable, as Table 2 indicates. People rated their satisfaction on a scale from 1 to 10.

Table 2. Satisfaction with different aspects of life, EU-15 and NMS-12

	EU-15		NMS-12	
	2007	2009	2007	2009
Family life	7.95	7.81	7.70	7.52
Job	7.22	7.21	6.84	6.95
Health	7.44	7.26	6.98	6.7

Source: Trends in quality of life in the EU: 2003–2009.

Satisfaction with family life is relatively high in all countries, and it is difficult to discern any consistent trend across the three points in time. However, there are two groups of countries in which satisfaction with family life fell between 2003 and 2007, and again between 2007 and 2009 – Germany and Austria; and Greece, Italy, Portugal and Spain. The views of older people appear to have changed somewhat more than those of the average citizen between 2007 and 2009, with a decline of 3% in their level of satisfaction with family life, compared with a fall of 2% for people aged between 35 and 64 years, and no change among those aged between 18 and 34. There was no difference between the ratings that men and women gave to their levels of satisfaction [13].

Between 2007 and 2009, levels of satisfaction with health fell by 4% among respondents in the NMS12 and by 2% among

people in the EU 15, the most marked drops being in Bulgaria, Romania and Portugal. However, people in Latvia were more satisfied with their health in 2009 than they had been in 2007, so it is difficult to know how to interpret such changes. Overall, average job satisfaction did not change between 2007 and 2009, and in the NMS12 it rose by 2%, on average. This appears paradoxical against a background of economic recession, growing job insecurity and deteriorating working conditions (for at least some workers).

6. Conclusions

From our point of view, the methodology proposed by UNDP in 2010 for QL assessment is interesting and relevant. It allows countries in the world to be compared according to several indicators. However, it is quite cumbersome and time-consuming to compile and systematize primary information. In conclusion, we argue that human development can be defined as a process of enlarging people's choices as much as possible. Every day people make many choices in the economic, social and political areas. From the perspective of human development, people's opportunities to choose are expanding in three critical areas: life expectancy, educational level and access to economic resources necessary for a decent life.

However, the fundamental human development framework is much broader. The concept of human development is linked in a compatible and complementary way to human rights. While human development aims at expanding opportunities and freedom enjoyed by members of the community, human rights is an approach to improving the social structures that facilitate or secure these capabilities and freedom. Other choice areas, whom people assign a high value, is the participation in social life, security, responsible governance and sustainability. In terms of human development all these factors are necessary in order to ensure productivity and creativity, self-respect and the sense of belonging to a community. Ultimately, human development means to develop people for people and through people. The essential difference between the concept of economic growth and human development is that the

former focuses exclusively on a single expansion possibility - to make money, while the latter involves the consolidation of all possibilities – either economic, social, cultural or political. From the viewpoint of the concept of human development, income is a means for human development, but not the only one. Using various methods, the benefits of income should be used to cover multiple aspects of development. Therefore, growth is a necessary but not sufficient condition for human development.

According to Human Development Reports, human development matters first, not quantity, but quality growth. Often governments, especially in transition countries, do not consider improving the quality of economic growth and expanding opportunities for people to choose from. Usually, they are concerned with other aspects of the transition process, such as macroeconomic stabilization, budget execution, foreign policy, marginalizing the importance, structure, quality, and influence of other factors on human development. The experience of several countries in transition in the last decade has proved that there is no direct link between stability, growth and human development.

But even if this link has been established, it may wither away, especially if strategic policies management is not consistent or appropriate to the goals of human development. For these reasons, human development should be incorporated into public policy debates and decision-making process agenda. We should not ignore that the definition of human development goes beyond per capita income, human resource development and basic needs as a measure of human progress. From this year on, the definition should also include the following factors: inequality and human development, social justice, international development assistance and international trade that can unlock the potential of human development.

QL assessment is performed by using more thoroughly standards at the regional (European) level than at the global level. The latter way does not contradict the logical links between the two approaches. We can say that these methodologies are in "cause and effect" relationship. The highest effects are registered at the global level, confirming the impact of regional factors in global

phenomena such as population migration, global warming, viral diseases expansion, less agriculture share in countries' economies, population's poverty increase, etc. [5].

Understanding the Efficiency of R&D Investments from the Aggregate Production Functions Perspective

Goschin Zizi

Danciu Aniela-Raluca

Academy of Economic Studies, Bucharest

zizigoschin@yahoo.com

Abstract

The rapid growth in the last decades of the investments in research and development have generated an increased interest for assessing their contribution to economic growth. Researchers have tried to model the economic growth including also the technical progress – based on R&D expenditures- as an exogenous or endogenous factor in the aggregate production functions.

Key words: investment, technical progress, R&D, exogenous factors, Cobb-Douglas production function

J.E.L. classification: O33, C21

1. Introduction

In the economic literature there are many studies which have approached the effects of the R&D investments by the means of econometric modelling. R&D investments, or the larger category- R&D expenditures, were used as a proxy variable for the technological change. In the growth theory technological change is envisaged as the expression of the impact of new knowledge on the production function of the firm or nation. Different variants of Cobb-Douglas production functions were usually employed in such empirical studies. The technical progress may be exogenous if it is issued outside the economic process or endogenous if it emerges from within the economic process.

Modern developments of classical Cobb-Douglas production functions belong to the New Growth Theory which reunites a series of models where growth is driven by the technical progress endogenously resulting from the research-development investments of the economic agents pursuing

maximisation of profit. This hypothesis implies the fact that the funds allotted to the R&D sector are able to determine the long-term economic growth rate.

2. Technical progress and the aggregate production function

The neoclassic models of economic growth originate from the Cobb-Douglas production functions, introduced for the first time in the year 1928 by the American economist Paul Douglas, together with the mathematician Charles W. Cobb. Starting with the works of Tinbergen (1942) and Stigler (1947) elements such as total factors productivity and efficiency were added as well. Fabricant (1957) estimated that approximately 90% from the per capita growth output in USA between 1871 and 1951 could be attributed to technical progress.

Other empirical applications on the aggregated production functions that followed (Douglas, Tinbergen, Abramowitz) were summarized by Solow (1957) who concluded that technical progress is the source of the largest part (87.5%) of the entire economic growth.

Solow formulated an aggregated production function under the form:

$$Y = F(K, L; t), \quad (1)$$

where Y is output and K and L represent capital and labour inputs, and the variable t (time) is expressing in the production function the technical progress. Solow explicitly called technical progress any shift of the production function, including the improvement of labour force training. When technical progress is neutral, the equation (1) may be reformulated as:

$$Y = A_t f(K, L). \quad (2)$$

Output elasticity depending on capital is defined as $w_K = \frac{\partial Y}{\partial K} \cdot \frac{K}{Y}$, and elasticity in

relation to the labour factor is $w_L = \frac{\partial Y}{\partial L} \cdot \frac{L}{Y}$.

Differentiating equation (2) in relation to time, there results that:

$$\frac{\dot{Y}}{Y} = \frac{\dot{A}}{A} + w_K \frac{\dot{K}}{K} + w_L \frac{\dot{L}}{L}. \quad (3)$$

If we assume the hypothesis of a constant returns to ($w_K + w_L = 1$), note $Y/L = y$, $K/L = k$

and consider that $w_L = 1 - w_K$, and $\frac{\dot{y}}{y} = \frac{\dot{Y}}{Y} - \frac{\dot{L}}{L}$,

then equation (3) becomes:

$$\frac{\dot{y}}{y} = \frac{\dot{A}}{A} + w_K \frac{\dot{k}}{k}, \quad (4)$$

which is easy to calculate based on data regarding output and capital per man/hour and the share of capital in output, considering the production competitive.

This model of Solow (1957) dominated empirical studies up to the beginning of the seventies. The initial conclusion of Solow, which attributed to technical progress almost the entire economic growth, began to pale as the statistical methodology and the national accounts improved. Nevertheless, there are relatively recent studies (Jorgenson 1990, Denison 1985, Matthews et al. 1982) which suggest that an important part of economic growth (about a third) is "residual growth".

A limit of the Solow type studies is that they do not allow for a more in-depth analysis of the determinant factors of technical progress and the measurement of their contribution to economic growth. The major difficulty relates to measuring innovative outputs. From all available data for measuring R&D inputs and outputs, most frequently the R&D expenditures are used, along with the number of patents, the technological balance of payments, machinery and tool import, and dissemination.

3. R&D investments as a factor in the production functions

The majority of researchers selected the R&D expenditures as measure of input in

innovation more for reasons of availability and correctitude of data than for theoretically substantiated reasoning. Studies of researchers like Griliches (1980a), Mansfield (1980), Nadiri (1980a), Scherer (1982), Terleckyj (1974), Griliches and Lichtenberg, (1984) estimated total factors productivity growth with production functions of the Cobb-Douglas type and have compared it (by regression models) with various input indicators, as a rule, the expenditures for research-development, either aggregated or decomposed on components such as fundamental and applicative research, or private or governmental research.

The typical evaluation model of total productivity of R&D factors and efficiency starts from a standard Cobb-Douglas function which includes the stock of knowledge as separate production factor (Griliches and Lichtenberg, 1984):

$$Y_t = A \cdot D_t^\beta \cdot K^{\alpha_1} \cdot L^{\alpha_2} \cdot e^{\mu t} \quad (5)$$

where Y_t is output, D_t is the stock of knowledge, L_t is the labour input, K_t is capital input, A is a constant and μ is a trend variable which catches other influences. Total factor productivity (TFP) is measured as:

$$TFP_t = Y_t / (K, L) \quad (6)$$

By combining equations (5) and (6) results:

$$TFP_t = A \cdot D_t^\beta \cdot e^{\mu t} \quad (7)$$

and in the logarithm it becomes:

$$\log TFP_t = \log A + \beta \log D_t + \mu t \quad (8)$$

Differentiating equation (8) depending on time and writing $[d \log TFP_t] / dt = \dot{T} / T$ results:

$$\dot{T} / T = \beta \dot{D} / D + \mu \quad (9)$$

From equation (5) we can consider β as being the output elasticity depending on the knowledge capital:

$$\beta = \frac{\partial \log Y}{\partial \log D} = \frac{\partial Y}{\partial D} \cdot \frac{D}{Y} \quad (10)$$

Equation (10) may be rewritten as:

$$\frac{\dot{T}}{T} = \frac{\partial Y}{\partial D} \cdot \frac{D}{Y} \cdot \frac{\dot{D}}{D} + \mu = \rho \frac{R}{Y} + \mu \quad (11)$$

where: $\rho = \partial Y / \partial D$ and $R = \partial D$ (net investment in knowledge capital).

Estimates of the effect of innovation on total productivity of factors can be obtained in two ways (Griliches and Lichtenberg, 1984):

- by using a measurement of the R&D stock of capital, as in the relation:

$$\log TFP_t = \log A + \beta \log D_t + \mu t \quad (12)$$

- by using a measurement of the R&D intensity (depending on output) in a regression relationship of the change of the total productivity of factors:

$$d \log TFP_t = \rho \frac{R_t}{Y_t} + \mu \quad (13)$$

where R_t is the R&D flow, in contrast to D_t which represents the accumulated capital of RDS.

Equation (12) offers a measurement tool of output elasticity depending on scientific knowledge (parameter β), while the equation (13) represents a measurement tool of the social efficiency (profitability) of scientific knowledge (parameter ρ), R and Y being expressed with the same measurement unit. The choice of one of the two methods depends particularly on access to quality statistical data and on the area of interest.

Applying these two methods rises some theoretical and practical issues. From the theoretical point of view, the issue of separating knowledge from the other factors of the production function is not fully clarified. Total of factors productivity is calculated, as a rule, by deducing from output the capital and labour factors, weighted by their specific weights. Under conditions of perfect competition, the price of the production factors is equal to their marginal productivity; hence their shares in output are equal to their exponents from the production function (Hall, 1990). Under conditions of imperfect competition, measuring the total productivity of factor would give errors.

From the empirical viewpoint, the usual issues appear in measuring the variables, especially in the case of value added and research-development. Value added can be affected by several errors, the most important being generated by the use of gross product deflator for building the series of real values added (Stoneman and Francis, 1994). The data referring to R&D raise even more issues due to the difficulty in defining the variable, resolving the aspects related to lag, depreciation and inflation (Griliches, 1988). An important aspects refers to taking into account the cyclic nature of the data regarding the total productivity of factors (Cameron and Muellbauer, 1996).

The theory of endogenous economic growth represented the starting point for a series of models where growth is driven by the technical progress resulting from the research-development efforts. The fundamentally different nature of investments in knowledge has a central place in the endogenous economic growth model of Romer (Romer, 1990). The model has four factors: capital, labour, human capital and technology. Knowledge is separated by the rival (competitive) component embedded in individuals – human capital H – and an non-rival technological component A which is independent from individuals and which can be accumulated without limits. Technology is represented by a stock of manufacturing industrial models (designs) of goods, which are accumulated in time, as result of research efforts.

4. Concluding remarks

The massive increase in investments for research and development and their orientation towards practical, exacting purposes have determined a growing interest for learning about the efficiency of these expenditures. Therefore aggregated R&D expenditures and their efficiency are representing an important research area related to economic growth modelling.

The dissatisfaction determined by the hypothesis of the exogenous character of technical progress adopted by the neoclassical theory of economic growth brought about new theoretical and empirical developments. Under the theoretical aspect, researchers like Arrow (1962), Kador and

Mirrlees (1962) have attempted to demonstrate the endogenous character of technical progress, while from the empirical viewpoint the researchers have tried explicitly to model the total factors productivity by including data referring to R&D investments. Several of these empirical studies use models that might be interpreted as pertaining to the category which renders endogenous the effects of innovation.

The analysis of efficiency of the R&D investments, envisaged by various economic growth models, pursues to identify a balance position between the dangers of over- or under-investment in certain activities, aiming at enhancing the overall economic efficiency.

Credit Insurance, Fluidization Level of Exchange of Goods

Gotcu Cezar Augustin Vasile
cezar.gotcu@yahoo.com

Abstract

Credit insurance activity appeared on the market as a result of the phenomenon of overlapping of the activities conducted by the financial institutions with those of insurance, by which the insurers take over the risks of financial losses from the banks, as a result of an analysis that would allow them to define the dimensions of risk, the probability of producing it.

By concluding the insurance contract for credit risk, the insured transfers to the insurance company the risk of non-payment of amounts owed by the buyer, due to a precarious situation of the buyer or not knowing enough of the buyer or special circumstances existing in the importer country (different regulations of some economic phenomena, conflicting states, war, embargoes on products, border protection regime).

Key words: risk, debts, insurance, credit .

J.E.L classification: G22 insurance .

1. Introduction

Commercial economic social activity in the current stage of development of society knows a high degree of diversification, with a high degree of interdependence and reciprocal interrelation, which involve at the same time both action and overlapping of a multitude of risks, more or less serious, more or less known, easier or more difficult to avoid.

2. Credit risk, component of economic activities

In definition given by OCDE in 1983 it is estimated that "*risk consists of possibility that a fact with undesirable consequences to occur*" [8; 76]; this definition is based on the eventuality (anticipated with a certain probability or unexpected by the decision

maker) to materialize and negatively affect certain aspects of economic activity. In fact, in this sense, the emphasis is on effects that respective event generates.

The Risk is a component of any economic activity and it can be found in the daily agenda of company managers. At any time you need to know what is the risk and if this risk is greater than earnings. Unexpected changes in interest rate evolution, exchange risk or the price of a product not only affect a company financial results, but may event lead to bankruptcy. In fact, financial decisions involve uncertainty. Financial decisions are taken according to cash flows provided by future contracts, which are by nature uncertain.

It is not surprising that an important function of the financial system is allocated the risk associated with interest rate evolution, stock price, exchange rates or the price of certain commodities, etc.

The business world knows a mobility that was unthinkable a few decades ago. Every year thousands of companies worldwide go bankrupt because they fail to ensure a balance between receipts and payments. At the same time thousands of companies are founded, with varied activity object from which less than a quarter manage to resist on the market more than a year, the other ending their activity because of the perfect ignorance of the market mechanisms, risks that act in the field of activity chosen by these companies remaining with large debts to partners. Many times the reason is the insolvability of their customers which makes impossible to recover these amounts and therefore continues the series of the problems and it flows on others, creating a chain reaction that affects a large number of market operators.

Carrying on the current activity assumes that market operators to conduct and carry out commercial transactions, but many of them do this thing without protecting themselves against the danger of not collect

the counter value of the sold goods from the buyers, executed works or performed services, especially during recessions.

A huge transformation suffered also the way of carrying out business, they no longer runs by using their own money, but by using to an increasing degree the commercial credit. Today, payment at the time of purchasing is used increasingly less, especially when business partners are not known, buyer hasn't a good reputation in the market or comes from a high-risk business environment (or country).

But most business is conducted through the use of commercial credit, respectively the goods are purchased now and paid later, sometimes after 60 or even 90 days, this thanks to both the good reputation got by the buyer on the market and some rules imposed on market regarding the payment modality of purchased products.

By law of bill, promissory note and check harsh sanctions are stipulated in case they are not honored on time, including penal sanctions. Commercial banks also have a strict record of these settlement instruments, having also the obligation in situation when a company registered a major incident regarding the use of bill, promissory note or check, they must proceed urgently to the following measures: to retry the instruments of that type released to that firm, not to issue that type of debit instrument to the firm for a year, to inform the police unit where it operates about that incident and to register it at Payment Incidents Register. The Payment Incident Register is an organism that is operating beside National Bank of Romania and which manages all payment incidents registered by the economic agents and which can be consulted both by commercial banks and traders. Under such conditions, in case an economic agent registers payment incidents, this fact may be quickly brought to the attention of other market operators and banks that will proceed to take protective measures against them, respectively: will provide in contractual relationships with these economic agents immediate payments ways for the counter value of goods shipped, executed works and performed services, as well as penalties for failure to pay obligations under contracts within time, will apply restrictive measures on access to credit of such economic agents asking for additional

guarantees and without accepting at discount the bills, promissory notes and checks issued by the economic agents with an inadequate record registered at the Payment Incidents Register.

Economic agents contract bank credits and investment credits for achieving their current activity in order to resume production process till they collect the counter value of the delivered goods, executed works and the performed services with different payment (further delivery time), as well as for the enlargement and modernization of existing production capacities.

But, as mentioned above, upon request of credits by economic agents, the banks make a detailed analysis of their activity, both economic and financial situation and reputation, seriousness and confidence they have in the business environment, in their relations with employees, with local and central budgets, as well as, compliance with environmental rules. The made analysis highlights the applicant's capacity to meet its outstanding obligations to suppliers, local and central budgets, employees and banks in time. Banks will also conduct an operative consult of the Payment Incidents Central, an institution set up beside the National Bank of Romania, whose operation requires the recorded of all delays registered by traders in paying their contractual obligations due to financial institutions (banks, leasing companies, etc).

Meanwhile creditors look for a protection in order to cover non-recovery of money lent by applying some forms of financial loss insurance.

3. Credit insurances – taking over instrument of the financial risks of economic agents

Insurances intervene in commercial activity by taking the risk related to the possibility that the debtor can not pay its contractual obligations on the appointed date, activity known as financial risk insurance. This type of insurance activities in accordance with economic environment conditions, in which risk factors act that are different from other forms of insurance.

The most important form of financial insurance is the insurances of loans to the

population or economic agents for carrying out current activity, for the production delivered at export or on the domestic market and for financing of the investment activity.

Credit insurance activity appeared on the market as a result of the phenomenon of overlap of the activities conducted by the financial institutions with those of insurance by which the insurers take over the risks of financial losses from the banks, as a result of an analysis that would allow them to define the dimensions of risk, the probability of producing it.

Credit insurances are different from bank guarantees by the fact that bank guarantees are made by the banks as an additional protection for the eventuality that the activity accomplished by the borrower, which until that moment has proven viable, not to allow payment on the appointed date of the outstanding rates and related interests, while by financial insurance risks are taken over only under certain conditions, namely analyzing the risk of non-payment sizes, risk analysis, its imminent to occur and the probability to appear in time.

By concluding the insurance contract for credit risk the insured transfers to the insurance company the risk of non-payment of amounts owed by the buyer, due to a precarious financial situation of the buyer or not knowing enough of the buyer or some special circumstances in the importer country (different regulations of some economic phenomena, conflicting states, war, embargoes on products, border protection regime). In these situations the credit insurance protects the producers and exporters of occurrence of non-payment risk, their debts can be accepted at lending by banks till their collection.

Costs charged by insurers for insurance receivables by the sellers are quite high, they varying according to specific situations in economy and being higher in case of deliveries of goods in countries with political instability, with high risk or in times of economic crisis. For this reason, credit insurance becomes sometimes a luxury insurance, especially in cases when insurance companies take over the risk of non-payment of the debts related to deliveries of goods, executed works and performing of services made by beneficiaries from countries with unstable political regime. In order to avoid

the use of credit insurances, suppliers of goods, works and services to beneficiaries from unstable areas prefer to take a series of measures to diminish the risk of default like: carrying out of receipts by first rank banks that offer them a full safety, stipulation in economic contracts of some definite settlement instruments (letters of credit, letters of bank guarantee issued by first rank banks) and avoidance of documentary collection or term payment unsecured by banking instruments issued by first rank banks, delivery of goods with payment in advance, etc.

Contracting an insurance credit involves several steps, beginning with investigation the risk of non-payment, this requires knowledge of the debtor status, its periodic review, its economic relations, its capacity to pay. Ongoing surveillance by permanent supporting of the insured in order to recover the amounts for deliveries he made and delayed at payment, by submitting the necessary documents on the banking circuit, by tracking in terms of meeting the protest refusals to pay and initiating the necessary legal proceedings to recover money, where appropriate. The support given by the credit insurer also consists in counseling the suppliers in negotiating the contractual terms concluded with the beneficiaries, by offering them information regarding the economic and customs legislation from beneficiary country, by supporting in establishing by contract of the law that governs the carrying out of that contract and judging of any disputes that may occur in its put into practice.

In order to stimulate the economic agents to take all measures to prevent the risk of debt default there are excluded from inclusion in credit insurances the following risk categories like claims for deliveries of goods or inadequate performances of services, penalties or other losses in connection with non-execution of the contractual obligations under the sale-purchase contracts concluded by the seller (insured) with the buyer, as well as unfavorable exchange rate differences which could be recorded in carrying out of the contracts for deliveries to export, these being independent of the action or inaction of the insurance company or insured.

The credit insurance is an indemnity insurance because it supposes the compensation paid to the insured for the loss suffered as a result of insolvency or inability to pay of the insured and not appearing an event that causes damages like in situation of other insurances. Therefore it is a pecuniary insurance, of financial loss and not material . [7 ; 42]

A form of credit insurance is the insurance of the credit rates , used in insurance of banking credits granted to the population and economic agents , rescheduled at repayment in more rates , on medium or long term . Takeover by the insurance companies of default risk by the borrower of the credit rates and the related interests is accepted only under condition that the insurer to participate with an own contribution of 25% minimum of the counter value made with bank credit.

In order to encourage the export more and more countries constitute specialized bodies as governments agencies or insurances companies that collaborate with government agencies and which take over a part of the non-payment risk during the export contracts in progress. The eventual losses of the credit insurance activity carried out are covered by the state concerned by the provision of budgetary allocations in this sense. Among the main operators on the market for the credit insurers we specify the French credit insurance company COFACE or EXIMBANK from our country that has as aim the encouraging the foreign trade of the Romanian companies , penetration of certain foreign markets, subsidizing of a part of the interest related to achieving the production for export and the export, etc, within the limit of an annual budgetary allocation approved by Parliament by the law of the state budget .

By the credit insurances the default risk is taken over by the insurer during the crediting period , namely the interval of time between the delivery of goods, execution of works or performing of services upon the receipt of their counter value. The responsibility of the insurer generally begins at the moment of coming into force of the contract between the insured and the buyer and expires at the moment of receipt by the insured party of the counter value of the deliveries made to the beneficiary under normal carrying out of

the contract or at full repayment of the loan , in the event of a damage or if the insured party fails to fulfill its obligations assumed by the insurance contract .

Analysis of the non-payment risk is made on the basis of analysis of a varied information range related to the business environment and the buyer like : the history of the company , economic financial indicators achieved by it in a certain period, usually 3 years , respectively patrimonial liquidation , patrimonial solvability , own capital profitability, indebtedness degree, the volume of outstanding debts to budgets , suppliers , shareholders and employees , the degree of contracting for the achieved production, information regarding the business relations with different partners , degree of creditor control, etc.

It is also analyzed the buyer's activity, the quality , professionalism and competence of its management , the relations with the suppliers , beneficiaries , banks , previous experience in the credit field , mainly full repayment of the credits and at deadlines , payment capacity , follow closely of the purpose for which the credit is granted, acquisition of new assets , investments and if all of these are consistent with its financial situation , determining the capacity of the company and all necessary features to frame in a certain type of borrower. The financial analysis completes the image about the buyer and it is based on the analysis of balance sheet and profit and loss account for the last three years, proceeding to drawing up and analysis of the cash flow for the period of crediting by which it is analyzed the evolution of receipts and payments in progress , checking the coverage degree of the payments from the projected revenues during the crediting period . The cash flow is prepared based on both receipts and payments on data resulting from carrying out of the economic activity of the insured party (the volume of the concluded contracts, the terms of collection stipulated in contracts , the payments for the supply of raw materials, materials, fuel, energy, wages required to achieve these contracts).

4. Conclusions

Credit insurances made their presence felt increasingly in the current economic crisis in which the risk of not collecting the value of products delivered to customers is more present, the economic agents preferring to apply these guarantee forms to collect the debts on the appointed date. In these periods the risk factors are analyzed with increased rigor, the managers of companies are in a position to choose the contracting of more expensive credit insurance products, solution that is preferred to fail to receive these debts and entry into insolvency. Through this, the credit insurances contribute to the mobilization of some internal reserves that will lead to increase of labor productivity and decrease of production costs. At the same time it is required that the state to intervene in the economic life by increasing the annual budget allocation approved by Parliament for governmental agencies (in our country EXIMBANK) in order to encourage the foreign trade of the companies, the penetration of certain foreign markets, by subsidizing of a part of the interest related to the achievement of production for export and export, respectively a part of the costs of credit insurance.

Abstract

Extending the applicability of marketing seems to surprise no commercial world today, in the context of the globalization trend imposed by the total rate requires a well-known for the development of nonlinear business area. This new work aims to underline the need for organizational decision maker's respondent's orientation towards marketing approaches that focus more visible in the eco area. This neo-positioning involves a set of measures based on media and means to identify the optimal information dissemination so as to ensure safe signals, concrete and real to the purchaser, consumer or user in order to reach level of accountability for their lifestyle.

Certainly the eco-marketing impact does not stop the progress we have presented in the conditions that continually occur and appear new extra connection in the marketing relationship with our business, particularly amid the economic and financial unrest and social effervescence that dominates current global trade pattern.

Key words: eco-marketing, globalization, development, eco-consumption, eco-behavior

J.E.L. classification: M31

1. Introduction

Considering that eco-marketing is a marketing technique which is able to promote a product/service based on the environmental benefits and its market impact direct and/or indirect, we are therefore able to grasp the fact that this approach is based on a complex mechanism of action, development and

evolution, implying clearly the orientation towards a management system [1] entirely responsible.

In fact, the quintessence of this neo-concept, without departing from the science which crystallized it, receives new meanings and new interconnections in the XXI century economy, while keeping intact all the essential powers [2] directly anchored to the representative 5P of the modern marketing mix.

In other words, the applicability of eco-marketing should be able to lead to a new orientation of the options and manufacturer thinking to the benefit and of the direct and/or indirectly that will directly reflect on BCU's contemporary life.

2. Method and materials

As a working method for this work it was chosen the achievement of a presentation regarding the current level of eco-marketing to what should become in the shortest time.

The novelty of this work is reflected in the proposed terminology, the figures presented and transparent way to deal with cross-marketing issues as opposed to the angle of the current professional literature cited in this paper.

Also, it is considered that a successful eco-marketing approach will not be able to produce only in the context if a responsible management will ensure its current moves on the EFS (economic-financial-social) global stage. This management responsibility will certainly be focused on methodological issues directly related to functional, organizational and practical mechanisms found in the modern marketing mix [3] if we consider the anticipation actions of NPE (needs, preferences, expectations)

corresponding to modern BCU (buyer-consumer-user), in a more natural and sustainable way [4], in order to generate repeatable consumer-purchase-utilization act regarding the concerned eco-products and/or eco-services.

Moreover, this eco orientation begins to take visible shape in the global business culture, especially in the context in which we're speaking more and often about DES (digital eco-sustainability) as a neo-concept allowing organizations to increase the informational current spectrum of the eco-product/service through on-line niches [5].

In fact, eco-business information accessibility seem to be positioned far from fully satisfactory level, if we think that apart from accessibility to information is really needed for the acceptability process to consume-purchase-use the products and/or services found in modern organizations book [6].

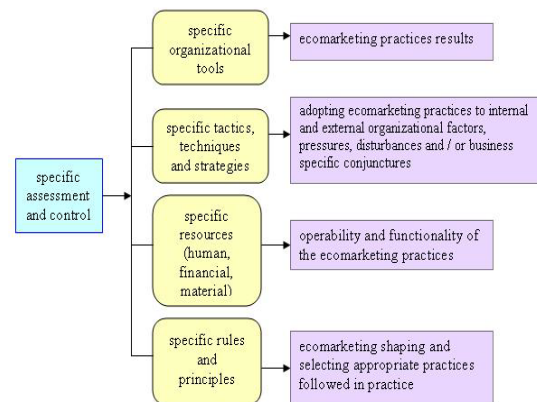

This is actually one of the main errors that are assigned to the current eco-marketing strategies respectively the focus almost exclusive on the phenomenon known as crowd-sourcing, relying on capturing the public interest to something new and beneficial to the own health and/or their individual benefit.

3. Results and discussions

In our view, tomorrow eco-marketing must be able to see and to understand all the benefits of the LRI (local-regional-international) empowerment barometer leading to an approach involving the contemporary BCU in a constant search of a better life, more qualitative [7] and sustainable based on sufficient eco-instruments, carefully anchored in the surrounding reality.

By this the millennium marketing carries on his shoulders the burden of vital role which it involves by the introducing and promoting of some eco-products and/or services so as to bring about a rationalization of resources consumption and a careful review of their own lifestyle and the current society as a whole. This requires effective and transparent understanding of the transformational approach imposed by eco-marketing in upstream and downstream of its concrete actions, namely:

Figure 1 Transformation approach imposed by the actions and commercial decisions of eco-marketing

In the current EFS (context, carrying out in the commercial practice of such a mechanism will be able to provide a visible long-term opportunity, given the general crisis pattern that dominates over the LRI contemporary business scene.

This is why we consider the marketing involvement as beneficial in this complex global term, especially since the modern BCU is able to accept a neo-oriented commercial offer based on eco-products /services [8], aspect which can be extended even under the form of acceptance and implementation of some corresponding and harmonized international eco-standards [9]. For this we also consider that it should be channeled in a synergistic way all the marketing efforts especially in the area concerning the justification of the sensitive high cost for the eco-products/services, especially under the current global financial instability.

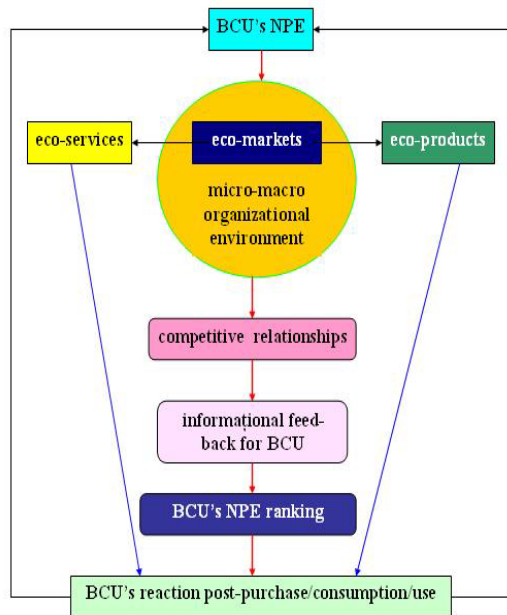

In this context, the eco-mix of such products/services should be based properly around such a SWOT which must remain perfectly justifiable and credible for the eco-guidelines views. Like this it will be caused a new level of informing the widely BCU regarding the full impact of the commercial-industrial trends on the environment and the global changes that can not be hidden from the contemporary human eye.

Furthermore, modern BCU seems so willing to abandon the traditional purchase-consumption patterns, and it becomes more interested in assimilation of some neo-ways

and/or practices in order to be accountable to the current and future LRI framework.

A valuable tool in this landscape is reflected in the arrangements of modern advertising and it disseminate more and more eco-messages whose main subject is the compatibility BCU's NPE towards the respect of modern global environment.

Figure 2 BCU's NPE versus current trade offer

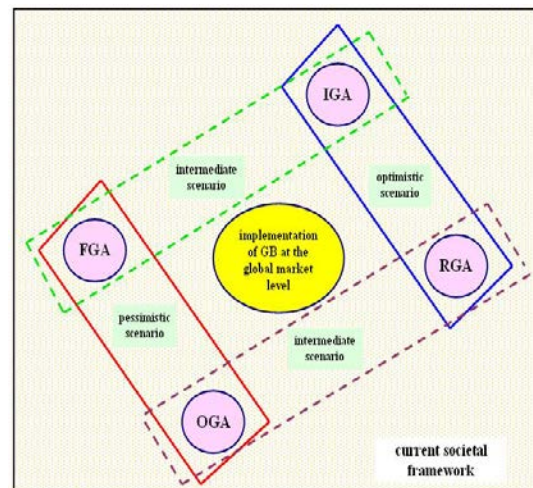

However, we must be fully aware that these campaigns can not fully impose the global will regarding the replacement by the BCU of the products/services/resources which are currently consumed-purchased-used [10] with others exclusively eco, as long as is currently missing a real sustainable context of self-discipline.

To arrive at this point it would be needed, obviously, channeling a proactive energy toward the absorption of a GMST (green modern sustainable training) especially for the proactive factors [11] responsible for the advertising space but also for the specifically one of current business, which must associated a GPA (Green practical advice) directly applicable to the eco-marketing area. If these efforts would be accomplished then we appreciate that it could reach a RVIC (green reaction of credible information) which once offered to modern BCU may be able to channel its NPE towards eco-NPE's on medium-term and long term. At the same

time, at this stage it will be able to openly talk about a GGB (green global behavior) specific for the orientation of the green company [12], which will expand to the market level given both an optimistic and a pessimistic scenario, without omitting intermediate scenarios.

All these aspects will occur in the context of the specific mutations that appear on the commercial global chessboard [13], where they're meet and confronting through material and/or immaterial relationship FGA (false green actors), OGA (opportunistic green actors), RGA (real green actors) and IGA (intelligent green actors).

Figure 3 Implementation of GB (green behavior) at the global market level

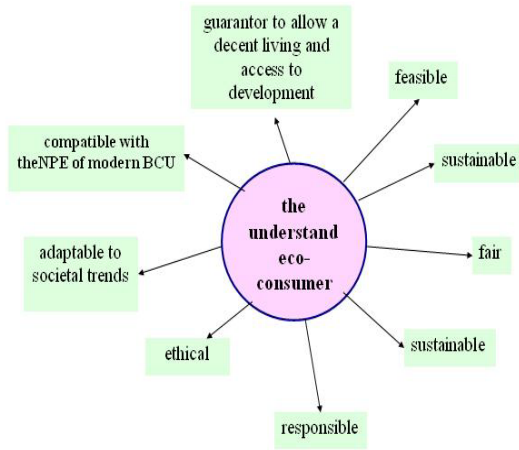

Given the typical scenarios to implement a GGB, we appreciate the fact that modern BCU will be able to extract its own green strategy, in order to satisfy the current and future options in order to include a pragmatically degree of acceptability towards the eco-trade offers, regardless of the specific organization activity, the implantation country or organizational size.

However, modern BCU will need to understand that this neo-perspective will not be able to influence negatively or uncontrollable the desires related on the comfort in living standards and/or present or future welfare level if it will produce a sincere guidance for eco-consumption.

It will thus attain an understanding eco-consumer stage, whose generic features are presented in figure 4, which will lead to a neo- perspective of the buying/consume-use

process for the general and/or specific products/services.

Figure. 4 Characteristics of the understood eco-consumption by BCU

More so, it must be known that from here it will follow a set of advantages that can be outlined carefully at a SLC (sustainable lifestyle choice) level along with the efforts channeled towards the careful selection of only those technologies and business and/or industrial practices likely to generate eco-efficient and eco-sustainable methods able to produce the maximization of the eco trends effects at LRI area.

There must not omit the fact that the BCU must focus the responsible efforts also towards maintaining a responsible eco-balance between the commercial report offer-demand both at the real market level and those potentials.

In addition, we appreciate that the principles of eco-consumption should be carefully selected and harmonized in a unstable global which must be then assume by all present and future organizational actors so that the effects that will follow naturally from their work to be transposed in a positive way both over the societal framework but also over the specific and global environment [14].

4. Conclusions

It becomes increasingly clear that eco-marketing currently holds a specific mission concerning the abandonment of the vicious circle hidden under the masks of current business practices, and they must be replaced

as soon as possible with another opportunity to support global business activities.

Thereby, the option for ensuring a sustainable and concrete development mustn't remain a simple goal stayed on the border between the evolving world and one in the developed process, but an actual law of modern BCU, for acceding to a neo-way of living and an eco-behavior [15].

However, scientific progress can't be still focused entirely in the direction of R&D orientation towards a real SLC, reason for that it is required a neo-global vision specifically for the sustainable development. Timely it can generate a deep reconfiguration of the current commercial pattern which must transform into a less dependent one on the energy consumption, integration of harmful and/or toxic substances, non-renewable material use, integration of components that can not be recycled, etc.

Just to achieve this goal it is recommended implementing of measures that will generate profound, structural and justified changes in the current model of consumption [16], involving all instruments capable of meeting this generic action until the moment when it will be reached the NCC (neo-culture of consumption) at the EFS sustainable level.

The Regions of Economic Development and Categories of Activities

Grigorescu Adriana

National School of Political Studies and Public Administration
adrianag@snsps.ro

Abstract

Regional development is a primary objective, representing the essential element in ensuring a decent standard of living and a quality level of life in the entire national environment. The study puts forward inter-regional differences from the viewpoint of the gross added value as a result of economic activity. Nevertheless we can distinguish regional differences in terms of inclination for some economic activity categories.

The share of counties in the total value of the VAB leads to the classification in 5 typological classes on which we can identify economic development factors.

Key words: regional development, positioning, classifications

J.E.L. classification: O1, O5, R5

1. Introduction

The harmonious regional development has been a constant concern that should allow the a similar level of life-quality within the entire national environment.

In order to reach these objectives, in 1998, the Law no. 151 defined 8 regions of development proper to the statistic level NUTS II, in accordance to the system performed into EU countries.

As it is stated within the document: "Unlike rural communities, municipalities and counties, the areas for development are not administrative-territorial units and do not have legal personality. The institutional framework, the objectives, the features and the instruments for the regional development policy in Romania have been revised in 2004 within the context of the 21st chapter "Regional policy and structural instruments' coordination", by the approval of the Law no. 315/2004 on regional development in Romania (The Romanian Government, The

National Plan for Development 2007-2013, 2005, p. 10).

The 8 regions are: 1. North-East (Bacau, Botosani, Iasi, Neamt, Suceava, Vaslui); 2. South-East (Braila, Buzau, Constanta, Galati, Tulcea, Vrancea); 3. South-Muntenia (Arges, Calarasi, Dambovita, Giurgiu, Ialomita, Prahova, Teleorman); 4. South-West Oltenia (Dolj, Gorj, Mehedinti, Olt, Valcea); 5. West (Arad, Caras-Severin, Hunedoara, Timis); 6. North-West (Bihor, Bistrita-Nasaud, Cluj, Maramures, Satu-Mare, Salaj); 7. Center (Alba, Brasov, Covasna, Harghita, Mures, Sibiu); 8. Bucharest-Ilfov (Bucharest, Ilfov).

The proposed analysis targets the regional gross added value and the 6 categories of economic activities. According to the National Institute of Statistics: "The gross added value measures the surplus value of goods and services produced more than the value of goods and services consumed for production, thus representing the new value created in production".

Categories of activities considered within the statistical reports are: A01 - Agriculture, hunting and forestry, fishing and fish breeding, A02 - Industry, including electricity, gas and water; A03 - Construction; A04 - Wholesale and retail trade, repairing of motor vehicles, of motorcycles and of personal and household goods, hotels and restaurants, transportation, storage and communications; A05 - Financial brokerage, real estate, rentals and services for companies; A06 - Public administration and defense, education, healthcare and social support.

2. Methodology of analysis

In order to determine possible limitations that underpin the evolution of a regional development model, a first analysis of the current status may provide useful information. The economic development of a region is depending on the economic activity

that takes place, on the potential on intensive development, as well as on its strategic opportunities for economic reorientation or simultaneous development.

Using statistical data for the timeframe 2002-2006, one could outline how the region evolved in terms of GDP, RGVA developments reported during this period, for each region and category of activity, expressed in percentages, as well as the ratios for each category in the formation of the RGVA, respectively the VAB share corresponding to each region, in a rundown for categories of activity.

By calculating the ratios and applying logical selection tests there will be a classification of counties into five categories of study in order to identifying conditions and factors that stimulate or inhibit the economic development.

3. Hypotheses for the Analysis

The assumptions the analysis intends to verify are:

I1 - the evolution of the GDP per development region depends on its initial level;

I2 - RGVA developments in different regions are depending on the category of activity;

I3 - the share of economic activities is constant during the 2006 period as compared to the 2002 timeframe;

I4 - regions' shares in the categories of economic activities is constant;

I5 - the shares of the counties in the categories of economic activities are different;

I6 - based on the ratios in the GVA formation on categories of activities, the counties can be grouped into types of contributors.

4. Results of the analysis

Using statistical data on the GDP for the development regions, one could observe that from 2005 to 2007 it experienced a constant, systematic increase in all regions. The only highlighted exception is the region Bucharest-Ilfov, which - unlike the other regions - recorded a spectacular growth.

Yet at a closer look one can perceive that it has increased in 2005 compared to 2002 about 3.5 times, about four times in 2006 and from 4.5 to 5 times in 2007 respectively, in all regions.

Source: the National Institute of Statistics

Thus I1 is confirmed in the sense that a higher initial value leads to spectacular values, in the context of constant growth rates.

RGVA evolution on categories of activity is presented as a percentage, having as basis the reporting year 2002, in order to highlight inter-regions differences.

In Figure 2 for A01 one could distinguish that the South-Eastern, Bucharest-Ilfov, South-Muntenia, South-West Oltenia regions recorded higher increases (between 250-300%) compared to other regions in 2004, while in 2005 and in 2006 there has been a return to the level of 150-200%. However the Bucharest-Ilfov and South-West Oltenia regions recorded higher positions.

Figure 2: The gross added value by regions of development - A01

Source: the National Institute of Statistics

In Figure 3 one can perceive that with respect to A02, the North-East region is placed in a position of decline, while South-Muntenia and West regions recorded the strongest increases.

Figure 3: The gross added value by regions of development - A02

Source: the National Institute of Statistics

The values shown for A03 and A04 highlight relatively constant increases from year to year for all regions, with the sole exception of the Bucharest-Ilfov region, which continuously recorded higher rates, after a period of five years recording a growth of about 50% (for A03 the general level is between 250-300% and between 200-250% for A04).

In figure 4 one could see that - unlike other categories of activities - A05 experienced a constant evolution without major differences between regions.

Figure 4: The gross added value by regions of development - A05

Source: the National Institute of Statistics

The Bucharest-Ilfov region registers a peak in the A06 compared to other regions.

Figure 5: The gross added value by regions of development - A06

Source: the National Institute of Statistics

One could note from the charts above that the hypothesis of RGVA different variation depending on the category of economic activity is partially verified. This should be overall understood as a general trend with consolidated exceptions. It is obvious that the Bucharest-Ilfov region is such an exception. Source: the National Institute of Statistics

A second form of RGVA analysis is where one can see the contribution of different regions to each type of economic activity considered.

The comparison is performed for the values for 2002 and 2006 respectively.

Figure 6: The share of regions in economic activities - 2002

Figure 7: The share of regions in economic activities - 2006

From the previous figures it can be easily noted that the West and South-West Oltenia regions contribute to all six categories of activities with ratios of 10-15%, the sum not exceeding 20%.

The Bucharest-Ilfov region is a major contributor within the A04 and A05 areas, where it contributes with about 25-30%. It also has significant contributions within the A03 and A06 areas.

The South-East and North-Eastern regions' contributions are of 10-15% in all economic activities' categories except the A01 where it records an increase towards 20%.

At the same time the North Central and West regions have constant contributions of about 10% for A03, A04, A05 and A06, their major contributions being focused in A01 and A02 but without exceeding 15%.

Figure 8: The share of economic sectors in gross added value by regions - 2002

Figure 9: The share of economic sectors in gross added value by regions - 2006

Source: the National Institute of Statistics

From the Figures 8 and 9 one could notice that the shares of different types of activities in the RGVA formation for the 8 regions have not changed substantially between 2002 and 2006. Also it might be noted that A02 and A04 are the categories of activities with the highest ratios in the RGVA formation.

The highlighted differences originate from the contribution of each type of activity. Thus, in the Central, South-West South-Muntenia and Oltenia regions, A02 has the largest share of over 30%. In Bucharest-Ilfov, A04 has recorded the highest share of over 30%, A02 reaching up only to 20%.

A more detailed analysis can be achieved at county level within the structure of a region. This will provide information on how each county participates in the creation of the RGVA.

If we look at the ratio of activities in the RGVA formation in two regions, namely North-East and South-Muntenia, one could verify if - inside the region - the contributions of each county are proportional or not.

The two presented regions are placed at the opposite sides of the regional analysis; the North-Eastern region has a relatively uniform distribution of the contribution of the categories of activities, as opposed to the South-Muntenia region which has a weighting in favor of a single category.

The ratio of the categories of activity in the North-East region is about 25% for A02 and A04 (considered as basic constituents in all regions), about 15% for A01, A05 and A06 and less than 10% for A03.

The county ratios show that each of these counties participates in a different way. Thus, Botosani and Vaslui register different ratios from those recorded throughout the entire region.

For the county of Botosani, A0, A02, A03 and A06 entail comparative ratios of about 20%, in the county of Vaslui, A01, A02 and A06 are maintained at 20%, while A03 and A05 are placed at 15%.

Figure 10: The share of economic activities in GAVR - North-East Region /2006

Source: the National Institute of Statistics

As seen in Figure 10 only the county of Neamț preserves the ratios recorded for the region. Certain uniformity in the ratios of activities' categories at the level of the regions is not based on homogeneity distributions in the counties, so one must identify the factors that determine these ratios at the county level.

The second example is the South-Muntenia region, shown in Figure 11, which unlike other studied region has a discrepancy ratio in favor of A02, positioned at about 35%.

Figure 11: The share of economic activities in GAVR - South-Muntenia region/2006

Source: the National Institute of Statistics

One might note from the chart that, for this region, the ratios for activity categories in counties are quite diverse. Thus, the Arges and Prahova counties record amounts above 40% for A02, while Giurgiu only 20% and Ialomita records slightly over 20%. At the same time, the Giurgiu county places A01, A02 and A05 on an equal level which – on their turn - are placed at 20%. Concurrently, Ialomita records 20% ratios for A01, A02 and A04.

If we calculate the ratios of the six activity categories for VAR in 2006, we find that the highest discrepancy values in the 41 counties and Bucharest are registered in Bucharest. These are 13% for A02, 24% for A06, 25.8% for A03, 26.35% for A04 and A01. In the case of A01 the amount is 0.09%, a very low level.

The following values are registered at less than half, namely 6.49% and 6.25%. For this reason the total ratios were calculated without Bucharest.

Table 1: THE SHARE OF ACTIVITIES IN GAV BY COUNTY *

	million lei - current prices					
	A01	A02	A03	A04	A05	A06
Alba	2.23%	2.83%	1.51%	1.69%	1.82%	2.36%

Tulcea	1.56%	0.99%	0.99%	0.74%	1.19%	1.49%
Valcea	1.86%	2.31%	2.55%	2.11%	2.14%	2.08%
Vaslui	2.35%	0.85%	0.83%	0.87%	1.39%	1.86%
Vrancea	2.49%	1.03%	1.23%	1.32%	1.79%	1.96%

* Calculations are carried out without the contribution of Bucharest Municipality

From Table 1 it should be noted that only the Constanta county registers a share over 8% in the case of A03. Between 7-8%, Constanta is placed in A04, Prahova in A02 and Timis in A05.

Between 6-7%, there are Arges - A02, Cluj - A03, Ilfov and Timis - A04, and between 5-6%, the number of "taxpayers" increases: Cluj - A03, A04, A05; Constanta - A02; Iasi - A06; Prahova - A03; Timis - A02, A03 and A06.

Another issue to be noted is that Timis county has homogeneous contributions placed between 4-8%, followed by Constanta (3 to 8.43%) and Cluj (3-7%). On the next level, there are Arad, Arges, Bacau, Bihor, Brasov, Dolj, Galati, Iasi, Mures, Sibiu. A special case is Prahova which registers only 1.98% for A01 and 7.47% for A02, exceptionally positioning itself in the first category.

A benchmark composed of 14 counties with remarkable results placed on two levels (as shown above) can be revealed, from their analysis being able to identify determinant factors of economic performance.

One could observe that counties which register ratios of less than 1% - for at least three categories of activities - are facing economic difficulties. We are speaking of Calarasi and Covasna (A02, A03, A04, A05) and Giurgiu, Tulcea and Vaslui (A02, A03, A04). The number of those who register ratios between 1-2% is high; however, it is relevant the manifestation of these ratios simultaneously with the ones under 1% or between 2 to 2.5% for all categories of activities.

Table 2: THE SHARE OF ACTIVITIES IN GAV BY COUNTY* - DEFICIENT AREAS

	A01	A02	A03	A04	A05	A06
Alba	2.23%	2.83%	1.51%	1.69%	1.82%	2.36%
Arad	2.77%	3.07%	2.54%	3.20%	3.59%	2.67%
Argeş	2.86%	6.48%	4.10%	3.42%	3.26%	3.10%
Bacău	2.95%	2.72%	4.29%	3.03%	3.00%	3.42%
Bihor	3.02%	3.53%	2.28%	3.92%	3.82%	2.97%

Doj	2.89%	3.35%	3.29%	2.97%	2.72%	3.91%
Galaţi	2.84%	2.30%	3.87%	2.21%	2.82%	2.70%
Giurgiu	1.60%	0.61%	0.86%	0.64%	1.28%	1.03%
Gorj	1.77%	3.06%	2.74%	2.12%	1.62%	1.78%
Harghita	2.03%	1.84%	0.95%	1.44%	1.52%	1.56%
Hunedoara	1.69%	2.90%	2.82%	2.30%	2.50%	2.55%
Ialomiţa	2.07%	0.91%	1.18%	1.20%	1.22%	1.19%
Iasi	3.50%	2.37%	4.59%	3.52%	4.44%	5.27%
Ilfov	1.39%	2.84%	1.54%	6.56%	2.36%	1.23%
Maramureş	2.59%	1.97%	1.58%	2.15%	2.37%	2.40%
Mehedinţi	1.57%	1.00%	1.66%	0.90%	1.17%	1.51%
Mureş	2.93%	3.44%	2.47%	2.73%	2.42%	3.12%
Neamţ	2.69%	1.65%	1.88%	2.55%	1.87%	2.32%
Olt	2.58%	1.64%	1.79%	1.03%	1.49%	2.04%
Prahova	1.98%	7.47%	5.58%	4.05%	4.85%	3.41%
Sălaj	1.47%	1.12%	0.55%	0.90%	1.28%	1.25%
Satu Mare	2.11%	1.77%	1.41%	1.30%	1.83%	1.91%
Sibiu	2.01%	3.06%	3.14%	2.49%	3.13%	2.60%
Suceava	4.15%	1.90%	1.68%	2.43%	3.01%	2.96%
Teleorman	2.50%	1.29%	0.58%	1.05%	1.53%	1.63%
Timiş	4.07%	5.67%	5.71%	6.26%	7.40%	5.25%
Tulcea	1.56%	0.99%	0.99%	0.74%	1.19%	1.49%
Vâlcea	1.86%	2.31%	2.55%	2.11%	2.14%	2.08%
Vaslui	2.35%	0.85%	0.83%	0.87%	1.39%	1.86%
Vrancea	2.49%	1.03%	1.23%	1.32%	1.79%	1.96%

* Calculations are carried out without the contribution of Bucharest Municipality

In our opinion, Calarasi, Covasna, Giurgiu, Mehedinți, Salaj, Tulcea are placed on the most vulnerable positions. On a second posture, but equally relevant one could find Bistrita-Nasaud, Braila, Caras-Severin, Harghita, Ialomita, Satu Mare, Teleorman and Vrancea.

A deeper analysis of these counties can provide information on possible vulnerabilities or conditions and factors that hinder economic development in these areas.

5. Conclusions

The conclusions drawn from this study are presented consistent with the established assumptions.

I1 - the evolution of GDP on development regions depends on its initial level - it has been partially verified, discovering also a large increase in the absolute value of GDP in the Bucharest-Ilfov region, which in 2002 (taken as reference) recorded the highest value. In percentages, all regions record - during the studied timeframe - comparable increases.

I2 - RGVA evolutions are different by regions, depending on the category of activity - the hypothesis was verified in part, the evolution of the RGVA highlighting a general trend of growth, similar in most regions. In other words, by categories of economic activities, in 2002-2006, a growing trend with highlighted exceptions can be revealed. The Bucharest-Ilfov region is an atypical case in all situations.

I3 - the ratio for economic activities is constant in 2006 with respect to 2002, leading to the conclusion that there are a number of factors of economic stability in the regions. Important for further studies is whether this stability is maintained also at the county level, an element that would be a starting point in determining regional economic development factors.

I4 - the ratios of regions in economic activity categories are constant - hypothesis checked from the perspective of the moments when determinations were made, but untested from the viewpoint of the regional structure. Calculations showed that the regions have relatively constant ratios of economic activity in each category for the five years analyzed. Each region's contribution to the GVA formation differs from one activity to the other.

For a better understanding of the phenomena that occur in the regions, the analysis was detailed at the level of counties. The hypothesis from which the study started is I5 - counties' ratios in economic activities' categories are different. The two studied regions have confirmed that the counties do not have a similar behavior at regional level, to be reflected in the results of the region.

The values acquired for the regions are the result of summing up the contributions from each county, which could be very different.

The last hypothesis that was the foundation of this analysis is I6 - based on ratios for GVA formation on categories of activities, counties are grouped into classes of contributors.

Consequently, five classes of registration were outlined:

- C1 - counties with major contributions;
- C2 - counties with significant contributions;
- C3 - county with average contributions;
- C4 - counties with vulnerabilities;
- C5 - counties with major flaws.

Starting from this classification of counties in terms of their contribution to the formation of the VAB on categories of economic activities, one could determine the similarities, conditions and factors that allow economic development, but also those which hamper possibilities. Combined with other regional analyses, the information might facilitate the creation of a system of relationships that could enable economic

recovery in all counties through concerted state actions and of the business environment.

Managerial Functions: Leverage to Improve Performance Indicators

Grigorescu Adriana

National School of Political Studies and Public Administration

adrianag@snsps.ro

Odagiu Cristian

"Valahia" University of Târgoviște

Abstract

This study aims to emphasize how performance indicators can be improved by implementing an appropriate management. The counterbalance of a poor funding from the state budget for a program can be achieved by using the levers of the management process functions, particularly referring to the planning and organization. The comparative method of the research data is applied to the institutional performance indicators obtained for four consecutive years.

The analysis of the results obtained in the study undertaken reflects an appreciable improvement of the performance indicators over a comparable funding from the state budget related to each of the four years for which the comparison is made.

The study value lies in presenting a specific case of a management policy aimed at improving performance indicators in virtually unchanged terms of a poor funding.

Key words: indicator, management, performance, program, public administration.

J.E.L. classification: A3, D73, M12, M54

1. Introduction

The managerial perspective on performance in public sector implies an increasing pressure on managers to implement a results-oriented vision. This fundamental shift in the nature of thinking and acting moves away the management from the administrative focus on processes and regulations (Callahan, 2009, p.4).

The usability of various resulting data from the performance indicators measurement of an organization is a managerial tool to help the improvement of efficiency and

effectiveness and to create value added. The process of creating a bond over time and space between individual capacities and organizational potential to achieve the expected results defines the performance (Table No. 1). In terms of efficiency and effectiveness, performance is determined by the manager's ability to change, to deliver, to understand and to learn (Proulx et autres, 2006, p.36, 37).

Table No. 1

Ways and means of intervention X (competences)	Ways and means of the organization =	Combined results
Organization	to understand	to orient
Strategy	to change	to manage
Management	to deliver	to serve
Continuous training	to improve	to progress

A management designed to improve performance indicators of public institutions requires the fulfillment of several conditions:

- to determine the precise objectives, to negotiate about the means at their disposal and about predetermined time;
- delegating responsibilities;
- results measurement using indicators;
- fair reporting of the results, regularly (monthly, quarterly, half yearly).

2. Case study for the Sport Directorate of Bucharest (SDB)

The study about SDB management is relevant in terms of its influence on the institution performance indicators. SDB is a decentralized public service of the National Authority for Sport and Youth, being in subordination of the National Agency for Sports (NAS) during 2006-2008 and in

subordination of the Ministry of Youth and Sport (MYS) during 2009. The institution is financed from the state budget and from own revenues, having as main attribute to support sports activities in the territory according to law number 69/2000 of physical education and sports.

The Government priority programs in the area on the promotion of sport performance (P1) and on the promotion of sport for all (P2) find their local support through the work being done under the direct coordination of SDB.

The main problem that stands in front of the management system refers to the efficiency of the institution activity in terms of budgetary allocations increasingly smaller. This means to find the opportunities of improving SDB performance indicators in the new created conditions.

3. Research hypotheses

Hypothesis 1. The link relation between the values of performance indicators and the amount of funding sports programs from the state budget is a clear and measurable working hypothesis.

Hypothesis 2. The use of the managerial functions to improve performance indicators may largely cancel their dependence from the budgetary allocations.

Budgetary financing policy aims to improve decisions during the budget process, a strengthening transparency and manager's accountability to increase efficiency and to achieve economies (Bouvier, 2007). The budget system must not be restricted only to put in context the use of resources, but it requires to improve quality and to increase performances and the use by decision makers of the managerial functions can respond to this challenge.

4. Research methodology

Comparative methods for the interpretation of research data allows for this case to pass from the hypothesis to the solution of implementing an efficient management to improve SDB performance indicators.

Dependency ratio on the budget for the performance indicators to achieve the objectives of the institution may be greatly improved by the internal logic of the budget

drafting provided in the general policy of the institution, according to the performance triangle as (Matei, 2009, p. 29).

Performance indicators represent a critical component of the results-based management system. They represent the source to allow the integration of results measurement from all the stages of implementing a program. Different levels of the indicators measurement are summary represented in Table No. 2 (OECD, 2010, p.7):

Table No. 2

Inputs	all the resources involved in the program
Activity	implementation and management process
Outputs	Services delivered by manager's intervention, under his responsibility
Outcomes	immediate effects of the programme for sports structures
Impacts	long-term impacts and indirect consequences of the intervention

From the implementation in the territory of the Government policy to support P1 and P2 programmes, we refer in this case to several indicators commonly used to evaluate institutional performances of the sports county directions and that of SDB.

Corresponding to the fundamental objectives, specific to support sports activities, in the next Table are represented the key performance indicators which are established by the coordinating institution NAS (later MYS), which is consistent with secondary objectives provided in the annual development plan of the sports calendar.

Table No. 3

Objective	Indicators
Organization and development of the activities in the field of sports performance	number of competitions provided in the calendar number of completed competitions progress of the sports competitions average cost / competition
Organization and development of the programme "Sports for all"	Idem
Increasing the role of factor for locally dynamic social and economic development through	number of participants in the program "Movement for health" population degree of the

characteristic means for sports activities	participation in sports-entertainment number of partnerships developed to sustain sports activities own revenues used number of school sport associations without legal personality
--	--

To make the calculation of indicators-aggregate (IPA), the percentage weights (P_i) given to each relevant indicator are determined according to their importance in getting the results that contribute to performance measurement at the institutional level, so that:

$$(1) \quad \sum_{i=1}^n P_i = 100\%$$

where n=number of performance indicators.

There are two variants of calculation. The first one uses absolute values of the 10 indicators which are considered representatives to evaluate performance. The second variant uses implementation indexes (reporting) which in the opinion of the authors eliminate discrepancies in calculations induced by the different orders of magnitude of the used values.

$$(2) \quad IPA = \sum_{i=1}^n P_i \times IP_i$$

Variant A

Performance quantitative indicators and their weights are represented in the table below:

Table No. 4

Indicator	Name	Weight (%)
IP ₁	Number of competitions provided in the calendar for the program P1	10
IP ₂	Number of completed competitions within the program P1	10
IP ₃	Average cost / competition (Ron) within the program P1	5
IP ₄	Number of competitions provided in the calendar for the program P2	15
IP ₅	Number of completed competitions within the program P2	15
IP ₆	Average cost / competition (Ron) within the program P2	5
IP ₇	Number of participants in the program "Movement for health"	15

IP ₈	Number of partnerships developed to sustain sports activities	15
IP ₉	Own revenues used (Ron)	5
IP ₁₀	Number of school sport associations without legal personality established in the current year	5

Variant B

Performance percentage indicators are derived from performance quantitative indicators. They are represented in the table below with weights to each of them:

Table No. 5

Indicator (%)	Name	Weight (%)
IP _{1,2}	The progress of the competitions for the program P1	20
IP ₃	The utilization /competition of funding the program P1	5
IP _{4,5}	The progress of the competitions for the program P2	30
IP ₆	The utilization /competition of funding the program P2	5
IP ₇	Population degree of the participation in sports-entertainment	15
IP ₈	The utilization /competition of collaborative partnerships	15
IP ₉	Own revenues utilization	5
IP ₁₀	The representation of school sport associations without legal personality established in the current year	5

IP_{1,2} and IP_{4,5} represents the ratio between the number of completed competitions and the number of competitions provided in the calendar for programs P1, P2 respectively.

IP₃ and IP₆ represent, similarly, the ratio between the average costs / competition and the number of completed competitions.

IP₇ is the ratio between the number of participants in the program "Movement for health" and the number of Bucharest population (it takes into account the number of two million inhabitants).

IP₈ is the ratio between the number of partnership contracts made and the total number of competitions completed (sum of both programs P1 and P2).

IP₉ is the ratio between own revenues used to support competitions and the total sum of own revenues received.

IP₁₀ is the ratio between the number of school sport associations without legal personality established in the current year and the total number of sport associations without legal personality.

Using statistical data provided by SDB, NAS and MYS, a comparison was made between the institutional performance indicators for a period of four years (2006-2008). To suggestively put in evidence research hypotheses, there will be used both work variants.

5. Research results

Variant A

Due to the different orders of magnitude of performance quantitative indicators (IP_i), to have a more fair accuracy in the calculation of obtaining the indicator-aggregate, there will be used the correction coefficients (C_i) which apply to each indicator. The values of these correction coefficients related to each performance indicator (see Table No. 6) are as follows:

$$(3) \quad C_1=C_2=C_4=C_5=C_8=C_{10}=10^0; \\ C_3=C_6=10^{-1}; C_7=C_9=10^{-2}.$$

Table No. 6

IP_i	P(%)	C	2006	2007	2008	2009
IP_1	10	1	199	150	80	233
IP_2	10	1	135	105	91	211
IP_3	5	0,1	829,63	1386	1159	1141
IP_4	15	1	92	77	75	78
IP_5	15	1	84	85	130	97
IP_6	5	0,1	682,27	952	957	742,27
IP_7	15	0,01	18848	32000	37000	26436
IP_8	15	1	5	16	34	9
IP_9	5	0,01	7311	22542	77456	5737
IP_{10}	5	1	0	0	75	19
IPA			100,04	123,16	161,52	124,89

An analysis of the achievement of objectives for the year 2007 in conjunction with the trend continues to reduce funding from the state budget for SDB imposed a realistic adaptation of the 2008 calendar for both of the programs P1 and P2 (indicators IP_1 and IP_4).

From the results can be seen a 23% performance increasing in 2007 over the previous year. Growth continues in 2008 with 31%, while in 2009 fell by 23%. The decrease is mainly due to the replacement (on political criteria) of the institution manager.

The paradoxical situation of IP_3 and IP_6 indicators is due to the compromise to be made between efficiency and quality: on the one hand, unit costs should be as small as possible, but on the other hand their values should be sufficiently large to ensure an acceptable quality level on European and

international scale. Success of sporting competitions requires for example to cover rents for the rooms and land competition, expenses related to providing medical assistance, payment of referees, sports awards, and other. Should be noted that an average cost / competition below 500 Ron does not meet the requirements of the optimal development of sports activities.

Performance indicator IP_8 has an important role due to attracting collaborators to support sports actions in partnership with SDB. In this way, part of required expenses to support some competitions are taken by the partners, creating the prerequisites for scale competitions, with international participation, but also some unexpected additional events (see IP_2 and IP_5 indicators).

Performance indicator IP_9 contribute with IP_8 to support sport shares by the possibility of mobilizing a part of the own revenues.

Performance indicator IP_{10} aims to attract a larger number of school-children to be involved in the official competition "School Sports Olympiad", initiated after the elaboration by the specialists in sports and education of the Common Order for approving "The Protocol for providing the framework of cooperation for continued development and permanent operation of the national system of physical education and sports".

Variant B

Performance indicators weights are determined depending on their importance of getting institutional results similiary with variant A. The values of the correction coefficients related to each performance indicator (see Table No. 7) are as follows:

$$(4) \quad C_{1,2}=C_{4,5}=C_9=C_{10}=10^0; \\ C_3=C_6=C_7=10^2; C_8=10^1.$$

$IP_{1,2}$ and $IP_{4,5}$ indicators were obtained from the ratio between IP_1 and IP_2 and between IP_4 and IP_5 (see Table No. 5), becoming in turn performance indices and cumulating shares previously owned by the two of the indicators. There was previously explained the way of calculating each of the indicators described in Table No. 5, the results being presented below based on the statistical data provided by the concerned institutions:

Table No. 7

IP _i	P (%)	C	2006 (%)	2007 (%)	2008 (%)	2009 (%)
IP _{1,2}	20	1	80	70	113,75	90,56
IP ₃	5	100	0,7407	1,5231	1,2878	0,871
IP _{4,5}	30	1	91	110,39	173,33	124,36
IP ₆	5	100	1,3645	1,904	1,914	1,0309
IP ₇	15	100	0,9424	1,6	1,85	1,3218
IP ₈	15	10	2,283	8,421	15,385	2,922
IP ₉	5	1	6,02	27,27	100	17,15
IP ₁₀	5	1	0	0	43,6	9,95
IPA			71,69	102,25	148,77	90,5

Results obtained are similar in trend, with higher values, i.e. a 43% increasing in 2007 over 2006, a 45% increasing in 2008 over 2007 and a decrease of 61% in 2009.

The financing of the institution for each of the two programs during 2006-2009 is presented in the table below (thousands of Ron):

Table No. 8

2006	2007	2008	2009
ATotal	ATotal	ATotal	ATotal
162	141	140	203

Where ATotal - total amount, sum of AP1- the amount allocated to Program 1 and AP2- the amount allocated to Program 2.

The recovery rate of the budgetary financing (efficiency financing) for each of the four years (η_F) is the percentage ratio between the performance indicator-aggregate and the total amount (A) related to financing (in thousands of Ron, including own revenues), according to the formula:

$$(6) \quad \eta_F (\%) = IPA/A$$

For a more eloquent clarification of checking research hypothesis, in the table below there are highlighted recovery rate values of the budgetary financing which are calculated for each of the two work variants:

Table No. 9

Recovery rate	2006	2007	2008	2009
Variant A	61,75	87,35	115,37	61,52
Variant B	44,25	75,52	106,26	44,58

It can be seen that even these ratios highlight similar increases and decreases, which confirms research hypotheses.

6. Conclusions

The experience of success management, which presumes having a strategic plan, a configuration of manager's mission, of his

own vision, of the purposes and objectives, of the measurement mode of success (Mader, 2009, p. 7), was the basis for guiding SDB organization to achieve performance indicators by maximizing values and reducing risks.

The horizon chosen for the program P1 (Promotion of sports performance) had in mind also the relatively short periods of peak performance for sportspersons (the exceptions in this case are very rare), medium or long-term prognosis considering more the program P2 (Sports for all) which has as targets the selection.

The creation of the premises for the performance indicators improvement is conditioned by the mode of realizing the functions to plan and to develop the actions plan for SDB. It should be noted that the activities programming for achieving objectives was done mainly by two vectors coordinators:

- the distribution in time of the updated goals by preparing and adapting sports schedules on programs, subprograms and sports;
- the distribution in space of the updated goals by establishing the work teams on programs, subprograms and by individual and team coordination for sports related to clubs and municipal sports associations.

In developing by the manager the framework programme to prepare SDB sports calendar there were also taken into account the provisions of the partnership contracts drawn up at that time. Depending on the priorities already established, the heads of programs distributed under the coordination of the manager the amounts needed to support each competition of the own calendar.

To be able to follow the numerous requests of supporting sports activities appeared during the running of the already budgeted calendar, the role of own revenues becomes predominant.

The managerial function of SDB organization took into consideration the annual repeatability of the same steps to follow into the decisional process regarding institutional results obtaining. Therefore, the changes of the Rules of Procedure and Operation (RPO) or that of the institution organizational structure were not timely, in contrast, another heads of programs were assigned for P1 and P2 both in 2007 and

2008. This fact had as a logical consequence the change of the job description for those employees but also for other members of the organization who took some of those secondary tasks.

In the action of team training and coordination to achieve the proposed goals, employee's motivation has an important role. Through the mechanisms which contributed in this direction we call: appreciation, personal material interest, work involvement, competition, and pride to belong to an institution. The same importance was also given to the continuous stimulation of the initiative and cooperation spirit within the team.

The improving of manager's style and methods proved to be absolutely necessary. So, managerial flexibility could make possible an equitable distribution of tasks and their balance depending on phenomena evolution, activities that represented an important reference.

Making corrections has been achieved also by including in the calendar a lot of unexpected competitions which appeared at the request of several internal or external partners, according to the institutions objectives. The use for this purpose of the financial resources from own revenues, attracting of new partners as well as concluding volunteering agreements during the entire year 2008, made possible the overruns represented by the indicators.

The post-operating dimension of the scoreboard gave to the manager the opportunity of acquiring the useful information on possible deviations and the causes that have generated and, according to these, the decisional side of this tool helped him to adopt the proper decisions.

Managerial acts to achieve SDB objectives represent the first step to performance in this institution. The analysis regarding the improvement of performance indicators proved that during the years 2007 and 2008, thanks to a period of stability at the management level, management tools could be used to obtain the best performances compared to both previous and next years.

The accuracy of the hypothesis formulated about managerial ability to improve significantly performance indicators of the public institution in the circumstances of a minimum funding from the state budget was

verified. This is another proof that management leverages can mostly compensate some major shortcomings that could compromise the quality of the delivered public services.

Taking into consideration that, beginning with the year 2009, the intervention of the political actors into the public administration disrupted the activity of this sector, the equation of the evaluation of the efficiency of the public service must also take into account the incidence of the political factor,, the major factor of adjusting the offer of the public sector, without which the analysis of the managerial results is only partial. The global evaluation of the performance of the public action implies both administration and politics: viewed only from the administrative angle, the evaluation of the management by results is illogical, inconsistent and useless (Proulx et autres, 2006, p. 54, 55).

Undoubtedly, performance analysis for public institutions by the methods of indicators-aggregate and of the upturn rate can provide relevant information on management quality.

Abstract

The international river law affirms its existence by linking specific legal rules with a significant number of legal rules from other fields and, particularly, from the international trade law. Their obvious general connection, their importance to the relations between co-riparian States is a crucial argument for the need of systematic knowledge within this branch of international law. No international bi - or multilateral treaty, no international river commission cannot provide the specific regulation required by circumstances, if such solutions will be somewhat improvised according to the specific circumstances of each situation, without precisely knowing in advance the specific legal rules.

Key words: The International River Law; international water way

J.E.L. classification: K33

1. Introduction

If the law of the sea has already got an international regulation by adopting the Convention on the Law of the Sea of 1982, the international river law entered the stage when some of its areas need universal multilateral rules, designed to mutually support the beneficial collaboration between the world economies of States.

In the literature specific to the area of international river law, Professor Crauciuc Olimpiu Adrian Gelu says that "the matter has evolved considerably over the years and the specific characteristics of each river have left their mark on the legal rules governing

their operation" [1].

The discipline of "international river law" consecrates its autonomy during the last part of the twentieth century. Professor Edwin Glaser supports the existence of an international river law, not the existence of a law of international drainage basins, as shown in the "Helsinki Rules", developed in the 1966 session of the International Law Association (ILA) [2].

Rivers present interest for the communication between States and people, when they are navigable and cross several states. They are important not only for navigation but also for the use of their waters for industrial, agricultural (irrigation) and energy (hydropower) purposes.

Professor Dumitru Toma says that "the international river law is composed of all the legal rules governing the relations between States regarding the use of non-maritime waters, primarily for navigation" [3].

In order to explain and present several notions, we consider necessary and sufficient to note that, in our opinion, there are several legal rules of river law and not legal rules of the law of national and international drainage basins [4].

The Barcelona Conference of 1921 brought the concept of international water, thereafter using the concepts of "basin" or "international watercourse system". However, some States categorically contested the concept of "basin". Nevertheless, the notion of "international water way", used by several States, should be legally and precisely defined. The aim is to determine the extent of the "internationalization" of its legal regime, the number and the extent of the obligations of States under the international law.

The International Law Commission has proposed, regarding the use of international watercourses, the concept of "shared natural resource", consecrated, *inter alia*, in the Charter of Economic Rights and Duties of States. This concept stresses the interdependence of the countries that share the waters of the same international hydrographic basin and focuses on the active solidarity and mutual obligations of States and we believe that it meets all the uses of an international river basin [5].

2. The evolution of international river law rules

The establishment of the international regime of several rivers began with the assertion and application of the freedom of navigation principle on some rivers for the commercial vessels of riparian States and, in certain circumstances, for the commercial vessels of non-riparian States. The idea of freedom of navigation on some rivers was affirmed by Hugo Grotius [6] and was consecrated by a French national act on 16th November 1972 [7].

The international regulation on the navigation on certain rivers was made by numerous treaties, conventions and international protocols. However, in the evolution of the cooperation between States on the international regime of certain rivers, their concern to establish some common principles of such regimes increasingly emerged, by adopting several general international acts.

2.1. The first regulations

a) A primary concern in this respect was manifested at the Congress of Vienna, which, by its Final Act of 9th June 1815, defined the concept of International River and established the general features of the international regime of the navigation on these rivers. It reaffirmed the principle of freedom of navigation on these rivers, consecrating the full freedom of the navigation for the commercial vessels of riparian States and only the freedom of commercial transport for the vessels of non-riparian States (art. 108-109). The principles established by the Congress of Vienna were applied through special agreements to the Elbe, Scheldt, Meuse and Rhine rivers. The

international regime of navigation on the Danube was established by the Peace Treaty in Paris on 18/30 March 1856 [8]. Nowadays, the Danube region contains about 115 million people in 14 countries [9] from Germany to the west to the Ukraine to the east.

b) The Congress of Berlin in 1885, by its general Act, extended the principle of freedom of navigation on Niger and Congo rivers, in Africa. Some peace treaties of 1919 and 1920 include provisions for the international navigation on some rivers. Thus, the Peace Treaty with Austria, in 1919, reaffirms the international navigation nature of the Danube river, based on the principles of freedom of navigation and equal treatment of all flags (art. 290, 292).

c) For the development of the international river law, the Barcelona Conference in 1921 is an important moment. Its importance lies in the development and adoption of several international instruments which aimed to establish several general valid rules for the international regime applied to several rivers. It adopted the "Convention concerning the regime of waterways of international concern", of 20 April 1921, which was ratified by a limited number of States participating in the conference. The conference also adopted a statute and a protocol.

The Barcelona Convention, in 1921, is still the only source of international river law with a universal character. The Convention provides that its provisions apply to "all water ways", which are naturally navigable towards the sea and from the sea. It establishes two basic principles of the international regime applied to certain rivers:

a) the principle of freedom of navigation for the commercial vessels of States (Article 3);

b) the principle of equal treatment for the vessels of all States, operating on these rivers (art. 4).

The Convention establishes the following obligations of riparian States: not to hinder the navigation on the rivers with an international regime and to maintain the navigability of these rivers in their domestic sector. It also establishes the right of cabotage only for the vessels of riparian States, in their national sector, and it grants the riparian States the right to levy taxes from the foreign vessels for their services.

After the Second World War there have been some regional acts on water regime in general, and multilateral agreements on the prevention of water pollution of rivers with international regime or of frontier waters. Within the Council of Europe, there has been adopted the "European Water Charter" of 1967 (or the Bern Agreement for the protection of the Rhine, in 1983, or the "Declaration of the Danubian States for the management and protection of waters against river pollution", adopted in Bucharest, in 1985).

2.2. Rules regarding the navigation on international rivers

The legal rules of international river law are emerging as a result of the cooperation among States in the field of international rivers and numerous international documents, which were adopted by them. The legal rules of international river law are part of public international law. The legal rules of international river law can be defined as all river customary and conventional rules and legal institutions governing the freedom of navigation on some rivers and other activities of States in this field, such as: the use of river waters as energy sources, for irrigation and for other purposes; the actions made in order to protect the waters of these rivers against pollution.

The international documents relating to the regime of several rivers reveal certain basic rules of their international regime. At the moment, these rules are more likely seen as "international standards" of the international regime of rivers, rather than as veritable elements of a general statute for rivers with international regime:

- a) each State is sovereign over these river sectors within its territory;
- b) the application of principle of freedom of navigation;
- c) only the riparian States may regulate the navigation on international rivers, by virtue of sovereignty [10];
- d) merchant vessels, in time of peace, enjoy full freedom of navigation; military [11], customs and police vessels of non-riparian States do not have access to international rivers; such vessels belonging to riparian States can navigate only in their sector; for the sectors of other States the authorization is necessary;

e) the riparian States are required to maintain river navigability; they may levy taxes; they have the right of customs and health control;

f) in principle, for international rivers, there are established committees composed of the representatives of riparian States, for the coordination of the activities of these countries [12].

2.3. The use of international rivers for purposes other than navigation

Since 1974, the UN International Law Commission has initiated work in order to codify the law applicable to the use of international rivers for purposes other than navigation, the Convention on the Law of International Watercourses use for other purposes than navigation (it is not in force) being adopted in New York on May 21, 1997. This document provides for the concept of natural shared resources [13], consecrated in the Charter of economic rights and duties of States [14]. From this concept, the following principles (developed in a project of 33 articles of the International Law Commission) derive:

- the equitable use and sharing of the watercourse (art. 5);
- the obligation not to cause significant damage to other States (Article 7);
- the general obligation to cooperate (Art. 8);
- the obligation to regularly exchange data and information on the status of the watercourse (art. 9);
- the need to protect the ecosystems, to prevent, reduce and control pollution.

3. Conclusions

Each river whose course goes through several countries - as it is the case of at least 214 rivers - is supported by a bed that crosses socio-economic-political borders [15].

By means of the globalized trade conducted via river transport, the world economy goes through a significant growth primarily reflected in the cost price per ton of freight, as among the lowest compared with the other existing means of transport.

Also, the international legal regulation of international navigable or non-navigable water courses represents the common interest of humanity on cooperation in protecting the

aquatic environment and of the application of harsh sanctions against the aggression on this environment by unauthorized discharges.

International legal measures, applicable for the countries that support the "absolute sovereignty" over the waters within their borders and that do not recognize the obligations to their neighbors, are needed. Upstream countries take advantage of natural unpolluted waters, but the legal rules in international waters should be strengthened in terms of their operation in an equitable cooperation and the avoidance of environmental damage.

- [4] Abud: *Drept internațional fluvial*, culegere studii de Edwin Glaser, Editura Academiei R.S.R., București, 1973, p. 11. The term on „the law of national and international drainage basins”, which is at the basis of the so-called „Helsinki Rules”, elaborated within the session of 1966 by the International Law Association (I.L.A.), is supported by the example of: L.A. Reclaff, *The River Basin in History and Law*, Haga, 1967; A.H. Garretson, R.D. Hayton; C.J. Olmstead, *The Law of International Drainage Basins*, New York, 1967; *The International River Basin*, edited by J.D. Chapman, Vancouver, 1963; W.L. Griffin, *The Use of Walls of International Drainage Basins under Customary International Law*, in: *American Journal of International Law.*, vol. 53, 1959, p. 50. The theory replacing the issue of using the waters of a national or international river, the issues of the „basin” whose waters are collected by this river, neglects in favor of a geographical factor the factor (essential and political) of the existence of several independent sovereign States which have to freely decide on their own interests, resources and natural riches which cannot be assimilated on their own territory, by a „majority” of States. Within the logic of the „basin” doctrine, the air space above the basin (there is an obvious interaction between them) would also be withdrawn from the territorial sovereignty of States. It is the continuation of the interventionist theories of the imperialist powers.

Corporate Responsibility and Control Risk

Grosu Maria

„Alexandru Ioan Cuza” University of Iasi
maria_lia24@yahoo.com

Abstract

Control risk (CR) refers to the likelihood that material misstatement of the financial statements can not be prevented or detected and corrected by the entity's internal control. This risk is assessed by the auditor after obtaining an understanding of the entity's control environment risk assessment quizzes (TER) and after obtaining evidence of operating effectiveness of internal controls through control tests (TC). Typically, the auditor establishes a high level of control risk, even 100% as the confidence in the SCI is low. However, there are exceptions, such as identification by the auditor's internal controls well designed and operating effectively, or when the auditor plans to conduct tests to support the extended control that risk assessment at a lower level. However, one thing is certain: the RC is higher; the volume of evidence must be higher to support an audit risk as small. In this study we demonstrate that the correct estimation of risk control as an appropriate methodology will help to streamline the audit process and reduce its costs.

Key words: internal control, control risk, corporate responsibility, auditor approach, control mechanisms.

J.E.L. classification: M14, M38, M41, M42, M48.

1. Introduction

It is important to note that control risk is introduced into the audit risk equation only when the auditor internal control confer a degree of trust and as a consequence, reduce the extent of substantive analytical procedures. Conversely, when the auditor does not intend to rely on the effectiveness of internal control, risk control will be assessed at 100%, and the auditor is forced to extend

substantive procedures to reduce audit risk to an acceptable level.

Knowing the elements of internal control, we use the analysis procedures that apply to the auditor to **understand the internal control system and control risk assessment**. Presented in the table no 1 "Listening tests and objective" *strict tests of internal control* of the five possible tests, namely: *risk assessment tests, including tests to obtain an understanding of internal control (TER), tests of control mechanisms or tests of controls (TC) tests of details substantive tests of transactions or operations (TDO), Analytical Procedures of the Fund (PAF), Tests of details of balances (TDS).*

Table no. 1 Tests of internal control

<p>Risk assessment tests, including tests to obtain an understanding of internal control (TER)</p>	<p>Involves fashion design and operational (implementation) of internal control mechanisms to control risk assess and plan the rest of the audit as efficiently.</p>
<p>Tests of control mechanisms or tests of controls (TC)</p>	<p>Sought to determine the adequacy of the design of certain mechanisms of internal control and their operational effectiveness. Are applied only if control risk is less than 100% and their purpose is to support the risk at that level.</p>

Internal control auditor obtaining approaches in the first stage, an understanding of it, and based on my

knowledge; it will carry out *the estimation of control risk*. As can be observed from the table above, the control risk assessment is less than 100%, the auditor tests use control mechanisms. The results of these tests after determining the underlying risk of detection and planned substantive tests (test details) wider or narrower.

In practice, the procedures used by auditors to understand the internal control vary from one client to another. For small businesses, often for reasons of efficiency, internal control mechanisms are ignored and estimates a maximum control risk as to the acceptable audit risk should be maintained at a low level by extending the test details. For large companies and recurring audit, it is estimated, usually a level of control risk below the audit plan before confirmation.

To plan adequately audit engagement, the auditor should understand well enough internal control. A typical method used by auditors is:

1. *Obtain an understanding of the control environment, risk assessment procedures by the management, information and communication system and methods of supervision to a sufficient level of detail;*
2. *Identification of specific control mechanisms (control activities) and assessment of control risk;*
3. *Testing the effectiveness of control.*

The auditor may support a control risk, low indeed, only go after all three stages..

2. Understand internal control

The auditor should follow, in this approach (understanding of internal control), two aspects, namely: how the various mechanisms have been designed internal control included in each component (shown above) and whether these mechanisms were implemented. In other words, this step aims to determine the procedures used for business intelligence, drafting documents, data processing, circulation of documents, recording data in synthetic and analytical accounting, in chronological record (Journal Register) and systematic (Book Sea), filing documents and books, etc.

As a procedure in which the auditor may seek to achieve these objectives (identification of control mechanisms designed and applied) listed:

- Update information relating to internal control, where recurring tasks;
- Interviewing staff at different levels: managerial, supervisory, operational;
- Gathering information from books of the entity-client system (codes of conduct of the entity, procedure manuals, flow charts, grids segregation of duties, etc.);
- Examination of documents and accounting records;
- Observation of entity activities and operations.

Therefore, interviewing, researching and observation in various combinations are the procedures used by the auditor to understand the internal control system.

To document their understanding of internal control, the auditor may use: presentation of narrative sequence diagrams and internal control questionnaires (CCI).

Narrative presentations (PN) are a written description of internal control mechanisms of a client (the accounting system and its associated control mechanisms) and should contain four elements:

- The origin of each document and records in the system registry (where I come from documents, whoever prepares, how many copies, etc.);
- all processing taking place (which worked out, for example, the computer system);
- place of each document and register of the system (how to classify, shipping to customers or cancellation);
- Presentation of the relevant control mechanisms for the control risk assessment (these include: segregation of duties, authorizations and approvals, internal controls, etc.).

Sequence diagrams (SD) are the schematic representation, using symbols, documents flow of an entity, which must contain the same elements as narrative presentations. These diagrams are useful for auditors because they provide an overview of the client system and to identify control weaknesses, in particular, by illustrating the (un) segregation of duties. Facilitating a clear understanding of the functioning of the internal control system, making it easier to

update, sequence diagrams are commonly used in practice than narrative presentations.

Internal Control Questionnaires (CCI) are a set of questions related to internal control mechanisms applied in every sphere audited (purchases, sales, investments, etc.). Questions are addressed in such a way that negative responses indicate potential shortcomings or weaknesses in internal control system.

CCI advantage is that each area can be analyzed rigorously audited, and even fast enough at the beginning of the engagement. The disadvantage is that they are considered parts of the internal control system, without creating a picture. In Table no. 2, we present a CCI (example) for sales cycle.

Table no. 2 Example Internal Control Questionnaire (CCI) on the sale [Arens, 2003]

<i>Sales cycle - a question and objective</i>		<i>Answer / Comments</i>
		YES/NOT/N/A
A. Recorded sales correspond to actual deliveries to existing customers?	<i>Existence</i>	
1. Record sales are justified and authorized shipping documents approved customer orders?		YES
2. Crediting a customer is approved by an authorized person of the firm?		YES
3. There is a written document delivery and renumbered, bound out of any assets of the entity?		YES
B. Existing sales are recorded?	<i>Completeness</i>	
1. Keep a record of delivery?		YES
2. Document delivery is controlled by a processor so as to ensure that all deliveries are invoiced?		YES
3. Document delivery are numbered and keep a record of their numerical sequence?		YES
4. Bills are numbered and keep a record of their numerical sequence?		NOT Are numbered, but not keep a record of the series. The tests require substantial.

C. Sales recorded correspond to the quantities of goods shipped and invoiced and recorded correctly?	<i>Accuracy</i>	
1. A comparison is made independent of the quantity of goods with the delivery of documents from sales invoices?		YES
2. It uses a list of authorized prices and limited access to systematic file prices?		YES
3. Customer statements are sent monthly summary?		YES
D. Sales transactions are properly recorded?	<i>Classification (correct attribution accounts)</i>	
1. A comparison is made independent of the sales chart of accounts?		N/A All sales are on credit and income is one mind
E. Sales are recorded at the correct?	<i>Timeline (period correct)</i>	
1. A comparison is made independent of the data in the delivery of data records in RJ?		NOT It is a weakness. The tests require substantial
F. Sales transactions are properly and correctly transferred to CM presented?	<i>Systematization and Summarizing</i>	
1. RJ totals are calculated and correlated with CM, independently, each operation?		NOT Examine the reasonableness
2. There is a comparison of the names of customers to deliver documents in the CM records?		YES

Note that the CCI is constructed so that it can be used for the six audit objectives related to operations. To eliminate the drawback of CCI, is ideal and the concomitant use of CCI DS.

To be sure that the system described is well understood, is the real, the auditor uses to use compliance tests, such as direct observation of how work, verbal

confirmation of the data using procedures, specific methods used for confirmation of operations (stamps, visas), observation post, which is to resume flow of documents from their source to test the road map.

3. Initial estimated control risk (CR)

After understanding the internal control system, the auditor shall make the initial estimate of control risk (CR). This estimate expresses the extent to which the auditor is expected that internal control mechanisms to prevent and not detect significant misrepresentations in financial statements. Control risk assessment is usually done for each major category of operations (accounting cycle) for each of the audit and related operations. This estimate can be made using qualitative measures (small, medium, large, maximum) or encrypted using probabilities (see sampling model based on risk).

RC initial estimate of the environmental analysis begins with control. If the auditor concludes that for immaterial internal control management, it is unlikely that the controls are reliable and should be recommended to estimate a maximum CR (100% or 1). Conversely, when leadership is a positive attitude towards the controllers, the auditor shall review all other elements of internal control as a basis for estimation of less than 100% RC.

As mentioned above, especially for small businesses, estimate the RC is at a maximum level for reasons of cost. That is, the auditor may consider it less expensive to expand tests of details only to test the control mechanisms related to operations.

Steps to go to control risk estimation are [Arens, 2003]:

1. Identification of audit objectives related to operations;
2. Identification of specific control mechanisms (usually the key mechanisms - the most important), which contributes to each objective related operations (policies, procedures and activities that ensure the control subjects);
3. Identify and assess the shortcomings (weaknesses) of control (absence of adequate control mechanisms that increase the risk of significant misrepresentations).

If the identification of weaknesses in internal control, the auditor should ascertain whether there is any compensatory controls introduced another component of internal control. For example, when the accountant has access to cash, but the owner manager is an analytical review of all documents related to daily cash, the auditor may consider that this shortcoming is eliminated. Internal control weaknesses may be presented in a separate worksheet ("Summary assessment of internal control"), to appear in columns: weakness, compensating controls, the potential error, significance, impact on audit evidence.

It is noted that most of this matrix control mechanisms covering several audit objectives related to operations, while. After identifying existing control mechanisms (strengths) and weaknesses (weaknesses) in internal control, related to audit objectives related to operations, the auditor may assess control risk (see last row of table). This estimate is used by the auditor in planning the engagement, to complete the worksheet in Section F (F3) - NMA, which is the basis for determining the sample size.

Deficiencies in internal control (weaknesses) are summarized in a report on internal control (Letter of reportable conditions) address as the entity's management. It should contain a description of the weaknesses identified, the consequences and impact on financial statements and settlement proposals and solutions to shortcomings or to improve the situation.

4. Control mechanisms testing

The reasoning below the maximum estimate of RC requires the auditor to perform tests of control mechanisms or tests of controls (TC). These tests aim to determine the adequacy the design of certain mechanisms of internal control and their operational effectiveness. Such tests are called tests of permanence.

Control risk estimate will be reviewed during the audit, if the tests show that these control mechanisms do not work effectively. Control risk estimate will be reviewed during the audit, if the tests show that these control mechanisms do not work effectively.

The procedures used by the auditor to make sure that control actually works mechanisms refer to the same procedures used to identify control mechanisms (understanding the internal control system): interviewing employees, reviewing documents and accounting records, observation of activities on control, customer replenishment procedures, etc. More specifically, to detect shortcomings in the functioning of the internal control system, proceed to the analysis controls for the prevention and detection controls provided by the enterprise. Preventive controls are carried out during the course of operations, before passing to the next stage and before the recording operation. These controls are reflected in a visa or signature on documents (eg verification of receipt and there is good order before giving a bill payment provider). Detection checks are carried out on a group of operations the same way to discover anomalies in the system or to ensure that these anomalies are.

So, support a control risk at a low level of testing necessary to expand the control mechanisms within the meaning of the use of larger samples of documentation procedures, observation and reconstruction. The key difference between the procedures used to identify control mechanisms designed (understanding of internal control) and those used for testing the actual applied (tests of control mechanisms) is that the former are applied only on one or several operations at one time, while what tests are performed on control mechanisms of larger samples of transactions and observations are made in several times.

In this last stage of the internal control assessment, determine the reality of the strengths, weaknesses of the system due to faulty design, as well as those due to misapplication of the procedures and make "Summary assessment of internal control" and "Report on Internal Control". Report on the evaluation of internal control is designed to inform management of the audited entity internal control system weaknesses and to help make organizational and methodological measures to increase the effectiveness of internal control. This report is structured as a rule, in two parts: an introductory and summary (which is synthesized design weaknesses due to poor and ineffective

operation of the accounting system and internal control and the proposals are to increase effectiveness these systems) and some content for detailed (structured and significant areas of audit objectives, listed in order of their importance and accompanied by appropriate recommendations).

In conclusion, we note that tests linking mechanisms control audit planning and control accounts, standing on the basis of defining the appropriate substantive tests (wider or narrower). So we can say that an appropriate internal control may reduce the amount of audit evidence to be collected. In other words, an assessment of control risk below the maximum level will allow the auditor to apply substantive tests on a smaller number of elements and thus a reduction in audit costs.

The Link between Company Competitiveness and Financial Performance

Gruian Claudiu-Marian
West University of Timișoara
Faculty of Economics and Business Administration
claudiu_gruian@hotmail.com

Abstract

Company competitiveness and financial performance are two terms often used in literature but they usually appear distinctly and the relationship between them is not examined. This article provides a reasonable clarification regarding the concept of company competitiveness and theoretically argues for the positive influence it has on financial performance. Theoretical arguments are supported by an empirical investigation based on a linear regression model applied to a sample of 62 non-financial companies listed at Bucharest Stock Exchange. Results confirm the proposed hypothesis, showing that the two variables are positively correlated.

Key words: company competitiveness, financial performance, Bucharest Stock Exchange

J.E.L. classification: D20, L20, L25

1. Introduction

In literature most authors treat the concepts of company competitiveness and performance independently, in spite of the fact that they are apparently similar. Thus there are performing companies and competitive companies. Is there a difference between the two concepts? What are the common elements of the two categories? Romanian literature treats the two concepts separately. Works that focus on company global or financial performance and other related concepts like efficiency, effectiveness or productivity do not mention anything about competitiveness. Also theoretical works that conceptualize company competitiveness do not show the link between this concept and global or financial

performance.

The performance concept at microeconomic level is often seen in literature, and there is a fairly comprehensive theory on this subject (e.g. [3]), but the competitiveness concept is still the subject of different points of view, which is why, until now there is no widely accepted definition of competitiveness and a comprehensive model for the formalization of its content hasn't been developed yet. Current state of research leaves the door open for conceptual disputes on competitiveness. Therefore this study will begin by outlining the concept of competitiveness at microeconomic level, considering the opinions of several authors. After clarifying the significance of competitiveness the hypothesis will be set and appropriate indicators for measuring the two variables will be grounded. On these bases we will analyze the correlation between the competitiveness and financial performance of the non financial companies listed at the Bucharest Stock Exchange, discuss the results and draw some conclusions.

2. Literature review and hypothesis

Despite the fact that there is no cohesive and comprehensive theory of company competitiveness, there are numerous explanations and points of view [1]. Generally competitiveness is a key feature of the contemporary economy. The complexity of the concept and the interest of researchers, practitioners and government are determined by the strong interactions between it and other concepts and areas of economic and social life. Maintaining the company in the competitiveness race means restructuring efforts, will, strategies and actions, managerial policies and mechanisms for effective corporate governance, concern for

education and creativity and risk taking ability.

According to several authors competitiveness is a concept invented by businessmen (practitioners) and not by economists (theorists) and therefore is not sufficiently conceptualized [6]. Thus competitiveness is still a fuzzy concept in literature because of insufficient theoretical justification. The practical character of competitiveness has emerged over time through measurement and assessment approaches, rather than definitions, which allowed the existence of several theoretical points of view and even confusions with other economic concepts (economic growth, foreign trade performance, efficiency, competitive advantage, etc.).

In literature, there are generally two approach levels to competitiveness: the macroeconomic level, describing the competitiveness of a country or region and the microeconomic level describing company competitiveness. Some works understand competitiveness in the light of external trade performance, emphasizing the importance of this activity within companies and economies. Another argument which stimulates the use of such a point of view on competitiveness is the ease with which data on external trade can be obtained.

At microeconomic level competitiveness cumulates elements that confer superior positioning for a company compared to its competitors. Competitiveness is the ability of companies to add value to the production factors and generate profit, based on a high level of utilization and on sustainable basis, in the conditions of a free market. Based on the concepts of competitiveness and comparative advantage given by the endowment with natural factors M. Porter [4] developed the concept of competitive advantage. This advantage is conferred, in addition to natural factors endowment, by the possession and use of appropriate intangible factors, generated primarily by research, development and marketing activities. Competitive advantage is also determined by the supply and demand conditions, the existence of support industries, firm strategies and market structures.

Competitiveness is directly linked to competition. Regarding the ability to sell, competitiveness reflects companies' results in

maintaining and strengthening their market position. The effect of competition is the take over of a company's market share by others, and the result is a change in market structure. A company is competitive if it is willing to accept the just revenue it can obtain by selling its products at market prices.

Uncompetitive companies collect inadequate revenues and are therefore forced to withdraw. In the microeconomic approach the factors affecting company competitiveness are defined by factors and effects of competition. Competitiveness is therefore a rivalry by prices, improved production techniques and marketing. But price is affected by cost, efficiency and productivity in transforming inputs into outputs. Schumpeter, in its theory, argues that competition is based on cost and quality advantage, which he considered more important than price because they capitalize an internal potential advantage. On the other hand, competition results, based on market share, should also be considered.

Industrial competitiveness is generally expressed by supply side characteristics, grouped into two categories: cost and quality. *Cost* is determined by the level of productivity, input prices and other supply side variables (management, investment, organization, etc.). *Quality* has several dimensions: innovation, technology and marketing. The first refers to the ability to incorporate novelty elements into products and services, to implement technical and technological innovations.

Technical dimension of quality refers to the fact that products should be reliable and consistent with their technological specifications. The marketing dimension of quality refers to company or product reputation (brand name) and how well it meets consumers' expectations. A high quality product can bring additional benefits compared to other products in its range. High quality products are competitive even if they have high prices, fact that positively influences profitability.

According to the Oxford Dictionary of Economics [7] competitiveness is the ability to compete in markets for goods and services. This is based on a combination of price, quality and reputation. With the same quality and a reputation already established, producers are competitive only if their prices

are as low as those of competitors. A new manufacturer that has not yet developed a reputation must use lower prices to compete. With a lower quality product than competitors a company may not be competitive even with a lower price, but on the other hand a company with a higher quality product can charge higher prices than competitors while maintaining its competitive status. Thus the reputation developed by advertising and positive customer feedback differentiates two companies that sell similar products in terms of price and quality. Companies with experience and a good reputation also have a competitive advantage over newly founded companies.

Nowadays, in order to improve their reputation, new companies must assume social and environmental responsibilities, not only regarding their own employees and stakeholders, but also regarding the local community and society as a whole. Such activities sensitize consumers, and have a psychological effect, motivating them to choose among similar products and companies. In conclusion competitiveness depends on at least three essential characteristics of the company: (1) cost level, (2) quality of products or services and (3) reputation.

To maintain a competitive position on the market for a longer period of time a company must have a high financial performance; otherwise it will not be able to allocate sufficient resources for activities such as research, development and marketing, which are not directly productive but maintain company's long-term competitive advantage over competitors.

Competitiveness is considered by some authors synonymous with long-term financial performance, company's ability to reward employees and offer owners a higher yield [6]. Companies with sales that generate losses are not competitive. What is surprising, however, is that previous analyses did not verify the link between competitiveness and financial performance, which we will analyze below.

Therefore the following hypothesis is proposed: *Competitive companies have higher financial performance.*

3. Research methodology

Due to difficulties in defining company competitiveness there are some difficulties in measuring it. Given the way we presented the concept above, we suggest an appropriate assessment method. We will start from an argument presented above, that a company is competitive if it is willing to accept the revenues obtained by selling its products at market prices. Uncompetitive companies will achieve inadequate income, insufficient to cover costs and therefore will be forced to withdraw.

Given the cost dimension of competitiveness, we can say that a company is more competitive if it has lower production costs than competitors. On the other hand, market products are differentiated in terms of quality, and they also have different prices. Companies that maintain their sales volume and charge higher prices than competitors due to the high quality of their products are more competitive. Therefore the difference between the costs and prices of products and services sold is a reasonable measure of competitiveness. Thus we will use as indicator for assessing company competitiveness Return on Sales (ROS), also found in literature by the name of Operating Margin, as it presents at the numerator the difference between operational revenues and expenses and at the denominator the market value of sold products. To assess financial performance we will use Return on Equity (ROE) because it is a generally accepted indicator and it is very often used in literature.

However Return on Sales indicator depends on the profile of the company. For example companies in the trade sector usually have a high level of sales and a low operating margin compared to their turnover (e.g. the Romanian company Farmaceutica Remedia, listed al Bucharest Stock Exchange – BSE, has a ROS that varies in the considered period between .25 and 3.33%). At the opposite end we have companies in the services sector that have very high operating margin compared to their turnover (e.g. Turism Hoteluri Restaurante Marea Neagră Company has a ROS ranging from 13.69 to 43.91%).

Considering these aspects it is appropriate to verify the correlation between competitiveness and financial performance for each sector separately. However, this desiderate can only be achieved in the manufacturing sector (NACE Section C, divisions 10 to 30) because other sectors do not have a representative number of companies listed at Bucharest Stock Exchange (BSE).

3.1. Sample and data selection

The initial sample used in this study is composed of all non-financial companies listed on the BSE, in the first, second and third category (a total of 63). Companies belong to the following sectors (according to CAEN national classification Rev.2 and the statistical classification used in the European community NACE Rev.2): mining: 3 companies, manufacturing - 44 companies, utilities - 1 company, construction - 5 companies, trade: 4 companies, transport and storage - 3 companies, hotels and restaurants - 3 companies. Collected data corresponds to a period of three years: 2007 - 2009.

The main data sources considered are the audited individual annual financial statements of companies, namely the Balance Sheet and Income Statement (Profit and Loss Account), obtained from the official website of each listed company and from the official site of BSE. The second source of information is the site of the BSE, which has been used where financial statements were not available in the form presented above.

After collecting the necessary data and calculating study variables, Oltchim Râmnicul Vâlcea Company was excluded from the sample because the value of the shareholder's equity indicator in the considered period was negative, so the values obtained for one of the variables were not relevant. Also for the year 2009 MJM Mailis company was excluded from the sample because the variable used to assess financial performance had an irrelevant value (ROE = -850.21%). Therefore the final sample contains 62 companies for the years 2007 and 2008 and 61 companies for 2009.

3.2. Variables definition

The independent variable used to assess competitiveness is Return on Sales (ROS). This is calculated as the ratio between company's operating income (EBIT) and its turnover.

$$\text{ROS} = \text{EBIT} / \text{SALES}$$

The dependent variable used to describe company's financial performance is Return on Equity (ROE). This is determined by reporting net profit to capitals invested in the company directly (through a capital contribution) and indirectly (by approving the reinvestment of obtained profits), amounts that actually represent the company's equity.

$$\text{ROE} = \text{NET PROFIT} / \text{SHAREHOLDERS' EQUITY}$$

Variables were calculated separately for each company and each year, and only values that belong to the same year were compared.

3.3. Regression model

For examining the relationship between the mentioned competitiveness measure and financial performance indicators we have chosen a simple linear regression, considering it appropriate for this study. The calculation of regression parameters, descriptive statistics and results relevance was done using Microsoft Excel 2003. The general formula of the model is as follows:

$$\text{ROE} = a_0 + a_1 \text{ROS} + e$$

4. Results

4.1. Descriptive statistics

Descriptive statistics for all study variables are presented in Table 1 (ROS) and Table 2 (ROE). We can observe a number of complementary aspects besides the ones that we focused on. Thus one can easily see a fairly low average profitability of non-financial companies listed on the BSE. The ROE indicator decreases from 5.69% in 2007 to the value of -1.23% in 2009. As an

explanation for these poor results we considered the low competitiveness of Romanian economy and the critical period analyzed, marked by the economic and financial crisis. The recession that occurred in 2008, was felt more strongly by some companies than others. The largest gap between the minimum and maximum profitability (of 116.40%) was recorded in the first year of crisis. This is reduced in 2009 when a larger number of companies were affected.

Table 1: Descriptive statistics for ROS

Variable	ROS		
	2007	2008	2009
Mean	7.60%	6.11%	3.99%
Standard Deviation	10.84%	12.01%	11.78%
Range	80.91%	73.74%	60.10%
Minimum	-37.00%	-45.64%	-31.03%
Maximum	43.91%	28.11%	29.07%
Sum	471.42%	378.93%	243.40%
Count	62	62	61
Positive	55	52	49
Negative	7	10	12

Table 2: Descriptive statistics for ROE

Variable	ROE		
	2007	2008	2009
Mean	5.69%	.07%	-1.23%
Standard Deviation	10.72%	18.60%	15.18%
Range	51.63%	116.40%	77.86%
Minimum	-24.61%	-82.54%	50.74%
Maximum	27.02%	33.86%	27.13%
Sum	352.91%	4.35%	74.98%
Count	62	62	61
Positive	55	49	47
Negative	7	13	14

Source: author's calculations

4.2. Hypothesis verification

The relationship between two variables, considering all non financial companies, is presented in Table 3. As we can see, there is a strong positive correlation between Return

on Sales and Return on Equity for all the three years considered. The correlation coefficient is significant for the number of observations made, with a very high probability, of over 99.9% ($p < .001$). Study hypothesis is therefore verified.

As we mentioned above, the value of ROS indicator varies depending on the profile of the company. Thus we also considered a sample of 43 companies from the manufacturing sector. The correlation analysis is presented in Table 4. The results matched expectations. The correlation between competitiveness, measured by ROS and financial performance, measured by ROE, is stronger when we consider companies with similar profile. Although the sample is smaller, the obtained results are significant.

Table 3: Correlation analysis: all companies

Year	No. Obs.	R	R Square	Signif. (p*)
2007	43	.693	.480	.000
2008	43	.671	.451	.000
2009	42	.763	.583	.000
*significant when smaller than .05				

Source: author's calculations

Table 4: Correlation analysis: manufacturing companies

Year	No. Obs.	R	R Square	Signif. (p*)
2007	62	.601	.361	.000
2008	62	.647	.419	.000
2009	61	.738	.545	.000
*significant when smaller than .05				

Source: author's calculations

4.3. Discussion

The study confirms the proposed hypothesis, sustaining the fact that competitiveness and financial performance are closely connected. Moreover it is noted that the relationship between variables is becoming stronger with the deepening of the economic and financial crisis occurs. Thus only competitive companies have managed to maintain an acceptable level of financial performance; and more and more companies recorded losses. In 2007 more than one third

(R Square =.361 in 2007) of company's financial performance was determined by competitiveness. In 2009 the influence is over 50%. Comparing companies that belong to the same sector proved to be relevant. The results obtained for manufacturing industry are very suggestive, validating the fact that it is recommended to compare similar companies for best results using the ROS indicator.

5. Conclusions, limitations and future research

The results obtained in this study confirm a significant positive link between company competitiveness and financial performance. While it may seem a paradox, competitive companies achieve two important goals that are apparently opposite at the same time. On the one hand they bring products to market at relatively low prices compared to their quality, and on the other hand they manage to achieve high financial performance. This is due to the three key elements of competitiveness that companies cumulate: low manufacturing costs, high quality of their products or services and a good reputation.

The limitations of the study are related to the particular sample of companies that contains only 62 companies, composed mostly of companies belonging to the manufacturing industry. Also the measure used for company competitiveness assessment is a synthetic indicator, which can be challenged. Another contextual element is the considered period that includes the economic and financial crisis that began in the year 2008.

To remove some of the drawbacks of this study future research should consider longer periods of time and the utilization of auxiliary analytical indicators for competitiveness measurement. The following studies may also verify the reverse hypothesis of this study, namely how the company's financial performance affects its future competitiveness.

Corporate Governance Practices That Positively Influence Company's Financial Performance

Gruian Claudiu-Marian
West University of Timișoara,
Faculty of Economics and Business Administration
claudiu_gruian@hotmail.com

Abstract

This study aims at comparing the efficiency of the main corporate governance practices utilized presently for stimulating the financial performance of listed companies. After analyzing the literature, including theoretical arguments and empirical research results, the study concludes that the dominant and most analyzed prerogatives of a financial performing company are: a reduced dimension of the board, a high proportion of outsider directors, a high ownership concentration, a shareholding management and an optimal indebtedness degree. Results also recommend an integrated approach to governance practices when analyzing their impact on financial performance.

Key words: corporate governance, financial performance, board of directors

J.E.L. classification: G30, G34

1. Introduction

In literature there are many empirical studies that measure the correlation between different corporate governance practices, systems or codes and company performance (e.g. [4], [3] and [5]). This correlation is often analyzed in theoretical and practical works and most results indicate a positive influence of corporate governance practices on financial performance. In spite of these results reality permanently brings new challenges and there are plenty examples of companies with a well-established corporate governance systems that failed. Therefore new questions appear about the effectiveness of these governance systems.

Corporate governance is the result of efforts made by company owners (shareholders) to ensure that managers and other individuals within the company defend their interests in all the actions they perform. The typical modern publicly owned company has a dispersed ownership that doesn't hold executive positions. Thus shareholders that own a negligible part of company shares are not interested in monitoring management, because this action is too expensive. Therefore a risk exists, that company leaders might not aim at maximizing the company's financial performance, but rather to increase its size and their personal earnings.

2. Theories on corporate governance practices and their impact on financial performance

Corporate governance practices are implemented to protect the interests of shareholders. The latter aim at obtaining a higher profit from their investment, which entails a high financial performance of the company they hold. Correlating the two statements we can say that the role of corporate governance is to achieve high financial performance in companies that have implemented this kind of control system. This article will try to analyze the extent to which various specific practices of governance affect financial performance.

Before proceeding to analyze corporate governance practices it is required a short presentation of the mechanisms and devices used for control. They can be divided into two categories: *internal and external*.

Internal control mechanisms are specific for each company and they are usually built and implemented depending on owners' desire. Their basic elements are: the board of directors, the internal control and audit

department and politics regarding management remuneration and the balance of power.

The main responsibilities of the *board of directors* are: the appointment, dismissal and remuneration establishment of management, supervision of managers, evaluating and approving decisions and strategic plans proposed by management, and others. Board structure is decided by shareholders. Members can be both individuals working in the company (insiders) and specialists from outside the company (outsiders).

Audit and Control Departments, including control procedures, implemented by the board, management or the audit committee, are designed to certify if the various compartments of the company meet their objectives, comply with legal regulations and that the information contained in the financial documents they prepare is true and correct.

Power separation practices refer to the fact that the decisional and the executive prerogatives in making payments and collections belong to different individuals.

Policy on remuneration refers to management and other employees salaries that can be based on personal and team results (to the extent that such activity permits). Such leaders will strive to achieve outstanding results to be compensated, thus defending the interests of investors and other parties and their personal interests at the same time. This type of reward has a beneficial effect, to attract and retain performing managers and employees. Considering its effectiveness, this method is widely used today, and managers usually receive incentives in cash and company shares. Thus they are stimulated to accomplish company's main long-term objective, first proposed by Jensen [10]: the maximization of company's market value.

External corporate governance mechanisms that foster an effective management belong to company's external environment and differ from one country to another. They are beyond the control of shareholders, being stronger in developed countries with powerful capital markets. Among the external entities that influence governance practices we mention: competitors, creditors (banks), securities commissions, capital markets, managers, media etc. The so called manager markets

and stock exchanges put pressure from both inside and outside the company to improve performance. These markets continually evaluate listed companies and remind managers and other company insiders that they need to be productive, because they are in constant competition with other companies in the industry [8]. Capital markets, through the requirements they have on the implementation of certain standards for performance and reporting, provide continuous monitoring on listed companies.

In literature there are many practices intended to maximize company's financial performance. For example Lawrence D. Brown and Marcus L. Caylor verified in a recent study [3] the relationship between a number of 51 external governance provisions and company's operational performance. This study will only analyze the most important internal ones. The best known and most verified specific governance characteristics that influence company performance are: shareholding by individuals within the company (especially leaders), board structure, board size, ownership concentration and financial debt.

Insider ownership has, theoretically speaking, a positive influence on company performance. Given the fact that their own savings are invested in the company, managers and employees are motivated to pursue a more successful business to increase company's market value, and at the same time the value of their portfolio. On the other hand they will be interested in achieving high financial performance, to qualify, along with the other shareholders for profit distribution in the form of dividends, bonus shares or other benefits of this kind. Through this practice agency problems are reduced because management and other insiders become shareholders are at the same time, thus having common interests with other shareholders.

Ownership concentration is another practice that has a positive effect on company's financial performance. This refers to the proportion in which the company is owned by a number of significant shareholders. High concentration of ownership tends to create more pressure on managers to maximize company value [17]. Thus if ownership concentration increases, one can usually observed an immediate

increase in the price of the company shares. In such situations significant shareholders that hold together a significant percentage of equity can organize easier to penalize management errors. Once a certain percentage is exceeded (50%) the further increase of concentration no longer has the same effect. Another case in which such pressure is put on the management is the change of main shareholders in case of sold companies.

Board of directors' size is apparently an unimportant feature. However, there is a first simple argument in favor of a board with fewer members on the grounds that it meets and makes decisions easier [18]. According to the same author as the board is augmented, individual members have less influence. So if a member disagrees with decisions taken by the chief executive officer, he is encouraged to argue his point of view and his opinion has more weight in a smaller board. According to some authors the optimal number of board members is maximum ten [18].

Board structure may influence the manner in which management defends the interests of shareholders because it monitors the way company is managed and take important strategic decisions, following their implementation by management. In fact, the most important issue is that the number of board members who are not company's employees (outsiders) must exceed the number of insider directors. Insider board members are subordinated to the chief executive officer and therefore they are in a conflict of interest and could be influenced to agree with some of their superiors' actions that aren't in the interest of shareholders or other stakeholders. Board members not involved in company management have greater freedom of expression and can not be constrained in any way to make decisions inconsistent with the interests of the company. Under this consideration in Great Britain there are regulations that require at least two thirds of the board members to be outsiders.

Company's indebtedness to lenders (banks) is theoretically an incentive to improve financial performance [11]. Just like major shareholders, major lenders (usually represented by banks) are concerned about their clients' performance. Thus they permanently monitor costumers in order to be

sure that they will recover their investment and the additional interests. By borrowing, managers show their willingness to be controlled by another group of stakeholders represented by banks. Problems arise, however, during periods in which the company has a poor financial performance. In those critical periods creditors claim the repayment of loans just like in periods of prosperity and this can result in a conflict between the two parties. Therefore, company boards often contain a representative of the lending bank especially in countries like Japan and Germany, where banks play an important role in local corporate funding.

3. Empirical studies on corporate governance practices and company financial performance

Each of the numerous theories that argue the influence of corporate governance practices on company performance is verified by a large number of empirical studies. Yet research results are mixed. So, one can encounter situations where several studies that examine the same corporate governance practice, obtained different results. This might be due to the specific characteristics of each study (the companies sample, the variety of methods, periods taken into account, etc.). Yet in verifying the effectiveness of corporate governance one does not question the usefulness of some of its characteristic structures such as the board of directors, audit and control departments, remuneration and power separation policies, but only some of their characteristics (composition, size, functions, etc.).

Indicators chosen to measure the financial performance of companies depend on authors' opinions about their importance and the data available for calculation. Generally the following indicators are used: Return on Assets, Return on Equity, Return on Investment, Return on Sales or Profit Margin, Tobin's Q, Price per Earning Ratio and others. Regarding the five characteristics theoretically presented above numerous empiric verifications have been done among which we will briefly present the results of several.

Companies in which the persons involved in management are equity holders are not necessarily more efficient than others. There are specific studies with conflicting results on this issue. Some shows that performance is positively correlated with management shareholdings [15]. McConnell and Servaes [14], after their research, revealed a curved-linear correlation between this feature and company performance. Other researchers after further studies, state that there is no significant relationship between the two variables. Other researchers have also revealed a non-linear correlation.

Empirical studies that analyze the influence of ownership concentration on company performance also have surprising results. Some research shows that the rotation of senior executives from companies with worse performance that have a more concentrated ownership is greater than in those with dispersed ownership [6]. Other studies on the same subject have identified a significant link between the two characteristics [16]. Moreover some research results show even a negative correlation between the degree of concentration of ownership and company performance [1].

Correlation between board of directors' size and the financial performance of the company they monitor is analyzed in several studies. The results obtained by some authors confirm that companies with fewer board members have better financial performance than others, finding a negative correlation between the two variables ([4] and [18]). The authors of a recent study [5], after evaluating the correlation between Tobin's Q and board size, concluded that there is no general rule on this link and that the size of the board depends on company complexity. Thus a small board is performing in the case of a small and simple business, and in the case of complex companies a greater number of members positively affect performance, because the presence of more specialists is beneficial.

The influence of board of directors' structure on company performance is extensively tested in literature but the results do not have a unitary character. A part of the studies concluded that there is a significant correlation between the proportion of outside directors (outsiders) and company's financial performance [12]. But other studies [2] didn't

identify a significant link between the two variables. Although results vary, they are not contradictory in the sense that there aren't studies that identify a negative correlation in this matter.

The fifth characteristic of corporate governance chosen for this study has fairly large presence in literature and practice, especially in studies that refer to countries where the German governance model prevails. According to several researches company creditors, mainly represented by banks, exercise a positive influence on company performance, through their monitoring actions. Therefore there is a significant positive relation between indebtedness and performance indicators where the company does not make excessive investments by credit [14]. Other studies did not identify a significant link between the two variables [1].

4. The integrated impact of governance practices on company performance

Corporate governance practices operate simultaneously. Thus they can substitute for each other. For example a company may have few board members that are outsiders and still have a high financial performance if those members are in the same time shareholders. Therefore the practice referring to the presence of outsider directors in the board is replaced by the practice sustaining that share holding managers perform better. An integrated analysis of all governance characteristics is therefore recommended to assess global governance effect on performance. To develop such study, some researchers used integrated corporate governance indexes calculated by specialized institutions for a large number of companies and even at country level. For example Durnev and Kim [7] identified a positive correlation between a corporate governance index built by Credit Lyonnais Securities Asia - equity broker and financial services group, and companies' growth opportunities and performance. Similar results were obtained by Klapper and Love [13] using governance indexes by same institution and Gompers et al. [9] using an index they designed. These researches once again confirm the usefulness of good corporate governance practices and the sound

perception among shareholders on their implementation.

Internal corporate governance practices make the difference between companies. On the other hand external corporate governance regulations affect all companies that belong to a country or companies that are listed at the same stock exchange. Similar companies with same performance, but belonging to different countries or listed on different capital markets may have different market values and performances. Therefore a combination between internal and external corporate governance practices leads to best company performance.

5. Conclusions and future research

The most important and widely analyzed corporate governance practices are bounded to board of directors' size and structure, ownership concentration, insider ownership and company indebtedness degree. After analyzing the considered literature the study concludes that generally, a relatively small board of directors, correlated to company size and complexity and a high proportion of outsider directors positively influences performance.

Financial performance is also enhanced by a shareholding management that adopts an optimal leverage. Moreover, a concentrated ownership stimulates the performance of management and of the company as a whole.

Yet results obtained in analyzing the individual influence of each corporate governance practice on company performance are varied. The main reason for these differences is that there are plenty of practices and others types of factors, which influence company's financial performance. Therefore the individual analysis of a single practice in comparison with company's overall performance is not relevant enough to confirm the effectiveness of that practice. Thus it is necessary to investigate the correlation between a set of specific features of governance and company performance. This can be done by using corporate governance indexes constructed by specialized monitoring institutions or proposed by different authors.

The bigger the number of corporate governance practices considered, the higher index accuracy obtained. Most studies

conclude that the performance and valuation of listed companies are higher for companies that apply internal governance practices and adapt to external mandatory or recommended governance provisions.

Considering the fact that corporate governance in Romania is in an early stage of development, companies listed at Bucharest Stock Exchange (BSE) are not very preoccupied of implementing such practices. Yet, some companies, mostly multinationals' subsidiaries, have made notable improvements in the field of corporate governance. Given the fact that such study has not been done yet we recommend the achievement of an empirical analysis of corporate governance practices' influence on the financial performance of BSE companies.

Abstract

Users of financial statements need information about an entity's exposure to risks and how those risks are managed. Such information can influence a user's assessment of the financial position and financial performance of an entity or the amount, timing, and uncertainty of its future cash flows. Greater transparency regarding those risks allows users to make more informed judgments about risk and return. Entities should describe the nature and extent of risks arising from financial instruments.

Key words: financial instruments, risks, financial performance

J.E.L. classification: M41

The International Accounting Standards referring to the financial assets and debts have been drafted out of the desire to reflect in accountability some of the most spectacular evolutions that have taken place on the global financial markets during the last decades. By the agency of these norms, the accountability practice has been brought up to day in order to reflect undeniable economic and financial realities, like the very frequent use of the products of the financial market with the goal to obtain the necessary resources to develop the activity, make investments or protect the business against the different risks of a financial nature.

In the perspective of a necessary and expected development of the Romanian capital market the Romanian companies will appeal more and more to the financial instruments. As a consequence, their accountabilisation and presentation and the description of the information concerning the individual or consolidated accounts and the analysis of the impact of using it on the

performances and financial position of the entities become very actual subjects for the Romanian professional accountants, for whom the aspects described in the paper proposed to be elaborated get more and more utility.

Accounting hedge operations of a fair value against risks aims to protect the assets, liabilities, unrecognized firm commitments or part of the risk against the amendment because the fair value of interest rate fluctuations, exchange rates or prices of goods.

An operation to cover the fair value will be charged as the followings:

- gain or loss resulted from revaluation of hedging instruments at fair value or the value of its currency accounting assessed in accordance with IAS 21 for a tool to hedge against risks nederivat will be recognized immediately in the profit and loss.

- gain or loss related to a covered item that can be attributed to the risk cover will be adjusted at the value of the item covered and will be recognized in the profit and loss. This principle applies if an item is covered in other conditions evaluated at cost. Recognition in profit and loss of earnings or loss attributable to the risk covered is covered if the item is available for sale financial asset.

For a fair value hedge of the exposure of a portion of a portfolio of financial assets or financial liabilities at the risk of interest rate, method of counting presented above can be achieved by presenting earnings or losses that may be presented to the covered item risk:

- in a single element - the active line, for those periods in which the revaluation of the item covered against risk is an asset, either

- in a single element - separate line in debt, for those periods in which the revaluation of the item covered against risk is a duty.

Separate line-items referred to in previous paragraphs will be presented along with financial assets or financial liabilities. Values included in these elements - line will be removed from the balance sheet when the assets or liabilities that are related are derecognized.

Only if certain risks that can be attributed to an item covered against risks are covered against risk, recognized changes in the fair value of assets covered against risks that are not related to the risk is already covered in the profit and loss when the entity entitled to receive payment is established.

An entity will discontinue hedge accounting prospectively specified above if:

- hedge against the risk expires or is sold, completed or exercised;
- coverage no longer meets the criteria to use hedge accounting or
- revoke the appointment by the entity.

When an unrecognized firm commitment is designated as a covered against risk, the amendment in the aggregate fair value of the firm commitment that is attributable to the risk covered is recognized as active duty or in the corresponding gain or loss recognized in the profit and loss. Changes in the fair value of hedging instruments against the risk are also recognized in the profit and loss.

If an entity enters into a firm commitment to acquire an asset or to assume a debt that is a covered against risk in a fair value hedging against risks, the initial value of the asset or debt arising from that entity and a firm commitment is honored adjusted to include changing the aggregate fair value of the firm commitment that is attributable to the covered risk was recognized in the balance sheet.

In category microcover operations included those hedging links through which it aims to cover the risks of individual items.

Covering against the interest rate risk is performed for items such as:

- loans and receivables generated by the entity or assets available for sale, bearing fixed rates;
- debt bearing fixed rates and are not held for trading.

Some examples of relationships of the fair value of hedging against such risk are presented in Table 1.1.

Table 1.1. Covering against the interest rate risk

The covered element	The covering instrument	The covered risk
Decreased rate	Interest rate swap that pays a floating rate and receives a fixed.	Variability of the value of a fixed-rate debt.
Growth rate	Interest rate swap that pays a fixed rate and receives a floating.	Variability asset value of a fixed rate.
Decreased rate	Buying a futures contract or a forward contract to purchase, with the active support of a fixed-rate debt.	Variability of the value of a fixed-rate debt.
Growth rate	Selling a futures contract or a forward contract of sale, with the support aciv a debt with a fixed rate.	Variability asset value of a fixed rate.
Growth rate	Buying a "cap".	Change the value of a fixed-rate assets resulting from fluctuations in interest rates over the limit set in the "head".
Decreased rate	Buying a "floor".	Change the value of a fixed-rate debt resulting from interest rate fluctuations under the level set to "floor".

Source: KPMG, IAS – *Financial Instruments Accounting*, KPMG International, September 2000, p. 128.

Suppose that a company bonds on 01.01.2006 with maturity over 3 years, at nominal value of 50000 USD, with an interest rate of 7%, payable annually. The company would prefer to pay a variable rate. To do this, it contracts an interest-rate swaps with notional value of 50000 USD , which pays LIBOR and receives a fixed rate of 7%. Evolution of the LIBOR contract period is as

follows: 7% in the first year, 5% in the second year and 9% last year. Derivative coincides with the maturity of the loan obligator. Initial fair value of swap is zero, which is why contract not generate any accounting entries.

Management entity to designate a relationship derived from a fair value hedge against interest rate risk. Operation is considered very effective. Issuance of bonds is recorded as following:

Accounts at banks from issuing loans = Bond 50000

Net flows of Treasury related derivatives during the three periods are calculated in Table 1.2.

Table 1.2.

Year	Variable interest rate (LIBOR)	Fixed interest rate	Cash flows estimated at exit	Cash flows estimated in entering	Net flows of Treasury
	7%	7%	(3.500)	3.500	0
	5%	7%	(2.500)	3.500	1000
	9%	7%	(4.500)	3.500	(1000)

In year 1, determine the fair value of swap by updating the estimated net flows of Treasury year 2 using LIBOR (5%).

$1000 / (1 + 0.05) + 1000 / (1 + 0.05) (1 + 0.05) = 1859$ USD

Therefore, change the fair value of derivatives has not been a gain of U.S. \$ 1859.

Swap = Unachieved gain from covering operations 1859

Change fair value of debt, calculated by updating the flow coming in the form of a loss recorded in the results (50000 USD - 51859 USD).

$3500 / (1 + 0.05) + 53500 / (1 + 0.05) (1 + 0.05) = 51859$ USD

3500 where the flow is the annual interest due, and the 53500 USD and is considering the loan repayment period to end.

Article accounting is appropriate:

Unrealized loss of loans=Operations cover the issue of bonds 1859

Interest paid in the first financial year for bonds issued are as follows:

Interest expenses = Bank accounts 500

The following year, the entity recorded a net settlement of swap in which the receiving 1000 USD, which they distributed among the

related interest income from financial debt previously recognized (1859 USD x 5%) and the claim itself. Registration will be related accounts:

**Accounts at banks = % 1000
Income 93 Swap(financial debt) 907**

Also, the flows were estimated at - 1000 USD for three of the century through the interest rate of 9% [$1,000 / (1 + 0.09) = (917)$] is an conversion of swap of debt financial debt and a loss of unrealized fair value changes. Article accounting is appropriate:

**Unrealized loss of = % 1869
Swap operations coverage (financial debt) 917
Swap (financial debt) 952**

Interest expense recorded by the entity issuing the bonds is U.S. \$ 51859 x 5% = 2593 USD. Therefore, payment cash flows of U.S. \$ 3500 generates the following accounting:

**%=Accounts at banks 3500
Interest expense 2593
Loans with issued bonds 907**

Present value of debt in the second year is $53500 / (1 + 0.09) = 49083$. It is noted that the debt is reduced from 51859 to 49083, which generates a gain unfulfilled.

Loans from the issue= Bond operations of unfulfilled gain coverage 859

In the last year of the contract, the entity record swap settlement and payment of 1000 USD expense to distribute the interest on financial debt represented swap (917 x 9%) and debt balance.

**% = Accounts at banks 1000
Interest expenses 83
Swap (financial debt) 917**

Interest expense on the debt this year is 49083 USD x 9% = 4417 USD. Accounting for relevant are:

**Interest expense=% 4417
Accounts at bank 3500
Loans of programs bond 917**

At the end of the debt is repaid.

Borrowing programs=Accounts at banks 50000

In all three periods of the relationship of coverage, efficiency is 100%, any change to the fair value of the loan is perfectly offset by the hedging derivative instrument. For this reason, changes in market interest rate do not affect any duty not its results.

Hedge accounting recognizes the offsetting effects on the symmetric profit or net loss for the fair value changes of hedging instrument and related events that are covered.

When a company booked a financial instrument as an instrument for hedging risks associated with anticipated future transactions, then the company will present the:

- description of anticipated transactions, including the time period until the emergence of risk is assessed;
- description of the instruments for hedging risks;
- value of any gains or losses deferred or unrecognized and when the expected recognition as income or expense.

An enterprise should present all gains or losses occurred in the financial risk to cover anticipated future transactions, whether those gains or losses have occurred or not in the financial statements.

oprea_margareta@yahoo.com

Abstract

Disclosure is an effective mechanism to expose financial risk management practices to market discipline. Disclosure should be sufficiently comprehensive to meet the needs of users within the constraints of what can reasonably be required. Improved transparency through better disclosure may reduce the chances of a systemic financial crisis or the effects of contagion because creditors and other market participants will be better able to distinguish between the financial circumstances that face different institutions or countries.

Key words: financial risk, financial position, accounting standards

J.E.L. classification: M41

During this last decade, the accountability of the financial assets and debts has experienced a real revolution as a result of the fact that the accountability norms regarding the acknowledgement and evaluation of the financial instruments. The provisions of the mentioned standards, elaborated with the declared aim to bring the accountability practices at the level of the most recent evolutions that have taken place on the global financial markets have significantly changed the way of accountability of the financial assets and debts and of the instruments of the own capitals, of the derivatives or of the operations of risks covering, as being a direct reflect of the nature of the transactions developed in the modern economy.

The complexity of the new rules contained by the norms generated animated debates and challenged the practitioners involved in preparing and drafting the

financial balances, for whom applying the requests referring to: the acknowledgement of all the derivatives of the balance, the evaluation of many of the financial assets and debts at their real value, the criteria that must be observed to annul the acknowledgement or the use of the special accountability treatment applicable to the protection operations against the financial risks etc. was, in most of the cases, an absolute novelty.

Covering the fair value against currency risk. Unlike operations cover other types of risks, the coverage in a relationship of this kind may originate among nederivate. This is explained by the fact that, in general, changes in exchange rates are reflected for financial assets and liabilities in the profit and loss.

Exceptions are non-monetary items (such as shares) denominated in foreign currency and classified in the category of assets available for sale to fair value changes recorded in equity. In this case, the exchange differences are recognized in profit or loss. Although IAS 39 does not prohibit the designation of such elements as tools for hedging currency risk, the relationship is unlikely to be effective.

Due to the requirements of IAS 21 to assess all elements of the monetary exchange rate at the close of the financial year and to record changes in the profit and loss accounting operations risk coverage is not needed. Non-monetary items (assets or financial liabilities) record exchanged differences relating to equity, where the transfer results in the cancellation only in the recognition of such items. These rules have the consequence of using a less extended accounting operation of a fair value hedge against currency risk.

The most frequently used instrument for hedging currency risk is the *forward contract*. If holding an asset denominated in a

declining exchange rate is covered by a contract of sale of foreign currency on time. In the possession of a debt denominated in foreign currency, increasing the risk of exchange rate shall be covered by a forward contract to purchase a currency at a future date but at a price determined today.

Cover the fair value against the risk of price of goods is made especially for assets valued at fair value, if possible price reduction. Ensure protection through a forward contract for the sale of a product / financial title or by purchasing a put option on a commodity or a title.

For example, a company which has the object of refining metals and their wholesale sales, wants to protect stocks of zinc held. To do this, it falls on 01.07.2008, in a forward contract (which has no intention of reimbursements by the delivery of metal) to sell at a zinc price. On 30.09.2008, the hedge relationship is still very effective. The fair value of the stock of zinc decreases with 25000 USD, while the derivatives increased by 25000 USD .

On 01.07.2008 there are no accounting entries because the fair value of derivative is zero. On 30.09.2008 is accounted:

- amend the fair value of the stock of zinc:
Unrealized loss of zinc stocks= Operations coverage 25000
- amend the fair value of forward contract:
Financial asset has not=Gain of 25000 (forward contract) operations coverage

At the end of the financial year, was identified that part of the hedge relationship is effective, but overall efficiency is maintained in the standard (80-125%), why not waive the application of particular accounting treatment. The fair value of the stock of zinc fell by 25000 USD, and the derivative with 22000 USD. Accounting for relevant are:

- amend the fair value of the stock of zinc
Unrealized loss of zinc stocks= Operations coverage 25000
- amend the fair value of forward contract:
Financial asset has not = A gain of operations coverage 22500

Firm commitments are another important issue of accounting transactions for hedging risks. Under IAS 39, they are irrevocable agreements of exchanging a specified

quantity of resources at a price set at a time or more determined future date. These commitments creates the risk of exposure to change in the fair value. However, IAS 39, the original version, to protect their operations applicable accounting rules for hedging cash flows. But a new version of the standard amends this provision, which harmonize with U.S. accounting rules. Thus, coverage is a strong commitment to the operation of the risk of fair value changes. If the commitment is denominated in foreign currency, the entity may choose to cover according to the rules relating to fair value and the cash flows.

When an importer shall issue a purchase order, requiring payment in foreign currency seller, it exposes the risks of currency and not the time of the acquisition. This period, up to the actual transaction is called *anticipatory period of transaction*.

Accounting treatment of firm commitments covered instruments designated as provided for in IAS 39 is as follows:

- subsequent amendments cumulative fair value attributable to the risk of commitment is protected admit, on the one hand, as an asset or debt in the balance sheet and, on the other hand, the losses or gains in the results. Changes in the fair value of hedging instrument are recorded in all the profit and loss;
 - initial value of the asset or debt resulting from the strong performance is adjusted to include the cumulative amendments previously recognized in the balance sheet.
- Next, we present an example of covering a firm commitment denominated in foreign currencies, fair value through method. On 2 October 2006, an American company has ordered the purchase of equipment from a French manufacturer for the amount of 1000000 Euro, delivered over 3 months (30 January 2007). Date coincides with the settlement. To protect against currency risk, the company enters into a forward contract of 1 Euro = 1.23 USD. To establish the effectiveness of the relationship using the "dollar offset". Evolution rates during the coating operation is shown in Table 1.1.

Table 1.1.

	02.10.2006	31.12.2006	30.01.2007
Spot rate	1 Euro = 1,20 USD	1 Euro = 1,25 USD	1 Euro = 1,20 USD
Forward rate	1 Euro = 1,23 USD	1 Euro = 1,26 USD	1 Euro = 1,23 USD
Home	0,03 USD	0,01 USD	-
Change:			
- Spot rate	0,05 USD	+0,05 USD	=0,10 USD
- Forward rate	0,03 USD	+0,04 USD	=0,07 USD
- Premium	0,02 USD	+0,01 USD	=0,03 USD

The accounting records are :

- on October 2, when contracts are derived, there is no record because the its fair value is zero;
- December 31:

-the associated lossis recognized of firm value due to the adjustment of the fair as a result of fluctuations forward rate [(1.26 - 1.23) x 1000000]:

Unrealized loss from operations = Firm engagement of coverage 30000

Related derivative gain (0.03 x 1000000):

Financial asset (forward contract)= Unachieved gaining 30000

- 30 January:

- Loss of commitment attached firmly established on the basis of forward rate [(1.30 - 1.26) x 1000000]:

Unrealized loss from operations=Firm engagement of coverage 40000

- Gain related forward contract (0.04 x 1000000):

Financial asset (forward contract)=Unachieved gaining 40000

- Purchase of equipment at the rate of 1.23 set in the forward contract:

% =Accounts at banks 1300000

Equipment 1230000

Firm engagement 70000

Net settlement of derivative:

Accounts at banks=Financial Assets 70000

If the item covered against risk is a financial asset or financial debt, it may be an item covered against the risks to the risks associated with only a portion of the cash flows and its fair value - such as one or more flows Treasury selected the contract or a portion thereof, or a percentage of fair value - provided that effectiveness can be assessed.

Thus, a portion of identifiable and can be evaluated separately from the exposure rate to produce an active interest which may be classified as risk covered (such as interest rate risk or without a standard rate of interest of the total exposure rate of a financial instrument covered against risk).

Production of Organic Beekeeping – an Area of Interest of Romanian Export

Gudei Corina Simona
Crețoiu Raluca Ionela

"Spiru Haret" University, Bucharest

Faculty of Marketing and International Economic Business
corinagudei@yahoo.com, raluca.cretoiu@yahoo.com

Abstract

Regarding the culture of bees and bee products, our country has a long tradition, representing an occupation since ancient times. Currently, under globalization, where all products must be more competitive, organic beekeeping acquires new traits, its main objective being to obtain the best quality of bee products and to meet European standards, thus encouraging the consumption of "healthy" products.

Key words: ecologic, tradition, export, trade
J.E.L. classification: Q50, Z13, Q17, F1

Organic beekeeping is dynamic sector in Romania, and registered producers in organic farming system, starting with 2000, have certificates for organic beekeeping. The main objective of beekeeping is to obtain pure bee products of the highest quality without using chemicals. The quality of honey and bee products certified in organic agriculture depends largely of its treatment over the hives of bees, environmental quality, and the extraction, processing and storage conditions of bee products.

Features of beekeeping on areas, according to organic production, are closely related to rules and principles of organic beekeeping. For the location of the hives must:

- to ensure that the bees have enough natural sources of nectar, sweet secretions, pollen, and access to water;
- to ensure that within a radius of 3 km around the source of pollen and nectar crops are organic and / or spontaneous vegetation, or organic crops are treated only with low environmental impact methods;

- to keep hives at a sufficient distance from the sources that can lead to contamination of bee products or deterioration in the health of bees.
- in addition, at the beginning of each year, the beekeeper is required to provide for the certification by inspection bodies the map the location of the hives. If these areas are identified, the beekeeper is required to provide for certification by the inspection bodies all necessary documents and justifications, including the analysis showing that the areas accessible to his colonies of bees meet legal requirements. For inspection and certification bodies may be defined areas where no one can practice organic beekeeping.

Marketing of honey and bee products is achieved by two means: through trade associations and directly by producers who have, also, machining processing facilities. The work field of the associations focuses on the acquisition honey from honey producers, processing and marketing honey and bee products, both in domestic and other markets. Thus, an essential aspect is the initiative of the associations to organize in each year, training for members of producer associations, by which they are prepared for standard meeting of committees of the EU beekeeping.

Recently, as a result of modernization projects, associations have been equipped with modern lines, and honey processing equipment has led to a diversification of product range and packaging. Since quality is an important factor in the organic agriculture system and accurate information to consumers is the basic principle in this system, some associations have their own laboratories for analysis, where quality control of the material is performed by collecting samples when they enter the

facility and on finished product samples. Certified organic honey and bee products are present in both the domestic and the intra-and extra-EU markets (France, Germany, Hungary, Japan). It should be noted that over 60% of Romanian ecological honey is exported.

What we have seen so far is that there is no national association to handle the sale of honey to the European market or other markets. Exports are generally managed by each association that deals with domestic trade. Thus, in 2008, exports of organic honey was made by the following associations: S.C. Apicola S.R.L. Bacău, S.C. Apidava S.R.L., Asociația apicultorilor ecologiști din România -"Fila Ronnin Apis" Gorj, Apiprodex Târgu Mureș, S.C. Tremot Dobre și Fiii, registered in the database as exporters. An important aspect is that the most important company in Romania on line trade organic honey is SC Filiomera Brasov, which collects and sells honey and bee products only internally. To sell and label the product as organic is required an organic beekeeping operator who must be registered in the system of inspection and certification (registration numbers with local authorities and the control system of a body appointed by the Ministry of Agriculture and Rural Development operation in Romania). Beekeeper task is to transition from conventional to organic systems with specific environmental equipment, once the contract is signed with the inspection and certification body.

A recent study on factors influencing organic honey and bee products identified six factors:

- Change of concentration. Processing always attracts new opportunities and will lead to frequent changes in business strategy. Usually, treatment focuses on smaller markets, but due to constant change and new markets, a processor can decide to switch to an entirely new market.
- Enterprise of risk. Processing typically involves a high risk and this will influence the business line and hence the marketing production.
- Motivation. The processing of the production is addressed directly to the consumer and thus provides a great path for business marketing, development of

new types of products and finding new customers.

- Power and influence. Persons responsible for a processing unit, those with decision-making power, will greatly influence the marketing of the product.
- Strategic directions. Managers are assigned on specific tasks (technical or operational management), tactics which are of current importance, not long-term importance, such as renegotiation of prices with a customer.
- General. Usually, managers of processing units are involved in all company activities, including trading.

An effective way of highlighting the strengths, weaknesses, opportunities and threats highlighted in the beekeeping sector is the SWOT analysis:

Strengths:

- existence of national and community legislation
- existence of a control system recognized by EU;
- a dynamic of beekeeping industry;
- granting specific subventions;
- competitive advantage

Weaknesses:

- poor coordination and lack of unification of the main participants in the organic beekeeping;
- insufficient action to promote environmental benefits of bee products;
- lack of specific information / training programs for manufacturers regarding the capacity of management;
- insufficient development of processing capacity, packaging and sorting stations to meet the requirements of foreign markets;
- underdeveloped services (specific inputs: beehives, bee colonies, frames, etc.)
- beekeeping sector underrepresented in the market (domestic and abroad)
- lack of investment in marketing, advertising and promotion;
- poor representation of ecological apiculture programs of specific research.

Opportunities:

- Favorable natural conditions for beekeeping
- Cooperation with similar organizations (IFOAM, FAO, PHARE, etc.)
- Beekeeping sector gains confidence of the consumers of organic products;

- A growing foreign market;
- Cooperation with mass media;
- Traditional farming methods based on clean, unchanged local species;
- State subsidies

Threats:

- Eco-scandals;
- Current confusions between "natural products" and "healthy products";
- Low level of available credit in the financial market;
- Incorrect labeling, with "fakes" coming on the market;
- Extension of GMOs;
- Natural events and climate events;
- Low population awareness regarding organic agricultural environment;
- Increasing the quantity of imported products on the Romanian market.

For developing organic beekeeping and to increase competitiveness of organic products in the purpose of targeting organic products for export, have been identified the following priorities:

- increase and maintenance of value added on production of organic honey and bee products in the value chain, as long as possible and directing production towards external markets;
- promoting organic honey and bee products in markets niches where there are not yet covered;
- strengthening our position in current markets and identify new export markets;
- applying EU and national law in the organic beekeeping in order to strengthen the control system, either by additional monitoring measures by the competent authority for high quality products for export;
- national coverage of the market with organic honey and bee products designed to meet consumer demands;

- development of industry-specific research in order to provide technological solutions to beekeeping operators;
- professional development for producers, processors, importers and exporters;
- creating associations specialized in the sale of honey and bee products.

Romania remains a leader in the supply of organic honey, with integrated certification and with a steadily increasing market penetration, the issuance of the export strategy of the Romanian organic honey taking place in the context of globalizing world market and a market tendency of consumption against the "healthy" products.

The Informational Limits of the Profit and Loss Account in Accurately Portraying the Company's Performances

Guni Claudia Nicoleta
"Spiru Haret" University of Constanta
borsanclaudia@yahoo.com

Abstract

For a long time the users of financial statements were limited to consulting the profit and loss account in order to find out information regarding the result sheet, considered the most significant measure of a company's performance. On the same trajectory there lies the theory of Economics, noting that the main objective of the economic activity is that of maximizing profits.

Key words: accounting policies, relevance, reliability, fidelity.

J.E.L. classification: G3; G32; G34

Given the fact that companies can choose, within certain limits, their own accounting policies, the results reflect their goals and not the reality. In this situation, is the outcome credible and relevant? The objectives of accounting policies vary by size of enterprise and economic environment in which it operates. As an example we may mention the following: decreasing published losses, reducing taxable profit, current income increasing or decreasing, increasing or decreasing the profit to be distributed, arranging temporary accounting results in order to reduce the perceived risk of financial environment.

Accounting policies are defined in the dictionary of accounting of Oxford University Press, as "specific accounting bases constantly used by an organization in financial statements; these bases are considered and determined by the organization to be most appropriate to fairly present its financial results and operations." [3].

In the view of IAS 8 "Net profit or net loss of the period - fundamental errors and changes in accounting policies", the

accounting policies are "specific fundamental principles, conventions, rules and practices adopted by an enterprise in the preparation and presentation of the financial information".

Choosing and applying accounting policies are responsibilities of the company's management, so that the financial statements comply with all applicable requirements of each International Accounting Standard and of each individual interpretation of the Permanent Interpretations Committee.

In the absence of specific requirements the management "must adopt policies to ensure the provision of information by financial statements, information which is to be:

- a) relevant to the decision-making needs of the users, and
- b) reliable in the sense that:
 - o it faithfully represents the results and the financial position of the enterprise;
 - o it reflects the economic substance of the events and transactions and not merely the legal form;
 - o it is neutral, that is unbiased;
 - o it is cautious, and
 - o it is complete in all material respects."

If there is no specific International Accounting Standard and an interpretation from the Permanent Committee for Interpretation, the company management appeals to professional reasoning in order to "develop an accounting policy that provides the most useful information to users of financial statements of the enterprise. In pursuit of this professional reasoning, the management takes into consideration:

- a) the requirements and recommendations of the International Accounting Standard relating to similar and related issues;

b) the definitions, recognition and measurement criteria for assets, liabilities, revenues and expenses under the IASB main framework, and

c) the rulings of other organisms entitled to establish the Standards and Practices accepted in the industry practices only if they are "consistent with the letters a) and b) of this paragraph".

The accounting policies are therefore a consequence of the choice made by managers and aims at: choosing (or modifying) assessment methods, choosing (or modifying) methods of presentation of the summary document, setting the pattern and degree of aggregation of information published in the accounts of synthesis in general and in the annex, in particular, establishing the information which is to be published in the management report, establishing the date of communication of financial information, voluntary publication of optional summary documents (e.g., Financing framework), choosing (or modifying) the auditor; alignment (partial or total) to the international accounting referential or to the acknowledged international accounting referential; abandonment of certain accounting principles.

In our opinion, the freedom of choosing the accounting policies, possessed by the company manager who wants to reach the given target, would "urge" the accountant to make a selective choice, either of reduction of income or of increase of income. For example, two similar companies that, for evaluating stocks, use the FIFO (first in - first out) and respectively the LIFO (last in - first out) methods will have, assuming the other elements are equal, different sizes of the results. The first will get a higher result, while the second will get a lower result. Managers have different 'targets', depending on the size of the enterprise and on the leverage of the enterprise.

In large companies, publicly traded, the manager's objective is to meet the information needs of the shareholders. If the business is controlled by managers, the objective will be that of increasing the output. Companies controlled by shareholders will try to accomplish income "smoothing". But the findings should not be made absolute.

In large companies, managers will choose the accounting policies that will lead to diminishing the outcome, because for large businesses, political pressures are greater than for small ones. Among the researchers who have confirmed this hypothesis the following can be mentioned: Daley and Vigeland (1983) for analysis of the capitalization / lack of capitalization of the development costs and Zmijewski and Hagerman (1981) for the analysis of the methods for stock assessment. Indebtedness of the enterprise influences the choice of accounting policies by managers. The 1990 study made by Dumontier, Labelle and Raffournier concluded that French companies with high indebtedness are also the companies using accounting policies that lead to increased income.

The accounting literature has a variety of works, where acknowledged researchers studied the method of choosing the accounting methods by companies; the positive theory of accounting has given rise to the following assumptions:

1. Businesses where the pay for the accounting managers is tied to the outcome prefer accounting methods which have the effect of increasing income (profit);

2. Managerial type companies where managers have fewer shares prefer accounting methods which result in the company's profit growth. Ownership-type companies in which managers have an important share of the capital, the preferred accounting methods are those that have the effect of reducing the outcome;

3. Companies whose dividend distribution rate is approaching the limit (maximum) fixed by contract prefer accounting methods that increase the outcome;

4. Companies whose indebtedness ratio is close to the limit fixed by a contract prefer accounting methods which reduce the apparent level of indebtedness;

5. Companies for which the rate of recovery of interest costs is approaching the limit set by contract prefer accounting methods resulting in the increase of the outcome;

6. Businesses whose working capital is approaching the limit set by a contract prefer accounting methods that increase working capital;

7. Large companies prefer accounting methods that result in decreases of the outcome;

8. High-risk companies prefer the accounting methods which diminish the outcome;

9. Companies that hold a significant share of the market or are in sectors characterized by high concentration of production and capital prefer accounting methods which lower their outcome.

10. 'Regulated' companies prefer the accounting method that reduces the outcome.

Besides accounting practices, decisions of management also play a role, when the main aim of these decisions is that of presenting a different image of the outcome, but without changing the company's situation. The elastic nature of the outcome limits the informational value of the profit and loss account, which can sometimes become tricky. A profitable business is not necessarily a company that has liquidities. Behind its profitability it may hide serious cash problems.

The profit and loss account provides information regarding the financial flows recorded by the company at the end of the financial year in the form of profit and loss. From this explanation it could be inferred that, by means of the profit account cash flows are generated. The answer is yes, under the conditions of a cash accounting system, and no, if an accrual accounting type is practiced.

Cash accounting requires recognition of revenue upon receipt and of expenditure upon payment. Therefore, the profit and loss account will show receipts and payments generating cash flows. According to the accrual accounting, revenue is recognized when obtained, and expenses when incurred, notwithstanding the time of their receipt or payment.

The IASB Framework provides for the development (of the financial statements) of the profit and loss account according to the accrual accounting and therefore releasing cash flows through this document cannot be achieved otherwise but by processing the information it contains, namely the transformation of revenue and expenditure into receipts and payments. Financial statements prepared on an accrual account basis respond to the needs of information of

the users by giving them information, "not only about past transactions that generated the receipts and payments but also about the future payment obligations and about the resources regarding future receipts and payments".

In the context of the expansion of transnational companies, financial information users are interested in the company's performance determined not based on the result sheet but on the economic outcome. This latter indicator cannot be revealed by the profit and loss account, because it has a much broader structure than the result sheet, including items not passing through the profit and loss account.

Financial information users are interested in information which the profit and loss account cannot provide. To satisfy their information needs, decision makers must rely on new sources of information. Therefore, the accounting profession is called upon to create new tools to eliminate information boundaries of financial statements. The statement of changes in equity and the cash flow statement are "new products" of accounting.

Income and Expenditure – Factors Influencing the Company's Financial Performance

Guni Claudia Nicoleta
"Spiru Haret" University of Constanta
borsanclaudia@yahoo.com

Abstract

It is difficult to choose the relevant piece of information out of the abundance of information provided by management accounting, having an impact on the company's performance. As we know, the information regarding costs constitutes the link between managerial and financial accounting. However, we choose the costs of quality. These are recognized directly or indirectly by the final results. Regardless of the manner in which they operate, the costs of quality represent an inducer of the company's performance.

Key words: cost of quality, costs of conformity, costs of internal faults, costs of external faults.

J.E.L. classification: G3; G32; G34

For any of us, quality means that a product is better than another, because of its characteristics. In an economic system, quality represents an operating environment where a product or service, delivered by the company to its customers, is in line with the requirements.

The necessity for a tool used to financially assess the measures taken by companies in the quality assurance field has become increasingly evident since the early 40s. This tool, called "costs of quality", acquired, in a relatively short period of time, a large applicability in practice, becoming one of the widely debated issues in the speciality literature. The first company to have introduced a form of management based on the costs

of quality was General Electric, back in 1946. This system was presented in 1953, during the 7th Congress of the

American Society for Quality Control. On this occasion, Lesser has defined the costs of quality as representing "the costs due to scrap, shake-outs, inspections, tests, deficiencies noted by the buyer, due to quality insurance, including quality control training programs, audit of the product quality, control and static analysis". Although there were other approaches to the structure of the costs of quality, the economic practice preferred the one established by General Electric. This methodology, developed by Masser in the year 1957 and integrated in a cost system called "Quality Cost Analysis", defines three quality cost categories: prevention, assessment and breakdown, meaning "nonconformity with the specification.

Addressing the same issue, Feigenbaum (1969) considers it appropriate to distinguish between the costs of internal failure and the costs of external failure, and proposed using the following cost categories: prevention, evaluation and control, internal failure, external failure. Based on the principle of "quality doesn't cost", Crosby (1979) proposes two categories of "prices": the price of conformity and that of nonconformity.

Approaches regarding the cost of quality do not stop there, rather, reunited, they lead to the idea according to which quality costs are "costs specifically associated with the achievement or failure to achieve of a certain level of quality for goods or services".

Global competition has led manufacturing and service providing companies to focus on delivering quality goods and services, lest they lose market shares and may even cease operations. A number of studies show that in general, the costs involved in correcting and preventing lack of quality and those for preventing and assessing it represent on average 25% of the turnover of the manufacturing companies and 5-15% of their

production costs. For service providing companies, experts consider that the value of these costs is much higher.

Therefore, the quality costs represent an important tool for valuing quality, a potential source of maximization of the company's profit. They are used by more and more companies as a tool to optimize the processes and activities relevant to quality. Quality-related costs consist of costs of conformity and costs of nonconformity.

Compliance costs concern the costs incurred to produce a certain good or to deliver a certain service. These include the costs of prevention and evaluation. The costs of prevention are the expression of the efforts to prevent the occurrence of faults. In this category we can include costs involving: defining products and processes, preparing documents related to quality management and quality system (plans, quality manual), quality improvement program, awareness, motivation and training of staff in the quality control area, evaluating the suppliers, benchmarking the company's quality with that of the competing companies, quality audit and other activities. Evaluation costs are the costs of tests, inspections and examinations meant to determine whether the requirements are met.

Vachetta formulated a more suggestive definition of evaluation costs, considering that they are "all costs incurred for a defective product to be prevented from reaching its internal or external customer". Such costs are determined by: purchased materials inspection and testing, laboratory tests, inspections and tests on the manufacturing flow, the salaries of staff performing these activities, materials and products which were destroyed on the occasion of the tests.

Nonconformity costs are costs incurred in view of correcting defects of a certain good or of a certain service. These costs include internal faults and external faults costs. Internal faults effectual costs are the costs incurred in view of correcting all nonconformities identified before the product or the service has been delivered to the customer. These costs are determined by: scrap, remedies, reconditionings and repairs, repeated tests, analysis of faults meant to determine their causes, loss of time (cease of production caused by material

noncompliance which hadn't been discovered upon the reception). External costs are costs resulting from correcting non-conformities discovered after the products have been delivered to the customers. Included in this category of costs are those determined by: customer complaints (costs of staff dealing with resolving these claims, tests which need to be performed, surveys), returned goods (costs generated by transport, storage of returned products), insurance premiums to cover liability of the company for the product, compensation for damages, penalties for late delivery.

Quality costs are manifested throughout the product life cycle, from the design phase, through the implementation and delivery phases and ending with its use, and non-quality costs increase as the product passes from one phase to another. Determination of quality costs meets obstacles, for several reasons.

We present a few of them: a series of quality-related costs are not quantifiable, therefore, can only be estimated and often this estimate is subjective; there is a significant lag between the time of occurrence and the moment when the gaps have been identified (a flaw, discovered by the customer, may have come from the phase of reception of the raw materials or from the design phase); there is an important gap that can occur between the moment of the preventive action and the moment where the effects of these actions on quality-related costs can be highlighted (launching an awareness program for the staff in the field of quality control can show its effects after a few months).

Because of these drawbacks, it is necessary for quality costs analysis and interpretation to be made on a long term basis rather than on a short term basis. Quality-related costs are determined based on existing information in the company, or on information coming from the customers. For a meaningful analysis of the costs of quality, it is necessary that the information collected should meet the reporting period, be properly identified and used either in the entire company, or in its sectors. For example we have to exclude the estimates made by extrapolation, taking into account information existing within a period of reference or in an area considered significant,

or other methods, which are valid for cases where those requirements are not applicable to certain costs .

Assessing of the effects of quality costs on the company's financial performance is relatively difficult. In the speciality literature, these costs are considered costs of the product. In our opinion, some of these costs, as are those of conformity, are only product costs.

The other component, non-compliance costs, represent only the costs for the given period; their influence on company performance can be viewed from two perspectives:

The first is that, being costs related to the period, they are recognized directly by the final result which it increases or decreases.

The second refers to the company-client relationship. Costs of non-compliance affects the satisfaction level of customers who would prefer other companies

Thus, the company's market share decreases, and thus so does the turnover. These two factors with direct and indirect impact on performance, transform the costs of quality into a powerful weapon owned by the company when fighting the performance, and at the same time they warn the company that, always, quality costs.

Conclusion

Quality costs represent an important tool for assessing quality, a potential source for maximising the company's profit.

Models of Credit Risk Measurement

Hagiu Alina
University of Pitesti
alinahagiu@yahoo.com

Abstract

Credit risk is defined as that risk of financial loss caused by failure by the counterparty.

According to statistics, for financial institutions, credit risk is much important than market risk, reduced diversification of the credit risk is the main cause of bank failures. Just recently, the banking industry began to measure credit risk in the context of a portfolio along with the development of risk management started with models value at risk (VAR). Once measured, credit risk can be diversified as any other financial risk.

The main purpose of the paper is to present the most important methods of credit risk measurement used in the banking industry: Credit Metrics, developed by J.P. Morgan, Portfolio Manager developed by KMV company, Credit Risk+ developed by Credit Suisse First Boston and Credit Portfolio View developed by the consultancy company McKinsey.

Key words: credit risk, models, management, strategy;

J.E.L. classification: G11, G32, G24;

1. Introduction

Because the Basel agreement regards the credit risk individually and not in a portfolio context, financial institutions have built their own credit risk models that take into account the time profile of exposure, rates of entry into realistic default and the correlations between them. Also may be taken into account the compensation and other ways of altering the exposure. The main advantage of these models is that they take into account the effects achieved through portfolio diversification.

The first model used for credit risk management has been the calculation of the risk adjusted return on capital (RAROC) developed in the early 80s by bank Bankers Trust. Currently, the main models on the market are *CreditMetrics* (developed by investment bank JP Morgan), *PortfolioManager* (of the Moody's KMV company), *CreditRisk +* (developed by investment bank Credit Suisse First Boston) and *CreditPortfolioView* (of the McKinsey consultancy company).

These models differ in the following characteristics:

- Defining risk. Credit risk models can be defined as default entry, or more generally by any change in the market value of an asset due to change in perception towards the possibility of entry in default of its issuer;
- Risk determinants. Credit risk can be modeled as being determined by changes in asset values, by macroeconomic fundamental factors or based on a statistical model;
- Correlations. Correlations between the bankruptcy risk for various counterparties could result from joint development of financial assets that have similar exposures or from macroeconomic developments;
- Recovery rates. They may be random or constant;
- Solution. This can be analytical or based on simulations.

2. CreditMetrics Model

CreditMetrics is a model used to assess portfolio risk caused by changes in value (market) loans due to changes in the borrower's financial situation (bankruptcy, improvement or worsening of the rating).

Addressing credit risk at portfolio level, the benefits of this model are:

- allows the systematic assessment of concentration risk (the additional portfolio risk resulting from increased exposure towards a certain borrower or a group of

borrowers whose activities are related - for example working in the same geographical area or the same industry);

- allows the effects assessment due to portfolio diversification.

CreditMetrics estimates the portfolio credit risk due to credit events - measure the volatility of future value (at the end of the horizon had in mind) of the portfolio caused by the debtor creditworthiness changes (bankruptcy, changes of the rating). In addition, the model allows the capture of certain components of market risk for instruments such as swaps and forwards, instruments for which induced volatility by changes into customer creditworthiness is enhanced by the financial institution exposure to the debtor.

The credit risk generator factors taken into account by the *CreditMetrics* model are:

- Credit rating;
- The degree of preference over other creditors of the lender in case of entry in default of the debtor (the priority level). It determines the recovery rate applicable to the credit instruments.
- The spread of credit (and in hence a credit risk-free interest rate), on which is revalued the present value of credit instruments.
- Correlations between migration/bankruptcy (for holdings of credit instruments) - determined from historical data (ratings, exchange rates) or estimated based on models.

Analytical estimation of distribution value of a portfolio of more bonds

Taking into account a portfolio of n assets, noting the value of these assets at end of the horizon envisaged with V_1, V_2, \dots, V_n and averages of these values with $\mu_1, \mu_2, \dots, \mu_n$, the variations of these values are $\Gamma^2(V_1), \Gamma^2(V_2), \dots, \Gamma^2(V_n)$.

At the end of the forecasting period, the portfolio value is $V_1 + V_2 + \dots + V_n$ and its average value is $\mu_p = \mu_1 + \mu_2 + \dots + \mu_n$.

The standard deviation of portfolio Γ_p is calculated using the relationship:

$$\Gamma_p^2 = \sum_{i=1}^n \Gamma^2(V_i) + 2 \times \sum_{i=1}^{n-1} \sum_{j=i+1}^n COV(V_i, V_j) \quad (1)$$

3. Portfolio Manager Model

The idea of applying options theory to evaluate loans and bonds is found in the literature since 1974, starting with the article published by Robert Merton and further developed by Galai and Masulis (1976).

Considering a firm that finances the acquisition of assets (risky), V , using the capital constituted by shareholders, E , and issuing a zero-coupon bond, with face value (including accrued interest) F and maturity T , whose market value is B . The loan taken by the firm is subject to credit risk - ie risk that at time T , the company's assets, VT , will be lower than the (nominal) loan value, F .

The credit risk exists as long as the bankruptcy probability, $P(VT < F)$ is greater than 0. Therefore, at time t_0 , $B_0 < F \times e^{-rt}$, ie the bond's yield, y_T , is greater than the risk-free interest rate, r , and the spread due to credit risk (*default spread*), spread which compensates the bond holders for the taken risk is $n = y_T - r$.

If there is no friction (on the market), transaction fees and incurred costs in the firm bankruptcy, then the present value (market value) of firm asset is the sum between capital value and loan: $V_0 = E_0 + B_0$.

Therefore credit risk is a function of the firm's financial structure:

- degree of leverage, $LR = \frac{F \times e^{-rT}}{V_0}$;
- volatility of return on assets company, Γ_V ;
- firm debt maturity T .

The idea from which started Merton (1974), is that if, at time T , $V_T < F$ then the company is, at least in theory, in bankruptcy, and value, market, capital is 0. If, at the same time $V_T > F$, then the company will pay its debt and its capital value will be $V_T - F$. As a result, the firm's capital at time T is:

$$E_T = \max(V_T - F, 0).$$

So, the capital of a company, E_t , can be considered a call option with the underlying market value of company assets, the exercise price V and the nominal value of company debt, F .

Ie, $E_t = f(V_t, F, \Gamma_V, r, T-t)$, where V_t and Γ_V are undetectable variables.

Applying the formula of Black-Scholes option valuation (1973), it follows:

$$E_0 = V_0 \cdot N(d_1) - F \cdot e^{-rT} \cdot N(d_2) \quad (2)$$

where:

$$d_1 = \frac{\ln \frac{V_0}{F} + \left(r + \frac{\sigma_V^2}{2} \right) \cdot T}{\sigma_V \sqrt{T}}$$

$$d_2 = d_1 - \sigma_V \cdot T. \quad (3)$$

Loan Value (market) is $V_0 - E_0$.

Risk-neutral probability that company to enter bankruptcy is $N(-d_2)$, but it is necessary to calculate V_0 and Γ_V , which are undetectable variables. But if the company is traded, can be observed the capital value, E_0 and, applying Ito's Leme, the equity volatility can be estimated, Γ_E :

$$\sigma_E \cdot E_0 = \frac{\partial E}{\partial V} \cdot \sigma_V \cdot V_0 \quad (4)$$

$$\text{or } \sigma_E \cdot E_0 = N(d_1) \cdot \sigma_V \cdot V_0 \quad (5)$$

Building a system of two simultaneous equations based on this relationship and the option price equation, it can be solved to obtain values of V_0 and Γ_V .

According to Black-Scholes model (1973), option price P is given by:

$$P_0 = -N(-d_1) \cdot V_0 + F \cdot e^{-rT} \cdot N(-d_2) \quad (6)$$

where:

$$d_1 = \frac{\ln \frac{V_0}{F} + \left(r + \frac{\sigma_V^2}{2} \right) \cdot T}{\sigma_V \sqrt{T}} = \frac{\ln \frac{V_0}{F \cdot e^{-rT}} + \frac{1}{2} \cdot \sigma_V^2 \cdot T}{\sigma_V \sqrt{T}}$$

$$d_2 = d_1 - \sigma_V \cdot T.$$

(7)

As a result, the cost to cover credit risk depends on the risk of company assets, Γ_V , firm debt maturity, risk-free rate, and the indebtedness of the company.

The *Yield of the company's debt* may be determined as follows:

$$y_T = -\frac{\ln \frac{B_0}{F}}{T} = -\frac{\ln \frac{F \cdot e^{-rT} - P_0}{F}}{T} \quad (8)$$

And the *spread of credit*, π_T , Defined as $\pi_T = y_T - r$, taking into account the equation of the put option price, P , is:

$$\pi_T = y_T - r = -\frac{1}{T} \ln \left(N(d_2) + \frac{V_0}{F \cdot e^{-rT}} \cdot N(-d_1) \right)$$

(9) So it is a function of leverage, asset volatility and firm debt maturity.

The spread of credit can be calculated as a function of indebtedness, of asset volatility and debt maturity.

4. CreditRisk + model

CreditRisk+ model, developed in 1997 by Credit Suisse First Boston, has an actuarial approach and discusses the process of bankruptcy, including the recovery rate of duty as exogenous, which means that the likelihood of the bankruptcy provided by the model are based on statistical historical dates.

CreditRisk+ model, assumes that the probability distribution for the number of bankruptcies for any length of time is a Poisson distribution. Based on these assumptions the model produces the distribution of loss for a portfolio of bonds or loans using the individual characteristics of each borrower and the correlation between instruments in the portfolio.

Model hypothesis are:

- For a loan, the bankruptcy probability in a certain period, e.g. one year, is as in any other year.

- For a high number of borrowers, the number of bankruptcies in a period is independent of the number of borrowers falling into bankruptcy in any other period.

Given these assumptions, the probability distribution of the number of bankruptcies in a given period follows a Poisson distribution. Poisson distribution has the advantage that can be specified using a single parameter - the media.

Under these conditions,

$$\text{Pr ob}(n - \text{bankruptcies}) = \frac{\bar{n}^n \times e^{-\bar{n}}}{n!} \quad (10),$$

for $n=0,1,2,\dots$

where n represents the average number of bankruptcies per year $\bar{n} = \sum_A P_A$.

The annual number of bankruptcies, n is a stochastic variable with the average \bar{n} and standard deviation $\sqrt{\bar{n}}$.

In order to determine the frequency of events of bankruptcy, it has introduced a new hypothesis: the average number of bankruptcies is itself a stochastic variable with the average \bar{n} and the standard deviation Γ_n^- .

To embed and severity of loss if the debtor goes into bankruptcy, each debtor exposure is adjusted to the expected recovery rate for calculating loss in case of bankruptcy of the debtor (LGD).

Thus, the expected loss (EL) for the debtor A is: $EL_A = LGD_A \times P_A$. (11)

In the derivation of a diversified portfolio loss distribution, losses (adjusted exposure by recovery rates) are divided into bands and the level of exposure in each band is approximated by a single number. Each band is considered a portfolio of independent loans/bonds.

Credit Suisse proposes some extensions of this model:

- Extending the model with one period to a multi-period model;
- Introduction of factors that influence the variability of production rates of bankruptcy, factors related to the activity sector of the debtor company. Thus, each factor, k , is represented by a random variable X_k , which represents the number of bankruptcies in the sector k and is considered to have a gamma distribution. Then, the average rate of bankruptcy for each debtor is considered to be a linear function of factors X_k . Moreover, these factors are considered independent.

In both cases, the *CreditRisk+* model suggests an analytical solution for the distribution of portfolio losses from loans/bonds.

This model has the advantage that it is easy to implement, calculating needs are limited and marginal impact on credit risk (introduced by a bond) is easily incorporated. Also needs of data are limited for each instrument being necessary only the bankruptcy probability and the exposure.

The main limitations of the model are that the methodology assumes that there is no relationship between credit risk and market risk (interest rates are assumed to be deterministic). In addition, the model ignores the risk of migration, each issuer exposure is

considered constant and not sensitive to possible future changes of the debtor's credit risk or interest rate changes.

Also, similar with *CreditMetrics* and *KMV models*, *CreditRisk+* model can not satisfactorily assess the credit risk of non-linear products such as options and currency swaps.

5. CreditPortfolioView Model

McKinsey consulting company has proposed an econometric model which measures the risk of bankruptcy (*default*), the probability of bankruptcy (*default*) depending on macroeconomic variables, some of them corresponding to the financial variables used as *proxy* for economic status: the exchange rate and interest rate, the growth rate of the economy, unemployment, government spending, and savings rate. This model corresponds to empirical evidence that credit cycles and business cycles are cointegrate. In addition, this model has the advantage of data availability.

Assumptions of this model are:

- diversification helps reduce the uncertainty of losses;
- there is uncertainty - systematic risk - in terms of losses, even for more diversified portfolios;
- systematic risk of the portfolio is determined in particular by the macroeconomic situation - in periods of recession and deteriorating credit ratings and default entries increase.

In developing this model were considered counterparts with speculative ratings (below BBB) which are more sensitive to credit cycles and macroeconomic data.

In this model probabilities are considered likely to be generated by a logistic function and depending on the country index with a speculative level of ratings, which in turn is determined by using multifactorial analysis of contemporary macroeconomic variables or with lag.

The probability of entry into bankruptcy for a debtor with speculative ratings in the sector / country j for period t is given by:

$$P_{j,t} = \frac{1}{1 + e^{-y_{j,t}}} \quad (12)$$

where $Y_{i,t}$ is an index

$$Y_{j,t} = \beta_j^0 + [\beta_j^1 \quad \beta_j^2 \quad \dots \quad \beta_j^m] \begin{bmatrix} X_{j,t}^1 \\ X_{j,t}^2 \\ \dots \\ X_{j,t}^m \end{bmatrix} + v_{j,t} \quad (13)$$

where:

β_j is the vector of coefficients (sensitivity) for the sector / country j that applies to the vector of values j , of m or macroeconomic variables, $X_{j,t}$;

$v_{i,t}$ is the error term, which is independent of $X_{i,t}$ and identically and normally distributed.

Macroeconomic variables are specified for each country, and when there is enough available data, the vector j_j can be calibrated. In addition, in the proposed implementation of McKinsey, one starts from the assumption that each of these independent variables follows an autoregressive process of order two (AR (2)) so that the process X_{jt} has memory:

$$X_{j,t}^i = \gamma_{j,0}^i + [\gamma_{j,t-1}^i \quad \gamma_{j,t-2}^i] \begin{bmatrix} X_{j,t-1}^i \\ X_{j,t-2}^i \end{bmatrix} + \varepsilon_{j,t}^i \quad (14)$$

where:

$X_{j,t}^i$ is the macroeconomic variable value i , for segment j . at time t , the vector of coefficients γ_i^j is the sensitivity to earlier information;

$\varepsilon_{j,t}^i$ is assumed to be identical with $\varepsilon_{j,t}^i \sim N(0, \Gamma_i)$ and ε is the vector of error terms for each of those i AR (2) equations in the segment j .

Above equations define the system which determines the evolution together of the bankruptcy rates for the countries / sectors with speculative ratings and related macroeconomic variables, system that must be calibrated.

In particular, for all the innovation vector,

$$E_t = \begin{bmatrix} v_t \\ \varepsilon_t \end{bmatrix} \sim N(0, \Sigma) \quad (15)$$

with

$$\Sigma \equiv \begin{bmatrix} \Sigma_v & \Sigma_{v,\varepsilon} \\ \Sigma_{v,\varepsilon} & \Sigma_\varepsilon \end{bmatrix} \quad (16)$$

where:

E it is a vector $(j + i) \times 1$ of the whole innovation system of equations;

Σ is the matrix $(j + i) \times (j + i)$ covariance for the errors of forecasting macroeconomic variables (v) and shock of entry into the sector-specific default (ε);

$\Sigma_{v,\varepsilon}$ is the matrix of correlation between forecast errors of variables macroeconomic (v) and shock of entry into default specific to each sector(ε).

Thereafter the calibration process, using Choleski decomposition of the matrix Σ ,

$\Sigma=AA'$ allows to stimulate the joint distribution of the bankruptcy probabilities for all segments.

Calculation of conditional transition matrix. Once entry rates in default are calculated for each country / sector of the economy, can cause Marcov single transition matrix for each of the countries / sectors.

Using stimulation the conditional transition matrix is reproduced several times to generate multivariate probability distribution of migration and default entry for any rating and any time horizon. From this distribution can be calculated any measure of *CreditVAR*.

6. Conclusions

The investment process has multiple facets: it may entail to invest money in bonds, joint shares, properties or any other assets, it may involve speculative actions on an increasing market or short sales on a market in decline, it may entail the choice of actions by growth "or" value", the choice of bonds, options and other securities financial, it can lead to accumulation of funds or dissipation of resources.

Diversity and competition are the main attributes of this effervescent area. In this labyrinth, an important place is occupied by the portfolio management, both in theoretical aspect, as well as practical aspects. Individual investors fund managers and institutional investors should decide on the objectives to be sought, and depending on this, to choose between possible alternative investments. As part of the risk control mechanism, the decision must be taken in the base of the selection of multiple assets to be able to build a portfolio which to balance the two fundamental elements: risk and earnings.

Behavioral finance is a study that sought to explain the inefficiency of the market by using psychological theories. Observing that people often make mistakes and allegations preposterous when it comes to their affairs the economical theory began to investigate deeply the psychological concept for explaining irrationality in people's thinking, based on elements such as overstatement, over-reaction caused by the influence of factors of aversion against loss, mental calculation and risk tolerance.

The Evolution of the European Car Industry in the Context of the Economic Crisis

Hagi Alina
University of Pitesti
alinahagi@yahoo.com

Abstract

The economic recession has had a huge negative impact on the car industry. The decline in car sales affects not only manufacturers themselves but also the considerable number of small and medium-sized businesses that depend directly on the car industry as suppliers and retailers. Thousands of jobs are consequently at stake.

The car industry is a key sector of the European economy contributing to employment, innovation and competitiveness in Europe. The industry must strive to continue developing the skills of its workforces. The focus should be on investment in innovative and green technologies. Renewal of the car fleet should also be encouraged to boost demand for new, safer and environmentally friendlier vehicles.

The paper aims to present the evolution of the European car industry before and in time of the economic crisis, and to present some tendencies for after the crisis.

Key words: car industry, crisis, development, perspectives;

J.E.L. classification: L62, O14;

1. Introduction

The European car industry is a very volatile industry with many peaks and falls. In fact, the EU is the world's largest producer of motor vehicles, so essentially it is central to Europe's prosperity. As such, the European car industry is an employer of a huge skilled workforce. It also represents Europe's largest investor in research and development and makes a major contribution to the EU's Gross Domestic Product (GDP), the European Commission states.

The European car industry has been deeply affected by the recession, so much so that governments throughout Europe and the world have passed stimulus packages to help the industry.

Because automotive is among the most important of European industries-perhaps the most important-many governments have passed stimulus packages to help stabilize their auto markets during the recession. The most popular stimulus is the so-called scrappage incentive that gives buyers of new cars a discount if they trade in old cars that generate more air pollution than new, cleaner vehicles. A May 2009 report from the BBC states that the global car industry was in crisis due to the recession, and how many companies had needed government help to survive.

The automotive industry is central to Europe's prosperity. The EU is the world's largest producer of motor vehicles, producing over 18 million vehicles a year and almost a third of the world's passenger cars. It is a huge employer of skilled workforce, directly employing over 2 million people but responsible for some 12 million jobs. It is a key driver of knowledge and innovation, investing more than € 20 billion a year in R&D, making it Europe's largest private investor in R&D. With an annual turnover of €780 billion and a value added of over €140 billion, it makes a major contribution to the EU's GDP. It exports far more than it imports, with a surplus of over €60 billion on overall exports of €25 billion. In addition, the sector plays a central part in tackling many of the key economic, social and environmental challenges faced by Europe today, such as sustainable mobility and safety.

Automotive manufacturing is closely linked with many other sectors. Electronics, mechanical and electrical engineering, information technology, steel, chemicals,

plastics, metals and rubber are all key suppliers. 20% of the EU's steel and 36% of its aluminium production goes into automotive production.

2. The evolution of the passenger car registrations

New passenger car registrations in W. Europe reached 14.5 million units in **2005**. This represented a modest drop of -0.2% relative to 2004. If we consider "total Europe" figures (i.e. enlarged EU + EFTA countries), 15.2 million new cars were registered, a fall of -0.7% relative to 2004. The slowdown of new passenger car registrations observed in 2005 was influenced by generally weak macroeconomic conditions in the EU, high energy prices and the deceleration of the British and Spanish automobile markets. New car registrations fell by 26% relative to 2004. The main factors accounting for this drop remain the unfavourable car taxation policies, the abolition of import tariff on used cars and the increase in new cars' prices.

In **2006** a total of 15,391,511 new passenger cars were registered in Europe (EU23 + EFTA) in 2006, representing a slight improvement (+0.9%) with regard to previous year. In December 2006, total new passenger car registrations in Europe (EU23

+ EFTA) remained flat as compared with the previous year and reached 1,074,369 units.

Buyer uncertainty, fed by fuel price fluctuations and rising interest rates, were – in addition to the lack of new models – the most frequently evoked factors affecting these markets in 2006. As regards the remaining EU15 countries, six of them posted growths ranging from +1% in Finland to +48.1% in the Netherlands, whereas the other four declined (Austria -0.1%, Sweden -4.5%, Denmark -7.4% and Portugal -13%).

Nearly 16 million new cars were registered in Europe (EU27+EFTA) in **2007**, or 1.1% more than the year before. Soaring oil prices, changes in taxes, shrinking credit availability and purchasing power restrained buyers' confidence and the demand for new cars in some of the Western European countries (+0.2%). In the new EU member states, where car density is still much lower and many households have been able to afford buying a new car only recently, a steady growth was recorded throughout the year (+13.9%).

Figure no. 1 New Passenger Car Registrations in the EU, 1990-2009

Source: European Union Economic Report, ACEA, Brussels, 2010

European new passenger car registrations fell by 7.8% to 14,712,158 units in **2008**, recording the sharpest decline since 1993. New car demand dropped by 8.4% in Western-Europe, with the downturn most

prominent in the last quarter (-19.3% compared to the fourth quarter of 2007).

Only four countries posted growth: Finland (+11.2%), Portugal (+5.7%), Belgium (+2.1%) and Switzerland (+1.0%). While fiscal measures helped sustain growth

in Finland and Portugal, the Belgian and Swiss sales levels seem to have better resisted the financial and economic crises prevailing throughout Europe.

Figure no.2 New Passenger Car Registration by Segment in Europe 2006-2009

Source: European Union Economic Report, ACEA, Brussels, 2010

In the new EU Member States, 2008 numbers leveled the results of 2007 (-0.7%). In absolute numbers, Poland remained the major market, consolidating its position with a 9.4% increase. The Czech Republic (+8.4%) also recorded a plus, but Romania (-8.7%) and Hungary (-9.2%) contracted.

Over the whole year **2009**, EU passenger car demand was 1.3% lower than in 2008, and 9.3% lower than before the crisis in 2007. Following a marked decline in the second half of 2008 and first half of 2009, EU new car registrations picked up in the second half of last year, reflecting the cautious upturn in the overall European economy as well as the impact of fleet renewal schemes implemented in 13 EU Member States. In total, 14.1 million new cars were registered in the EU in 2009. Besides Slovakia (+6.7%) and the Czech Republic (+12.5%), only Austria (+8.8%), France (+10.7%), and Germany (+23.2%) posted growth compared to 2008, with results lifted by scrapping incentives. Results were cushioned for similar reasons in Italy (-0.2%), the UK (-6.4%) and Spain (-17.9%).

3. The evolution of the New Commercial Vehicle Registrations

• New LCV Registrations

New LCV registrations Europe reached 1.980.422 units in **2005**, representing an increase of +3.1% relative to 2004. With the exception of Italy (-2.4%) and the UK (-2.0%), all the main markets contributed positively to this result: Spain (+15.9%), Germany (+3.0%) and France (+2.8%). In the other markets, significant growths in new LCV registrations were recorded in particular for Denmark (+24.2%), Ireland (+22.3%) and Sweden (+11.5%). In contrast, the Netherlands reported a marked fall (-24.3%) in new LCV registrations.

Over 2 million new Light Commercial Vehicles (LCV) were registered in **2006** in Western Europe, rising +4.1% above last year's result. Fourth quarter acceleration in registrations (+10%) was linked to the 1.1.2007 deadline for new vans to comply with Euro IV emission standards.

In **2007**, the demand for new commercial vehicles in Europe was overall 6.8% higher than last year. The European market ended the year with 7.1% more vans, 5.1% more trucks and 4.4% more buses & coaches registered. The steady upward trend recorded throughout the year thanks to a healthy and

dynamic European and foreign demand in the sector weakened somewhat in December.

In **2008**, demand for new commercial vehicles decreased by 9.0% across Europe reflecting the impact of the economic crisis in the second half of the year and marking the sharpest downturn in demand since 1993. After a slight increase in the first quarter of 2008 (+1.3%), new registrations backtracked in the second quarter (-2.7%) and dropped more dramatically in the third (-12.0%) and fourth (-24.0%). In 2008, the segment of light commercial vehicles was the most severely hit by the crisis (-10.4%) in spite of the 5.1% growth posted in the new EU Member States.

Overall results were pulled down by the performance recorded in Western Europe (-12.0%). Of the biggest markets, France (-0.3%) and Germany (+0.8%) proved to be relatively stable, while Italy (-8.7%), the UK (-14.9%) and Spain (-39.7%) faced a more heavy drop. In the new EU Member States, the Czech Republic (-3.3%) and Poland (8.9%) remained the largest markets.

In **2009**, new commercial vehicle registrations in the EU declined by 32.6% compared to 2008, affecting all segments and all countries. In total, 1,650,840 vehicles were registered throughout the year.

Figure no.3 New Commercial Vehicle Registrations in the EU 1997-2009

Source: European Union Economic Report, ACEA, Brussels, 2010

• New CV Registrations

Europe new CV registrations above 3.5t reached a total of 358.890 units in **2005**, a rise of +5.8% relative to 2004.

Although new truck registrations plummeted by -16% in Europe in December **2006** (28,382 units), the market remained on a positive trend as regards yearly result (+4%). Monthly registration figures were distorted throughout the year by deadline effects of new legislation coming into force. In **2007**, new truck registrations in Europe continued to boom throughout the year (+5.1%), mainly helped by growth on the German (+5.5%), Spanish (+10.2%) and new EU member state markets (+38.9%).

Over the **2008** year, new truck registrations fell by 4.0% in Europe, mainly because of the 21.1% decrease in the new EU Member States. In **2009**, new van

registrations totaled 1,375,856 units, or 30.5% less than in 2008. The decrease was 27.9% in Western Europe and 49.7% in the new EU Member States, ranging from -18.8% in France to -77.7% in Latvia.

• New Bus & Coach Registrations

The market for new Buses and Coaches in Europe also plunged in December **2006** (-37%), reaching 2,369 new B&C in total. In **2007**, the substantial December growth in new bus & coach registrations in Western Europe (+41.4%) and in the new member states (+74.1%) helped to improve the cumulative result in Europe (+3.1%).

Despite a 7.5% decrease in December, the segment of buses and coaches was the only one to expand in **2008** (+12.1%). Growth was posted both in Western Europe (+6.6%) and in the new EU Member States (+58.7%).

New registrations of buses and coaches were down 9.6% in **2009**, amounting to 37,533 units in the EU.

4. New Motor Vehicle Production in Europe

Automobile production in Europe, showed a fairly weak pattern in **2005**. In total, 17.9 million vehicles (PC, LCV, CV, Buses & Coaches) were produced, a -1.1% drop relative to last year. This fall was due essentially to the slowdown of passenger cars

production which experienced a decrease of -1.8% relative to 2004. In contrast, the production of commercial vehicles continued to increase, although at a slower pace than in 2004. After some dynamic growth in the first three months of **2006** (+6%) and a decline in the second quarter (-2%) as compared with the same period in 2005, the production of motor vehicles stagnated in the third and fourth quarter. In total, 18,6 million vehicles were produced in 2006 in Europe, 1% more than previous year.

Figure no.4 Passenger Car Production in Europe 1990-2009

Source: European Union Economic Report, ACEA, Brussels, 2010

Nearly 19.7 million motor vehicles were produced in Europe in **2007**, 5.3% more than in the previous year. In **2008**, over 18.4 million motor vehicles (passenger cars, trucks, vans and buses) were produced in Europe, which is 7% less compared to 2007 when 19.7 million vehicles were manufactured. As automakers further adapted stocks and output levels to the economic situation, total vehicle production in **2009** fell by 17% compared to 2008 and 23% compared to the pre-crisis level of 2007, amounting to 15.2 million units.

5. The European Car Industry after the end of the crisis

Three quarters into 2010, a total of 12.6 million motor vehicles were produced in the EU, which is 15% more than over the same period last year. Compared to the pre-crisis

level of the first three quarters of 2008, total production was down 14%. New passenger car production in the EU grew in the first half year before contracting by 5% in the third quarter, in correlation with the drop observed in new registrations. Three quarters into the year, production of cars was up 13% compared to the same period last year, but down 11% compared to the first three quarters of 2008. Production of vans increased throughout the first three quarters of this year. However, compared to the levels of 2008, output levels were still down 29%. Truck production continued to decrease in the first quarter of this year, before rebounding in the second and third but still remaining well below the level before the crisis (-53%). Germany remained the largest manufacturing country, both for motor vehicles and passenger cars, the production of which expanded by 15% and 14%

respectively. While 36.4% of new cars were produced in Germany, Spain, as well as France, accounted for 12.9%, followed by the UK (8.3%), the Czech Republic (7.1%), Poland (5.7%), Italy (3.9%) and Slovakia (3.6%).

6. Conclusions

The automotive industry crisis of 2008–2010 was a part of a global financial downturn. The crisis affected European and Asian automobile manufacturers, but it was primarily felt in the American automobile manufacturing industry. The downturn also affected Canada by virtue of the Automotive Products Trade Agreement.

The automotive industry was weakened by a substantial increase in the prices of automotive fuels linked to the 2003-2008 energy crisis which discouraged purchases of sport utility vehicles (SUVs) and pickup trucks which have low fuel economy. The popularity and relatively high profit margins of these vehicles had encouraged the American "Big Three" automakers, General Motors, Ford, and Chrysler to make them their primary focus. With fewer fuel-efficient models to offer to consumers, sales began to slide. By 2008, the situation had turned critical as the credit crunch placed pressure on the prices of raw materials.

Car companies from Asia, Europe, North America, and elsewhere have implemented creative marketing strategies to entice reluctant consumers as most experienced double-digit percentage declines in sales. Major manufacturers, including the Big Three and Toyota offered substantial discounts across their lineups. The Big Three faced criticism for their lineups, which were seen to be irresponsible in light of rising fuel prices. North American consumers turned to smaller, cheaper, more fuel-efficient imported from Japan and Europe. However, many of the vehicles perceived to be foreign were actually "transplants," foreign cars manufactured or assembled in the United States, at lower cost than true imports.

Looking ahead, and beyond issues of straightforward capacity, car manufacturers face a number of challenges that will likely require significant restructuring to realign production capacity with changing patterns of demand, including coping with:

- Higher prices of automotive fuels driven by increasing demand for oil and policy interventions to reduce CO2 emissions. This will likely accelerate the trend towards smaller more fuel-efficient cars which command lower profit margins. Furthermore, the bulk of demand in the rapidly growing Chinese market is for smaller cars.

- A changing geographical pattern of demand. Most trend sales growth will be in the BRIC countries and other emerging markets while mature OECD markets will remain relatively stagnant.

- Ongoing globalisation, which will likely influence minimum efficient scale economies and the configuration of companies worldwide.

Alvin Toffler's Acceptance about the Society on the Millenniums Threshold and Its Determinant Factors

Haller Alina-Petronela
Romanian Academy, Iasi Branch
hallalina@yahoo.com

Abstract

In the present paper we analyse, from an epistemological standpoint, the phases of economic and social development in Alvin Toffler's perspective. In his works, he analyses economy and society at three distinct levels, which he calls "waves".

In Toffler's view, humankind passed through two such phases (waves) and presently it is prepared to enter the third one, the knowledge one.

The way from the first to the current (third) wave was long and difficult, marked by deep changes in all domains as well as at a mental level. From an agrarian society, whose primary objective was subsistence, characterizing the first wave, we have now reached the stage of a society where knowledge comes to the forefront, the third wave, after having transited the industrial one, which has characterized the second wave.

The risks associated to the second wave (the wave of industrialization) are certain causes of the shift of paradigm and of the more and more important emphasis on knowledge. If in the industrial society technology dominated both the economic and the social levels, in the knowledge society man will dominate technology and will have the control of the major directions of progress.

Key words: knowledge society, industrial society, development, growth, development waves

J.E.L. classification: A14, B29, O11

1. Introduction

From its early beginnings to now, humankind has covered, in its evolution, a long way and has suffered significant physical and mental modifications, which,

altogether, represented the basis of the current progress and the platform of the future one. There have been several crucial moments in history: the agrarian revolution, the industrial revolution and the revolution of knowledge. All of these propelled the humanity on higher steps of economic and social development.

In his works, Alvin Toffler analysed this evolution and anticipated the future one. From his point of view, we are now standing on a third evolution level, which he calls the third wave (in the present paper, we will use the terms wave, civilization and society to describe the stages that humankind has covered from its early beginning up to now with a similar meaning).. Each of these three waves has its own characteristics. From the primitive, mainly agrarian society, we passed to the industrial period, dominated by technology and are now in the third wave, dominated by knowledge. Toffler thinks that at the end of the 20th century, the first wave, characterizing the agrarian society, abated, while the second wave, of the industrial society, which revolutionised everybody's life, keeps on going, still powerful (there are underdeveloped and developing countries who still fight to develop their agriculture and industry, and which are separated from the developed countries by huge gaps of development and economic and social growth.); meanwhile, a third wave, more important than the previous ones, set out. Many countries simultaneously feel the impact of two or even three completely different waves of change, moving along with different speeds and pushed by different degrees of force [Toffler Alvin, 1983, p. 49]. Each new type of society emerges at the moment when, in their dynamics, the waves of history cohere and whole civilizations collide [Toffler Alvin, 1995, p. 31].

Each wave or stage that the society covered involved, in Toffler's view, a redefinition of God, of justice, of love, of power, of beauty; it roused new ideas, attitudes and analogies; it undermined and replaced old opinions about time, space, matter and causality, the conception about the world.

We will present here the three waves of social evolution from Alvin Toffler's perspective and through his eyes, from the first social forms to that kind of civilization where knowledge rules.

2. The Society in the second half of the twentieth century or *the second wave society*

In Alvin Toffler's acceptance the society has developed in stages or „waves”, from the agrarian waves to present. The agrarian society has developed from the beginnings to the daylight of industrialization. The second half of the twentieth century is named by Toffler „the industrial wave” and the beginning of the third millennium brings new challenges and opens the prospects for a new type of society.

Over the decades, agriculture beat a retreat, while industry, under the form of manufacturing, at the beginning, progressed. The first sector withdrew, while the second moved forward. Although there is no exact delimitation, Toffler considers that the moment of passage from the agrarian to the industrial society is the year 1712, when the steam engine appeared. The emergence and utilization of electrical power allowed for a huge step to be made forward at all levels: the economic, the social and the cultural one. The population was somehow forced to leave its lands in order to provide labour to the more and more numerous manufactures. The passage from the agrarian to the industrial society was a conflicting one: strikes, uprisings, insurrections. Yet, the industrial society was quickly enrooted. Over the second wave, the wave of the industrial society, the distinctive sign was the sign of technique and industry.

The first wave of change, due to the agrarian revolution, was not depleted when the first industrial revolution started, in Europe (17th century), and grounded the

industrial society. The industrialization generalized fast. According to Toffler, two waves of change occurred concomitantly, separately and with different speeds. One with a lower speed, the other with higher speed. The emergence of the railways and of streets opened the access to the inside of communities and states.

The industrial society was auspicious to investments and to the great corporations, and people adapted themselves to that. The family became, according to Toffler, nuclear, that is limited (mother, father and three children at the most), and people are now attending, in their big majority, factory-like schools, where the focus is placed on punctuality, submission, repetitive (mechanical) work. The mass education system makes nothing else but prepares the labour for the great corporations. Children go to school earlier and earlier, and the schooling gets longer and longer. Each phase in a human's life is dominated by a key-institution.

The social and economic evolution that took place in the industrial society allowed the existence of some intercorrelated dimensions: the technosphere, which produced and distributed wealth, the sociosphere, which created the specific social networks, and the infosphere, which provided and allowed the spreading of information, so that the whole system should work properly. The technosphere, the sociosphere and the infosphere represent the architectonics of the industrial society.

If the civilization of the first wave predominantly lived outside the market, the civilization of the second wave obtains necessities by exchanges, this being dependent on the market.

A characteristic feature of the second wave economy is standardization. The standardization process has initially manifested itself as far as products were concerned, but subsequently it concerned methods, procedures, labour, education, money, prices and life. The “bon à tout faire” man was replaced by the narrowly specialized employee, very good in his own field and able to carry on repetitive activities.

Centralization is another characteristic of the industrialized society. The decentralized economy of the first wave needed, in time, centralization, as the mass production had to

be sold on larger and larger markets, and the international exchanges need rigorous organization and not isolation. The national markets became components of the global market. Cultures that had lived, for thousands of years, independently from the economic point of view, producing their necessary food, were absorbed, whether they wanted it or not, into the world commercial system and obliged to participate in the trade or disappear [Toffler Alvin, 1983, p. 138]. The population's standard of life became dependent on the economies of other countries, very remote ones from a geographical point of view, lying on different continents.

The mass production, mass consumption, mass education, mass media, they all gave birth to the industrial society.

The industrial society, due to the progress it registered, created hope for the diminishing of poverty, of hunger, of diseases, for peace, for a better life expectancy and a higher standard of life.

In the euphoria of progress and of gains, within the industrial society, decisions were made whose medium and long run consequences were neglected. The idea that nature was meant to be exploited offered a welcome rational explanation for myopia and egoism [Toffler Alvin, 1983, p. 145], especially that the idea that history irreversibly goes on towards a better life and a higher standard of life for the whole humanity was a dominant idea. Reality however opposes this idea: "never before has a civilization created the necessary means to literally destroy a whole planet, not a city. Never before has been threatened with poisoning whole oceans, have species disappeared from the earth because of the people's greed and inattention..., and has the thermal pollution threatened the planet's climate" [Toffler Alvin, 1983, p. 173].

At the moment when a major part of the population understood the situation that the planet reached because of the overexploitation, as well as the risks that humanity is exposed to, the intensity of the second wave started to diminish and make place to the third wave, dominated by knowledge.

Many would think, starting from a natural logic and from the technological dynamism, that the industrial society will be

followed by a supraindustrial one, but, to everyone's stupefaction, the third wave has another dominant characteristic, namely knowledge, by which humanity will be able to make a "quantum leap forward". Knowledge, which has undergone some impressive dynamics all over the industrial society, unbalanced, by its outcomes, the natural man-environment equilibrium, which now it has to recover, during the third wave, that of the knowledge society.

The industrial society or civilization, a product of the second wave of major changes, approximately spans the period 1650-1950. Over two centuries (1750-1950) it dominated the planet, but at the end of the 20th century, the development of communications (computers, aircrafts, robotics, space conquest, etc.) it has left room enough for a new type of civilization and society, that is for a third wave.

3. The Society at the beginning of the third millennium or the *third wave society* (the *knowledge society*)

The knowledge society (or the third wave) has its epicentre in the USA of the 1955s, being started by some innovations and revolutionary actions.

Land, labour and capital represented the main factors of production in the industrial society. Knowledge (information, images, symbols, culture, ideologies and values) represents the primary factor of production in the knowledge society, becoming the main modality to obtain wealth.

The society of knowledge brings forth changes in what family, economy, the way of living, of working, of loving are concerned and, above all, it brings forth a modified consciousness.

Toffler, anticipating, characterized the third wave as a totally new civilization that we are building and which will lead, sooner or later, to social upheavals and restructuring, ampler than ever.

The knowledge society is called by Toffler a society of prosumption, as it is a very technical and at the same time anti-industrial society, founded on sources of diversified recoverable energy, on modern methods of production and on corporations that are totally different from the current ones, on new behaviours, on the elimination

of standardization, so that a suture will occur between producer and consumer.

The role of technologies in the knowledge society has changed. They should create labour opportunities, avoid environment pollution and degradation, produce especially for the personal or local benefit and less for the world one, avoid waste, allow each secondary product of one branch to become the raw material for another branch. The result of this will be the humanization of technical progress, a major characteristic feature of the knowledge society. In the third wave, attention will be rather focalized on humans and less on profit.

Changes will be radical due to the massive flux of information, which will be accessible to everyone, unlike the case of the traditional society, where changes were taking place slowly and information was received from few sources. The knowledge society opens a new era of the demassified media. Knowledge will collapse those who will not be able to or will refuse to assimilate it, but will make competent those who will capitalize it; it will strengthen personality, it will change manners of acting and living. The man's intelligence, imagination and intuition will be much more important than machines in the immediately following decades [Toffler Alvin, 1983, p. 238].

Mass production will be replaced by the limited production, personified according to the clients' tastes. The third wave will comprise both an unpolluting technosphere, which will allow a rational consumption of raw materials and resources, and an infosphere that is based upon a big volume of information and a sociosphere centred on varied family structures, where the traditional family will lose ground, the number of individuals that are not involved in some couple relation will increase and the family centred on adults – that is without or with no more than two children – will dominate. Family, in the knowledge society will be built, according to Toffler, on feelings, on human qualities, and not on financial situation and intellectual power [Toffler Alvin, 1983, p. 276].

Family is not the only one that gets divided and diversified; information too, as well as production and market. The last one is divided into minimarkets, which grow more and more numerous, and are

continually changing. In this type of market will work demassified corporations, responsible for both the production they make and for the effects of their activities on environment and consumers.

The knowledge society, it seems, will be, as far as its development shows us, similar with the agrarian society in many respects, such as: decentralized production, recoverable energetic sources, deurbanization, work from home, high level of prosumption. A careful analysis shows that knowledge society has more similitude with the agrarian society than with the industrial one.

Knowledge, the dominant characteristic of the current stage, offers new possibilities to the poor countries and populations, provided that research and new technologies should be oriented in their direction.

Knowledge again will change trajectory in the education field. The educational system specific to the industrial society is blamed everywhere. In both the rich and the poor countries (that have lately borrowed the educational models from the industrialized countries, which turned out to be ineffective) the re-examination of conceptions and concepts about education is required. First of all, because in the knowledge society the main, inexhaustible and continually dynamical resource is information. The people who will assimilate it in a responsible thorough manner will be productive and effective, while those who will do it in a superficial way will be the laggards of the new system.

Therefore, the world is made of three sectors: the sector of the first wave provides the agrarian and mineral resources, the sector of the second wave provides cheap labour and achieves the mass production, while the sector of the third wave, continually expanding, goes up on the dominant position, basing upon new ways of creating and exploiting knowledge (Toffler Alvin, 1995, p. 36).

If the agrarian society spans thousands of years and the industrial only 300 hundred years, the knowledge one, says Toffler, will pass through history and reach its completion point in a few decades, in order to make room for the society of consciousness, anticipated by Mihai Drăgănescu

[Drăgănescu Mihai, pp.1-2], probably the society of the fourth wave.

4. Conclusions

The deepest economic and strategic society of all times is, as Toffler says in *War and Anti-War. Survival at the Dawn of the 21st Century*, the imminent division of the world into three different civilizations potentially colliding: one attached to the land, a product of the agrarian society, one originating in the first scientific discoveries, attached to techniques and technology, and one obviously attached to knowledge.

The knowledge society will gradually impose new archetypes. Technique will not be the one that establishes the objectives any more, but the people who use knowledge in order to stop the process of irreversible deterioration of the environment.

The knowledge society does not involve the emergence of a completely new economy and society, but it will merge the characteristic features of the agrarian and industrial societies, that is the characteristics of three contrasting societies: one symbolized by the plough, one by the assembly line and one by the computer.

Currently, humanity faces a turning point, that Toffler regards as a "quantum leap" towards a totally different civilisation. The changes of the third wave will be deep and will eventually open the way to a consciousness society, as *Mihai Drăgănescu* calls it in his book "Culture and the knowledge society", a much subtler and maybe anti-economic one.

Main Determinants of Living Standard in Modern Society

Haller Alina-Petronela
Romanian Academy, Iasi Branch
hallalina@yahoo.com

Abstract

In this paper we want to present, in a succinct and in a theoretically way, the possible relation between economic liberalization, human development and standard of living in the present society based, more than ever, on knowledge.

It is known that economic liberalization is one of the phenomenon that manifest themselves in increasingly active manner in recent decades so, nobody can denies its benefits especially on human development - economic and social main objective of all states, regional and global formations.

Actually, the progress in human development translates into improved population standard of living. A better life, a decent standard of living for the greater share of people is the real proof of the effectiveness of economic and social processes including liberalization, economic growth and development and the motivation for future efforts to be made in this direction.

Our theoretical approach will be made on the basis of some specific indicators characteristic to the analyzed processes, indicators compiled and made available by various international organizations in the field. These statistical figures will enable a comparison between the situation of some representative countries, including Romania.

Key words: living standard, modern society, knowledge society, development, growth, liberalization.

J.E.L. classification: I10, I30, J17, N10, N30, O11

1. Introduction

The dominant feature of the current economic system is, undoubtedly, globalization. The process was caused and maintained by the economic liberalization, whose actions have gradually grown more dynamic. The very multiple advantages of liberalization led many of the countries to render this process a purpose in itself, starting from the premise that a high degree of liberalization opens the way to progress, human development and implicitly to a better standard of living.

The socio-economic evolution has been, since the beginnings, sinuous but ascendant, on the whole. Yet, poverty could not be eradicated. In the third millennium, dominated by information and knowledge, the low standard of living remains one of the greatest problems of the whole humanity.

Ensuring a high standard of living for as many people as possible is one of the major objectives to reach at the world level. In the **United Nations**, a series of objectives were established, known as the *Millennium Goals*, which aim at eradicating or diminishing failings of the global economy and society and which are to be fulfilled by 2015. The targets that the **United Nations** established can only be achieved through the correlated efforts of all the world states, of both the developed and the developing ones.

The approaching of the year 2015, a year to take stock, when we will see to what extent the Millennium Goals were achieved, urges us to analyse in the present paper the concept of standard of living in the light of economic liberalization and of human development, Romania's case included.

2. Liberalization - Human Development - Standard of Life Relation

Liberalization can be defined as a process by which bi- or multilateral framework measures are taken, meant to eliminate or reduce the barriers to free circulation of goods, investments, capitals and persons.

The beneficent outcomes of liberalization do not represent conclusions of theoretical analyses, but of realities proved in different countries and regions, so that the idea of economic opening was accepted at an increasingly wider scale, including in autarchic states like China.

We cannot deny that in a knowledge-based period, like the one our society is now going through, when everything converges from and towards knowledge, the economic liberalization causes the acceleration of technical renewal, and productivity grows faster than production on the whole.

The importance of the process of economic liberalization resulted, among others, from the fact that it supposed the emergence of:

- new markets, connected at the global level, continuously operating due to new technologies, especially the informational and communicational ones;
- new activities, as part of international organizations like WTO (World Trade Organization) or UN (United Nations), with acknowledged authority upon the national states and the transnational societies, many of them endowed with an economic power sometimes bigger than that of numerous developing countries;
- new rules, that is multilateral agreement concerning both the economic and the social sphere, sometimes more powerful than many local policies.

The benefits of liberalization are obvious; from among them, we mention:

- a better distribution of resources;
- higher rates of productivity and profitability;
- an always faster propagation of innovations and of the results of scientific research;
- easier access to production and sale markets;

- advantages for the local consumers by buying at low prices from third markets and capitalizing the surplus internal production on foreign markets;
- the possibility to extend production and therefore to get advantages from the economies of scale;
- the creation of employment opportunities and resorption of unemployment;
- the augmentation of national and individual incomes and of the GDP;
- the making up of the balance of trade and of payments;
- the strengthening of the competitive force of the national organizations and the stabilization of prices;
- opportunities for the economic and human development.

The last objective is also the one that defines the importance of the process, the effects upon the population, as a result of the contribution to the economic and human development, so the relationship economic liberalization-development becomes one of conditionality.

The final objective of any action is *human development*, a process that generates economic, social, quantitative and, particularly qualitative changes, which causes the national economy to cumulatively and durably raise its real global product and to offer population a higher standard of living [Haller A.P., 2008, p. 7].

Leszek Balcerowicz defines *development* as a process that involves quantitative, qualitative and structural changes, with a positive impact on economy and on the population's standard of living, and which follows a continuously rising trajectory [Balcerowicz L., 2001, p.23].

The efforts of development are made at the level of each country apart, as well as at the world level. In the *General Assembly of the United Nations* in September 2000, known as the *Millennium Summit*, was analysed the condition of human development in the diversity of its aspects and was adopted a set of eight goals with their stages and deadlines. Aspects of alarming intensity and seriousness were found in some countries and areas of the world.

The Millennium Development Goals are: end poverty and hunger, universal education,

gender equality, child health, maternal health, combat HIV/AIDS, environmental sustainability, global partnership. Achieving so bold objectives involves, as we have already mentioned, economic and social cooperation between states, and the easiest form is liberalization.

Human development, a both qualitative and quantitative phenomenon, is very hard to assess. Yet, since the 1990s, *The Human Development Index – HDI* started to be calculated under *Amartya Sen's* careful supervision, a 1998 Nobel laureate in economics. This index offers the total image of the way in which people live, being calculated on the basis of three indices: life expectancy at birth; the population's education, calculated, in its turn, on the basis of two other indices (schooling and degree of literacy); the standard of living indicated by the level of incomes and of the GDP per capita at purchasing power parity.

As already mentioned, the improvement of the quality of life is the final wish for each action and decision. The standard of living depends on multiple factors, some of them with a direct action, other with indirect action. We therefore speak about: the rising of the life expectancy, the protection of the environment, access to drinking water, access to health assistance, access to education, increasing of incomes per capita, especially in the developing and underdeveloped countries of the world. In spite of the progress humanity makes now, in a period characterized by knowledge and by the interdependence between states, poverty is still one of the humanity's great problems, including the states with a very high human development.

The improvement of the standard of living involves efforts in all directions for the Millennium goals to be achieved. Although, according to *The United Nation Human Development Report 2008*, almost one billion people on the planet do not have access to drinking water, about 2.4 billions do not have access to health assistance, 11 millions children aged under 5 die annually (equalling over 30,000 deceases a day), about 1.2 billions people live with less than one dollar a day, and 2.8 billions live with less than 2 dollars a day, there are some encouraging tendencies: a child born in 2002 might live about eight years more than a

child born in 1970; the percentage of families in the rural environment having access to drinking water is over 5 times higher than in the 1970s.

The outcomes of the fact that the standard of living, over time, rises are to be recognized in the rising of the average life span. If during the Upper Palaeolithic the average life span was 23.66 years, in Antiquity about 20-30 years, in 2008 it reached the level of 70 years, an aspect that proves that real progress has been registered from the point of view of the standard of living.

Table 1
Average Life Expectancy Over Time

Period	Average Life Expectancy
<i>Superior Paleolithic</i>	33
<i>Neolithic</i>	20
<i>Bronze Age</i>	18
<i>Ancient Greece</i>	20-30
<i>Ancient Rome</i>	20-30
<i>Middle Ages</i>	20-30
<i>Beginning of the XX Century</i>	30-40
<i>Beginning of the XXI Century</i>	70

3. The evolution of the life span in Romania – a consequence of the improvement of the standard of life

Romania is the EU member state with one of the lowest life expectancies and standards of living. Although it is part of the second group of human development, that of the countries with high human development, the standard of living in Romania is still a low one.

From the point of view of the life span, Romania has a low life expectancy comparing to most of the member states. In women's case, the life expectancy is 75, and men's one is 68.2.

The major causes of the low life expectancy in Romania are:

- deficient health system;
- precarious hygiene, particularly in the rural environment;
- inadequate, calorically poor food;
- daily stress.

All causes are related to a low level of the people's standard of living and to the incapacity of the health system to fund treatment, especially in the case of the chronic diseases. For instance, Romania is on the first position in the heart disease death statistics, on the sixth place in the lung disease death statistics and on the third position in the high blood pressure death statistics, on the fourth position in the liver disease death statistics, on the eighth position in the colon cancer death statistics, on the ninth position in the stomach cancer death statistics, on the eleventh position in the breast cancer death statistics, on the twelfth position in the suicidal death statistics, on the thirteenth position in the road accident death statistics, on the seventeenth position in the diabetes death statistics, on the forty-seventh position in the birth traumatism death statistics. Of the 86 death causing diseases taken into consideration in order to make up the world statistics, Romania is placed, as showed above, on top positions as a result of the analyses of mortality at a world level, for 189 of the world states. We have to mention that the data are taken from the site <http://worldlifeexpectancy.com>, where different specific indices are offered to illustrate life expectancy and death causes at the world level and at the level of each country apart.

The standard of living and implicitly the life expectancy are influenced by numerous factors that we will refer to along our paper. Yet, we have to consider that, as *Amartya Sen* said, the standard of living and the life span depend, among other things, on the nature of life as well, and people understand life differently, according to education, culture and personal experiences. [Sen A., 1985, p.33].

From the point of view of the life span, Romania is on the eighty-seventh position among the 189 states for which estimations are made, starting from a wide range of economic indices. In the table below we present Romania's situation from the standpoint of the life expectancy comparing to other states, without displaying all the indices involved in the estimations of the life expectancy.

Table 2
Representative indicators for the calculation of life expectancy - 2008 -

	Romania	Bulgaria	China	Germany	Japan	USA	Norway
Population:	221.9421	7.204687	13.38612068	8.2320738	12.7078679	307.212123	4.660359
0-14 (%)	15.5	15.8	19.8	13.7	13.5	20.2	18.5
15-64 (%)	69.7	68.5	72.1	66.1	64.5	67.0	66.2
65+ (%)	14.7	17.7	8.1	20.3	22.2	12.8	15.2
Birth Rate %	10.53	9.51	14.0	8.18	7.64	13.82	10.99
Mortality Rate %	11.88	14.31	7.06	10.90	9.54	8.38	9.29
Infant Mortality Rate %	22.90	17.87	20.25	3.99	2.79	6.26	3.58
Population Growth Rate %	-0.15	-0.79	0.66	-0.05	-0.19	0.98	0.34
Literacy rate %	97.3	98.2	90.9	99.0	99.0	99	100
GDP per capita / USA dollars.	12.200	12.900	6000	34.800	34.200	47.000	55.200

Source: <http://worldlifeexpectancy.com>

The country with the highest rate of young population is USA (20.2%), while Japan is the country with the highest rate of aged population (22.2%). The highest birth rate is in USA (13.85%), which also registers the lowest death rate, with a positive rate of natural increase. In the case of this country one can notice that it registers a level of literacy of 100%, with no illiterate individual, with the highest level of GDP per capita and an infantile death rate of 3.58%.

Romania is the country with the highest infantile mortality rate of the seven states analysed (22.9%), with a negative rate of natural increase and demographic decrease. Out of the total population, 2.7% is illiterate, and the rate of GDP per capita, of \$12,200, places Romania, according to table 3, on the sixty-ninth position in the world.

Table 3

From the point of view of the life expectancy, Romania is on the eighty-seventh position in the world statistics. The country with the highest life expectancy is Japan, while Norway is on the fourteenth place, Germany on the twenty-first, USA on the thirtieth, and China on the seventy-eighth. Bulgaria, although it has a high rate of aged population (17.7%) and a negative rate of natural increase, has a GDP per capita of

\$12,900, coming on the eighty-third position from the point of view of life expectancy, higher than Romania.

From the *HDI (Human Development Index)* perspective, the seven states that were analysed come from three different groups: Norway, Japan, USA, Germany are states with very high degree of human development, Bulgaria and Romania are states with high degree of human development, China is a country with average human development.

Source: Klugman J. et. al., *Human Development Report 2009*, 171-174

Note: the statistics are slightly different depending on their source

Human development is a continuously rising and very slow process. The economic growth, its major determinant, cannot be totally recovered in development. A country can register very high rates of economic growth and not make progress in development, just like it can register negative rates of economic growth and not decline from the point of view of development, due to the exclusively quantitative contribution of the process of economic growth. Only when the quantitative growth is accompanied by the qualitative one, we obtain a progress of HDI.

From table 4, we understand that life expectancy is correlated with human development. The population of the countries from the group with very high human development live, on the average, more than the population of the countries that are part of the groups with lower human development. For instance, a Norwegian lives on the average 80.5 years, a Japanese 82.7 years, while a Romanian's life expectancy is 72.5 years, 6 months less than a Bulgarian and four months less than a Chinese. The access to education, to health assistance, to drinking

water and the rise of the population's income are necessary conditions for the increasing of the life expectancy and of the standard of living.

A general tendency towards life expectancy rising is accompanied by that of HDI rising, as we can see in table 5.

Table 5

- 1980-2007 -*

	Life Expectancy at Birth (years)	Adult Literacy Rate (% aged 15 and above)	Combined Gross Enrollment Ratio in Education (%)	GDP per capita (PPP US Dollars)	Life Expectancy Index	Education Index
Norway	80,5	-	98,6	53 433	0,925	0,989
Japan	82,7	-	98,6	33 632	0,961	0,949
USA	79,1	-	92,4	45 592	0,902	0,968
Germany	79,8	-	88,1	34 401	0,913	0,954
Bulgaria	73,1	98,3	82,4	11 222	0,802	0,930
Romania	72,5	97,6	79,2	12 369	0,792	0,913
China	72,9	93,3	68,7	5 383	0,799	0,851

Source: Klugman J. et. al., *Human Development Report 2009*, 167-168

Romania has a HDI of 0.837, calculated on the basis of the indices corresponding to the year 2007, which includes it in the second group, that of the countries with high human development and on the sixty-third position in the world, lower than Bulgaria, which occupies the sixty-first position. Romania has in 2007 a HDI that is smaller than Germany's one in 1980. The economic crisis characterizing the current period will modify the HDI in a negative direction in the case of some countries, among which we will probably find Romania too. The decrease of the population's incomes and the increase of the poverty will contribute to the decrease of HDI. This tendency will be more obvious in the case of the developing countries, much more vulnerable in front of the socio-economic upheavals.

Table 6

*Life Expectancy Trends (years)
- 1980-2008 -*

China	66,0	68,1	69,6	72,6	73,1

Source: <http://data.worldbank.org>

The data the *World Bank* provided with regard to the life expectancy show that in 2008, a Romanian lived, on the average, 73.4 years, one month more than a Bulgarian and

three months more than a Chinese. Comparing to the statistics for 2007, registered by *Human Development Report* (table 4), one can notice an improvement in the life expectancy of the seven analysed states, both the developed and the developing ones, on the background of the sustained economic growth and of the improvement of the standard of living. As we have already mentioned, the economic crisis will probably change the general image starting with 2009, when its outcomes will become visible in the case of all of the world states.

Life expectancy is an index that characterizes the level of economic and social development of a country. At the beginning of the last century, in Romania the life expectancy was only 36.4 years, reflecting a very high level of the mortality rate [Ghețău V., 1978, pp. 142-152]. In the first decades of the 20th century, the life expectancy increased with 5.6 years, that is less than 0.2 per year, half of the rise registered by the other European states in the same period [Ghețău V., 1978, 143]. After World War II, modifications appeared: the rising of the standard of living, the population's access to health assistance, a rise of the educational level of the population, so that in 1961, the life average expectancy reached 66 years, and in 1975 – 69 years, about 5 years under the level of the developed countries. In the period 1900-1975, in Romania, the life expectancy rose with 33 years, so that in 2008 it reached the average of 73.4 years; a real progress, which however remained under the level of the countries with high human development.

4. Conclusions

Between economic liberalization, human development and standard of living there is an obvious relationship of interconditionality. Liberalization leads to economic growth and human development, and the latter allows the improvement of the standard of living, that is of the life quality and average span.

Over time, at the level of the whole humanity, obvious progress was registered; the evolution of the indices of human development and of life expectancy proves it. But one can notice that life expectancy is higher in the states that are included in the category with very high human development.

The life span depends on the standard of living, that is on how well people live, on incomes, on the access to health assistance, to decent conditions of life, but also on the degree of culture and education. The rise of income alone can influence the standard of living, but if the other factors that influence it stay unchanged, it cannot guarantee a better or a longer life. The essentials for a decent standard of life includes a home, access to health and education assistance, access to food, entertainment and safety products. Unfortunately, a high rate of the world population does not enjoy a minimal standard of living. At the beginning of the third millennium, in a period when development firstly relies upon knowledge, but which is also affected by an important economic crisis, poverty – quite significant in some regions – urges the world states to try, together, to fight it, acting first of all on the complex of factors that determine the economic and human development, among which liberalization as well, so that the great majority of the people could enjoy a higher and higher standard of living and life span.

Community Budget Financial Instrument of EU

Haralambie George Alin
Petroleum-Gas University of Ploiesti
haralambiegeorgealin@yahoo.com

Abstract

The general budget of the European Union is the instrument which set out and authorises the total amount of revenue and expenditures deemed necessary for the European Union and European Atomic Energy Community for each year. According to this can be observed every year EU policy priorities and guidelines. Its evolution over time reflects the successive transformations of European construction.

EU budget differs fundamentally from national budgets of EU Member because, first of all, public institutions are in the responsibility of Member States and are funded from national budgets, and on the other hand, costs of government institutions (European Commission, Parliament, Council, Court of Justice) are reduced..

Key words: Community budget, Community funds, own resources, gross national income, EU expenditures.

J.E.L classification F36, G18, H27, H61

1. Introduction

The budget is an important component of finance contributing to the economic policy objectives in accordance with the directions set by government policy for each individual year. By budget ensure the achievement of balance between collective needs and the means with which to cover.

Financial Regulation of the European Community defined budget as the act that provides and authorizes in advance each year, expenditure and income communities.

From the legal point of view, budget structure focuses all public revenues and expenditures for a strictly limited period of time, usually during this period no more than one calendar year.

From an economic perspective, budget reflected those macroeconomic correlations determined by evolution and level of gross national income.

The budget are developed public financial resources who take the form of a financial plan, the structure of which includes income and expenditure relating to a period of time to fulfill certain tasks and objectives set by public entities subject to that budget.

The Community budget results from a long process of harmonizing the interests of Member States.

2. General considerations on the Community budget

Functioning of the European Union requires a series of own financial resources provided by the member states necessary for the purpose for which it was created and its objectives. They are set in a legal framework by a decision of the Union Council of Ministers, ratified by the legislative authorities of each Member State.

Established by the Treaty of Rome (Treaty of the European Economic Community space-EEC, 1957) which clearly affirmed the principle of financial solidarity, Community budget was originally be decreased in size, its main expenditure is for the common agricultural policy (CAP). Funding of this budget is figured, at the beginnings of European construction, from two own resources: drawings (taxes) on imports of agricultural products from the outside community and customs duties (taxes) on imports of products manufactured outside the Community space, and the amounts obtained were sufficient to meet the necessities of common funding.

In the late 70-ies the first disagreement between EEC members have appeared, regarding the distribution of the common budget, caused by three factors: 1) the liberalization of the international trade under

GATT, which led to the reduction of customs duties; 2) the emergence of surplus in European agricultural production and, default, reduction of imports of agricultural products, therefore reduction in the drawings to the Community budget; 3) the first enlargement of the EEC, with the accession of Denmark, Ireland and Great Britain the last one having then a modest agriculture but being a major importer of agricultural products from the Commonwealth's (mainly in Australia and New Zealand) which figured that from tax and drawings British agricultural imports were higher than those of other European partners, but without the United Kingdom enjoy the same level of allowance from the Community budget.

In order to supplement the resources attracted, in the same period were created two other sources of European financing: drawings from the VAT and input of the national GDP of each Member State (GDP).

In recent years, calculating the national contributions to the EU budget is reported to GNI (gross national income).

The maximum ceiling of the total resources of the European budget was established in 1988 ("Delors Package I"), to limit its rise, being set at 1.27% of GDP, which corresponds to a 1.25% of GNI.

The financial reforms initiated by J. Delors were: method of determining the total ceiling of own resources, for all categories, as a percentage of EU GNI and not by the VAT, as before;

Since 1998, the Union's annual budget is determined in accordance with a medium term financial plan, which defines the limits of the annual EU spending.

3. The principles underlying the Community budget

European Community budget respects the general rules applicable in Member States, aimed at ensuring transparency in the revenue and expenditure decisions and clarity in the monitoring and control of budget implementation for the protection of EU financial interests.

The application of the budget law and the procedure of development, approval, execution and completion of the Community budget is generated by certain principles, enshrined in the Financial Regulation of the

European community. The budget is established and implemented in compliance with the principles of unity, budgetary accuracy, annuality, equilibrium, unit of account, universality, specification, sound financial management and transparency. The budget approved by the EC has also provided a separate chapter on advertising in the Official Journal of the EU budget.

a) The principle of annuality. Assume budgetary operations to be carried out during the budget year that lies between 1 January and 31 December. The income who must be earned in the current financial year and have not been charged in that year's revenue to the budget next year. Exceptions may exist. For example, if the legal basis for certain expenses has been adopted towards the end of the year and expense could not be committed and payments made by the end of the current financial year it is possible to approve the transfer of such expenditure in the budget for next year. Note that, several EU projects and actions is carried out over more than one calendar year. EU use on medium-term, the instrument "financial perspectiv".

In order to connect the multi-year projects and activities to the budget, which refers to a particular financial year, in EU practice are used two concepts about spending: "limit the employment of expenditure" and "limit payments."

The first represent the size of all obligations arising from a project with a performance period greater than one year, which is being developed for the financial year budget.

Payment limit is the amount budgeted for the project.

b) The principle of unity and the principle of budgetary accuracy requires that all EU budget revenue and expenditure to be contained in one document. From these principles are mentioned two exceptions:

- financial arrangements for certain activities in common foreign policy and security. In these cases, certain revenue (aid, grants etc.) are used directly for such activities without being included in the budget;

- european agencies (EU decentralized bodies) have their own budgets that are supplied with transfers from the EU budget.

Like annuality principle, in contemporary literature of public finances is assessed that the principle of budgetary unity is based on two types of incentives some financial and other policy.

c) The principle of universality of the budget. In practice two rules are complied with EU budget:

(1) not affecting revenues, ie once that is paid to the EU budget, these revenues depersonalizes being used in their entirety to fund all costs;

(2) unwrought budget presentation, that the inclusion of revenue and expenditure in gross amounts, without any gaps.

In applying this principle, there are exceptions. Certain revenues are directly affected funding for research programs, and some countries make donations specifically to fund specific policies, such as humanitarian aid.

d) The principle of budgetary balance. In the EU, revenues are equal to or greater costs, the EU is not allowed to borrow to finance expenditure under the EU budget. Therefore the normal situation for implementation of the budget is the surplus of income over expenditure, which is required in the budget over the next year.

As such, in the EU budget it is not reflected the lending operations of the European Community or EU institutions are authorized by the treaty to make them (for example, loans granted to individual Member States and candidate countries to support the balance of payments).

This feature in applying the principle of budgetary balance in the case of EU is the most important difference from the budgets of the Member States where deficits are common.

e) The principle of budgetary specification requires the inclusion of revenues in the EU budget by categories established by origin, in relation to the specific sources and of expenditure by purpose, according to budget classification. In this purport confusion are eliminated in the budget decision and its execution. Budget classification used by the EU includes sections, titles, chapters and paragraphs.

f) In accordance with the principles of unit of account, the budget is drawn up and implemented in euros and the accounts shall be presented in euros.

g) The principle of sound financial management is defined by reference to the principles of economy, efficiency and effectiveness.

4. Community institutions responsible with the budget process at EU level

By its nature, EU is a community based on solidarity among its members. Its founding treaty commit themselves to strengthen the unity of their economies and ensure their harmonious development by reducing disparities between various regions and the backwardness of the less favored regions. Redistribution is such a clearly defined objective.

In principle, the Council and Parliament decide, together, each year, the European budget.

To avoid budget crisis similar to the years 1988, 1993 and 1999, the Council and Parliament works henceforth, starting from the Commission proposal in a multiannual financial framework (MFF), who is bearing the name of "financial perspective".

This framework, covering several budget years, sets a total budget and a ceiling for expenditure in each area.

Therefore, each annual budget must comply with the limits in the financial perspective.

However, the agreement has left a margin of flexibility for unexpected situations—mainly in the financing of foreign policy. European Commission as the EU's executive, is responsible for implementing a large part of the budget, and with drafting a budget proposal each year. Under the Treaty of Lisbon, long-term EU budget plan is mandatory. Financial perspective is necessary for the adoption of European Parliament approval. Under the Treaty of Lisbon, the European Parliament has equal powers with the Council in determining the EU budget. In addition, the Lisbon Treaty simplifies the budgetary procedure and enter binding financial perspective.

Under the Treaty of Lisbon, Parliament decide, together with the Council on all expenditure. In 2011 was canceled difference between the "Mandatory" expenditure (agriculture and international agreements) and "soft expenditure." The decision procedure in two readings was replaced by a

single reading (in Parliament and the Council).

The European Commission is responsible for implementation of the budget throughout the budget year. Funds must be spent during the year for which they were intended. In certain circumstances, they may be delayed next year.

The Commission may make proposals for amending budget, amendments enter into force when they are adopted by the President of European Parliament.

The Commission is politically responsible for budget implementation, but over 80% of funds are managed, in fact, at national level, this presenting to the Council and Parliament the report on budget execution, with the accounts for the previous financial year.

Parliament is the only institution that can grant or deny a discharge for the implementation of the Community budget on the annual report published by the Court of Auditors and the Council recommendations.

While amending budgets are managed by the Committee on budgets, budgetary control Committee is pursuing implementation of the budget. Discharge procedure begins with the submission by the Court of Auditors of the annual report to members of the Committee on budgetary control. Commission seeks implementation of the budget by hearing the various commissioners charged with the policies which benefit from a significant budget. Budgetary Control Committee then prepares a discharge report to be voted in plenary.

Budgetary Control Committee organize, as a result of budget execution public, hearings with various European Commissioners who are responsible for specific policy areas that with significant budgetary implications.

5. Implementation of the Community budget

The budget presents appropriations and resources by purpose (activity-based budgeting) with a view to enhancing transparency in the management of the budget with references to the objectives of sound financial management and in particular efficiency and effectiveness.

The EU has its own system of income, EU budget covering four categories of income:

- traditional revenues;
- part of value added tax (VAT) in the Member States;
- share of gross national income (GNI) of the Member States;
- other income

Traditional own revenues are collected by Member States due to EU policies- Customs Union and Common Agricultural Policy (customs duties levied on imports, agricultural levies).

EU VAT revenue is part of value added tax levied by Member States, calculated by applying a percentage of base tax (for VAT).

Share of GNI of the Member States is a variable income which is established by the EU budget each year. This revenue is collected from Member States only if their other income (traditional revenues and income from VAT) are not sufficient to cover expenses. The magnitude of this income can not be greater than the difference between: the maximum of all the EU's own revenues, approved by the European Council, as a percentage of aggregate GDP of Member States, and other own revenues (traditional income and revenue from VAT).

The main income included in the group "other income" are: interest and penalties for late payment obligations to the EU budget; penalties paid by companies for breach of common rules (for example, in competition); taxes on salaries of employees of EU institutions; income from different administrative operations of the EU institutions; surpluses from previous financial years.

Budgetary revenue totals 126527133762 euro. The uniform rate of call for VAT resource is 0,30% (except for Austria, Germany, Netherlands and Sweden for which the rate of call has been fixed at 0,225%, 0,15% and 0,10% for the last two of them) whilst that for GNI resources is 0,7538%. Traditional own resources (customs duties and sugar levies) account for 13,26% of the financing of the budget for 2011. The VAT resource account for 10,90% and GNI resource for 74,72%. Other revenues for this financial year is estimated at 1421368232.

The expenditures authorized by the budget for 2011 totals 141909398849 euro in commitment appropriations and 126527133762 in payment appropriations, representing a growth rate of 0,25% and 2,90

5 respectively by comparison with the 2010 budget.

Budget spending are structured and arranged into six sections: European

Parliament-I, Council-II, Commission-III, Court of Justice-IV, Court of Auditors-V, The Economic and Social Committee and Committee of Regions-VI.

Operational appropriations managed by the European Commission have the following destinations:

1. agricultural financing under the EAGGF, guarantee section;

2. financing structural funds: European Regional Development Fund (ERDF), European Social Fund (ESF), EAGGF Guidance Section, the Cohesion Fund, Financial Instrument for Fisheries Guidance (FIFG);

3. cover the costs of education (Socrates), training (Leonardo), broadcasting (media program), culture, communication, social relations, public health;

4. to cover expenses allocated for energy ;

5. to cover expenses allocated to improve the functioning of the internal market;

6. funding research and technological development programs;

7. financing costs related to various economic and financial cooperation measures with third countries;

8. to cover expenses resulting from actions in foreign policy and security policy;

EU Structural Funds are managed by the European Commission and are intended to help finance structural measures at Community level, in order to promote the regions with delays in development, conversion of areas affected by industrial decline, tackling long term unemployment, employability of young people and promoting rural development.

The European Parliament approved the European Union budget for the period 2007-2013 to 864, 4 billion euro.

6. Romania's contribution to EU budget

Last year Romania was able to absorb only 800 million euros of EU funds. In total, in four years, in our country entered on this path only 2.18 billion euros, approximately 7% of the total allocations of our country since 2013.

On the other hand, Romania has paid to the EU budget 4.53 billion euro, equivalent to about 45% of the amount that Romania should contribute between 2007 and 2013.

In short, Romania's net contribution to EU budget was 2.35 billion euros. The amount is not insignificant if we think that is greater than the annual deficit to be covered by the pension budget.

For the period 2007-2013, for Romania has been allocated 19.67 billion euros, of which 19.21 billion euros for the Convergence objective, and 460 million euros for the European territorial cooperation objective, according to the Strategy Partnership with World Bank.

National Co-financing for these amounts is estimated to 5.53 billion euros, which raises the value of cohesion policy funding for seven years to 25.2 billion euros.

2011 is considered an important year for European economic recovery, and the Community budget is the basic instrument for this goal. The European Members tried to find a balance between the need for EU funding and the need for rebalancing actions through innovation and research, supporting poor regions and the presence of EU diplomacy in the world.

Total budget for Romania is set to 28-30 billion Euro, distributed on the following areas of interest:

-Agriculture and Rural Development-over 11 billion euro;

-Structural Instruments-over 17 billion euro (minimum co-financing -85% for ERDF for eligible expenditures and 80% for CF financing ineligible expenditures).

14 areas can attract and can be financed from EU structural and cohesion funds:

- Research and technological development;
- Informatization of society;
- Transport;
- Energy;
- Environmental protection and risk prevention;

- Tourism;
- Culture;
- Urban and rural regeneration;
- Support for companies and entrepreneurs;
- Access to stable employment;
- Social inclusion for disadvantaged people;
- Human capital development;
- Investment in social infrastructure, including health and education;
- Promoting partnership.

Financial perspectives for the period 2007-2013 is divided into five chapters:

1. sustainable Growth: this section includes structural funds, research and education, with a budget of 382 billion for seven years;

2. conservation and management of natural resources: it's about common agricultural policy and environmental policy, with a budget of 371 billion;

3. citizenship, freedom, security and justice: 10.7 billion euros are intended for activities related to justice and home affairs. This amount will cover programs that encourage European citizenship, town twinning and European dimension of media and culture;

4. European Union as a global actor: 49.5 billion euros will be allocated shares in favor of developing countries, promoting human rights, common foreign and security policy and support for the development of neighboring countries;

5. administration will receive 49.8 billion euros, or 5.75% of the total budget.

7. Conclusions

Tensions in the European Union related to budget projection 2013-2020 are at high rate and this one was shown by the previous budget negotiations for 2007-2013, when France and Great Britain, major beneficiaries of EU funding, duel in arguments, because neither wants to give up their own facilities.

Abstract

The purpose of the paper is to analyze foreign direct investment flows and international competitiveness in European Union countries. The result of the analyze shows that is a direct correlation between foreign direct investment flows (FDI flows quantify by UNCTAD) and international competitiveness (measured by World Economic Forum through global competitiveness index – GCI). In 2010 most of the European Union countries improved their score on international competitiveness even if the FDI flows has declined from a year earlier, including Romania.

Key words: FDI flows, international competitiveness, European Union countries, Romania

J.E.L. classification: F21, O10, O52

1. Introduction

The economic and financial crisis of nowadays have affected the FDI flows, booth FDI inflows and FDI outflows. In many countries, in 2009, the FDI flows have decreased considerably. Mach more, some economies have confronted with a lowest level of FDI flows from the last 10 years. Also, international competitiveness of economies has suffered in the last 2 years because the governments have concerned to face of to the domestic issues in order to reduce budget deficit, to obtain macroeconomic stability and economic growth.

2. FDI flows – brief description

FDI is an important vehicle for the transfer of technology, contributing relatively more to growth than domestic investment. However, the higher productivity of FDI holds only when the host country has a minimum threshold stock of human capital. Thus, FDI contributes to economic growth only when a sufficient absorptive capability of the advanced technologies is available in the host economy [1]. FDI is a form of international capital flows. It may play an important role in the general allocation of world capital across countries [2].

Many developing countries have been eager to attract foreign direct investment. This is hardly surprising given the potential benefits of FDI because they are not as volatile as other types of flows. FDI can boost technological and managerial transfer in order to increase competitiveness of a host country and economic growth [3].

In the literature are identifying a various types of FDI flows [4] like:

○ *Market-seeking FDI.* Small size severely limits investment in production destined for the local market. On the other hand, low competitive pressures in many industries can result in relatively high market shares for foreign or domestic investors, somewhat mitigating the impact of the small size of the market.

○ *Efficiency-seeking FDI.* This type of investment requires host countries to offer advantages such as low-cost production or specialized expertise, as well as low-cost trade, as the output of efficiency seeking investment is mainly sold to other MNEs affiliates or the parent firm.

○ *Resource-seeking FDI.* This type of investment is driven by the local availability of natural resources and low-cost labor.

○ *Strategic asset-seeking FDI*. This type of FDI is driven by access to created assets such as special skills and technology.

According to World Investment Report 2010 global FDI flows began to bottom out in the latter half of 2009. This was followed by a modest recovery in the first half of 2010, sparking some cautious optimism for FDI prospects in the short term. In the longer term, from 2011 to 2012, the recovery in FDI flows is set to gather momentum.

3. Defining international competitiveness

What a theory of international competitiveness must do is to establish the links between the growth and balance-of-payments position of an open economy and factors influencing this process [5]. But that was available in the 90.

Today the notion of competitiveness has become a prominent concept in the assessment of countries, regions and locations. The competitive advantage of nations and the competitiveness of locations have become important topics in economic policy [6].

According to Krugman the concept of competitiveness is "elusive or meaningless when applied to national economies; for economies with little international trade, competitiveness is a specifically maintained to be a funny way of saying productivity" [7]. Other author consider that international competitiveness is said to occur whenever the economic welfare of a nation is advanced through an increase in the flow of trade or through an alteration in the conditions of trade starting from a presumed initial equilibrium [8]. From Siggel (2006) point of view countries may compete for market share or for foreign investment, but the attribute of stability, good government and profitable investment opportunities, are better summarized as a favorable business climate than competitiveness [9].

European Commission in European Competitiveness Report emphasize the fact that competitiveness "is understood to mean high and rising standard of living in a nation with the lowest possible level of involuntary unemployment, on a sustainable basis" [10].

In the literature are a various institutions/organizations that defining and measure the international competitiveness such as: World Economic Forum [11], Institute of Management Development [12], European Commission [13] and other.

In this paper we use Global Competitiveness Index proposed by WEF in order to analyzed FDI flows in correlation with international competitiveness.

4. Data analysis

With the entry into force of the Lisbon treaty on 1 December 2009, the European Union acquired the exclusive competence of foreign direct investment under the Union's common commercial policy [14].

For data analysis we used as sources Global competitiveness Report 2010-2011 and World Investment Report 2010.

In the table below are show the values for FDI inflows, FDI outflows and GCI in every obtained by every country of European Union.

In 2009, European Union FDI inflows were 361949 millions dollars while FDI outflows were 388527 millions dollars. Result a difference about 26578 millions dollars in favor of FDI outflows which means that the European Union countries have made more foreign direct investment than have received. Some countries had values with "-" at FDI inflows like Hungary (5575), Slovakia (50), and Slovenia (67). All other 24 had value with "+"; France had the biggest level of FDI inflows (59628).

In parallel, some countries had value with "-" at FDI outflows like Latvia (23), Bulgaria (136), Hungary (6886), and Belgium (15064). All other 24 had value with "+"; France had the biggest level of FDI outflows (147161).

The average of FDI inflows in European Union countries was 13405.22 millions dollars. For de FDI outflows the average was 14389.89.

Even if Romania had a lower level of FDI inflows ranks on position 14 in top European Union countries. In terms of FDI outflows Romania had a very low level having position 21 in rank from 27 countries.

Table 1. FDI inflows, FDI outflows and GCI for European Union countries

Economy	FDI inflows	FDI outflows	GCI
Austria	7051	3766	5.09
Belgium	33782	-15064	5.07
Bulgaria	4467	-136	4.13
Cyprus	5797	5110	4.5
Czech Republic	2725	1340	4.57
Denmark	7800	15797	5.32

Average	13405.52	14389.89	4.70

Source: UNCTAD and WEF

The global economic crisis has hit a number of European countries particularly hard, leading to rising unemployment, plunging demand, and, in some cases, concerns about the sustainability of sovereign debt. However, overall Europe continues to feature prominently among the most competitive regions in the world. As described above, six European countries are among the top 10, and twelve are among the top 20, as follows: Switzerland (1st), Sweden (2nd), Germany (5th), Finland (7th), the Netherlands (8th), Denmark (9th), the United Kingdom (12th), Norway (14th), France (15th), Austria (18th), Belgium (19th), and

Luxembourg (20th) [15]. Romania ranks in position 67 with 3 places lower than previous year, but with a better score of 4.16.

The priorities of the Europe 2020 strategy should contribute to European competitiveness by eliminating further barriers to the European Single Market, encouraging investment in better skills, and supporting innovation. But the data highlight the fact that many countries still need to take measures to improve basic competitive requirements, such as their institutional setting and infrastructure levels; they must also improve their market efficiency, technological readiness, and level of skills. It will take the combined effort of all European and national authorities to improve the economic potential of the European Union so that it remains a prominent player in the 21st century [16].

Figure 1. FDI inflows and GCI in European Union countries in 2009

As it can be observe from the Figure 1, between FDI inflows and GCI it is a direct correlation but not a strong one. This means that international competitiveness of European Union countries is not very strong influenced by the FDI inflows, especially in western countries of European Union. That can be also demonstrated by the R² value that is 0.2962.

Figure 2. FDI outflows and GCI in European Union countries in 2009

As it can be observe from the Figure 2, between FDI outflows and GCI it is a direct correlation but not a strong one. This means that international competitiveness of European Union countries is not very strong influenced by the FDI outflows, especially in western countries of European Union. That can be also demonstrated by the R^2 value that is 0.1524.

5. Conclusion

FDI flows are very important for international competitiveness and economic growth. For European Union countries the importance of FDI flows occurs in two directions: developed countries are concerned to expand FDI outflows in order to increase their international competitiveness; developing countries are concerned to attract FDI inflows in order to increase their international competitiveness taking into consideration the fact that through FDI inflows they have access to technologies and managerial knowledge.

Given the Lisbon Strategy from 2010 for Europe 2020, which establishes three priorities such as: smart growth, sustainable growth, and inclusive growth it may be possible that developing couniteires to catch-up the developed countries in order to achieve the main objective of the strategy: Europe the most competitive and dynamic knowledge-based economy in the world.

The Core-Periphery Pattern. Methods to Measure the Peripherality

Horodnic Adrian Vasile

Mazilu Sorin

"Alexandru Ioan Cuza" University of Iași

adi_horodnic@yahoo.com

mazilu.sorin@yahoo.com

Abstract

The subject considered (e.g. dividing a country into a developed center and a periphery underdeveloped) was the subject of early researches in regional development. This paper aims to present the studies from the literature undertaken in the domain of a center-periphery structure. In the first part of the paper are brought into discussion some clarification on the term "peripherality". The paper continues with a brief presentation of the core-periphery pattern developed by Krugman and reviewing the improvements to the pattern. Also, this paper brought into discussion the main methods to measure the peripherality. As a conclusion it is emphasized the usefulness of an economical approach for peripherality that can lead to the development of a composite index for measuring the peripherality.

Key words: peripherality, core-periphery, core-periphery pattern, indicators for measuring the peripherality.

J.E.L. classification: R11, R12, O18, F15.

1. Meanings of the term "peripherality"

Since the nineteenth century, various theories of development presented in the literature, have offered different definitions and explanations of "peripherality". According to classical theories of polarization of Hirschman's (1958) and Myrdal (1959), peripherality is nothing but an "economic delay" caused by "vortex effect", determined by urban agglomeration. Friedman apud. Panebianco (1972) explains "the peripherality" based on "the effects of

modernization": central regions are more flexible, learn faster and they have, economically speaking, more success [1]. For Krugman (1991), peripherality is the result of lack of economies of scale and high transport costs [2]. A different view on this term/ terms is found in the studies of Vanolo A., author who places the phrase "core-periphery" among geographical metaphors, with phrases such as: North-South, Third World etc. The term "core-periphery" (with global scope) refers to the unequal distribution of power in the economy, society and politics, emphasizing the dominance/ dependence relations between different regions of the world [3].

2. The core-periphery pattern

The effect of economic integration on industrial location has become a political issue of considerable interest because of the type of integrative agreements like EU and NAFTA. Consequently, "geography and trade" or "new economic geography" has become the main trade theory research. Krugman's paper, "Increasing Returns and Economic Geography" is considered the basis of the theory of economic geography. In the work cited, Krugman developed a simple model that shows how a country can differentiate into a "center" industrialized and a "periphery" agricultural.

Thus, the pattern proposed by Krugman considers three central parameters [2]:

- transportation costs,
- economies of scale and
- the share of manufacturing in national income.

In the center-periphery pattern the labor is immobile but industrial workers can move geographically. Thus, Krugman, trying to

justify "why" and "when" the production of goods is concentrated in some regions (leaving the others underdeveloped) show two phenomena [2]:

- the demand connection: when workers shift to another working place, then the demand of employment increases; an increased demand triggers many other companies, which, at their turn attract many other workers.
- the offer connection: being about several companies, they shall reduce the price level (price index) at the destination, which implies increased actual incomes; they attract an increased number of employees, which, at their turn draw few other companies.

Krugman apud. Pușcaci & Pușcaci consider that these cumulative conditioning processes may determine an industrial powerful concentration, although there is a dispersal force opposing to the process. As a part of the labor force, the agrarians sector is presupposed to immobile from the geographical point of view and there shall always be a fix demand in each region. Along with the commercial costs the immobile demand provides geographical spread of the labor force. The results depend by the relative intensity of the concentration and disperse forces [4].

3. Center - periphery pattern improvements

Taking as its starting point the center-periphery pattern proposed by Krugman, researches in this area is intensifying. Venables (1996) and Krugman & Venables (1995) developed "the vertical pattern", model that differs from the center-periphery pattern in that it considers the work geographically immobile, but mobile between sectors. This time, the phenomena are as follows [5]:

- vertical connections: agglomeration means in this case a complete specialization in the industry. The concentration forces derive from companies based on other companies' intermediary inputs.
- demand connection: the greater the number of companies within a certain

emplacement is, the bigger is the product market for a potential company entering that emplacement.

- offer connection: the greater the number of companies offering intermediary input, the lower the production costs are for a company entering the emplacement.

Krugman apud. Pușcaci & Pușcaci consider that the circular interaction implied in companies' emplacing decisions may determine significant amendments in the industrial landscape. These concentration forces are balancing with the dispersal force, the same way as in the centre-periphery pattern. As the vertical pattern has to offer geographical fix jobs, it may be considered as being more applicable to an international context [4].

Based on the model developed by Krugman, authors such as Lanasp L.F., Sanz F., Mossay P., Hojman D.A., Szeidl A., Brulhart M., were concerned with steady-state model [6]. Labor mobility as a factor with influence in the center-periphery relationship, can determine the concentration of economic activity in a single region, if two conditions are met [6]:

- the taste for variety of products and the remuneration to be large enough and
- transport costs are low enough.

Therefore justify Mossay P. the spatial configuration of center-periphery equilibrium. The same author developed the model by configuring a "symmetrically balanced" according to which economic activity is distributed equally among regions. Thus, the balance short-term (instantaneous) is determined implicitly by the current labor distribution across all regions [7].

A different view (even that of Krugman - which proposes a general equilibrium) can be seen in the works of authors such as Lanasp L.F. & Sanz F. These researchers give up the premise of constant transport costs considering them as variable and it correlates with the size of the manufacturing sector in that region. In addition, it tries to control the interaction between the two elements that influence the location decisions of economic agents: congestion costs (which increase with the size of the region in question) and infrastructure.

The main result of this approach is that it has obtained various asymmetric equilibrium, and this aspect was not taken into account in the original model [8].

Hojman D.A. & Szeidl A. proposes a pattern approach as networks. The new pattern provides two common points between social and economic networks [9]:

- a center-periphery structure and
- a positive correlation between revenue and network center.

Baldwin R. E. & Forsild R. are those who founded the theory of dependency between center and periphery, theory which has as justification increasing, in time, the economic disparities between the developed and less developed countries: center was developed by drawing resources from the periphery, leaving developing countries without resources [10].

Pelkmans (2001) focuses its research on the effects of agglomeration and dispersion. In the analysis undertaken Pelkmans consider two regions: a central region richer and a poorer peripheral region [11]. According to research conducted by Baldwin et. al. apud. Hojman & Szeidl, the central region is positively related to higher academic performance. On the other hand, Lin V. apud. Hojman & Szeidl maintains positive association with finding a better paid job and Powel C. et. al. apud. Hojman & Szeidl argues a positive association with firm performance [12].

Returning to Pelkmans, the macroeconomic model proposed by him includes [11]:

- the crowding index: a measure of merger activity - calculated as the ratio between the number of firms in the central region richer and the total number of firms.
- index of inequality: measured as the ratio between income per capita from the central region of the richest and poorest peripheral region.
- the geographical effect (centripetal force): the relationship between the degree of agglomeration and regional disparities of income level is positive (the regional disparities are greater, the firms have an incentive to locate in the central region richer, thanks to market higher sales).

- the relationship of growth: the agglomeration of activities generates technological externalities, reducing the cost of innovation; innovation rate will be higher and will generate a higher growth rate (at national level).
- the effect of competition (centrifugal force): a strong competition leads to a reduction in profits in the central region richer; so there is a negative relationship between inequality index and the index of agglomeration.

Krugman, in an article published in 1998, explains the phenomena of concentration by means of the two forces [13]:

- centripetal force → factors: the effects of market size, labor market size;
- centrifugal force → factors: immobile factors, rents.

Pfluger M. & Sudekum J. add a new factor to centrifugal force: the housing deficit [14].

Some of the literature considers the peripherality an inverse function of accessibility: the availability is higher; the region in question is less peripheral. Thus, there were studies that fall into the category of determinants factors of the periphericity, the transport infrastructure. Authors such as Martinez-Zarzoso I. & Marquez-Ramos L., Ramcharan R. attach a great importance to quality of transport infrastructure [15], [16]. The same reasoning is found in the studies of Takahashi T., this time on the transport technologies [17]. Unlike them, Panebianco S. draws attention to a phenomenon of diminishing the importance of transport infrastructure due to factors such as [1]:

- a high percentage of high-value goods for which transport costs are less relevant;
- given the increasing role of telecommunications, which start to partially replace the physical transportation;
- a growing importance given to factors related to quality of life and culture.

The literature is particularly interested in the role played by foreign direct investment in a center-periphery system. Presented mostly in the form of empirical studies, the works of some authors like Tavares A. T., Kottaridi C., Filippaios F., Papanastassiou M., Barriost S., Dimelis S., Louri H., Stroblt E., shows a concentration of foreign direct

investments in areas considered central, not peripheral [18], [19], [20], [21].

Lately, some studies in the literature are complementary to core-periphery model, trying to determine the role played by innovation and research development.

Baldwin R. E. & Forsild R., focusing on the stability of the model showed that growth shares are a strong centripetal force, and information flows are a strong centrifugal force [10]. J. Kranich introduces a new variable that influence a center-periphery structure: international research mobility [22]. Copus A., Skuras D. and Tsegenidi K. consider the differences between the rate of innovation in central and peripheral regions a result of non-observable factors which are a mix between "behavior and environment" (once, in advance, were split into two factors: observable and unobservable) [23].

As a result of a rapid technological developments and structural changes in the international economy (particularly in the tertiary sector) the peripherality content appears to be changing. The economic success of the regions is influenced to a lesser extent by geographical location and a greater extent by a number of "aspatial" factors [24], [25]:

- information and communication technology infrastructure;
- human capital (percentage of skilled labor);
- cooperation between local firms (horizontal networks) and cooperation with other companies outside the region, but active in the same sector (vertical networks);
- human capital;
- institutional network (cooperation between different partners);
- local and global links (e.g. skills, education, local entrepreneur's adaptability, human capital).

Since the transition to knowledge-based economy brings new opportunities for the region, analysis of the literature focuses on new factors. Ottaviano G. & Forslid R., Crozet M. and Itoh R. are part of the authors who took into account the human capital and labor migration [26], [27].

Fujita M. and Thisse J. F. propose a new model of endogenous growth where the growth rate, measured by changes in the

number of product types, generates changes in the spatial distribution of skilled workers. Thus, the authors attach a particular importance to the spatial distribution of the innovation sector across regions because moving from dispersion to agglomeration, the rate of innovation tends to increase (conditions in which growth triggered by the agglomeration effect is strong enough, the periphery will take advantage of this situation) [28].

Following this reasoning, authors such as Socol C. & Socol A. proposed a series of policies aimed to reduce disparities between center and periphery [29]:

- improving infrastructure (reducing transportation and transaction costs);
- providing funding for industrial reconversion in the peripheral regions;
- policies to promote innovation through research grants for development, educational infrastructure, capital markets.

In the analysis of center-periphery structures, information and communication technology sector plays an important role. Authors such as Irvine W., Anderson A. R., Malecki E. J. and McQuaid R. W. turned their studies to develop the model in this perspective [30], [31], [32].

Castro S. B. S., Correia-da-Silva J. and Mossay P. had developed the pattern of Krugman taking into account a number of three regions. The authors concluded that the model with two regions favors the dispersion, while the model with three regions favors the concentration of economic activity [33].

4. Measuring peripherality

The researches in the area have stopped on the methods for measuring the peripherality through some indicators.

Copus A. K. divides the indicators for measuring the peripherality into two groups [34]:

- the first group includes the indicators that estimates the "economic potential" or "market potential". In this case, it is assumed that the potential for economic activity for any location is a function both of its proximity to other economic centers as well as the economic dimension. The analogy with the law of gravity is explained by

the fact that the influence of each center on the economic potential of a location is assumed to be directly proportional to the volume of economic activity and inversely proportional to the distance separating them.

- the second group includes indicators such as "travel time / costs" and "accessibility." This group of indicators has been developed greatly in recent years and there's even a "soft" that estimates the peripherality.

Spiekermann K. and Neubauer J. provide a summary of accessibility indicators as shown in Table 1.

Table no. 1 - Models of accessibility

Author	Generic type of indicator	Factors	Type of transport	Space
Keeble et al. (1982; 1988)	Potential	Road distance	Road	EU9 EU12
Lutter et al. (1992, 1993)	Daily transport costs	Transport time	Road, rail, air intermodal	EU12
Spiekermann and Wegener (1994, 1996)	The daily potential	Transport time	Rail	pan-Europe
Chatelus and Ulied (1995)	Daily transport costs	Transport costs	Road, rail, air intermodal	EU15, Norway, Switzerland
Gutierrez and Urbano (1995, 1996)	Transport costs	Transport time	Road, rail	EU12
Copus (1997, 1999)	Potential	Transport time	Road	EU15, Candidate Countries, Norway, Switzerland
Schürmann and Talaat (2000)	Potential	Transport time	Road	EU15, Candidate Countries

Source: adapting Spiekermann K. & Neubauer J. - *European Accessibility and Peripherality: Concepts, Models and Indicators*, Nordregio Working Paper, 2002

The most common index is the "European Peripherality Index" proposed by Schürmann C. & Talaat A. [35]. To note that in the context of a center-periphery structure may be taken into account a number of indicators and composite index designed to measure the disparities between regions.

5. Conclusion

In the literature there are a number of criticisms directed to the core-periphery pattern (authors like: Currie M. & Kubin I., Martin R. & Sunley P. etc). The main criticism is based on the fact that the model is becoming less and less applicable to the advanced economies, but remains valid as long as there are disparities between regions [36]. In his model, Krugman shows how a country can distinguish in a "center" industrialized and a "periphery" agricultural. The researches that followed led to the development of the model proposed by Krugman and the calculation of some indices for measuring the peripherality. Being developed by the research branch of geography, most indexes are calculated based on the "travel time/ costs" and "accessibility". Therefore, prove to be useful an economical approach for peripherality that can lead to the development of a composite index for measuring the peripherality.

Mergers & Acquisitions Market in 2010

Humă Elena

Academy of Economic Studies, Bucharest, Doctoral School
humaelena@yahoo.com

Abstract

How well did the market of Mergers& Acquisitions in 2010? Who were the main players on the market? What were the key-figures of last year? What were the main sectors where most of mergers& acquisitions took place? The transactions issued were comparable with those from previous years? How is the European market of mergers& acquisitions influenced by the transactions from the global market?

This article is a summary of all the important figures that characterize the movements, actions, players, sound-names that made a difference on the mergers& acquisition market during previous year.

Key words: contracting market, IPO (initial public offering), deal, transaction

J.E.L. classification: G34

1. Introduction

The mergers and acquisitions market has melted in 2010. The Romanian market of mergers and acquisitions (M&A) shrank dramatically in 2010 compared with 2009, reveals a market report carried by the Capital Partners. The total volume of finalised transactions last year amounted 302 million euros, down by 71% compared to 2009, when the market was in amount of 1.045 billion euros, according to the investment bank Capital Partners. In terms of number of transactions, were concluded 72 agreements, down with 10% compared to 2009, when 80 deals were concluded. "I hope that 2011 will at least stabilize the situation, in terms of stopping the decline. The Romanian M&A market has contracted so much in these two years that if this trend continues, in 2011, the market would be almost insignificant in a regional context, let alone globally" said for

Wall-Street.ro, Mr. Doru Lionachescu, partner of Capital Partners, Investment House.

2. Worldwide, the M&A market rebounded in 2010

2.400 billion dollars - last year's global total amount of mergers and acquisitions. This represents 22.9% more than in 2009, marking the best evolution after 2008, according to annual statistics provided by Thomson Reuter's research. Emerging markets have generated a third of the market share, amounting to 806.3 billion U.S. dollars, with 76% more than previous year. The four most important transactions of last year topped 20 billion dollars each. The largest deal was the acquisition of Carso Global Telecom by the America Movil SAB, valued at 27 billion dollars. Second place in the ranking is occupied by the transaction by which GDF Suez Energy International was bought by International Power PLC for \$ 25 billion. CenturyLink Inc. paid \$ 22,100,000,000 for Qwest Communications and Weather Investments bought VimpelCom for 20.6 billion dollars, ranking 4th in this top. Goldman Sachs has regained its first place in the top consulting companies of M&A, according to Thomson Reuters, ahead of the Morgan Stanley ranked third followed by JP Morgan Chase. Capital markets activity shrank by 2% to 854.2 billion U.S. dollars, registering an accelerated pace last quarter, Thomson Reuters also said.

On the IPO segment were also recorded top levels. In this sector were highlighted GM's and AIA Group initial public offerings, with 23, respectively 20.5 billion U.S. dollars. In the fourth quarter IPOs totalled 122.2 billion U.S. dollars globally and totalled over 2010, 269.4 billion U.S. dollars, twice more than in 2009. The highest value of IPOs was attracted to companies that have

initiated a public offering in China, the 471 IPOs have generated 104.4 billion dollars, the amount exceeds U.S. and Europe combined.

3. M&A decreased by 32% in 2010 to 1.6 billion euros

The value of closed deals last year decreased by 32% compared to 2009, rising to about 1.6 billion euros, while their number increased by 12% to 212 deals, according to DealWatch Emerging Europe M&A Report 2010. Most attractive sectors for investors last year were trade, that recorded 41 deals, followed by industry with 39 deals. The same sectors were the top ranking in terms of trading value, the industrial sector being the first with 610 million euros and trading with 370 million euro.

The largest transaction of 2010 was that the Romanian state, through the Ministry of Finance has become the shareholder of Rompetrol, owning 44.7% of the capital, after Rompetrol shareholders decided to convert the bonds into shares worth 464 million euro. Another significant transaction was the acquisition of Plus Discount stores by German retailer Lidl for an estimated \$ 200 million. In third place was the increase in capital worth 118 million euros made by Garanti Bank in the company which owned financial services control firms Motoractive and IFN Ralfi Domenia. According to DealWatch consultants specialized in transactions such as mergers and acquisitions, 2011 is expected to bring an improvement in the number of transactions and mentioned as one of the renewable energy sectors with significant potential. However, not all are very optimistic regarding the return of the overall M&A activity and believes that large transactions are still to come.

4. Emerging markets in Europe brought 3164 transactions

The number of mergers and acquisitions in Central and South-East Europe in 2010 grew by 7.7% to 3164 transactions, according to Emerging Europe DealWatch M&A Report 2010.

In 2010, the most dynamic sector, both on the number of transactions and in terms of value was the industry with 578 deals and a total of 34 billion euros, followed by Finance and Insurance with a value of about 25 billion euros. The most intense M&A activity in the region, both in terms of number of transactions, and their value was registered in Russia, which contributed 31.3% of the total number of transactions and the total value of 57.8% . Poland came in second place with 18% of total transactions and 14.8% in value. Third place was taken by Ukraine in terms of number of transactions by 13.3%, and Turkey in terms of trading value, 14.4% of the total. It can, also, be found that the average value per transaction diminished almost by half, from around 8.2 million euros in the first half of last year to 4.2 million at year end. In terms of distribution by industry, most transactions (11) were made in the FMCG segment, followed by IT&C (10 transactions) and financial services transactions in September.

Mr. Lionachescu Doru² states that a possible slippage in the relationship with international investors would kill the market. Otherwise, says the investment banker, a negative perception of Romania in the context of lack of investment interest for Europe in general is so strong that two or three specific measures of the Government would be totally inadequate. "It takes a radically different approach to relations between Romania and potential foreign investors, and this view now seems very far."

Currently, the investment house Capital Partners is working at a normal pace compared to last two years, about six active warrants, but crucial issues remain the same: working long duration and uncertainty of completion.

The Romanian M&A market was in decline after the first semester of last year, during which the total volume of closed transactions amounted 228 million Euros, meaning a decline of 8%.

Source: www.dealwatch.com

In the fourth quarter of 2010 were signed deals worth 52 million Euros after nine months when, in September, the Capital Partners Report revealed a total volume of 250 million Euros. The methodology used by Capital Partners is a standard one, meaning they are considered only announced transactions, which are allocated to the month in which they were officially announced, so do not count estimates of amounts and unconfirmed rumours.

5. The value of global M&A market in 2010: \$ 2.400 billion

2400 billion dollars - last year amount of mergers and acquisitions globally, 22.9% more than in 2009, marking the best evolution after 2008, according to annual statistics provided by Thomson Reuters quoted by foxbusiness.com. Emerging markets have generated a third of market share, amounting to 806.3 billion U.S. dollars, with 76% more than the previous year. The four most important transactions of last year topped 20 billion dollars each. The largest was the acquisition by America Movil

SAB of Carso Global Telecom, a transaction valued at 27 billion dollars.

6. The situation in the financial banking system

The stock of loans has increased slightly since the beginning of 2010, by 4.7% in local currency and 3.3% in Euros, driven by the foreign lending (8.3% up in Euros). Nonetheless, the stock of bank loans has remained more or less constant since the end of 2008, when the credit crunch occurred, and unblocking lending is broadly seen as paving the way to economic expansion. In our view however, broadening the financial intermediation mechanism is also needed in order to improve the resources' optimization. In regard to the deadlock on the credit market, both lenders and investors have visible problems in adjusting to the new situation.

While the banks have not settled their bad loans problem, investors are very reluctant to take risks. None of them seems however to have adhered to the low-margin strategies that will be needed on medium to long term. The convergence-driven logic of doing business in Romania before the credit crunch in 2008 was an inflationary logic of high profit margins and high interest rates.

At that time, sustainable, low-risk businesses were generally discarded by loan officers in favor of high profit deals that proved high risk ex-post. This resulted in a poor quality of the investments in the years before the credit crunch. For various reasons including but not limited to lower potential growth rate at home, currency wars and sustainability, bankers will have to reconsider their lending policies and investors also need to focus quality sustainable projects. The Romanian bank's aggregated loss diminished to EUR 55mn) from EUR 150mn in Q2, local media reported quoting central bank governor Nicolae Cinteza³ in late October. The majority of the large banks generated profits in the quarter and the problems accumulate in the region of smaller banks.

However critical might seem banks' financial circumstances at this moment, the Non-Bank Financial Institutions, namely leasing companies and consumer finance firms, have fared even worse last year. The

good news for the pension system is that the second pillar, namely the compulsory private pensions, are not being dismantled as it just happened in Hungary and Bulgaria. The mandatory and voluntary pension funds generated average yields of 15.1% and 11.5%, respectively, as at end-2010. The premium income of the domestic insurance market decreased by 5% in local currency or 4% in Euros to RON 6.3bn (EUR 1.5bn) in January September⁵, market surveillance body CSA said. The general government deficit narrowed by 8.6% nominally to RON 33.3bn (EUR 7.8bn) in 2010, or 6.5% of the estimated GDP down from 7.4% in 2009, revealed the preliminary data from the ministry of finance.

The financial services also face problems in terms of activity (volume of lending) and profitability. The stock of total bank loans expressed in Euros has hovered between EUR 48-49bn during the whole year, the new loans hardly covering the repayments. The stock of overdue payments on bank loans however kept rising sharply, by 104% to reach 7.8% of the total stock of bank loans up from 4% one year earlier. Nonetheless, the financial system's stability remains sound thanks to large profits cashed by banks in the past years and to an IMF-supervised agreement of the central bank with the foreign banks operating in Romania under which parent financial groups maintain their exposure.

Data Distribution Techniques in Distributed Databases

Iacob (Ciobanu) Nicoleta - Magdalena
University of Pitesti, Faculty of Mathematics - Computer Science
nicoleta.iacob_2007@yahoo.com

Abstract

The distributed databases are fundamental elements of the informatics systems contained in the infrastructure of an economic organization with offices distributed in various locations around the world.

This paper presents the techniques by which a distributed database management system provides data distribution. For this, there are described fragmentation and data replication methods. The aim of data replication is to improve performance and to protect the availability of applications.

Key words: distributed database, fragmentation, replication, methods.

J.E.L. classification: C61, C88, L21.

1. Introduction

The distributed database approach, as basic elements of integrated informatics systems in an economic organization, must consider three important trends that redefine their role in the economic applications:

- **The Internet** - the medium that connects in real-time key players: producers, sellers, distributors and customers.

- **The market globalization** - the business environment requires storage and processing of large databases distributed in all geographic locations involved in a particular activity or economic process.

- The transformation of industrialized countries in **information societies** (information economies) emphasizes the importance of efficient informatics and communication systems on top of which the distributed databases play the decisive role.

A **distributed database** (DDB) is a collection of multiple logically interrelated databases that are located in the nodes of a computers network. Specifically, a DDB is a

collection of distributed sites interconnected by a communication network.

The distributed database management (DDBMS) is the software that ensures working with DDB and supplies an access mechanism which makes their distribution transparent to all users.

To ensure compliance with **the DDB's specific objectives** such as: increase of system reliability and data availability, decentralization and better use of system resources and increase of system adaptability to changes in organizational structure, the DDB design aims to follow some *principles*:

- *Maximizing local processing of data* can be done by placing data closer to the applications that require them. In a properly designed DDB approximately 90% of the total data should be locally accessed and only 10% from remote locations.

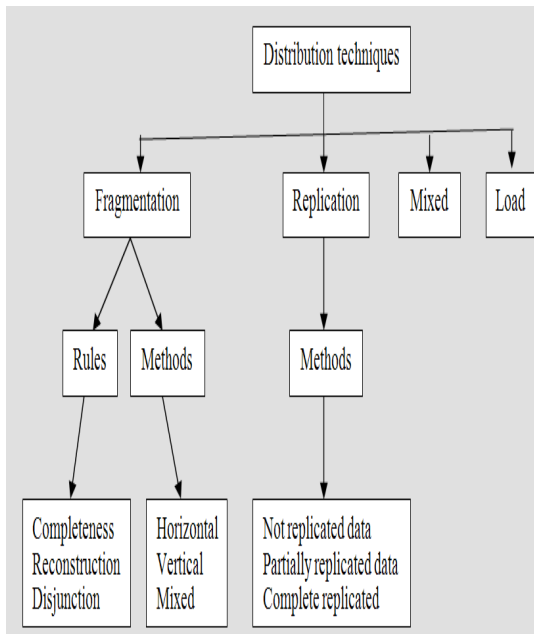

- *Providing a high level of data security and availability* can be done by making data replication to numerous sites. In this way, the system can use an alternative copy when the one which should have been accessed under regular circumstances is not available.

- *Parallel data processing* can maximize the use of CPU processing power for each station node.

2. Techniques for data distribution

Techniques by which a DDBMS ensure the distribution of data are represented in Figure 1: fragmentation, replication, mixed distribution, load distribution.

Figure 1: Distribution techniques

2.1. Distribution by fragmentation

Distribution by fragmentation is the operation of logical decomposition of global collections in disjoint parts called fragments, by using special operators.

Fragmentation is the partitioning of a global relation R in fragments R_1, R_2, \dots, R_n , which contain enough information in order to reconstruct the original relation R [5].

To achieve fragmentation DDBMS must respect certain rules and methods.

The rules which must be accomplished by fragmentation are:

- *completeness*: means that the entire global relationship should be partitioned into fragments;
- *reconstruction*: means that in any case it must be possible to reconstruct the global relationship from its fragments;
- *disjunction*: means that the fragments must be disjunctive, so that data replication can be controlled explicitly at data allocation level.

The methods that can be used for fragmentation are:

- **horizontal** signifies that decomposition of global collection in fragments is done by extracting a set of records while keeping all fields of the initial collection. In relational terms a horizontal fragment amounts to a subset of the rows of a table [1]

- **vertical** signifies that decomposition of global collection in fragments is made by extracting a set of fields while maintaining all records of the original collection.

- **mixed** means that decomposition of global collection in fragments is made by successively applying the horizontal and vertical methods.

2.2. Distribution by replication

Distribution through replication is the operation of storing portions from a database, as copies, on multiple nodes on a network. If a user updates a local copy then DDBMS automatically updates all copies of that data.

Replication is a process that consists in making and distributing copies of data between different places, at remote or mobile users, by using Internet. In addition, allows changes to be propagated consistently to the relevant copies. Distribution of these replicas aims to ensure local data processing in order to maximize efficiency and reduce communication costs. Furthermore, replication provides more reliability, minimizes the chance of total data loss, and greatly improves disaster recovery [3].

Replication improves performance and protects availability of applications because there always is an alternative access path to data. The application can run even if a local server should fail, but other servers with replicated databases remain accessible. It also increases system security and improves speed of data processing operations.

The methods that can be used for replication (Table 1) are:

- **not replicated** data means that DDBMS allocates space for some data on a single node from a computer network. The characteristics of this method are: minimal redundancy, data access concurrency is maximum, update time is small and retrieval time is great;
- **partially replicated** data means that DDBMS allocates for a part of data a single copy on a computer, and for another part of data multiple copies on multiple computers on the network. The characteristics of this method are: redundancy is increased, concurrency access to data is decreased, update and retrieval time is medium;
- **complete replicated** data, means that DDBMS allocates for the entire database

multiple copies on different computers on the network. The characteristics of this method are: redundancy is high, concurrency access to data is minimal, the time update is great and retrieval time is small.

Table 1: Methods of data replication

	Not replicated	Complete replicated	Partially replicated
Data consistency	Large	Small	Small
Storage costs	Small	Large	Medium
Reliability and availability	Small	Large	Medium
Update speed	Medium	Small	Small
Communication costs	Large	Large	Small
Redundant	Small	Large	Medium
Concurrency access to data	Large	Small	Medium
Update time	Small	Large	Medium
Retrieval time	Large	Small	Medium

The replication of a fragment R_i at j station, formula (1), is justified if the fragment allocation cost is less than the cost of remote accessing the applications k from j station to other copies of the fragment found on other stations j' ($j' \neq j$):

$$C_{ij} < \sum_k d_{kij'} \quad (1)$$

The replication is a solution for a distributed database environment when we need:

- to copy and distribute the data to one or more places;
- to distribute the copies of the data on a scheduled basis;
- when needed, to allow more users to make changes, then send data changes together, and even to resolve potentially conflicts;
- to build applications with data which can be used in online or offline environments;
- to build Web applications in which the users can access large volumes of data.

An important aspect is that replication does not usually involve the entire database (in which case we are dealing with a full replication). The most common case is to replicate a table, but is often used replication of data subsets from a table or more tables, which raises even more the complexity level of replication. Replication refers not only to data distribution, but also to processing distribution. Distribution of these replicas must ensure that the data processing is done locally [2].

2.3. Mixed distribution

Mixed distribution is the operation of successively applying fragmentation and replication for the same global data collection. This technique takes advantage of the other two, but it is more difficult to implement. The fragmentation and the replication can be combined: A relationship can be partitioned into several pieces and can have multiple replicas of each fragment [4].

2.4. Distribution by load

The load distribution is a scheduled copy operation of an entire centralized database or of a portion of a centralized database on local nodes. It is the simplest technique and is used when data are stable (not changing rapidly) or when not all users need to have access to the latest data.

3. Conclusions

The use of distributed databases in the economic environment needs to ensure both improved access to information and rapid data collection. The fragmentation operation for a database increases the system security and minimizes system response time by increasing the parallelism. Replication improves performance and protects applications by offering data availability, increases system security and improves speed of data processing operations.

Distributed Transactions in Transnational Companies

Iacob (Ciobanu) Nicoleta - Magdalena
University of Pitesti, Faculty of Mathematics - Computer Science
nicoleta.iacob_2007@yahoo.com

Abstract

The present society is without any doubt an information society. The implementation of complex informatics applications needed to support the various organizations, most of them with geographically distributed offices, resulted in the need for distributed database systems capable to ensure high efficiency and greater flexibility.

This paper describes distributed transactions used in distributed database systems with their properties and operations. The aim of a distributed transaction is to ensure data concurrency and data consistency for all the users of the database.

Key words: distributed databases, distributed transactions, two-phase commit protocol, concurrency control.

J.E.L. classification: C88, L21.

1. Introduction

The world economy is a system composed of fundamental components - national economies, transnational corporations, interconnected economic organizations, and derivatives - the world division of labor, international economic relations, the global market. The derivative components appeared as a result of the action of the fundamental components, together determining the evolution and dynamics of the economy and global trends.

Distributed databases have appeared as a natural consequence of the fact that most of the economic organizations in expansion have offices in different locations distributed around the world.

A **distributed database** is a set of databases on several computers that is seen by the application as a single database (located on a single computer). Fragments may be replicated. Every database must at

least support the ability to "create" new data content (store new data values in the database) and the ability to retrieve existing data content [3].

A **distributed database (DDB)** is a collection of logically interrelated data which are physically distributed on computers (nodes) over a network. Every computer in the network has the autonomy to process local applications. Also, each computer participates in the execution stage of at least one global application that requires accessing data from multiple computers [2].

In a distributed database located in multiple nodes of a network, access to data objects is usually done through transactions.

The transactions are logical groups of SQL (Structured Query Language) instructions. Each transaction ends with either a *finish* or a *rolling back* result. *Finish* result to permanently save of database changes made by transactions. *Rolling back* cancels all database modifications made by transaction.

The transaction management ensures the concurrency and consistency of data for all database users. In the absence of transaction management, data quality and accuracy would be compromised, and the database would become almost unusable.

The synchronization of access mechanisms applied in order to maintain database integrity is called **concurrency control**.

2. Distributed queries

A user interacts with the database by providing read and write requests in the database. These read and write operations are grouped into *transactions*.

The global users working with DDB would work as with a centralized database:

- make requests (global transactions);

- requests are assessed, decomposed and delivered to distributed execution supervisor;
- the supervisor send the requests to nodes in which there are local databases that will be queried;
- queried databases send replies to the supervisor.

The factors which affect the evaluation of queries in a distributed system are: the fragmentation details for relations, the location of these fragments / tables from the system, and connection speed of links used for communication of the *sites* from system (Rahimi & Haug, 2010).

2.1. The algorithm for achieving distributed queries

When sending a query which data processing located in different nodes a node will take the role of coordinator and other nodes will be cooperating nodes.

1. The coordinator node sends the message: *PREPARE* to the cooperating nodes;
2. The cooperating nodes are preparing for execution - reading and writing the updated or outdated data in local journals then send the message *READY* to the master node;
3. The master node sends the message *DO*;
4. The cooperating nodes run queries (inserted updates in DDB) then:
 - 4.1. If the system is correct functioning will send the message *DONE*;
 - 4.2. If the system does not function correctly will send the message *ABORT*, and *return*;
5. It restores the original database (the one before query release).

3. Distributed transactions

In a multi-user database system the procedures that cause changes to a database or retrieve data from the database are called transactions [1]

The transactions are atomic units that perform data update, by which a database goes from a coherent state into another coherent state.

A transaction allows the programmer to group one or more SQL (Structured Query

Language) instructions into a single, indivisible one. The transaction begins with the first executed SQL statement and ends when the effects of the transaction are saved or rolled back.

Definition. It's called a **transaction** a sequence of actions, executed by the user, which maintains a consistent and secure database. Intuitively, a transaction takes data from the database, performs some calculations and changes certain values of the database.

Example transaction:

```
begin transaction
extract (account1, amount);
submit (account2, amount);
updateHistory ();
commit transaction
```

If all operations succeed: COMMIT

If one operation fails: ROLLBACK

Running a successful transaction is not equivalent with finishing the transaction. A successful execution of a transaction means that SQL statements were executed without errors. However, the effects of successfully executed transactions may be rolled back as long as the transaction is not completed.

3.1. Transaction properties

To ensure integrity of the data, we require that the database system maintains the following properties of the transactions:

- **Atomicity:** the changes of a transaction status are atomic, meaning that they occur all or none.
- **Consistency:** a transaction constitutes a correct transformation of the database state.
- **Isolation:** even if the transactions are executed concurrently, each transaction T "sees" the execution of other transactions as being produced prior to T, or after T, but not both.
- **Durability:** once a transaction has been executed successfully (so it was "completed" or "committed"), the changes it has produced in the database state will not be affected by faults.

These properties are often called the **ACID** properties; the acronym is derived from the first letter of each of the four properties [4]- **A**tomicity, **C**onsistency, **I**solation, **D**urability.

3.2. Operations

1) **BEGIN TRANSACTION** marks the beginning of transaction execution. The transaction administrator records in a table the following:

- transaction identification number,
- the application of these transactions,
- transaction occurrence time, etc.

2) **READ** works as follows:

• if the access unit referenced is stored locally, management module returns its value,

• if the access unit referenced is not stored locally selects a copy of its and requires its value.

3) **WRITE** determine writing the access units (locally).

4) **COMMIT** announce the successful completion of the transaction, validation of changes made to the database and visibility of changes made for other transactions; from this point, changes cannot be canceled, or lost by a subsequent failure of the system (if the recovery mechanism of DBMS is working properly).

5) **ROLLBACK** (or **ABORT**) marks the failure of a transaction; any effect that it had on the database will be canceled. There are some systems in which after **ABORT** command the management module will indirectly try to recover a part of the actions of canceled transaction.

6) **UNDO**: is similar to rollback operation, but applies only to a single operation, not to an entire transaction.

7) **REDO**: specify that some operations of a transaction must be executed again in order to validate the entire transaction.

8) **END TRANSACTION** marks the end of execution for a transaction.

3.3. Two-phase commit protocol

The validation protocol in two phases (*two-phase commit*) - 2PC relates to a transaction that makes the database upgrade.

In the first phase:

The source (a database server) will require targets (other database systems) to prepare for executing the transaction and will wait for confirmation from them.

When all targets are prepared, the source will ask the execution of transaction and will wait for each target to report the success.

Each server responds with:

• The **READY** message, if it is prepared to validate the transaction; after this point, the server cannot cancel transaction unless the coordinator asks.

• The **REFUSE** message, if it cannot validate the transaction.

Phase two:

If coordinator received **READY** from all servers - all targets were successfully committed the transaction - it send **COMMIT** message to all servers and each server will validate the transaction.

If coordinator received **REFUSE** from at least one server, which means that at least one target cannot commit transaction, then it sends **ROLLBACK** to all servers and each server will cancel the transaction.

If all servers are working properly and there are no network errors, 2PC ensure atomic distributed validation for transactions.

However, taking into account the possibility of errors occurrence, other protocols are necessary to be used during validation process.

3.4. Concurrency control

If the transactions are serialized, time is wasted when the server waits for an input/output operation, or during other breaks. On the other hand, if the transactions are executed in parallel, we have concurrent transactions. Concurrency will increase efficiency, but also necessitate control mechanisms to be implemented because otherwise it can lead to database inconsistency.

Concurrency control in a database is the activity of coordinating transactions which operate in parallel, access shared data and can potentially interfere with each other. Concurrency control together with a recovery protocol guarantees the ACID properties of a transaction. The goal of concurrency control is to keep atomicity of transactions.

Concurrency control problem arises for the operation of reading (it is possible to allow multiple transactions to read data from a common data entity) and the operation of writing (do not allow many transactions to write the same data entity).

There are two large categories of concurrency control:

- **Optimistic concurrency** - Delay in synchronization between transactions until the operations are completed. In this case, the conflicts are unlikely to happen but are visible only at the end of the operation, making the rollback operation more expensive.

- **Pessimistic concurrency** - potential concurrent execution of transactions is synchronized during the execution cycle. The locks are more probable but, because they are visible, the cost of the rollback operation is minimized.

Distributed transactions provide consistent execution units which group different operations in different nodes and keep the database consistent. *Two-phase commit* protocol 2PC ensures transaction completeness and consistency. For large distributed transactions involving different nodes there is the solution of decomposing these transactions in smaller units.

4. Conclusions

Distributed transactions provide consistent execution units which group different operations in different nodes and keep the database consistent. Two-phase commit protocol ensures transaction consistency and completeness. For distributed transactions and for large transactions, which involve different nodes, there is the solution to decompose these transactions in smaller units.

Following the demands of increasing availability, reliability and flexibility of database systems and the progress in database technology and communications, distributed database systems are now widespread. The process of creating a distributed database system is justified when performing with large databases, which provide support for most of the activities in an organization, or in case that are planned frequent extensions of existing informatics system.

Abstract

The present research paper aims to present the framework and the achieved progresses on the application of ISO 26000 – Social Responsibility standard at the level of the European countries. The paper is structured into five main parts, each one emphasizing a specific research objective: brief description of CSR and its voluntary character; comprehensive review of the main benefits that CSR brings on for the responsible companies; general presentation of ISO 26000; research on the computed analysis of ISO 26000 application at the European level; recommendations and conclusions. The innovative element is represented by the attempt to offer a macroeconomic computed approach on the main CSR key-drivers at the European level in order to identify the specific country-level progresses on the implementation of ISO 26000 associated core subjects and issues.

Key words: ISO 26000, Corporate Social Responsibility (CSR), Social Responsibility (SR), European countries, common framework

J.E.L. classification: M14.

1. Introduction

The present economic and social context – especially market by the globalization process of the last decades and the recent economic and financial crisis – puts a stronger emphasis on (corporate) social responsibility. The organizations, in general, and the companies, in particular, aiming at long-term profitability, operating efficiency and credibility are realizing that ethical and

socially responsible criteria should become an integral and strategic part of their business operations.

The European Multi-stakeholder Forum on CSR (EMF on CSR, 2004) defines CSR as “a concept whereby companies integrate social and environmental concerns in their business operations and in their interactions with their stakeholders *on a voluntary basis*” [1, p. 3], putting a great emphasis on the not-mandated and not-compulsory character of CSR.

In this way, a voluntary international standard for offering guidance in terms of SR (common basic definitions, working methods and methods of evaluation) is a necessary instrument for the companies aiming to apply a common framework for implementing and evaluating their CSR policies.

2. Benefits of Adopting a Socially Responsible Behaviour

Theoretical and practical evidence show that organizations that involve themselves in socially responsible practices will gain competitive advantages. In a more pragmatic and economic views, the benefits for responsible companies are at least the following:

- Obtaining a social operational licence from the main stakeholders of the company, not just from the shareholders
- Harmonizing business practices with the expectations of all the stakeholders
- Increasing efficiency and cost reduction
- Achieving sustainable competitiveness: improving corporate image, reputation and brand; increasing buyer’s loyalty with respect to the seller; increasing the sales’ efficiency, productivity and quality; improving corporate financial performances

- Creating new business opportunities and winning a comparative advantage
- Differentiating from competitors and achieving production or commercialization brand loyalty
- Increasing possibilities of recruiting and retaining high quality employees
- Attracting and retaining high quality investors and business partners: increasing the shareholders' value; reducing the volatility of the shares; decreasing the cost of the capital; obtaining good access to socially responsible investment funds; reducing risks by adopting the best practices of the business partners
- Cooperating with local communities
- Avoiding crises due to CSR deviations and better managing operational and commercial risks
- Obtaining governmental support and avoiding stricter governmental regulations
- Building political capital [2].

3. General Presentation of ISO 26000 – Social Responsibility

The International Standard *ISO 26000 – Guidance on Social Responsibility* provides harmonized, globally relevant guidance for private and public sector organizations of all types based on international consensus among expert representatives of the main stakeholder groups from developed and developing countries, and so encourages the implementation of best practice in social responsibility worldwide [3, p. 3]. ISO 26000 emphasizes what organizations need to do in order to operate in a socially responsible way.

ISO 26000 is an international standard, but not a management system standard; it contains voluntary guidance, but not requirements; it is not being intended for third-party certification or for regulatory or contractual use.

In applying ISO 26000, it is advisable that an organization takes into consideration societal, environmental, legal, cultural, political and organizational diversity, as well as differences in economic conditions, while being consistent with international norms of behaviour [4, p. 3].

ISO 26000 offers guidance on the following elements (seven clauses and two annexes):

- Scope of ISO 26000 (*Clause 1*)
- Terms and definitions related to SR (*Clause 2*)
- Understanding SR: Background, factors, characteristics and trends of SR (*Clause 3*)
- Principles and practices relating to SR (*Clause 4*)
- Recognizing SR and engaging stakeholders (*Clause 5*)
- Core subjects and issues of SR (*Clause 6*, see Table 1)
- Integrating, implementing and promoting SR throughout an organization (*Clause 7*)
- Examples of voluntary initiatives and tools for SR (*Annex A*)
- Abbreviated terms (*Annex B*) [5, p. 5].

Table 1: Core subjects and issues of SR addressed in ISO 26000

Core subjects and issues
1. Core subject : Organizational governance
2. Core subject: Human rights
<i>Issue 1:</i> Due diligence
<i>Issue 2:</i> Human rights risk situations
<i>Issue 3:</i> Avoidance of complicity
<i>Issue 4:</i> Resolving grievances
<i>Issue 5:</i> Discrimination and vulnerable groups
<i>Issue 6:</i> Civil and political rights
<i>Issue 7:</i> Economic, social and cultural rights
<i>Issue 8:</i> Fundamental principles and rights at work
3. Core subject: Labour practices
<i>Issue 1:</i> Employment and employment relationships
<i>Issue 2:</i> Conditions of work and social protection
<i>Issue 3:</i> Social dialogue
<i>Issue 4:</i> Health and safety at work
<i>Issue 5:</i> Human development and training in the workplace
4. Core subject: The environment
<i>Issue 1:</i> Prevention of pollution
<i>Issue 2:</i> Sustainable resource use
<i>Issue 3:</i> Climate change mitigation and adaptation
<i>Issue 4:</i> Protection of the environment, biodiversity and restoration of natural habitats

5. Core subject: Fair operating practices
<i>Issue 1:</i> Anti-corruption
<i>Issue 2:</i> Responsible political involvement
<i>Issue 3:</i> Fair competition
<i>Issue 4:</i> Promoting social responsibility in the value chain
<i>Issue 5:</i> Respect for property rights
6. Core subject: Consumer issues
<i>Issue 1:</i> Fair marketing, factual and unbiased information and fair contractual practices
<i>Issue 2:</i> Protecting consumers' health and safety
<i>Issue 3:</i> Sustainable consumption
<i>Issue 4:</i> Consumer service, support, and complaint and dispute resolution
<i>Issue 5:</i> Consumer data protection and privacy
<i>Issue 6:</i> Access to essential services
<i>Issue 7:</i> Education and awareness
7. Core subject: Community involvement and development
<i>Issue 1:</i> Community involvement
<i>Issue 2:</i> Education and culture
<i>Issue 3:</i> Employment creation and skills development
<i>Issue 4:</i> Technology development and access
<i>Issue 5:</i> Wealth and income creation
<i>Issue 6:</i> Health
<i>Issue 7:</i> Social investment.

Source: ISO, *Discovering ISO 26000*, 2010, pp. 6-7.

The standard for SR came into being at the end of 2010 (November 2010). The ISO Working Group for Social Responsibility (ISO/WG SR) was formed by 450 participating experts and 210 observers from 83 ISO member countries as participating countries, 42 liaison organizations and 16 ISO member countries as observer countries. Each ISO member country that took part in the process was represented by a NSB (National Standards Body). Romania was an observer and it was represented by ASRO (Romanian Standards Association) [6, pp. 3-12].

The development process of ISO 26000 was special in a number of respects, particularly with regard to the number of participating countries (99 – the highest number ever in all ISO standards) and the efforts made to ensure the fair participation of developing countries (twin leadership between a developed and a developing country in the ISO/WG SR) [7].

4. Analysis of ISO 26000 Application at The European Level: Data, Methodology and Results

At the European level, the understanding of CSR is country specific and the adoption or implementation of ISO 26000 highly depends on the economic, social, cultural and political situations in different countries.

Taking into account the four components of CSR (economic, social, environmental and second-order requirements), a recent study (2008) conducted at the level of Central-Eastern Europe (CEE) and Western Europe (WE) countries emphasizes the fact that the economic dimension of CSR is the most important one for both CEE and WE companies. While WE companies rank second-order requirements (e.g.: transparency and participation, stakeholders' involvement, reflectivity, integration of the other three dimensions and intergenerational equity) second, CEE companies give environmental responsibility issues a considerably higher importance, especially in the last 10 years. Apart from this difference, the importance of the economic, social and second-order dimensions is almost identical for the surveyed CEE and WE companies. Generally speaking, WE countries tend to put the same emphasis on ecological and social issues [8, p. 30].

The purpose of the research that we are going to present is to analyse the progresses that different European countries made (computed macroeconomic approach based on corporate or organizational initiatives collected at the country-level) in order to accomplish the criteria and issues of ISO 26000.

Data: We collected and synthesized information about CSR trends, its key-drivers and current CSR focus in different European countries from the CSR Europe's publication (October 2010) "A Guide to CSR in Europe: Country Insights by CSR Europe's National Partner Organisations" [9].

Methodology: In order to obtain a clear view of the main focus on CSR key-drivers in European countries (see Table 2 and Table 3) and the progresses that countries made for adopting part of the issues presented in ISO 26000 standard, we tried to identify for each analysed country those specific ISO 26000 issues that are most frequent in the respective

country. The approach was a computed one, because the information was initially collected for the corporate level and then a national and regional pattern was identified. The common framework that we used for analysing the European countries was the one offered by ISO 26000. For the respective analysis we took into account only 22 European countries, not all of them members of the European Union: from the 24 countries presented and analysed in the CSR Europe's publication mentioned above we excluded Hungary and Scotland because we wanted to keep for the analysis only participative or observers countries in the elaboration process of ISO 26000 standard. The analysed countries were: Austria, Belgium, Croatia, Czech Republic, Finland, France, Germany, Greece, Republic of Ireland, Italy, Luxembourg, Netherlands, Norway, Poland, Portugal, Serbia, Slovakia, Spain, Sweden, Switzerland, Turkey, and United Kingdom.

Source: Authors' synthesis and adaptation using CSR Europe (2010, p. 6-87) and ISO 26000 information.

Results: The two tables (Table 2 – part 1 and Table 3 – part 2) offer a synthetic image of CSR achievements on each of the analysed countries, based on the common framework offered by ISO 26000.

Important achievements were made by the analysed countries in what concerns the 4th and the 7th core subjects of ISO 26000, respectively “The environment” and “Community involvement and development”. Moreover, for the most developed countries and Nordic countries, a special focus is put on “Human rights” (2nd core subject) and “Labour practices” (3rd core subject), confirming the results of the study of Steurer and Konrad (2009, p. 31). As one can easily observe from the two tables presented above (part 1 and part 2), there are some countries (e.g.: Germany, Netherlands, Norway, Sweden, Switzerland and even Spain) that are considering almost all the core subjects and associated issues of CSR. At the same time, in the publication “A Guide to CSR in Europe”, France is one of the most active countries (besides Switzerland) in specifically promoting the ISO 26000 standard. On the other hand, there still are European countries that do not put a great emphasis on CSR (they have already included it into their public policies and it lost its voluntary character or they do not consider it so highly important compared with other economic priorities of the moment).

5. Recommendations and Conclusions

Although, in general, companies and countries tend to consider the economic responsibility of CSR as the most important component, a special focus should be put on “Fair operating practices” (5th core subject) and “Consumer issues” (6th core subject) for coming closer to the recommendations of ISO 26000 standard.

For increasing the efficiency of CSR, specific necessities should be addressed at corporate, sub-sector or sector level and not at national or regional level, because of the highly CSR context dependence.

Finally, the responsible companies should correlate their CSR practices with their main object of activity for achieving unique competitive advantages.

As a conclusion, especially in the last decade, the European countries made consistent progresses in what concerns the implementation of CSR practices and their inclusion in the core business activities. The appearance of ISO 26000 will offer them a higher support in implementing and reporting procedures, which will generate higher benefits for the responsible companies in the European countries.

Comparative Study of Agro-Food Sector in Romania and EU-27

Ignat Raluca

Academy of Economic Studies, Bucharest

raluca.ignat@ase.ro

Abstract

Inside European Union confronted with an unbearable still raising unemployment rate, with a difficult situation of GDP/capita in all EU-27, all European stakeholders are determined to reach the goals of Europe 2020 Strategy. Romania is on seventh position on EU-27 top of agricultural land. If until 2007 Romanian farmer organised his production by tradition and own needs, now he has to manage his production according to the existing demand, he is forced to produce for market, according to European model.

The paper presents a comparative analysis of the agro-food sector between Romania, EU-27, and six European countries. The analysis emphasizes the poor results of Romanian agriculture and represents the key point of elaborating some measurements that national stakeholders should assume.

The research was run based on documentation, synthesis of data, statistical analysis and comparative analysis.

Key words: agriculture, agricultural output, agricultural holdings, comparative analysis, farm labour force

J.E.L. classification: Q10

1. Introduction

European authorities are in an ongoing process of building a more competitive European economy. The question still resists: is still possible to obtain economic performance in such shaking world?

In his speech on 7th September 2010 in front of European Parliament in Strasbourg, the President of European Commission, José Manuel Durão Barroso, presented The State of the Union 2010. With this occasion, he mentioned five challenges for the Commission for 2011:

- “dealing with the economic crisis and governance;
- restoring growth for jobs by accelerating the Europe 2020 reform agenda;
- building and area of freedom, justice and security;
- launching negotiations for a modern EU budget;
- pulling our weight on the global stage.”

In an European Union confronted with an unbearable still raising unemployment rate, with a difficult situation for GDP/capita in all EU-27, all European stakeholders are determined to reach the 2020 Europe Strategy. But, this seems to be harder and harder, still the EU-27 unemployment rate was 9.5% in January 2011, compared with 9.6% in December 2010. It was 9.5% in January 2010, while between 2008 and September 2010, 63 million persons lost their jobs and the employment rate for 20 to 64 years was 69%. Plus, “contraction in GDP wiped out on average four years of growth” (*Annual Growth Survey: Summary of the economic analysis and messages*, Brussels, 12 January 2011).

In order to reach Europe 2020 objectives, the European Commission plans for 2011 and ahead involve:

- creation of “European Vacancies Monitor”
- elaboration of “Platform Against Poverty”
- providing 6,4 billion euro for FP 7 Programme, for both researchers and business, especially for SMEs which offer 2/3 of the EU jobs;
- promotion of Southern Corridor as a possibility to provide Europe’s energy supply security;
- development of a forward-looking agriculture in order to provide food security, sustainable management of

natural resources, and to fight against biodiversity loss.

Starting this goal of the Commission, I analyse and compared indicators of agriculture and agro-food sector in several countries, including Romania and EU-27.

2. Romanian agriculture and agro-food sector against some European best practice

Romania is on seventh position on EU-27 top of agricultural land, after Spain, France, Great Britain, Italy and Poland and the fifth position on EU-27 top of arable area, after Spain, France, Germany and Poland (www.madr.ro, accessed on 3rd of December 2010). Romanian rurality has a great importance within national economy, given its main characteristics: the wealthy of natural and human resources. Natural resources were used, as Romania has a long tradition in agriculture, its soil being used especially for cereals. Still, the economic performance of this sector is absolutely missing.

After 1989, Romania has known structural changes with major economic and social impact. Transition to market economy seems for Romania, somehow, an ongoing failure. Still, numerous laws and regulations were promulgated in order to regulate national economy and to support rural activities.

The EU integration represents for Romanian rurality and agriculture and their specific activities a decisive moment in order for them to modernise and become more competitive. If until 2007 Romanian farmer organised his production by tradition and own needs, now he has to manage his production according to the existing demand. Therefore, he is forced to produce for market, according to European model.

Step by step, once the pre-adhesion and structural funds were accessed, Romanian economy, in general, and agriculture, specially, ameliorated the values of the macroeconomic indicators.

Because the existing restrictions of Romanian rural area are so important, the rural economy is the weak chain of national economy. But the absolute potential of this area may be the start point of so much wished and expected development. And agriculture, the dominant part of this area, may be the focal point of this development.

On the other hand, EU agriculture has performance and competitiveness. The gross added value has considerable values, while this sector's contribution to GDP respects the structure of a healthy economy.

Table 1. Agricultural holdings in comparison

	Number of agricultural holdings (1 000)			Holdings with dairy cows (1 000)			Holdings with irrigable area (% of UAA)

http://epp.eurostat.ec.europa.eu/cache/ITY_OFF_PUB/KS-CD-10-220/EN/KS-CD-10-220-EN.PDF, accessed on 9th of March 2011

Romania has almost half (48%) of the total number of small agricultural holdings in EU-27, around 6.4 million. The small agricultural holdings have less than 1 ESU (European Size Unit, 1 ESU=1200 Euro" (www.insse.ro, accessed on 15th of March 2011). As response to this situation, both small agricultural holdings and commercial agricultural holdings in Romania increased its average surface, as shown in the following table.

Table 2. Average surface of agricultural holding in Romania, between 2002 and 2007

Agricultural holding	2002	2005	2007
Agricultural holding	3,1 ha	3,3 ha	3,5 ha
Small agricultural holding	2,3 ha	2,2 ha	1,7 ha
Commercial agricultural holding	270,5 ha	263,1 ha	274,4 ha

Source: www.insse.ro, accessed on 15th of March 2011

The total number of agricultural holdings decreased with 8,8% in EU-27 between 2003 and 2007, because of several structural changes in Estonia. In the same time, many of the commercial agricultural holdings in Portugal, Bulgaria and Hungary finished their activity and determined an importance diminution of the total EU-27 number of this type of holdings. Therefore, the total number of commercial agricultural holdings in EU-27 was 7,3 million in 2007.

The total farm labour force in EU-27 in 2007 was around 11,7 million persons, the majority of them, 92% were involved in the activity of commercial agricultural holdings.

Table 3. Farm labour force, 2007

	Total farm labour force (1 000 AWU) (1)	Regular farm labour force (% of total)	Full-time regular farm labour force (% of total)
UE - 27	11 693	92	34
Bulgaria	491	95	38
France	805	89	67
Germany	609	91	50
Hungary	403	97	25
Poland	2 263	97	34
Romania	2 205	93	4
Spain	968	82	42

Source: Europe in figures, Eurostat yearbook 2010, http://epp.eurostat.ec.europa.eu/cache/ITY_OFFPUB/KS-CD-10-220/EN/KS-CD-10-220-EN.PDF, accessed on 9th of March 2011

Romania's contribution to European total farm labour force is 18,8%, while Poland's contribution is 19,4%, France's is 6,89%. It is remarkable that the western countries gather

small population in this sector and accomplish superior economic results, as seen in Table 4.

Crop output and animal output represent the main parts of the agricultural output. The analysis took into consideration three years, 1998, 2003 and 2008. In all the studied countries, the crop output, the animal output and, obviously, the gross value added of the agriculture industry knew slightly small diminution in 2003 against 1998, except Romania and Spain. The 2008's values rose much higher than the other both analysed years. The most interesting fact is to see that Romania with its potential and advantages has such a small gross value added of the agricultural industry.

Table 4. Agricultural output at producer prices (mil eur), 2007

	Gross value added of the agricultural industry			Crop output			Animal output

Index of income from agricultural activity represents the real income of factors in agricultural activity per annual work unit (Europe in figures, Eurostat yearbook 2010, accessed on 9th of March). Year 2005 has the initial value. We may see that between 1998 and 2008 the income from agricultural activity knew superior values. This proves an increasing efficiency of the agricultural process. This is the case of Bulgaria, France, Germany, and Poland. Romania lost of its efficiency and obtain lower values of the income from agricultural activity.

Table 5. Index of income from agricultural activity (2005=100)

	1998	2003	2005	2006	2007	2008
Bulgaria	-	86.4	100	96.0	98.5	127.0
France	117.8	106.8	100	110.4	122.2	109.4
Germany	70.7	76.1	100	104.8	125.7	116.6
Hungary	92.8	63.0	100	111.7	120.0	142.4
Poland	69.3	58.5	100	110.4	135.1	111.3
Romania	104.6	106.9	100	99.3	78.8	101.2
Spain	106.4	123.1	100	95.6	100.5	98.0

Source: Europe in figures, Eurostat yearbook 2010,

http://epp.eurostat.ec.europa.eu/cache/ITY_OFFPUB/KB/CD-10-220/EN/KB-CD-10-220-EN.PDF, accessed on 9th of March 2011

In year 2008, the best value belongs to Hungary, while Spain has the lowest value of this indicator. Thus, the values diminished in 2008 against 2007, in the case of France, Germany, Poland and Spain. The Romania values just emphasize once again the situation of its sector. It is incapable of obtaining higher values in this sector, even if it has so many and important advantages.

3. Conclusion

The analysis demonstrates once again the lower economic performance of Romanian agriculture, while European countries improve their results each year. It is obviously that Romanian rurality and agriculture confront major challenges:

- a poor infrastructure of roads, railway, public services, water and canalization, modern and adapted information;
- a weak manifestation of entrepreneur spirit which determines a high unemployment rate and a fragile jobs' offer;
- an unbalanced access in time and space of pre-adhesion and structural funds which determines economic and social differences;
- a high subsistence and semi-subsistence sector of agricultural holdings;

- a poor endowment of those agricultural holdings with specific equipments;
- a high percentage of self-consumption especially within individual agricultural holdings;
- a high numeric difference between individual agricultural holdings and commercial holdings.

In order for the country to obtain superior results and truly articulate its policy, immediate intervention in the sector need to be accomplished. The local and national authorities should:

- analyse the local and regional situation and interfere with state support where it is the case;
- improve the absorption of national and European funds;
- support local, regional and national traditional products;
- boost the private-public partnerships to built up new business in the sector;
- enhance the cooperation between individual agricultural holdings in order to integrate the production;
- create a legal framework to stimulate young and educated professionals to accommodate in rural area;
- provide chances for technological and knowledge transfer between research and practical agriculture.

An integrated policy of Romanian authorities and a coherent effort of all stakeholders may conduct to superior results of this traditional Romanian sector. This should determine economic growth and social welfare.

This approach may lead to a better understanding and management of the Europe 2020 goals, according to European behaviour.

Abstract

The present paper is a conclusion of several ideas and comments over the effects of the 2007-2009 economic crisis, revealed in mass media over the last sixth months. The main topics that authors considered are: A new professional code of ethics for economists is needed? There is a link between inequality and financial crisis? Which are the real understanding and knowledge about the financial system? How is the market viewed by the different companies? How the economic states influence the terrorism? How severe is the impact of weather over the economics? The authors must admit that they will not debate the presented subjects but emphasizes some aspects that will considered important.

In conclusion the authors considered that new policies, methods and new ways of defining and control economics should be used in order to observe and manage the global economic change.

Key words: crisis, code of ethics, growth, market.

J.E.L. classification: F01

1. Introduction

We consider this article more like a way to make known different point of view presented in specialized and known magazines like The Economist or Financial Times. The Romanian academic media must consider those views and develop policy and eventually regulation for preparing our country for the economic future.

There are new challenges, new threats and as we will see in this paper, present unknown issues that we must try to determine in order to avoid or be prepared for future crisis.

2. A New Professional Code of Ethics for Economists is Needed?

For the January 6th 2011 annual meeting of the American Economic Associations (AEA) close to 300 economists (among who will find George Akerlof – Nobel laureate and Christina Romer – heading Barrack Obama's Council of Economic Advisers) [1] sign a letter that urges the AEA to adopt a code of ethics for the economics profession.

The main issue of the code can be found in the conflict of interest that arises from the way that economist considered to express their opinion in matters that involved companies and industries with which they have financial interests.

There is no evidence that the economists' professional judgments are influenced by their financial interests. But questions regarding the way that the economist can offer their financial expertise reveals themselves.

The most common problem is that the non-academic affiliation of the economist is often unknown and what is more somehow disturbing is that economists rarely disclosure their affiliations.

Others (George DeMartino – University of Denver) [1] considered that many economists were too eager to impose the free-market policies ignoring the bases of economic theory.

The bottom line is that more and more voices demand for a change in how the ethics of economics are defined and applied.

3. There Is a Link Between the Inequality and the Financial Crisis?

Mr Raghuram Rajan, of the University of Chicago Booth School of Business, in his book "*Fault lines*", argues that the increased inequality – especially the political response to it – cause the financial crisis [5]. This was presented at this January meeting of the American Economic Association (AEA).

What is Mr Rajan logic to determine such an idea? The inequality starts from the technological progress that imposes the demands for skilled workers, because of the supply of skilled could not keep pace with the demand. This determines the gap of wages between them and the rest of the workforce. Here the politics intervene.

The politicians cannot let the poor and unskilled fell farther behind the skilled ones in the matter of level of living. And the easiest way to prop up the living standards were the credits for the poor. For example, American Fannie Mae and Freddie Mac were pressured to lend more to poorer people [5]. But this credit boom inflated the known housing bubble, whose collapse precipitated the financial crisis.

So according to Mr Rajna: "*well-intentioned political responses to the rise in inequality that many found disturbing ending up having devastating side effects*" [5].

But two prominent economists, Daron Acemoglu (Massachusetts Institute of Technology) and Edward Glaeser (Harvard University) considered Mr Rajna idea plausible but less flawless. Even so, Mr Acemoglu considers that there is a link, not causal, between the increasing inequality and the crisis.

So even not directly there is a link between the inequality and the financial crisis. And we have to consider that inequality is present anywhere in the world and looks to become more and more important.

This is important for Romania now because we are in the same case as such presented by Mr Rajna: there is a more and more inequality not only on wages grounds but even in standards of living.

4. Which Are the Real Understanding and Knowledge about the Financial System?

The policymakers today find themselves in almost the same situation as those from the Great Depression when America developed the national accounts and gross domestic product used for a better economy measure. Even that we have organizations with the goal to maintain financial stability, like European Systemic Risk Board or America's Financial Stability Oversight Council, the unknowns of crisis emerges from the current situation.

In order for a better control and an accurate view of the financial system the International Monetary Fund and the Financial Stability Board (FSB) defined new priorities.

- System-wide measures for borrowing activities and "maturity-mismatch";
- Links must be established between the major banks and the others organizations of the financial system;
- Determining data and information about the "non-bank financial firms that often slip below regulators' radar".

Also, a common reporting template was developed by the FSB in order to have a better view on the global banks and the exposure to different financial sector and national asset markets. The problem that can emerge from this is how to persuade the financial organizations to fill this template. Also there are legal issues and confidentiality that we should think about.

Other problems are imposed by the luck of data in certain financial sectors like the hedge funds, money-markets funds and over-the-counter derivatives.

But this huge amount of data will imply the necessary human and technical resources and also the intelligence to decide when and how to act.

5. How Is the Market Viewed by the Different Companies?

Who better can reveal the future situation of the financial market then two of the biggest financial firms like Goldman Sachs and Societe Generale (SocGen). Both kept meetings on January 17th in London.

Goldman Sachs team formally dressed and using book of graphs keep a long speech about a beautiful future. The SocGen team was dressed somewhere between "outward-bound course or a company disco" [5] used a small slide book which advise their clients to use for the future "umbrellas and gas masks" [5].

So here we have to different approaches of two very different predictions. While Goldman Sachs considered that the emerging economies (Brazil, Russia, India and China) will help a stronger than expected growth of global economy for this year, the Societe Generale outlook was fundamentally modified by the financial crisis of 2007-2008. In their view the central banks will try to keep the interest rate low so that asset prices will rise and the consumer confidence is restored. But this can result in another bubble and another bust.

So which group is right? How this views and outlooks will convince the investors? But more important how can be such a difference between the economic views of organizations from the same field?

6. How the Economic States Influence the Terrorism?

Barack Obama said: „Extremely poor societies ... provide optimal breeding ground for disease, terrorism and conflict" [4] in his speech in favor of more development aid to poor countries.

The idea is based on several conclusions made observing the last years of terrorism activities. The terrorist usually came from poor countries were the education systems are ill-financed and wrong implemented (ex. low literacy).

But people who don't have much to lose and generally are ill-educated can be found easily between the terrorist?

There is no evidence that sympathy for terrorism is greater among deprived people. But some argue that poverty could be at the root of terror even if the terrorist are nor themselves poor. [4]

Several research shows that poor countries or countries with poor literacy or countries were the economies are relatively stagnant did not produce more terrorists. And contrary to the expectations the suicide-attackers came not from very poor countries.

What link the poorest countries with the terrorism might be explained especially through the means of education. A certain level of education makes it more likely that that people will become more politicized. But this level of education isn't it in relationship with economic value of the country?

But even this consideration was modified in time. The terrorist organizations are recruiting more educated suicide-bombers for more important targets.

So considering that more educated terrorists are more effective means in the other words that the economic conditions can and does influence the terrorism effectiveness. A collection data (recorded by Esteban Klor – Hebrew University in Jerusalem and Messrs Benmelech and Berrebi) regarding the suicide-attackers between 2000 and 2006, determined that because of high unemployed rate in Palestine the terrorist organizations can recruit more educate, mature people.

Maybe the terrorism is not the best reason to promote the economic development in comparison with civil and political rights for example. But if we add to the terrorism the level of crime or the corruption we can definitely considered that the economic status of a country can influenced the peace even on global level.

7. How Severe Is the Impact of Weather Over the Economics?

The snowstorms and freezing weather in the week before last Christmas closed down many cities and airports from the eastern coast of America and much of the Europe. The economical statistical results of this winter phenomenon can be seen in numbers as follows:

- in Germany the country's industrial production shrank by 1.5% and the construction results decline with 24%;
- in Britain the Gross Domestic Product (GDP) fall by 0.5% for the last quarter of 2010 because of the December bad weather.

A British trade group – Federation of Small Businesses (FSB) estimate that the British economy lost £1.2 billion for each day of snow. The group based its calculation on the "one-fifth or so Britain's workers who

it reckons did not make it to the office, the factory or the building site" [3] during the snowy days.

Considering that the data are exaggerating and the calculus were wrong, we cannot deny the facts that the bad weather affects the economy. Also this is happening at the end of the economic crisis establishing the grounds for delaying the recovery. So even we can question the methods, the database or the time scale used for the statistics we should consider the consequences of this phenomenon. Because we are talking about the global economy the effects are seen not only on local area but also on other regions (ex. the Heathrow closing forecourts of terminals).

So the question is which can be done to avoid such financial problems?

8. Conclusions

As we can see above that the crisis of 2007-2008 raises several important questions about the way that the global economy is observed, measured and controlled. Also the crisis revealed situations and problems that the world of economics was not prepared for and how the first reactions at the first sign of crisis were more political than economical.

We considered that a new code of ethics for economists is needed and more important new means of measuring and controlling the global economy and its performers.

Abstract

The major changes that took place in the last decades in the European economic environment, prompted by the deregulation of the financial markets, the European integration process and lately by the financial crisis started in 2007 have determined also shifts in the corporate governance models used at European level. In this context it is only fitting to raise the question about the existence of a convergence process toward a single European corporate governance model. Our research aim is to provide an overview of this subject through a qualitative analysis based on a comparative approach between the two main models of corporate governance that exist at the European level. Through this approach we will not only compare the two models but also underline the factors that contributed to a possible convergence of the two models and also the ones who tend to hinder any closeness.

Key words: corporate governance model, European Union, integration process, financial crisis

J.E.L. classification: G23, G30, G32

1. Introduction

Institutional investors have become starting with the 1980 and the Big Bang of the London Stock Exchange relevant international investors. The importance of this type of investors derives from their role in the dynamics of the international financial markets and the fact that they tend to own significant blocks of the shares in the firms in which they invest.

Pensions and mutual funds are the most active and important types of institutional investors on the international financial markets. Despite the fact that their product lines and investment processes tend to be different and must obey different types of rules and regulations, these investors tend to manifest a high level of investment homogeneity, mainly because their interests and financial demands tend to coincide on key issues. This is most relevant in the case of the reforms undertaken in the last decade at European level regarding corporate governance issues, as most of these were undertaken taking into consideration the specificities of the US mutual and pension funds, which represent the main institutional investors in the European financial markets.

The power of the institutional investors derives from their massive financial assets that they manage – approximately 40,329 billions of dollars in 2005 according to OECD data. Still, their geographical distribution tends to be very unbalanced as almost 51,84% of them are located in the US, while only 17,93% in Japan, 8,42% in the UK, 5,73% in France and 5,63% in Germany.

Graphic 1 – The evolution of the value of the financial assets owned by institutional investors between 1995 and 2005

Source: Own simulation based on OECD data

The academic literature identifies three major factors which have led to these developments. First of all, the world wide deregulation process that has characterised the mid 90 and the first years of the last decade has led to an unprecedented development of the financial markets, especially as a result of the removal of the barriers that hindered the free flow of the capitals across borders.

Secondly, the expansion of the western economies which has been mainly financed through an increase of the public deficit financed through the issuing of governmental bonds, which carried little risks, started at the end of the 1980. Taking advantage of the globalisation process, most of the European governments have considered the opportunity to finance restructuration and development programs through the financial markets and especially by attracting foreign investors. Nevertheless, also the massive privatisation programmes started in the eighties and continued through the nineties especially in Central and Eastern Europe have played a decisive role in attracting mutual and pension funds from the US on the European financial markets.

Nevertheless, the long time period in which financial assets rose, started in the mid 1990 and continued until the start of the financial downturn in 2007, represented for investor an incentive for an aggressive policy regarding their international portfolios. This evolution was also sustained by the favourable changes that occurred in the taxation policy regarding capital gains. On the other side, the high uncertainty regarding the way in which retirement pensions will be financed determined employees to increase their own saving plans. Also, the development of the stock markets in eastern and central Europe has been a key factor in the development of mutual funds in these markets, despite the fact that the investment tradition in these countries has been inhibited for a long period of time. A key element in these developments was played by the fact that the government has used the privatisation of the traditional infrastructures to attract foreign investors which have helped the development of the local stock markets, which have provided households with an alternative saving and investment opportunity beside the banking sector.

The development of institutional investors has triggered a shift in the way the capital of the major firms is distributed among shareholders. In France or Germany large blocks of share were held by friendly companies who through different combinations controlled these companies. As institutional investors have become more important, these blocks of share have been transferred from these friendly companies to institutional shareholders.

This trend has started in the 1990 and in many European countries corporate capital was transferred from the ownership of a few individual or strategic shareholders to large independent institutional investors, which tend to own a limited amount of these shares rather than large blocks. As an effect of these transformations cross-shareholdings and the use of dual classes of share has diminished considerably in Europe in the last two decades. Also, taking into account all these, many European Union countries have undertaken law reforms regarding corporate governance issues, to better suited the rules and regulations in place to the new environment and to raise the attractiveness of national companies to outside investors.

2. Different Models of Corporate Governance

If we take into consideration the definition of corporate governance than this relates with the separation between ownership and management in large corporations, underlying the way in which different interest groups or stakeholders are able to influence the corporate decision making process. If we take into consideration the two main classifications of the financial systems (systems dominated by the banks or systems dominated by the financial markets) then corporate governance presents two distinctive models – the shareholder model (which is based on external control exercised by shareholders) and the stakeholder model (which is based on internal control exercised by various parties which have an interest in that specific firm: e.g. local authorities, employees, creditors, banks, etc). The classification of corporate governance main seem stiff if it is reduced to only these models, as in reality there is a variety of models which are between the two extremes.

But still, the model of corporate governance adopted by the firm will tend to be focused on one of the two models, either by trying to maximize the market value of the firm or by satisfying the demands of all the parties involved.

2.1. The Shareholder Model Type

In regard to the shareholder model, this model tends to characterize especially the Anglo-Saxon countries. Despite the fact the corporate governance models from the US and the UK fall into this category they tend to be extremely different between them. Thus, the firm's main goal is to maximize the wealth of its shareholders and its market value represents most of the time the sole indicator of the management performances. In this context, corporate governance tends to be associated with the principal-agent theory. The managers tend to be very well remunerated and in a position of great power when opposed to the dispersed shareholders. Thus, the access to information tends to be very unequal between these two categories, as the costs that the principals (the shareholders) must cover in order to control and react to their agents' decisions (the management) can be very high.

In this case the main referees of the firm's performances are in the market. They are outsiders as they do not have direct access to the firm's information or can influence its decisions. In this situation the possible opportunistic behaviour of the management team is regulated by outside forces especially through the takeover market (Jensen & Meckling, 1976). In the case that the economic performances of the firm decline the shareholders have little interest at the individual level, or little means of actions, to intervene. Especially in the case of individual investors, these tend to have a relatively small stake in the company and thus, do not possess the necessary financial power to invest in monitoring operations.

In the case that these shareholders would invest in such activities there is the possibility that the benefits could be used by others freely (free riders). If the shareholders hold a diversified portfolio on a developed and liquid stock market then they have the possibility to sell their participation in these opaque firms and thus make them possible

targets for hostile takeovers. If this treatment seems real enough it could be a good incentive for the manager to rethink their strategies and concentrate more their activity in enhancing the wealth of the shareholders. If not, then the company could become the target of a raider or a competitor who will seek to acquire it and replace the current inefficient management team. The new owners will seek to raise the stockholders' value through strategic restructurings and by improving the operational efficiency of the firm.

2.2. The Stakeholder Model Type

In the case of the stakeholder model the capital structure of the firm is divided among very few stockholders who tend to have the control. In general these large stockholders (for example banks in Germany or financial and industrial corporations in France) tend to protect the management team against hostile takeovers. The managerial process is based on the fact that these privileged stockholders have access to inside information and can influence the decision-making process.

Despite the fact that Berle and Means (1932) tend to be presented as the first ones who developed the shareholder model, the fact that their thesis emphasises the importance of the firm's management to create not only added value for the shareholders but also for its employees, customers, suppliers and the community in which they are active, thus emphasising the core concepts of the stakeholder model. This model tends to be more familiar to continental European firms which tend to take into account more the impact that their decisions and actions influence different parties. Moreover the firm is considered to have a *de facto* obligation to these different involved parties.

One of the main characteristics of this model is represented by the fact that hostile takeovers are very rare and moreover long-term relationships tend to form between the firm and different financial institutions. In this case the financial market does not function as a transparent tool for the minority shareholders. Also, the company tends to become part of networks that will allow the development of long-term commercial relationships with both customers and suppliers. The typical example of this type of

relationships is represented by the German capitalism model, which relies on a tight relation between banks, industry, government, syndicates and the civil society.

3. Convergence Factors

Despite the fact that financial globalisation tends to manifest itself differently in every country the free circulation of capitals has become a common characteristic for this process. Alongside this, the adoption of the single European currency represents a strong factor of the integration and convergence process at least at EU level.

The globalisation process has been also accompanied by a series of structural changes. As a result of these, the investments management process has become more professional, even in the case of the banks and insurance companies from continental Europe. The asset management departments have been generally externalised allowing them to more pro-active and seek better investment opportunities (e.g. avoiding constrains that derive from the relationship between banks and industry in Germany or the existence of cross-holdings in the case of French companies). Also financial analysts have become more specialised, the country approach being gradually replaced by the sector approach.

We cannot argue that financial markets cannot impose their views and requests on firms, but in the last decades it has become clear that the latter are in no position to neglect the requirements that come from these markets (e.g. the need to use a standard international financial communication policy).

We must also take into consideration that the internationalisation of firm's does not represent a new phenomenon. Many corporations had been present at international level even at the beginning of the twentieth century. It is arguably that the first wave of the internationalisation process can be attributed to the entry strategies which allowed outside firms to break into local monopolies. Every national market has been independently regulated by the local governmental authorities in regard to the organisation of the competition. This characteristic was so deeply rooted that the European integration process has triggered o

series of major industrial and commercial reform in every country of the Union in regard to the competition laws and regulations (Ponssard, 1997).

Nowadays, the situation has changed allot. Firms, tend to develop more broad strategies, covering vaster geographical areas, sometimes taking a directly global approach. These approaches have created global interlinks and networks which have allowed not only the transfer of tangible and financial goods and assets but also of know-how and information. In this context, firms become more globally, developing little by little an internal culture that breaks away from the national customs and adopts more broad international standards (e.g. the board of directors tends to include foreign people, the human resources department adopts a global recruiting strategy, etc).

Nevertheless, political and governmental authorities, when faced whit these types of developments tend to adopt one of the two approaches: either they directly interfere in the process or try to become a part of the new regulatory forces, which manifest themselves this time not at national but at regional or international level (e.g. at European level or globally).

Despite all these the evolutions are still hesitant. There are still many cases where strong public reactions have lead to direct interventions from governmental authorities in the internal affairs of private firms (e.g. in the Danone case in France or Nokia in Germany). Despite all this, it has become obvious, especially in the aftermath of the financial crisis stated in 2007, that governmental bodies and political forces have the capability of organising themselves at an international level in order to counteract the deficiencies of the economic forces.

These changes have are having direct links to corporate governance issues, as they tend to: enable the establishment of standard prudential rules (which are mainly designed to prevent excessive risk taking by investors), enhance the usage of internationally harmonised accounting rules, leading, at least at the European level to a harmonisation process of the corporate laws and their adjacent fiscal policies and nevertheless the development of benchmarks which facilitate the analysis of the corporate governance evolution in different countries (e.g. the way

in which minority rights are enforced).

4. Divergent factors

There are also a series of factors which hinder the development of a common corporate governance model, mainly because these rules cannot be exported as they are from one country to another. One of the main reasons is represented by the differences that exist in the economical, juridical and social framework of each country, even in the European Union.

While the US system recognise that the social interest of the firm is one and the same as that of the shareholders, the European approach considers the firm a institution of stakeholders, in which all the involved parties (management, employees, suppliers, costumers, public authorities and civil society) have an interest that must be reflected in the organisation and behaviour of that firm.

Taking these into consideration we can argue that in the case of the Anglo-Saxon approach to corporate governance the rules and regulation are abundant and emancipated, underling exactly what the legal implications are while in the case of continental Europe the approach relies more on principals which need to be respected, following the belief that substance prevails over form.

5. Conclusions

Most of the academic literature emphasises that in any scenario the most efficient institutional framework will prevail in time. In the current economic environment the discussions about corporate governance models in the European Union are emphasising the pressures that the financial markets are putting on the abandoning of the stakeholder model, which tends to address the requests of a large panel of interested parties and the adoption of a shareholder model, which tends to be more focused only on the requests of that come from a single direction. Despite this, it has become obvious that the switch between the two models is not a simple matter of importing regulations, as most evolutions, even in the case of corporate governance tend to be related to path dependency issues. This underlines the fact

that the development of a common European corporate governance model is far from being a straight forward road, as the development and changes in corporate governance rules and regulations still depend in a great deal to national driven factors and decision makers.

Methods of Forecasting the Market Evolution Case Study on the Romanian Insurance Market

Ionci  Maria
Petrescu Eva-Cristina
Petrescu Marian

Academy of Economic Studies, Bucharest
eva_petrescu@yahoo.com

Abstract

There are various methods of evaluating and forecasting the evolution of a market, each method having advantages and disadvantages. In this paper we shall present and exemplify on the case of the Romanian insurance market some statistical methods: average growth method, linear trend method and Markov chain.

Key words: average growth method, linear trend method, Markov chain, insurance density, insurance penetration

J.E.L. classification: M31, G22

1. Introduction

The forecast constitutes the final goal of marketing research [1].

To forecast the market evolution we can choose from a large number of forecasting methods. The different methods have different degrees of complexity: from simple methods (intuitive judgments) to complex methods that use statistical techniques.

The theoretical literature and the practical use of forecasting methods have established there are two major categories of methods: quantitative and qualitative methods. The quantitative methods consider that variables are in permanent change, but history is repeating to a certain degree, and the best way of prediction relies on the identification of the liaison between the predicted variables and the time variable or between the predicted variables and other variables. [2]

The qualitative methods are based on the information obtained from specialists. Those methods are not based on the hypothesis of the constancy of the configuration, or on the

historical information about the variable studied, but the qualitative methods assume that in future there will be new, unexpected events from the environment of the studied variable. [3]

The quantitative methods of forecast can be classified function of the types of models used: dynamic series analysis methods and causal methods. The dynamic series analysis methods are endogenous methods that are based on the study of the past evolution of variables and on the identification of the specific of the series and on the extrapolation in the future of the data. The causal methods are exogenous methods that are assuming a cause-effect relation between the variables for which the forecast is realized and one or more independent variables. [4]

In the opinion of marketing specialists, the common forecasting techniques fall into five categories: executive judgment, surveys, time series analysis, correlations methods and market tests. [5]

The time series analysis supposes that the forecaster tries to discover a pattern in the historical data and the method assumes that the pattern will continue in the future.

The analysis of the insurance market can be realized using a series of indicators, among which the most important are: the volume of gross written premiums in insurance contracts, insurance penetration in the economy, the insurance density, the number of insurance contracts, the structure of the market, the number of insurance companies, the market share of insurance companies, the rate of market growth etc. [6]

In this paper, we have used in the prediction of the Romanian insurance market the following indicators: the volume of gross written premiums in insurance contracts, the insurance penetration in economy, the insurance density and the market structure

(by percentage in life insurance and general insurance).

The quantitative methods used in this paper for forecasting the insurance penetration in Romanian economy and the insurance density are the average growth method and the linear trend method.

The structural changes on the market can be analyzed and predicted by using the Markov chain method. [7] Therefore, in order to estimate the future structure of the Romanian market, we have used the Markov chain method.

2. The main characteristics of the insurance market in Romania

The insurance market in Romania is a developing market. Insurance demand is concentrated in areas of above-average economic activity, the supply is varied and the competition is increasing.

The evolution of the satisfied demand on this market is reflected by the evolution of the volume of gross written premiums in insurance contracts (see Table 1).

Table 1. Development of the volume of gross written premiums in insurance contracts 2002-2009

Years	Volume of gross written premiums (lei)	Volume of gross written premiums (mil. Euro)
2002	1,914,534,300	548.00
2003	2,673,816,291	650.29
2004	3,476,543,926	876.52
2005	4,417,165,819	1,201.26
2006	5,729,284,541	1,694.20
2007	7,175,789,699	2,033.83*
2008	8,936,286,505	2,242.48**
2009	8,869,746,957	2097.86***

Sources: [8], [9], [10], [11], [12], [13], [14], [15], [16], [17]

*Computed function of the leu/Euro exchange rate from the 31st December 2007: 3.582,

** Computed function of the leu/Euro exchange rate from the 31st December 2008: 3.985

*** Computed function of the leu/Euro exchange rate from the 31st December 2009: 4.228

The data from the Reports of CSA (Insurance Supervisory Commission) shows that between 2002 and 2008, the volume of gross written premiums in insurance contracts has increased from 548 million

Euros to 2,242.48 million Euros, but since 2009 the market decreased.

Till 2008 the market has increased, but due to the crises in 2009 compared to 2008 the volume of gross written premiums in insurance contracts has registered a real decrease of -5.24% (see Table 2).

Table 2. The growth of the volume of gross written premiums in insurance contracts 2002-2009

Years	Nominal growth compared to the previous year (1)	Inflation Rate (2)	Real Growth (3)=(1)-(2)
2002	-	17.8%	-
2003	39.60%	14.1%	22.40%
2004	30.02%	9.3%	18.96%
2005	27.07%	8.6%	17.01%
2006	29.70%	4.8%	23.68%
2007	25.25%	6.57%	17.53%
2008	24.53%	6.3%	17.15%
2009	- 0.74%	4.74%	-5.24%

Sources: [8], [9], [10], [11], [12], [13], [14], [15]

The evolution between 2002 and 2009 of an important indicator for the insurance market: the insurance penetration in the economy is presented in Table 3. In this period, the insurance penetration in the economy has recorded a slow growth. If in 1996, insurance penetration in the economy was of 0.51%, in 2002 the indicator exceeds the 1% level. In 2009, insurance penetration in the economy was calculated as being the gross written premiums from direct insurance-to-GDP ratio and it was of 1.8%.

Table 3. Development of insurance penetration in Romania in 2002-2009

Years	Gross written premiums (lei)	GDP (billion lei)	The degree of insurance penetration (%)
2002	1,914,534,300	151.2	1.27%
2003	2,673,816,291	189.1	1.41%
2004	3,476,543,926	238.7	1.46%
2005	4,417,165,819	287.2	1.54%
2006	5,729,284,541	342.4	1.67%
2007	7,175,789,699	404.7	1.77%
2008	8,936,286,505	504.9	1.77%
2009	8,869,746,957	491.3	1.80%

Sources: [8], [9], [10], [11], [12], [13], [14], [15]

Although recording an increase compared to the previous years, insurance penetration in the economy stays at a low level compared to values recorded in Central and Eastern European states (between 3 and 5%) or to the values recorded in developed countries in the European Union, of over 8%.

The gap compared to developed countries in the EU of insurance penetration in Romania is significant. To estimate the period necessary to reach the level of countries with a developed insurance market, we shall use the average growth and the trend methods.

Another important indicator for the insurance market is the insurance density. The insurance density represents the volume of gross written premiums in insurance contracts per person.

The evolution between 2002 and 2009 of the insurance density is presented in Table 4.

Table 4. Insurance density

Years	Population (million persons)	Insurance density (Euro/person)
2002	21.79	25.14
2003	21.73	29.92
2004	21.98	40.44
2005	23.50	55.59
2006	19.87	78.56
2007	20.19	94.23
2008	21.30	104.28
2009	21.46	97.75

Sources: [8], [9], [10], [11], [12], [13], [14], [15]

Till 2008 the insurance density has increased arriving at 104.28 Euro / capita, but in 2009, due to the economic crisis, the insurance density has registered a decrease.

3. The average growth method for forecasting insurance penetration

According to the average growth method, the annual average growth of insurance penetration was of 0.08% in the period 2002-2009.

We have used the following formulas:

$$\bar{\Delta} = (y_n - y_1) / (n - 1)$$

where:

$\bar{\Delta}$ = the average growth

y_n = insurance penetration in the last year

y_1 = insurance penetration in the first year

n = the number of years

$$\sigma = \sqrt{\frac{\sum (y_i - \tilde{y}_i)^2}{n}}$$

where:

σ = the average square deviation of the adjusted series compared to the real series

y_i = the real values of the series

\tilde{y}_i = the adjusted values of the series

$$\nu = \frac{\sigma}{\bar{y}} \cdot 100$$

where:

ν = the variation coefficient

\bar{y} = the average of the series = $\sum y_i / n$

Table 5. The average growth method – forecast regarding insurance penetration

Years	The degree of penetration y_i	\tilde{y}_i	$(y_i - \tilde{y}_i)^2$
2002	1.27	1.27	0.0000
2003	1.41	1.35	0.0036
2004	1.46	1.42	0.0016
2005	1.54	1.50	0.0016
2006	1.67	1.57	0.0100
2007	1.77	1.65	0.0144
2008	1.77	1.72	0.0025
2009	1.80	1.80	0.0000
Total	12.69		0.0337
2010		1.88	
2011		1.96	
2012		2.04	

Source: computed

$$\bar{\Delta} = (1.8 - 1.27) / 7 = 0.0757$$

$$\sigma = \sqrt{0.0337 / 8} = 0.0649$$

$$\bar{y} = 1.586$$

$$\nu = 4.09\% < 5\%$$

Using this method for forecasting, in 2011 the insurance penetration will be 1.96%, in 2012 of 2.04%, and it would follow that in approximately 77 years, we could reach, if the current trend continues, a 8% level of insurance penetration.

4. Trend method for forecasting insurance penetration

In the case of the *trend* method, to choose the function for adjusting we will first represent in a graphic the evolution of insurance penetration (see Figure 1).

Figure 1. The evolution of insurance penetration in Romania in 2002-2009

Sources for data: [8], [9], [10], [11], [12], [13], [14], [15]

According to the graphic representation, we shall use the linear trend method, the evolution of insurance penetration recording an approximately constant growth in the period analyzed.

Table 6. Linear trend method – forecasting insurance penetration

Years	y_i	x_i	x_i^2	$x_i y_i$	\tilde{y}_i	$(y_i - \tilde{y}_i)^2$
2002	1,27	-7	49	-8.89	1.31	0.0016
2003	1.41	-5	25	-7.05	1.39	0.0004
2004	1.46	-3	9	-4.38	1.47	0.0001
2005	1.54	-1	1	-1.54	1.55	0.0001
2006	1.67	1	1	1.67	1.62	0.0025
2007	1.77	3	9	5.31	1.70	0.0049
2008	1.77	5	25	8.85	1.78	0.0001
2009	1.80	7	49	12.6	1.86	0.0036
Total		0	168	6.57		0.0133
2010					1.94	
2011					2.01	
2012					2.09	

Source: computed

$$y_i = a x_i + b$$

where:

y_i = insurance penetration in the year „i”

x_i = values corresponding to the year „i”

a, b = coefficients

$$a = \sum x_i y_i / \sum x_i^2 \rightarrow a = 6.57/168 = 0.039$$

$$b = 1.586$$

$$\sigma = \sqrt{0.0133/8} = 0.04077$$

$$V = (0.04077/ 1.586)100 = 2.57\% < 5\%$$

The method adjusts well the data series and can be used for forecasting.

Function of the equation: $y_i = 0.039 \cdot x_i + 1.586$, the forecast of the insurance penetration indicates the following values: 2011: 2.01%, 2012: 2.09%. When forecasting by using this method we have reached the same conclusion as in the case of the previous method.

5. The average growth method for forecasting insurance density

The evolution between 2002 and 2009 of insurance density is presented in Table 7.

Table 7. The average growth method – forecast regarding insurance density

Years	Insurance density	\tilde{y}_i	$(y_i - \tilde{y}_i)^2$
2002	25.14	25.14	0.0000
2003	29.92	35.51	31.2481
2004	40.44	45.88	29.5936
2005	55.59	56.26	0.4489
2006	78.56	66.63	142.3249
2007	94.23	77.00	296.8729
2008	104.28	87.38	285.6100
2009	97.75	97.75	0.0000
Total	525.91		786.0948

Source: computed

Using the data from Table 7 we have obtained the following values:

$$\bar{\Delta} = (97.75 - 25.14) / 7 = 10.37$$

$$\sigma = \sqrt{786.0984 / 8} = 9.9127$$

$$y = 65.73875$$

$$V = 15.1\%$$

6. Trend method for forecasting insurance density

In the case of the *trend* method, to choose the function for adjusting we will first represent in a graphic the evolution of insurance density (see Figure 2).

Figure 2. The evolution of insurance density in Romania in 2002-2009

Sources for data: [8], [9], [10], [11], [12], [13], [14], [15]

Table 8. Linear trend method – forecasting insurance density

Years	y_i	x_i	x_i^2	$x_i y_i$	\tilde{y}_i	$(y_i - \tilde{y}_i)^2$
2002	25.14	-7	49	-175.98	21.39	14.0625
2003	29.92	-5	25	-149.60	34.06	17.1396
2004	40.44	-3	9	-121.32	46.73	39.5641
2005	55.59	-1	1	-55.59	59.40	14.5161
2006	78.56	1	1	78.56	72.07	42.1201
2007	94.23	3	9	282.69	84.75	89.8704
2008	104.28	5	25	521.40	97.42	47.0596
2009	97.75	7	49	684.25	110.09	152.2756
Total		0	168	1064.41		416.608
2010					122.76	
2011					135.43	
2012					148.10	

Source: computed

$$a = 6.336$$

$$b = 65.739$$

$$\sigma = \sqrt{416.608/8} = 7.21637$$

$$V = 10.98\%$$

The forecast was made through the linear trend method because the smallest variation coefficient was obtained by using this method, reaching the following estimates of insurance density: approximately 135 Euro / person in 2011; 148 Euro / person in 2012.

7. Markov chain

Andrey Andreyevich Markov discovered a mathematical system that transits from one state to another in a manner similar to the chain. The statistical models were called after him and the Markov chains are frequently used in economy due to their numerous applications.

In Table 9 the evolution of life-insurance and general insurance on the Romanian market is presented. We can notice that the

most important contribution to the total volume of gross written premiums from insurance came, on the whole period analyzed, from general insurance. In 2009, the general insurance sector represents 81.64% of the total volume of written premiums and life insurance sector represents 18.36% of the total volume of written insurance premiums.

Table 9. Development of gross written premiums from life-insurance and general insurance 2003-2009

Years	Total insurance mil. Euro	Life Insurance (LI) %	General Insurance (GI) %
2002	548.00	22.96	77.04
2003	650.29	23.19	76.81
2004	876.52	21.98	78.54
2005	1,201.26	23.50	76.50
2006	1,694.20	19.87	80.13
2007	2,033.83	20.19	79.81
2008	2,242.48	20,90	79,10
2009	2097.86	18,36	81,64

Sources: [8], [9], [10], [11], [12], [13], [14], [15]

In order to study the evolution of the structure of the Romanian insurance market we have used statistical methods such as the Markov chain.

Table 10. Transition matrices 2007-2008

	LI	GI	2007	
LI	20.2	-	20.2	-

Total	39.3	160.7	200.0

Source: computed

The transition probabilities matrix is:

$$\begin{pmatrix} 0.93917 & 0.06083 \\ 0.00441 & 0.99559 \end{pmatrix}$$

The calculation of the forecasting structure of the Romanian insurance market for 2011:

$$\begin{pmatrix} 0.93917 & 0.00441 \\ 0.06083 & 0.99559 \end{pmatrix} \begin{pmatrix} 18.4 \\ 81.6 \end{pmatrix} = \begin{pmatrix} 17.64 \\ 82.36 \end{pmatrix}$$

In conclusion, for 2011 the forecasted structure of the insurance market using the Markov chain method is: life insurance 17.64%, general insurance 82.36%.

8. Conclusion

The statistical methods presented in this paper have the advantage that using existing information concerning the Romanian insurance market we can create a picture of the possible future of this market, but they have a major disadvantage: the fact that they can not take into account the new elements that can change the course of events: the crises, the changes in legislation etc. For example, the coming into force on 15th July 2010 of the Law requiring the mandatory insurance, Law no 260/2008 [18] may influence the evolution and the structure of the Romanian insurance market. So, in order to have a more realistic picture of the possible future of this market, it is necessary to use not only quantitative methods of forecasting, but also qualitative methods (for example the Delphi method).

The Implementation of the Phillips Curve to Romania's Realities

Ioneci Mihaela
Mîndreci Georgiana
„Constantin Brâncoveanu” University of Pitești
ioneci_mihaela@yahoo.com
g_mindreci@yahoo.com

Abstract

The Phillips curve represents a tool used in economics which presents the relationship between the rate of unemployment and the rate of inflation. Its analysis using the values recorded by these two indicators in Romania shows the existence of a link between these two rates only on short term.

The choice between these two macroeconomic imbalances is difficult given that there is no link between indicators to allow influencing one by means of another.

Key words: the Phillips curve, inflation, unemployment

J.E.L. classification: E24, E31

1. Introduction

The economist Alban William Phillips from New Zealand demonstrated by means of the Phillips curve the inverse relationship (but considered non-linear) between the variation of nominal salaries and the unemployment rate.

Phillips has made a graph with the help of which he highlighted the increase of the variation rate of nominal wages while reducing unemployment. The graph was made by using data from the UK economy specific to the 1861 – 1957 period. [4]

The Phillips curve was considered important for the macroeconomic models and an aid for the decision makers in choosing the macroeconomic policy, namely the choice between unemployment and inflation.

In fact, the Phillips curve demonstrates that:

- at high rates of unemployment, the nominal wages grow more slowly;
- at low rates of unemployment, the nominal wages grow faster.

Figure no. 1 The Phillips curve

Source: Stiglitz J., Walsh C., 2005, *Economie (Economics)*, Editura Economică, p. 625

The formula determined by Phillips is:

$$\Delta W_t = f(U)_t$$

where: ΔW_t – the rate of change of the nominal wage

U – the rate of unemployment

t – time

The above-mentioned statements have been supported starting from the belief that if unemployment is low, the employees will want higher wages, and if they do not receive them, they will not seek new better paid jobs. Conversely, if unemployment is high, the employees will accept a lower salary because the job offer is significantly higher than the labour demand and getting a new job is more difficult to achieve.

2. Content

Over time there have been economists who have brought changes to the idea presented by Phillips. Among them:

- Richard Lipsey brought changes to the Phillips curve, considering that the relationship is linear and not

nonlinear, as claimed by his predecessor.

- Monetarists, including Milton Friedman, have changed the formula established by Phillips, replacing the nominal salary with: the real salary, the expected rate of price growth (inflation) and then with the money supply growth rate. Monetarists have shown that we can take into account the Phillips curve only on short-term, because on the long term the relationship between unemployment and inflation is not preserved. [2]

Usually, for greater relevance, the Phillips curve is used employing the rate of inflation instead of the nominal wage growth. This change does not distort the meaning of the explanations, because between the nominal wage growth and the inflation rate there is a direct relationship, since the wage increases result in increases of the production cost, which is then reflected in the prices.

The choice between inflation and unemployment is a real dilemma, but by using the Phillips curve, inflation becomes the key in an economy, the government being in the position to choose between the two while establishing the macroeconomic policies. One can go on a low level of unemployment, but with the price of high inflation, or vice versa, a high level of unemployment is accepted, but with low inflation as a benefit.

We have already shown that the relationship established by Phillips between the variation of the nominal wages and the unemployment rate underwent various transformations. In this paper, we aim at analyzing taking the example of Romania's economy the possibility of the existence of a link between the unemployment rate and the inflation rate. If there is a relationship between the two, the next step is to establish its meaning.

In today's economy, both unemployment and inflation are macroeconomic imbalances with strong effects on the economic activity. The policy makers were in a real difficulty in trying to determine what is best for the Romanian economy, especially in the 1990 - 2000 period when changes happened quickly one after another.

Romania was confronted with high values of the inflation rate in the 90s, 1993 recorded the record by obtaining the value of 256.1%. Along with this year, our country recorded for another four years rates which have exceeded 100%, thus: in 1992 to 210.4%; in 1991 - 170.2%; in 1997 - 154.8%; in 1994 - 136.7%.

The unemployment rate has generally recorded values under two-digit, values that did not greatly vary in close periods of time. The highest recorded unemployment rate was in 1999 when it was 11.8%. Other years in which the values exceeded 10% are four in number, namely: in 1994 - 10.9%; in 2000 - 10.5%; and in 1993 and 1998 - 10.4%

Table no. 1 Unemployment and inflation in Romania

<i>Year</i>	<i>Unemployment rate</i>	<i>Inflation rate</i>
1991	3	170.2
1992	8.2	210.4
1993	10.4	256.1
1994	10.9	136.7
1995	9.5	32.3
1996	6.6	38.8
1997	8.9	154.8
1998	10.4	59.1
1999	11.8	45.8
2000	10.5	45.7
2001	8.8	34.5
2002	8.4	22.5
2003	7.4	15.3
2004	6.2	11.9
2005	5.9	9
2006	5.4	6.56
2007	4.1	4.84
2008	5.6	7.85
2009	7.8	5.6
2010	6.8	7.96

Source: www.insse.ro, www.mmuncii.ro/ro

The relationship between unemployment rate and inflation rate over the period analyzed (1990 - 2010) is shown in Graph no. 2, using the above mentioned values in Table no. 1.

In the analyzed period of time it is difficult to establish a certain relationship between the two macroeconomic imbalances. The meeting points related to unemployment and inflation are dispersed, only for the last

period one can notice certain proximity. Thus, on long term it is difficult to notice by the graphic method the existence of a certain relation of dependence between the two macroeconomic imbalances, not to mention to determine the intensity of the relationship between the two variables.

Graph no. 1 The unemployment – inflation relationship in Romania

Source: Data from table no. 1

Further we shall try to analyze the existence of a connection between the two variables, but within 10 years. To highlight this relationship we propose dividing the analyzed period in two segments, namely: 1991 - 2000 and 2001-2010.

Graphic no. 2 Inflation and unemployment in Romania during 1991 – 2000

Source: Data from table no. 1

From graph number 2, we see that during 1991-2000 the values recorded by the inflation and unemployment rates are quite varied, which does not establish a relationship between the two macroeconomic imbalances. One can easily see that during the first three years both indicators have increasing values.

Graph no. 3 Inflation and unemployment in Romania during 2001 – 2010

Source: Data from table no. 1

For the last period 2001 - 2010, the trend is to order the points of intersection on the first bisector. Using the graphic method specific to the statistical correlation, the link between the two imbalances is a direct one. Thus we can see that the reduction of the unemployment rate led to the reduction of the inflation rate, a statement valid until 2008. Starting this year, it is obvious that the effects of the crisis make their presence felt in the Romanian economy, the recorded values do no longer comply with the direct link established at the beginning of the period. Thus we can see that in the last three years we can no longer establish again a connection between the two variables.

To complete the demonstration of the existence or non-existence of a link between the two variables, we shall also use another statistical method to highlight the relationship and the intensity of the connection between the phenomena.

The existence and the intensity of the connection between the two variables is determined by using one of the nonparametric methods for determining the relationship between the phenomena, namely the ranking method. Only the Spearman coefficient shall be calculated, which involves establishing the specific ranking for each variable separately.

The unemployment is regarded as being the independent variable, and it will still be denoted by X, and the inflation rate is considered to be the dependent variable and it will continue to be marked with Y.

The Spearman coefficient calculation formula is shown below.

$$C_s = 1 - \frac{6 \sum_{i=1}^n (Rx_i - Ry_i)^2}{n(n^2 - 1)}$$

Where: Rx_i – rank of X;
 Ry_i – rank of Y; n – number of pairs

By substituting in the formula the values calculated for the two variables, we determine the Spearman coefficient value for the period 1991-2000.

$$C_s = 1 - \frac{6 * 200}{10(10^2 - 1)} = -0,21$$

Thus, by the result obtained it is obvious that between the two indicators there is no connection, which means the unemployment rate could not influence the rate of inflation in the period under review.

By substituting in the formula the values calculated for the two variables, we determine the value of the Spearman coefficient and show the existence and intensity of the connection between the two variables for the period 2001-2010.

$$C_s = 1 - \frac{6 * 48}{10(10^2 - 1)} = 0,71$$

Following the calculations made the result is of 0.71, which demonstrates again that the connection between the variables is direct. The approaching to 1 shows the intensity of the link between the variables, so that between the unemployment rate and the inflation rate there is a strong connection.

3. Conclusions

The values recorded in Romania show that on long term it is difficult to establish a relationship between unemployment and inflation, but that nevertheless it can be demonstrated on a short period (the period from 2001 to 2010 being obvious).

The use of the Spearman coefficient completed the demonstration of the link between the unemployment rate and the inflation rate. We note that in the early stage of the analysis there is not this link between the two indicators, but it is demonstrated in the second part of the analyzed period. Certainly, the transition from one economic system to another has led to these various trends and in the first stage without connection between the indicators. After passing the transition period, the evolutions of the indicators are totally different, finding again the interdependence between them.

What is important to pursue in the next period is the evolution of the unemployment rate and of the inflation rate during the economic crisis, but also after passing it.

In conclusion, the idea that one can choose between inflation and unemployment has governed in the beginning when the Phillips curve was used in its first form. Over time it was concluded that one can not choose an imbalance in favour of another, but it takes macroeconomic policies to support and to monitor both imbalances, trying thus to reduce the negative effects or the influence on the population.

Population Ageing and Its Effects on the Pension System

Ioneci Mihaela

Mîndreci Georgiana

„Constantin Brâncoveanu” University of Pitești

ioneci_mihaela@yahoo.com

g_mindreci@yahoo.com

Abstract

The economic crisis has emphasised the fragility of the pension system in Romania. The ageing tendency of our country's population completes the already bleak economic picture concerning the pension system. Romania's situation is not unique, it is found in most developed European states, in which the population ageing phenomenon is more pronounced. Accepting the imperfections of the pension system and finding the right solutions for the next period are the current requirements. At European level there appeared the concept concerning the implementation of a new culture of active ageing as one of the possible solutions for improving the pension system.

Key words: the pension system, the economic crisis, aging population

J.E.L. classification: E24, E60

1. Introduction

The economic activity, regardless of its nature, means the capitalization of labour so that this production factor becomes indispensable for economy. It is understood that alongside with the labour factor the other production factors take part in obtaining the results from the economic activities.

The changes to which the Romanian economy took part in the last decades determined the substitution effect to be specific to many Romanians. The desire to have a better life and to harness the great diversity of offers available on the market, determined them to try to increase their available income. [1]

The wish to have a living standard higher than before represented the impetus to look for a job paid according to the aspirations.

The same desire determines the Romanian employee to turn his/her thoughts to the future, anticipating the income he/she will receive during the retirement years. The current comments and forecasts fail to reassure the future retirees who see that it is possible that after decades of work and contributions to the pension fund as a future retiree may not obtain an amount of money that would ensure a peaceful existence, much less a certain comfort in old age. The economic crisis has emphasized this problem and it has shown that the pension system in our country has multiple disadvantages.

This situation is not specific only to Romania; it can also be noticed at European level, but obviously with other imperfections. The European parliament is concerned with the future possibilities of the member states to ensure entitlements to future retirees. In their vast majority, the European countries are faced with an ageing of the population, which will lead in the future to a more and more reduced basis of the active population and growth of the inactive population.

2. Content

The current problem of the labour market is represented by the youngsters who are not part of the working people. This aspect is determined, on the one hand, by the desire for further study and training in higher education, and on the other hand, by the impossibility to find a job for unskilled youth.

The discussion about increasing the retirement age is based on the population's evolution, especially in the developed countries. For 2010 the situation is not at all favourable to these states which have started to confront the problem of ageing population.

Table no. 1 European states with ageing population

Country	Population over 65 years (%)
Germany	20,5
Italy	20,4
Sweden	18,3
Greece	18,3
Portugal	17,3

Source: Calculations made by the authors using the data provided by <http://epp.eurostat.ec.europa.eu>

Table no. 1 lists the states which that occupy the first five positions in terms of ageing population. In order to complete these data we must also analyze the degree of economic dependence of the elderly population from Europe. The calculations carried out by Eurostat on the evolution of dependency of people aged over 64 inactive on the labour market as compared to the working population aged 15 - 64 show the future problems of the pension systems. This trend is highlighted in table no. 2, the values representing the percentage of people aged over 64 in relation to the working population.

Table no.2 The economic dependency ratio of elderly people in the EU

Country	2008 2030 2060 (%)		
EU 27	37	51	78
Euro area 15	40	54	73
Belgium	41	56	68
Bulgaria	38	52	91
Denmark	29	46	50
France	39	57	66
Germany	42	57	73
Hungary	40	53	91
Ireland	21	30	55
Italy	50	64	89
Poland	31	54	106
Romania	30	43	99
Spain	36	46	79

Source: <http://epp.eurostat.ec.europa.eu>

It is more than obvious, by looking at table no.2 that the economic dependency ratio of people aged over 64 years inactive on the labour market as compared to the working population aged 15 – 64 will record in the

future values much higher than those obtained in 2008.

In 2008 within the European Union the ratio between employed and retired people was of 4/1. For 2020 it is expected that this indicator will record a ratio of 5/1, and for 2060 the ratio will drop dramatically, recording 2/1. The ageing trend of the population is more than obvious, especially given that the birth rate does not record values which could lead to a reduction of dependency of the elderly population on the working population.[2]

In 2010 the average retirement age in the UE was of 61,4 years. In Romania, in 2009 the average retirement age was of 54 years, a value determined by the high number of retired people who have taken this state before the standard retirement age, but also by the reduced retirement age for certain categories of employees (military and police officers, magistrates and auxiliary staff in courts and courts of appeal, civil aviation personnel).

The comparison between the values recorded as average retirement age and life expectancy at birth indicates the duration in which the retiree enjoys the rights won during the period of activation within the employed population.

Life expectancy at birth in Romania significantly differs by gender, since for men life expectancy is of 69.6 years and for women is of 77.1 years. For the entire population, without further categorizing by sex, life expectancy at birth is of 73.3 years. Based on data presented, life expectancy at birth is about 19 years higher than the average retirement age in Romania, but completed by the evolution of the population in the future, the difficulties in supporting the pensions by the state are inherent.

In this situation it is clear that the macroeconomic policies implemented by each state must be based on the figures that show the population's progress. The importance of the population for a country's economy mainly derives from two aspects:

- it provides the workforce needed in any economy
- it achieves the consumption of goods and services

These two points are sufficient to understand the place held by the evolution of the population in an economy, regardless of the degree of its development, especially the fact that the rethinking of the pension system is required.

In our country the evolution of the population in the coming years is decreasing, so that in 2050 according to forecasts there will be about 17.279 million people (this is the average option of calculating the number of population).

Table no. 3 Evolution of the number of people in Romania (thousands)

Year	Total population
1990	23 207
1995	22 681
2000	22 138
2005	21 635
2009	21 275
2010	21 190
2015	20 787
2020	20 380
2025	19 961
2030	19 489
2035	18 978
2040	18 439
2045	17 877
2050	17 279

Source: World Urbanization Prospects: The 2009 Revision Population Database
<http://esa.un.org/wup2009/unup/p2k0data.asp>

The forecasts concerning the evolution of Romania's population were made from several alternatives aiming at changing the number of population, these being the following:

- the optimistic scenario considers that Romania's population in 2050 will be of 19.721 million persons;
- the pessimistic scenario considers that Romania's population in 2050 will be of 15.102 million persons;
- the scenario in which fertility is kept constant considers that Romania's population in 2050 will be of 16.269 million people.

The decrease of Romania's population is accompanied by the growth of the population over 50 years of age and by the reduction of

the young population. The age pyramid for 2050 shows the continuing trend of population aging in our country.

Figure no. 1 The age pyramid in Romania (2050)

Source: <http://populatiaromanieiincotro.unfpa.ro>

In the coming decades, Europe's population will undergo dramatic demographic changes due to low fertility rates, continuous increases in life expectancy and the retirement of the baby-boom generation.

Figure no. 2 The age pyramid in the European Union

Source: Interim EPC-SPC. Joint Report on Pensions - <http://www.europarl.europa.eu> (the red bar indicates the most numerous cohort)

Though the exact impact will be determined by several factors, ageing populations will pose major economic, budgetary and societal challenges. It is expected to have a significant impact on economic growth and lead to strong pressures to increase public spending. This will make it

difficult for Member States to maintain sound and sustainable public finances in the long-term. Ensuring fiscal sustainability requires keeping the EU's fiscal house in order, which involves addressing budgetary imbalances before the budgetary impact of ageing starts to be felt in earnest. [2]

The concerns found in the European Union are also found in Romania. The forecasts bring worrying figures, so that the finding of viable solutions and changing the current pension system is the current option.

The figures show a critical situation in the future concerning the possibility to support pensions, because the reduction in population is accompanied by an increase of the elderly people.

3. Conclusions

The European Union aims to maintain some "adequate, reliable and secure" pension systems; each Member State being responsible for establishing the pension system. The European Parliament through the decisions adopted can only suggest solutions for the pension system, which must then be adapted to the characteristics of each state. At European level certain aspects of the pension systems are coordinated related to the functioning of the internal market, the observance of the requirements of the Stability and Growth Strategy 2020 Treaty.

The report "Towards European suitable, viable and safe pension systems," component part of Europe 2020 strategy, has brought forward some ideas that might be adopted by the European states:

- increasing the retirement age;
- deterring the layoffs of the elderly;
- stable employment;
- alternative pension systems as solid as possible.

The central conclusion of the report aimed at creating a culture of active aging.

At the level of the European Union it is considered that a solution is to achieve an annual economic growth of 2% which would have the power to boost the labour market, thus providing new jobs.

In addition to the country's adoption of the proposed solutions to the European Union, we can adopt and implement various decisions that will lead to:

- increasing the birth rate;
- transition from undeclared work to formal employment;
- improving and streamlining the medical system;
- creating jobs for the elderly.

If there are not viable and appropriate measures taken to reform the pension system, supplementing the state pension received with a private pension is the solution to achieve a better life.

Analysis on the Evolution of Public Expenditure Financed by the State Budget Law of Romania

Ionescu Alexandra
"Dunărea de Jos" University of Galați
al3xandra_ionescu@yahoo.com

Abstract

State budget expenditures, provided by the annual laws of the state budget, are part of the public expenditures. Figures recorded in the past years show that Romania's public expenditures have been constantly increasing, and their ascending trend was accompanied by a similar evolution of the state budget expenditures. However, the trend was an expected one, given the fact that the majority of the European countries recorded such evolutions, especially considering the deterioration of the economic environment. Through this paper we intend to analyze past and present evolution of Romania's state budget expenditures, focusing on their structural changes.

Key words: public expenditure, public deficit.

J.E.L. classification: H50, H60.

1. Introduction

Within any economy, the state plays a central role in the present days. It acts in order to fulfill the general public needs. Undoubtedly, satisfying these needs means spending money.

Nationally speaking, the need for financing different fields or economic sectors claims the existence of a large revenues so that these expenses may be covered. In the context of the transition to market economy, Romania's public expenditure recorded a tendency of significant increase, in both real and nominal terms. The increase maintained over the past decade and is predicted to preserve over the next period, as well. As the level of resources is limited and the needs are amplifying and diversifying with a rapid rate,

it is imperiously necessary that public expenses should be made under strict conditions of economic efficiency. That is why resource allocation for public expenses is made by taking into account the priorities of the national economy.

Moreover, due to the deterioration of the economic climate, public expenditure policy has become an essential instrument in order to control, influence or intervene in the economic activity.

2. The evolution of public expenditure financed from the state budget

As mentioned above, Romanian public expenditure recorded an ascending trend over the past decade, with a significant increase from year to year. Moreover, the volume of expenditure surpassed each year the financial resources of the state, so that Romania is one of the countries presently managing a budgetary deficit. The increase of public expenses, determined by both objective and subjective factors, is reflected in the increasing proportion they have in the gross domestic product. Actually, public expenditure determines a proportional increase of gross domestic product, as public expenditure is a component of the latter. The evolution of the proportion that public expenditure has from the gross domestic product over the period of 2006 – 2010 is presented in the table below.

As shown, in 2010 budget expenditures amounted 201.9 billion lei, which represents a nominal increase by 4.2% in comparison to 2009. This increase was mainly a result of financing budget deficits accumulated in the previous years, especially social security spending (7.3% increase) due to higher unemployment ratios.

There can be noticed the great increase in public expenses especially starting with 2007, the medium increase until then being that of 1%. A significant increase of public expenses was recorded in 2008, respectively that of 2.1 percentage points, when public expenditure represented 35.4% of the gross domestic product at the end of that year. In

fact, the share of the public expenditure in the total of GDP reflects the negative evolution of the economy since the end of 2007, with its peak in 2009. Improvements recorded in 2010 led to a lower percentage of the public expenditure in the total GDP, that of 33.3%, compared to 36.4% in 2009.

Tabel no.1–Romania’s public expenditure compared to GDP (billion Lei)

Indicator	2005	2006	2007	2008	2009	2010
Public expenditure	92.73	112.00	137.43	181.67	193.00	201.90
GDP	288.9	344.6	412.7	513.2	491.9	512.3
Publicexpenditure/GDP (%)	32.1%	32.5%	33.3%	35.4%	36.4%	33.3%

** Source: Report on State Budget Law 2010*

Analyzing Romanian public expenditure in relation to its income, the first recorded higher growth rates than the latter, which reveals the fact that, in the case of Romania, public income growth generated an even higher public expenditure growth. The evolution recorded over the past four years amplified the discrepancy between the two, which lead to a subsequent increase of the budgetary deficit, especially starting with 2007. The negative evolution is shown in the chart below.

Chart no.1 - General government budget balance

**Source: State budget laws*

Concerning the structure of Romanian state budget financed public expenditure, there was a difference over 2005-2008, according to the sectors that needed prior financing. The structure of state budget financed public expenditure on the main chapters of the functional taxonomy reveals the fact that the greatest part of the funds

allotted from the state budget was used to finance socio-cultural actions, that is education, health, culture, leisure, religion, insurance and social assistance. Expenses with defense, public order and national safety also had an important share of the total state budget expenditure, being followed by economic actions and general public services expenses. The smallest share of the state budget expenditure was used for financing the public development services.

From the point of view of the economic structure of expenditure, the greatest share was represented by current expenses – 84.3% of the total state budget expenditure over 2006; that is 90.7% in 2007 and 86.1% in 2008 – having an ascending trend over the analyzed period.

The capital expenses, representing a small share of the total expenditure, indicates the fact that there were no prior allocation of funds for public investments from the state budget, as Romania had access to European funds in this direction, that is structural funds and cohesion funds that the European Union had allotted to Romania in important amounts in order to realize investments, but these were used in a low proportion (the funds’ draw was approximately 6% of the total volume of the allotted funds).

Taking a closer look at the current expenses of the state budget, we note that the percentage of the personnel expenses from the state budget had a downward evolution, reaching 20% from the total of the current expenses in 2008, compared with 24% in 2006. a downwards share was recorded for

the goods and services expenses – 5% in 2008, compared with 8% in 2006, and subvention expenses – 8% in 2008, compared with 12% in 2006. The amounts allotted from the state budget for transfers among state institutions had the opposite evolution; these represented 13% of the current expenses in 2006 and 19% in 2008. Social security expenses represented 20% of the total current expenses from the state budget in 2008.

The 2009 state budget law states that the maximum level of expenditure is that of 94 767.5 million lei, with an increase of 20.1% compared to 2008. This volume of the allotted expenses for 2009 deepens the forecasted budgetary deficit.

The structure of the state budget within the functional taxonomy indicates a high level of socio-cultural expenses, which underlines the fact that the financing of these sectors will continue to be a priority.

Chart no.2 – Structure of current expenditure of Romania's state budget

*Source: Annual state budget laws

Actually, the current need for restructuring and modernization of the health and education sectors, compel making high expenses, just as in the case of social assistance. At present, there is a strong accent on increasing the efficiency of social security activities, as well as ensuring respectable life conditions for all citizens, which implies an improvement of the insurance and social security system. Prior financing for these expenses is reflected in the structure of the state budget expenses which allots important amounts of money to this end, as presented in the following chart.

A significant importance is given to financing economic activities, which benefit from increasing funds from the state budget. In this regard, there is an allocation of funds from the state budget of 2009 for the implementation of an aid scheme for regional development, as well as for offering minimis aid for the development and modernization of companies or for stimulating exportation.

The expenses for public services also have a significant share of the state budget expenses, closely followed by defense, public

order and national safety expenses. The smallest funds allotted from the state budget over 2009 are those destined to services and public development, environment and waters. This is due to the fact that Romania wishes to access European funds in order to finance public development activities, especially regarding infrastructure development, as the European Union allotted important funds in this regard, but most public investment made over the past years were made from internal resources.

3. Perspectives on Romania's budgetary policy

On the short-term, according to the 2011-2014 Convergence Program, assumed budgetary policy for 2011 is a prudential and restrictive one, which aims fiscal consolidation throughout reaching the targeted deficit of 4.4% of GDP (in cash). Expenditure policy for 2011 considers continuous expenditure adjustments, maintaining budget constraints and further

structural reforms as a main challenge.

Personnel expenditure was limited to 39 billion lei in 2011 (excluding social security contributions for the military, worth 1.6 billion lei, under the new pension law), as a result of a restrictive policy. In addition, limiting the spending on goods and services has been extended to 2011, together with several subsidies reductions.

On the medium term, the specific objective of fiscal policy is adjusting the budget deficit, given the fact that planned targets are below 3% of GDP in 2012, 2.5% of GDP in 2013 and 1.8% of GDP in 2014 (cash methodology).

On the expenditure side it is considered restructuring public expenditure in the sense of adjusting the current ones to sustainable levels in order to reduce budget deficit and finance large investment projects. Therefore, special attention will be given to personnel expenses, for which prudential policy started in 2009-2010 will be conducted in the future 3 years, targeting a reduction of their share in GDP to approximately 6.5% in 2014 (from 9.4% of GDP in 2009).

Another priority of the budgetary policy accelerating the absorption of EU funds. Financing public investments throughout European funds rather than using internal resources will facilitate the adjustment process and will ensure achieving the specific medium-term objective.

In addition, during 2011-2014, the effect of reducing personnel costs, subsidies, and spending on goods and services together with the public pension system reform will lead to an increase of only 24.2% of total expenditures (in absolute value). This will actually result in a reduction of 3.7 points percentage of their share in GDP in 2014, compared to 2010. The effort of adjusting the current spending will allow maintaining an increasing trend of the investment expenditures (increase of almost 1.2 percentage points relative to GDP in 2014 compared to 2010), and a strong reduction of the budget deficit, with nearly 20.7 billion lei between 2011-2014.

4. Concluding remarks

In the present context of accelerated economic development, expenditure volume increase is inevitable. This growth tendency was noted over time for all the states in the world, but the growth rates were different, according to the existing economic reality.

For Romania, public expenditure recorded significant increases in the period after 2007, which points out the dynamic character thereof, but also the negative effects of the crisis. The total of the state budget public expenses recorded the same upward trend, as a component of the total public expenses.

The state budget fund allocations presently consider stimulating public investments, improving the insurance and social security system, as well as prior financing of sectors such as health and education. On the long run, there is envisaged that the allocation of important amounts for investment expenses, with a multiplying role in the economy and an important means of economic decline prevention, European funds accessing and an increased absorption rate thereof, protecting the economic interests of the population and ensuring social security, represent important priorities for Romania.

In the perspective of 2011, the accent will be set on further limiting public expenditure, preventing the foreshadowing economic decline. This main objective set for 2011 will be accomplished by the prior financing of investments expenses, a part of these expenses coming from the state budget.

A View of Capital Market Internationalization Bank Wave Mergers and Acquisitions

Ionescu Gr. Ion

*"Dimitrie Cantemir" Christian University,
Faculty of Management in Tourism and Commerce Constanta*
iionescu_levant@yahoo.ca

Abstract

The studies over the fusions and banking acquisitions have tried to identify the economic mode for them. The result that the efficiency is common to banks, and the internal fusions, between partners of the same dimension, signify the trying of the banking efficiency, so that the specialists call it X-Efficiency. This isn't realised quickly, but in a very caution sincronization of the effort effect, the fuzions and the acquisitions that represent an excellent way of reorganization of the banking activities, to see the growth of the efficiency. Generally, the examination, in time, the economic function of the process of the fusions and the banking acquisitions, this is the growth of the profitability of the new entity that was formed.

Key words: fusions, acquisitions, reglementation, effects, economy

J.E.L. classification: G34, K2

Regarding this fact, it has to be mentioned the existence of the empiric studies in USA, and in Europe, these present a large vision regarding the problems of fusions and the banking acquisitions, seen in the general conclusions, and the most important are these:

1) The banks that are operated on the marketing shown on a big concentration, practic, big intrests at the enterprises for the small business and pay the reduced intrests, the colected deposits with the retail operations. The recent evolutions show that:

- The new channels of distribution of products and banking services are factors favorized for the banking marketing and contestable;
- The dereglementation (liberalization) that came to the increase of the competition of the local marketing;
- The banking products, became goods, they made a competition more alert, and they modified the power of marketing;

2) Studies that show the power of marketing, realised by the specialized company of the financial - consultance, they have shown the complexe results of the procedures of fusions and acquisitions, in time.

It was examined, in a special way, the profitability of the institutions that participate at the fusions, before and after fusion, that are compared with the profitability of the institutions, unemployeed in other activities.

3) The modifications of the reglementations that created a large marketing, with the erase of the restrictions, refering at the banking systems in USA and in European Union, and in Europe, the creation of an euro zone played an important role.

Fig.1 The last wave of fusions and aquisitions (1997 – 2000), superior of the previous wave (1987 – 1990)

Source: Maurice Obstfeld, Alan M. Taylor, **Globalisation and Capital Markets**, Working Paper, 8846, 2002.

The benefits resulted in the adjustmen of costs of explotion can be estimated easy and seeing the fusion between financial and banking institutions and intern, so for the cause of the financial groups that are anticipated of the future incomings from the entire sort of activities specified to the group of new format. An image for the costs can be structurated - to the activity object of that institution, combined with cronological informations refering at the annual costs and nominal, from the evidence.

In the International Reglementation Bank, for the finish of the last century, at the level of august 1999, for example, the fusion and the aquisitions of the banking industry is shown in billions USD (Fig. 2). The statement shows that an increase of the fusion vaule and fusions at 17,5 bld.USD , in 1991- 1992 , then a decrease of it at 14,6 bld. USD, in 1993 – 1994, then comes with another increase from 19,1 bld USD , in 1995 – 1996, at 100, 4 bld. USD, in 1997 – 1998, for ground zero – Austria, Irland, Luxemburg and Portugal.

Source: Simon G. Evenet, **The Cross Border Mergers an Acquisitions Wave of The Late 1990s**, Working Paper 9655, NBER, 2003.

The european banking system crossed a period of 10 years in wich the international banking level, of the way to fusions and

aquizations, was very high, even comparing with USA.

The level is shown with the reduction of the credit institutions, from 12.256 – in 1985, at 9.285 – in 1997. [1]

fusions and aquisitions of the afferent effects, for activities, places to work, sales, generally [2]; (Fig. 3).

“After year 2000, it has appeared, in terms of speciality that is called the global slow, the effect beeing the reduction of number of

Fig. 3 Effects of the major aquisitions and actions, at the end past century, forward of the global slowness

INDICATORI

Source: UNCTAD Statistics, 2002.

The economic ration of the most important, in the process of aquisitions and fusions look for [3]:

- *the decrease of costs, based on economy at scale,, in wich the eficiency of the costs is realised in the decrease of the unity enviroment of costs.* The large consense it was that a very tiny bank has the potential of the economy at a scale, and the cost curve of the enviroment turns, much or less, the payment to the big firms.

- The variation of the optimus size that is influenced of the progress of the techonological factors and the dereglementation (liberalization) banking that permits for the new stage of organization of the considerable size. In Europe, after the introduction of the unique european coin, the European Comision has examined the existence of the economic scale, at an active of over a 25 bld. UDS, and the economists have estimated that this size is between 10 and 100 bld. Euro.

- *the growth of the brand* (the comercial name), on the base of some economy of scale. The size can permit the notice of the

efficient brand, at a low cost. This is a special type of economy at a scale, with the costs of marketing per unity of product, looking at the brand, that represents a potential source of a competitive advantage, for the future, when the customers of financial services can be found at a large scale with the help of the new “integrators“.

- *the incoming of the economic scale.* The size of the bank and capitals can permit the accordance of big credits and subscribe’s of the title of valorification of the positive impact over asking of some titles. In context of euro and the integrity of marketing, of capital size, it will represent a source of competitiveness and advantage.

In 1997, an economist said that the fusions have permission to the american banks to transfer the actives, representation actions of low value to the generators of big value.

This is the way that the megafusions help at the diversification of portfolio and the reduction of risks, letting the consolidated banks to accord more credits to the same level of capital.

- *The assurance based on scale economy.* If a bank comes to be very big, it comes to be what it is now named "too big, to fail" or to big to come to a ruin. This shows an competitive advantage in the conditions, for a low cost – for a particular level of the capital risk, so the large positions accepted by the partners.

- *The cost based on the realisation of economy.* The efficiency of the costs are realised with the offering of a large scale of financial products to the clients of base. This can generate the fixed costs in the offer of the data base of equipment that can be used for a large scale of services. Studies of efficiency from U.S.A. have measured, in comparison, the specific cost of firms that offer a large scale of financial services, that should represent the cost, if this services were to be offered from a series of firms that have a reduced scale of financial products.

- *The incomings that have the base of realisation of economy.* It has been hoped that a bond of the new products, to them have a client base – for example, the banking products and insurance. So, some economists (1996) tried to evaluate if the banking incomings realised can offer a scale of services. "They said that the absence of some incomings on the way to economy can interpret the results on the fact that every customer can evaluate individual the offer, but the competition don't permit to banks to rise the prices, and the simple customers aren't capable to evaluate the offer individually. So far, this arguments must be analysed with caution, to show the banks services of assurance, with the banking onss, second, induced by" [4] and the inclusion of the firms that offer only a service, so that it shows the estimation of the economic sphere not to be simple.

- *Financial diversification, based on the realisation of economy.* The standard portfolio theory show that a portfolio is imperfect, correlated on risk, can reduce the general volatility or the profit. In consense of Pillof and Santomero, the volatility can be reduced or can increase the financial health of actions in, some ways. "The first, it refers the the costs of value of ruin, can be reduced, seeing that o good part of costs of a ruin can be determined by the loss of value of the franchise caused by ruin, the second it referears at taxes that have to be payed if it

get's to a ruin, and the third at the loss of the values resulted from partnership with other clients, made in many years of coloboration" [5].

- *The X-Efficiency* it referears at the volume given at the exits, when a firm doesn't opperate with a maxim cost of efficiency, and rentability, that they are exploited, causes losses (for example, a structure to big of costs) [6]. This source of efficiency is qouted as a first motivation for internal infusions , when two banks fusion for the coordonance of the size reduction of the link, formed after the fusion entity.

- *The power of marketing.* The horizontal fusion reduces the number of firms that opperate on market and can lead to a reduction of competition and the growth of profit. "The fusions between industries can permit a larger profit, tie to the firms that can offer more products". [7] A long series of studies tried to measure the impact of concentration to credit and depozits. It is true, the benefics that were waited for, from the efficiency of costs, can be created and concentrated and can facilitate the cost and performance and credit and depozit. To be mentioned, the study of Carletti (2002) can conclusionate the fact that, in general, the concentration makes bigger credits and reduced at depozits. As a remark, in Germany, France, Spain, these institutions, fighting for size, attract a part of the banking profit and private commercial. The situations can evolve so that a part of this institutions can change their legal status.

- Of course, dereglementation, started in 1980 and the creation of marketing and mutual fonds, reduced the ability of banking to increase the deposit, and the acces of the large companies of capital marketing, in subscribing the value papers and forces, has reduced the potential impact over the credit of small and middle enterprising, it is first of all satisfied of the local sucursals of banking.

- *Selfdefence against the base of economy at scale.* "Can't be evidented on a direct link, in the measurement of a bank and probability of this can be participated at a process of fusion" [8] shown that the majority of fusions in U.S.A. " have implicated bigger banks of aquisitions some of them small".

- "The benefics of fusions and aquisitions. A series of studies, in U.S.A, analysis, when the fusions and aquisitions helped the banks to make their X-Efficiency better, profitability and of course, to identify a modality, to realise this way. In the study over megafusions", [9] show that "the measurements helped at the profitability, not to the growth of profitability, but to the chance of the mix of exit, in the favor of more credits and actions possessed. Also, the profit has to be big and efficient for some banks, and has to be pronounced. At micro level [10]. (Maurizio Zollo, 1998) economist considers that the experience is codificated, as "a key that determines the succes in the future of fusion".

Another part of specialised literature and analyses the impact of fusions over the value of actions on the capital marketing. Many studies have tried to observe a good relation, between fusions and safeness of the stock actions, it is observed that the safeness is transferred, from the aquisitor firm, at the firm that is aquisitioned. Using the dates reffering the 54 tranzactions, between 1988 – 1997, [10] showed that the positive effects for the internal fusions and the "industries" of assurance and no value created of fusions from commercial banks and firms of real estate values. The recent studies examined the european efficiency in a single case and observes "a low efficiency in France and Spain" [12].

Shipping Marketing and Management

Ionescu Gr. Ion

"Dimitrie Cantemir" Christian University,

Faculty of Management in Tourism and Commerce - Constanta

iionescu_levant@yahoo.ca

Abstract

The shipping enterprises carry on a large variety of activities that concentrate on the market provision of services. Supply and demand synchronization represents the fundamental objective of marketing. Planning becomes thus essential for modern naval administration in the sense that it yields long-term profitability as well as it enables the management to successfully distribute the business resources. Against the background of strong competition (with particular focus on international transport market) the use of the appropriate tools for the foundation of strategic decisions has determined the emergence of various models of strategic analysis of the competitor environment. The dominant characteristic of the supply/demand model in shipping is represented by the obvious discrepancy in stability between demand, which changes rapidly and unpredictably, and supply, which undergoes slow and well-balanced changes. The contemporary international transport is performed in accordance with numerous regulations of international trade policy that sometimes are different for certain partner countries.

Key words: shipping, marketing, management, company, market

J.E.L. classification: M0

The management of marketing refers to "analysing, planning, implementing and controlling the programmes designated to create, extend and maintain the advantageous transactions with the respective consumers in order to accomplish the objectives of the organisation" [1].

The dynamics of shipping "was determined by the production of goods that need transportation of raw materials as well as finished materials and products, on the one hand, and by the profound changes at the level of service provision in shipping, on the other hand" [2].

The existence of shipping as an area of research in marketing is due to its specific characteristics: the market, the marketing policies and the organisation of the activity: "The shipping enterprises carry on a large variety of activities that concentrate on the market provision of services. Supply and demand synchronisation represents the fundamental objective of marketing" [3].

With reference to shipping, "marketing development presupposes constant predictions that interest the recognition of the economic-social environment as well as the adaptation of service supply" [4] of sea transport and harbour activities to the actual demand. The quality of the services offered "presupposes a direct participation of the beneficiary, especially in international traffic where service provision implies frequent encounters of the carrier with the customs, the ecological and the border police authorities" [5].

Planning represents a managerial process that results in co-ordinating the marketing activities in order to accomplish the objectives of the organisation [6]. Planned task implementation consists of resource and responsibility management. Planning becomes thus vital for the modern naval administration in the sense that it yields long-term profitability as well as it enables the management to successfully distribute the business resources.

The main objective of planning in shipping is "to identify the commercial opportunities and to develop them by supplying the necessary resources. Shipping

companies encourage mobile acquisitions to be made efficient use of: it implies the transfer of ships from a route to another as well as the allotment of new ships to profitable areas" [7].

Shipping companies, in general but also in particular with reference to liners, have developed a business plan that constitutes a strict system of budgetary control. The business plan of the shipping company establishes its objectives for a period of five or ten years, depending on the nature of the business: "The competition will be tougher on Ro-Ro market and the trade volume will increase" [8]. In addition, the container market has rocketed since 1992 and it has resulted in the emergence of new tonnage. The new container ships have replaced the twin deck ships and they will eventually eliminate the bulk carriers. This recent ship model has completed the six-year container ship implementation programme that was meant to replace the inventory of double deck ships, which was exhausted [9].

The business plan of the company ought to be revised periodically to record any variations of the circumstances such as economic trade decrease, crisis periods, and the outbreak of any hostilities.

The net profit, the punctuality and the factors influencing the tasks of the individual services ought to be thoroughly looked into on a regular basis as well so that the ships involved are equipped in accordance with the predominant conditions.

In theory the traffic forecasts represents the evaluation of the circumstances that are likely to happen for a period from one to five years. It basically involves all the details of total transportation that are available on the market for a particular year in conjunction with the market share that the ship operator expects to hold: "The economic forecasts illustrate the approximate level of the industrial production for a certain year that may interest the ship operator in terms of available goods for export and transport. Other examples include the rate of interest, the bunkering prices etc." [10].

The forecasts refer to uncontrollable circumstances that the ship operator is to consider. They differ in relation to the budget administration and they include the industrial use and the policy in accordance with the economic forecasts regarding salary rates,

inflation, industrial production and unemployment. The forecast data is completed by an evaluation of the event probability [11].

Financially speaking, the global administration of the budget is a method of activity co-ordination for the entire shipping company - a "plan of action" that is based on previous productivity as well as the evaluation of the factors influencing the business in the future. The budget administration represents a thorough analysis of the past and a careful estimate of probable or future operations.

The forecast techniques are also used for the ship administration as well as the business plan. The most significant indicators are the level of the exchange rate, the economic growth, the level of the bunkering prices, the interest rate and the market information.

The maritime management represents "a form of administration that is based on the anticipation of changes that need to be operated within the organisation as well as its interaction with its environment in order to avoid the occurrence of situations in which service provision and service acquisition do not concur" [12].

The shipping enterprise represents a complex reality: a distribution agent or a service provider and a profit centre with its own identity and organisational culture, an organism, an environmentally friendly dynamic system. The shipping enterprise holds responsible for significant economic, social and ecological issues.

The process of formulation and implementation of the enterprise strategy (strategic management) is threefold: reasonable and analytic (the economic dimension) socio-political (the human dimension) and bureaucratic (the organisational dimension) [13].

The strategic management in shipping and harbour activities represents a form of administration based on strategic thinking with focus on actions against competitors in order to maintain competition for the purpose of business development. [14].

The emergence of various methods of strategic analysis of the market competition has resulted from the use of the appropriate means of strategic decisions against strong competition in international shipping. [15].

The shipping industry has expanded vastly on the international market. The maritime trade is as dynamic as the world economy and the sea transport has reached the pinnacle of world economic activity. The political-economic issue of the maritime market is not to be neglected in this respect.

Shipping and sea traffic have influenced the progress from the isolated communities to the global community in our days. It was, however, a reciprocal exchange that determined major transformations in the maritime industry.

The concept of shipping as a catalisator in economic development is not at all new: Adam Smith, generally known as the father of modern economy, considered shipping a cheap transport source, the stepping stones of economy. The economic development has generally gone hand in hand with sea trade for reasons of economic efficiency that Adam Smith explains as it follows: "By means of sea transport a gradually wider market addresses any type of industry and alongside the borders of the rivers opened for navigation any industry starts subdividing naturally and often improving as a result and also expanding towards inland. [16; 17].

The most important and recent technical innovation is the introduction of systems for multimodal and packaged transport of goods by liners.

Before WWI for a period of fifty years the shipping market recorded regular and normal six-eight-year cycles in between two periods of maximum. L. Isserlis pointed out that the freight shares between 1869 and 1936 peaked upon six occasions and they coincided with the pinnacles of world economic cycles. Isserlis also highlighted the importance of

political events. He thought that the pinnacle in 1873 was partially due to demand for transportation ships towards France and Germany for trade restoration after the French-German war whereas the pinnacle in 1990 could be the result of transportation needs determined by the South-African war.

Although the shipping market was intensely cyclic before WWI, the circumstances were in general auspicious and the expansion stages on the freight market compensated the ship owners more than enough after the tough recession years.

After WWI there was an overflow of commercial ships and the economic growth was never strong enough to overcome it. At the beginning of the economic crisis in 1929, the ship owners were confident in a return of favourable market conditions but the Wall Street Crack in October 1929, as well as the world trade recession pushed the shipping industry into a long depression. Regarding the fifty-year period after the WWI there was a succession of maximum and minimum values on the freight share market.

The practice is relevant for the explanation of the causes for the occurrence of changes in the market. The recurrent element of the freight market share is the equilibrium demand – supply that implies the usual techniques for the market analysis of demand and supply.

Among various influences on the shipping market, there are ten significant issues: five of them affect the demand of sea transport means and the other five determine the supply. These include:

THE TRANSPORT CAPACITY DEMAND	THE TRANSPORT CAPACITY SUPPLY
1. world economy	1. world fleet
2. maritime trade	2. ship construction output
3. average maritim route	3. fragmentation and loss
4. transport costs	4. fleet performance
5. political eveniments	5. operațional environment

With reference to demand, the world economy generates the fundamental demand for sea transport that can be modified by the evolution of the trade of certain goods (for example, an increase in the price of petrol influences the demand for petrol) as well as by changes in the routes the goods are transported on with a final service demand for shipping measured in tones-miles.

With reference to supply, the commercial fleet represents a fixed resource of transportation means that could be extended by the building of new ships as well as by the reduction of fragmentation.

A tanker fleet with transportation speed of 11 knots in ballast on return route transports far less goods per year than a similar fleet of bulk carriers with transportation speed of 14 knots that transports goods at maximum capacity on return route.

The performance, namely the ship efficiency, represents a significant variable that determines the supply available in shipping services, which is counterbalanced by demand.

The demand – supply relation is dynamic in the sense that the demand and the supply are considered from different points of view. The supply theoretically follows the demand upon the condition that decisions are met carefully – the level of demand and the coherent course of action are taken into consideration for the adjustment of the supply available. The decisional staff consists of ship owners, banks, governmental officials and ship builders who hold a certain control over supply oscillation, albeit their objectives may be different. The predominant characteristic of the demand – supply model in shipping is represented by demand instability that is rapid in change and unpredictable whereas the supply is slow in change and well balanced.

Many specialists refer to “market equilibrium” and a real equilibrium between demand and supply could be attained by chance or during periods of demand stability.

The external market refers to an assembly of demand and supply of different ships, containers, transport provisions, conflict conditions and settling as well as economic relations that consequently emerge between partners from different countries.

For an operation of sale-purchase (transport provision) to be included within the activity of the external market, the external element must play an important part.

The international market consists of bills of sale and the relations regarding the exchange of goods and transport services between different countries as well as the exchange on the internal market. The world market includes the total of markets: the market of mineral bulk carriers, the market of tankers, the market of container ships, the market of general goods ships, the market of ship building, the market of ship sale and purchase, the market of freights – all this not as a simple arithmetic sum but as an assembly of reciprocal relations between different interdependent markets. “The practice of international exchange relations has resulted in a terminology that is specific for different ways of act and relation development within external markets such as the characteristic market for a certain product that is representative of the market with the highest transactional volume (commodity exchange) as well as the representative market that represents a reference point due to its qualitative level or to certain conditions of the commodities on the respective market” [17].

The characteristic factors of the external markets could be classified in accordance with “different criteria such as: area of action, method of action, length of action, nature of factors determined by the specific area they belong to” [18].

The first condition to ensure the performance of the trading activity is “the evaluation of the potential buyers by the beneficiary as well as the elaboration of complex market research programs” [18].

Consequently the evaluation of exchange relations and the possibility to enter new markets have become important for the decision concerning the respective products or services.

The modern view in international transport presupposes that the negotiation needs a thorough analysis regarding the external market, the partners, and the economic situation, even some features or personal habits of the partners. The objectives of the research are numerous and they vary in approach.

The political relations with the partner countries and especially the trade relations represent a general objective that influences the potential initiation of international trade operations.

The contemporary international trade is regulated by various trade policy stipulations of different countries that sometimes act differently in relation to certain partners. Consequently, the exporters ought to know the general policy that the other countries have towards our country - the trade policy stipulations start with the traditional custom taxes and a series of other trade policy tools as well as the stipulations that concern international transactions.

Financial Auditor's Professional Judgement and Challenges Faced in a Global Audit Environment

Ionescu Iancu Octavian
Academy of Economic Studies, Bucharest
octavian.i.ionescu@gmail.com

Abstract

In an increasingly globalised economy, the quality and professionalism of a business is becoming more important than ever before. The audit profession is no exception. This paper examines audit professionalism alongside audit efficiency, its trend and its relationship with professional judgement. It is discovered that there is a contradiction between the commercial logic and the professional logic in the audit practice. It is also discovered that professional judgement is an essential tool for the auditor and that there is an opposition between efficiency and effectiveness in the audit practice. This article argues that the key to bring a balance to these contradictions is professional judgement.

Key words: audit, professional judgement, professionalism, efficiency, effectiveness.

J.E.L. classification: M10, M41, M42.

1. Introduction

Financial audits exist to add credibility to the implied assertion by an organization's management that its financial statements fairly represent the organization's position and performance to the firm's stakeholders and to consolidate trust in the business world. The financial statements must present information that are true and fair, that reflect the economic reality of the transactions, that are impartial, prudent, relevant and credible. As a professional and an expert in accounting, the financial auditor and his work, respecting laws and International Standards on Auditing, adds credibility to the financial statements.

Recent events in the economic arena brought trouble in the audit world. Global corporate scandals alongside the current financial crisis fuelled the society and regulator's critics. Different researchers

investigating the issue place emphasis on a variety of phenomena that created the environment in which these major scandals were possible. The consequence was that the entire accounting and audit profession has had its reputation tarnished. The forces at work were numerous and complex. Corporate and individual greed, delivering services that acted to impair independence, becoming too close with clients, and participating actively in finding ways to avoid the provisions of accounting standards were only a few of the causes but the main cause that embedded all the rest was deficient professionalism. The profession's historical defences to combat these forces proved ineffective. The bottom line is that the profession and the society as a whole, has paid a high price for the accounting profession's failure to meet the expectations of investors, creditors, and other users of financial statements.

All these facts prompt to a more considerate approach towards the use of professional judgement in every stage of an audit and to allocating a greater importance to the issue of professionalism.

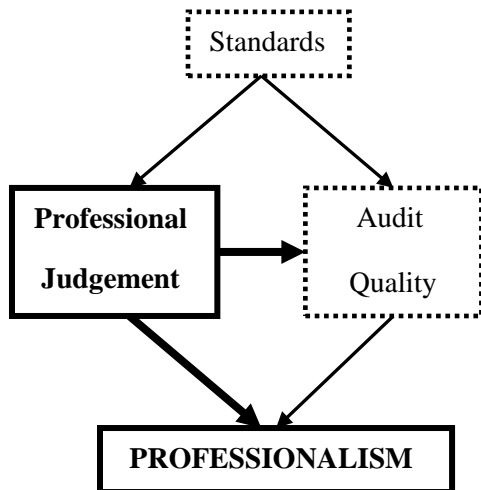

2. The concept of professional judgement

Throughout his work, the financial auditor uses an important and central element: professional judgement. Professional judgement is the cornerstone for the audit profession and is applied in all stages of an audit, from planning stage to the audit opinion. Professional judgement is an integral part of audit and cannot be dissociated from it.

Professional judgement in auditing is the application of relevant knowledge and experience, within the context provided by auditing and accounting standards and the rules of professional conduct, in reaching decisions where a choice must be made between alternative possible courses of action [1]. By referring to professional standards, concepts like independence and objectivity,

professional competence, integrity, professional scepticism and responsibility are implicitly incorporated in the definition of professional judgement. It is clear that professional judgement takes place in the context of professional standards reflecting the collective judgements of the profession. Professional standards are therefore important in exercising professional judgement as they act as references and lighthouses for auditors. The absence of comprehensive professional standards combined with factors such as the increased frequency of business failures and the inability to meet public expectations have increased auditors' exposure to liability claims. The quality of professional standards will definitely impact the professional judgement of the auditor and both will impact the quality of the audit work. The professional judgement exercised by the auditor in the course of an audit together with the quality of the audit work will, consequently, impact the level of audit professionalism (see Figure 1.).

Figure 1. The relationship between professional judgement and professionalism

Source: Original conception of the author

3. The concept of professionalism

Many attempts have been made to define a profession, in general, and professionalism, in particular. The essence of professionalism is a commitment to develop one's skills to

the fullest and to apply them responsibly to the problems at hand. Professionalism requires adherence to the highest ethical standards of conduct and willingness to subordinate narrow self-interest in pursuit of the more fundamental goal of public service [2].

Professionalism is an aspirational standard with a few essential elements: competence, personal integrity, responsibility, accountability and public obligation. The competence element comprises relevant, up-to-date skills and capabilities appropriate to the particular task and a broader foundation of relevant experience, knowledge and understanding. Competence, as part of professionalism, must also include appropriate non-technical skills such as communication, business, leadership, management competences. Competence must also be supported with relevant qualifications and maintained through continuing professional development. Integrity refers to a clear commitment to abide by a code of ethics which is recognised and administered by the professional community. Responsibility and accountability comprises a set of personal obligations and responsibilities which sit alongside the contractual obligation to an employer or client and a matching accountability which is also separate from that of an employer. Public obligation is another essential element of professionalism which refers to a contribution to protect the public interest, to social responsibility commitment and to a contribution to the professional community alongside support from that community [3].

4. Commercialism versus professionalism

Throughout the audit profession the push was on to extend the range of services provided. The consulting practices grew in different ways among the firms, mainly directed by the different talents of the personnel with the firms. These people were not paraprofessionals, but rather they were relatively high-paid personnel with strong skill sets in areas only distantly or even unrelated to accounting or auditing. Their numbers grew rapidly, and their success in generating high-margin fees gave them an increasing voice in firm management. Their relative success created enormous pressure

on the auditing and tax practice, both to grow revenues and to increase margins. This added to the pressures already faced by the auditors in terms of cultural, political, economic and social factors, pressures that make auditor independence an ideal difficult to attain [4]. The successes in the consulting practice increasingly influenced behaviour by auditing leaders and the impact of these behavioural changes gradually affected the behaviour patterns of audit personnel as well. Improved profitability became the key focus. These changes associated with the growth of consulting practices evolved relatively slowly over a period of about forty years. In essence, the cultures of the firms had gradually changed from a central emphasis on delivering professional services in a professional manner to an emphasis on growing revenues and profitability [5]. The focus on delivering quality professional service did not disappear, of course. No one rang a bell in a firm and announced that quality professionalism is out. But, on the other hand, keeping the client happy and doing what was necessary to retain the client achieved a prominence that did not exist prior to the advent of the successful consulting arms within the firms. As a direct consequence, it can be concluded that over the last forty years the core values of the professional firm were undermined by primarily commercial interests.

5. Efficiency and effectiveness in auditing

In approaching an audit mission there is a contradiction between efficiency and effectiveness. Because of the limited resources of time and personnel, efficiency in audit is driven by economic and commercial factors of the cost-benefit analysis type. In contrast, effectiveness is based on professional and ethical factors of the work well done type and audit quality. Although the academic theories that have warned against the unacceptably high level of compromise between efficiency and effectiveness seem to be contradicted by some studies [6], big scandals and frequent litigations in the audit profession indicate a rather high level of compromise between efficiency and effectiveness. In this situation of contradiction between efficiency and effectiveness, professional judgement is,

again, of critical importance. Whether used in risk assessment procedures, in tests of controls or in analytical procedures, professional judgement is a key element in choosing an adequate level of compromise between efficiency and effectiveness during an audit. In this context, depending on each and every economic sector, the need arises for a more attentive analysis of the equilibrium between efficiency and effectiveness through the use of professional judgement. The focus on delivering quality professional service did not disappear, of course. However there is a strong sense of contradiction between the effectiveness and the efficiency of the audit work. Action is therefore needed in order to improve the quality of the audit and consultancy products and to better prepare the audit profession for the challenges it may expect from the present as well as from the future.

6. Conclusion

The possibility of human error in decision making is a critical reason why the study of decision making tasks and, in particular, professional judgement is important. The audit framework was undermined, and the result was what we have recently seen in massive bankruptcies, corporate restructurings and ongoing litigation. The gradual changes in internal firm culture effectively altered the long-standing value systems of firm leaders and the results have been costly and problematical to reverse. The cultural changes evolved over a long period and have become pervasive in nature. However, the professional auditor has a powerful tool at his/her discretion: professional judgement. Now, more than ever, is the time to use professional judgement in order to restore the balance between the logic of commercialism and the logic of professionalism as well as to resolve the contradiction between efficiency and effectiveness in the audit process, for the benefit of the audit profession and the society at large. Therefore, the current challenge of firm leaders has to be to gain an understanding of how the current culture evolved and how to make the best use of auditor's most important tool - professional judgement.

Personal Factors That Influence Audit Manager's Risk Behaviour

Ionescu Iancu Octavian
Turlea Eugeniu
Academy of Economic Studies, Bucharest

Abstract

Risk is a fundamental concept in audit as well as in the business world at large. Yet, little is known about the personal factors that might influence the risk attitude of a decision maker. The business decision makers are usually faced with a degree of uncertainty when they have to assess risk and make decisions. This paper examines risk behaviour from an audit firm manager perspective and from an academic perspective. The emphasis is on the managerial risk behaviour in business decision making. The research objective is to identify the extent to which personal factors like gender and age are determinants of risk behaviour. It is discovered that the issue of establishing the determinants of risk behaviour has been debated by many authors but no conclusive theory is currently accepted.

Key words: risk behaviour, decision making, audit, manager.

J.E.L. classification: M10, M42.

1. Introduction

Audit firms are business entities that provide financial services and their management is ruled by the same forces that govern the global business world at large. The manager of an audit firm in today's globalised economy is required to make decisions that will imply a certain degree of risk that will impact on the firm's profitability and reputation. Risk is a central concept to both the audit process and the management of the audit firm, so this paper will be of interest for both the auditor and the manager. The concept of risk taking has played a central role in business research in the last few decades. The idea of risk has

been present in business ever since man began to trade but never before the globalisation age has risk been more diversified in nature and more present on every business agenda. Risk is a concept whose definition has not generated a consensus in the academic or business circles but is generally accepted that it relates to issues of unpredictability, decision making and potential loss. Risk is intrinsically linked with decision-making and every decision made in business implies a certain degree of risk. The importance of risk to decision making is attested by its position in decision theory, by its standing in managerial ideology, and by the high level of interest in risk assessment in management. This paper will look into research on gender and age as personal factors that influence risk behaviour, building on previous research done by many scholars.

2. Behavioural aspects of risk taking

Academic theories which attempted to explain the risk behaviour of decision makers date back as far as 1738 [1] and there are a significant number of empirical studies in the area of risk taking behaviour. However, these studies have not produced uniform findings. Some scholars underline the importance of understanding the personal attitudes to risk and considers the attitude and behaviour dimension one of the key dimensions to understanding risk. The rationale of the importance of understanding the decision makers' risk behaviour is that, to a certain extent, the strategies of an organisation reflect the dispositions of their managers in terms of their background, beliefs, attitudes and problem-solving styles [2]. This behavioural aspect of managers' risk taking in decision making introduces the fundamental question about the determinants of risk behaviour. What exactly determines or influences a manager's risk behaviour when

making a decision? There are currently several views accepted, like the dispositional view and the situational view, but there are also views that consider a relationship between personal factors like gender and age which influence the risk behaviour of a decision maker.

3. Relationship between gender and risk behaviour

There have been many studies into gender differences in risk behaviour and decision making quality but their results are contradictory. From the middle of the last century to present day, the stereotype that, when confronted with risky decisions, women choose low-risk alternatives whereas men choose alternatives with higher risks has been disputed in academic circles. Studies conducted in the 1950s and 1960s show consistent findings that, even when differences such as intellectual aptitude and special abilities are controlled, women apparently show inferior quality of problem solving. Johnson and Powell [3] comments on previous literature and observes that women were found to be more easily persuaded and influenced than men, irrespective of the risk involved, less aggressive, more conforming in group pressure situations and had less confidence in their decisions. Other scholars' findings support the body of evidence that men are more inclined to take risks than women in a variety of situations. There is evidence from survey data which suggests that the nature of wealth holdings of single women is less risky than those of single men of equal economic status, which might imply that women are more risk averse than men. However, Wallach and Kogan [4] found that women were more conservative than men when unsure of their decisions but more extreme than men when very sure of their decisions. Wallach and Kogan conclude that a simple generalization about gender differences in judgement and risk taking cannot be made and that the level of certainty of the decisions together with the subject matter they concern must be analyzed. Extrapolating the investigation on gender differences in the management domain, Powel [5] conducted an extensive review of research on sex differences in management and, in determining the level of support for each of

these viewpoints, considered four types of possible differences: in behaviour, motivation, commitment and subordinates responses. Powel found insignificant differences and concluded that there is little reason to believe that either women or men make superior managers, or that women and men are different types of managers. Later, in a study on managerial and non-managerial populations of men and women, Johnson and Powell found that women differ from men in their risk propensity in the non-managerial population but found no difference in the managerial population.

4. Relationship between age and risk behaviour

Compared with the literature on the relationship between gender and risk behaviour, a lot less has been written about the relationship between age and risk behaviour. Most of the literature comes from psychology, sociology, economics and behavioural sciences and only a small proportion comes from management sciences. However, this is only an observation, not an inconvenience, as the nature of studying the relationship between age and risk behaviour in a business context transcends from the management domain into psychology, sociology, economics and behavioural sciences. While conventional wisdom suggests that individuals take fewer risks as they age, the evidence from empirical studies yields contradictory results. In an early study on the relationship between age and risk behaviour, Wallach and Kogan [6] compared risk-taking behaviour of college age and elderly men and women, and found that the older subjects, both males and females, were significantly more conservative than the college students. Recognizing the shortfalls of examining two extreme age groups, Kogan and Wallach [7] comment in a later review article on the need for further exploration of age – risk-taking relationship using less extreme age groups. In an attempt to satisfy this need, Vroom and Pahl [8] investigate the age-risk behaviour relationship on a sample of almost 1,500 managers with age ranging from 22 to 60 years. After plotting the data obtained using the Kogan and Wallach [9] choice dilemma questionnaire as a measure of risk propensity, Vroom and Pahl found that the slope of the

relationship between mean riskiness and age is greatest in the age range 22 to 32 years, flattens out in the age range 33 to 48 years and increases again in the age range 48 to 58 years. This means that for the managers used in Vroom and Pahl's study, the age group 22 to 32 years and 48 to 58 years appears to be more risk seeking whereas the age group 33 to 48 appears to be more risk averse.

5. Conclusion

Since scholars first articulated the fundamental question about the determinants of risk behaviour, the issue remains unresolved. However, there have been attempts, along the years, to resolve this issue by researchers who advanced the integrative theories but with little or no success at all. The most popular theories about the determinants of risk behaviour consider the personal characteristics such as the gender and age of a decision maker as natural predisposition towards taking or avoiding risk. It appears that, similarly to the relationship between gender and risk behaviour, the relationship between age and risk behaviour is not conclusive and that additional variable factors must be taken into account. The process of globalisation has altered the way business managers and auditors perceive risk. As the risks in a globalised economy have become more pervasive in nature, if better decisions are to be taken by managers and auditors alike, the determinants of risk behaviour must be better understood.

Financial and Macro-Economic Views of the Mondial Economic Crisis

Ionescu Ionel Eduard
Oprea Cristian Constantin

"Spiru Haret" University of Bucharest, Faculty of Finance and Banking

eionescu.fb@spiruharet.ro

coprea.fb@spiruharet.ro

Abstract

The global economy has significantly deteriorated in 2009 and the comeback looks to be irregular. The weakest performances in terms of reverting to the situations before the onset of the crisis are predicted to show for the countries of the European Union. Even though the monetary and fiscal stimuli have been consistent, the lack of sustainability of public debt and the risk of rising prices bring up discussions of initiating measures for the gradual retraction of stimuli.

Key words: world economy, financial markets, economic deficit, crisis, recession.

J.E.L. classification: G01, H61, H68

1. The Context of the Current Crisis

Even since the end of 2007 or the beginning of 2008, when credit collapse was considerably covered in the press, and governments tried to adopt extraordinary measures to control the effects, there have been successful investors, public servants, economic analysts who tried to predict the trend of the crisis. Most of them gave positive forecasts over the real growth with a medium estimate of 2%, and the most optimistic estimate was 5%. The only one who predicted correctly was Jan Hatzius from Goldman Sachs who had put forth the value of -0.4%, the real modification of GDP between the two periods taken into account being -0.8%.

At that time, these economists had not understood and had no idea about the global effects of the phenomenon.

The global economic activity in 2009 remained at a very low level, after suffering a severe contraction in the last quarter of the previous year. The world economy was also

negatively affected by the adjustment of firm balance sheets and population incomes, by the wealth effect and by the lowered level of confidence which prevailed, despite the measures of systemic risk limitation and financial stabilization put in place by governments and central banks.

The modification of international financial system characteristics starting with the second half of 2007 was no surprise, numerous supra-national institutions (IMF, BIS, ECB) drawing attention to the fact that the risk is under evaluated and that a negative evolution is an increasing possibility.

The main identified causes for the problems in the financial systems of developed countries have been [2]:

- the development of financial innovations without an adequate understanding of the risks assumed and without the implementation of adequate risk management methods
- the significant excess of liquidity in the context of low interest rates which promoted the assumption of great risks for obtaining high turn-over
- the transparency of investments in innovative products as well as the implementation framework were insufficient .

The central banks reacted promptly through immediate measures consisting of urgent liquidity supply, the use of new financing facilities over the ones offered by current monetary policy operations and, in some situations, the reduction (aggressive within the FED) of monetary policy installments.

Regarding international financial markets, dominated by people who invest other people's money, often within a context in

which a destructive behavior gives birth to fabulous wealth, their evolution was marked by volatility and a significant drop in stock prices.

The slowdown of advanced economies, under the conditions of a reduction in global trade as an effect of the lowering of global demand, especially affected the manufacturing industry of countries with emergent economies.

The global activity, in the second quarter of 2009, returned to a rising trend, being stimulated by the monetary and fiscal policy measures implemented in many states, meant to contribute to the stabilization of the financial sector. Initially stimulated by the manufacturing industry and later by the services industry, the economic recovery occurred faster in emerging economies, whose direct exposure to the crisis was reduced. Worldwide production fell by 0.6% this year, after a 3% increase in 2008 and 3.8% increase in 2007.

The influence of the crisis over actual activity was also felt in the evolution of world trade, which registered a decrease of -11.3% in 2009, as compared to an increase of 4.4% in 2008 and one of 6.3% in 2007. Following the decision of OPEC to reduce production, as well as the improvement of the perception over economic perspectives, the price of oil (the BRENT quotation), stabilized in the first quarter of 2009, after which it began to rise, reaching 77.8 USD per barrel at the end of the year, on the whole, however, the price of oil averaging 62.5 USD per barrel, 36.4% less than the average for 2008. It is worth mentioning the fact that the price of oil peaked at 147.5 USD per barrel (reached in July 2008), followed by a sharp drop up to the end of 2008 and reaching a minimum of 38.5 USD/barrel. This fact was an effect of consolidation the US oil supplies and of the impact of the financial crisis over the perspectives of global economy. However, on the whole of the year, the average price was 3.5% over the average of 2007, with a value of 98.3 USD/barrel.

With regards to the prices of raw materials (exclusively energy resources), expressed in USD, they were very volatile throughout 2008, registering a sharp increase in the first quarter, determined by the prices of agricultural products and followed by an abrupt drop in the second half of the year, on

the backdrop of the reduction in the prices of energy resources; the prices of non-energy commodities rose on average by 14% in 2008 as opposed to 2007 and in 2009 they dropped on average by -18.7% as opposed to 2008, with the exception of the prices of metals, which registered increases, due to the measures of infrastructure development announced by China.

Worldwide inflation was strongly affected by the evolution of global economies and the abrupt movements of the prices of commodities. Due to the increase of prices for foodstuffs and energy resources in the first half of 2008, inflationary pressures were considerable, the average inflation rate reaching 4.8% in July (this data is for OECD countries). In the second half of the year, inflationary pressures subsided, the average inflation rate in OECD countries decreasing to 3.6% in December, registering a negative rate in the first half of 2009, determined by the decrease in international commodity prices and the reduction of the degree of using production capabilities, as a result of the restriction of economic activity. Starting with the second half of 2009, the comeback of international commodity prices raised the inflation rate to 1.9% in December [1].

2. Aspects of the Crisis in Countries Belonging to the Euro Zone

With regards to the Euro Zone, it showed a significant economic slowdown, from 2.7% in 2007 to 0.8% in 2008, due to the worsening of economic conditions starting in September, along with the accentuation of tensions on the financial market. In 2009, the Euro Zone registered a -4.1% economic decrease, after an increase of 0.6% in 2008, on the backdrop of the reduction of private capital expenses and the restriction of international trade (the states included are the 16 EU members which belonged to the Euro zone at the beginning of 2009, as opposed to 15 states at the end of 2008: Australia, Belgium, Cyprus, Finland, France, Germany, Greece, Ireland, Italy, Luxemburg, Malta, The Netherlands, Portugal, Spain, Slovakia and Slovenia).

. Worldwide economic growth entered negative territory for the first time in 1980 (-0.6%), and the economy of the Euro Zone decreased by -4.1% (WEO Update, iulie 2010), significantly affecting commercial

exchanges, which dropped by -20% at a global level, and by -16% at a European level.

The gross fixed capital formation decreased by -10.9%, especially in the corporate field, as a result of the restriction of demand and in the construction field, on the backdrop of the decrease in housing prices.

In the first half of 2008, internal demand was considerably dulled due to the decrease in the real incomes of population households, on the backdrop of the increase of increase in the international prices of commodities.

Private consumption was reduced by 1.2%, being affected by the lowering of the real available income of population households, as a result of the decrease in the degree of occupancy and the tightening of crediting conditions.

At that point the decline of residential investments also began (affected by the fall of the housing markets) as well as the decline of productive investments (due to the tightening of financing conditions), and the consumption of public administration rose by 2.4% as opposed to 2008, being stimulated by the anti-cyclical fiscal measures, thus limiting the economic decrease of the Euro Zone.

External demand was limited by the slowdown of economic growth, both in advanced and in emerging economies.

If, in 2007, the export of goods and services in the Euro Zone were rising by 5.9%, in 2008 they were slowed to a mere 1% increase, and imports of goods and services from a 5.8% increase in 2007 to just 1% in 2008, due to the reaction to the evolution of internal demand; in 2009 the exports of goods and services were reduced by 13.3% and the imports of goods and services by 12%. This reduction of exports was determined by the evolution of external demand and by the substantial appreciation of the Euro, while the decrease of imports of intermediate and capital goods was determined by the compression of exports.

The slowdown of economic activity, from a sectoral perspective, was reflected in all fields, but especially in the manufacturing industry - determined by the decrease of external demand, the quickly diminishing internal orders stock and the reduction of activity in the automobile and construction industries. The activity in the construction

industry registered a significant decrease on the backdrop of the deterioration of the housing sector, especially in the countries where its GDP input rose in the period predating the financial crisis. The activity in the services sector suffered a collapse as well, especially in transports, car rentals, consultancy and publicity, being affected by the diminishing private consumption and production activities.

The average annual inflation rate, measure by a harmonic index of consumption prices, fell from 3.3% in 2008 to 0.3% in 2009, being the lowest level ever registered since the introduction of the Euro, this being due to reduced inflationary pressures. This evolution was determined by the reduction of the prices of international commodities, especially of energy resources which, in 2008, came in at the highest level since the introduction of the Euro and over the level which defines price stability in the Euro Zone.

If, beginning with 2006, the conditions on the labor market had seen a significant improvement up to the middle of 2008, the conditions on the labor market of the Euro Zone deteriorated in 2009 for the second consecutive year. The BIM unemployment rate [4] increased from 7.6% in 2008 to 9.4% in 2009, significant increases in unemployment rate being registered in Ireland and Spain, while in Germany and Italy, the increase were not as drastic.

With regards to the budgetary deficit of the Euro Zone, it rose from 2% of GDP in 2008 to 6.2% in 2009 being the largest budgetary deterioration since the creation of the Economic and Monetary Union, on the backdrop of the evolution of the financial crisis, the major economic contraction and the anti-cyclical methods of fiscal stimulation. In 2009, in the majority of countries, the budgetary deficit exceeded the reference value of 3% of GDP, becoming the object of the excessive deficit procedure instituted by the European Commission, with terms for correcting the budgetary deficit between 2012 and 2014. The lowest shares of budgetary deficits of GDP were registered in Luxemburg - 0.7% and Finland -2.2% and in three countries of the European Union there were recorded shares of budgetary deficit of GDP of over 10%: Ireland -14.3%, Greece - 13.6% and Spain -11.2%.

In 2008, as an effect of governmental interventions for the financial system stabilization, the rate of public debt of the euro zone rose by 3.3% over the previous year, reaching 69.3% of GDP. Compared to the previous year, in 2009, the rate of public debt of the Euro Zone rose by 9.4% reaching 78.7% of GDP, as an effect of the decline of economic activity, of governmental intervention for the stabilization of the financial system and the increase in budgetary deficits. All of the states in the Euro Zone have recorded a rise of the share of public debt of GDP, of which 10 exceeded the 60% reference, the largest being recorded by Italy -115.8%, Greece -115.1%, Belgium -96.7%, France -77.6%, Portugal -76.8% and Germany -73.2%.

Due to the transformation of the deficit of commercial balance into surplus and the halving of the income balance deficit, the aggregated current account of the Euro Zone closed at a deficit of 67.6 billion Euro (0.6% of GDP), as opposed to 161.6 billion Euro in 2008, compared to a surplus of 13.5 billion Euro in 2007. The commercial balance of the Euro Zone closed at a surplus of 46.4 billion Euro in 2007, under the conditions of a sharper drop in imports compared to exports. The later stabilization and re-invigorating of exports was sustained by re-establishing external demand, but the favorable effect of these facts was limited by the decrease in the zone's competitiveness, through the appreciation of the Euro, compared to the second half of 2008 when the Euro saw important devaluations.

If we are referring to direct and portfolio investments in 2009, they recorded net inputs of 229.8 billion Euro as compared to 145.4 billion Euro in 2008, the increase being a reflection of the net influxes of participatory portfolio investments (due to the attempt of global investors to modify the investment portfolio to favor their resident countries) and the decrease of direct investment outputs. These evolutions were partly limited by the reduction of net influx such as debts.

The governmental incentives were significant in 2009, the average fiscal deficit in the European Union reaching almost 7% of GDP, while the external public debt expressed as a share of GDP rose by 12%, with another increase, by about 6%, being projected for 2010. These evolutions are not

sustainable, imposing measures of fiscal consolidation in the majority of European economies, and the withdrawal of fiscal incentives could affect the resumption of economic growth in the main European countries.

In 2009, an important incentive was received by the international financial system from the monetary and fiscal authorities. The central banks of many developed economies have resorted to extraordinary measures to provide liquidity. For example, the most important measure of the European Central Bank to supplement liquidity regarded the providing of unlimited fixed rate liquidity for all refinancing operations. Other measures of the ECB for supplementing liquidity were: increasing the maturity length of long-term refinancing operations (from the maximum of 3 months, prior to the crisis, to one year); insuring financing in other currencies (dollars, Swiss francs, etc.) through establishing some financing programs between the ECB and other central banks; extending the list of eligible collateral; buying guaranteed bonds.

Also in 2009, some central banks went from the return-based approach to the quantitative approach because conventional methods of relaxing monetary policy were almost exhausted. For example, for the Euro Zone the measures led to the increase in the volume of liquidity injected into the market, from approximately 460 billion Euro in September 2008, to about 900 billion Euro in July 2010, with the result of a significant increase in the balance sheets of central banks from the respective developed countries and the increase of already owned mature actives.

The accessing of banks of these supplemental resources was asymmetrical. With regards to the ECB, the Greek credit institutions have significantly used the existing facilities, the volume of refinancing operations exceeding 20% of GDP in December 2009, therefore the gradual elimination of these measures will have to be initiated having into account the dependency on external financing of certain banking groups. In the first months of 2010, the measures initiated by the ECB have led to the continuing extension of the support offered to the banks.

The fiscal authorities of certain member states of the European Union have adopted in 2009 also, important measures of support for the banking sector, over 60% of the value of banking recapitalizations coming from this source. These governmental actions have permitted, by the end of 2009, that the banking losses be covered through the volume of newly induced capital.

The banking sector of the ECE is also dominated by Euro Zone banking groups. This is also reflected by the homogeneity of the degree of vulnerability to local shocks, the problem of common creditor being very important. As can be observed from Table 1, in the matrix regarding the importance of transmission channels, a high indicator value implies a high contagion degree. The row sums represent the importance of the country in question for the transmission of regional shocks, while the column sums represent the vulnerability of the respective country to regional shocks. The matrix represents the importance of the transmission channel between two countries based on the exposure to a common lender, considering only the banking calculus and assuming the hypothesis of uniform shock transmission between the countries in question. The crediting countries used were: Austria, Greece, France, The Netherlands and Italy. The criteria was the importance of the banking groups from these countries for the Romanian banking sector. The method of calculating regional exposure is based on the definitions used by the BIS with regards to banking exposures and is taken from Fratzscher, M., "On Currency Crises and Contagion", European Central Bank, #139, April 2002.

The degree of contagion through the banking channel did not suffer any important modifications in 2009 at the level of the ECE, with the exception of Russia for which the regional importance index was lowered. Countries such as Poland, the Czech Republic, Romania and Russia can have the largest impact over the ECE region, through the common creditor channel, due to the high volume of Euro Zone bank exposure in the respective countries.

3. Conclusions

It was to be expected that in 2010, economic growth would see a comeback, however in a non-uniform manner, on the international level. The countries of the European Union are predicted to record some of the lowest performances (1% economic growth as opposed to the 4.6% world average) and the comeback from this crisis is estimated to be the result of both the packages of fiscal measures adopted by the authorities as well as the result of the incipient re-invigoration of activity in the private sector, although the viability of this comeback remains affected by short-term uncertainties.

The Global Economic Crisis, Deglobalisation and Recovery

Abstract

The global economic crisis has sparked short-term divergence of economic performance between the West and emerging markets, and thereby accelerated the longer-run convergence of the latter on the former. This Shift to the East is also even more evident in international trade and FDI than it is in other channels of globalisation.

But emerging markets' political and economic institutions, and intra-regional divisions, continue to hold back their rise. That means the Shift to the East will not translate into Chinese or other emerging-market leadership for a long time to come – if ever. The USA is still the fulcrum of international relations, and the world is far from being “post-American”. Thus the economic shift to emerging markets, accelerated by the crisis, does not translate into a paradigmatic shift in global political-economic order. But it does insert more multipolarity and uncertainty into that order, and leaves more of a leadership vacuum.

Key words: crisis, economy, deglobalisation, development

J.E.L. classification: G01

1. Introduction

World trade is recovering from its steepest fall since the 1930s – part of the biggest “deglobalisation” the world has seen since the Great Depression. The good news is that rampaging 1930s-style protectionism has not returned; indeed new crisis-related protectionism has been remarkably restrained. But protectionism has resurfaced

nonetheless, creeping out of the thicket of domestic “crisis interventions” and the seeming return to “big government”. Trade liberalisation had already stalled around the world before the crisis; the latter, predictably, increased all-round defensiveness.

The global economic crisis has also ushered in a dramatically different political and economic context compared with benign pre-crisis conditions. It has narrowed the gap between the West and emerging markets. An anaemic recovery and pervasive gloom cloud the West; talk of American decline and Eurosclerosis is back in fashion. Roaring growth and sunny optimism brighten emerging-market skies, especially in Asia; China and India shine brightest of all. But skies also shine brightly in parts of Africa and Latin America, notably Brazil. Russia has also rebounded after a searing recession.

2. The goldilocks global economy before the crisis

The pre-crisis global economy enjoyed golden conditions. The quarter-century up to the crisis saw the fastest increase in economic growth, globalisation and prosperity in history. International trade increased sevenfold between 1980 and 2008, outpacing the increase in world GDP in the same period; world foreign direct investment (FDI) far outpaced both. The global stock of outward FDI increased from USD 579 billion in 1980 to USD 16206 billion in 2008. The number of transnational companies in 2008 was estimated at 82 000, with 810 000 affiliates representing sales of USD 30 trillions [1].

The global economy had its “Goldilocks” moment in the half-decade from 2002.

Growth, trade and FDI soared to ever-greater heights; financial globalisation soared even higher. Comparative advantage worked in textbook fashion. Labour-abundant Asia rose, powered by the opening and global integration of China and, to a lesser extent, India. China became deeply enmeshed in east-Asian manufacturing supply chains linked to final markets in the West. Resource-abundant Latin America, Africa and the Middle East did well in a China-led commodity supercycle. And the capital- and technology-abundant West also prospered.

Modern globalisation has two engines: technology and policy liberalisation. Technological innovation has slashed the transaction costs of trade by shrinking physical distance; the information-technology (IT) revolution – a combination of the Internet and mobile phones – has obliterated it altogether. Advanced IT has created new global manufacturing supply chains as well as new, highly tradable services sectors.

But technological innovation has not occurred in a vacuum; it has been enabled by internal and external policy liberalisation. Internal liberalisation has reduced or eliminated regulations in product, capital and labour markets, thereby liberating the “animal spirits” of competition and entrepreneurship. This was the essence of the Reagan, Thatcher and European Single-Market revolutions in the 1980s and early 1990s. External liberalisation has lowered barriers to cross-border trade and investment. Developing countries liberalised massively and integrated into the global economy in the 1980s and ‘90s, with ex-Soviet economies following from the early 1990s. Average tariffs in developing countries fell from about 30 per cent in 1985 to just above 10 per cent in 2005. There were corresponding reductions in non-tariff trade barriers, FDI restrictions and restrictions on trade in services. The Washington Consensus reigned, reaching its apogee in the late 1990s. According to Jeffrey Sachs and Andrew Warner, around a quarter of the world’s population lived in open economies in 1980. By 1993, a majority of humanity lived in (more or less) open economies [2]. Today, adding China and India, that figure is closer to 90 per cent.

Finally, there was a conducive geopolitical environment. America became the sole superpower in the 1990s, replacing Cold War bipolarity. And global economic institutions, especially the IMF, World Bank and WTO, were at the height of their powers.

This was the global economic and geopolitical context for major emerging markets until 2008. The BRICS (Brazil, Russia, India and China) and other large emerging markets (such as Indonesia, Mexico and South Africa) undertook massive external liberalisation in the previous two decades. They became much more globalised, with increasing trade volumes, trade-to-GDP ratios, growing shares of world trade and exported value-added, and increasing FDI inflows and outflows. And, to varying degrees, they enjoyed “catch-up” growth. OECD analysis indicates that those countries and sectors in the BRIICS (Brazil, Russia, India, Indonesia, China and South Africa) that opened up most have enjoyed the largest growth spurts. Export-oriented manufacturing in China, much of it driven by openness to inward investment, is one notable example. The emergence of globally competitive services providers in India, especially in a young, lightly regulated IT sector, is another [3].

3. The global economic crisis, deglobalisation and recovery: different effect on the west and emerging markets

The financial crisis that exploded in September 2008, preceded by the credit crunch that started a year earlier, transformed a benign global political and economic context into something more malign. A sharp contraction in global growth ensued. This was reinforced by even sharper contractions in trade, FDI, financial flows and other channels of globalisation. The world suffered its worst deglobalisation since the Second World War. Contrary to some predictions, Asia and other emerging markets did not “decouple” from the West; they too were dragged down. Contractions in growth, industrial output and trade bottomed out towards mid-2009, followed by a halting global recovery. The crisis has induced both divergence and convergence between the

West and emerging markets. Post-crisis economic performance has diverged markedly; but this has accelerated the long-run catch-up or convergence of emerging markets with the West.

Diverging economic performance has its roots in the crisis itself. The West had a financial crisis. That translates into a deeper-than-normal recession and a slower-than-average recovery [4]. The picture looks very different in emerging markets, particularly in Asia. Unlike the West, Asian and many other emerging markets did not suffer a financial crisis; their banks and balance sheets (household, corporate, government and external) were reasonably solid. Rather they suffered a trade or deglobalisation crisis as the financial crisis, originating in the West, spread to the "real economy" and demand for exports collapsed. But they rebounded quickly – much more so than the West.

4. Trade policy, emerging protectionism and the 1970s' precedent

Will domestic crisis interventions spill over to trade protectionism? There is an optimistic answer – and a contrasting pessimistic one.

Start with the optimists. One aspect of the post-crisis conventional wisdom – dear to the hearts of Keynesian and other social engineers – is the belief in "Keynes at home and Smith abroad" (otherwise known as "embedded liberalism" in International Relations jargon). Greater government macro- and microeconomic interventions at home are needed to stimulate recovery and preserve social stability – and thereby prevent a slide into protectionism. But this should proceed in tandem with open markets abroad, which require robust international policy coordination (sometimes labelled "global governance").

To Jan Tumlrir, the GATT's long-time in-house philosopher, the source of the problem is overactive governments in cahoots with domestic organised interests. Cumulative interventions distort prices, rigidify economies, and make public and private actors more resistant to adjust to external change. The predictable corollary is a "fear of trade" and the resort to import protection.

Thus "protectionism is the inherent logic of the redistributive state working itself out externally." This is how Tumlrir accounted for twentieth-century protectionism, in the 1920s, 1930s, 1970s and 1980s [5].

We agree with Smith and Tumlrir. I am more worried about the medium-term competition-restricting consequences of BigGovernment, including protectionism, than I am about a short-term contraction of aggregate trade and demand in the wake of the crisis.

A review of the troops

Now turn to the major players in trade policy and see how they have responded to the crisis. This section starts with the United States and the EU, and then goes on to the major emerging markets and Japan.

United States

America is down and diminished, though not out. On foreign policy, President Obama's rhetoric on soft power and multilateralism has not translated into effective American leadership abroad, on either security or economic agendas. Economic woes at home clearly cramp the USA's ability to lead abroad; weakness at home translates into weakness on the global stage.

Trade policy has deteriorated in the United States since the Obama administration took over. The Bush administration, for all its faults, did not do a bad job on this front. Its major achievement was to contain protectionism at home, especially against China. President Obama, on the other hand, while no clear-cut protectionist, has ambivalent views on the subject and is not an instinctive free-trader. He has powerful protectionist forces inside his tent – among Congressional Democrats, the AFL-CIO, and at his Cabinet table. The Office of the United States Trade Representative is packed with staffers with close links to trades unions as well Congressional lawmakers with protectionist voting records. This makes the Obama administration different from previous administrations, including the Clinton administration.

EU

The picture in the EU is similar to that in the United States: internal weakness and external defensiveness. True, some European economies show signs of healthy recovery. But that is not the overall picture. Symptoms of *malaise* abound: sovereign-debt crises, still-malfunctioning banking systems, industrial strife, sclerotic labour markets, bloated welfare states, intergovernmental squabbling and weak EU institutions.

The EU has behaved better than most in terms of headline protectionist measures. It has not increased tariffs, nor – unlike the Americans and Chinese – has it resorted to discriminatory public-procurement measures. And there has been no significant increase in anti-dumping actions and other “trade remedies”. But worrying signs persist. They concern crisis-related regulatory measures that could easily spill over into protectionism. The relaxation of EU state-aid rules during the crisis opened the door to discriminatory subsidisation, especially to the financial and automotive sectors. The EU already has the most stringent food-safety and technical standards in the world. These could become more restrictive, especially on environmental and climate-change regulations.

Caribbean and Pacific countries, and bilateral negotiations with several countries in Asia, the Middle East and Latin America. Trade relations with China are also adrift and replete with tensions. The exceptions to this rule are the freshly ratified FTA with South Korea, and ongoing negotiations with Canada, Singapore and India. And the EU’s vaunted “soft power”, outside its immediate neighbourhood, is hardly taken seriously – when not dismissed as a joke. The European Commission’s new trade strategy, announced in November 2010, does nothing to change these facts on the ground, rather being an update and slight modification of established policy [6].

Finally, the EU suffers from a paradox. With enlargement and greater market size it is weightier in the global economy. But at the same time its decision-making has become more fragmented, making it more difficult to coordinate national positions and speak with one voice. That decreases its ability to wield collective power abroad. In the one arena

where the EU is a global heavyweight -- trade policy -- competence has been divided on several issues, notably services and investment. An enlarged EU made it extra-difficult to have credible positions in international negotiations on services and investment. The Lisbon Treaty is supposed to overcome these problems by streamlining decision-making and unifying competence on services, investment and intellectual property rights. But this is counter-balanced with “co-decision” for the European Parliament. That confers the EP greater power in EU trade policy. Market-sceptical forces and single-issue fetishists in the EP are bound to complicate decision-making and could tilt policy outcomes in a more protectionist direction.

China

China has powered through the crisis with a turbo-charged fiscal and monetary stimulus equivalent to almost 45 per cent of GDP in 2009. It is the leading contributor to post-crisis global growth. China’s continuing industrial revolution. That is also true of other east-Asian economies, who, in addition, export parts and components to China for assembly and export elsewhere. Increasingly, they are also gearing up to export finished goods to a booming Chinese consumer market.

China is now one of the Big Three in the global economy. Until recently, it imported “global order”: it absorbed policies, rules and institutions that materialised from decisions made elsewhere. China still imports global order; but, given its market size, and like the USA and EU, it now exports global order as well. Decisions made in China reverberate around the world. And they do so to a much, much greater extent than decisions made in the other BRICS. China accounts for about 60 per cent of BRICS’ output, two-thirds of its foreign-exchange reserves and exports, and one-third of its inward investment. China plays in its own league among emerging markets. The other BRICS play in an inferior league; they are still much bigger net importers of global order [7].

Japan

Japan is still about as large as China in absolute market size, and is still Asia's richest economy (in terms of per-capita income). But it is stuck in a political and economic quagmire that has lasted two decades. The Japanese political system is blocked; it seems hopelessly incapable of delivering clear policy choices, including economic reforms. The economy has sputtered along a low-growth track, now with astronomically high public debt. The crisis seems to have made Japan even more averse to reform. Exceptionally in Asia, Japan has had a Western-style crisis: Keynesian macroeconomic policies alongside escalating public debt; and growth contraction followed by modest recovery. Conditions would be much worse if not for roaring growth in its neighbourhood, especially in China.

India

India has weathered the crisis well, buoyed by exuberant domestic consumption. Previous market reforms, especially since 1991, have liberated domestic producers and consumers. and opened India to the world. Trade and FDI liberalisation has been critical to India's recent global economic integration. Internal and external market reforms have transformed the business landscape and spawned an aspiring, vibrant urban middle class. But relatively high levels of protection remain: agricultural tariffs and NTBs, peak industrial tariffs and big-ticket services sectors (such as professional services, banking, insurance, retail and distribution, and aviation) [8].

Russia

Russia is exceptional among the BRICS. Since 2003/4, previous market-opening reforms not only stalled; they were reversed and policy went in a strongly deliberalising direction. Politics has become increasingly authoritarian; and it has been used by the state to nationalise energy assets, promote monopolistic practices by favoured national champions, and generally apply laws and regulations in a highly selective, arbitrary manner. "State capitalism" is the order of the

day. Its external manifestation is "hard mercantilism". Foreign policy is aggressive towards Russia's neighbours, its "near abroad". Arbitrary trade measures, such as cutting off gas supplies to other countries, and unlawful treatment of foreign investors, have become more frequent. Trade mercantilism extends to playing off EU member-states against each other in order to entrench EU energy dependency on Russia [9].

The impact of the global crisis on Romania's economy

During the first quarter of 2009 the gross domestic product of Romania fell by 2.6 percent compared to fourth quarter of 2008 (adjusted data taking into account the seasonal variations) and 6.4 percent compared to first quarter 2008 (data not adjusted). The fourth quarter of 2008 witnessed a reduction of gross domestic product by 3.4 percent over the third quarter. The second quarter of 2009 saw another decline of GDP, by 1.1 percent compared with the previous quarter and by 8.8 percent compared with the same period of 2008. So, according to the technical definition of a recession, i.e. a decline in GDP for two consecutive quarters, Romania has entered recession in 2009.

The global crisis has seriously affected in 2009 the industrial sector, whose main branches are under the majority control of foreign capital and subsidiaries of multinational corporations, being more exposed to international markets. In the first seven months of 2009, the industrial production decreased by 9.6 percent over the same period of last year. On sections, a decline by 10.8 percent has been recorded both in extractive industry and manufacturing. On industry groups, more severe production drop was in intermediate goods (-15.3 percent) and durable consumer goods (-17.4 percent).

In the first eight months of 2009, compared with the same period of 2008, the biggest fall in the industrial production was registered in manufacturing of basic metals, manufacture of other nonmetallic mineral products and textiles. Other manufacturing industries in decline were clothes, paper and

paper products, chemicals and chemical products, rubber and plastics, petroleum products, furniture. Industries less affected by the crisis and where production has increased during the analyzed period (wood processing, publishing houses, printing and reproduction of recorded media, manufacture of electric equipment), even are not touching essential sectors of the economy, could see a more rapid recover [10].

5. Conclusions

The global economic crisis has sparked short-term divergence of economic performance between the West and emerging markets, and thereby accelerated the longer-run convergence of the latter on the former. That is particularly evident in globalising Asia. This Shift to the East is also even more evident in international trade and FDI than it is in other channels of globalisation. And it creates very different economic and geopolitical conditions to those that prevailed under US leadership and a transatlantic-centred world economy in the second half of the last century. Western and emerging-market elites are only just beginning to recognise this shift, but they still have little clue how to deal with it.

But emerging markets' political and economic institutions, and intra-regional divisions, continue to hold back their rise. That means the Shift to the East will not translate into Chinese or other emerging-market leadership for a long time to come – if ever. The USA is still the fulcrum of international relations, and the world is far from being "post-American". But the USA is diminished; it is less capable and willing to exercise global leadership – clearly evident under the Obama administration. Europe is also no substitute for US leadership. The EU has the world's biggest unified market. But that is the extent of the EU's global power. Its hybrid nature, internal divisions and absence of hard power (a unified military capacity) will always prevent it from having a serious, coherent foreign policy. Its soft power, outside the greater European neighbourhood, is mostly postmodern hot air.

On a final contextual note, the global economic crisis has brought Keynesian macroeconomics back to fashion, and with it

Pigovian welfare economics – microeconomic interventions to fix alleged market failures. A social-engineering mentality – the belief that superior technocratic minds can solve complex social and economic problems with targeted interventions – has been in the ascendant. Welcome to the world-view of Mr. Bentham, Mr. Keynes, Mr. Stiglitz and Mr. Krugman. That of Mr. Hume, Mr. Smith and Mr. Hayek – the belief that markets are complex organisms; that governments, however expertly staffed, cannot possibly have enough knowledge to "fine-tune" macro- and microeconomic outcomes with detailed, prescriptive regulations; that governments also "fail" through human fallibility, political pressure and corruption; and, consequently, that regulation should err on the side of caution and stick to general rules to allow markets to operate effectively – has become less popular.

The Impact of the Global Crisis on the European Labour Market. Case Study: the Labour Markets of Spain and Romania

Ionescu Romeo

"Dunarea de Jos" University of Galati

ionescu_v_romeo@yahoo.com

Abstract

The paper deals with a comparative analysis of the labour markets in Spain and Romania, countries which are powerfully connected under the migratory stream. The first part of the analysis is connected to the Spanish economic environment which was able to support a high labour demand until 2008. The second step is to present the situation of the Romanian labour market under present crisis.

A distinct part of the paper deals with the European balancing labour market prospects, including Spain and Romania.

The main conclusion of the paper is that the labour market is far away to find the equilibrium. Moreover, its situation in Romania is worst. The analysis and its conclusions are supported by neutral statistical databases, tables and pertinent diagrams.

Key words: migratory stream, unemployment rate, active population, labour cost.

J.E.L. classification : J60, J61, J62.

1. Introduction

The European Commission referred to the labour mobility deficit in the EU. Only 2% of the EU working-age population work in other member state. On the other hand, the foreign workers from the EU are two times more mobile than the European citizens [1].

In order to obtain better jobs, the European citizens have to move from a place to another. The young workers started to understand it. The latest Eurobarometer survey demonstrated that about 70% of the young workers support the geographical and professional mobility in order to build their career. Moreover, they practice multi mobility, a paradigm which covers short term

jobs, according to the employer or employee's needs time.

The European Commission's implemented measures achieved partly the mobility increase.

According to the European Labour Force Survey, the number of the mobile workers in the EU15 grew, from 470000 in 2000, to 680000 in 2008. These data have to be corrected with the casuals.

Even that 2006 was the "Year of the EU workers mobility", there are barriers against the labour free movement, related to: administrative formalities, housing cost, difficulties in hiring spouse, pensions, language, children's schooling and so on.

Nowadays, the potential migration from the latest EU member states decreased, after a boom during 2004-2008.

2. Regional unemployment under the global crisis

At the end of 2009, the community regional unemployment rates varied between 2.1% in Zeeland (Netherland) to 27.1% in Reunion (France). During 2008-2009, the unemployment rate increased in 90% of the NUTS2 regions. 28 regions had an unemployment rate less than 4.4% and a half rates equal to the EU average. From the second category belong 11 regions from Netherland, 5 from Austria, 3 from Italy, by two regions from Belgium, Czech Republic and Germany and by a region from Bulgaria, Romania and UK.

At the other extreme are 13 regions with unemployment rates of 17.8% or greater: 9 regions from Spain and 4 regions from the French Departments [2].

The female regional unemployment rates were lower in Zeeland (2.4%), Utrecht (2.9%) and Tirol (2.9%). The greatest female regional unemployment rates were in Mellila (33.6%) and in 4 French Departments.

Table 1. Total regional unemployment rates (2009, %)

The lowest unemployment rates		The highest unemployment rates	
Region	Rate	Region	Rate
Zeeland (Netherlands)	2.1	Melilla (Spain)	33.6
Gelderland (Netherlands)	2.8	Reunion (France)	29.0
Bolzano (Italy)	2.9	Ceuta (Spain)	28.2
Utrecht (Netherlands)	2.9	Andalucia (Spain)	27.1
Tirol (Austria)	2.9	Canarias (Spain)	27.0
Prague (Czech Rep)	3.1	Guadeloupe (France)	26.3
Noord-Brabant (Netherlands)	3.2	Guyane (France)	25.9
Noord-Holland (Netherlands)	3.2	Extremadura (Spain)	25.3
Salzburg (Austria)	3.2	Martinique (France)	23.0
Trento (Italy)	3.5	Castilla-La Mancha (Spain)	21.4
Friesland (Netherlands)	3.5	Valenciana (Spain)	21.0
		Murcia (Spain)	18.8

Source: <http://ec.europa.eu/eurostat>

Practically, the female unemployment has the same rates as the total one. As a result, Netherlands and Austria had lower unemployment rates, but the French Departments had the highest ones.

Table 2. Female regional unemployment rates (2009, %)

The lowest unemployment rates		The highest unemployment rates	
Region	Rate	Region	Rate
Zeeland (Netherlands)	2.4	Reunion (France)	27.1
Utrecht (Netherlands)	2.9	Canarias (Spain)	26.2
Tirol (Austria)	2.9	Andalucia (Spain)	25.4
Gelderland (Netherlands)	3.1	Melilla (Spain)	24.2
Prague (Czech Rep)	3.2	Guadeloupe (France)	23.4
Noord-Brabant (Netherlands)	3.3	Martinique (France)	21.8

Bolzano (Italy)	3.4	Valenciana (Spain)	21.1
Noord-Holland (Netherlands)	3.4	Murcia (Spain)	20.7
Flevoland (Netherlands)	3.5	Extremadura (Spain)	20.5
Drenthe (Netherlands)	3.6	Guyane (France)	20.2
Overijssel (Netherlands)	3.6	Ceuta (Spain)	18.9
Zuid-Holland (Netherlands)	3.6	Castilla-La Mancha (Spain)	18.8
Salzburg (Austria)	3.6		
Bucharest-Ilfov	3.6		

Source: <http://ec.europa.eu/eurostat>

The greatest disparities are connected to the young people unemployment. The situation is better in Netherlands (Zeeland 4.0%, Gelderland 5.4%, Overijssel 5.6% and Utrecht 5.7%), but worst in the French Departments (Guadeloupe 50.3%, Martinique 57.6% and Reunion 49.6%).

Across 35 regions, the young people unemployment rates were less than 9.9%: 14 regions from Germany, 12 regions from Netherlands, 5 from Austria and by one region from Czech Republic, Slovakia and UK. Across 7 regions, the unemployment rates were above 39.8%: by three regions from Spain and France and a region from Italy.

Across 75% of the EU regions, the young people unemployment rates were at least two times greater than the EU total average unemployment rate. Only Bremen had a young people unemployment rate less than the total unemployment rate.

Table 3. Young people regional unemployment rates (2009, %)

The lowest unemployment rates		The highest unemployment rates	
Region	Rate	Region	Rate
Zeeland (Netherlands)	4.0	Guadeloupe (France)	59.3
Gelderland (Netherlands)	5.4	Martinique (France)	57.6
Overijssel (Netherlands)	5.6	Reunion (France)	49.6
Utrecht (Netherlands)	5.7	Canarias (Spain)	47.9
Tubingen (Germany)	5.8	Andalucia (Spain)	45.0

Noord-Holland (Netherlands)	6.1	Sardinia (Italy)	44.7
Noord-Brabant (Netherlands)	6.3	Extremadura (Spain)	41.2
Oberbayern (Germany)	6.4	Melilla (Spain)	39.7
Tirol (Austria)	6.4	Valenciana (Spain)	39.5
Freiburg (Germany)	6.7	Sicilia	38.5
Bremen (Germany)	6.9	Basilicata (Italy)	38.5
Oberpfalz (Germany)	6.9	Campania (Italy)	38.1

Across the Euro area, the average unemployment rate was 10.1% on September 2010 regarding 9.3% on the same month 2009.

Figure 1. The unemployment rate trend (%)

Source: personal contribution using [3]

Eurostat forecasted the EU total unemployment stock to 23,109 million persons in 2009. About 16 million of them were from the Euro area. The unemployment rate in the Euro area is greater than that in the EU (9.6%). On the other hand, the lowest unemployment rates in 2010 were achieved in Euro area: Netherlands (4.4%) and Austria (4.5%). The paradox is the highest unemployment rate came from the Euro area,

as well: Spain (20.8%) [4].

In 2010, the unemployment rate was 9.6% in USA and 5.1% in Japan. As a result, the EU average unemployment rate is two times greater than in Japan and the same with that from USA.

The monthly unemployment stock evolution in the EU and Euro area during September 2009 – September 2010 is presented in figure 2.

Figure 2. The unemployment stock trend (mill. persons)

Source: personal contribution using [3]

3. Labour market analysis in Spain and Romania

More than 1/3 from the Romanian households had at least a member went abroad still 1989 [5]. 12% of the people aged 18 to 59 years worked abroad still 1989.

This phenomenon grew after 2002, as a result of the Romanians free movement across the Schengen space.

Nowadays, 75% of the Romanians who work abroad are in Italy and Spain. The Romanian legal workers in these two countries are about 1.8 million persons. Moreover, there are at least 400000 persons who work illegally. The Romanian workers activate in construction, agriculture and domestic works.

The Romanian abroad workers represent an important source of incomes and an important investment, as well. The money from abroad was used in housing, cars, electronics and other durable goods. The sources of the migration are the less development regions from Romania.

During the present crisis the Romanian labour market was influenced by the agreements with IMF and the high labour migration abroad. As a result, even the

employment growth rate was low, the unemployment rate and the unit labour cost grew (see figure 3).

Figure 3. The employment, unemployment rate and real unit labour cost in Romania (%)

Source: personal contribution using [3]

The European Commission's forecasts talk about a low employment growth during 2011-2012. The unemployment rate will decrease lowly during the same time period. An important decrease will be achieved by the real unit labour cost.

This information has to be used carefully. On the first hand, the private sector covers 2/3 of GDP in Romania. This is why the influence of the public sector wages decreased on the market. On the other hand, the implementation of the European social model, as a result of Romania's adhering to the EU, will grow the power of the trade unions of the labour market. Third, the great migration of the Romanian workers and the wages' decrease, especially in the public sector, supported the lack of specific labour categories. This is balanced by a labour surplus in other industries. The simultaneous occurrence of shortages and surpluses represent not only a characteristic of the transition economies [6], but one of the emergent or low developed economies.

Maybe these imbalances are caused by the labour market rigidity [7]. This is why Romania, with an unemployment rate of 7.5%, and Poland, with 20.1%, in 2010 face to the same lack of trained labour in some specific industries.

The Spanish economy faced to the powerful impact of the crisis. Until 2008, Spain supported a significant development of the constructions and the real estate.

Even that the GDP decreased was only of

0.2% in 2010, the employment decreased powerfully during 2009-2010. The European forecasts talk about a recovery in 2012. The unemployment rate increased during 2008-2010, and it will be high during 2011-2012. Spain faced to constant high unemployment rates still 2007. This evolution of the labour market supported a low decrease of the real unit labour cost (see figure 4).

Figure 4. The employment, unemployment rate and real unit labour cost in Spain (%)

Source: personal contribution using [8]

The tone-alarm is that the unemployment rate in Spain will be high in 2011 and 2012, even that the GDP growth rate will be positive in both years. The new jobs will be created at the end of 2011.

The National Bank of Spain forecasted a gradual improvement of the labour market, especially in the private sector [9].

In 2010, 4.6 million Spanish workers faced to the unemployment. The unemployment affected 800000 Romanians who lived in Spain. Romanians are first ranked among immigrants. The same unemployment rate (20.1%) was achieved only in 1997. As a result, many Romanian workers are forced to return home [10].

The unemployment rate in Romania was better than Spain. Eurostat ranked Romania on the 20th position in the EU under the unemployment rate, in the 4th quarter of 2010. Eurostat talks about 23 million unemployed persons across the EU [11].

4. Conclusions

The great concern about the Romanian economy is that the main pylons from the financing agreement signed with the international institutions were not able to

support the economic growth. As a result, 2011 is the third year of crisis even that the political leaders have another opinion. It will be difficult to grow the labour demand on the market and to ensure jobs for the Romanian workers from abroad.

Moreover, IMF agreed the decrease of the unique tax to 12% still 2012. The public gross debt will achieve 33.4% of GDP in 2011, regarding 30.4% in 2010.

IMF considers that Spain will achieve a weak and fragile economic recovery in 2011. But this recovery depends on further deficit reduction plan, pension reform and labour market flexibility growth.

The question is if the labour migration abroad is a solution? Maybe it is a individual solution as long as the minimum wage in Spain was 728 Euros and in Romania only 153 Euros (see figure 5).

The problem is that the minimum wages is more than 1380 Euros in Belgium, Ireland, Luxembourg or Netherland.

Figure 5. The minimum wage in Spain and Romania (Euros)

Source: personal contribution using [12]

The real solution is the economic recovery. The unemployment represents a waste of the most important economic input.

European Accounting Normalization between Directives and IFRS Standards

Ioniță (Nistor) Nicoleta
Ioniță (Predescu) Lorena
"Valahia" University of Targoviste
nicoletta.nistor@yahoo.com
lorevlad@yahoo.co.uk

Abstract

The contemporary evolution of accounting can be characterized by large phenomena like: normalization, harmonization and convergence. Thus, it is taking into consideration the improvement and the reducing of the disparities between national accounting practices and regulations, the development of principles and norms that lead to achieving of information and coherent picture on entities, the comparability in time and space of the information drawn from financial statements.

In this article I have given a special attention for the research of initiatives and concerns of the European standardization body, retaining those measures and actions that led to the adaptation of European accounting directives to make them compatible with IFRS.

However the approaching of this issue requires a short review of the normalization process and accounting harmonization in order to coordinate the principles, norms and accounting objectives at international level. This also led to discussion of options in the principles and accounting rules.

Key words: normalization, harmonization, European regulations, IFRS

J.E.L. classification: M41

1. Introduction

The accounting normalization is spread over three levels: national (by general accounting plan), regional (regulation 1606/2002 and directives 4 and 7) and international (by international standards of financial reporting – IFRS).

The next paragraphs will be dedicated to the issue of regional normalization.

From an economic perspective, European integration is based on the unification of national markets and, consequently, the removal of barriers to free movement of persons, services, goods and capital. However, it would be pointless to say that the free movement of capital is possible without a minimum harmonization of accounting standards of the member states, which is essential for rational investment decisions of economic actors.

Normalization of accounting in the European Union (EU) started with the adoption of IV and VII guidelines by the Council of the European Communities. The Directive IV in 1978 which aims the coordination of provisions regarding the structure and content of individual annual financial statements, valuation methods and the publication of these situations and the Directive VII in 1983, which has done the same in terms of conditions to prepare consolidated financial statements.

However, despite ongoing efforts, the European Commission has failed to determine member states to go beyond the minimum harmonization, so that, under the pressure of investors, the companies were forced to adopt accounting standards USGAAP to have access to international markets. Thus, the scandals that occurred in the early 2000s (Enron, WorldCom, Andersen Consulting ...) have shaken U.S. financial sector and stressed, however, deficiencies in the U.S. accounting system through the adopted accounting rules itself. In addition they have evolved, but not enough to take into account the changes in the economy, including the increasing scale of operations and financial instruments. The

accounting rules have not been able anymore to provide a "real picture" of the company. Therefore, the need for new accounting standards, together with the development of financial markets and the opening of national and international economies, occurs as a result of a triple requirement: to ensure better comparability of the accounts of listed companies, facilitating access to international financial markets and improving the reliability of accounting data. It is clear that the IASB and IFRS standards satisfy these requirements.

To align these requirements and to support this way the member states to access international markets with minimal costs, the EU had no other option than to adopt IFRS, which is the only credible alternative to USGAAP adoption. By a strange trick of history, European countries, which held to their accounting sovereignty, were forced to give the supremacy of the accounting standards to an international private body, the IASB (International Accounting Standards Board), on which they had no control.

Therefore, the interest of harmonizing the accounting systems at international and European level has resulted in the compatibility program of EU accounting directives with international accounting standards. International accounting harmonization was a two speeds process: fast for large listed companies and more slowly for others [3]. Discussing about the distinction between standardization and harmonization, Professor Bernard Colasse states that the accounting harmonization is less restrictive than normalization, it establish equivalence between a variety of accounting practices and thus is a modified form of normalization and a first step towards this [3]. Other authors define the harmonization as the process by the components of conceptual accounting framework are related, compatible and standardized [9].

2. Regulation 1606/2002 of the European accounting normalization

2.1. Adapting the European accounting directives to make them compatible with IFRS

The modernization process of European regulations aimed the eliminating possible

incompatibilities with current and future IFRS. Thus, European legislation (Regulation 1606/2002) provides that the accounting directives (IV and VII) will continue to apply to listed companies that publish their financial statements according to IFRS standards. Thus, in 2003 the European Parliament and the Council of European Union adopted the Directive 2003/51/EC which has brought modernization and upgrades to the European accounting texts (Directives IV and VII). These changes concern both compatible with IFRS, as well as the option of Member States regarding the processing of annual accounts for listed companies.

Thus, the main changes brought to directives are related to the adaptation format of the balance sheet and profit and loss account so as to take into account the provisions of IFRS, the possibility of revaluation of all property, the possibility of assessing the assets at fair value (not only of financial tools, as provided in the Directive), the adaptation rules of constitution of provisions for risks and expenses at IFRS standards; the compulsory of consolidation of subsidiaries, presentation of financial statements, annual and consolidated, supplementary; the consolidation of all ad-hoc controlled companies.

The need to modernize the European directives was imposed by the fact of, from their adoption (in 1978, respectively 1983) have not changed in substance, while accounting concepts and principles have evolved significantly.

However, some issues covered by the directive are inconsistent with IFRS standards. Although they have played an important role in the adoption of IFRS, these regulations must ensure „equality of processing between companies that do not apply IFRS standards and those that apply them,, [5].

The process of modernization and updating of the EU accounting texts had the main objective the assurance of their flexibility for integrating the future changes in modern accounting practices. From this general objective, it can be emphasized two secondary objectives: elimination of any discrepancy between these directives and IFRS standards, thus facilitating the preparation and presentation of financial

statements according to IFRS standards by listed companies and the possibility of option of Member States to apply the accounting options offered by IFRS for unlisted companies.

2.2. Other considerations about European accounting mechanism: the abandon of European accounting ambition

Regulation 1606/2002 provides for the applicability of IFRS in Europe, after their approval by the European accounting mechanism consists of: Accounting Regulatory Committee (ARC) and the European Financial Reporting Advisory Group (EFRAG). This adopting mechanism is meant to pronounce on the applicability of IFRS standards in the EU in that they must meet the criteria strictly defined by it, namely: not to be contrary to the real image of the directives, to answer the European public interest and meet the criteria of intelligibility, relevance, reliability and comparability of financial information required.

In the European Commission and European Parliament report on the implementation of Regulation 1606/2002 [13], it is mentioned that by the approval (certification) of IFRS norms by EU it is assured the technical quality, political legitimacy and relevance to business environment. As the European Commission said in its remarks (November 2003) on some articles of Regulation 1606/2002 "in a system based on principles such as IAS, there are always transactions or agreements not covered by explicit rules. In these circumstances, it is specifically required the professional reasoning to define the most appropriate accounting treatment. (...) national law can not, by prescribing specific treatments, restrict or impede the exercise of judgment" [13]. Therefore, "the IAS Regulation is directly applicable, member states should take care not to try to expose the companies to additional provisions of national legislation to prevent, or contradict the compliance of these adopted IAS" [14].

The adoption of this regulation, the delegation of accounting sovereignty, de facto, by the European Union, to a private international organization, was developed on the base of a quasi-generalized indifference

in Europe, probably because it was a far and uncertain perspective, having in view a complex and technical meaning that only a few have understood it. However, the "approval" of IFRS norms gave a precise content which forced these companies to more accurately assess the consequences that involve changing the accounting referential. They are, without doubt, banks that have struggled most to obtain from the European Commission the refusal to "certify" the standards that affect them directly, for example, IAS 32 Financial Instruments: Presentation and IAS 39 Financial Instruments: Recognition and evaluation.

The adoption mechanism involves the following stages: technical evaluation by the EFRAG, adopting by ARC, the application decision taken by the European Commission, the translation in each of the official languages of the EU, publication as a regulation in the European official journal, since January 1, 2003.

Although the European body of accounting regulatory said that it has no material and intellectual resources for elaboration of accounting norms adapted to meet the needs of information in the ongoing development and diversification, however, it considers the accounting normalization too important to be entrusted only to professional bodies (in this case IASB), so that, by means of the mechanism of adopting the IFRS standards, Europe assumes the means of pressure, if necessary, to the international body, where a standard would not sufficiently protect European interests.

Therefore, European accounting directives will remain important, despite the implementation of IFRS standards because, as set out in Regulation 1606/2002, they play an important role in the mechanism of IFRS standards adoption by the listed companies. On the other hand, for listed companies, the directives remain the basic accounting legislation, and besides, for areas not covered by IFRS standards, the directives continue to cover important aspects (e.g. to prepare a report for management, publishing requirements, certification of accounts).

3. Where is Romania in the frame of European normalization?

Regarding the evolution of accounting in our country, Prof. N. Feleaga, in the preface of the book "Financial Accounting - An European and international approach", notes that "against the winds and tides, our country has become a part of the European Union in the context of international events that face: globalization of economies and globalization of financial markets" and "our paradoxical country has never lived in times of a Romanian accounting!" [5].

In Romania, financial reporting and audit requirements continue to suffer changes and make progress towards implementation of standards comparable to those applied in the EU. We note that since 1999, the Ministry of Finance has initiated a project to harmonize the Romanian legislation in the field of accounting and auditing to international standards and European directives which led to some fundamental changes in legislation: OMPF 94/2001 (harmonization of financial reporting in Romania with requirements of International Accounting Standards and Directive 4 of the European Union for companies that do not apply OMPF 94/2001), OUG 75/1999 approved by Law 133/2002 (establishing a body responsible for training and regulation of financial audit, the Chamber of Financial Auditors from Romania); OMPF 1752/2005 (approval of accounting regulations harmonized with European Directives); OMPF 3005/2009 (approval of accounting regulations according to European Directives), OMFP 907/2005 (approval categories of legal entities applying IFRS accounting rules).

Since January 2010, OMFP 1752/2005 was replaced with OMFP 3005/2009 that cover, in a single law the financial reporting applicable to entities, structured in two parts according to the transposed Directives. This legislation brings new elements on the accounting treatment and general framework of preparation and presentation the financial statements. The innovation items aim the highlight, in the balance sheet, of negative goodwill (the un-resumed part of incomes) as distinct position, and separate highlighting of amounts to be resumed from income recorded in advance by 1 year and over 1 year. In terms of profit and loss account,

according to the new regulations, the commercial discounts granted, and received subsequent billing, are shown separately in the turnover, material costs respectively. The resumed part of income from negative goodwill is also recorded as a separate item. The new regulation requires more detailed evidence of certain information such as the separate presentation of research and development expenses incurred in public or private funds, the shares in affiliated entities, as well as short-term investment for residents and nonresidents.

Regarding the adoption and application process of IFRS standards in Romania, it is based on EU legislation relating to the implementation of IFRS in the Community, that the provisions of European Regulation 1606 and the Council on the implementation of International Financial Reporting Standards. But for large businesses and multinational companies the impose by national normalization bodies of local regulations, other than international, appears as a barrier to access to major financial markets. These entities are also required to submit financial statements in accordance with international standards, which generate additional costs for re-treatment information.

We conclude that Romania has aligned itself with European accounting standardization, the conclusion of monitoring by the specialized direction of European Commission is relevant regarding the level of compliance for the Romanian accounting regulations with European Directives 4 and 7 which shows a high degree of compliance with European rules.

What deserves to be emphasized is that has not opted to take over entirely for getting closer the local accounting law to the European and international accounting regulations. This harmonization has been achieved naturally, by adopting those improvements necessary to align with EU directives.

Such guidance is a first step towards a fundamental change of optics in the field of financial and accounting information, the provided data aimed to meet common user requirements.

4. Premises for the future: principles versus accounting rules

The controversy of standards based on principles or rules-based standards has been and is widely debated in the literature.

Therefore, analyzing the reference of internationally recognized accounting we can say that in Europe (Regulation 1606/2002 and IFRS standards) it goes on the concept of accounting principles that leaves significant room for professional reasoning, while the USA is going on accounting rules (U.S. GAAP consists in a work of about 140,000 pages and responds to most issues of interpretation). The process of normalization and global accounting convergence also requires resolving the controversy between the accounting thinking from European and American spaces. This issue has been discussed by several authors: Schipper [11] found that the American normalizers often call the principles in formulating of accounting rules; Nelson [7] highlights that the substantiation of standards on principles, more or less, and the development of rules that would better meet the normalizers requirements, would reduce the accounting options that managers call for tuning the company's image.

U.S. accounting standards have been criticized because they often contain too many rules and too few principles, which led to their complexity. Thus, in an article, Nobes [8] proposed that standards be based on principles and not on rules. The author supports the idea through a number of relevant examples that IFRS standards could be clearer, simpler and better supported. Although considered that the rules can contribute to more relevant comparison and clarification, he notes that sometimes in standards, the principles are either absent or too poor. The author concludes that the existence and application of a proper principle reduces the need for arbitrary and detailed rules.

Experts Federation of Accountants in Europe the promoter of implementation support of IFRS in the EU until 2005, supports the approach based on the principles of IFRS standards [4]. Therefore, clear principles designed to serve the public interest reinforces the rules that show how these principles should be applied in concrete

situations. By this, it promotes firmness and transparency and helps companies to respond appropriately to complex situations to new developments in business practice. At the same time is prevented the issue of too many regulations and diminishing "technical omissions" that can occur where detailed rules are developed in an effort to cover all eventualities that may arise in the accounting practice from an entity. If we consider both principles-based approach disadvantage (the possibility of too much "creativity" can be made to serve a cosmetic accounting information) and disadvantages of the approach based on detailed rules (such as suppression initiatives; creating the false and extremely damaging impressions that if the rules are followed all goes well or creating the temptation and even some mechanisms to bypass the rules) we believe that exclusive choice of either of the two approaches may be proved not to be sufficient to create quality works and accurate reporting.

5. Conclusions

The failure of European accounting normalization requires an exercise of reflection. Even if, by its structure, the EU had to look for consensus among its members, the inability to achieve this goal, and the intellectual, technical and financial failure needed for the production of accounting standards comparable at international level, have forced it to accept an accounting referential prepared by a private international body over which it could not exercise the control.

Looking back, the choice of the European Union - but was it really a choice? – to apply IFRS rules, can hardly be disputed. If it is something to be emphasized, it does not take much of the application of IFRS as a result of the failure of the European Union to develop its own accounting standards, but that it had not negotiated the influence on the IASB and its work program, even if was able to do so.

We believe however that the normalizers' roads tend to meet, there are many attempts internationally regarding the comparability of information provided by financial reporting. We base this statement on the increasing scale that took the consultations and joint

work of American, European and international normalizers. Thus:

- the most significant change was achieved through regional harmonization at EU level through directives and specific regulations;
- Directive IV has produced changes in most EU countries in terms of format and content of financial statements, disclosure and assessment procedures;
- the Directive VII has significant implications for the harmonization of financial statements of the group;
- financial reporting in the EU has been transformed as a result of political changes and economic reforms that have taken place (regulation 1606/2002);
- by harmonizing EU accounting standards and adoption of IFRS standards, the accounting profession is gaining status and influence compared with the period before the normalization process, harmonization and convergence of accounting.

Strategies for Tourism Development in Coastal Spas, Nationally and Internationally

Ioniță Roxana

pindichielena@yahoo.com

Abstract

Based on the assumptions that Romania is a luxury tourig resort at an European level, it should be adopted a set of strategies for tourism development Spas. Development strategies in coastal resorts vary by national or local level of the resort location in the hierarchy at a country level.

Key words: strategies, tourism, spa, resort

J.E.L. classification: O29

The strategies adopted to develop tourism seaside Spa can be:

1. Product strategy. These strategies should consider setting up tourism product based on the characteristics of spa tourism in our country and coastal area, a competitive product, quality to satisfy as many segments of both Romanian and foreign tourists. In this respect, may be taken four main types of spa tourism products strategies[1]:

- strategies of differentiation, compared with similar European countries competing bids;
- strategies to diversify tourism benefits;
- strategies for flexibility;
- strategies to enhance the quality of tourism products and services.

Differentiation strategy offers compared with countries with which Romania should enter into direct competition to create tourism product based on the original, appealing to refine existing extremely valuable therapeutic resources in coastal areas such as mud, marine factors cleaning etc, but also other categories of tourist resources, the natural and anthropogenic. Not ultimately be valued and experience in the field of medical spa treatment personnel from bases on the coast. Nature of originality, quality assured natural healing factors must completed and by

combining the programs of interest, with other properties, depending on valuable points near the resort for tourists, such as seaside tourists can come visit, according to the spa resort where they are accommodated, and other tourist attractions like museums, archaeological relics, monasteries and churches in the county of Constanta even Tulcea and the Danube Delta area.

Another way is to combine the seaside spa tourism with other forms of travel (within certain limits, of course) in the same programs of interest.

Products and services offered tourists a touch of originality to ensure that all elements of differentiation, service quality provided by a staff of professionally competent but also by implementing quality management system in tourism-facilities. Romanian health tourism should focus mainly on the exploitation of minerals within regimens are unique in the strategy of differentiation. Between existing therapeutic minerals of the Rumanian Black Sea coast that fall into this category is present in lakes and therapeutic peloidele few places in Europe, but whose value is recognized internationally curative. Black occupies a privileged place in the wealth and quality of existing therapeutic mud in the lake Techirghiol and lakes near Mangalia. Experts consider that the lake mud Techirghiol is one of the most valuable, not only in our country but in Europe, is reason enough to exploit its therapeutic properties in Eforie Nord, Eforie Sud and Techirghiol. Foreign tourists who come every year before the mud belt Eforie Nord, Pell-Amar, Gerovital Boicil and could be drawn back here, whether in addition to product differentiation strategy and upgrades offered, mostly carried out at The treatment of complex Europe and Anna Helth Spa Great Star of Eforie Nord, will enhance and

promote actions, supported by a standard pricing strategy combined with low-price strategy. These types of strategies have been implemented by our Bulgarian neighbors, which have attracted a greater number of tourists due to the low correlation with a better quality of service.

Diversification strategy has to satisfy the requirements and needs of as many segments of tourists, particularly through the development of health tourism offer. In addition, for categories of tourists, without medical problems can exploit various forms and activities in the tourist resorts on the coast, given the complexity and variety of existing tourism potential in the area.[1]

Thus, can be developed and promoted by sea and water sports on the lake, rest and recreation, participation in cultural events, arts or sports, other leisure activities (Aqua-parks) and other forms of tourism such as tourism business, cultural, etc.[3]. These forms cover such a wide range of motivations and travel preferences, as well as an extension of tourist season on the coast rather limited, which can and should cover most of the year.

Also, spa tourism products by expanding tourism offer will address both the residence, charged in the increasingly prevalent in the seaside resorts and tourist traffic, requiring interest supplement existing equipment with new additional units accommodation (cottages, campgrounds, motels) and upgrade existing ones (in modernizing and improving the comfort level). With changes in the structure of demand generated by the development of wellness tourism, has become the choice of diversification strategies to adapt and satisfy as many segments of tourists. This type of strategy is considered to be the key to success on the road so that every seaside resort in the country and aims to make it come to market with a competitive offer, comparable to that of other European countries. Can there be such a diversification to meet the travel motivations of people without health problems, young people and adults who choose the course of wellness (wealth) or primary prevention diet to maintain their health, their body composition to ensure preparing the body to resist stress and environmental pollution that can cause problems with some pretty serious

consequences[2]. These disorders can be prevented with successful resorts located in the seaside resorts, which in addition to marine aerosols and other factors are favorable natural treatment that can be used effectively.

Diversification strategies involve the development of wellness centers (wealth), which take priority over high quality medical services and professionalism. Also in the strategy of diversification will be considered as new products offered to tourists to include a minimum of different types of treatment such as: cure to comfort the climatoterapie, physiotherapy, hydrotherapy, dietoterpie balances the nervous system functions leads thermoregulation and balanced diet, cure, "fitness" or "aerobic workout" cure "stress" is one of the most important forms of health courses, known for its relaxing effects. These types of treatment are successfully exploited in the health center Anna Helth Spa in Eforie Nord, and can be achieved in other resorts. Specialists in Balneoclimatology presented as suggestions and other types of "wealth cure" that might include spas, some of them are already practicing in countries with tradition in this form of tourism in Europe. There are straps to prevent aging (geriatric prevention) and weight reduction. Strategy is characterized by flexibility to adjust supply to demand permanent tourists and is based on knowledge and market research, forecasting a tourist flows, the motivations and needs of consumers. Spa tourism offer flexibility can be achieved by developing and promoting tourism programs appropriate to each market segment, through their continuous adaptation to changes in demand. To this end of the season, guests can enjoy special offers from programs: "Decade of bathing," "Black for all", etc.. If the offer is built rigid packages of services can be complemented by other types of recreational activities combined with other forms of tourism so as to satisfy the requirements of various categories of tourists.

Quality Growth Strategy has an important role for the competitiveness of Romanian spas offer. All that means tourist accommodation facilities, catering to the medical spa treatment to be superior standards of quality to provide a maximum degree of comfort to tourists. A key role in this respect is to staff employed in tourism,

which should behave properly, an open attitude towards helping to attract its clientele, but the bases and medical personnel to provide professional treatment, patients tourists.

2. Price and distribution strategies.

Pricing tourism products and services will be based on the quality and structure of services offered, product life cycle, the elasticity of demand, and the objectives pursued. The seaside spa tourism can adopt the following pricing strategies:

- low price strategy, used to facilitate penetration of foreign markets to customers with modest incomes (Hungary, Ukraine, Moldova, Serbia, Croatia etc. and win in markets with strong competition[4];
- high price strategy, which may be adopted for some very unique products or better quality, such as sludge and Techirghiol of Mangalia. Of course, the critical factor in ensuring the competitiveness of such products is to establish an optimum value for money in terms of tourism benefits;
- travel arrangements applicable standard price strategy (marketed under the formula "all inclusive"), which could be used for stays longer active.
- price differentiation strategy adopted in the characteristics of demand, seasonality, consumer segments, way of organizing the trip;
- price flexibility strategy always correlated with fluctuations in demand, changing economic conditions of the health tourism market, the competitive situation;

In the field of spa tourism, pricing should be made taking into consideration their psychological edge because prices are too low can lead to distrust in the quality of services and prices are too high can destroy demand. Also, pricing should take into account the different market characteristics: a high price for the Romanian tourists can be a very low price for the German and Israeli tourists.

3. Spa tourism promotion strategies aimed at the main promotional activities aimed at this form of tourism. Promoting tourism product is very important in creating the image quality of the product offered as a tourism product market success depends to a large extent on how the one who made that product fails to effectively communicate to

potential clients and brokers to offer their qualitative dimension[5].

The seaside spa tourism promotion activities may include: printed or broadcast advertisements in different media: television, radio, catalogs, brochures, leaflets, posters and leaflets, printed material sent by mail, billboards, Internet, audiovisual materials (CDs, cassettes, video presentations of tourist destinations, direct marketing methods: games, contests, sweepstakes, lotteries, gifts, participation in fairs, exhibitions and tourist events, excursions familiar, Group sales, price reductions, press conferences, seminars, directories, sponsors, their own media: the magazine business, special events, presentations and business meetings, incentive programs.

Recovery spa insufficient resources and natural healing factors, lack of funds and investments in technical and material base stations, lower purchasing power due to the current economic climate, poor management that characterizes some of the seaside resorts, the lack of legislation are the main causes of the state of degradation and lack of interest from both tourists facing seaside resorts in the area but also in other parts of the country. Among existing resorts on the Black Sea, Eforie Nord and Mangalia are resorts that attracted national and international interest in recent years a large number of foreign tourists and therefore efforts must be made for these to regain his position in the international circuit. Also, the adoption of strategic objectives to target the other spas on the coast, because they play an important role in the development of spa tourism in the coastal zone.

The main strategic objectives of these states could be following:

- spas offer their competitiveness;
 - Strengthen position in domestic and international tourism market;
 - increase employment, economic efficiency and mitigation activities seasonality;
- To achieve these goals may adopt different strategies, namely: strategy for construction, refurbishment and retrofit of foundations and treatment centers. It will be focused on building new treatment centers in or near a hotel, as SPA example, in the Neptun-Olimp and Anna Helth Centre Spa in Eforie Nord, or the modernization of existing treatment, both

through provision of modern medical technology to cure fever, and by carrying out maintenance centers in physical shape, stress, and beauty, health tourism specific. The coordinates of such a strategy will cover:

- selection of areas with potential high Spas, to build new centers and bases of Treatment;
- selection based on functional zoning, the premises of the treatment that will be subjected to modernization and spaces through redeployment could be allocated to health tourism;
- realignment and modernization of the destination spa facilities, which are characterized by a high degree of physical and moral wear;
- the acquisition of modern medical facilities and equipment, the latest generation;
- Selection, staff training will also provide assistance for new services to be offered;
- to conduct an economic analysis, costing estimates for both the construction of new centers, as well as in the case of upgrading existing ones;
- preparation of a feasibility study to obtain the amounts needed for the program.

Given that the vast majority of tourist reception and catering on the coast are old enough, before 1989 is designed for mass tourism, but in the last 20 years have made little investment is than necessary to achieve modernization programs and raising the level of comfort. Although requiring a significant investment effort these programs should be implemented in order to be competitive on the EU similar to that in recent years have shown a trend of increasing demand by firms with a high degree of comfort, classified in four -5 stars.

The situation may improve in a short time if the villas, which both in size and as proportions (20.20% of total accommodation of the spa) are smaller and thus require a lower investment level. The total number of existing accommodation in the seaside resorts, it can be appreciated that in the first instance at least 30% should be upgraded and provide higher comfort category, which would satisfy the preferences of a more demanding clientele and greater purchasing power[6].

In addition to the accommodation, the catering should provide, in addition to a higher category of comfort, a more broad and diverse range of menus, from traditional

Romanian from the European or Asian cuisine, without neglecting the importance of vegetarian menus low calorie dietary spot established with personnel trained in this area. This aspect should be taken into account especially in catering establishments that serve basis and treatment centers. Another major problem facing the spa offer is the seaside resorts and entertainment. Far from the application requirements and what is offered in European countries with similar resorts tradition, Romanian and entertainment resorts have "reshaped" by:

- creating and equipping the premises clubs tourist complexes;
- establishment where conditions permit, recreational centers of projection and performance halls, bowling, billiards, table tennis, pool and small food establishments such as: cakes, pastries, coffee bar
- refurbishment and upgrading old recreational facilities: mini-golf trail, golf or protected spot outdoors, fun, game rooms, mechanical and electronic games etc.
- Creating Aqua Parkuri, complementing some resorts offer recreational, following the example of Aqua Park Mamaia resort Ballad of Saturn[6];
- in the vicinity of certain internationally known resort, you can find great locations for setting up golf courses, which over time would become points of attraction for foreign tourists, amateur or professional, with significant economic benefits for these areas;
- modernization riding centers, as one example of Mangalia[6].

Conclusions

Recreational services for each tourist reception facilities will be prepared with the highest requirement, and staff to provide these services will have to prove, in addition to appropriate qualification, kindness and interest in meeting the growing demands of tourists.

Romanian specific product development strategy is a way to relaunch the Romanian health tourism product in the international market. Are recognized and appreciated products abroad "Gerovital" for the treatment of rheumatic diseases, nervous and anti-aging, "Aslavital" to treat nervous disorders and anti-aging, "Boicil" for rheumatic diseases and blood disorders. In Eforie Nord,

Mangalia, Saturn, Neptune are offered cures like Gerovital, Aslavital, Boicil but it would be most successful if complemented by an aggressive promotion on the market in European Union countries, the results of treatment with these products. For this type of treatment we might introduce Gerovital products companies, Hofigal, Plant extracts that have registered good results in treating certain diseases by natural means. Efforts to attract demand through strategies presented, require creating and sustaining an image of the coastal resorts.

It should also promote foreign markets and resort area, with the offer spa and other local tourist attractions, at specialized fairs abroad and the media.

Country Risk - an Externality of the Globalization Process

Iovițu Mariana

Academy of Economic Studies, Bucharest

marianaiovitu@yahoo.com

Iliescu Elena Mihaela

"Nicolae Titulescu" University of Bucharest

mag_mihaela@yahoo.com

Abstract

Global economy generates conflicting issues regarding timeliness and relevance of the protectionist theory and also on interpreting country risk. Forasmuch, protectionism is seen as a tool for stimulating domestic industry and a means of defense against foreign competition, while economic globalization is assessed in terms of free movement of capital.

Analysis of concepts like protectionism, globalization, economic patriotism and country risk, and also the eco-socio-political correlations arising from the dynamic evolution of these dimensions, requires updated interpretation of the Romanian economist Mihail Manoilescu's ideas. Therefore, his question: "Do we have the right to force nature and make it enter into certain intellectual aesthetic frameworks like the "Procrustean bed"?" leads us to conclude that it requires constant adaptation of theories to reality.

Without taking any scientific risk, we consider that, so far, the development of economic science was within this trajectory. It remains for the future to confirm further this trend.

Key words: globalization, protectionism, country risk, externality, the eco-socio-political integration.

J.E.L. classification: F01, F20, F41

Harmonizing the theory with the reality is based on new objectives imposed by the diversification of the international economic flows and adapting the role of the state to the new situation requires the reformulation of the protectionist vision.

As a consequence, in order to be consistent with the real life, the traditional concepts were adapted, however in parallel, new concepts have emerged. They express (qualitative-quantitative) the socio-economic status of the globalizing economies and of the globalized ones.

1. Changing theoretical levels

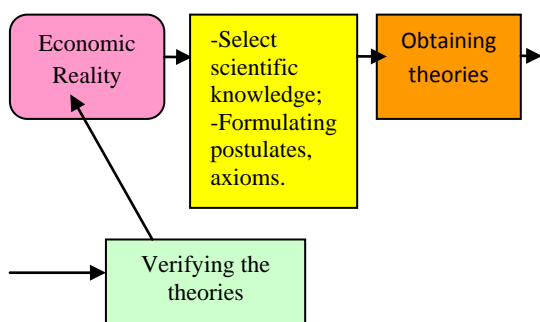

The economic patriotism of the global economic agents is the formula by which the protectionist practice continues. The years 80-90's represent the beginning of the approaches regarding country risk concept as a result of economic globalization.

Initially the country risk indicator was used exclusively in the banking sector having regard only to foreign loans (public and private). Its scope has increased due to expansion of risk also on other international business. Foreign direct investments, foreign portfolio investments, commercial transactions, insurance and licensing area have become areas of risk.

Given the theoretical evolution, but also the practical one of these concepts (protectionism, globalization, economic patriotism and country risk) well know and currently in discussion, once again it has been proven the still standing principle according to which the economic science is adapting and growing in time. And as science needs theoretical foundation, the theory must be the result of knowing the new reality.

The next logical approach describes very well this point of view: [1]

Fig.1 Theory-practice report

In light of the foregoing, the globalization process requires constant readjustment and reformulation of the economic theory, in such a way that we are able to speak, equally, about “globalization theory” and “globalization of the economic theory”. Alongside the theoretical approach, the mathematical approach is gaining ground in the quantification area.

Given that “theories without facts can be barren, but facts without theories are meaningless” the merger between the factual and theoretical approach of the economic phenomena becomes inconceivable. [2]

The socio-economic dynamics led to the perception of new dimensions of risk. For example the concept of political risk emerged in 1956, during the nationalization of the Suez Canal. Sovereign risk has been formulated as a result of the payment default of some Latin American countries in the 70’s, and regarding the foreign loans, unsecured by the government, have defined the transfer risk.

Together with the multiplication and the diversification of the independencies in the global economy the role of the country risk indicator has exceeded the banking environment. It has become (according to some opinions) a consumer economic good of basic necessity in taking expanding business decisions outside the borders.

Currently, the country risk indicator, most often used as a sovereign risk has also a political dimension although, political risk is treated mostly separately. The global market challenges impose upon the adjustment of the indicator to the risks involved in globalization.

If globalization is a multidimensional phenomenon that is difficult to quantify, its implications for quantitative and qualitative perception of life can be measured.

Currently, aggregate indices were created with which annual rankings are prepared and published, according to the intensity of globalization of the national states: KOF Index of Globalization, AT Kearney Globalization Index, study of Globalization and Regionalization.

Composite indices of globalization follow three paths:

- *Economic globalization*
- *Social globalization*
- *Political globalization.*

The differences occur in the calculation methodology because the weighting coefficients, the data used, the number of countries examined are different.

Regarding the quantification of the economic globalization several indicators can be used. Organization for Economic Cooperation and Development has developed a “handbook for assessing the economic globalization degree” according to the methodologies used by several international institutions (U.N.O., European Commission, etc.). According to this handbook, the standard method is based on analysis of the share of gross capital flows (Using gross flows is more relevant because they capture in terms of value all external financial transactions in a given period of, usually, 1 year) and trade in GDP (foreign direct investments in GDP and imports plus exports in GDP).

2. Quantification deadlock

In general, however, studies on this issue are related to two of these statistical tools: Kearney index, the 1st attempt to assess the degree of globalization of a country and KOF index, the most recent developed index. The latter enables knowledge and comparison of the degree of integration in the global environment in all aspects of life.

Economic integration is measured by combining data on external trade and foreign direct investment. In order to estimate the index of personal contacts combine data on international travel and tourism, international telephone calls, international remittances and private transfers (remittances wage, salary

and other compensation for personal and non-governmental transfers).

To quantify technological connectivity we refer to the number of users and of suppliers of internet and the number of servers with high safety standards.

The subindex of the political commitment includes data on participation as a member state in representative international organizations, personnel and financial contributions to U.N.O.'s missions, the number of treaties ratified and government transfers (receipts or payments).

The final score is obtained by adding the four scores of the weighted subindices, as follows:

- $\frac{1}{2}$ for economic integration
- $\frac{1}{4}$ personal contacts
- $\frac{1}{4}$ technological connectivity and political engagement.

This methodology allows a comparison of the country risk index evolution, from year to year, therefore an analysis on the globalization dynamics of a state, and at the same time, enables the comparison of the globalization degree between states.

The increased interest and the researches made in this area of study led to the emergence of a new composite index of globalization.

The result of the research of Axel Dreher is the index of Axel Dreher [3]. It comprises 3 subindices, with different weights:

A. **Economic globalization** 36% which comprises : 50% of current flows, trade (percentage of GDP) 18%, foreign direct investment flow (percentage of GDP) 21% stock of foreign direct investment (percentage of GDP) 22%, portfolio investment (% of GDP) 19% , income paid to foreigners (% of GDP) 20%, tightening 50%, hidden import barriers 24%, average tariff rate 28%, taxes on international trade (% of current revenue) 27%, capital account restrictions 20%.

B. **Social globalization** 38% which comprises: 30% data for personal contacts, telephone charges (traffic-output) 13%, transfers (% GDP) 6%, 28% international tourism 28%, foreign population (% of total population) 26%, correspondence (letters) International (per capita) 28%, international data flows 35%, Internet users (per 1,000 inhabitants) 25%, cable television (per 1,000 inhabitants) 25%, newspapers trade (% f

GDP) 21%, radio (per 1,000 inhabitants) 29% , data on cultural proximity of 35%, number of McDonald's restaurants (per capita) 40%, number IKEA stores (per capita) 41%, trade with books (% from GDP) 19%.

C. **Political globalization** 25% which comprises: embassies within the country 35%, member in international organizations 36%, participation in missions of the UN Security Council 29%.

The index measures the globalization on a scale from 1-100, and the ranking it is published annually for 122 countries. The elevated values express a greater degree of globalization. Starting with 2007 the initial methodology for evaluating the degree of globalization has been revised. The new conditions and also the involvement of country risk as one of the components from which globalization is forced to take into account have complicated the corresponding materialization of the two phenomena.

If globalization means opening, expansion of the international economic relations and the country risk indicator generates some limits or adjustments of the external activities, the place and role of country risk in this process are in question.

In the above context, two points of view have emerged, and apparently are in contradiction.

According to the hyper-globalists, as a result of globalization, the traditional nation-states are in decline. Being replaced by a single global market based on the global competition mechanism, the assessment of country risk no longer has economic interest.

According to skeptics, the nation-states lose a part of the prerogatives regarding the influence of the macroeconomic results, implementing the social programs, the consolidation of the strategies for economic coordination, while country risk is related to socio-political and economic events, partially under the control of the government of the receiving country.

From this perspective, country risk assessment is no longer subject to the study. The reality, however, disproves the hyperglobalists' theory. Globalization has reduced the leeway for maneuver of the governmental politics, but it didn't cancel them. For example:

- stock markets had become highly interdependent in their daily variations depend on national conditions (cycles of pessimism and optimism about national politics);

- the economic policies have adapted to the economic changes which occurred within international finance, without losing their national character;

- the monetary policy reacts to interest rate developments abroad differently from country to country, with no overall convergence rate;

- budgetary and fiscal policy bears the national imprint;

- the competitiveness of its domestic businesses depend on the public infrastructure, transportation, telecommunications, education, encouraging innovation.

3. Country risk a globalization externality ?

Therefore, the national character subsists, inclusively in the highly integrated countries in the global system. As a result, the globalization does not represent the expansion of the international economic relations without an appropriate analysis on the opportunities and risk they entail.

Under these circumstances, the country risk assessment becomes essential for decisions on the conduct of international operations.

If between the country risk and globalization there is a mutual causal relation, varying inversely, any decision regarding international operations must take into consideration the country risk indicator. But equally important is the other sense of the relationship because country risk is in fact an externality of the globalization process (positive or negative, depending to the degree of integration into the global economic circuit and the states capacity to absorb and capitalize the emerged opportunities).

In this explanatory context, country risk is a consequence of the globalization and one of the factors that support it, because, knowing the risks, the economic agents will seek the most effective international activities, and will adapt the strategy to the

specific economic, social and locally political environment.

If initially, the two terms seem to be incompatible, and globalization represent an opening based on liberalization of international economic relations, country risk establishes certain limits and restrictions. However, the country risk level influences the attitude of foreign agents, but at the same time, their confidence in the receiving economies affects the country risk indicator.

We present and analyze further the globalization index and its correlations with the eco-socio-politic framework.

Chart no.1. KOF globalization index

Source: KOF Swiss Economic Institute - 'KOF Index, Globalization 2008 ', Press Release

Chart no.1 clearly shows the difference between the three components of the KOF index and also the different trends.

It is noted that the KOF globalization index is surpassed by the economic globalization (EG) and in some areas (the period centered on 1990) is surpassed also by the index of political globalization (PG).

There may be two explanations: a) on the one hand the economic interest of the investment expansion force in geo-economic profitable areas, and b) on the other hand, the wave of key policy changes (collapse of communism and the transition to a market economy) which has opened new opportunities for the globalizing countries toward countries and emerging markets in the South-eastern Europe.

In the same context we mention the opening of the European market for the eastern European countries, a process that was completed and sustained by creating a new institutional framework, suitable for the political, economic and social changes.

Although the interest for economic globalization is visible, preponderant, although as a result of the economic globalization, social globalization has been also recorded, nonetheless the data undermine this normative. Why? One explanation could be the reluctance of the population regarding the penetration of new social patterns (even if they are benefic for the growth of civilization degree, and of the qualitative standard of the living conditions. Here we can comprise mentality, customs, and traditions specific to the local-national framework.

Based on KOF ranking for this year, the situation of the most globalized countries as well as of the least globalized can be illustrated as follows. [4]

Chart no. 2 Top 15 countries in a globalized world

Source: KOF Swiss Economic Institute – “KOF Index, Globalization 2008”, Press Release

Figure 2 illustrates the hierarchy of the globalizing states. It is noted that the economic segment is exceeded considerably by the political one; we appreciate, in this direction, the community between the political interests of international organization as forms of international support of globalization. Moreover, the

almost maximum share of politic globalization has a suggestive significance regarding the recognition of the democratic framework necessary for globalization. We are not questioning the hypothesis of interdependence between United Nations by respecting the same qualitative values and with the proximate development levels, which contributes to similar levels of political globalization.

Naturally, as a reply to this timetable emerges the situation of the least globalized countries.

Chart no. 3 Last 15 countries in a globalized world

Source: KOF Swiss Economic Institute – “KOF Index, Globalization 2008”, Press Release

The graphical representation illustrates the considerable difference both in terms of economic globalization (low interest from some countries) and sustained efforts for an extremely necessary social globalization for these countries underdeveloped or in full process of development. Even though the globalization seems low, it triggers, however, social and political effects.

4. Key-conclusions

Comparative analysis of methodologies and classifications presented leads to the conclusion that currently there hasn't been yet formulated a unique method for measuring the intensity of the globalization process. This conclusion is based on the fact that the economic dimension is evaluated

quantitative as well as qualitative, having interpretative crossroads with the social globalization.

If we consider that the rating is based on indicators which characterize the economic, social and political situation of the states, it becomes obvious the positive correlation between the degree of globalization and country risk.

Thus, a good rating therefore creates the attractiveness of international flows, as a result increasing the degree of globalization; this way a country placed in a low risk class shall be more easily integrated into the global economy, being more attractive to foreign creditors and investors.

Country risk is therefore not an obstacle to globalization, to the expansion of international economic flows, but can be considered one of the factors that have led to polarization, to the marginalization of poor countries and thus, poorly rated in risk rankings.

A high degree of risk doesn't mean the expulsion from a global market. The low participation of foreign entities will influence very little the international environment. A receiving economy with high risk will practice exports, leasing, licenses, and then, after lowering the risk, the involvement degree of foreign capital will grow.

In conclusion, as the country risk level is lower, the higher the degree of involvement of the foreign businesses on the domestic market.

At the same time, it is recognized the fact that an open economy, with a high volume of foreign trade and of foreign direct investment, beneficiary of foreign loans (public and private) used effectively, ensures socio-economic positive conditions and thus improving the country rating. It is considered that long term imports have a role as important as the one of exports in stimulating growth. [5]

Comparative analysis of the ratings given to the states and their position in the globalization rankings constitutes an additional argument to support the link between country risk and the degree of globalization.

Abstract

This work proposes to remove the current impact of the financial crisis in Romania, the current public debt, and a perspective of its next years. Also the structure of the public debt is analyzed on types of instruments, i.e. state loans, bonds, the bonds, eurobonds. Their is even risks detailed on what rhythm they entail with growing public debt in Romania, not only in terms of debt level itself, as the pace in the place, taking into account the fact that more than a third of the loans of authorities are contracted in the short term, and the reimbursement will be carried out in the period 2012-2015.

Key words: debt and loans, domestic Gross Product (GDP), domestic financial obligations, external financial obligations

J.E.L. classification : G01, G 01, G 31, H 62.

The financing of public expenses, as a expression of the needs of society, is achieved through:

- Public financial resources taken from taxpayers and shown in the general budget consolidated on its components;
- Non-reimbursable foreign funds
- Internal or external loans, guaranteed directly or indirectly by the administration, both central and local.

All direct and indirect financial obligations assumed by the central and local administration with the domestic market and/or foreign capital highlights public debt.

Direct financial obligations are the outcome of direct contracting by public authorities central and local of loans from various creditors, natural and legal resident or

non-residential in the country debtor. In contrast, indirect financial obligations are generated by granting guarantees by the central government and the local borrowing on the domestic market/or foreign capital by the authorities and public institutions, legal persons whose activity is the national interest or local.

The distinction between its financial obligations of central and local authorities public is:

- Debt governmental, expresses all internal and external financial obligations of the state, at one moment, from borrowing directly guaranteed by the government or by the Finance Ministry, on behalf of Romania, in the financial markets.

- Local debt, which highlights the whole financial obligations and domestic affairs of local public authorities, at one moment, from loans obtained directly or guaranteed by these in the financial markets.

Financial obligations are the result of contracted loans on:

- The intern market, by the authorities of the local/central administration which forms the intern public debt, on it's governmental and local components;
- The external market, by the authorities of the local/central administration, which expresses the external public debt , on it's governmental and local components.

So the governmental public debt is formed from two components, respective the internal governmental public debt and the external governmental public debt;

Total public debt represents the whole of obligations pecuniary of the state (government, public institutions, administrative-territorial units) at one moment, resulted from internal and external loans (in lei and currency) contracted in

short, medium and long term, and the obligations of the state towards its own treasury for the temporarily advanced amounts in order to cover budget deficit.

The public debt of Romania reached in January of 2011 to 190,4 billion lei (45 billion euro), dropping with 3,5 billion lei with the registered level at the end of 2010.

The sharing of debt in GDP dropped to 34,97%, from 37,75% in december 2010.

Practically, it seems to repeat the evolution from the beginning of 2009. And in January of 2010 , it has been registered a drop of debt by 4 billion lei, in comparison to december of 2009, at 148 billion lei. But, in the months that followed , the trend was ascending.

Analysing the structure of public debt on currency, it can be observed that in january of 2010, most of it is in lei and euro, with shares of 44,76%, respective 43,4% of total.

On types of instruments, state loans have a share of 40,6% from the public debt, obligations 19,8%, and treasury certificates 19%. Eurobonds have only 5,83% of total.

Figure 1

The average yield paid to post the titles has slightly increased rising from 7.35% to 7.4%.

Last year, the public debt has risen in a increasing rythm of 32%, in the conditions in which the state state has borrowed massively and has reached a new historic peak of 194 billio. lei (46 billion euro). Practically, the public debt has increased from 35 to 46 billion euros in 2010, i.e 1 billion euros a month.

The treasury has fortified issuance of governmental bonds with maturity in 2017, borrowing a total 412 million lei (100 million euros) from banks, compared with 300 million lei, as proposed initially. The average

yield paid on the net titles has been in a slight increase from the auction of februarie, climbing from 7.35 percent to 7.4 percent.

In the year 2011 Romania will have to borrow about 9.1.4 billion euros to cover the deficit, which means an average of 460 euros per second.

The Romanian state will take with 1.2 billion more than in 2010, when I reached the level of 420 euros per second, from International Financial Institutions, from banks or from foreign investors. Raising the level of debt is not caused by budget expenses, as the fact that the state should pay even the older loans.

Public debt will amount to 35 billion euros in 2009, as reported by Ministry of Finance, and 48 billion euros in 2010 to 54 billion euros in the year 2011.

Worrying for Romania isn't the fact that the public debt will reach 41 percent of gross domestic product, the level is 50 percent below the EU average, but that the level of debt has increased dramatically, practically doubled compared to 2008, when it was located at 22 percent.

The big problem was that loans contracted in recent years have gone into social security costs, instead of going into investments, which would have helped the development of the economy.

Public debt of Romania has increased by 10 billion in March 2011 to february 2011, amounting to 30.6 percent of GDP. Increasing debt has been determined significantly since the launch issuance of its worth one billion euros. Public debt reached 165 billion lei at end of the first quarter, compared with 155 at the end of February, when represent 28.7 percent of GDP.

Table no.1

A. Public Debt*		
Public debt composition (RON mln)		
	31 December 2010**	31 January 2011**
Outstading public debt	193,894.4	190,381.7
% GDP	37.75%	34.97%
out of which:		
A. Government public debt	94.03%	93.88%
Local public debt	5.97%	6.12%

B Government direct debt	91.92%	91.90%
Government guaranteed debt	8.08%	8.10%
C.Negotiable	41.33%	46.59%
Non-negotiable	58.67%	53.41%
D. RON	46.21%	45.69%
EURO	42.58%	43.19%
other currencies	11.21%	11.12%

GDP: for 2010 RON 513.641 mln and for 2011 RON 544.426 mln * including the state and local authorities guaranteed debt according to EOG 64/2007 ** revisable data

Figure 2

*) loans from the availabilities of the Treasury General Accounts

In the 165.07 billion public debt, governmental occupies a weighted by 93.6 percent, while local debt represented only 6.36 percent. An important contribution to increasing public debt has had it with loans of the Finance Ministry, carried out by the sale of bonds.

Loans of state have a weighted by 40.6 percent of public debt structure, while broadcasts of bonds had a combined contribution of nearly 34 percent of the total. In total, the Finance Ministry has borrowed from the beginning year a total of 19.82 billion. In early may, however, the Finance Ministry refused four times all offers banks for the sale of bonds.

The lack of a financial package from the IMF and the European Commission, the public debt to Romania will reach 70.4 percent of GDP in 2013, exceeding by more than 10 percent one of the criteria of

Maastricht, necessary for joining the euro zone.

According to data transmitted by the government, in the context abandonment of the IMF accord and, consequently, the financing related understanding public debt, governmental increased from 45.2 percent of GDP in 2010, to 55.1 percent in 2011, to 63.6 percent in 2012 and, finally, at 70.4 percent of GDP in 2013.

Otherwise, the situation continuing stand-by agreement, the public debt will reach 30.1 percent in 2011, growing up to 40.9 percent in 2013, with about 19 percent below criterion reference Maastricht (60 percent of GDP).

Under pressure of a budget crisis poorer and the need to pay pensions and salaries, the government has become indebted more and more on last year. Loans from IMF, the European Commission and the banks of the local market, in large part in the short term, we have public debt doubled in the past two years, according to data published by the Finance Ministry (MFP). The government has borrowed about 1.3 billion euros a month to cover current expenses.

Thus, from a debt of 109.1 billion dollars, equivalent to 21.6 percent of GDP, the end of 2008, Romania has come to record a debt of 193.89 billion lei (37.9 percent of GDP), 31 decembrie 2010.

At the end of 2009, the debt of the government and local authorities was 147.3 billion dollars, equivalent to 29.99 percent of GDP.

Economic analysts have warned repeatedly on the risks it involves rhythm galopant with growing public debt. In this moment, worrying is not the debt level itself, but the pace. And over one third of the loans of authorities are contracted in the short term, 64 billion, requiring more new refinancing. Other 42.7 billion are debts in the medium term and 75.4 billion in the long term.

Romania's debt has increased by 46.5 billion during the year 2010. In total debt, the share of the government has increased from 92.65 percent in 2009 to 94.03 percent in 2010. Practically, government debt rose to 45.31 billion, from 137 billion in 2009 to 182.31 billion in 2010.

The new loans contracted by the government last year were worth 66.3 billion. In other words, the Romanian government

lent the average per month as many as 5.52 billion lei (1.3 billion euros) to cover current expenses.

Most of public debt is under contract for the most expensive creditors, i.e from banks. At the end of last year, loans taken by the State of the private banks are state budget amounted to 129.48 billion, i.e 66.7% of total debt.

The largest loans were incurred by the state lei, the euro and SDR (Special Drawing Rights, foreign currency in which turns IMF money). The debt in lei amount to 82.6 billion, euro at 77.97 billion dollars, followed at a distance of SDRs to 9.64 billion.

The loans taken so far by the Romanian state of the IMF and the European Commission will begin to be returned in 2012. Until then, only pay interest on these loans. Thus, in 2012 will return 124.13 million euros, and in 2013 almost 968 million euros to the IMF, following the 2014 to send in international financial institution accounts over 1 billion euros.

Table no. 2

*) The tranches drawn by MPF at January 31, 2011

Period	IMF		EC (mln Eur)	WB (mln Eur)
	(mln DST)	(mln Eur)		
2012	107.38	122.41	-	-
2013	837.31	954.53	-	-
2014	865.87	987.09	-	-
2015	135.93	124.96	1,500.00	-
2016	-	-	-	-
2017	-	-	1,150.00	-
2018	-	-	-	-
2019	-	-	1,000.00	-
2020	-	-	-	-
2021	-	-	-	-
2022	-	-	-	300.00
TOTAL	1,946.49	2,218.99	3,650.00	300.00

Year 2015 will be one difficult, since comes maturity to 157 million euros by the IMF, but also for a tranche of 1.5 billion euros from the EU. The loan from the Commission will be repaid and the 2017 (1.15 billion euros), and in 2019 (1 billion euros).

For that reason will increase interest companies and citizens for the bonds, treasury bonds in lei currency worth almost 1 billion of them are in possession of

individuals from Romania. They were at the end of last year, state bonds worth 948 million lei. Foreign nationals held bonds of 3.5 million lei. The Romanian companies had state bonds worth a total 10 billion dollars, while foreign companies held bonds of 5.4 billion.

In total, at the end of 2010, companies and individuals held 31.68 percent of the bonds in lei currency. In last year, the interest companies and individuals for the bonds rose after the end of 2009, the share these price was 24.82 percent, according to data MFP.

But still most of the securities is owned by state banks. We can conclude that the budget deficit of 2011, was financed mainly from external sources. That never until now, the Finance Ministry have proposed that over half (56.5 percent of the budget deficit to be covered from external sources.

According to the report for last year, for 2011 is scheduled as from domestic sources to be covered only 41.8 percent of the budget deficit under 2 percent will be covered from income from privatisation and recovery AVAS.

The government pledged to creditors outside that the budget deficit this year will not exceed the limit of 4.4 percent of GDP.

Fiscal Levers Meant to Attenuate the Effects of Crisis and to Support Economic Revival under the Conditions of the Financial Markets Imbalance

Istrate Luminita Gabriela
Academy of Economic Studies, Bucharest
istrate_luminita@yahoo.com

Abstract

A good planning of the economic development also implies the insurance of money funds needed for financing from internal sources (banks, investment funds, cooperative institutions of credit, factoring and insurance companies, credit agencies, governmental and non-governmental organizations) or from external sources (World Bank, International Monetary Fund, The European Bank for Reconstruction and Development (EBRD, European Bank of Investments).

Taking into consideration the several challenges which the Romanian economy must get through, it is absolutely necessary the adequation of the macro-economic policies mix to the changes occurred in economy.

Key words: Value Added Tax deductibility, taxable profit, deductible expenses, lump-sum tax

J.E.L. classification: H20, H21, H30

1. Introduction

Whatever how much the economic agents would be to the idea of fiscality, legal and long-lasting existence of a firm on the market imposes knowledge and observance of legislation of the country where it develops its activity.

Practically, apparition of taxes is bound to the apparition of exchange economy. The concept regarding the role of the state in economy experienced important modifications especially after the crisis from 1929 – 1933. The need of solving the big economic problems

that the world market encountered in that moment, determined the radical change of the concepts regarding the role of the state in economy and implicitly of the role of taxes, which become firstly economic-financial factors, by means of which the state aims stimulation of the economic interest of the entire collectivity.

Romania experienced a difficult evolution regarding fiscality, determined by the evolutions from the real economy.

During this article I shall mainly insist upon presentation of the main aspects regarding the taxes and rates, the possible distortions which these might create upon the activity of the Romanian firms, also offering some ideas of fiscal optimization at micro-economic level. In present conditions, of disequilibrium on the financial markets there becomes very important finding of some optimum solutions regarding fiscality, not to overburden more the Romanian firms, already affected by the crisis.

2. Short presentation of the existing situation on European level

European Commission (EC) outlined several initiatives regarding a better coordination of the national systems of direct fiscality in the Union. This aims elimination of discrimination and of double taxation of the enterprises benefit, fact that would lead to decrease of costs determined by obligation of complying with more fiscal systems.

Likewise, the European Commission shows the interest to help the member states to define their principles that shall allow to order some coordinated solutions and thus to attenuate practical modalities of administrative cooperation. The coordinating initiative of the fiscal systems is

complementary to the initiatives created by the Commission regarding the direct fiscality. It is estimated that the only systematic means to fight against fiscal obstacles that the enterprises encounters and that affects the operations in more than one member state, is to allow the multi-national corporations to be taxed for the activities developed in the European Union, on the basis of a common tax assessment for the profit taxation.

The plan of economic revival of the European Community comes as a response to the economic and financial crisis in which Europe is situated. Jose Manuel Barroso asserted long time ago that the package of measures destined to the fighting with the crisis effects and supporting the economic revival must be "enough wide and enough daring to have results on short term, but also strategic and sustainable to transform the crisis in an opportunity on long-term. We must make sure that the help is received by those who need it the most".

Thus, for fighting the crisis effects, the European Commission lays on a fiscal system based on a coordinated action of the member states, based on proposals of acceleration of the structural reforms, but also on helping measures of the Small and medium Sized Enterprises.

One of the main elements of the plan of economic revival takes into consideration "a fiscal incentive at the right moment, temporary and well-aimed". Thus, the measure of decreasing taxation in the present international economic context is considered opportune.

Likewise, the decrease of social contributions paid by employers is one of the recommended measures, that aims maintenance of jobs, concomitantly with a decrease of the income tax meant to contribute to the increase of purchasing power.

As far as the business environment is concerned, it is proposed the allowance of some guarantees to the Small and Medium Sized Enterprises, so that to obtain an immediate release of the funds from the banks, rapid loans and money to help the companies to invest in ecological technologies even in the present economic situation. A special importance to sustain the economic revival is the diminishing of the

business cost by decreasing the administrative and fiscal burden.

Having a look at the anti-crisis fiscal measures adopted in several European states, we state that they mainly aim decrease of taxes and rates as viable solutions for supporting the enterprises to overstep the present financial problems.

Thus, in Austria it has been decided the decrease of taxation on the re-invested profit, but also the applicability of accelerated depreciation on physical fixed assets.

In the Check Republic, it has been decreased the taxes on companies income, but also the level of contributions to the social insurances of health both for employers and for employees.

Our neighbors from South, the Bulgarians announced the profit tax exemption for 5 years for the companies which invest in disadvantaged areas.

Whatever form it takes, the anti-crisis measures represent at present the zero priority for the authorities from all countries from the European Union.

3. The impact of fiscality upon treasury of Romanian firms

Each tax that the Romanian firms are forced to pay make a double impact upon these. On one hand, it is about an administrative cost connected with the action of taxes and rates which the firm bears in capacity of tax collector, and on the other hand, it is about a cost of treasury. The latter appears as a result of the existing gap between the moment when the obligation of payment appears and the collection of taxes. Also, there are important the differences that interfere between the moment of tax accounting and the moment of the proper payment.

For the economic agents, one of the most important taxes is the tax on profit, respectively the tax on income for micro-enterprises which chose the payment of this type of tax.

Financial logic of the existence of a firm imposes the completion (periodical) with profit of the developed activity, from which it shall be insured the future economic growth of the firm. Taxation of this profit can draw contrary reactions from the taxpayer: on one hand, he wants to get a bigger profit and on

the other hand, he tries to identify the most "legal" modalities to decrease the incomes or to increase the expenses so that the gross profit to be as low as possible and in accordance with this, the paid tax to the state to be as reduced as possible. The ideal solution is identification of a middle way so that the firm to operate legally, the treasury to be less affected by the payment of these taxes and to exist effectively a profit sufficient for the economic agent to exist and to develop further on.

In the present economic situation, the provisions of the Fiscal Code regarding the profit tax can have an impact upon the decision of investments by the regulations regarding deductibility of expenses with interests.

The degree of indebtedness is one of the most important restrictions regarding expenses deductibility with interests, being considered as a percentage report between the borrowed capital and the proper capital. The deductible character of expenses with interests have influences upon the available cash-flow, upon the indicators used in decision of investments, founded on the basis of the available cash-flow, upon the gap between the value of the indebted firm and non-indebted firm.

Introduction of some restrictions in allowance for expenses with interests and indirectly upon the degree of indebtedness shall determine some distortions at the level of the firm. Thus, the fiscal savings shall be decreased with unfavorable impact upon the value of the firm or upon the degree of attractiveness for a project of investments and possibly upon the value of the indebted firm in comparison with the one of the non-indebted firm, by reduction of the advantage generated by existence and dimension of the analyzed fiscal savings. However, it is possible that this decrease of the value of the indebted firm to be compensated by the decrease of the risk of bankruptcy, if the firm reduces the value of loans which it would have contracted in another way in the conditions of some legal restrictions.

Depreciation expenses belong to another category of expenses with many influences upon more indicators and also upon the decisions of investments and financing.

Allowing the right of direct option for the accelerated depreciation, without

supplementary approval from the territorial fiscal bodies, as well as the alternative to this solution, respectively allowance of some supplementary expenses of depreciation, create several advantages for the firm. Thus, it is being offered the possibility of a faster recovery of the funds invested in fixed assets, especially in case of equipments with high moral wear and tear (for example the computers). The resulted surplus of fiscal economy shall contribute to the increase of available cash-flow proper for the first year, which can increase respectively the attractiveness of investment project. Likewise, there shall be increased the depreciation fund created at the level of the firm, that shall lead to increase of the internal financing sources at its disposal. The firm shall not need to indebt or to issue new actions to identify supplementary sources of financing.

Liability of tax payment until 25th of the month of the next semester for which it has been calculated, it offers to the firm a temporary excess of treasury for the period between the end of the last month from the trimester for which it is calculated and 25th of the next month. In the same time, if the firm does not dispose at the end of the trimester of the amount needed for paying the tax, than this shall dispose of 25 days from the next month to make incomes from which to pay fiscal liabilities without bearing penalties. Less advantageous for firms was the regulation according to which the tax for trimester IV must record the same value as the tax on profit for trimester III of the same year. In case that the firm registers a loss or a decrease of the rhythm of economic growth in the last semester of the fiscal year, and which does not finish the previous financial year until 15th of February of the current year, shall pay a tax higher than it would be according to the developed activity effectively in trimester IV, so it shall record a shortage of treasury, respectively a cost of opportunity of the sums paid in addition in the account of the tax on profit.

Advantages and disadvantages regarding the incidence of the taxed paid by firms upon their treasury can be identified also in the case of the other taxes and rates, as it is the case of liabilities regarding the insurance and social protection, of the excise taxes or of the VAT.

Regarding the VAT, for example, we could talk about a financial incidence given by the operations of sales and respectively of purchasing.

Financial incidence of the collected VAT depend on the duration of credits allowed by the firm to its customers. If these have a duration that exceeds payment deadline to the state budget, than the firm shall pay to the budget a sum which they haven't cashed yet and shall confront with a temporary shortage of treasury, until they cash the debits from the customers. If on the contrary, the firm establishes the contracts with the customers so that the duration of debits to be shorter than the term of acquaintance of VAT, than the firm shall dispose of a financial source.

Financial incidence determined by an operation of purchasing is given by the duration of the credit allowed by providers. If this is shorter than the payment date of the VAT to the budget, than, the firm shall register a shortage of financial resources, while, if this duration of the credit allowed by the providers is bigger than the payment date of the VAT, than, it is created a plus of financial resources.

Without having the pretence to have analyzed all financial implication generated by the payment of taxes and rates owned to the state by economic agents, we have tried to frame an image of the way in which any firm can administer its relationships with the state, so that the earnings to be as high as possible, and the costs of opportunity to be as low as possible.

4. Fiscal measures meant to decrease the crisis effects upon the Romanian companies

In the present conditions in which the profit of the Romanian firms register a strong descendent trajectory, burdening them with masked taxes and rates under different forms drives an impressive number of firms towards bankruptcy.

Increase of the VAT quota to 24%, increase of local taxes, increase of the contribution to Health Insurance House, increase of the excise taxes on tobacco and alcohol have already invaded the business environment. Instead of stimulating the cashing to the budget, these measures, considered anti-crisis, shall determine a decrease of the

budgetary incomes because, once being tightened the fiscal "shrew" in the absence of a clear and unitary legislation, the firms shall search "artifices" to avoid payment of the contributions towards the state.

In case the sales decrease on the basis of the high diminishing of living standard, and the increase of the prices, practically become an impossible mission, many shall chose the solution of producing on the black market, not to pay taxes and rates.

The accelerated increase of the excise taxes on tobacco shall lead to the proper increase of the prices, and this thing shall lead to increase of the black market, supplied by the networks of tobacco traffic from Bulgaria or the ex-soviet area.

Likewise, the increase of alcohol excise tax shall drive many economic agents from this sector towards fiscal evasion, without which in current conditions, would disappear from the market. The value of the alcohol excise tax is 750 Euro per hectoliter in Romania, in comparison with 550 Euro per hectoliter in the rest of Europe.

In most of the European states, the adopted anti-crisis measures aim the decrease of taxes and rates as a main solution of supporting the economy.

Is Romania capable to administer the crisis so that not to reach a situation without precedent of distinction of all mechanisms which might support for the future the economic revival? Certainly, this thing shall not be realized by the actual tendency, oriented towards the increase of the taxes and rates level owned to the state by the Romanian firms.

Likewise, in accordance with the specifications of the Convergence Program of the European Commission, it is intended the outrun of the calendar of increasing the excise taxes, actualization of the taxable value for buildings and lands and return to the level of fiscal contributions from the first part of the last year.

5. Conclusions

Economic experience during crisis shows that rate relief is opportune for stimulating the firms to employ, to tax the incomes. A decrease of the taxes would generate a higher liquidity for companies which might lead to an increase of investments. But in Romania

the signals from the authorities announce an intensification of fiscality instead of fiscal stimulation for which it has been decided in the rest of Europe.

One of the financing sources, at least discussable, is the increase of taxes with the most regressive character: the excise. Analyzing the fact that from the total of yearly public incomes, 10% represent excise revenue from which half of them are the ones on alcohol and tobacco, decision of the Finance Minister seems justified. Only that in countries as Moldavia or Ukraine, the prices are much more smaller, and the majority of excises is favorable to intensification of the activity of smuggling which shall determine a considerable decrease of the state incomes.

Another industry specially aimed at by the Fiscal Code is that of gambling. But this is already a supra-taxed industry, that's why the effect in GDP (Gross Domestic Product) shall be only 0,004%. For these firms, there is established a minimum quota of at least 5% applicable to the earned incomes, but also the liability of collecting and transfer to the National Fund of Solidarity of the social stamp tax of 10% on each participation in gambling.

Super-taxation of the luxurious products also belongs to the category of penalty of vicious persons. Though, to support the domestic industry, but also to offer an alternative of collecting the income to the budget during crisis time, it would be a good idea introducing an automobile tax not only for the old automobiles but also for the new luxurious automobiles from the import, starting from the premise that the ones who afford purchasing of such an automobile in the actual conditions, dispose of necessary liquidities to do this thing. In this way, the ordinary citizen who weigh so little money harder and harder, wouldn't be penalized by introducing the pollution tax for all vehicle owners.

Regarding the possibility of compensating the VAT to be collected with the VAT to be paid or with other taxes owned to the stat budget in the next months following the month for which it has been laid down an application of restoration, as well as after expiration of the legal term of 45 days, a solution meant to support the Romanian firms would be the payment of the VAT at the invoice cashing, not before, because in

present conditions where the interests on credits reached alerting quotas, many companies cannot afford to finance the budget.

To reduce as much as possible the impact of the economic and financial crises on the Romanian economy, there is the moment to give up to the periodical fiscal measures, of circumstance, which overturns the business environment and there must be created a Fiscal Code on medium and long term. Lacking a coherent plan, the underground economy shall continue to develop in Romania, as I have tried to prove in the above lines.

Concept of Web Usage Mining

Istrate Mihai
University of Pitești
mihaifrance@yahoo.com

Abstract

Web mining is the use of data mining techniques to automatically discover and extract information from World Wide Web documents and services.

This article considers the question: is effective Web mining possible? Skeptics believe that the Web is too unstructured for Web mining to succeed. Indeed, data mining has been applied to databases traditionally, yet much of the information on the Web lies buried in documents designed for human consumption such as home pages or product catalogs. Furthermore, much of the information on the Web is presented in natural language text with no machine-readable semantics; HTML annotations structure the display of Web pages, but provide little insight into their content.

Some have advocated transforming the Web into a massive layered database to facilitate data mining, but the Web is too dynamic and chaotic to be tamed in this manner.

Key words: web mining, web usage mining, data preprocessing.

J.E.L. classification: M

1. Introduction

The overall process of usage-based Web personalization can be divided into two components. The offline component is comprised of the data preparation tasks resulting in a user transaction file, and the specific usage mining tasks, which in our case involve the discovery of association rules and the derivation of URL clusters based on two types of clustering techniques[1].

The recommendation engine is the online component of the Web personalization system based on usage mining.

Web usage mining refers to the automatic discovery and analysis of patterns in click stream and associated data collected or generated as a result of user interactions with Web resources on one or more Web sites.

The goal is to capture, model, and analyze the behavioral patterns and profiles of users interacting with a Web site. [2]

The discovered patterns are usually represented as collections of pages, objects, or re-sources that are frequently accessed by groups of users with common needs or interests.

The increasing interest in the Web Usage Mining domain, from both research and business communities, is explained by the high number of its possible applications.

Although an interesting topic, the application of WUM results goes beyond the subject of our thesis. We enumerate some of the most important applications, but the interested reader may refer to for detailed surveys of the domain [3]:

- *Web Personalization* groups the techniques that deliver personalized Web content (pages) depending on the user people (or previously visited pages). It can have different forms, such as a recommender system or an intelligent/adaptative Web site.

A recommender system will propose links of possible interest to the user. For instance, if a visitor requests a paper about Web Usage Mining on INRIA's Web site, the system may suggest him/her to visit the home page of the AxiS research team.

The intelligent (adaptative) Web site is based on an idea proposed by Perkowitz and Etzioni [PE98]: a Web site may adapt its content to each user visiting the Web site in order to deliver personalized information.

- *Site improvement* that may be achieved either by modifying the logical structure (by adding new links) or the physical structure (modifying the organization of the Web pages in sections) of the Web site. The modification will be done depending on the

access patterns of the Web site users.

- *Intelligent Web caching* represents another possibility for improving the quality of service for a Web site as the pages are delivered faster to the visitor when using this kind of system. It is well known that users are less likely to spend time on a slow Web site. By using the results of a WUM analysis, an Intelligent Web caching system is capable of predicting the next request for a user and, therefore, to anticipate and load in a cache (or buffer) the Web page to be requested.

In this way, the user will not have to wait for the page to be loaded from the disk and the speed of the Web site is improved.

The number of WUM applications is growing continuously, especially due to the business interest in e-commerce Web sites and the related Web-marketing applications[4].

Moreover, the growing interest in the Web semantic field and the recent field of Web semantic mining will bring new perspectives for the WUM-related applications.

Web personalization can be described as any action that makes the Web experience of a user customized to the user's taste or preferences.

Principal elements of Web personalization include modeling of Web objects (such as pages or products) and subjects (such as users or customers), categorization of objects and subjects, matching between and across objects and/or subjects, and determination of the set of actions to be recommended for personalization[5].

Web usage mining is the third category in web mining. This type of web mining allows for the collection of Web access information for Web pages. This usage data provides the paths leading to accessed Web pages.

This information is often gathered automatically into access logs via the Web server. CGI scripts offer other useful information such as referrer logs, user subscription information and survey logs.

This category is important to the overall use of data mining for companies and their internet/intranet based applications and information access.

This web mining also enables Web based businesses to provide the best access routes to services or other advertisements. When a company advertises for services provided by other companies, the usage mining data

allows for the most effective access paths to these portals. In addition, there are typically three main uses for mining in this fashion.

The first is usage processing, used to complete pattern discovery. This first use is also the most difficult because only bits of information like IP addresses, user information, and site clicks are available. [6]

With this minimal amount of information available, it is harder to track the user through a site, being that it does not follow the user throughout the pages of the site.

The second use is content processing, consisting of the conversion of Web information like text, images, scripts and others into useful forms. This helps with the clustering and categorization of Web page information based on the titles, specific content and images available.

Finally, the third use is structure processing. This consists of analysis of the structure of each page contained in a Web site.

This structure process can prove to be difficult if resulting in a new structure having to be performed for each page.

2. Related Works in Web Usage Mining Preprocessing

In recent years, Web usage mining (WUM) has emerged as a new field of data mining and gained increasing attention from both the business and research communities.

A particular area of importance is data preprocessing for Intersites WUM. The proposed methodology for this process has two main objectives.

The first is to use classical preprocessing (data fusion, data cleaning, and data structuration) to significantly reduce, but in a relevant manner, the size of the Web servers' log files.

The second is to use advanced data preprocessing, which employs an extra step called data summarization to increase the quality of data obtained after classical preprocessing. To validate this methodology's efficiency, an experiment joined and analyzed log files from four related servers[7].

After illustrating the use of our WUM preprocessing methodology through different WUM processes, we will present in this section the main related works in this

domain. In the recent years, we have seen much research on Web usage mining.

However, as described below, data preprocessing in WUM has received far less attention than it deserves.

a) Main Related Research Works in WUM Preprocessing

In this section, we describe and compare our methodology with the most significant works in this domain.

Cooley presented methods for user identification, "sessionizing" (i.e. constructing or reconstructing sessions), page view identification, path completion, and episode identification. However, some of the heuristics proposed are not appropriate for larger, more complex Web sites.

For example, they propose to use the site topology in conjunction with the ECLF file for what they call the "user identification" (in our research, this is addressed under the term "user session"). The proposed heuristic aims to distinguish between users with the same IP address by checking every page requested in a chronological order.

If a page requested is not referred by any previous page requested, then it belongs to a new user session.

The drawback of this approach is that it considers only one way of navigating in a Web site, by following links. However, in order to change the current page, the users can, for instance, type the new URL in the address bar (most browsers have an autocompletion feature that facilitates this function) or they can select it from their bookmarks.

Moreover, the sessionizing heuristic is complex as it defines the session boundaries according to five categories of Web pages (e.g. "head", "media", "navigation", "look-up", and "data entry"). Classifying Web site pages is not a simple task, due to their large number and because sometimes a page does not fit in just one of these five categories.

Berendt use the service-based conceptual hierarchy for modeling the query capabilities of an online catalog (SchulWeb). This Web site offers browsing and searching services for schools worldwide.

The authors wanted to evaluate the queries rather than the content of the Web pages generated, hence their service-oriented conceptual hierarchy. Concerning the preprocessing step, the authors propose three

heuristics including one similar to the "Browsing Speed".

The other two heuristics refer to the number of requests without the referrer field and to the requests repeated for the same resource from the same host. However, we believe that the later one should be tested against other heuristics to validate its effectiveness.

In another work, the authors compared time-based and referrer-based heuristics for visit reconstruction.

They found out that a heuristic's appropriateness depends on the design of the Web site (i.e. whether the site is frame-based or frame-free) and on the length of the visits (the referrer-based heuristic performs better for shorter visits).

Huysmans analyzed the Web log data from an online wine shop (eshop). They developed a tool for preprocessing (in Delphi) and implementing some of the operations already described in this chapter.

They mentioned that the preprocessing of this data, and especially the images removing, reduced its initial size by a factor of 10. This was obviously due to the type of the Web site analyzed, as e-shops and e-commerce Web sites, in general, have many images in order to display the products sold.

Another interesting remark made by the authors is that by using a classical log analyzer program (Analog in their case), the size of the log file was reduced only by 15%, which shows again that appropriate tools are essential for an effective preprocessing step.

Marquardt addressed the application of WUM in the e-learning area with a focus on the preprocessing phase.

In this context, they redefined the notion of visit from the e-learning point of view. In their approach, a learning session (LS), visit in our case, can span over several days if this period corresponds to a given learning period.

A learning session may also correspond to the set of accesses made to accomplish a given task. The authors also identified episodes similar to by classifying Web pages into three page types (auxiliary, content and resource) based on the existing knowledge about the Web site.

Bonchi also developed a data warehouse for storing Web log files. Unlike our relational model, their model does not

contain structured information about the usage (sessions, visits, etc.), users or aggregated variables.

The objectives of their work was Web caching, therefore, the data warehouse, implemented in Microsoft SQL Server, was populated with Web logs from several Web servers. For Web caching applications, all the requests present in the Web logs are important and have to be stored, thus, the preprocessing step is different from other WUM tools because almost all requests are kept.

Regarding the user and the session identification, the authors only use the notion of "user", identified using the IP heuristic.

As shown, the preprocessing step is important and should be present in all WUM analysis.

Therefore, we compared our preprocessing methodology with the preprocessing described in other general WUM research works.

b) Comparison Criteria for WUM Preprocessing

The comparison table focuses only on the data preprocessing step and the table shows how different preprocessing features were implemented in the main related works. We enclose below a brief description of these features grouped by the preprocessing step[8]:

- Data Source - represents the data used as input in the WUM preprocessing.

- Data Preparation - includes the operations carried out when several log files are being preprocessed and when the analyst intends to "de-personalize" the log file through anonymization.

- Data Cleaning - contains the main filtering operations used for eliminating: images, Web robots' requests and requests for other non-analyzed resources.

- Data Structuration - includes all the processes used for grouping the requests (in sessions, visits, etc.).

- Data Reduction - represents the final step of the preprocessing and contains all the operations that are designed to reduce the size of the data, like data generalization and data summarization.

In conclusion, our methodology is more complete because:

- It offers the possibility of analyzing jointly multiple Web server logs;

- It can define a hierarchy of semantic page topics that can also serve to generalize pages and identify episodes;

- It employs effective heuristics for detecting and eliminating Web robot requests;

- It proposes a complete relational database model for storing the structured information about the Web site, its usage and its users;

- It uses an advanced preprocessing step for enriching the structured information by calculating different statistical measures for the objects stored in the database and it also facilitates the addition of new user-defined measures (that will be used as parameters in the data mining step).

3. Conclusion

In theory, the potential of Web mining to help people navigate, search, and visualize the contents of the Web is enormous. This brief and selective survey explored the question of whether effective Web mining is feasible in practice. We reviewed several promising prototypes and outlined directions for future work. In essence, we have gathered preliminary evidence for the Structured Web Hypothesis; although the Web is less structured than we might hope, it is less random than we might fear.

In this paper emphasis is placed on Web usage mining. The reasons are very simple: With the explosion of E-commerce the way in which companies are doing businesses has changed. E-commerce, mainly characterized by electronic transactions through Internet, has provided a cost-efficient and effective way of doing business.

Unfortunately, to most companies the web is seemingly nothing more than a mysterious place where transactions take place.

They perhaps do not realize that as millions of visitors interact daily with Web sites around the world, massive amounts of data are being generated. And it is arguable that with the exception of the major players in electronic commerce, most businesses do not realise the value that this information could be to the company in the fields of understanding customer behaviour, improving customer services and relationship, launching target marketing campaigns and measuring the success of

marketing efforts.

The Web is providing a direct communication medium between the vendors of products and services, and their clients. Coupled with the ability to collect detailed data at the granularity of individual mouse clicks, this provides a tremendous opportunity for personalizing the Web experience for clients. In e-commerce parlance this is being termed mass customization.

Web usage mining has emerged as the essential tool for realizing more personalized user-friendly and business-optimal Web services. Advances in data pre-processing, modelling, and mining techniques, applied to the Web data, have already resulted in many successful applications in adaptive information systems, personalization services, Web analytics tools, and content management systems. As the complexity of Web applications and user's interaction with these applications increases, the need for intelligent analysis of the Web usage data will also continue to grow. Usage patterns discovered through Web usage mining are effective in capturing item-to-item and user-to-user relationships and similarities at the level of user sessions. However, without the benefit of deeper domain knowledge, such patterns provide little insight into the underlying reasons for which such items or users are grouped together. Furthermore, the inherent and increasing heterogeneity of the Web has required Web-based applications to more effectively integrate a variety of types of data across multiple channels and from different sources.

Thus, a focus on techniques and architectures for more effective integration and mining of content, usage, and structure data from different sources is likely to lead to the next generation of more useful and more intelligent applications, and more sophisticated tools for Web usage mining that can derive intelligence from user transactions on the Web.

Web Mining Techniques for E-Commerce

Istrate Mihai
University of Pitești
mihaifrance@yahoo.com

Abstract

Recently, the web is becoming an important part of people's life. The web is a very good place to run successful businesses. Selling products or services online plays an important role in the success of businesses that have a physical presence, like a retail business. Therefore, it is important to have a successful website to serve as a sales and marketing tool. One of the effective used technologies for that purpose is data mining. Data mining is the process of extracting interesting patterns from large databases. Web mining is the usage of data mining techniques to extract interesting information from web data. This paper presents the three components of web mining: web usage mining, web structure mining and web content mining and the main data preprocessing tasks for web usage mining.

Key words: E-Commerce, Data mining, Web mining.

J.E.L. classification: M

1. E-Commerce and Retail websites

In e-commerce instead of having your business in a limited physical place and a limited sector of customers who are usually near to your store or business, you have it in the web. In e-commerce websites you have the ability to sell, advertise, and introduce different kinds of services and products in the web. E-commerce websites have the advantage of reaching a large number of customers regardless of distance and time limitations. Furthermore, an advantage of e-commerce over traditional businesses is the faster speed and the lower expenses for both e-commerce website owners and customers in completing customers transactions and orders.[1]

Because of the above advantages of e-commerce over traditional businesses, a lot of industries in different fields such as retailing, banking, medical services, transportation, communication, and education are establishing their business in the web. But creating a successful online business can be a very difficult and costly task if not taking into account e-commerce website design principles, web engineering techniques, and what e-commerce is supposed to do for the online business. Understanding the requirements of both e-commerce website owner and customer is an important aspect in building a successful e-commerce website. There is a lot of information need to be defined before starting building the e-commerce website such as identifying business goals and how the website will target those goals, if the website supposed to attract new customers or increase the sales of current customers, identify if the proposed website will increase the business overall profit, and identify the most suitable tools and techniques need to be used/ followed in order to target those requirements.

Retail websites aim to inspire, reflect a good image about the business and improve it online. An important factor in having a successful retail website is to know your competitors. On one hand, by identifying their points of strongness and trying to get benefit of them by improving those strongness points and adopting powerful strategies. On the other hand, identifying weakness points of your competitors and avoid them is a good practice in having a successful retail website.

2. Web mining

The usage of data mining to maintain websites and improve their functionality is an important field of study. Patterns extracted from applying data mining techniques on

web data can be used to maintain websites by improving their usability through simplifying user navigation and information accessibility and improving the content and the structure of the website in a way that meets the requirements of both website owner and user which will consequently increase the overall profit of the business.[2]

Web mining is the use of data mining techniques to extract useful patterns from the web. Those extracted patterns are used to improve the structure of websites, improve the availability of the information in the websites and the way those pieces of information are introduced to the website user, and to improve data retrieval and the quality of automatic search of information resources available in the web. Web mining can be divided into three major categories: web usage mining, web content mining, and web structure mining.

2.1 Web Usage Mining

Web usage mining or web log mining is the process of applying data mining techniques to web log data in order to extract useful information from user access patterns. Web usage mining tries to make sense of the data generated by the web user's sessions or behaviors. The web usage data includes data from web server access log, proxy server logs, browser logs, user profiles, registration data, cookies, and user queries. Web usage mining tries to predict user behavior while user interacts with the web and learns user navigation patterns. The learned knowledge could then be used for different applications such as website personalization, business intelligence, usage characterization and adaptive websites. There are two approaches for web usage mining process:

- Mapping the log data into relational tables before an adopted data mining techniques is performed.

- Using the log data directly by utilizing special preprocessing techniques[3].

The Web usage mining process consists of three phases: data preprocessing, pattern discovery, and pattern analysis. Pattern discovery is that set of methods, algorithms, and techniques used to extract patterns from web log file. Several techniques are used for pattern discovery such as statistical analysis, clustering, classification, and sequential pattern mining. After patterns are discovered

they need to be analyzed in order to determine interesting and important patterns, besides the removal of redundant patterns. Pattern analysis has several different forms such as knowledge query mechanism, visualization techniques, and loading usage data into a data cube in order to perform Online Analytical Processing OLAP operations.

A web server log file records users transactions in the web. Usually, the web log file contains information about the user IP address, the requested page, time of request, the volume of the requested page, its referrer, and other useful information. The web log file can have different format, but there is a common log file format that is mostly used. The common log file has the following format:

```
remotehost rfc931 authuser [date]  
"request" status bytes
```

where *remotehost* represents remote hostname (or IP number if DNS hostname is not available), *rfc931* represents the remote logname of the user, *authuser* represents the username as which the user has authenticated himself, *[date]* represents date and time of the request, *"request"* represents the request line exactly as it came from the client, *status* represents the HTTP status code returned to the client, and finally *bytes* represents the content-length of the document transferred. The WWW Consortium (W3C) presented an extended format for web server log file that is able to record a wide range of data to make an advanced analysis of the web log file. Web log file is the main source of data analysis in web mining but a lot of preprocessing efforts need to be performed in order to prepare the web log file to be mined.

2.2 Web Content Mining

Web content mining is mining the data that a web page contains. The contents of most of the web pages are texts, graphics, tables, data blocks, and data records. A lot of research has been done to cover different web content mining issues for the purpose of improving the contents of the web pages, improving the way they are introduced to the website user, improving the quality of search results, and extracting interesting web page contents[4].

Web content mining is still a large field. It contains:

- structured data extraction;
- sentiment classification, analysis and summarization of consumer reviews;
- information integration and schema matching;
- knowledge synthesis;
- template detection and page segmentation.

A large amount of information on the Web is contained in regularly structured data objects which are data records retrieved from databases. Such Web data records are important because they often present the essential information of their host pages, lists of products and services.

Two of the most used methods for extracting structured data are *wrapper induction* (given a set of manually labeled pages, a machine learning method is applied to learn extraction rules or patterns) and *automatic extraction* (given a set of positive pages or given only a single page with multiple data records, generate extraction patterns).

2.3 Web Structure Mining

Links pointing to a document indicate the popularity of the document, whereas links coming out of a document indicate the richness or the variety of topics covered in the document. Web structure mining describes the organization of the content of the web where structure is defined by "hyperlinks between pages and HTML formatting commands within a page"[5],[6].

Understanding the relationship between contents and the structure of the website is useful to keep an overview about websites. One of the approach allows the comparison of web page contents with the information implicitly defined by the structure of the website. In this way, it can be indicated whether a page fits in the content of its link structure, and identify topics which span over several connected web pages. Thus supporting web designers by comparing their intentions with the actual structure and content of the web page. Other studies deal with the web page as a collection of blocks or segments. By partition the web page into blocks and by extracting the page-to-block, block-to-page relationship from link structure and page layout analysis, a semantic graph can be constructed over the WWW such that each node exactly represents a single

semantic topic, this graph can better describe the semantic structure of the web. Structure within a web page can be used to help machines understand pages.

3. Web Usage Mining Techniques

In this section, we discuss data mining techniques that are mostly used in web usage mining such as *statistical analysis techniques*, *clustering*, *classification*, *association rule mining*, and *sequential pattern mining*[7],[8].

Statistical analysis is the process of applying statistical techniques on web log file to describe sessions, and user navigation such as viewing the time and length of a navigational path. Statistical prediction can also be used to predict when some page or document would be accessed from now. It makes use of the N-grammer model which assumes that when a user is browsing a given page, the last N pages browsed affect the probability of the next page to be visited.

Clustering is the process of partitioning a given population of events or items into sets of similar elements. In web usage mining there are two main interesting clusters to be discovered: usage clusters, and pages clusters. An approach is to cluster web pages to have a high quality clusters of web pages and use that clusters to produce index pages, where index pages are web pages that have direct links to pages that may be of interest of some group of website navigators.

Classification is dividing an existing set of events or transactions into another predefined sets or classes based on some characteristics. In web usage mining, classification is used to group users into predefined groups with respect to their

navigation patterns in order to develop profiles of users belonging to a particular class or category.

Association rule mining is the discovery of attribute values that occur frequently together in a given set of data. Association rules mining techniques are used in web usage mining to find pages that are often viewed together, or to show which pages tend to be visited within the same user session. A re-ranking method with the help of website taxonomy is to mine for generalized association rules and abstract access patterns of different levels to improve the

performance of site search. Another approach for predicting web log accesses is based on association rule mining. Association rule mining facilitates the identification of related pages or navigation patterns which can be used in web personalization[9],[10].

In *sequential pattern mining* a sequence of actions or events is determined with respect to time or other sequences. In web usage mining, sequential pattern mining could be used to predict user's future visit behaviors. Some web usage mining and analysis tools use sequential pattern mining to extract interesting patterns such as SpeedTracer and Webminer.

4. Discussion

From previous, it is clear that making changes and adaptations to websites with the help of extracted patterns using different data mining techniques is very effective, but doing that in the maintenance phase can be costly and time consuming and suffers from different drawbacks. In commercial companies which are companies that sell different kinds of products on the web, in order to make an effective maintenance to their websites, the companies have to wait some period of time, for example one year, in order to have a representative log file that reflects customers transactions in their website and can give a clear image about their behavior. This amount of time is considered very big especially for the companies in which the time factor plays an important role in their success strategy, and has many competitors who can attract their customers if they have no solid marketing strategies in order to keep their customers as loyal as possible[11],[12].

On the other hand, most businesses gather information about internet customers through online questionnaires. But, many customers choose not to complete these questionnaires because of the amount of time required to complete them as well as a lack of a clear motivation to complete them. Several companies use cookies to follow customers through the WWW, but cookies are sometimes detected and disabled by web browsers and do not provide much insight into customer preferences. This is because customers are feeling that their profiles are not secure so a number of customers choose

to give incorrect information about themselves.

Furthermore, in web mining different strategies are implemented to identify sessions such as defining a time threshold that a session should not exceed or assuming that consecutive accesses within the same time period belong to the same session. In some cases, it is difficult to identify users, for example, when two users use the same machine and the same browser with the same IP address and look at the same set of pages. We can conclude from that, that those session and user identification strategies cannot give a guarantee that those identified users and sessions represent the actual users and sessions.

Abstract

The concept of fair value challenged the interest of both the accountant normalizers and that of professional accountants, being an omnipresent notion in all established articles to the subject by the IFRS. The actual concerns of organisms that emits accounting standards are focused over norms improvement, regarding financial instruments evaluation based on their liquidities and of holding time horizon, debates having as central pillar the fair value and accounting at fair value.

Key words: historical cost, fair value, market to market, market to model

J.E.L. classification: M4, M41

1. Introduction

For accounting information to be relevant and credible, are necessary more conditions: the information has to be appropriate for decision making by users, benefits as result of information has to exceeds its cost, to establish a balance between the qualitative characteristics of financial information.

The entry value in accounting based on historical cost is a reliable and verifiable value, registered into a document that certifies asset ownership law, a claim law or a debt. It reflects the correctly value at the moment of their initial recognition, being a fair value as at that date. Referring the fact, that the modern economies are characterized by inflation, the question that arises is related to the great disadvantage of the historical cost. The answer to this question is: the inflation that makes obsolete the historical

cost value. In terms of inflation, information furnished through historical cost observance has no longer value. Therefore, must be made corrections of historical costs either by reassessment or by using the accountancy indexed at inflation, but these are insufficient for a faithful image [1].

Assessment at fair value opposes prudence principle one of fundamental principles of French accounting law (taken over by the Romanian accounting standards), through which account possible losses but not the potential profits. The problems that appear relate to the impact at fair value over enterprise accounting information and especially over the balance sheet and respectively to the profit or losses account drawn up on the base of fair value registration. At the same time, the fair value measurement established organization on new bases of reporting enterprise performance. Hence appears the question „is it closer by truth and more credible a result calculated on the base of fair value than one established on the base of historical cost?”.

2. Historical cost versus fair value

2.1. Historical cost

Evaluation at historical cost is an older accounting principle. Its first appearances date back to June 1979, in a project of the French accounting plan, after numerous theoretical debates. The historical cost can be defined as the original cost, evaluated, measured and recorded at the entry of assets and debts creation [2]. Historical cost is a value that comes from the past, reason for which it was established in accounting evaluation principle at historical cost, which

has the quality to be verifiable and objective. If evaluation method at historical cost carries a guarantee of reliability it tends to undervalue assets related to market tendencies. In the evaluation of assets at year end, the enterprises have a relative freedom of choice. Some of them abuse of this freedom for understatement or overstatement of assets, playing with depreciation (the choice of duration assets, depreciation methods) and provisions [3].

The historical cost can be defined like the "sacrifice that was accepted to bring the good in the enterprise at its entry date" [4]. Considering that any cost or sacrifice accepted is, in the conditions of entering in role of alternative costs, an untapped opportunity, as in order to assure its functioning, the enterprise must abandon certain choices (its resources are not available for alternative uses), we can conclude: historical cost used in measuring the real value, can be defined like the voluntary sacrifices (costs incurred) plus the cost associated with untapped opportunities (lost revenues). We can assimilate historical cost with opportunity cost, that appears as an alternative cost or giving up cost, any option leading to giving up of another solution had in consideration. From accounting point of view such cost represents a conceptual incompatibility, as accounting records what is it, not what could be. As a conceptual similarity, the opportunity cost is reflected in decision-making situations and at statistician L.J. Savage, who formulated the rule of regrets minimization recommended to adopt the decisions in uncertainty conditions. According to Savage's analysis, the decider must to be concerned about continuing to minimize regret not to has been chosen optimum decision [5].

Over time, it was found that in times of inflation, historical cost furnishes a distorted representation of economic reality. This fact has a negative influence on enterprise performance that cannot be properly assessed because of the overstatement of profit, the enterprise incurring a tax over inflation and distributing the fictive dividends, which actually means the distributions from the capital enterprises. The company result established on the base of historical cost reflects less the real potential, especially in service sector companies and high

technology, that invest an important part of resources in intangible assets (intellectual capital). For these companies, traditional accounting model based on historical cost does not reflect the real value of the company. Also, by applying the prudence principle, which considers that an asymmetrical approach potential pluses and minuses value, perhaps by recording probably expenses, but non recognize of value of latent pluses, enterprise accumulate accounting losses, which do not reflect their real potential. At this is added the development of various financial engineers at which companies resort to assure financing needs in increase and for risks management connected by modern businesses.

It can be concluded that, in the new business context, accounting model based on historical costs do not assure the reflection of reality. Once with losing pertinence of evaluation in historical cost, the question that arises is: "What will replace the historical cost, if this accounting recording model is no longer suitable in future, characterized by the triad: globalisation – technology - complexity?"

2.2. Fair value

Appeared for the first time in 1953 in publications from Accounting Research Bulletins regarding to balance sheet revaluations, fair value notion, was then introduced by the IASB in 1998 for evaluation of financial instruments (IAS 39) and responds to a logical evolution of accounting. The concept of fair value is reflected in context of international accounting standards elaborated by the IASB: „fair value is the amount at which an asset could be exchanged or a liability settled, willingly, between the parties informed, in a transaction where the price is determined in an objective manner”.

Accounting experts have sought to know the relationship between fair value and market value, in conditions in which market value indicates that the price must be looked for on a market.

Summarizing the opinions presented by François Mousel [6] regarding to the fair value can be said that fair value is a concept

with evolving and multifaceted character. This assertion is justified by those listed below. The market value may be the fair value when there are active markets, quoted, liquid, organized, etc. (a situation particularly common in anglo-saxon accounting model). For revaluations regarding an asset at a previous moment of relevant transaction, does not exist, by definition, in general, such a fair value. An example of an exception from this finding there are fungible financial instruments, negotiated on an organized and liquid market. For such instruments, the price quoted at one time is the amount for which these instruments can be exchanged between the parties informed and in agreement. This is because, historically, the concept of fair value was first imposed for certain financial instruments. Furthermore, usefulness of applying the fair value of financial instruments held at the end of negotiation, will facilitate consensus, because the value of these assets for enterprise would be well represented by a potential sale price, materialize at any moment. Fair value would be justified by a trade deal imminent. As regards tangible and intangible assets an enterprise has to choose between two accounting methods: the cost and the revaluation model. The logic of the used model for the revaluation of tangible and intangible assets is quite different from that which relates to financial assets. In fact, the first ones are intended to be permanently assigned to normal activity to the enterprise. Thus, they are the subjects of amortization which is defined by IFRS as the systematic allocation of the depreciable amount (cost of the asset or any other amount that replaces the cost minus residual value) of an asset on a utility duration. Superposing thus amortization technique and revaluation model, IFRS referential recognizes clearly that net accounting value of an immobilization in the sense of model of the cost (acquisition cost less amortization accumulated) is not, in many cases, a relevant information identical as real value of this asset.

Fair value measurement of assets and liabilities allows rapid transmission of information required by investors and shareholders. For example, Pascale Revault [7] quotes Jacques Richard (Professor to the University Paris Dauphine) illustrates very

significant the concept of fair value through the following example: A company that holds securities A, quoted at Stock Exchange, which recorded a decrease of 100 u.m. and B securities, which have increased by 150 u.m. can reflect this situation as follows: according to principle of prudence - a loss of 100 um (potential capital gains are not recorded); according to principle of fair value - a profit of 50 um (market value is thus immediately reflected by enterprise accounting).

National accounting rules states: fair value of assets is determined, in general, according to market dates, through an assessment, usually by qualified professionals in the assessment. In case there is no data on the market on fair value because of the specialized nature of assets because of the specialized nature of assets and of reduced frequency of transactions, the fair value can be determined by other methods typically used by professionals in the assessment.

Currently, the fair value measurement is favored by international accounting regulations, which seeks to award the fair value of the item assessed by reference to its market value - *mark to market*. "*Markets, in the measure of their existence and extent of their effectiveness, provides in every moment fair value. In the case of an inactive market in which they do not exist or are ineffective the fair values must be calculated, usually by derivation from a model forecast that calls for: the definition of a horizon, estimating cash flows for an asset, in according with this horizon, by recourse to hypothesis more or less explicit, with predilection on their likelihood of developing and adopting a discount rate*" [8].

Proposed methods by the IFRS to perform models to establish fair value, shows the difficulties of evaluation rule *mark to model*. In terms of theory, the fair value of an asset is given by the present value of various cash flows expected from him in future. Given the difficulties that may arise, these methods suggest that fair value generalization as criteria (model) to evaluation of all assets and liabilities (the full fair value) seems to be a utopian project, because the practical use of a model can be associated with more risks that can generate losses. For example, under IFRS, estimation of net cash flow to received or to paid for the sale of an asset at the end of

its useful life should be the amount that an entity expects to obtain from disposal of the asset within a transaction in objective conditions, between the parties concerned and knowledgeable of the facts, after estimated cost associated to asset giving up were deducted. Also, if there is not a market price for the item which is subject to fair value, must find a substitute for market value. Between market value and its substitute there is a difference because the market value information is an observed information by the company management and which is achieved independently by its value judgments, but the element that substitutes market value is a value determined by management, that is estimated function of own professional judgments. This information is achieved independently by its value judgments, but the element that substitutes the market value is a value determined by management, that is estimated function of own professional judgments.

In the same time, the fair value use as base of evaluation in accounting is a permanent adjustment of acquisition costs of assets with market value which is a reevaluation of financial situation of enterprise. "Recourse to evaluation to fair value requires including in the enterprise result of operational result obtained from effective transactions, but also of virtual elements, arising from market developments, which are only potential gains or losses. This virtual result obtained from adjustments of enterprise assets and liabilities value, function of market value, represents only a latent enrichment or pauperization of shareholders is volatile and usually is caused by reasons that can not be controlled by the decisions of managers undertaking being induced by the development of market parameters such as interest rate, exchange rate, exchange rates, housing market prices, etc." [9]

In order to estimate the fair value of assets and liabilities can use a hierarchy with three levels: level 1: Review existing prices in active markets, Level 2: analysis of observable market data, Level 3: unobservable market inputs. The fair value at level 3 is the most difficult to estimate, requiring the employment of independent evaluators to remove suspicions of fraud risk. This is because the use of fair value changes result in a manageable components (net

profit) in an uncontrollable component (net asset value). Appears thus the difficulty of explaining to the shareholders on the change in value of assets using fair value.

3. The accounting information provided based on fair value accounting

Concept of fair value attracted the interest of both that of accountants and accounting professionals. Have been brought both criticism and praises to this notion so controversial.

I. Jianu summarizes the advantages of the fair value as presented below [1]:

- *The prediction*: the fair value is the best basis for forecasting future financial flows;

- *Comparability*: fair value reflects the present value of all the tools, regardless of their nature;

- *Coherence*: The fair value is adapted to active administration of financial risks;

- *Reduced complexity*: a unique pricing model is simpler than a model that enables application of different methods of cost and value;

- *Neutrality*: fair value is independent of the intent and the quality of the parties, the date of origin of operations, the nature of the instruments.

Criticism of accounting information based on a fair value accounting are studied on three axes:

1. *The fair value is not reliable and has elements that lead to erroneous interpretations.* Only the values generated by an active market can be reliable and neutral. The most majority of financial instruments issued, negotiated especially used by credit institutions, are not quoted and they have not an organized market (in this sense, one can analyze the hierarchy of FAS 157 *Fair Value Measurement* and FAS board position). Consequently, their evaluation is based on internal models, recognized by banks, because involve estimated parameters, but with degrees of uncertainty, so that they incorporate variables to model risk adjustment, liquidity risk, volatility, etc. It may be said, therefore, that the fair value evaluation includes in its content, methodologies and models that secure a random character. Even if the expert is

honest accounting in determining fair value, such value in preserving a degree of reliability. In other words, fair value is neither reliable nor devoid of elements that lead to erroneous interpretations (or neutral).

2. *The fair value is not always customary methods for determining them.* Since there is not a market price for the whole financial instruments held by companies and groups, the fair value method is based on the current value or other valuation methods, based on conditions that dominate the market, when drawing up such balance-sheet. The values thus calculated are strongly influenced by secondary hypotheses, relative to level and cash flows order and discount rates applied. In conclusion, using the same fair value, financial institutions, raise issues of comparability, the default of financial analysis.

The lack of comparability and neutrality in presenting the fair values call into question the usefulness of information to investors who see themselves thus deprived of the main characteristic of information, namely its relevance. The cost of determining the fair value is not insignificant in size. In the absence of external quotes for most financial instruments used, the fair values must be calculated inside the enterprises, appealing to models those conception, achievement and control are costly and possibly prohibitive for some businesses and institutions, at least in relation to the benefits conferred on those values.

3. *Fair value is extremely volatile in nature* which it manifests, especially in case of credit institutions. The question that may arise is: fair value is a cause or an effect of volatility? Logical answer is that in the financial crisis decreases the amount of bank guarantees, so the debt rate will be higher for companies indebted. Once the debt increases, therefore increases the risk of leveraged company and the asset value will be lower because the same flux generated is now a greater risk.

In present circulate perception of a tight connection between financial crisis and some types of financial instruments in case of accounting standards relating to these instruments. Thus accounting standards being charged mainly because of rules related to fair value rules.

In this sense can also occur other critics regarding fair value:

Fair value has a "pro-cyclical nature" and maintained a downward spiral of the stock market. A such opinion has emerged at the European meeting of accounting professionals in December 2008 (Paris). At this meeting Christian Noyer (governor to the Bank of France) said: the biggest sensibility of balance sheets at market fluctuations is induced by a fair value accounting and is not clearly irrelevant to financial stability.

Fair value has a pro-cyclical character as a result of the fact that the valuation of certain assets, especially financial, is made based on market value: when market value increases, assets value increases and vice versa. Jacques Mistral (director of economic studies of the Institut Français des Relations Internationales, the abstract debate of 11 December 2008: *Fair value - the role of new accounting rules in financial crisis.*) estimated that the new accounting rules were fed during the growing period gains a sense of sustainability.

The fair value cannot always rely on markets in the case when are ineffective. Normal conditions of competition specified in the definition of fair value are not always respected. Sometimes we cannot determine the fair value because markets are affected (a situation that began in the second half of 2008). The theory of the efficient markets which justify the use of fair value as an evaluation criterion is invalidated by the reality of the current economic crisis [10]. In this case it's necessary to resort to mathematical models, based on an assessment of future cash flows, introducing some subjectivity in the choice of modeling parameters to fair value.

Financial reports related to financial instruments, fair value and risks are lack of transparency and comparability. The main criticism was the argument that financial reports ought to provide a clearer and more appropriate to the risks involved in using sophisticated financial instruments, which to allow investors and other stakeholders in correct evaluation of assets, liabilities and equity of companies. Noteworthy is the fact that since 2007 (first year of application of IFRS 7 "Financial Instruments: Disclosures" and SFAS 157 "Fair Value") appeared the first information on financial crisis of

mortgage loans. Even if the information provided by the above standards are also comprised positive aspects of the methods of evaluation, more transparent description of the credit or liquidity risk, etc., Information about financial instruments, fair value and financial risks information was impressive volume. This prevented the increase comparability and transparency expected to be provided by new rules. The same was reported in 2008, the second year of application. The financial reports were characterized by an increased volume of supplied information in the detrimental of comparability and transparency.

4. Conclusions

Opposition historical cost - Fair value is still active between traditional Europe (especially France), which is blamed for his excess of caution that sometimes lead to some inertia and anglo-saxon countries who seeks to obtain any term profitability Short and encourage investors. Opposition historical cost - Fair value is still active between a traditional Europe (especially France), which is blamed for excess of caution that sometimes lead to some inertia and Anglo-Saxon countries that look for before anything to get a short term profitability and to encourage investors.

At first sight, the concept of fair value lets a priori to understand that fair value is a market value that materializes through a commercial transaction, which is independent of the influence of internal factors specific to the company. At the same time, this general definition presents this concept, meaning that market value would be an external reference value, objective and verifiable and does not require subjective evaluation.

From a practical approach in the process of fair value determination, there are two basic situations:

- Existence of an active market and a quoted price;

- Absence of active markets involves the application of valuation techniques. The objective assessment techniques is achieved a realistic estimate of fair value of the asset, which must reasonably reflect how the market is expected to evaluate it.

Considered the best estimation of market value, international accounting normalization instances validated the practice of fair value in a manner that tends to include most extensive balance sheet assets. Thus, any asset shall be treated as a financial asset for which a true and accurate value is given by the present value of expected cash flows to be generated by the asset, taking into account the risks involved. It follows that the fair value is a value oriented towards the future, because it estimates the most correctly cash flows that the firm expects to gain from the sale of its assets.

Reimbursement Mechanism for the ESF Projects in Romania. Case Study: SOP HRD 2007-2013

Jaliu Dragoş

*National School of Political Studies and Public Administration,
Structural Consulting Group
jaliud@fonduri-structurale.ro
jaliudragos@gmail.com*

Abstract

The causes of the low absorption rate are deeply connected with the limited capacity of the institutions responsible for the implementation of the structural funds in Romania.

Delays in the payment of refunds have a tremendous impact on the implementation of projects financed from European funds, the applicants and the partner organizations, and thus on the absorption of EU funds in Romania.

This paper was prepared based on information collected through an online poll conducted on www.fonduri-structurale.ro in the period February-April 2011, attended by organizations that are implementing projects funded under the Sectorial Operational Programme Human Resources Development 2007-2013. The pooling of data showed that the average value of remittance of money waiting from MA SOP HRD is around 146 days.

Key words: human resources programme, beneficiaries, project analysis, reimbursement, structural funds absorption

J.E.L. classification: O022

1. A general overview of the SF absorption in Romania

The absorption of the structural and cohesion funds is one of the top priorities of Romania. Nevertheless, with an absorption rate of only 13 % (roughly 70% of the total payments represents pre-financing, the rest can be considered real absorption) (according to official data on 31st of July 2011) the overall situation is particularly alarming,

considering the slow paces of the effective project implementation and of the recovery of expenses from the European Commission.

Structural and cohesion funds are financial instruments for economic and social restructuring in the Community.

The overall Structural and Cohesion Funds allocation for Romania is 19.668 billion Euro of which 12.661 billion Euro represent Structural Funds under the Convergence Objective, 6.552 billion Euro are allocated under the Cohesion Fund and 0.455 billion Euro under the European Territorial Cooperation Objective(National Strategic Reference Framework 2007-2013).

We believe that the role of structural funds is to grant financial assistance where, when, and how it is needed, but in order to benefit from this support, beneficiaries must comply with "rules of the game", meaning to treat seriously all stages of this process, from idea and the draft project until signing the contract financing and to respect all procedures required.

The causes of the low absorption rate are deeply connected with the limited capacity of the institutions responsible for the implementation of the structural funds in Romania.

2. Case study HRD SOP – the reimbursement mechanism

Because “absorption” means the effective spending of funds assigned by the EU, in the following, we intend to make an assessment of how the reimbursement system works; in an attempt to be as specific as we can, we focused on one of the most important OP of Romania, developed under the Convergence objective: Sectorial Operational Programme Human Resources Development (SOP HRD).

Why SOP HRD? For two reasons: first of all, because the human capital lies at the core of the development policy of Romania, considering the fact that there is a strong connection between social and economical development, and SOP HRD joins the main objectives aimed at a sustainable development of the above named capital. To continue with, SOP HRD is the operational programme with the most projects in implementation, more than 2000. The 2007-2013 allocation for SOP HRD is 18% out of the total allocation for convergence objective, SOP HRD being ranked 5th after Transport, Environment and Regional (NSRF 2007-2013).

Year	Submitted	Approved	Signed
2008	2.842	254 (2 have been retreated)	110
2009	5.250	1691	533
2010	8.265	2434	1962
July 2011	10.166	2894	2116

Source: SOP HRD – the evolution of the submitted approved and signed projects until the 31st of July 2011 according to the *Annual Implementation Report 2008 (Raportul anual de implementare 2008)* and official data from ACIS

The total payments for SOP HRD - 3,209,841 lei (as of 31st of July 2011), represents 21,04% absorption rate, of which 15,56% correspond to pre-financing ;

The institutions and organizations that benefit from SOP HRD financing, *i.e.* the organizations that have projects in implementation, are schools, institutions, universities, research centres, the structures of the Education and Research Ministry, the accredited training providers, professional organizations, the Chambers of Commerce and Industry, trade unions and employers, the National Council for Professional Training of Adults, the National Agency for Employment and its local and county structures.

These actors face a real problem: the long period of time they have to wait for the reimbursement of costs.

The reimbursement principle is the most important principle when dealing with structural funds. This implies the fact that the beneficiaries pay the providers of works or services from their own funds and only afterwards, on the basis of the paid invoices and payment orders, they request the reimbursement of expenses. Basically, the beneficiary must submit a reimbursement request together with a technical and financial report (this document mentions the stage reached and the expenditure). The financers (the Managing Authority of SOP HRD, the Intermediate Bodies) evaluate and certify the payment and only subsequently transfer the appropriate amount.

During March-April 2011, through www.fonduri-structurale.ro I began a campaign to assess the repayment mechanism on EU funds for gathering relevant information regarding the time span of the process of reimbursement of expenses, especially on projects funded from the European Social Fund through the Sectoral Operational Programme Human Resources Development 2007-2013.

Under partial information, collected and centralized by the end of April 2011, 38 participants in the survey where representatives of beneficiaries of EU funds through the Sectoral Operational Programme Human Resources Development 2007-2013 (SOP HRD). The structure of the respondents can be found below:

- 16 respondents (42.11%) from the NGO sector;
- 14 respondents (36.84%) from the academic sector (universities, colleges and schools)
- 7 respondents (18.42%) from the business sector (companies) ;
- 1 respondent (2.63%) from public authorities and institutions;

The survey aimed at collecting information on both the process of reimbursement for beneficiaries who filed claims for reimbursement and have not yet been transferred the money and the beneficiaries who filed claims for reimbursement in the last period and they money was paid.

The main issue raised by the survey's participants was the major delay in the payment of refunds by the Managing Authority (MA).

Under the financing agreement (valid until June 2010) [Article 9, section B "MA SOP HRD obligations", paragraph (5)] MA SOP HRD will make the reimbursement no later than 45 (forty five) calendar days from the submission date of the application for refund, accompanied by all documents requested. Since July 2010 the deadline stated in the contract was reduced to 30 days.

In the case of the reimbursement requests filed and still pending until completion of the survey, the duration of the refund process has reached in some instances up to 325 days. The pooling of data showed that the average remittance of money is in the range of 120 days.

30 of the 38 beneficiary-respondents had 35 requests for reimbursement submitted and still unresolved. In other words, some beneficiaries had more than one request for reimbursement pending until the date they participated in the survey. In 32% (11) of cases, the period of time between the request for reimbursement and the participation in the survey was between 121 and 200 days, and in 14% (5) of the cases, the beneficiaries had been waiting for more than 200 days.

Chart 2: Waiting time since the submission of the reimbursement claim

In the case of the reimbursement claims submitted and settled by the date of completion of the questionnaire, the process of reimbursement had lasted, in some instances, up to 436 days. The pooling of data showed that the average value of

remittance of money waiting from MA SOP HRD is around 146 days.

In 23% (5) of the cases, the waiting period from the date of application for reimbursement to the actual transfer of the money ranged between 121 and 200 days and in 18% (4) of the cases, it exceeded 200 days.

Chart 3: Waiting time from the submission of the reimbursement claim until the money was transferred to the beneficiary

The number of organizations affected by these delays exceeds 38 respondents, given that such projects are typically conducted in partnership. More specifically, according to information collected during the campaign, 103 national and trans-national organizations were affected, of which 30% are NGOs, 30% public authorities and institutions, 26% universities and 14% are organizations from the business sector.

Chart 4: Number of affected organizations (beneficiaries and partners)

Chart 5: Number of affected organizations (beneficiaries and partners)

The total amount of repayments expected by the survey respondents was 13.459.285,96 lei (about 3,28 million euro).

The main complaints of the funds beneficiaries, in addition to systematic delays in settling claims for reimbursements submitted, refer to:

- Poor communication with the Managing Authority and Intermediate Bodies;
- Lack of transparency of the Managing Authority and Intermediate Bodies in relation to beneficiaries;
- Imposing unfair contractual clauses;
- Failure by the Managing Authority and Intermediate Bodies in honouring the contractual clauses.

This information leads to the conclusion that on the circuit of the reimbursement request there are too lengthy checks, a large number of clarifications in the relation with the beneficiaries, unclear approaches and overlapping verifications that require a thorough analysis in view of the checking procedures, attributions that must be carried out by every actor involved (IB, MA, CPA).

Along with the speeding up of the SOP HRD implementation, there comes the major risk that, as the number of reimbursement requests from the beneficiaries rises, the system will become "suffocated" and, consequently, we shall witness an increase in the verification and payment period. Therefore, measures to simplify the checking process become mandatory, along with the substantial increase of the verification capacity (including the help of specialised technical assistance).

Romania is still in an infant state, accommodating the system. Until now, in this matter, the specialists can bring a series of reproaches; Romania must learn the lessons from the older member states or from those that joined the EU in 2004, so that the 2007-2013 period would not be entirely compromised. Looking into perspective, for 2014-2020, a reformed and invigorated system is compulsory and the setting appears to be favourable due to experience, lessons learned, but also, we hope, due to a more prosperous economic space.

The Lattice of Filters of a Pseudo BL-Algebra

Jeflea Antoneta

"Spiru Haret" University of Constanta
antojeflea@yahoo.com

Abstract

In this paper we begin the investigation of filters and congruences. We define the filters of a pseudo BL-algebra A and we denote by $F(A)$ ($F_n(A)$) lattice of all filters (normal filters) of A ; we put in evidence some results about these lattices. By using the two distance functions we define two binary relations $\equiv_{L(F)}$ and $\equiv_{R(F)}$, related to a filter F of A ; these two relations are equivalence relations, but they are not congruences. They quotient set $A/L(F)$ and

$A/R(F)$ are bounded distributive lattices. We give characterizations for the maximal and prime elements on $F(A)$ ($F_n(A)$) and we prove the prime filter theorem. We characterize the pseudo BL-algebras for which the lattice of filters (normal filters) is a Boolean lattice and the archimedean and hyperarchimedean pseudo BL-algebras.

Key words: filters, pseudo BL-algebra, normal filters, maximal elements

J.E.L. classification: C02

Definition A non empty subset $F \subseteq A$ is called a filter of A , if the following conditions are satisfied:

(F_1) If $x, y \in F$, then $x \otimes y \in F$;

(F_2) If $x \in F, y \in A, x \leq y$, then $y \in F$

Clearly $\{1\}$ and A are filters; a filter F of A is called proper if $F \neq A$.

Remark Any filter of the pseudo BL-algebra A is a filter of the lattice $L(A)$.

Remark For a nonempty subset F of A the following are equivalent:

- (1) F is a filter;
- (2) $1 \in F$ and if $x, x \rightarrow y \in F$, then $y \in F$;
- (2') $1 \in F$ and if $x, x \Rightarrow y$, then $y \in F$.

We denote by $\mathbb{F}(A)$ the set of all filters of A . For a nonempty subset $X \subseteq A$, the smallest filter of A which contains X , i.e. $\cap \{F \in \mathbb{F}(A) : X \subseteq F\}$, is said to be the filter of A generated by X and will denoted by $[X]$.

If $X = \{a\}$, with $a \in A$, we denote by $[a]$ the filter generated by $\{a\}$ ($[a]$ is called principal).

For $F \in \mathbb{F}(A)$ and $a \in A/F$, we denote by $F(a) = [F \cup \{a\}]$.

Proposition The lattice $(\mathbb{F}(A), \vee, \wedge)$ is a complete Brouwerian algebraic lattice, the compact elements being exactly the principal filters of A .

For $F_1, F_2 \in \mathbb{F}(A)$ we put $F_1 \rightarrow F_2 = \{a \in A : F_1 \cap [a] \subseteq F_2\}$

Lemma If $F_1, F_2 \in \mathbb{F}(A)$ then

- (i) $F_1 \rightarrow F_2 \in \mathbb{F}(A)$;
- (ii) If $F \in \mathbb{F}(A)$, then $F_1 \cap F \subseteq F_2$ iff $F \subseteq F_1 \rightarrow F_2$, that is, $F_1 \rightarrow F_2 = \sup \{F \in \mathbb{F}(A) : F_1 \cap F \subseteq F_2\}$

For $F_1, F_2 \in \mathbb{F}(A)$, the relative pseudocomplement of F_1 with respect to F_2 is defined by $F_1 * F_2 = \{x \in A : x \vee y \in F_2, \text{ for all } y \in F_1\}$.

Proposition For all $F_1, F_2 \in \mathbb{F}(A)$, $F_1 * F_2 = F_1 \rightarrow F_2$.

Corollary $(\mathbb{F}(A), \wedge, \vee, \rightarrow, \{1\})$ is a Heyting algebra, where for $F \in \mathbb{F}(A)$,

$$F^* = F \rightarrow 0$$

$F \rightarrow \{1\} = \{x \in A : [x] \cap F = \{1\}\}$, hence for every $x \in F$ and $y \in F^*$, $x \vee y = 1$. In particular, for every $a \in A$, $[a]^* = \{x \in A : x \vee a = 1\}$.

We define two distance function on pseudo BL-algebra A by:

$$d_1(x, y) = (x \rightarrow y) \otimes (y \rightarrow x) \text{ and}$$

$$d_2(x, y) = (x \Rightarrow y) \otimes (y \Rightarrow x)$$

Proposition Let us consider a filter F of A. Define two binary relations $\equiv_{L(F)}$ and $\equiv_{R(F)}$ on A by:

$x \equiv_{L(F)} y$ iff $d_1(x, y) = (x \rightarrow y) \otimes (y \rightarrow x) \in F$ and

$x \equiv_{R(F)} y$ iff $d_2(x, y) = (x \Rightarrow y) \otimes (y \Rightarrow x) \in F$.

For a given filter F, the relations $\equiv_{L(F)}$ and $\equiv_{R(F)}$ are equivalence relations on A;

moreover we have $F = \{x \in A : x \equiv_{L(F)} 1\} = \{x \in A : x \equiv_{R(F)} 1\}$.

We shall denote by $A/L(F)$ ($A/R(F)$, respectively) the quotient set associated with $\equiv_{L(F)}$ ($\equiv_{R(F)}$ respectively);

$x/L(F)$ ($x/R(F)$, respectively) will denote the equivalence class of $x \in A$

with respect to $\equiv_{L(F)}$ ($\equiv_{R(F)}$, respectively).

Let us define the binary relation $\leq_{L(F)}$ on $A/L(F)$ by:

$$x/L(F) \leq_{L(F)} y/L(F) \Leftrightarrow x \rightarrow y \in F.$$

It is straightforward to prove that $\leq_{L(F)}$ is an order on $A/L(F)$.

Similarly, we define an order $\leq_{R(F)}$ on $A/R(F)$ by:

$$x/R(F) \leq_{R(F)} y/R(F) \Leftrightarrow x \Rightarrow y \in F.$$

Proposition $(A/L(F), \wedge, \vee, 0/L(F), 1/L(F))$ ($(A/R(F), \wedge, \vee, 0/R(F), 1/R(F))$ respectively) is a bounded distributive lattice, such that $\leq_{L(F)}$ ($\leq_{R(F)}$, respectively) is the induced order relation.

Definition A filter H of A will be called a normal filter iff (N) for every $x, y \in A$, $x \rightarrow y \in H$ iff $x \Rightarrow y \in H$.

Remark Clearly, $\{1\}$ and A are normal filters. If $f : A \rightarrow B$ is a morphism of pseudo BL-algebras, then that $f^{-1}(1_B)$ is a normal filter of A.

We denote by $F_n(A)$ the set of all normal filters of A.

Proposition If $a \in G(A)$, then $[a] = \{x \in A : a \leq x\} \in F_n(A)$.

Remark Let $H \in F_n(A)$. Then

(i) $x^- \in H$ iff $x^\sim \in H$

(ii) $x \in H$ implies $x^=, x^\sim \in H$.

For a filter H of A and $x \in A$ denote $x \otimes H = \{x \otimes h : h \in H\}$ and $H \otimes x = \{h \otimes x : h \in H\}$.

Proposition For a filter H of A the following are equivalent:

(i) $H \in F_n(A)$

(ii) $x \otimes H = H \otimes x$, for all $x \in A$

Proposition Let \equiv be a congruence on A and let $H = \{x \in A : x \equiv 1\}$. Then

(i) H is a normal filter of A;

(ii) $x \equiv y$ iff $d_1(x, y) \equiv 1$ or, equivalently, iff $d_2(x, y) \equiv 1$.

Proposition The congruence relations \equiv_H of A and normal filters H are in one-to-one correspondence.

Starting from a normal filter H, the quotient algebra A/H becomes a pseudo-BL algebra with the natural operations induced from those of A.

Then the function $p_H : A \rightarrow A/H$ defined by $p_H(x) = x/H$, for all $x \in A$ is a homomorphism from the pseudo BL-algebra A , onto the pseudo BL-algebra A/H .

For $x, y \in A, x/H \leq y/H$ iff $x \rightarrow y \in H$ iff $x \Rightarrow y \in H$ and $x/H = 1/H$ iff $x \in H$. If $x \in B(A)$, then $x/H \in B(A/H)$.

Proposition Let H be a normal filter of A and $a \in A/H$. Then

$[H \cup \{a\}] = \{x \in A : h \otimes a^n \leq x, \text{ for some } n \geq 0 \text{ and } h \in H\} = \{x \in A : a^n \otimes h \leq x, \text{ for some } n \geq 0 \text{ and } h \in H\} = \{x \in A : a^n \rightarrow x \in H, \text{ for some } n \geq 1\} = \{x \in A : a^n \Rightarrow x \in H, \text{ for some } n \geq 1\}$.

Proposition If $F_1, F_2 \in \mathbb{F}_n(A)$, then

- (i) $F_1 \wedge F_2 \in \mathbb{F}_n(A)$
- (ii) $F_1 \vee F_2 \in \mathbb{F}_n(A)$.

Proposition If $(F_i)_{i \in I}$ is a family of normal filters of A , then

- (i) $\bigwedge_{i \in I} F_i \in \mathbb{F}_n(A)$
- (ii) $\bigvee_{i \in I} F_i \in \mathbb{F}_n(A)$

Corollary $\mathbb{F}_n(A)$ is a complete sublattice of $(\mathbb{F}(A), \wedge, \vee)$

Definition For a nonempty subset $X \subseteq A$, the smallest normal filter of A which contains X , i.e. $\bigcap \{F \in \mathbb{F}_n(A) : X \subseteq F\}$, is said to be the normal filter of A generated by X and will be denoted by $\langle X \rangle$. Obviously $[X] \subseteq \langle X \rangle$, so, if F is a filter, then $F \subseteq \langle F \rangle$.

Proposition If $H \in \mathbb{F}_n(A)$ and $a \in G(A)$, then $H(a) \in \mathbb{F}_n(A)$.

Proposition For $a \in A$ and $n \geq 1$, the following assertions are equivalent:

- (i) $a^n \in B(A)$;
- (ii) $a \vee (a^n)^- = 1$;
- (iii) $a \vee (a^n)^{\approx} = 1$;

Proof (i) \Rightarrow (ii) Since $a^n \in B(A)$ we deduce that $a^n \vee (a^n)^- = 1$. But $a^n \leq a$, so $1 = a^n \vee (a^n)^- \leq a \vee (a^n)^-$. We obtain that $a \vee (a^n)^- = 1$.

(ii) \Rightarrow (i)

Since $a \vee (a^n)^- = 1 \Rightarrow a^n \vee [(a^n)^-]^n = 1$

Since $[(a^n)^-]^n \leq (a^n)^-$, we obtain $1 = a^n \vee [(a^n)^-]^n \leq a^n \vee (a^n)^-$, so

$a^n \vee (a^n)^- = 1 \Rightarrow a^n \in B(A)$.

(i) \Leftrightarrow (iii) analogously

Theorem The following assertions are equivalent:

- (i) $(\mathbb{F}(A), \wedge, \vee, *, \{1\}, A)$ is a Boolean algebra;
- (ii) Every filter of A is principal and for every $a \in A$ there exists $n \geq 1$ such that $a^n \in B(A)$.

Theorem The following assertions are equivalent:

- (i) $(\mathbb{F}(A), \wedge, \vee, *, \{1\}, A)$ is a Boolean algebra;
- (ii) Every normal filter of A is principal and for every $a \in A$ there is $n \geq 1$ such that $a^n \in B(A)$.

Proof (i) \Rightarrow (ii). Let $F \in \mathbb{F}_n(A)$; since $\mathbb{F}(A)$ is Boolean algebra, then $F \vee F^* = A$. So, for $0 \in A$, there exist $a \in F, b \in F^*$ such that $a \otimes b = 0$.

Since $b \in F^*$, it follow that $a \vee b = 1$.

We deduce that $a \wedge b = a \otimes b = 0$, that is, b is the complement of a in $L(A)$.

If $x \in F$, since $b \in F^*$ we have $b \vee x = 1$. Since $a = a \wedge (b \vee x) = (a \wedge b) \vee (a \wedge x) = 0 \vee (a \wedge x) = a \wedge x$,

We deduce that $a \leq x$, that is $F = [a]$. Hence every normal filter of A is principal.

(ii) \Rightarrow (i) The proof results from the previous Theorem

Conclusion

This paper is very interesting and it represents the base for the study of some open problems: characterize the normal filter generated by a non-empty set.

Performance Indicators in the Customer Relationship

Jeflea Victor

„Ovidius” University of Constanța, Faculty of Economic Sciences
jefleavf@yahoo.com

Abstract

In the early years of direct marketing, much of the growth in revenue took place through the acquisition of new customers. Today, however, markets are more saturated. New customers are gained mainly at the expense of competitors. This makes it more difficult and expensive to acquire new customers. To compensate, many companies are relying on their current customer base to generate the bulk of their profits. They are staying competitive by placing more emphasis on developing new products and services to offer to their existing customers. This not only affects the value of existing customers, but it changes the value of a potential customer or prospect. As a result, companies are willing to spend more to attract new customers by focusing on long range or lifetime value (CLV).

Key words: CLV, cost, profit

J.E.L. clasification: C63

1. Indicators

From the multitude of examples of indicators analyzing the customers portfolio, we suggest a group of five indicators which reflect from a financial perspective how our customers appear and how important they are for the company activity. They project an analysis both at the individual level (each customer) and at the aggregate level (the whole customers portfolio).

1.1. The Expansion of the Customer Account

It measures the degree at which the business relationship with the existing customers may increase, more exactly, the percentage with which the business figure realized in comparison with these ones may

increase. Concretly, the business figure realized with the existing customers in the current period is percentage reported to the business figure realized with the existing customers in the previous period of time

1.2. The Business Figure Generated by the First Three Customers

It measures the percentage of the business figure totalized by the first three customers (from the point of view of the purchase value made by the customers). It is important to monitorize as it desirable each customer to purchase more, if the business depends to a large extent on some important customers, the risks are bigger. A value of 30-40% can be beneficial and comfortable for the company from the point of view of risks

1.3. The Profit per Customer

It measures the medium value of the profit realized at the level of customer. Thus, it implies to measure the profit realized by each customer and to calculate the average of these values. At a practical level, this indicator has the limit of being calculated difficult, as the difference between the revenues and the costs associated to each customer.

1.4. Profitable Customers

Starting from the analysis of the profitableness per customer, it can be calculated by reporting the number of profitable customers to the total number of customers, as a percentage. Finally, for a more comprehensive image, and very important too, it might be a fifth performance indicator in relationship with the customers.

2. Customer Lifetime Value – CLV

This indicator reflects an updated estimation of the profits made by the customer in what it is predicted to be his lifetime.

2.1. The CLV Concept

Kotler and Armstrong define a profitable customer as a person, family or company whose revenues exceed in time the company costs by an acceptable sum, consisting in attracting, selling and serving the customer. In some literatures, CLV is also referred to as "the customer's surplus". As a matter of fact, some researches define the CLV as the customer's surplus without the purchase cost.

In the past, the estimation of the efficiency of the customers relationships management was a difficult process to be done; the firms knew that the customers number was increasing or decreasing but only few firms knew a real fluctuation of the customers flow. At present, the advanced technologies of the databases and the investments for programmes destined for diminishing the customers migration rate and increasing the customer's loyalty allow the determination of the customers value throughout the three stages of their lifetime: attracting new customers, making faithful the existing ones and developing the customers relationships.

The CLV concept was adopted by the companies of direct marketing at the end of the second millennium, due to the databases.

The customers lifetime value represents the net value of the profits made by the customers of a firm, due to the transactions flow in the period of time in which they purchase the products and services of a firm.

There are many possibilities of calculating the customers lifetime value. One of the simplest method consists in dividing the annual profit by the customers number in a certain period of time, but this approach does not give any indications about the sums of money spent by each customer. Another technique of determining the customers value consists in dividing the business figure by the customers number in a period of time, but the inconvenience of the first method is not eliminated, although there can be made correlations among the sales on each

category of customers. To determine correctly the customers lifetime value, it must resort to a detailed analysis of the purchase behaviour and the segmentary criteria used.

One of the mistakes made by the organizations consists in concentrating the efforts and resources only on the customers segments with a high profitableness rate, neglecting those segments with a lower profitableness, which can be turned to account for a long term and the former customers who can be attracted by special programmes and can make considerable profits for a long term. However, any firm is confronted with a profitable and unprofitable customers portofolio and it must be made a segmentation of these customers; on an average, the most profitable customers of a company represent only 10%, while 60% there are just on the line of the profitableness threshold and 30% bear losses.

The firms must determine those success-key factors which contribute to making a high profitableness and look for methods to apply them to the other categories of customers. The resources allocated to the unprofitable customers can be diminished only after having tried to change them into profitable customers, using specific marketing actions.

2.2. The formula of CLV

The formula of CLV can mathematically be defined as follows:

$$CLV = \frac{NP_t}{(1+r)^t} \text{ (for a single period)}$$

$$CLV = \sum \frac{NP_t}{(1+r)^t} \text{ (for multiple periods)}$$

The formula states that we divide the total of expected net profit in each period by a discounting factor. The factor can be defined from the company's rate of credit interest. Then the figures from all periods are added, resulting in the customers CLV.

As shown by the formula, CLV depends on three main factors:

1. The rate of interest used
2. The net profit in each period
3. Customer lifetime

2.3. The objectives of calculating CLV

The calculation of CLV can be made in a very simple way, for example based on general assumptions (rules of thumbs) and by using average numbers. Alternatively, the calculation can be made in a very sophisticated way using statistical methods or even software simulation, calculation of individual customer CLV etc.

The best way to decide how to use CLV will depend on what your objective is in calculating CLV. Is it:

- To illustrate for employees, in general terms, that some customers are more profitable than others?
- To demonstrate the expected result of a new campaign?
- To make a business case for a strategic company change?
- To analyse, plan, decide and implement a strategy?
- To evaluate the customer asset of a company?

The best way to calculate CLV in a given situation will also depend upon the knowledge and acceptance of ROI driven customer management and marketing within the company. Further it will depend on the quality of customer data, whether there is an internal customer database or not and how customers are defined.

2.4. Components of Lifetime Value

Lifetime value can be calculated for almost any business. In its simplest form, it has the following base components:

Duration. The expected length of the customer relationship. This value is one of the most critical to the results and difficult to determine. And like many aspects of modeling, there are no hard-and-fast rules for assigning duration. You might think that a long duration would be better for the business, but there are two drawbacks. First, the longer the duration, the lower the accuracy. And second, a long duration delays final validation. See the accompanying sidebar, for a discussion by Shree Pragada on assigning duration.

Time period. The length of the incremental LTV measure. This is generally one year, but it can reflect different renewal periods or product cycles.

Revenue. The income from the sale of a product or service.

Costs. Marketing expense or direct cost of product.

Discount rate. Adjustment to convert future dollars to today's value.

Some additional components, depending on the industry, may include the following:

Renewal rate. The probability of renewal or retention rate.

Referral rate. The incremental revenue generated.

Risk factor. The potential losses related to risk.

2.5. Modeling CLV

The basic formula for calculating CLV for customer i at time t for a finite time horizon (T) (Berger and Nasr 1998) is

$$CLV_{i,t} = \sum_r^T \frac{Profit_{i,t+r}}{(1+d)^r}$$

where d is a pre-determined discount rate. In multi-service industries, $Profit_{i,t}$ can be defined as

$$Profit_{i,t} = \sum_{j=1}^J Serv_{ij,t} * Usage_{ij,t} * Margin_{j,t}$$

Here J is the number of different services sold, $Serv_{ij,t}$ is a dummy indicating whether customer i purchases service j at time t , $Usage_{ij,t}$ is the amount of that service purchased, and $Margin_{j,t}$ is the average profit margin for service j . In line with the business practice of the company in our application, we use margins that are not customer specific. According to the company, obtaining accurate estimates of individual level profit margins is not possible for the insurances they sell as this requires an accurate assessment of the individual-level risks that are insured.

3. Conclusions

The firms must determine those success-key factors which contribute to making a high profitableness and look for methods to apply them to the other categories of

customers. The resources allocated to the unprofitable customers can be diminished only after having tried to change them into profitable customers, using specific marketing actions.

CRM Information System in the Insurances Field

Jeflea Victor

„Ovidius” University of Constanța, Faculty of Economic Science
jefleavf@yahoo.com

Abstract

Insurance companies use a number of tools to make coverage decisions and set premiums. Databases are among the most common tools used by the industry, and insurance company officials use a number of different databases to make these important decisions. Insurance companies need a way to keep track of their current policyholders and the type of coverage they have, and many companies will use a master database to hold that important information.

Key words: CRM, databases, Information System

J.E.L. clasification: C63

1. Components of SI for CRM

In the present SI for CRM have the following components:

- **The automatization of the sells' forces.** These systems contribute to the automatization and optimization of the sells processes to reduce their cycle and to increase the sells' productivity. They allow to the company to follow and to administrate all the relations, contacts and qualified opportunities during the sells cycle, including the client's support. They improve the efficiency of the marketing communications programs to generate quality tops as a bigger accuracy in the sells' pre-view. The Internet may be used by the company to assure an appropriate training of the sells forces. The detailed information about products, the data bases specialized with solutions, the questionnaires conceived to sustain the sells forces and a set of internal information about Internet can improve the productivity of the sells forces.

- **Call Center** Call Center contributes at the operations automatization with entry and exit calls generated between the company

and his clients. These solutions integrate the transformation of the automatic telephonic systems' voices with a host-program of the agent, allowing the automatic directioning of the call to agents, the automatic presentation of the relevant data about client, predictable number forming, Interactive Vocal Answering systems with auto-service, etc. These systems are useful in clients segments with elevated volume as retail. In present, new interaction channels with clients appear as a result of the new technology, as the call centers based on the global telephony and Internet. The banks concentrate themselves to offer solutions that will force the Internet in the creation of wide CRM systems which allow them to approach the relations with the clients in all forms.

- **Data storage** A data warehouse is an implementation of an informational data base used for the data storage which can be divided and have their origin in a data base for registering and in the data sources from the external market. This is in a typical mode a data base on subjects that allows to the users to connect at a large storage of the company of operational data to search and to answer to the business' tendencies and facilitates the pre-view and the planning efforts.

- **Data research and OLAP (On-line Analytic Processing)** The data research involves software specialized instruments that allow to the users to search in a big quantity of data to discover the relations between data content and to build prediction models of the clients behavior. The data research uses statistic techniques and of mechanical learning for the construction of models for the prediction of the client's behavior. OLAP (Online Analytic Processing), also known as multi-dimensional analysis of data, offers advanced capacities of investigation and analyzing of the information from a data warehouse. For some of the CRM initiatives, OLAP plays a

major role in the secondary analysis which has place after the client's segmentation. For example, in CRM, based on the management systems of the companies, OLAP is an excellent instrument for the success or failure analyzing of the promotional companies.

- **Decisions support and Reporting instruments** Web allowed the existence of some reporting instruments and the information executive systems are used to dispose the economical information which has been discovered. This big knowledge level of the client is distributed to the executive factors of decision, as to those from the operational points of contact with the client. The applications prescribed with some of these sophisticated modeling practices, developed in the data research step are applied to the individual contacts in real time.

- **The points of electronic sell (EPOS)** The main benefit of EPOS and of the retail scanner systems is the quantity of the exact information and at time which they provide. The technological progresses contributed significantly to the enlargement of the data analysis. Beside the data connected initially to scanner concerning the sells rate, price and margin, the banks detain now information concerning the demographic, socio-economical aspects and the characteristics of the clients' life style.

2. Databases for CRM

Insurance companies use a number of tools to make coverage decisions and set premiums. Databases are among the most common tools used by the industry, and insurance company officials use a number of different databases to make these important decisions. Insurance companies also use databases to keep track of their current policyholders and prospect for new business.

2.1. Actuarial Databases

Insurance company decisions are based on a number of factors, but actuarial science plays a big role in the success or failure of insurance underwriting. Insurance companies employ actuaries who examine public records, death information and other statistics to find the right premium level for each person who applies for an insurance policy.

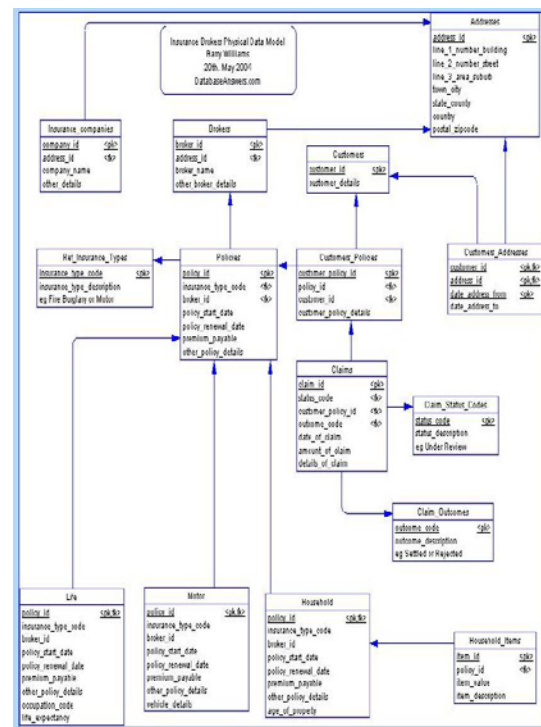

Keeping this vital information in a database is often the best way to ensure the data is there when it is needed.

2.2. Current Policyholders

Insurance companies need a way to keep track of their current policyholders and the type of coverage they have, and many companies will use a master database to hold that important information. It is important for companies to capture as much information as possible when building these databases, including the name and address of each policyholder, as well as the type of coverage each customer has, the coverage limitations, and information on any claims that have been filed. The more information that is included in the database, the more useful it will be.

2.3. Prospective Customers

Insurance companies use databases to keep track of individuals who are prospective customers. This information can be gathered from a variety of sources, but all of the information will be entered into a master database that salespeople can use to prospect for new customers.

Information can be gathered when customers log on to an insurance comparison website and enter their contact information.

Insurance companies can also gather information based on customers who call for additional information. That information can be particularly valuable in terms of sales, since those customers have already expressed interest in the company's products and services.

A general model of the databases for the insurance brokers is given by Barry Williams a consultant of DatabasesAnswers.com.

This structure of the databases is found in the projection of SIMBA software for the insurance officers who manage the processes specific to the brokerage activities in the insurance, on the casual chain in which it is carried on: Documents entrance with special regime (internal transfers, return), filling in the insurance policy, issuing the insurance policy (listing), managing documents annexed to the insurance policy managing the numbers of the deposit sheets, generating the deposit sheets, the situation of the insurance policies/ unregistered instalments, pursuing the due dates, generating deductions and notifications, pursuing the cashing/payments of the insurance premiums, pursuing the cashing/payments of the commissions, the situation of the realizations, previsions, generating specific reporting situations (CSA), communication with the insurance company (email, fax), communication with the customers (sms, email ,fax, letter). Thus it is structured on the following modules:

- Insure natural and legal persons-with the option of the registering the contact relatives or persons, with the options of registering the information necessary for the payments notices
- Insurance companies
- Insurance products, as they are defined by the insurance companies, with the implementation of the insurance classes according to the law
- Brokerage personnel, structured on four access levels: administration, secretariate, group manager, agent
- Broker commission-including the components level of the insurance products
- Documets with special regime (policies, receipts, green book documents, vihnetters or other types of documets) with the automatization of the operations of transferring from the insurance broker to the personnel and vice versa.
- Policies concluded, including free supplemets or not, with a device for defining the necessary information for the insurance policies which do not take part in the great categories such as: motor vehicles, goods, or civil responsibilities
- Insurance objects: motor cars, goods, railway, aerial and naval means
- Damagers record; late of exchange

3. Conclusions

Insurance company decisions are based on a number of factors, but actuarial science plays a big role in the success or failure of insurance underwriting. Keeping vital information in a database is often the best way to ensure the data is there when it is needed.

A Synthetic Form of a Public Policy Implementation and the Exogenous Factors that Determine the Performance of a Policy

Judeu Viorina Maria

„Agora” University of Oradea, Faculty of Law and Economics

viorina@univagora.ro

Brailoiu Liviu

Bujduveanu Aurica

Abstract

Once approval has been obtained for all decision makers on the best variant of solving the problem, it should be known to all those involved to stimulate the creation of legitimacy on the outcome.

In some cases, it is necessary at this stage, the decision maker to make the accumulation of new resources (negotiation, realization of partnerships, hiring new staff) and/or modify certain organizational structure - to create new organizations, to modify / enhance the responsibilities old organization.

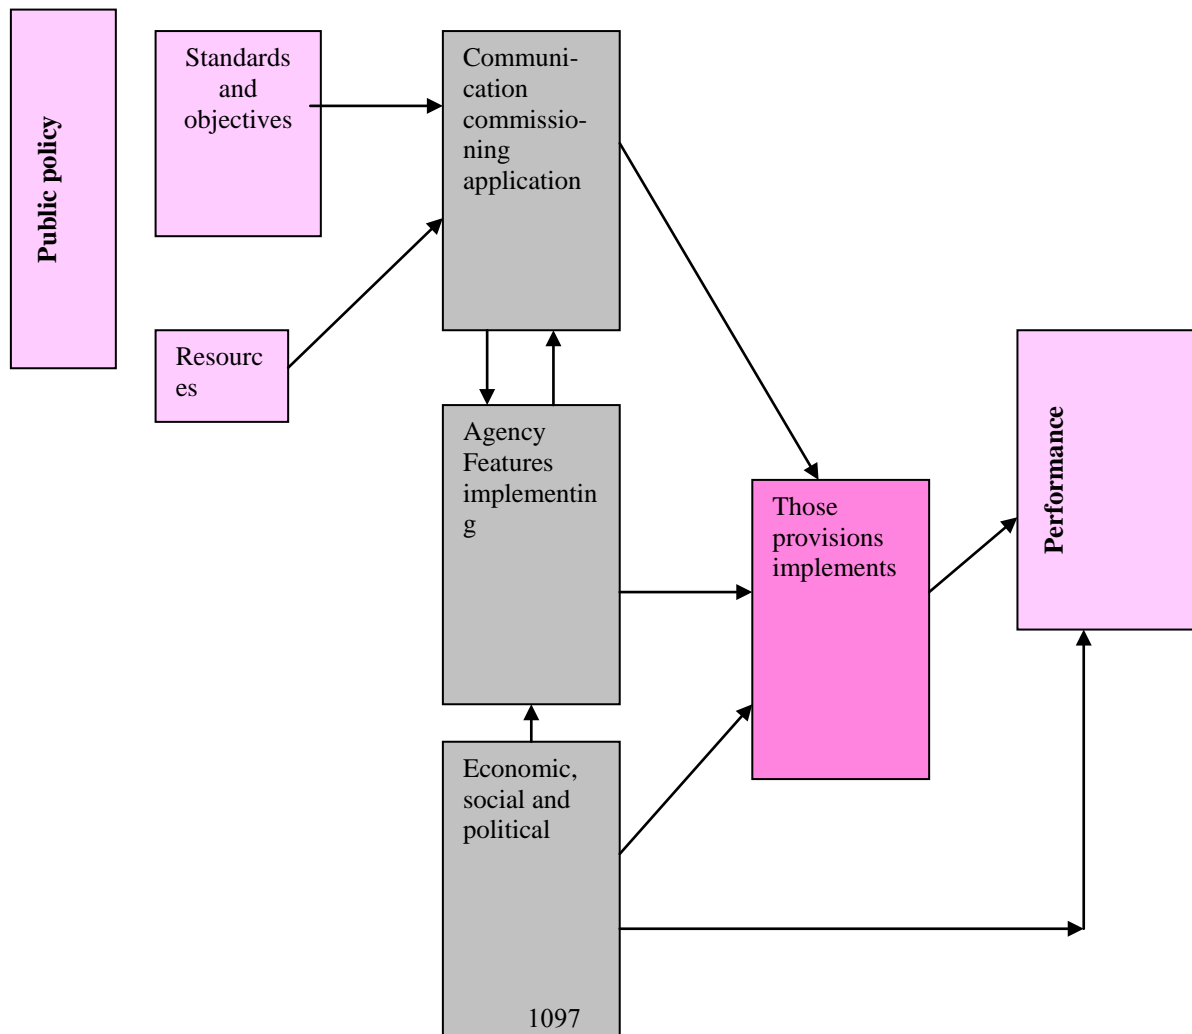

Also in this step, it will choose the tools by which policy is implemented (legislative, institutional, etc.) and the implementing agency (government, other public authorities, private sector organizations, etc.).

Key words: public policy, exogenous factors, performance

J.E.L. classification: H0

The diagram below shows a simplified model of the process of implementing a public policy decision-making circuits in the same time, but also exogenous factors that determine the performance of a policy.

Public policy implementation

Implementation of public policy presupposes, in equal measure, and adopt an action plan which proposed alternative solution to the problem that public policy is practically implemented.

For each of the subsequent activities identified will determine the specific terms of achievement, will specify who is responsible for carrying out such activities, estimates the budget necessary to accomplish the work and shall specify the expected outcomes and indicators proposed for measuring these outcomes.

NGOs can play a fundamental role throughout the process of formulating public policies, methods, techniques and tools used are different depending on the stage at which the organization seeks to intervene.

The process of influencing public decision is typical especially for those organizations that have included in their mission this type of intervention, but it can be met if organizations working directly with beneficiaries (eg social organizations). The most common techniques used in campaigns by persuading a public authority (be it central or local) non-governmental organizations are lobbying and advocacy. The Anglo-Saxon bill, the two terms came into common usage without a corresponding Romanian appropriate. For this reason, they are often encountered difficulties in defining the two terms, especially by comparison.

Advocacy is action to defend / support a principle or a point of view (general or organization) to a legislator or government institutions. Typically, advocacy imply any decision already outlined, to which an organization is positions for or against.

Lobbying involves the promotion of individual interest, group or an organization which at one time may become public interests by influencing public policies of government or legislature.

The main steps of the public policy process in which an NGO can arise are:

- agenda-setting stage (problem definition);
- stage of formulating the variants;
- monitoring and evaluation stages.

Basically, except for implementation that can also be, in turn, partially delegated to a non-governmental organizations (eg within a public policy aimed at reducing pollution by encouraging the use of environmentally

friendly, awareness component may return non-governmental organizations profile), all stages of formulating public policy may be subject to interference from a non-governmental organizations.

Agenda-setting process and the formulation of public interest matters that fall on this agenda is one that involves negotiation between different actors, including NGOs. Thus, using the techniques of advocacy / lobbying, NGOs may, at some point, make institutional agenda an issue that affects a large group of people or by nature, generate significant consequences for society.

Depending on the level / degree of impairment of the problem, are target key decision makers in shaping the agenda are:

At the local level:

- advise local / county;
- mayor;
- chairman of county council;

At central level:

- parliamentarians;
- members of the executive (ministers, secretaries of state).

When the process of consultation / negotiation fails, civil society and other methods used to shape the agenda: media pressure (by sending messages to the media) or direct pressure (public protests, demonstrations, strikes, etc..). Typically, these methods center of gravity moves from the expertise of the organization that initiated the process of influencing the agenda to create a critical mass of pressure on decision makers. Influencing the choice solution to the problem NGOs may also have a major role in choosing a problem-solving on the public agenda.

Moreover, this situation is most commonly seen today in terms of NGO involvement in public policy formulation process.

At this stage, the decision-maker takes the initiative to launch a consultation on alternatives to solve a problem. According to Law no. 52/2003 on decisional transparency in public administration, public authorities have the obligation of transparency which is required to inform public debate and to submit draft legislation, to allow access to administrative decisions and minutes of public meetings. (Article 3, paragraph a).

The same law specifies that the public authority concerned is obliged to decide how to organize a public meeting to discuss the draft bill, if this was requested in writing by a legally constituted association or by another public authority (art. 7). This law is applicable to local decision-making process, namely the ministries. The law does not apply to the legislative process of the Romanian Parliament.

Typically, the consultation process in Romania has a formal character, since the decision-maker (the Authority has jurisdiction to hear the matter) is launching the consultation process only after it has been selected variant of solving the problem, which basically requires the organizations to

position themselves for or against this alternative.

Regardless of which party takes the initiative of launching a consultation process on public policy, it is recommended that NGOs intend to put forward concrete recommendations for the closure of a public policy to do so in a manner articulated and specific instruments uzând such as:

- study (document) public policy;
- public policy analysis

The main differences between the two types of instruments are shown in the table below:

Public Policy Tools

Difference	Type of the instrument	
	Type of instrument Study of Public Policy	Public Policy Analysis
audience	Public policies aimed at other specialists	Involves makers
Accent	Based on the problem: general recommendations and information on public policy issues	Based on the client: the design of specific policies to be implemented on the ground
Methodology	May include extensive primary research	Rarely includes primary research
Ideas / language used	It can be specific discipline / technical	You must be very clear and simple
Extent	Up to 20,000 words	Usually no more than 5,000 words

A synthetic form of a public policy document, this time used by the government (central), is the proposal for public policy.

As regards the specific regulations of the Romanian Government which originated mainly from 1 January 2006, is the obligation to present their proposals in the form of public policy, according to GD no. 775/2005 approving the Regulation on procedures for drafting, monitoring and evaluation of public policies at central level.

This measure was aimed at professionalizing and empowering Romanian decision-making at the executive level, in that it requires virtually all ministries base their proposal sufficient information to reflect: analysis of the facts (problem),

potential alternatives to improve situation, along with estimated costs of each option, the justification for the preferred option, providing for specific actions on the implementation, development tools (indicators) for monitoring/evaluation of the degree to which future public policy will achieve its objectives.

Conclusions

Monitoring and evaluation are two types of actions are carried out simultaneously with the implementation of public policy. Basically, ensure correspondence monitoring targets with proposed actions for implementation, and evaluation quantifies the

results provide the basis for the next cycle of implementation and public policy, an issue on the agenda may be called at any time, in another form, according to public policy development original. Monitoring and evaluation of both the tools for implementation, and results as such. At this stage, we measure both effectiveness (maximizing results - outputs in relation to invested resources - inputs) and effectiveness of public policy (the ratio of objective performance and objective to be achieved).

Monitoring and evaluation have distinct roles in this phase. Monitoring Points:

- institutional changes arising from policy implementation
- situation changes the target groups;
- situation at a time implementation costs;
- timeliness and content of the activities provided in the Action Plan;
- delays / difficulties in implementation activities and their motivation.

The Evolution of European Union Regional Policy - Social, Political and Economic Arguments

Judeu Viorina Maria

„Agora” University of Oradea, Faculty of Law and Economics

viorina@univagora.ro

Caraman Tania

Teliceanu Claudiu Daniel

Abstract

To implement a regional policy in the EU arguments are based on social, political and economic. These arguments can be summarized as follows:

✓ *inefficient spatial distribution of income: there is an inverse connection between growth and inequality in income distribution. However, people can improve income distribution leads to a less efficient allocation of resources affecting the level of welfare. For this reason, the argument of equity in income distribution is more a social than an economic one;*

✓ *adapt more easily to changes in economic structures or major macroeconomic shocks: issues related to EU enlargement Thus, a candidate may face more serious problems after it joins the EU, such as unemployment. As a result, Member States may grant aid to overcome these problems by joining the new state;*

✓ *work factor to optimize the allocation and mitigation of unemployment: in areas where economic activity is underdeveloped, unemployment is high. Regional policy can contribute to economic development and employment reintegration underused factor in terms of ensuring a high mobility of its activation and lower operating costs benefits obtained from this reintegration.*

Key words: regional policy, reform, partnership

J.E.L. classification: R58

Although regional policy is implemented at the EU Member States, the need for a common regional policy arising from:

✓ need for greater resources to implement an effective regional policies, resources have not all EU Member States The financial argument is quite correct. Greece, for example, had to spend in the period '80 - '90, a much larger part of its GDP on non-EU state aid together.

On the other hand, Greece and Ireland spent a much smaller part of their GDP on infrastructure and research and development, compared to other countries;

✓ recital that the regional problems of a state is also good for other member states. This consideration is related to the fact that any EU Member State should enjoy the same benefits related to welfare;

✓ benefits of integration within U.E. requires an equitable distribution, which can be ensured by regional policy;

✓ need to allow compensation for some Member States which have suffered from implementation of other EU policies such as CAP, transport policy and policy research and development. This argument is often linked to the need for regional transfers within the EU, especially the peripheral regions, which have suffered most.

Regional Policy U.E. are implemented on the basis of allocations from the Community budget and only in areas designated in the Member States. This implementation should be monitored at EU level because:

- net donors of funds for regional policy seeking to ensure that these funds will be used to increase the economic potential of less developed regions. This is intended as a temporary support for regions with a lower level of competitiveness;
- regional authorities in many EU Member States may not be safe to apply the most effective measures for

developing regions in their countries. As a result, the European Commission is the body viable solution to this inconvenience;

- as regional policy measures in a Member State have an impact on other Member States, it is necessary to coordinate regional policy at Community level;
- regional policy approach at national level can only lead to the emergence of a race between different locations to obtain as large subsidies.

Initial elements of the common regional policy are related to the European Social Fund - which had the objective, inter alia, increasing the employment factor and occupational employment and geographical mobility within the EU - And by the European Agricultural Guidance and Guarantee Fund. Oil shock in 1973 and the first EU enlargement have led to increased emphasis on Community regional policy. As a result, regulation 724/75 U.E. led to the establishment of the European Regional Development Fund.

The primary objective of this Fund was to support the main mitigating regional imbalances within the EU, mainly due to imbalances of industrial reconversion and industrial decline.

Initially, the resources allocated to the European Regional Development Fund consists of contributions - the default rate - the Member States. Member States U.E. cofinanced projects F.E.D.R. national public funds, in accordance with the principle of additionality.

Almost 85% of regional projects undertaken by the ERDF in the period '70 - '80, aimed at improving infrastructure.

Extensions U.E. the years 1981 and 1986 have led to regional disparities and the need to compensate for some states, like Greece, France and Italy, for losses suffered as a result of enlargement to the south. As a result, programs were developed Mediterranean integration, which proved to be pioneers of reform of European regional policy in the late '80s.

The main stimulus for the development of European regional policy was the formation of the European Single Market. Single Market required the financial assistance of EU member states to help them increase their

economic competitiveness. To this end, the European Commission's powers were increased and fixed the quota system was abandoned for participation in ERDF.

Maastricht Treaty, in Article 2, spoke of the objective economic and social cohesion, which could not be achieved without a proper European regional policy. The Maastricht Treaty led to the modification of regional policy instruments. Were created Fund and European Investment Fund, European Investment Bank related. Cohesion Fund was established under the provisions of Article 161 (2) of the Maastricht Treaty, to ensure funds for the development of infrastructure and environmental projects in Member States whose GDP per capita was less than 90% of EU average European Investment Fund was designed to facilitate the financing of EU projects in peripheral areas, which implied acceptance of a risk of higher than standard bank loans with the European Investment Bank operations.

A new amendment was the establishment of the Committee of Regions (in accordance with Articles 263-265 of the Treaty), which act as a consultant for the European institutions involved in implementing regional policy.

The current European regional policy is based on the following principles:

- concentration;
- programming;
- partnership.

Reform of EU regional policy, which took place in 1988, was based on its focus on those parts of the EU most in need of support for development. As a result, areas which were subject to national support automatically became subject to the allocation of European Structural Funds. EU regional policy objectives have evolved over time. For the period 1994-1999, these objectives were:

1. development and structural change in the less advanced regions in the EU;
2. conversion of regions or areas that were heavily affected by industrial decline;
3. Long-term unemployment and improving the employment of youth;
4. facilitate structural adjustment;
5. a. accelerate structural adjustment in agriculture and fishing cases; b.

Supporting the development and structural adjustment of rural areas;

6. support areas with a very low population density (North).

For the period 2000-2006, EU regional policy objectives were:

1. Combining 1, 5a and 6 of the 1994-1999 period;
2. Combining 2 and 5b of the 1994-1999 period and completed with the specific problems of urban areas, those dependent on the fishing industry and the services sector is subject to reform;
3. supporting the adaptation and modernization of education, training, and policies aimed at labor, and follow up further, as 3 and 4 of the 1994-1999 period.

EU regional policy objectives can be divided into regional goals and objectives themselves horizontal. For the 2000-2006 period, Objective 1 and 2 were considered regional and horizontal Objective 3.

In addition, quantitative criteria have been established to enable European regions tie. For regions covered by Objective 1, was considered a criterion for regional GDP per capita.

As a result, have been categorized those regions whose regional GDP per capita is less than 75% of the average GDP per capita EU in the last three years, before starting the calculation. Furthermore, classical regions, located under Objective 1 are: the French overseas departments, Azores, Madeira, Canary Islands, and sparsely populated regions of northern EU According to the principle of concentration, the regions covered by Objective 1 are NUTS-II type, not smaller.

Designation of regions that are under Objective 2 is slightly more complex. This is because, in 2000-2006, these regions have been limited to 18% of the population, of which 10% covers the industrial and service areas, rural areas 5% 2% 1% urban areas and areas dependent on fishing industry .

To establish those areas, the European Commission uses a set of economic, social and demographic considering proposals under which Member States relating to areas that may be considered under Objective 2.

Lists of Member States proposals are reviewed by the European Commission, after consultation with Member States, finalizing the final list of areas that will be covered by Objective 2.

However, as the limit of European regional policy, was considered since 1988 as Objectives 1 and 2 cover the region in which to live up to 40% of the population Part of the proceeds U.E. regional policy are intended for community initiatives. These initiatives are aimed at helping different types of regions are in decline due to factors such as their location on the outskirts of the EU In 2000-2006, Community Initiatives have been grouped into four broad categories:

- border and interregional cooperation (INTERREG);
- conversion socio-economic urban areas (URBAN)
- rural development (LEADER +);
- transnational cooperation in the fight against discrimination and inequalities in the labor market (EQUAL).

The Community Initiatives, in 2000-2006, representing 5.35% of total Structural Funds, compared with 9% in the period 1994-1999. Regional policy objectives for 2007-2013 are:

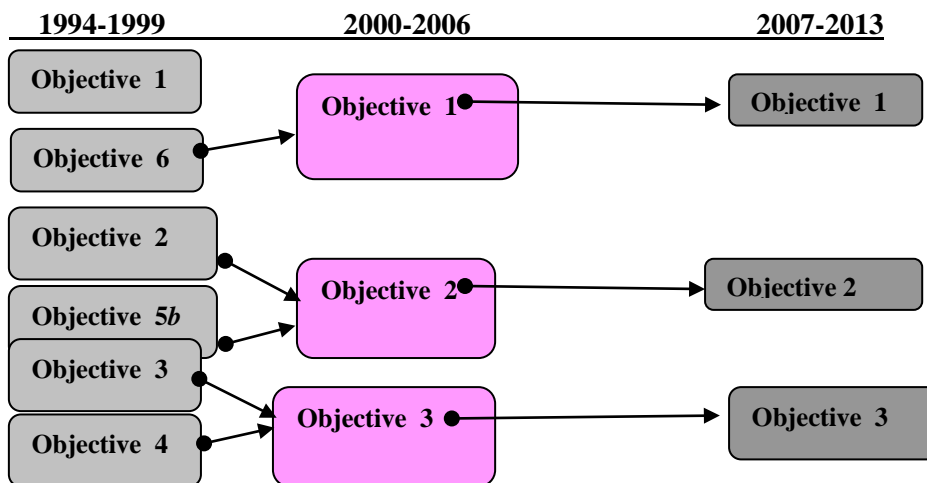

O1 - Promoting convergence and economic development and job creation in the least developed Member States.

O2 - Promoting regional competitiveness and employment by preparing work to attend and meet the labor market changes.

O3 - Promoting regional cooperation at European level.

Programming is that principle that shapes regional policy implementation in a given area must be included in the development plan of that area. The basic idea was to ensure consistency between individual regional policy measures, regional, national and Community level.

Figure 1 Evolution of the main Objective is pursued by the EU regional policy

Source: Personal contribution

In 2007-2013, EU regional policy programming algorithm requires the following steps:

- adoption by the European Commission guidelines outlining common priorities for all three regional policy objectives. These priorities were reflected in all regional development programs aimed, inter alia: increasing competitiveness, increasing in Objective 1 and 2 regions. In addition, there are large regional and national differences between the size of the areas covered by the same objective and between certain Member States the tools they prefer to implement their regional policies.

On the basis of national or regional plans, the European Commission together with national and regional authorities, created the Community Framework for Relief, which provides specific information on regional development plans. In the case of Objective 1, this information is structured into the following categories: supporting productive investment, human capital formation and infrastructure.

Support to productive investments aimed at: industry, services, rural development, fisheries, tourism and agriculture.

Human capital formation covers education, training and research and development, while infrastructure refers to transportation, communications, energy and water, environment and health;

- preparation of detailed operational: it is made only at the national and regional authorities in each Member State. During the

employment of labor, equal opportunities for men and women;

- national regional development plans are translated into effective action plans for other national authorities and / or regional. There are big differences between these two types of plans;

First, these plans may differ in respect of employment implementation of these plans, there are many of these consultations with European authorities.

The current algorithm implementation of European regional policy, presented his three steps leading to an increased role of the European Commission, along with increased decentralization of management of regional development programs.

It refers to the obligation of each member state to support public expense each subject at least the same level as in the previous programming period.

The partnership aims to close cooperation between European, national and sub-national, in order to effectively implement regional policies. This partnership takes three basic forms:

- coordination between the different Structural Funds and other EU financial instruments;
- coordination between EU structural policies and national policies of Member States;
- coordination between the Commission and national authorities of Member States.

Increase budgetary allocations related to European regional policy highlights the importance given to structural actions in the EU

Financial resources have been concentrated in the period 2000-2006 at a rate of almost 70% in regions covered by Objective 1 and those in transition. The remaining third was divided regions were placed in Objectives 2 and 3.

Since 1993, four countries (Ireland, Spain, Portugal and Greece) have benefited from cohesion funds for financing of transport infrastructure and environmental projects. In absolute terms, Spain was the largest recipient of Structural Funds in 2000-2006, followed by Germany, Italy, Greece, Portugal and the UK. Community allocations per capita in the period 2000-2006, ranged from 220 €/ person (in Greece and Portugal), 140 €/ person (in Spain) and 100 €/ person (in Ireland). In the developed countries of the EU, these benefits are only 20 €/ person (in the Netherlands, Belgium and Luxembourg) or 50 € / person (in Italy). European Union began to provide financial support candidate countries in Central and Eastern Europe in 1989, through the PHARE program.

The level of financial assistance U.E. by these countries has significantly increased since 2000, by implementing two new programs, SAPARD and I.S.P.A.

Until 2004, the 12 EU candidate countries received financial assistance of EUR 3 billion. Last 12 states that joined the U.E. in 2004 and 2007 became eligible for financing under the Structural and Cohesion Funds. From 1 May 2004 until late 2006, these countries have received 21.7 billion Euros. Almost two thirds of these funds from the Structural Funds, while the third Cohesion Fund (European Commission, 2003).

Due to the low level of GDP per capita, many regions of the 12 new EU member states fall under Objective 1. The only exceptions are the regions to Prague, Bratislava and Cyprus. Implementation of Structural Funds in these countries is a challenge even for themselves, because it involves highly complex procedures and programs.

However, regional policy is not only practical purpose the elimination of regional asymmetric shocks, but also improve the

competitiveness and long-term growth of the assisted regions. To achieve these objectives, regional policy is necessary to obtain positive effects of supply in these regions.

Conclusions

Research conducted on the dynamics of regional policy instruments enable us to achieve a tie in their traditional instruments and contemporary instruments. The coverage, regional policy instruments, can be viewed from several angles, are differentiated in the following categories:

- microeconomic policy instruments used at regional level in order to influence the allocation of labor and capital factor between different industries and inter-regionally;

- macroeconomic policy instruments used at regional level, whose range of action is focused on revenue and expenditure changes made at the regional level;

- government policy instruments used at regional level to achieve policy coherence between national and regional policy;

- European Union regional policy instruments used to achieve economic and social cohesion (between Member States) and to achieve a socio-economic development level similar to the average level registered in the EU (If the candidate countries for accession).

European regional policy evaluation is done according to specific models:

- HERMIN models: analyzing the effects of policies on both supply and demand at regional level, focusing on developing infrastructure and human capital. If the four member states covered by the Cohesion Fund and East Germany, the forecast shows that annual GDP growth will always be 1-2% higher than in the absence of funds;

- QUEST II model: consider some short-term positive effects of regional policy can be reduced in deteriorating trade balance (between the real exchange rate appreciation), or due to the evolution of private investment (in the case of real interest rate increase). The conclusions reached through the application of this model are similar to those resulting from the application HERMIN models. In addition, QUEST II

model shows that factor in the same direction as the work progresses regional GDP;

– econometric models: they are more pessimistic regarding developments at the regional level. Some models even try to minimize the impact of Structural Funds on Convergence in the EU.

Others, however, conclude that the Structural Funds are extremely imported into the regional income convergence.

Clusters in Romanian Tourism

Jugănaru Ion-Dănuț

Jugănaru Mariana

"Ovidius" University of Constanta, Faculty of Economic Sciences

juganarudan@yahoo.com

Abstract

Clusters regarded as groups of companies in a certain field of activity, region or area together with the institutions they closely collaborate with aim at stimulating innovative activities, development of experience and knowledge exchange, in order to develop and to contribute to the respective region development.

To the end of clusters development the European Commission allocated 86 billion EUR for their financing during 2007-2013.

As far as Romania is concerned even though the concept of "cluster" is still little known a growth in preoccupations regarding policy regarding this issue is obvious. At least seven studies have been developed until now regarding the fields and areas where clusters might be opportune. First results have emerged in the field of tourism. In November 2010 the "Carpathian Tourism Cluster Romania" was founded in Brasov. Also, there are premises for the founding of such a cluster in the area of Dobruzha in 2011.

Key words: clusters, tourism, development, region, Dobruzha

J.E.L. classification: L 83

1. Introduction

In English, 'cluster' means „bundle, bunch, group". Similarly, in practice, a cluster represents a group of industrial enterprises or organizations, operating in the same field, that establish cooperation relationships, based on which the partner companies improve their performances.

Within a cluster, the group of companies, the economic stakeholders and related institutions must be in proximity to each other, must act in a specific field, with the

aim of stimulating innovative activities, by developing experience and knowledge exchanges and by contributing to the transfer of technology, networking and dissemination of information among partners.

2. Implementation and development concerns regarding clusters at European level

The tendency to regulate and boost such entrepreneurial behavior led to the definition of a set of policies regarding the activity and functioning of clusters. Most of these policies, concerning clusters, have been and are implemented by different programs or governmental initiatives. [1]

In what concerns the programs and cohesion policies of the European Commission regarding the actions of improvement of knowledge, economic growth and innovation, it must be mentioned that the amount of 86 billion Euro has been allocated for the period 2007 – 2013. A large part of this amount is destined for the support of cluster initiatives and infrastructure. At present, it is estimated that there are over 500 clusters in Europe, many of them having been created out of these funds during the last two – three years.

With the purpose of supporting clusters the European commission launched the Seventh Framework Program for Research and Innovation, the Lead Market initiative and a series of programs which are part of the Cohesion Policy.[1]

3. Cluster projects in Romania

Even if the cluster concept is little known by many companies, the increase of concerns regarding the outline of a cluster policy in Romania can be noticed.

Starting from the definition of the cluster as an agglomeration of companies, the Romanian state, besides the unproductive sectoral intervention, has tried to promote company agglomeration by means of public policies. These policies have generated what specialists call "public clusters", which, by law, have the statute of industrial parks, scientific and technological parks. [2] Unlike the latter, something innovative must happen inside a cluster, something which will differentiate the respective region or country and which will ensure its development.

Besides "public clusters", "natural clusters" can also be identified in Romania, meaning an "agglomeration", a partnership between SMEs, multinationals, universities, research institutes, chambers of commerce, municipalities etc, based on collaboration between partners in view of increasing the competitiveness and development of a region.

Studies regarding cluster competitive economic agglomerations have been initiated in Romania since 1998, the first study being probably the one coordinated by the International Centre for Entrepreneurial Studies (CISA) of Bucharest. The research was requested by the Institute for Economic Development of the World Bank and was targeted on the competitiveness of the entrepreneurial sector of Romania. The study identified the existence of three "incipient" forms of clusters in software production, in maritime industry and wood industry. [3]

Another study, published in 1999, was elaborated by Marco Riccardo Ferrari, assistant –researcher at the Department of Economics of the Bocconi University of Milan. This study, which was based on the Italian methodology regarding the identification of industrial districts, identified three "proto-districts" in Romania, in wood industry, textiles and ceramics industry. [4]

A third study followed, elaborated in 1999 by the specialist Valentin Ionescu (ex-Minister of Privatization). Upon valorization of the documentation pertaining to previous studies and their completion with his own research, V.Ionescu stated that there are no functional clusters in Romania, yet admits to the existence of two "proto-clusters" or "emergent clusters" in ceramics and software industry. We must however highlight certain limitations of this study that especially regard

the fact that the research was limited to only two possible clusters: the first in ceramics industry, in Alba county and the second in software production, in Bucharest area. [5]

The fourth study targeting clusters in Romania is represented by the VICLI Project, developed within the European Program INTERREG II C – CADSES – Central European Adriatic Danubian South-Eastern European Space), carried on between 1999 – 2001. The objective of the project was to identify and support cluster development in Romania by a regional know-how exchange.[6]

The final VICLI report for Romania identified four potential clusters in Harghita county (the county being selected as the proper pilot area for implementing the project methodology) in wood processing, pottery, typography, and equipment industry. It was noticed that Harghita is one of the few counties in which the input/ output analysis evidenced important industrial interconnections (between wood processing, cellulose production and typography). [7]

Fifth of all, we must mention the project INCLUDE (Industrial Cluster Development), financed by the INTERREG III B, CADSES, European Initiative for the European Regional Development Fund, for the period 2000 – 2006. This project unfolded between 2003 – 2004 and aimed at achieving an analysis of potential clusters in partner countries from Central and Eastern Europe, and further, to assist these countries in developing such clusters, using the experience and know-how of Italy and Austria.

The research performed within the project identified certain potential clusters in Romania, in the field of textile industry (North –East region of Romania, especially Bacau county and Western region, Timis county); software (Timis, Cluj and Bucharest); wood processing, steel components and metallic products (Central region of the country). Brasov county drew attention on the cluster agglomeration of companies in the field of chemical industry, structural metal products, general use machinery and engines.

We must mention that within INCLUDE project there were selected two clusters for a thorough analysis and in view of offering support, based on the interest of external

partners from EU, mainly: textiles in Bacau county and wood processing in Mures county. For each of these clusters a SWOT analysis was performed. Moreover, the cluster from Mures county was selected as pilot-project for the elaboration of a feasibility study, in view of establishing the opportunity of financing a Cluster Services Center (CSC), as a first step in the institutionalization of clusters in Romania. For now, the set up of the CSC is hindered by the lack of financial resources to remunerate the staff to be employed within the CSC (3-4 persons) and by the absence of a leader – company, capable to rehabilitate the remainder of the companies included in the cluster. Without the CSC, the economic agglomeration in Mures shall not reach the statute of functional cluster.

The sixth study was drafted within the project WEID (West – East Industrial Districts), financed by the European Commission through the Fifth Framework Program (FP5). This project unfolded during 2001 -2004, including partners from 7 countries from Western Europe (Germany, Italy and Great Britain) and four countries from Central and Eastern Europe (Czech Republic, Poland, Slovenia and Romania) and had the objective of investigating, by means of case studies, the relationships between clusters at European level.

Out of 15 case studies, included in the project, two were performed in Romania, researching the existence of potential clusters in two areas: Banat – Crisana and Arad – Timisoara, in sport articles industry and footwear industry.

Especially Timis county drew attention, because of the increased level of Italian investments in the area, a large concentration of Italian SMEs, which almost made possible the de-location process of Italian clusters to Romania. [8] The seventh study on cluster development in Romania was drafted within the CURAS program (Clustering and Upgrading Romanian Automotive Suppliers), which was established with the Cooperation Agreement between the Romania and the Flemish governments. This project was implemented during 2003-2004 by the National Agency for Small and Medium Size Enterprises and Cooperation and by CZK Limburg (ALLANTA) – the Flemish promoter that manages the Center for

Management and Support for Automotive Components Sector, from Genk, Belgium.

The objective of the project was to improve the quality level and efficient use of SMEs' resources in the field of automotive components, and the result of the project resides in achieving clusters of suppliers in this field of activity, and in implementing a Center for the chain of suppliers, as a private NGO, as a first step towards the institutionalization of a functional cluster in the automotive sector, located in Pitesti – Arges area, near Dacia –Renault factory. It must be mentioned that the CURAS program represents the only initiative in what natural cluster development is concerned, supported by the government.[9]

4. Clusters in Romanian Tourism

On the 1st of November 2010 the "Carpathian Tourism Cluster Romania" was established, at the initiative of the Association for Tourism Promotion and Development of Brasov county (APDT Brasov), along with Monteoru Renaissance – the Association for Regional and Sustainable Development in Tourism. The Carpathian Tourism Cluster Romania is a non-governmental, non- profit organization, established as an association, according to Romanian law, headquartered in Brasov. It is the first interregional tourism cluster of national interest in Romania. The cluster comprises tourism and regional development associations, NGOs, local and national authorities, tour – operators, tourism agencies, tourist guides, event agencies, accommodation providers and other providers of tourism industry. "Carpathian Tourism Cluster" is based on the national cluster strategy of Romania, a strategy supported by the European Commission.

The objectives of the cluster are: innovation and diversification through development of tourist offer and of modern and innovative services, to maintain and attract new tourists in the areas of interest of the Carpathian Mountains; increased competitiveness through the optimization of the value chain in local tourism industry; improvement of the quality of tourism services at the level of European standards; development of the exchange of common ideas and projects between tourist regions of

the Carpathian Mountains; sustainable development of the region; promotion of Carpathian Mountains of Romania as "destination of excellence" within the national strategy of tourism promotion. Romania – Explore the Carpathian Garden".

The tourism cluster targets Carpathian and sub-Carpathian tourist regions in Brasov, Buzau, Prahova, Sibiu, Covasna and Arges counties.

The members of the cluster can benefit from multiple advantages such as: exclusive access to information, services and contact data of the Carpathian Tourism Cluster; strategic cooperation opportunities with other tourism companies and service providers along the entire tourism value chain, new ideas and knowledge for diversifying and improving the quality of services; access to European structural funds; special offers/preferential tariffs for seminars and trainings; joint activities of buying/purchasing and of promotion; joint marketing at local, regional, national and international level and selling activities for the Carpathian tourist region.

The Carpathian Tourism Cluster Romania, the first interregional tourism cluster of national interest in Romania aims to fulfill a consultative role as well, for the public authorities (especially for the Ministry of Regional Development and Tourism, regional administrations, etc). [10]

5. The Premises for a Tourism Cluster in Dobrudzha Area

Considering the well known tourism potential of Dobrudzha and Constanta county, it may be stated that there exist the following premises for the development of a tourism cluster :

- The Romanian Riviera represents over 40% of the accommodation capacity at national level, which means a high concentration of competitive enterprises (hotels, restaurant, leisure, cultural, sport, spare time service providers);
- The high rate of small and medium size enterprises, but also the rather small number of large tourist operator –enterprises which significantly contribute to the

development of the sector and to trend setting;

- The tradition of associating into professional and employers' organizations;
- The favorable geographic location, between the Danube and the Black Sea, endowed with an outstanding natural potential: natural reservations, caves, beaches all over the seaside, various cultural and cooking traditions, resulting from the diversity of the ethnic community;
- The presence of important stakeholders in the area: medium and higher education institutions specialized in tourism, entities for seaside and Danube Delta tourism promotion , business support organizations;
- The presence of the horizontal value chain: suppliers of passenger transport services, tourism agencies and tour – operators, providers of tourism training services for human resources ;
- The existence of formal and informal relationships between the partners of the potential cluster, mainly horizontal, between tourism agencies and operators and providers of tourism services.

Currently, a public- private partnership exists and functions–Romanian Riviera – Danube Delta Tourism Promotion and Development Board, including members such as local authorities, companies representing private initiatives and NGOs: ANAT, Constanta County Council, Tulcea County Council, Constanta Municipality, Constanta Chamber of Commerce, Mangalia Municipality, Navodari Municipality, Eforie Municipality, National Company " Maritime Ports Administration" SA Constanta, the International Airport M. Kogalniceanu Constanta, Mamaia Employer's Association, "Ion Movila" Tourism Employer's Association – Eforie Nord and Danubius TUI Romania.

It is obvious that the local authorities of Constanta are involved and consider the development of local tourism as being a priority, collaborate based on common interest with the authorities of the region and

consider extending the collaboration in the field of tourism, at cross-border level.

6. Conclusion

The interest for clusters development in Romania is obvious. The seven studies developed until now (most of them developed within the framework of European financed projects) show that the most suitable fields of activity for clusters are the textile industry, footwear industry, ceramics, wood, chemical and software, while the most attractive counties are Brasov, Harghita, Bacau, Cluj, Arad, Timis and Bucharest.

The most recent cluster in Romania is in the field of tourism, "Carpathian Tourism Cluster" which is based on a national strategy, supported by the European Commission. In the same context, efforts are made to found a tourism cluster in the area of Dobrudzha.

Clusters and Regional Development Strategies

Jugănaru Mariana
Jugănaru Ion-Dănuț
Moraru Andreea

„Ovidius” Univerity of Constanta, Faculty of Economic Sciences
mjuganaru@univ-ovidius.ro

Abstract

The intensification of concerns on cluster development can be noticed at European level, accepted as formulas which reunite enterprises, universities, research centers, local authorities, etc, within certain structured partnerships.

Given the importance of clusters for the regional and European economic development, one may notice the increased concerns of the European Commission and of the member states regarding the development of different programs which may contribute to the promotion of trans-national cooperation between European clusters, to the elaboration of proper cohesion policies, to the granting of necessary support, including alternatives for financing of innovative clusters.

Key words: cluster, strategy, development, region

J.E.L. classification: L 83

1. Introduction

It is becoming more and more obvious that clusters are more often than ever a topic for debate/ discussion, at different levels and in various contexts.

Michael Porter defines clusters as "...geographic concentration of interconnected businesses and institutions, in a particular field". Clusters include a group of related industries and other important entities, in what concerns competitiveness. These include, for example, suppliers of specialized input, such as components, machineries and services, or suppliers of specialized infrastructure. Many times clusters extend themselves downstream,

towards various distribution channels and clients, and sideways, towards producers of subsidiary products and towards related industries, by means of qualification, technologies or common inputs. Last but not least, some clusters include governmental and other type of institutions – such as universities, agencies, think tanks, providers of professional training and employers' organizations –which ensure specialized training, education, information, research and technical support [1].

Clusters can also be defined as a group of companies, economic stakeholders and related institutions, placed in proximity to each other, which have reached the satisfactory level so as to develop competences, services, suppliers and specialized skills. [2]

There are, however, specialists who talk about both the classic model of the cluster (the triple helix): state, industry and research, as well as about the "Four Clover" model: research – education, public authorities, consultancy companies and chambers of commerce, employers' associations, civil society, etc.

2. What is specific for clusters?

Based on the above given definitions, we may highlight certain elements which are specific to clusters:

- Grouping based on geographic criteria of some stakeholders, pertaining to a certain field;
- Development of interrelations between the stakeholders, with the objective of achieving special results and increased performance. Because of this, the cluster is perceived as a pole of competitiveness, a technologic pole, a pole of excellence in which

stakeholders act and collaborate under a common collaboration strategy and remain in the competition;

- A major importance is given to issues concerning teaching/ education, information, research and technical support;
- The better use of the resources pertaining to the regions where companies (especially SMEs), universities, research centers, local authorities etc, carry out their activities, within structured partnerships.

3. What are the advantages of clusters?

Within the context of an increased global competition between the markets, the chances for economic success of a country or region result from offer specialization and increase of developmental concerns towards key-areas, where competitive advantages, resources and competencies may be gained. Based on this approach we can estimate that a successful solution is represented by innovative clusters, because these have the capacity to achieve a combination of different stakeholders (companies, education – research units, civil society, etc), in order to develop strong cooperation and collaboration connections, transfer of knowledge, reflected by pro-active synergies between the main stakeholders in innovation.

Also, given the same context of increased globalization tendencies and enhanced competitiveness on national, European and international markets, being part of a cluster represents a real advantage for small and medium size enterprises, consisting of: easy and fast access to scientific results, in view of applying them to production and creating innovative products; use of high performance technologies; implementation of common development strategies, starting from cooperation strategies for production and purchase of technologies and high performance equipment, destined for common use and ending with marketing strategies.

Clusters function as a large consortium of companies which have important chances of accessing EU fund and of ensuring financing.

Innovative clusters contribute to the increased attractiveness of an area, support the development and trade of innovative products and services (especially those concerning design, marketing, transport and logistics).

At European Union level, innovative clusters are perceived as the 'engine' of economic development and innovation, being able, at the same time, to set up the corresponding frame for business development, for collaboration between companies, universities, research institutes, suppliers, clients and competitors pertaining to the same geographic area (local, regional, national and trans-national).

4. Innovative Clusters

The approach of the "Community Framework on State Aid, Research, Development and Innovation" considers clusters as the binning of independent enterprises (start-ups, small, medium and large enterprises as well as research units) which operate in a specific field and area, with the purpose of stimulating innovative activities, by promoting intensive interactions, sharing facilities, experience and knowledge exchanges, and by means of contributing to the transfer of technology, networking and dissemination of information among member companies of the cluster. [2]

Certain aspects regarding the regulation and boosting of such entrepreneurial behavior have determined the set up of a set of policies concerning the activity and functioning of the cluster, resulting from the research, innovation, industrial policies and SME's policies. The current European experience proves that the majority of policies regarding innovative clusters have been or are implemented by means of different governmental programs or initiatives.

The European Cluster Observatory, established in 2006 by the European Commission, has as main objective to inform the interested policy-makers about European clusters and on the policies in this field. Also, it provides quantitative and qualitative statistic data as well as comparative analyses on cluster situation in Europe. The researches and studies elaborated by the European Cluster Observatory in more than 30

European states, have identified more than 130 national measures of cluster support, measures which could be classified as policies concerning clusters. Within this context, it can be stated that in almost all EU member states, measures and programs on cluster promotion and development are being implemented, and thus it can be estimated that that these may constitute an important element of the national strategies on the support of innovation.

Cluster related policies may be classified in groups, depending on the objectives and motivations underlying their adoption:

1. *Facilitation policies* –aim towards the creation of a favorable microeconomic environment for development and innovation, which contributes indirectly to cluster emergence and dynamics;
2. *Traditional framework-policies* – refer to policies concerning SMEs and industry, research and innovation policies, regional policies on clusters, as instruments of improving cluster efficiency;
3. *Development policies* –are directed towards research and mobilization of specific cluster categories, with the purpose of developing a specific economic sector. It can be observed that this group of policies is the only one that directly targets clusters issue.

It is becoming more and more obvious that at European Commission level, the concerns regarding cluster support, the improvement of Europe's knowledge bases, and the optimization of European research and innovation exploitation potential are intensified.

The recent economic crises warned about the need for a powerful, competitive and innovative industry in Europe, which should be based and should encourage innovative clusters/ poles of competitiveness and cluster networks. [2]

5. Clusters – an alternative for the development strategies of the enterprises pertaining to a certain region

If, in theory, cluster means in English „bundle, bunch, group”, in practice a cluster means a group of companies which operate in the same field, and which agree to come together, to adopt the same strategy, however remaining direct competitors. Cooperation and collaboration relations are established between the companies joint in a cluster and because of these relations they improve their performance.

The managers of the companies which are reunited in a cluster must see this undertaking as a survival strategy. However, intelligence, trust and the establishment of clear rules of action are necessary to set up a cluster. The initiative must start from the bottom: the economic unit and the business environment. The state cannot force anybody to associate, but it can, by means of certain measures, support clusters development.

At European level, clusters fall under two categories:

- a) One category refers to the poles of competitiveness, which comply to the state policy, as happens in France, where over 70 organizations are estimated to exist. Even if the mechanism is considered somehow bureaucratic, it is estimated that through the formation of clusters the tendencies towards monopoly, abuse of dominant position will be eliminated.
- b) Another cluster category (existent in the majority of European states, the most significant instances being Germany and Sweden) is based on massive collaborations initiated by the business environment (bottom-up principle).

If, in what Romania is concerned, the cluster concept is relatively new, at European or international level one can talk about, at this point, about the development of powerful clusters at regional level and, recently, about the development of top level international clusters.

In Romania, the cluster issue is of interest to the companies, but a significant level of development has not yet been reached. It is estimated that clusters can be set up in different industry branches (textiles, leather goods, footwear, wood processing, chemical industry, vehicle building), in agriculture, tourism, transport.

EU requested that Romania drafts a cluster map to be added to the one of the Community. To this purpose, several data centering actions have been undertaken, as well as the drafting of a special guide for those willing to create a pole of competitiveness. [2]

According to a press release issued by the Ministry of Economy, Commerce and Business Environment (MECMA), in 2010, 22 clusters from Romania were identified and included in a specialized catalogue „Romanian Clusters Mapping” and the Guide for the implementation of the innovative cluster concept in Romania was elaborated. These actions have been carried out within the project Inov-Cluster – Development of the technological pole concept at regional level and of the cluster in regional networks, support for increasing the competitiveness of economic agents in processing industry”, a project coordinated in the period 2008 – 2010 by the General Directorate Industrial policy and Competitiveness of MECMA, within the Sectoral Plan in the field of Research – Development in Industry. Upon unfolding of this project, the following proposals have been made: elaboration of an integrate cluster funding system, creation of web platform to animate clusters in Romania, the creation of a national network of innovative clusters and their inclusion in trans-national networks [3].

In what concerns the financial instruments which may be used to set up a cluster, the companies have at their disposal, on the one hand, the EU program which supports the industrial policy and which provides funding of up to 200.000 euro/project, the non refundable financial allocations being available also within the Sectoral Plan for Research, and, on the other hand, the funding may also come from the members of the group (such as the cluster established by Renault).

As a strategic approach, we must mention that, in what clusters are concerned, an appropriate management, a marketing policy,

an action plan, a budget and competent administrators are required. Upon its establishment, the cluster must produce something innovative, that will distinguish/differentiate the respective region/country from what is considered to be series production.

6. Conclusions

The European policy for innovative clusters represents, for a country such as Romania, a new approach, oriented towards partnerships between industry and research at regional level, by stimulating the exchange of good practices and cooperation between clusters, with the aim to conquer new markets.

Innovative clusters may accelerate development, trading and dissemination of top technologies in all European industrial sectors and services.

The challenges which European industry must face are related to market fragmentation, the weak link between industry and research, but also the modest collaboration between European clusters.

An important element of innovative cluster strategy is represented by the development of trans-national cooperation between European clusters.

The High Level European Group on cluster policy – ECPG, provided a written report to the European Commission in December 2010, including recommendations on the role of clusters within the context of the European Innovation Plan. Within this context, innovative clusters are considered part of the new economic environment, and the cluster programs are part of the new industrial policy. Innovative clusters constitute a natural platform for public-private partnerships. Implementation of certain recommendations present in the documents of the ECPG group involves a period of a couple of years and will depend on both the efforts of the European Commission and of the member states (Ministry of Economy, Commerce and Business Environment, General Directorate of Industrial Policies and Business Environment).

Methodology of Economic Assessment of Corporate Finance Management Effectiveness

Juscu Nicolae Cristian
Free International University of Moldova
alexcri74@yahoo.com

Abstract

"The methodology of economic assessment of corporate finance management effectiveness" deals with the analysis of the basic issues of economic aspects of corporate finance management effectiveness; the paper presents the essential issues of the existing methods for establishing the economic effectiveness of corporate finance management and control; it also proposes the improvement of the approach regarding the assessment of finance management effectiveness of a company.

Key words: finance management, corporate finance management, corporate finance control.

J.E.L. classification: G15

1. Introduction

The practice in Romania and the international one show that the first to be interested in assessing the effectiveness are contracting companies and finance managers who promote anti-crisis management. This is due to the fact that across the world nowadays the cases of bankruptcy, scandals related to it as well as the consequent losses have reached an unprecedented level. Thus, the study carried out by World Bank specialists indicated that annually an average of 1% of the total companies of developed countries reached bankruptcy during the last decade.

The necessity for an appropriate assessment of company finance management effectiveness is also felt in the Romanian system because the actual financial status of Romanian companies is still under the influence of the economic crisis. According

to official statistics, more than 56% of the autochthonous companies tend towards insolvency.

2. Analysis of data

The complex analysis of the basic aspects of assessment of corporate finance management economic effectiveness should comprise two directions. The first direction is the analysis of the approaches that will lead to understanding the essence of one of the highly assessed characteristics of corporate finance management – its effectiveness. The second direction is the analysis of effectiveness assessment as a specific type of activity, following the quantitative assessment of this characteristic.

In many cases, the integral coefficient is proposed as a main indicator in assessing the economic effectiveness of corporate organizations, and it comprises individual components of the indicator system chosen. However, it is our belief that this fact does not exclude the main difference of the narrow interpretations regarding effectiveness.

The process of assessing the economic effectiveness of corporate finance management as a specific activity implies both technical difficulties and other basic issues. As for the basic issues, which give rise to the development of the approaches regarding the assessment of this characteristic of financial activities, they are the following:

- 1) principled measurability of the effectiveness
- 2) the degradation of performance indicators;
- 3) demonstration of extrapolation.

The issue of principled measurability or nonmeasurability of such characteristics as effectiveness is closely related to the possibilities of human thought, the capacity to

formalize and measure different categories. The category apparatus allows the constitution of structures, included in the management effectiveness of the company, such as the social and psychologic costs, as well as making the comparison and choosing while lacking some definite criteria. However, the assessment of effectiveness in such a broad interpretation, as well as the attempts to formalize the human thinking process is extremely difficult.

Any indicator for effectiveness assessment is appropriate to be put into practice only if it allows the comparison of two objects from the point of view of their effectiveness. The examination of any effectiveness indicator is realized by establishing its capacity to distinguish between the levels of effectiveness (high level, low level). In order to do so it is necessary to determine a certain variation of this indicator, previously set for a certain group of the analysed objects. If the value of the selected indicator does not vary sufficiently from an object within the group of another object, then that indicator is not useful to make an assessment.

Nevertheless, we do not find that an adequate assessment of the economic effectiveness of corporate finance management is impossible to achieve as a principle. It can be obtained with relative precision. Having to consider that the negative influence of the fundamental factors, which influence the assessment of effectiveness, cannot be eliminated, it has to be reduced to the minimum by developing some specific methods for the assessment of the corporate finance management effectiveness.

The interpretation given here, referring to considering corporate finance management effectiveness as the company's capacity to reach and maintain a certain financial level by using the available resources in a certain period of time, allows to assimilate the methods for effectiveness assessment to the methods for assessing the financial status of the company. Moreover, various categories of methods, formally defined as „methods for the forecast of company bankruptcy”, should also be analyzed, because in our opinion, these methods can also be included to the category of methods for the assessment of the financial status of the company.

As objects to be analysed we choose both methods which are largely known as well as new studies proposed by specialists for the assessment of the financial status of the company. A condition of constituting the methods for the assessment of economic effectiveness of corporate finance management is their complexity. Therefore, the group of analysed methods may be reduced to the complex methods for the assessment of the financial status of the company, namely those methods which characterize at least two of the four basic aspects of the financial status of the company (profit, turnover, liquidity, stability). The majority of methods within the complex analysis for the assessment of the financial status are some formal methods, which are based on certain numeric algorithms. Moreover all the formal methods for the assessment of corporate finance management are formed according to one of the two aspects. According to the first aspect, there is constituted an integral coefficient out of the elements of the indicators system forming the base of assessment methods, then the values of this coefficient are used to make the necessary assessment. Such methods (defined as integral methods) are the most popular in practice.

It is our belief that in order to obtain an optimum variant for the comparative analysis of the data provided by these methods the calculations should be made on the basis of the data regarding a group of companies, which should include both companies about to fall for bankruptcy and companies that operate normally. Thus, if we consider bankruptcy as a situation of maximum ineffectiveness of corporate finance management, then these calculations may indicate the applicability of these methods for the assessment of corporate finance management effectiveness. However, the lack of statistic data regarding the companies in Romania that have already gone bankrupt, does not allow us to use this method in Romanian practice.

The methods based mainly on rating assessment can be considered satisfactory, while statistic, expert and cluster methods have dissatisfactory results in assessing corporate finance management.

3. Conclusions

Many experts emphasize the duality of the sources of corporate finance management effectiveness. Theoretical reflections regarding management effectiveness have demonstrated that the specificity of a company's management consists of the fact that the management objective is achieved both within the management system (the management subject) and within the managed object. This complexity of objectives interaction within the management-production system involves the examination of the results of the two subsystems – the leading and the subordinate ones. Each of these subsystems has its own resources whose proper use should be taken into account.

The assessment of the effectiveness of corporate finance management system proposed in formula (1.) and the effectiveness of financial management (2.), have a common position regarding the assessment of corporate finance management effectiveness.

$$I^{(\phi)} = \mu_F + \mu_{FM} - u(\mu_F, \mu_{FM})$$

(1.) Own Source

$$\mu_{FM} = \begin{cases} +\infty, & \text{pentru } Q \text{ complex} \\ \left[\sqrt[3]{\frac{\sqrt{|\mu_F|}}{2} + Q} + \sqrt[3]{\frac{\sqrt{|\mu_F|}}{2} - Q} \right]^2 \end{cases}$$

(2.) Own Source

where

$$Q = \sqrt{\frac{(\mu_F - I^{(\phi)})^3}{27} + \frac{|\mu_F|}{4}}$$

adelazegrean@yahoo.com

Abstract

Even if most successful joint ventures are created when economy is in glorious times, the reality of the last years has shown true possibilities of obtaining advantages by considering joint venture strategies during economic crisis. Some Romanian companies, as presented in the paper, have noticed that could transform the crisis into an opportunity, by offering foreign investors the perfect place to implement a joint venture strategy.

Consequently, under the name of a joint venture agreement, companies can develop their businesses on local and international markets, benefiting from better qualified work force, new technologies, larger resources and experience.

Key words: joint venture, strategy, strategic advantages, economic crisis

J.E.L. classification: L24

1. Introduction

The most debated topic in the past years is the global economic crisis, felt to a certain extent all over the world. The main focus is on the effects of the crisis, as well as on the numerous strategic approaches to combat or ameliorate them. The recession of the global economy affected the quality of social-economic life. Companies are among the most affected entities, struggling to survive a turbulent environment in which former strategies do not succeed anymore.

In Romania, companies are facing the burden of loans, as well as the difficulties in paying suppliers and employees. The banking system is defining a new financing system, not at all in advantage for companies having already difficulties. However, the companies struggling to cope with unfavorable

economic conditions are looking for new ways to attract foreign capital in the form of international economic associations or European structural funds. Companies considering the option of international associations take into consideration the opportunities and benefits joint venture strategies can offer.

2. General approach of Joint Venture strategies

The concept of *joint venture (JV)* first appeared in the Anglo-Saxon area, defining a joint cooperation of physical of legal origin between two or more partners aiming to obtain profit. In time, the concept was spread to wider areas, with different names, although the most common is that of *joint venture*.

At international level, the meaning of the term is related to the legal nature of the agreement between the parties. Some experts have defined the term as a method of reducing risks, in which two companies combine their forces to jointly produce and promote a product. Others complete the above explanation, stating that the JV is a method of penetrating foreign markets, as long as a foreign company is working with a local company as a partnership.

Nowadays, we talk about joint venture strategies, joint venture agreements and joint venture companies. JV companies appeared as a consequence of the business internationalization and their spread is largely related to the need of strengthening the competitive capacity by exploiting geographical areas with rich and cheap resources. [4] In this respect, Romania has aroused the interest of foreign investors in time.

Since Romania has had a market economy, with a set of permissive regulations, the number of JV has significantly increased: from 5,499 JV companies at the end of 1991, to 38,900 JV companies in 1994 (under the first wave of foreign investments), at present the number of JV companies exceeding 165,000.

The attractiveness for implementing JV strategies can be found in the mutual benefits for the partners. The option for such a strategy may have beneficial effects on both short and long term. In a first phase, the role of a joint venture partnership is to revitalize activities facing difficulties. In this respect, the foreign partner can provide consulting services, can contribute with capital and introduce advanced technologies, developing strategies and recovery policies, all in the context of the local experience. But, the real value of JV strategic alliances is given by the lasting impact on strengthening the company's position in the business. The success of a JV strategy is measured in terms of quality, management development, and change of staff attitude, higher productivity of employees and technical capital, high quality products/services, major social and environmental changes.

The foreign partner's interest for a JV strategy starts from an economic-based motivation, establishing the goals to be reached. Amid the economic downturn spread throughout the world, the investor seeks to maximize profits in order to sustain its economic activity for a long period. While population's incomes decrease continuously and demand also decreases, entrepreneurs are forced to focus on costs in particular, to reduce them as far as to obtain a profit margin able to ensure their continuity. This is the reason behind the penetration into new, affordable markets, with cheap material resources, skilled labor force and low labor costs. Meanwhile, the foreign partner can strengthen its business reputation by expanding the offer towards new markets, in terms of high quality products and services.

The local partner chooses a JV strategy based on economic reasons related to the impossibility or difficulty to enter foreign markets with local products, due to the lack of organizational capacity, legal or cultural barriers. From the perspective of the local partner, the foreign partner's capital satisfies the local need for monetary resources and

advanced technology and creates the premises of conquering new markets, by adapting to the qualitative requirements of foreign markets. At the same time, the local company, through his foreign partner, can reach a worldwide prestige.

On the other hand, we should not undermine the social importance of JV companies, as in difficult times a great interest must in maintaining as many jobs as possible. It should also be noted the advantages of technologies and performant systems, as a measure to protect the environment.

Encouraged by the chaotic economic situation, unpredictable on long-term, entrepreneurs seek to define strategic partnerships more and more visibly, being animated by the famous motto of Henderson&Harrison Company: "Two heads are better than one." Recent studies show that as long as the capacity to involve into transactions continues to strengthen, for 2011 is forecast an improvement in the activity of mergers, acquisitions and joint ventures.

In 2010, the demand on this market was stimulated by the constant accumulation of capital in big companies and the need to access new markets and technologies. Romania has also recorded promising tendencies. The recovery of the local market in the JV sector is demonstrated by the increase in the value of transactions, but we should mention that the companies aiming to attract investors should avoid the extreme approach of reducing costs on short term and to develop instead a long time strategy to earn a market share. Reducing investments in technology, marketing, R&D and human resources may often be seen as easy measures when costs reduction is a priority. But the experience demonstrates that companies which maintained investment in IT, innovation, a brand and elite human resources find themselves in a better competitive position to enjoy the positive effects when economy recovers.

In order to demonstrate that economic reality confirms what we pledged for above, we will present as follows a couple of JV companies appeared on the Romanian market.

3. Case study regarding JV companies on the Romanian market

A convincing example regarding the benefits of such a strategy is offered by the JV between Macromex, a Romanian company specialized in importing and distributing food products and La Lorraine, a Belgian company, leader in producing and distributing fresh and frozen bakery products, one of the most important European companies on the bakery market.

The joint venture between Macromex and La Lorraine established in 2010 resulted in a new bakery factory in Câmpia Turzii, a common investment of 8 million euros equally shared, which created at least 100 jobs, both at management and operational level.[5] Although Macromex has a good image on the local market, the JV allows it to enter the European market, as it is favored by La Lorraine's prestige in high quality products and interest in satisfying customer's needs.

The food market seems to be a very interesting one, as we have another example of JV between Caroli Foods Group – Campofrio Food Group.[8] Caroli Foods Group is one of the leaders between the meat producing companies in Romania, managing after 16 years to achieve the second place as market share. Campofrio Food Group is Europe's leading company on the meat market and one of the five largest meat processors in the world with a turnover of around 2.1 billion euros, directing its efforts to expand business and production throughout the European area. It now covers eight countries considered part of the central market of interest and employs about 11,000 people.

The JV agreement joins the two companies under the name of Caroli Foods Group (51% of Caroli Foods and 49% of Campofrio Food), helping Caroli to achieve its goals: to overcome the local leader by a larger market share and to promote products in the emerging regions of the South East Europe.

The association with Campofrio brings for Caroli valuable know-how in processing meat at the highest standards, as well as an increase in the value of social responsibility that Campofrio Group has already assumed by taking social and environmental actions.

Another aspect that Caroli considered when signing the joint venture was the advantage of power in negotiations with retail chains. Although some views appreciate this JV atypical for the local market, dominated by small family businesses, the new company may determine the strengthening of a field affected by current economic conditions and the transition to a new image for the local food sector.

Specialists have predicted that one of the most attractive sectors for JV is the energetic one. To prove that, we have the example of a new company, Wind Energy Service East Europe (WESEE), resulted from the JV of Electrogrup, Montage and Windenergy Service.

Electrogrup is one of the major national companies active in energy infrastructure construction, telecommunications and civil service, while Windenergy and Montage are German companies active in the energy construction sector. The three companies aim to participate in the aeolian project at Fântânele, run by CEZ, a utility group from Czech Republic. For the three companies, the project represents a great challenge and an opportunity in negotiating works to do. The JV company, having as main activity installation and maintenance services of wind turbines, is considering a program of advanced professional training for the staff in Romania through accreditation, training and testing according to German standards, increasing performance in work quality, without consuming important financial resources, which can be diverted to other investment sectors.

This JV creates a good opportunity to highlight Electrogrup's competitive force in other European regions, diversifying its portfolio of competences and experience.

Another example arising from the energetic sector is that of the JV between Termoelectrica, a national company producing electric and thermo energy, E.ON Kraftwerke, the largest private-owned company in energy distribution sector and Enel, the most important energetic company in Italy. [6]

In 2008, the three companies signed an agreement committing to participate in building a coal power stations, with an estimated investment value of about 1 billion euros. The advantage of the partnership with

the German-Italian consortium is of financial nature and a great opportunity for a sector with potential, but which needs constant upgrades and adjustments to existing rules of international environmental protection. Therefore, the construction of the new power plant will have an immediate effect on environment quality, achieved by reducing emissions. The project ensures the success of such an objective through the implementation of Clean Coal Technology, the best available technology for coal power plants.

A project of this magnitude also brings social benefits, as electricity consumers will have lower tariffs and, obviously, there will be additional jobs and most employees will be trained and specialized in new technologies.

Summarizing the benefits of the partnership, it can be concluded that although Termoelectrica's remuneration for investing in the joint venture's capital will be well below the financial benefits of the two foreign partners, according to the proportion of initial contribution, the local social and environmental benefits are more important.

Last, but not least, we can talk about AgroAdvice, a JV between Agricover Group, a leader in Romania on the market of technological packages and integrated services for agriculture and Danish Agricultural Advisory Service, one of the most important European companies in agro food consultancy.

The joint venture was supported by their common objective to have a larger market share in agriculture consultancy and has as mission to assist Romanian farmers in optimizing processes and improving financial performance in agriculture, with effect on increasing their competitiveness on the European market.

The option of the Danish company for Romania is explained by the agricultural potential. The JV strategy specifies the development of know-how transfer for improving quality in consultancy for revigorating the agricultural sector.

4. Conclusions

The examples mentioned above and the advantages of implementing JV strategies, demonstrated, as demonstrated by the economic reality, highlight that, regardless of the economic conjuncture, Romania may still be a desired destination in the international business environment, due to a wide range of investment opportunities in different sectors.

Romania opportunity to enter the market of more developed countries, in a time when all countries are trying to promote a protectionist policy, can be exploited by formulating attractive and profitable joint venture strategies.

Although the success of joint venture strategies is easily noticeable in times of growth, when the future of businesses can be viewed as sure and optimistic, the innovative spirit of entrepreneurs is challenged to find optimal solutions even in crisis conditions.

Human Resource Planning

Lache Cătălina
"Petre Andrei" University of Iași
catalina_lache@yahoo.com

Abstract

The objective of human resource planning is to adapt the human capital needed to develop the enterprises' activities and to accomplish their priority objectives on the medium and/or short term. Human resource planning is a dynamic activity, time being an essential variable, both in what regards the quantitative side (adapting the number of jobs according to the organisation's evolution in time) and the qualitative side (harmonising the jobs' complexity with technological changes). The quantitative side is indissolubly connected to the relative inertia of human resources while the qualitative one is characterised by human adaptability. The article presents a research regarding the way human resource planning is carried out in Romanian private railway firms.

Key words: human resource planning, staff headcount, competences.

J.E.L. classification: M12

1. Introduction

Human resource planning consists in projecting the necessary number of employees needed in an enterprise for a medium or long amount of time, in an adequate structural organisation, ensuring the competences needed, such as: qualifications, know-how, the motivations needed to perform in the variety of jobs and positions, assuming the responsibilities needed to ensure the firm's smooth operation and progress. Firms that neglect these activities may be confronted with a serious lack of competences needed for the activities developed or with an excess of employees overcome by the evolution of the firm's environment.

2. Theoretic considerations

The objective of human resource planning is to adapt the human capital needed to develop the enterprises' activities and to accomplish their priority objectives on the medium and/or short term.

Human resource planning consists in projecting the necessary number of employees needed in an enterprise for a medium or long amount of time, in an adequate structural organisation, ensuring the competences needed, such as: qualifications, know-how, experience and aptitudes, the motivations needed to perform in the variety of jobs and positions, assuming the responsibilities needed to ensure the firm's smooth operation and progress.

Human resource planning is a dynamic activity, time being an essential variable, both in what regards the quantitative side (adapting the number of jobs according to the organisation's evolution in time) and the qualitative side (harmonising the jobs' complexity with technological changes). The quantitative side is indissolubly connected to the relative inertia of human resources while the qualitative one is characterised by human adaptability.

The process of human resource planning may be summarised as follows [14]:

- assessment of the human resources available at a given moment by comparing the men / jobs situation and formulating a diagnosis;
- analysis of the company's objectives, strategic development axes and establishing the objectives related to professions and headcount;
- personalised regularisations, both quantitative and qualitative, formally included into the action plans that regard the following activities: recruiting, forming and developing competent people, enterprise reorganising, staff mobility, ensuring some activities by contracts for services;

- regular control.

Headcount and competence planning is part of human resource planning and consists in creating, implementing and controlling the policies and practices that aim to reduce, in an anticipative manner, the gap between an enterprise's needs and its resources, both at the quantitative level (headcount) and the qualitative level (competences). This projection is part of the firm's strategy [8]. Headcount and competence planning have two dimensions: collective and individual. At the collective level, it aims to integrate human resources into the firm's strategy by monitoring the employee's medium and long-term evolution, both qualitatively and quantitatively. At the individual level, it aims to offer to each employee the chance of being an active participant in the labour market by elaborating a career evolution project based

on the competence and the individual evolution potential of each employee. Human resource planning uses a wide array of anticipative methods and reunites a heterogeneous collection that differs from an enterprise to the next.

This activity was given numerous pages in specialised literature which describes a sequence of the evolution of the objectives, activities, the methodology used and the means of implementation, approaching concepts and definitions that settle the strategic nature of the human resource function. [2,4,6 8,10,12].

The crucial issues that may trigger human resource planning procedures are summarised in table 1.

Table 1. Crucial issues that may trigger human resource planning procedures

A	Managing social relations and complying with legal provisions	A1	Ensuring the project's cohesion and an adequate social climate
		A2	Limiting layoffs to a maximum
B	Communicating to and involving the employees	B1	Mobilising the staff in order to achieve the enterprise's strategic objectives
		B2	Making the employees adhere to the firm's values, promoted through management
		B3	Improvement management quality
C	Developing competences	C1	Preparing the staff for their future jobs
		C2	Adapting jobs to the current needs of the enterprise
		C3	Developing competences
D	Developing mobility	D1	Favouring mobility
		D2	Preserving basic competence by keeping the best specialists
E	Adjusting headcounts Improving productivity	E1	Rationalising the management of payrolls
		E2	Developing employee flexibility: short term employment, mandating competences, collaboration contracts, consultancy, contracts for services
		E3	Reducing headcounts
		E4	Recruiting collaborators

Carrying out headcount and competence planning activities is a difficult endeavour, which integrates a various number of concepts, that is:

A. Strategic integration

Headcount and competence planning is a strategic enterprise component. Through this action human resource management is anticipatively connected with the other

functions of the firm (financial, technological, commercial, etc.) and integrated into the general strategy. The decision to approve the human resource plan belongs to the general management of the firm, the human resource department being the executants.

B. Anticipation

The central element to the headcount and competence planning approach is the anticipation of the enterprise's major evolutions and of their consequences in terms of professional competences and of the job and headcount situation. By identifying, with the help of strategic analysis, the impact of changes on human resources and their competences, preventive measures can be taken to counteract economic, financial and social risks.

C. Quantitative analysis of human resources

The quantitative analysis of human resources should be undertaken for every job and function, as specified in the occupation list. The fact that there is a likely deficit might be covered by re-qualifications, multi-qualification, professional reconversion. The analysis of the human resources available at a given moment represents the starting point of anticipative projections.

D. Continuous professional training and guidance

By anticipating the enterprise's needs through the headcount and competence planning process, by analysing the employees' individual potential, individual professional progress plans can be made. Thus the continuous professional guidance of the employees may be carried out within the firm or outside it, avoiding social convulsions or the deterioration of organisation climate.

E. Competences

When creating an anticipative model, by headcount or competence planning, a double

connection is established between the enterprise's needs (necessary competences) and its resources, and this adaptation practically represents the balancing of the qualitative aspects of human resource management. In what regards the second connection, competence is its key element, which allows the passage from the management of the employee body, as a whole, to individual management.

Competence-based human resource management assumes, by the policies it promotes, the following roles: competence acquisition (recruitment), competence development (professional training and improvement), competence disposal (layoffs), competence recognition (wages, social benefits, personalised bonuses).

Specialised literature presents a wide array of definitions on competence. The concept of competence refers to the collection of knowledge, savoir-faire, savoir-etre, technical abilities, experiences and behaviours that are manifested in a job (profession), in well-established situations of action development.

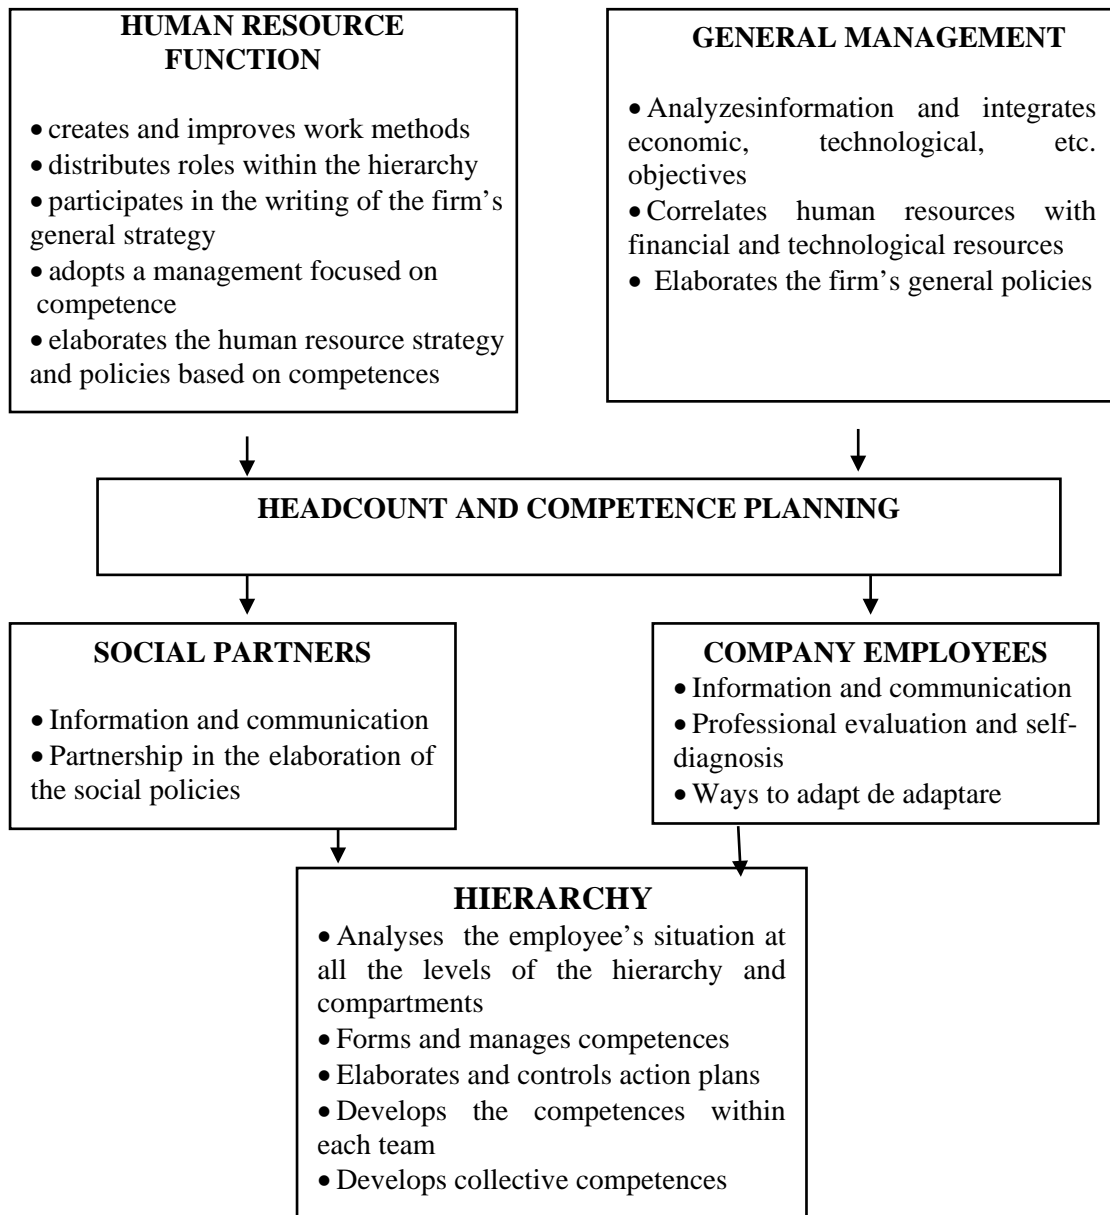

The competence a person makes proof of in solving professional problems correlates the multitude of knowledge and experiences of which they dispose with the resources available in an organisation.

F. The main players involved in headcount and competence planning

An important tactical and strategic component of human resource management is represented by the forecast of an organisation's headcount needs. The forecasting determination of human resource needs must take into account a multitude of elements related to the competitive environment, the market evolution, technological changes, the cycles of economic activities, etc.

The main players involved in the headcount and competence planning process, along with their roles, are presented in figure2.

Figure 2. The main players involved in the headcount and competence planning process [2]

3. Study regarding human resource planning in firms from the N-E Region of Romania

The study was conducted from January 2010 to March 2010 in five privately-owned railway firms from Romania, using a closed-question questionnaire. The question variables have been assessed with various Likert scales. According to this evaluation grid, the privately-owned railway firms analysed are very well positioned, having obtained the VERY GOOD score – within

the answers given to the questionnaire, 14 out of 16 possible situations coincided with the ideal, as follows:

Strategic and operational planning:

$$Score = \frac{14}{16} \cdot 100 = 87,50\% = \text{VERY GOOD}$$

Table 2. Questionnaire on human resource planning

HUMAN RESOURCE PLANNING	
1. Existence of strategic human resource planning (non-existent/ incipient/ medium/ full)	A B C D
2. Concern with strategic human resource planning (none/ very small/ medium/ major)	A B C D
3. Importance granted to strategic human resource planning by the firm's management system (none/ very small/ medium/ major)	A B C D
4. Existence of rational principles of human resource planning (non-existent/ more in theory/ available effectively)	A B C
5. Ensuring, in time, the continuous human resource adaptation to the functions and the jobs generated by the enterprise's activity (none/ to a small extent/ occasionally/ in general/ to a great extent)	A B C D E
6. Existence of adequate means for human resource planning (non-existent/ simple/ averagely complex / very complex)	A B C D
7. Computerisation degree of provisional human resources (very low / low/ average/ high / very high)	A B C D E
8. Cooperation between the human resource compartment and the other compartments within the firm (very low /low / average / high / very high)	A B C D E
9. Provision of the conditions needed for good human resource planning (information, equipment, qualified staff, financial resources) (low / average/ high)	A B C
10. Extent to which the qualitative aspects of human resource management are taken into consideration (the study of policies and strategies, provisional headcount diagrams, adaptation men/jobs, competence analysis, work conditions, social climate, information and social communication) (small and occasional/ small but continuous/ average / great)	A B C D
11. Managers are concerned and take measures to influence the human resource plan (less and occasionally/ less but continuously/ averagely/ greatly)	A B C D
12. Human resource planning is analytical (qualifications, age, sex) (generally / averagely / in detail)	A B C
13. Existence of human resource policies (none/ very general/ for the most important parts / for all the parts and analytically)	A B C D
14. There is an analytical management of needed competences (general and specific knowledge, practical experience, personal aptitudes) (there is none/ in principle/ incipient/ average, non-analytical/ total)	A B C D E
15. Staff mobility planning (layoffs, job changing, leaves, discharge, etc.) (in very general lines/ regarding main jobs/ total and analytical)	A B C
16. Level of operational human resource planning (short term) (unavailable/ empirical/ average/ analytical and total)	A B C D

4. Conclusions

The activity of human resource planning, of adjusting the headcount quantitatively and from the viewpoint of socio-professional structures, has a crucial role in the development of enterprise activities. For this activity to be efficient, the following individualised exigencies should be added to it:

- the management of the employees' competences by providing the much needed chances to get professionally updated, to get informed and to participate in debates and communications, in the elaboration of the propositions regarding the company strategy and work-related legislation, including in training courses paid by the firm; this way of managing individual competences is compulsory in order to ensure the employees' adaptability to the evolutions of the current technological, economic, social, legal and informational environment;

- the development of initiative and autonomy, offering the chance to think anticipatively to the employees with a superior level of professional training and to the managers at all the levels of the hierarchy;

- providing the chance to go beyond mass and "common" training, included in an internship program, through systematic theoretical and practical training in the field where the worker is actually employed and works, getting a varied professional experience, broadening his horizon and stimulating, at the same time, motivation and responsibility.

The human resource management from Romanian railway firms is strongly affected from when it comes to adjusting their headcount to the actual conditions of the global economic and financial crisis, which has also struck Romania. The research conducted in privately-owned Romanian railway companies revealed major problems that should be solved by the companies' management with the human resource department:

- adjusting the headcount in accordance with the real needs that it can sustain financially;

- ensuring compensations for employees who leave on layoffs;

- solving the problems related to the provision of decent revenues such as they were negotiated through collective work contracts;

- correlating wages with the increase in productivity;

- correlating the evolution of human resources, by structures and functions, with technological developments, the introduction of information and communication technologies in all company structures and the dilution of the bureaucratic phenomenon.

- granting due importance to each component (sub-function) of human resource planning, by preparing the shaping of changes and the adaptation of the system to the peculiarities of an ever changing environment.

In the field of headcount planning it is necessary to establish strategies and create plans and programs rigorously grounded taking into account the economic and social exigencies of the current period of economic and financial crisis and those forecasted in the future taking into account the new aspects generated by the evolution of the basic management theories, principles and the practical management experience of European Union states.

Abstract

With this study we're trying to bolster up the idea that digitization of information combined with the Internet is a form of general purpose technology, which rose a wide range of new possible combinations that could be provided by the digital economy. The impact of the digital economy over societies can be seen and recognized even if only part of it is measurable. The effects of digitalization the economy are seen more in the new activities and products than the productivity.

Key words: Technology of Information and Communications, New Economy, Informational Society, Society of Knowledge, Economic Development, Economic Growth, Development of Localities, Economic Indicators,

J.E.L. classification: L10; O3; O4

Digital economy was born as a result of the ongoing transformation of economic activities as a result of using digital technologies that provide access, processing and storing information in a cheaper and easier way.

New digital technologies allow access storage and transmission of information increasingly easier and more accessible. Featuring digital information, this can be transformed into new economic and social values, creating huge opportunities for developing new products and services. Information is key resource for digital economy.

Enormous amount of information is changing the markets functioning, making possible the restructuring of enterprises and creating new opportunities for creating value through exploitation of available information.

The Internet has the most important role in the development of digital economy. Digital transactions allow new opportunities and business environments; new laws that weren't possible before. In classical economy the physical factors such as labor, nature and capital had an important role, in the digital economy, the innovation, technology and intangible assets have an essential role.

Daniela Archibugi and Bengt Ake Lundvall consider that the new economy is dominated by global influences and speed of communications and information. They believe that its basic features are globalization and digitization characterized by offering intangibility to the international transactions, both commercial and direct investment. They don't make the difference between the information and knowledge, without which the "new economy" could not exist.

Manuel Castells motivated that in the last 20 years of the 20th century a new type of economy arise in the world. He characterized it as a new brand of capitalism, with three fundamental characteristics. „The production and competition are strong functions of knowledge creation and processing, firms and territories are organized in networks of production, management and distribution; fundamental economic activities are global, meaning that they have the ability to work as a unit in real or induced time, globally”- Castells, Manuel - the Rise of the Networked Society, Blackwell, Oxford, 1996, p. 52.

Digital economy is causing social economic progress by developing and enhancing trade between the countries of the world. Any country, as a result of the changes taking place in the world labor division, of expanding economic trade between the states has to give and to receive something in the circulation of material values created in the world.

The main vector of the new economy is the globalization of capitalist economy on a planetary scale supported by the explosion of new technologies that took benefit from the information revolution and promoted by the ultra liberalist ideology of the global free market and multiculturalism.

Assimilation of scientific achievements has resulted through the possibility of passing to work organization on modules. This generated novel forms of behaviour: "industrialization" of the intelligence set up a new type of worker, "the knowledge proletarian", called by Peter Drucker.

In sequel we will discuss the restructuring of some industries in the digital economy.

- The banking system evolution consists in increasing of web providers based on self-service technology. This changes the interaction between banks and their customers; banks staff are facing the automated channels based on the Internet
- Internet and new technologies penetration in the banking system led to savings in costs and increased efficiency on the one hand and the best customer service on the other hand.
- Increased use of Internet in the air industry has allowed the customers to shop and buy tickets which led to structural changes in the industry.
- The automotive industry is another example of a beneficiary of digitization. Major automotive manufacturers are seeking the business-to-business exchanges in the system of production and supply. It also appeals to business-to-consumer in orders and purchase systems; otherwise traditional, such systems have the potential

to improve efficiency in the industry. The

Internet orders from customers are greatly diminishing the role of conventional dealers (Kwoka, 2001).

- Equipment industry provides another example of restructuring of the economic activity as a result of collaboration via the Internet. A new generation of collaboration based on web- technologies makes it easier for companies to work hand in hand with partners to bring new products on the market much faster and cheaper than before.

As it can be seen in the examples above, the digital economy, an economy of speed, the companies continually seek continuously new business to stand the increased competitive pressures generated by markets globalization.

Frequent and profound changes in technology impose firms to innovate continuously and to adapt their own business models. Introducing information technologies and telecommunication in the economic life on an increasingly larger scale led to the emergence of new business models of companies.

Category	Weight
Connectivity and technology infrastructure	20%
Business environment	15%
Social and cultural environment	15%
Legal environment	10%
Government policy and vision	15%
Consumer and business adoption	25%

The most digitalized economies	Scoring criteria and weights
Denmark	8.87
Sweden	8.67
USA	8.6
Finland	8.30
Netherlands	8,64
Norway	8,62
Honk Kong	8,33
Singapore	8,35
Australia	8,21

Source: Economist Intelligence Unit, 2010

First position, Sweden, is found on the 5th place in the country top, with the highest penetration degree of Internet. In ranking the top there are also found: Iceland, Netherlands, New Zealand, and Norway.

Denmark is the owner of first place in the ranking, Sweden, the second, the difference being very narrow shows a high degree of connectivity and good scoring better on all fronts, from quality to business until a public policy of sound on ITC and levels where consumers and companies can actually use digital services.

It is worth mentioning that these countries can be found on the top and with the highest GDP/capita.

Digital economy's impact on society can take the following forms:

1. society as a whole must become informatics and telecommunications users as a result of quasi generalized computerization of the social space;
2. economic basis of the entire production will be the production of specialized knowledge;
3. politics will keep its vocation and powers they have in conceiving and designing economic and social action, but will focus, particularly, the research strategy and human capital formation;
4. exponential increase of social space diversification of brought to the fore the issue of social cohesion of the global social space.

Conclusion

Digital economy era imposed to the companies continually innovation and adaptation to new market models. The Internet continues to have an increasingly important role, showing its mark on the entire economic, social and cultural life and leading the modern world.

The social phenomenon entirely due to digitization cannot be compared with anything in the past and represents a reality that defies all social and mental paradigms known to date.

International Regulation of the Right to Life

Lazăr Patrick
„Spiru Haret” University of Constanta
patrick.lazar@yahoo.com

Abstract

The right to life represents the most important component of the value system that constitutes the subject of the international regulations on the legal protection of the human rights. This is the “first of the human rights” and it represents an assumption for the existence of the other rights; exercising the other rights would be senseless unless a protection of the human rights exists. The entire system of civil rights is actually subordinated to this right since these rights accompany the individual from the moment of his birth or some of them even from the moment of his conception until the moment of his death, some of them having legal effects after his death as well. Under these circumstances, the necessity for a regulation and an efficient protection of the right to life appear as an imperative for the international concerns in the field of human rights.

Key words: right to life, fundamental human rights, international protection of human rights

J.E.L. classification: K

“What is the right to life? First of all, it is a great uncertainty” [1].

The right to life [2] is the most important component of the totality of values that are the target of international concerns in relation to the legal protection of human rights.

The right to life is considered “the first of human rights” [3] and is a prerequisite for the existence of other human rights; without the existence and protection of the right to life, the exercise of other rights would be meaningless. The whole sphere of civil rights is practically subordinated to this right, as they accompany the individual from birth - or some of them, even from the conception moment - until death, some of them having legal effect even after death (such as the

inheritance will, when inheritance rights are opened from the moment of death, emerging from the deceased’s will) [4].

The right to life is enjoying a great popularity in the field of international treaties and conventions on human rights; its protection is enshrined in the most important contemporary international documents.

Even since the eighteenth century, the Virginia Bill of Rights (The Virginia Declaration of Rights - June 12, 1776) listed among the inherent human rights, also “the right to enjoy life” [5], and the U.S. Declaration of Independence (July 4, 1776) considered that “all humans are endowed by their Creator with certain unalienable Rights”, among them also the right to life [6].

Under article 3 of the Universal Declaration of Human Rights [7], “everyone has the right to life, freedom and self security” [8]. Article 6 of the International Covenant on Civil and Political Rights [9] states: “The right to life is inherent in the human person. This right shall be protected by law. No one shall be arbitrarily deprived of life” [10]; even the International Covenant on Economic, Social and Cultural Rights, adopted by the UN General Assembly on December 16, 1966, protects life: art. 10, section 2 states the need for special protection in the pre- and post- natal period, and art. 12, section 2 requires States to ensure the reduction of mortality and infant mortality [11].

The African Charter on Human and Peoples’ Rights [12] (adopted in Nairobi, Kenya, on June 27, 1981 and entered into force on October 21, 1986) states in Part I, Chapter I, Article 4: “Human beings are inviolable. Every human being has the right to respect for his integrity and his person. No one shall be arbitrarily deprived of this right”.

The Universal Declaration of Human Rights in Islam, from Cairo (September 19, 1981) also proclaims in article 2, the right to

life, with some peculiarities: "a) Life is a gift from God and the right to life is guaranteed for everyone. It is up to individuals, societies and states to protect this right from any violation, and is forbidden to take someone's life unless there is a reason provided by the Sharia. c) The protection of human life throughout the time willed by God is a duty prescribed by the Sharia." Under art. 3, in the case of using the force or of an armed conflict, the killing of non-belligerents (elderly, women and children) is prohibited; the mutilation of corpses is also prohibited". Article 4 stipulates the person's inviolability and her sacred character, which lasts during life, but also after death; the state must protect the relics and tombs [13].

The new Arab Charter on Human Rights, adopted in Tunis in May, 2004 provides in art. 5 that the right to life is inherent in any human person, and art. 9 of the same document forbids the submission to medical or scientific experiments and the use of organs without the person's free consent and full knowledge of their consequences; also, medical procedures such as to guarantee personal security must be strictly observed, and the trade with human organs is prohibited [14].

The Human Rights Committee described the right to life as "the supreme human right" [15], and the European Court of Human Rights ruled that the right to life "is an inalienable attribute of the human person and represents the supreme value on the international scale of human rights" [16] and is "one of the fundamental values of democratic societies which form the Council of Europe" (*Case McCann v. United Kingdom* - 1995), enshrining the pre-eminence of the right to life within provisions of the Convention, which it considers "primary" (*Case Pretty v. United Kingdom* - 2002) and emphasizing "the principle of the sanctity of life protected by the Convention" [17].

The right to life is the first substantive right regulated by the European Convention on Human Rights (art. 2); its location in the structure of Title I - Rights and freedoms – is not at all coincidental [18], in front of the importance that this right has within the ensemble of rights and fundamental human freedoms. In this sense, one speaks of "rendering sacred the right to life" [19].

Next to the prohibition of torture and inhuman or degrading treatments (article 3), to the prohibition of slavery and forced labour (article 4), and the non-retroactivity of criminal law (art. 7), the right to life is included, by the specialized literature, in the category of so called intangible rights, protected by the European Convention [20].

The European Union Charter from December 7, 2000 on fundamental rights recognizes the right to life and in medicine and biology are provided: the prohibition of eugenic practices, the prohibition of transforming the human body and its parts into a source of profit and the prohibition of reproductive cloning of human beings [21].

The doctrine points also means of protecting the right to life *lato sensu*, among which the African Charter on the Rights and Welfare of the Child of 1990, under which the crimes committed by children will not be punished with death, the Inter-American Convention on forced disappearance of persons of 1991 or the International Convention on the protection of all persons from forced disappearance, adopted by the UN General Assembly on December 20, 2006.
